## ABSTRACT

The Water Quality Index (WQI) is a technique used to evaluate the overall water quality of a river. It provides a representative value of overall water quality by measuring the level of contamination and suitability of water for particular uses. In this study, the water quality index was carried out on six water quality parameters, like turbidity, total dissolved solids (TDS), chlorides, nitrates, total hardness and biological oxygen demand (BOD), from five sampling sites for the year 2023-24. In the present study, the weighted arithmetic index method is used for calculating the Water Quality Index (WQI) of the Pandu River. The findings revealed that the WQI was higher at all sites, with the highest value at site 3 due to the dumping of untreated sewage and the release of industrial effluents into the river. Biological Oxygen demand (BOD) was also found to be maximum at site 3. The overall WQI of the study area across all five sampling sites falls within grade IV, indicating that the river water is not suitable for consumption without proper treatment.

**Keywords:** Water Quality Index (WQI), Pandu River, Physico-chemical parameters, contamination, Water Quality Rating

## INTRODUCTION

Rivers, among all sources of water, are most important and valuable as they make a network of regular water supply and are considered the arteries of human civilization [1]. Including domestic use, river water is also critical for commercial and industrial development, hydroelectric power generation, agricultural applications and new multipurpose dams [2]. River Pandu- a tributary of the river Ganga originates from a lake in Purwa Umed Village and passes through five districts: Auraiya, Kannauj, Kanpur Dehat, Kanpur Nagar and Fatehpur before its confluence with the Ganga River at Fatehpur district. The Pandu River has a stretch of 242 km, which runs between latitudes 26°52'38.77"N and 26°9'50.08"N and longitudes 79°32'31.68"E to 80°35'49.03"E. The water quality of the Pandu River is deteriorating day by day due to the dumping of industrial and domestic wastes into it, resulting in typical and characteristic changes in the chemical and physical conditions of the streams and associated aquatic biota has led to the reduction of dissolved oxygen level, production and development of the toxic zones in the streams [3, 4]. Water Quality Index is a very effective tool as it assesses and conveys the overall water quality in a simplified manner [5]. Water Quality Index (WQI) is a form of average derived by relating a group of variables to a common scale and combining them into a single number. It creates a univariate expression by combining many sub-indices of constituents (quality variables) to summarize data [6]. In other words, WQI consolidate several water quality parameters into a single numerical value and makes easier for people to better understand about the water quality [7]. Over a period of time the water quality index has been computed using a variety of models and methods. Based on ten water quality characteristics observed in the majority of water bodies, Horton created the first WQI model in the 1960s [8]. Following Horton, Brown created the Weighted Arithmetic Index Method, a more exacting version of Horton's WQI model, with assistance from the National Sanitation Foundation (NSF)[9, 10]. The weighted arithmetic index method was utilized for calculating the water quality index given by Brown *et al*., 1972 [11]. The weighted arithmetic water quality index classified the water quality according to the degree of purity by using the most commonly measured water quality variables [12]. The method has been widely cited in literature and used by various scientists. This method reflects the composite influence of different parameters and is quite useful for the communication of overall water quality information to the concerned citizens and policy makers [13]. Some water quality parameters like pH, dissolved oxygen, turbidity, total dissolved solids and concentrations of different contaminants like heavy metals, nitrates, and pathogens are measured and evaluated in order to calculate the water quality index. The values obtained for these parameters are then compared with the standard values given by different organizations and agencies to determine their acceptability for their specific use. In this study, the weighted arithmetic index method has been implemented for the analysis of the WQI of the Pandu River water at five different sites for the year 2023-24. The prime thrust of this paper is to analyze the water quality variability, examining key physicochemical parameters and their variations. The objective of the present study Was the use of the water quality index (WQI) as an indicator of the water quality of Pandu River and provide insights into the factors influencing water quality, and offer recommendations for sustainable management practices.

## MATERIAL AND METHODS

**Study Area**

The study area covered a stretch of the Pandu River in Kanpur district. Sampling sites were selected following a preliminary survey conducted to assess the river's significance for nearby communities and to understand the degree of pollution resulting from surrounding activities. Based on the findings of this survey, five locations were strategically chosen along the river's course within the district (Figure 1, Table 1)

**Sample Collection**

Water samples were collected with the utmost care to ensure accurate analysis. The collection of water samples was conducted over a period of one year, that is 2023-24, at 5 different sampling sites. The water samples were collected at a depth of six inches below the river surface. The sampling was conducted during the morning hours, and the water

samples were collected in 1 L pre-cleaned polyethylene bottles. All samples were properly labelled with details of the source, date of sampling, time of sampling, and address.

**Sample Analysis**

The initial step of the WQI process is the parameter selection and significant variations were determined amongst models in terms of the type and quantity of parameters used as well as the rationale behind them. The physico-chemical parameters like turbidity, total dissolved solids, chlorides, nitrates, total hardness and biological oxygen demand were determined adopting methods given by APHA [14]. WQI has been calculated by using the standards of drinking water quality recommended by the World Health Organization (WHO), Bureau of Indian Standards (BIS) and Indian council for Medical Research (ICMR) [15, 16 17].

**Calculation of Water Quality Index (WQI)**

In the present study, all the quality parameters were selected to calculate the water quality index. The WQI has been determined using the standards permissible limit of drinking water quality recommended by the World Health Organization (WHO),Bureau of Indian Standard (BIS) and Indian Council for Medical Research (ICMR) [15, 16, 17]. The weighted arithmetic index method [11] has been implemented for the analysis of the WQI of the water. According to Brown's method, water quality rating is divided into excellent, good, poor, very poor and unfit for consumption (Table 2).

The following steps are involved in WQI determination

**Weighted arithmetic index method (Brown *et al*., 1972)**

**Step 1:** Calculate the unit weight (Wn) factor for each parameter by using the formula

$$\mathbf{Wn} = \frac{k}{Sn}$$

$$\mathbf{K} = \frac{1}{\frac{1}{S1}+\frac{1}{S2}+\frac{1}{S3}+\cdots\ldots+\frac{1}{Sn}} = \frac{1}{\Sigma 1/Sn}$$

Sn= Standard Desirable Value of the nth parameter

On summation of all selected parameters, unit weight factor Wn=1(Unity)

**Step 2:** Calculate the subindex (Qn)value by using the formula

$$\mathbf{Qn} = \frac{[(Vn-Vo)]}{[(Sn-Vo)]} \mathbf{x\ 100}$$

Where,

Vn = mean concentration of the nth parameter

Sn = Standard Desirable Value of the $n^{th}$ parameter

Vo = Actual values of parameters in pure water (Generally, Vo=0)

**Step 3:** Combining Steps 1 and 2, WQI is calculated as follows

Overall $\mathbf{WQI} = \frac{\Sigma WnQn}{\Sigma Wn}$

## RESULT AND DISCUSSION

The physico-chemical parameters such as turbidity, total dissolved solids, chlorides, nitrates, total hardness and biological oxygen demand (BOD) were analyzed for the water samples collected from Pandu River. The water samples for these parameters were taken monthly at the five sites of the Pandu River water course for the year 2023-24. All the parameters with the mean value (Vn) and standard value (Sn) of the data for calculation of water quality index at all sampling sites were calculated (Table 3) and then the value of the water quality index (WQI)was calculated and graded as per the water quality rating given (Table 4). The Turbidity can be defined as the degree to which the presence of suspended water particles causes the water to lose its transparency[18]. The turbidity serves as a key indicator for river water pollution, as higher amounts of turbidity can affect light penetration, aquatic life, and

treatment processes. Turbidity indicates the level of cloudiness and pollution sources in the river water, and it is measured in NTU. The mean concentration of turbidity at all sites ranged from 11.56 to 16.90 NTU (Table 3). The highest value of turbidity was recorded at site 4, which is 16.90 NTU. At site 4, the main source of pollution in the river water is through faecal pollution (Table 1), which contributes to increasing turbidity in the river because the waste material that is dumped contains suspended solids (organic matter and soil particles) that fuel the growth of microorganisms like bacteria and algae, which all make the water cloudy or murky [19].The Total Dissolved Solids (TDS) in water is a measurement of the combined contents of all inorganic and organic components present in water as molecules, ions, or micro-granular suspended forms[20]. The mean concentration of TDS in the sampled water ranged from 114.5 to 191.4 mg/l (Table 3). The maximum value of TDS was recorded at site 5,which is 191.4mg/l. Erosion and Sedimentation are the main sources of pollution at site 5 (Table 1), which increases the range of TDS in the river because eroded soil particles and materials contain soluble mineral salts and contaminants that dissolve into the water[21]. The chloride in river water originates from natural sources, sewage and industrial effluents, urban runoff containing de-icing salt and saline intrusion. The mean concentration of chloride ranged from 25.99 to 51.90 mg/l (Table 3). The highest amount of chloride was reported at site 4 due to human activities like washing off roads, urban runoff, sewage wastewater and also from natural sources like rock weathering. The higher chlorides can make water taste salty and increase corrosion in pipes. The higher levels of chloride can occur with high biological oxygen demand (BOD), chemical oxygen demand (COD), hardness and conductivity, indicating complex pollution.

Elevated levels of chlorides at site 4 are detrimental to the aquatic life, affecting their reproduction and survival. Since chloride cannot break down, it becomes more difficult for freshwater-adapted plants, insects, and fish to survive if there is a constant flow of chloride into the river and insufficient water to dilute the chloride[22]. Nitrate is a vital nutrient that influences the productivity of aquatic ecosystems and speeds up the growth of algae and macrophytes. Nitrates enter freshwater through the discharge of sewage and industrial wastes and run off from agricultural fields [23].The higher level of nitrate results in oxygen depletion in the river water, algae die, decompose, and use up dissolved oxygen, which creates anaerobic conditions for fish and other organisms to survive. The mean concentration of nitrates ranged from 2.32 to 3.35 mg/l (Table 3). The highest amount of nitrate was reported at site 4, indicating agricultural runoff (fertilizers, manure), sewage or wastewater and atmospheric deposition in the river water, leading to issues like eutrophication (algal blooms, dead zones) and potential health risks in drinking water. The Total Hardness of the water is a feature resulting from the presence of alkaline earth metals in natural waters, particularly calcium and magnesium [24].Hard water impacts the taste and overall water quality of river water. The mean concentration of total hardness ranged from 59.36 to 77.50mg/l. The highest amount of total hardness was reported at site 3,which is 77.50 mg/l, indicating higher dissolved minerals, mainly calcium and magnesium, often from passing through mineral-rich rocks in the watershed (like limestone), making water hard [25]. The biological oxygen demand (BOD) is the measure of the quantity of oxygen required by bacteria and other microorganisms under aerobic conditions in order to biochemically degrade and transform organic matter present in the water bodies.

It indicates the amount of perishable organic matter present in water. The higher level of biological oxygen demand (BOD) in river water signifies the severity of organic pollution from sources such as sewage or industrial waste that enhances the microbial breakdown in the river water and thus depletes the dissolved oxygen (DO) in the river water, affecting aquatic life. As a result, a low BOD indicates good water quality, whereas a high BOD suggests contaminated water[26]. The mean concentration of BOD ranged from 76.79 to 58.5 mg/l. The maximum value of BOD was reported at site 3 indicating that the river water is polluted with organic matter (like sewage, farm runoff) that microorganisms consume, drastically lowering dissolved oxygen (DO). The Water Quality Index (WQI) is carried out to simplify the complex water data into a single and understandable number. It also identifies the pollution sources (sewage or agricultural runoff) and checks the suitability of water for drinking or irrigation purposes and over time tracks changes in the water and helps in incorporating policy for management and treatment [27].Urbanization and increased human activity around the river ecology have significantly disrupted the health of the river, affecting both people and the environment. In addition to urban runoff, the primary causes of deteriorating water quality in metropolitan environments include residential, commercial, industrial, and recreational activities.

The river water contamination is caused in part by urbanization and the density of populations along riverbanks. A significant quantity of sewage is directly discharged untreated in megacities due to the very inadequate and outdated sewage treatment infrastructure. As a result, this study aims to evaluate the level of cleanliness and quality of river water, which is one of the health indicators for the river basin. Water quality indicators are used to identify the problems affecting the health of the river. One of the most used methods for characterizing water quality is the Water Quality Index (WQI).

It is based on a single number between 0 and 100 that is derived from physical, chemical, and biological components. In this study, the WQI analysis was performed to check the water quality status of Pandu River for the year 2023-24. The WQI was calculated and shown in Table 4. The WQI of S1, S2, S3, S4 and S5 was found to be 805.8, 710.5, 845.5, 699.8 and 763.2, respectively. The WQI of all sites is graded E as per the water quality status given by Brown *et al*. (1972) (Table 2). The findings revealed the increasing trend of WQI of Pandu River, which falls above the scale of 100, indicating that the water quality of Pandu River at Kanpur is not suitable for drinking purposes at all sampling sites. The highest value of WQI was reported at site 3, which is 845.5 and graded E. The maximum value of WQI at site 3 indicates a higher amount of pollution; the main source of pollution at site 3 is through wastewater pollution (Table 1). The wastewater pollution is the contamination of water bodies by pollutants like untreated sewage, industrial discharge and agricultural runoff, which harms aquatic and human health. It releases pathogens, nutrients, chemicals and other contaminants into the river water. Due to release of massive untreated sewage and industrial waste into the river raises the value of parameters like biological oxygen demand (BOD), turbidity, coli forms and heavy metals, making water unfit for use [28]. As the value of Water Quality Index (WQI) is highest at site 3 (Table 4) so the value of BOD is also highest at site 3 as compared to other sites (Table 3). The value of BOD reported is many-fold higher than the prescribed value, indicating the severity of pollution in the river water at site 3. The higher BOD directly affects the amount of dissolved oxygen (DO) in the rivers and streams. The greater the BOD, the more rapidly oxygen is depleted in the streams. The consequences of high BOD and low DO are borne by aquatic organisms as they become stressed, suffocate and die. The value of turbidity at site 3 is also higher than the prescribed value (Table 3), indicating higher suspended solids (organic matter and soil particles) in the river water and thus contributing to a higher level of WQI at site 3.

## CONCLUSION

The physico-chemical parameters of the Pandu River were studied at five sampling sites along the course of the Pandu River. The mean values obtained showed that Turbidity and Biological Oxygen Demand (BOD)were higher than the permissible limit at all five sampling sites, but BOD was found to be maximum at site 3 (Table 3). It was due to the dumping of untreated sewage and the release of industrial waste into the Pandu River. The Water Quality Index (WQI) was also calculated for all parameters at five sites and ranged between 699.8-845.5(Table 4). The WQI was higher at all sampling sites, indicating an increasing trend of pollution at all sites, but it is maximum at site 3that is 845.5, as compared to other sites. BOD and turbidity are the main water quality sub-indices that reflect the impact of anthropogenic activities on the water quality of this river system. The Water quality index (WQI) was maximum at site 3, so the value of BOD was also highest at site 3 as compared to other sites. The quality of water at all sampling sites during the study period was graded E as per the water quality index given by Brown *et al*. (1972) (Table 2). River degradation has led to an extensive loss of habitats and additional pressures on the aquatic and terrestrial species that use them. It also affects the quality of our drinking water, resilience to climate change, and ability to store and hold back floodwater [29]. Damage to river systems has been so extensive that an urgent need has emerged to conserve and restore these systems[30]. As the Pandu River's health is threatened, there is a need to restore the natural water quality, flow of the river and clean up the polluted river by making little efforts to educate and train people living around the Pandu River and to promote restoration techniques for the river ecosystem.

## ABSTRACT

*Ayurveda* looks at *Mukhadushika* as a body problem that shows up as spots on the face. In *Ayurveda, Mukhadushika* comes from an imbalance of the *Pitta* and *KaphaDoshas*. In this review, I examine the view of *Mukhadushika*. I examine the cause of *Mukhadushika*, the signs of *Mukhadushika*, the way *Mukhadushika* works in the body and the ways to treat *Mukhadushika*. Acne vulgaris is a skin condition. Teenagers and young adults are frequently affected by acne vulgaris. Acne vulgaris presents as blackheads, whiteheads, pimples, pus-filled areas, and deeper masses or cysts. Modern medicine says acne comes from changes, too much oil, bacteria and inflammation. *Ayurveda* says acne needs the *Doshas* to be balanced, the digestion to work well, the body to be detoxified, and stress to be reduced. *Ayurveda* offers a natural, whole-body way that can be an alternative to acne vulgaris treatments. This study looks at the ideas behind *Mukhadushika*. The study examines how a *Pitta* and *Kapha* imbalance, caused by food choices, daily habits and emotional stress, can lead to *Mukhadushika*. The study shows that the acne that is called *Mukhadushika* can start when the *Pitta* and *Kapha* are, out of balance. Clinical manifestations: comparing the various comedones, papules, pustules, and nodules of *Mukhadushika* with the various forms and intensities of acne vulgaris. Pathophysiology: Analyzing how *Ayurvedic* theories of *Dosha* imbalances impact inflammatory processes, sebaceous gland function, and the skin's microbiota in order to reconcile them with modern theories of acne causation. Therapeutic Approaches: Analyzing the all-encompassing *Ayurvedic* approach to *Mukhadushika* treatment, which comprises: Shamana *Chikitsa*: Herbal remedies, dietary modifications, and lifestyle adjustments to balance *Doshas* are examples of pacification treatments. *Shodhana* (*Chikitsa*): Purification procedures, such as *Panchakarma* treatments, to cleanse the body and

restore equilibrium. *Shodhana* (*Chikitsa*): Purification procedures, such as *Panchakarma* treatments, to cleanse the body and restore equilibrium. The review links traditional medicine. The review gives the understanding of acne vulgaris. The *Ayurvedic* understanding of acne vulgaris can give treatment strategies for the skin condition acne vulgaris. By looking at both the approach and the *Ayurvedic* approach the review shows how the two can work together to help people with acne vulgaris.

**Keywords:** *Mukhadushika*, Acne vulgaris, *Ayurvedic* management

## INTRODUCTION

Acne is a prevalent skin disorder that primarily affects teens and young adults, and it affects a large number of people worldwide. Papules, pustules, comed ones, nodules, cysts, and other lesions are caused by dead skin cells and oil clogging hair follicles. In *Ayurveda*, a holistic medical system with origins in ancient India, One *Mukhadushika* is a common treatment for acne vulgaris. Even though acne typically affects the face, trunk, and occasionally the buttocks, untreated or poorly managed cases can leave scars and psychological distress. The skin is an essential sensory organ, particularly the *Sparshendriya* (sense of touch), which covers the entire body and is intimately related to the Mana (mind), according to the ancient Indian physician Maharshi Charak.2 Shifts in skin tone may indicate imbalances in the body. According to *Ayurveda*, *Mukhadushika* is a facial eruption that resembles Shalmali Kantaka (silk cotton tree thorns) and is frequently observed in teenagers. The vitiation (imbalance) of the *Kapha*, *Vata*, and *RaktaDoshas* is said to be the cause of this condition[3.4]. Along with *vaktrasnigdhata* (unctuousness of mouth), *Acharya Sarangadhara* regarded *Yuvana pidika* (acne vulgaris) as a waste product (*mala*) of *shukradhatu* (semen). Since*shukrapradurbhava* (semen production and release) occurs during adolescence, acne vulgaris is most common in this age group. These eruptions, primarily affecting young people (*Yuva*), manifest as small pustules or boils (*Pidika*), hence the term "*YuvanaPidika.*"[5]

***Mukhadushika*: Definition and *Ayurvedic* Perspective**

The term "*Mukhadushika*" refers to a skin condition that usually affects the face and is characterized by lesions that resemble acne, pimples, or eruptions. The primary cause of *Mukhadushika*, according to *Ayurveda*, is an imbalance in the *Doshas*, or bioenergies. While modern medicine usually attributes acne vulgaris to factors like hormonal fluctuations, stress, and environmental pollution, *Ayurveda* links it to disruptions in the body's internal balance, especially the *PittaDosha*.

***PittaDosha*:** *Pitta*, the element of fire, controls the body's digestion, metabolism, and metamorphosis. When *Pitta* becomes agitated, the body overheats, which can lead to conditions like acne vulgaris. *Pitta* imbalances often manifest as redness, inflammation, and irritation, all of which are features of inflammatory lesions associated with acne.

***KaphaDosha*:** *Mukhadushika* can also be caused by imbalances in *Kapha* (earth and water), especially in people with oily skin. Sebum buildup in the skin's pores due to excessive *Kapha* can cause comedones, which may eventually become infected and inflamed.

## MATERIAL AND METHODS

A detailed literary review has been done to understand the concept of Acne vulgaris and *Mukhadushika* (acne vulgaris) from the existing *Ayurveda*, contemporary sciences and modern dermatological textbooks. The latest trends for understanding the disease are also being studied from various peer-reviewed journals of both *Ayurveda* and modern sciences.

**Aetiology of *Mukhadushika* in *Ayurveda* [5,6]**

The *Shastras* offer limited descriptions of the disease "*Mukhadushika*." While all *Samhitas* identify *Kapha*, *Vata*, and *Rakta* as causative factors, *Bhavaprakasa* attributes it to *Svabhava* (natural disposition). The *SharangadharaSamhita* mentions *Vakrasnigdhata* and *Pidika*, associating them with *Shukradhatumala* (semen impurities).

In *Ayurveda*, the root causes of *Mukhadushika* are multifactorial and include

**Dietary Factors:** Consumption of excessively oily, spicy, and sour foods, or foods that increase *Pitta*, is considered a key factor in aggravating the condition.

**Emotional Stress:** Anxiety, anger, and other *Pitta*-aggravating emotions are thought to have a direct impact on the skin, triggering outbreaks.

**Poor Digestion (*Agni*):** A weakened digestive fire (*Agni*) is often considered to play a critical role in skin diseases, including *Mukhadushika*. Impaired digestion leads to the accumulation of toxins (*Ama*), which can manifest in the skin as acne.

**Hormonal Imbalance:** Similar to modern medical interpretations, hormonal changes, particularly during puberty, menstruation, or pregnancy, are recognised in *Ayurveda* as factors contributing to skin eruptions.

**Environmental Factors:** Exposure to excessive heat, pollutants, and humidity can exacerbate *PittaDosha* and worsen the condition.

**Morden aspect[7]**

**Seborrhea:** Excessive androgen production or availability of free androgens or intracellular binding capacity.

**Comedone formation:** Increase keratinocyte proliferation and decrease desquamation.

**Propionibacterium acnes colonisation**- Enzymes may promote follicular wall rupture. - Heat shock proteins promote inflammation. - Porphyrins may lead to adjacent tissue damage. - Toll-like receptor-2 binds to P. acnes and leads to the release of proinflammatory cytokines IL-8 and IL-12.

**Inflammation** - Local perifollicular CD4 T-cells and IL-1 levels - Increased neutrophils → pustules
- Increase lymphocytes and foreign body giant cells → papules, nodules and cysts.

**Clinical Features of *Mukhadushika*[8]**

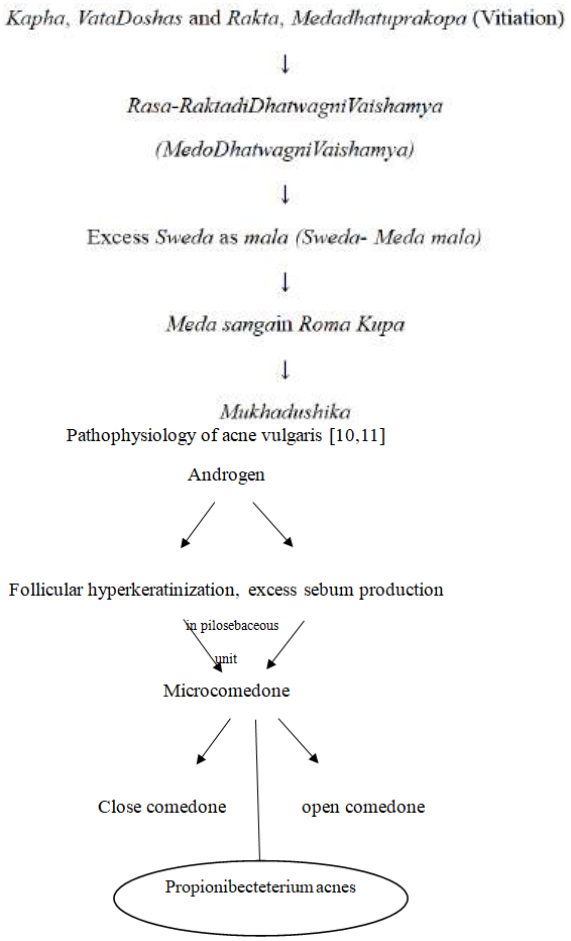
*Mukhadushika* typically presents with *Pidika* (This term signifies an eruption), indicating the disease manifests as skin eruptions, *Medogarbha (*Comedones, Whiteheads and blackheads) resulting from clogged pores are also common, *Saruja* (Painful cysts or nodules). In severe cases, deeper nodules or cysts can form, leading to scarring, *Ghana*(this word describes the eruptions as thick, hard, or indurated), *Yuna*mukha(This refers to the location of the disease, specifically the face of adults),Excessive Oiliness particularly in individuals with *KaphaDosha* imbalance. These are often found on the face but can also affect the chest, back, and shoulders.

**As per Modern:** Clinical Manifestations[7]

- Face involved in 99%, back involved in 60%, chest in 15%.
- Noninflammatory lesions (Comedones, macrocomedones, submarine comedones)
- Inflammatory lesions (Papules, pustules, nodules, erythematous nodules)
- **Scars:** Atrophic (Icepick, boxcar, rolling).

Hypertrophic (keloid, papular, bridging).

Samprapti of *Mukhadushika* (acne vulgaris) as per *Ayurveda*[8,9]:



Inflammatory lesions i.e. acne formation(papules, pustules, cysts, nodules)

**Samprapti of Mukhadushika (Pathogenesis)**

*Ayurveda* describes the pathogenesis as

- Vitiation of *Kapha*, *Vata*, and *RaktaDoshas*.
- Impairment of *Rasa-RaktadiDhatwagni* (metabolic fire), particularly *MedoDhatwagni*.
- Excessive *Sweda* (sweat) as *Mala* (waste product).
- Accumulation of *Meda* (fat) in *RomaKupa* (pores).
- Manifestation of *Mukhadushika*.

**Pathophysiology of acne vulgaris [10,11]**

Acne vulgaris is a chronic inflammatory skin condition primarily affecting the pilosebaceous unit (hair follicle and sebaceous gland). Its pathophysiology involves a complex interplay of several key factors:

**Increased Sebum Production**

- Stimulated by androgen hormones (testosterone and dihydrotestosterone).
- Leads to excessive oiliness, creating an ideal environment for acne development.

**Follicular Hyperkeratinization**

- Abnormal keratinocyte proliferation and shedding in the follicle.

- Leads to clogging of hair follicles, forming microcomedones, which evolve into blackheads (open comedones) or whiteheads (closed comedones).

**Proliferation of *Cutibacterium acnes* (formerly *Propionibacterium acnes*)**
- This commensal skin bacterium overgrows in the clogged follicle.
- Produces lipases, which break down sebum into pro-inflammatory free fatty acids.

**Inflammatory Response**
- *C. acnes*triggers an immune response, releasing cytokines (IL-1, IL-6, TNF-$\alpha$) and recruiting neutrophils.
- Leads to the formation of papules, pustules, nodules, and cysts.

**Additional Contributing Factors**
- Hormonal fluctuations (e.g., puberty, menstrual cycle, polycystic ovary syndrome).
- Genetics (family history of acne).
- Dietary factors (high glycemic index foods, dairy).
- Stress (increases cortisol, which stimulates sebaceous glands).
- Medications (e.g., corticosteroids, lithium).

Understanding these mechanisms helps in targeted acne treatments, such as
- Retinoids (normalise keratinisation).
- Benzoyl peroxide and antibiotics (reduce *C. acnes*).
- Anti-androgens and isotretinoin (reduce sebum production).
- Anti-inflammatory agents (to modulate immune response).

The Investigator Global Assessment (IGA) scale, approved by the FDA in 2005, is a widely used tool for assessing acne severity in clinical trials. While reliable, its "severe" category lacks granularity and may not provide adequate guidance for treatment decisions. A more refined system categorising acne as moderately severe, severe, and very severe, along with considering nodule size (e.g., >1 cm), is needed to improve treatment selection. Table 1: Investigator Global Assessment Scale (IGA) by US FDA[12]. **IGA:** Investigator Global Assessment, FDA: Food and Drug Administration.

***Ayurvedic* Treatment of *Mukhadushika* (Acne Vulgaris)[13-16]**

*Ayurveda* emphasises a holistic approach to treating *Mukhadushika*, focusing on restoring balance to the *Doshas*, improving digestion, and eliminating toxins from the body. Key treatment modalities include:

1-*NidanaParivarjana*
2-*ShodhanaChikitsa*
3-*ShamanaChikitsa*

*Samana* and *ShodhanaChikitsa*(Table2*)*:

***Vamana karma***

*Vamanakarma*, according to *Sushruta*, paste of *vacha, lodhra* and *saindhav* mixed with *sarsapa* should be given to the patient for emesis[14].

***Raktamokshana***

The *Doshas* involved in *Mukhadushika* are *kapha*, *vata* and *rakta*. So, *raktamokshana* is one of the best treatments explained in *samhitas*, in *Mukhadushika*, *siravedh* and *jaloukaavcharan* are performed mainly[13].

***Lepa* application**

Ancient *Ayurvedic* texts highlight the effectiveness of *Mukhadushikalepa* (topical application), offering a variety of formulations for clear, healthy skin.

According to *AstangaHrudaya*, a paste of *rodhrakustumburu* and *vacha* is useful for *Mukhadushika*, or a paste of tender leaves of *vata* and *narikelasukti*(coconut shells)[13]. According to *SushrutaSamhita*, the application of medicinal plasters consisting of *vacha*, *lodhra*, *saindhava* and *dhanyaka*or of *kustumburu*, *vacha*, *lodhra*, *kustha* pasted together is beneficial [14]. According to *Yogaratnakara*: *Jatiphaladilepa*: *jayaphala*, *raktachandana* and *kalimarich* equally taken and made a paste and applied, or *vacha*, *lodhra*, *dhanyaka* pasted together are beneficial or *Gorochana* and *marich* equally taken and made a paste and applied. They are useful in *Mukhadushika*; other than this formulation, various formulations are given in *Yogaratnakara*[6,16].

**Herbal Remedies:** *Neem* (*Azadirachta indica*): Known for its antimicrobial and anti-inflammatory properties, neem is widely used in *Ayurvedic* formulations to treat acne.

***Haridra*(*Curcuma longa*):** Turmeric's anti-inflammatory and antiseptic properties help in reducing the redness and swelling associated with acne.

***Kumari*(*Aloe Vera*) :** Known for its soothing properties, aloe vera gel is commonly used to reduce skin irritation and promote healing.

***RaktaChandana* (*Pterocarpus santalinus*):** This herb has cooling and astringent properties that help in reducing inflammation and controlling excess oil production.

***Manjistha* (*Rubia cordifolia*):** Often used to purify the blood and detoxify the body, *Manjistha* is considered beneficial for treating skin conditions like acne.

**Dietary Modifications**

***Pitta*-balancing foods:** Foods that reduce *Pitta*, such as bitter greens, cucumbers, and cooling fruits (like melons), are recommended to balance the heat in the body.

**Avoiding *Pitta*-aggravating foods:** Spicy, oily, and fried foods, along with excessive intake of dairy products, should be minimised to avoid further aggravation of acne.

**Promoting Agni (Digestive Fire):** Consuming easily digestible foods and including herbs like ginger and cumin to stimulate the digestive fire can help in the elimination of toxins (Ama).

**Topical Treatments:**

**Face Masks:** Masks made from natural ingredients like multanimitti (Fuller's Earth), turmeric, and honey help to cleanse the skin, reduce inflammation, and provide a cooling effect.

**Oil and Ghee Applications:** Oils like coconut oil, rose oil, or ghee (clarified butter) may be used in small amounts to hydrate the skin and balance *Pitta*.

**Lepa application**

**Lifestyle Modifications**

**Stress Management:** Techniques such as *yoga*, meditation, and *pranayama* are recommended to reduce *Pitta*-aggravating stress and promote emotional balance.

**Regular Cleansing:** Gentle facial cleansing routines are encouraged to keep the skin free from dirt and excess oil, preventing pore blockages.

**Adequate Sleep:** Sufficient rest is crucial for skin health, as it helps regulate hormonal levels and maintain overall bodily balance.

## DISCUSSION

*Mukhadushika*, or acne vulgaris, is a dermatological condition with differing interpretations in *Ayurveda* and modern medicine. *Ayurveda* attributes its development to imbalances in *Pitta* and *KaphaDoshas*, which lead to excessive sebum production, inflammation, and toxin accumulation in the body. It emphasises treatment through detoxification (*Shodhana*), pacification (Shamana), herbal formulations, dietary modifications, and lifestyle adjustments. On the other hand, modern dermatology links acne to factors like excess sebum, bacterial colonisation, hormonal fluctuations, and inflammatory responses, treating it with antibiotics, retinoids, and dermatological procedures. *Ayurvedic* treatment focuses on the root causes by restoring internal balance and eliminating toxins through methods such as Vamana (therapeutic emesis) and Raktamokshana (bloodletting). Herbal remedies like *Neem*, Turmeric, Aloe Vera, and Sandalwood have shown antimicrobial and anti-inflammatory properties, supporting acne treatment naturally. *Ayurveda* also emphasises dietary guidelines to balance *Pitta*, reducing spicy, oily, and processed foods while encouraging cooling and detoxifying foods. Stress management through yoga, meditation, and lifestyle modifications is also recommended. Modern dermatology, in contrast, relies on pharmaceutical interventions, including topical and oral antibiotics, hormonal therapies, and advanced dermatological techniques like laser treatments and chemical peels. These methods effectively manage symptoms but may lead to side effects such as antibiotic resistance, skin irritation, or hormonal imbalances. Despite these advancements, modern medicine often lacks a long-term, systemic approach to treating acne. Both *Ayurvedic* and modern perspectives recognise the role of diet and stress in acne development. *Ayurveda*'s holistic approach aligns with the growing demand for natural and sustainable therapies, which are increasingly gaining scientific validation. However, despite its promising potential, more rigorous clinical studies are needed to establish standardised *Ayurvedic* treatment protocols and ensure efficacy in diverse populations. The integration of *Ayurveda* with modern dermatological practices could provide a comprehensive approach to acne management. By combining natural therapies with evidence-based medical treatments, a more personalised and effective strategy can be developed. This integrative approach would not only address symptoms but also target underlying imbalances, offering a long-term solution for individuals suffering from acne vulgaris. Future research should focus on bridging these two medical systems, exploring their synergies, and developing integrative treatment plans. By leveraging the strengths of both *Ayurveda* and modern medicine, healthcare practitioners can offer a more holistic and effective acne management strategy, ensuring better patient outcomes and improved skin health.

## CONCLUSION

*Mukhadushika*, or acne vulgaris, from an *Ayurvedic* standpoint, is a complex condition rooted in an imbalance of the *Doshas*, particularly *Kapha* and vata. *Ayurvedic* treatment focuses on restoring balance to the body through a combination of dietary modifications, herbal remedies, and lifestyle changes. While modern dermatology often relies on chemical treatments and antibiotics, *Ayurveda* offers a more holistic approach by addressing the underlying internal imbalances that contribute to acne. Through personalised treatment plans that include both external and internal therapies, *Ayurveda* presents a valuable alternative for individuals seeking to manage and potentially resolve acne vulgaris in a more natural, systemic manner.

## ABSTRACT

*Sesbania grandiflora, Solanum nigrum, Alternanthera sessilis* and *Spinacia oleracea* are greens cultivated and distributed throughout India. The entire plant is traditionally used by local people for many ailments and as a nutritious dish. Owing to its beneficial effects, this study aimed to determine the antioxidant, and antibacterial activity of fresh and ethanol extracts, as well as the phytochemical constituents in the four plants. Extraction was performed by cold-maceration using ethanol solvent. Fresh extracts were obtained from fresh juice of the leaves. Antioxidant activity was evaluated by DPPH radical scavenging assay. The antibacterial activity was tested by agar well diffusion method against three Gram-positive: *Staphylococcus aureus, Bacillus cereus* and *Streptococcus pyogenes* and two Gram-negative bacteria: *Escherichia coli* and *Pseudomonas aeruginosa*. Our results showed that the fresh extract of the leafy greens contains many phytochemicals including phenols, alkaloids, flavonoids, tannins, terpenoids, and saponins. Both fresh and ethanol extracts displayed the ability to inhibit DPPH free radical formation and prevent the growth of all the tested microorganisms. Thus, the four leafy greensis evident topossess prominent secondary metabolites aiding to be an excellentantioxidant and antibacterial agent.

**Keywords:** *Sesbania grandiflora, Solanum nigrum, Alternanthera sessilis, Spinacia oleracea,* DPPH assay, agar well diffusion assay.

## INTRODUCTION

Oxidative stress is an imbalance between the generation of reactive oxygen species (ROS) and a low activity of antioxidant mechanisms in the body. Oxidative stress caused by overproduction of ROS harms lipids, proteins, and DNA in the cells, and interferes with metabolic and cellular signalling, damaging cellular structures and tissues [1], leading to the onset and progression of chronic illnesses like cancer, diabetes, heart disease, and neurological disorders [2]. Likewise, bacterial infections continue to be a significant global health concern. Serious infections acquired in hospitals and the community are caused by pathogenic bacteria like *Pseudomonas aeruginosa*, *Escherichia coli*, and *Staphylococcus aureus*[3].Overuse of antibiotics has led to the prevalence of multidrug-resistant strains further mounting the problem. However, since ancient times, plants have been used as important sources of medicine for combating oxidative stress and infectious diseases. Phytochemicals like phenolics, flavonoids, alkaloids, and terpenoids identified in plants act as natural therapeutic substitutes by scavenging free radicals and preventing microbial growth[4]. Their use for bacterial infections and oxidative stress-linked disorders is supported by both scientific validation and traditional ethnomedical knowledge. They are increasingly gaining momentum due to their low cost, decreased toxicity, and pharmacological diversity[5]. *Sesbania grandiflora* (Family: Fabaceae) is used as food by local people. The leaves, flowers and fruits can all be consumed alone as a vegetable and as curries or salads. The plant is reported with antioxidant, hepatoprotective, wound healing, antiulcer, antibacterial, anti-inflammatory, anti-diabetic, immunomodulatory, and antiproliferative effects [6]. *Solanum nigrum* (Family: Solanaceae) is a popular plant with all its parts used as food and medicine. Fruits are consumed raw. Leaves and unripe berries are cooked and being eaten. Hepatoprotective, immunostimulant, antimicrobial, anti-gastritis, anti-ulcerogenic, cardioprotective, analgesic, anti-diarrheal, anticancer, anti-hyperlipidemic and antioxygenic activities have been successfully studied [7]. *Alternanthera sessilis* (Family: Amaranthaceae) leaves are eaten fried with ghee, which gives cooling effect to eyes, and disease-free life. With its diverse phytochemicals, anti-microbial, anthelmintic, anti-diabetic, lipid-lowering, anti-inflammatory, analgesic, anti-cancer and other biological activities have been sighted[8]. *Spinacea oleracea*(Family: Amaranthaceae) is widely used as a vegetarian food characterized by multifaceted therapeutic properties [9]. The present work was aimed to prepare fresh and ethanol extracts of *S. grandiflora, S. nigrum, A.sessilis* and *S. oleracea*, to perform preliminary phytochemical analysis, to compare the antibacterial activity and to investigate the antioxidant activity in order to prove the usage of the four leafy greens in traditional medicine and as a nutritious dish.

## MATERIALS AND METHODS

**Collection and authentication of plant material**

**The leaves of four plants:** *Sesbania grandiflora, Solanum nigrum, Alternanthera sessilis* and *Spinacia oleracea* were collected from a local market in Tirunelveli District, Tamil Nadu, India and authenticated from a Professor from the Department of Botany, St. Xavier's College, Palayamkottai, Tamil Nadu, India.

**Preparation of plant extracts**

For the preparation of fresh extracts, leaves were washed, air-dried, pulsed in a mixer, and the collected fresh juice was filtered using a filter paper to obtain the extract. For the preparation of ethanol extracts, cold maceration method was followed [10]. The leaves were washed, shade-dried at room temperature, ground to fine powder, and 20 g of the dried leaves were soaked in 100 ml ethanol for 72 h. The solvent with the extract was then filtered using a muslin cloth, and evaporated in water bath to yield concentrated extract. The crude ethanol extract was stored in an air-tight container.

**Qualitative phytochemical analysis**

Fresh extracts of *S. grandiflora, S. nigrum, A.sessilis and S. oleracea* were screened to detect phytochemicals such as alkaloids, carbohydrates, oils and fats, phenolic compounds, tannins, proteins, saponins, flavonoids, terpenoids, steroids, gums and mucilage using standard protocol [11].

**Agar well diffusion assay**

Agar well diffusion method was used to determine the antibacterial activity [12] of the fresh and ethanol extracts against five bacteria. *Staphylococcus aureus*, *Bacillus cereus*, *Streptococcus pyogenes*, *Escherichia coli* and *Pseudomonas aeruginosa* were used in the study. Prior to the assay, all the glass wares and media employed were sterilized by autoclaving at 121 °C for 15 minutes at 15 lbs pressure and dried at 160 °C in hot air oven. 3.8 g Muller-Hinton Agar was dissolved in 100 ml distilled water, autoclaved, and poured into sterile Petri plates. Bacterial cultures were spread using a sterile swab under aseptic condition. The wells made with sterile borer were filled with 40 µl of plant extract (10 mg, 5 mg, 2.5 mg, 1.25 mg and 0.625 mg), standard antibiotic streptomycin (1 µg) and control (distilled water or ethanol). After incubating overnight at 37 °C, the plates were observed for bacterial growth and the zones of inhibition recorded in mm.

**Antioxidant analysis**

The antioxidant activity was assessed using DPPH (1,1 -diphenyl-2-hydrazyl) assay as described earlier with minor modifications[13]. 0.2 ml plant extract (20 mg, 10 mg, 5 mg, 2.5 mg, 1.25 mg) was mixed with 1 ml 0.2 mM DPPH and incubated for 30 min in the dark. The absorbance was read in UV-Vis spectrophotometer at 520 nm. Ascorbic acid was used as standard. DPPH scavenging activity was calculated, {(Absorbance of control – Absorbance of sample)/Absorbance of control} × 100. $IC_{50}$ was calculated from the dose-response graph plotted by percentage inhibition against extract concentration.

**Statistical analysis**

Graphs were plotted and $IC_{50}$ values were estimated in MS-Excel 2021.

## RESULTS AND DISCUSSION

Leaf vegetables, also called leafy greens, vegetable greens, or simply greens, are plant leaves eaten as a vegetable. In Tamil Nadu cuisine, boiled greens are a common side dish popularly favoured for its rich nutritious content. For our study we selected four leafy greens: *S. grandiflora, S. nigrum, A. sessilis and S. oleracea* and evaluated its antioxidant and antibacterial efficacy with fresh and ethanol extracts.

**Phytochemicals in the extracts**

Phytochemical constituents are secondary metabolites of plants that serve as defence mechanism against many microorganisms and insects [14]. The results of phytochemical analysis of fresh extracts of *S. grandiflora, S. nigrum, A. sessalis and S. oleracea* are tabulated in Table 1. *S. grandiflora* contains alkaloid, carbohydrate, protein, phenol, tannin, saponin, oil and fat, gum and mucilage, flavonoid, terpenoid and steroid thus increasing its medicinal importance, while terpenoid and carbohydrate are absent in ethanol extract [15]. *S. nigrum* contains protein, carbohydrate, saponin, oil and fat, gum and mucilage, flavonoid, terpenoid, and steroid similar to ethanol extract [16]. *A. sessilis* contains carbohydrate, protein, phenol, tannin, flavonoid, terpenoid, oil and fat, gum and mucilage in both the extracts [17] and absence of alkaloid, steroid and saponin in fresh extract. *S. oleracea* fresh extract contains carbohydrate, protein, phenol, tannin, flavonoid, terpenoid, oil and fat, saponin, steroid, while only tannin, phenol, steroid and glycoside in ethanol extract [18].

**Antioxidant effect of the extracts**

DPPH method employed for assessing the antioxidant effect is simple and applies to measure the overall antioxidant capacity and the free radical scavenging activity of fruit and vegetable juices [19]. Results of DPPH scavenging for fresh and ethanol extracts of *S. grandiflora, S. nigrum, A. sessilis and S. oleracea* are depicted as graphical representation in Figures 1 and 2. The antioxidant efficacy of the eight extracts were determined by estimating the $IC_{50}$ values, the concentration at which the extract shows 50% inhibition of DPPH free radicals, similar to providing a measure of potency of an antagonist drug in pharmacological research [20]. Low $IC_{50}$ value indicates the drug to be effective at low concentrations [21]. In our study, the $IC_{50}$ of fresh extracts of *S. grandiflora, S. nigrum, A. sessilis* and *S. oleracea*

were estimated to be 80 mg, 25.97 mg, 1137.89 mg and 58.10 mg respectively (Figure 3 A-D). The results indicate that the fresh extract of *S. nigrum* exhibited the lowest $IC_{50}$ making it the most effective antioxidant when compared to the other fresh extracts. And the order of antioxidant potential from greatest to the least is: *S. nigrum >>S. oleracea>>S. grandiflora >>A. sessilis.* Similarly, the $IC_{50}$ of ethanol extracts of *S. grandiflora, S. nigrum, A. sessilis* and *S. oleracea* were calculated to be 7.31 mg, 0.80 mg, 34.38 mg and 13.50 mg respectively (Figure 3 E-H). The results indicate that among ethanol extracts, *S. nigrum* exhibited the lowest $IC_{50}$ making it the most effective when compared to other ethanol extracts. And the order of antioxidant potential from greatest to the least is: *S. nigrum >>S. grandiflora >>S. oleracea>>A. sessilis.* On comparing fresh and ethanol extracts of the four leafy greens, ethanol extract exhibits more antioxidant property than the fresh extracts. The greater free radical inhibitory activities exhibited by ethanol extracts compared to fresh extracts could be ascribed to the higher or unique phytochemical component of the plants [22], which needs to be proved further by quantitative phytochemical analysis. Two previous studies, one in methanol extract of *S. nigrum* and another in aqueous extract of *A. sessilis* have identified 92% and 80% inhibition of DPPH free radicals [23, 24].

**Antibacterial effect of the extracts**

The results presented in Table 2 show the antibacterial potential of the fresh leaf extracts (10 mg) of *S. grandiflora, S. nigrum, A. sessilis,* and *S. oleracea* against five pathogenic bacteria. Among the fresh extracts, *S. grandiflora* exhibited the strongest activity, producing inhibition zones ranging from 28–34 mm, followed closely by *S. nigrum* (20–33 mm). *S. grandiflora* extracts produced measurable inhibition zones supported by an earlier report on the antibacterial activity of stem bark fractions showing ethyl acetate and butanol fractions of ethanol extract with pronounced activity and Gram-negative efficacy [25]. In comparison, *A. sessilis* and *S. oleracea* demonstrated moderate antibacterial effects with zones between 18–22 mm. Although none of the extracts outperformed the standard antibiotic streptomycin (40 mm), all extracts showed measurable activity, confirming their broad-spectrum antibacterial potential. Table 3 highlights the inhibitory effects of ethanol extracts at the same concentration. Unlike the fresh extracts, *A. sessilis* showed the highest activity with inhibition zones of 19–25 mm against all tested bacteria, particularly strong against *E. coli* and *S. pyogenes* (25 mm each). *S. grandiflora* and *S. nigrum* produced moderate inhibition (12–16 mm), while *S. oleracea* exhibited the lowest activity (8–14 mm). Although still lower than streptomycin (40–45 mm), the ethanol extracts demonstrated clear antibacterial properties, suggesting that ethanol may selectively extract active phytochemicals responsible for antimicrobial action.Yet another work demonstrates dose-dependent antibacterial activity of ethanol extract of *S. nigrum* against *E. coli, P. aeruginosa, S. aureus,* etc. similar to this study[26]. Kumar et al. reports antibacterial and antifungal effects of ethanolic extracts of *A. sessilis*, consistent with the relatively higher activity of our study [27]. An earlier study with minimum inhibitory concentration determination and diffusion assays for ethanolic spinach extracts, *S. oleracea* shows comparatively lower antibacterial zones in ethanol extracts [28]. It is established that solvent polarity and solvent choice strongly influence the phytochemicals in the extract [29], and hence the difference in measured antibacterial activity between the fresh and ethanol extracts of the four plants.

## CONCLUSION

Our study aimed to assess the phytochemicals of fresh extract, antibacterial and antioxidant activity of both fresh and ethanol extracts of four very common greens: *S. grandiflora, S. nigrum, A. sessilis* and *S. oleracea*. These leafy greens are used in traditional medicine and also used to make various dishes. The phytochemical results of our study provide supportive scientific evidences that all these four leafy greens, fresh extract possess many bioactive compounds which are pharmacologically active in treatment of various ailments. Antibacterial study involving both the fresh and ethanol extract suggests the usefulness of fresh leafy greens against several pathogenic bacteria. Antioxidant assay further confirms the extracts of leafy greens having great free radical scavenging activity. These greens must be used in various supplements to cure various diseases.

## ABSTRACT

Natural food colorants demand was increasing due to consider about the safety and quality assurance of synthetic alternatives among consumer. Plant-based pigments are of interest as they can offer both color and bioactive compounds with potential health benefits. This study aims to evaluate *Solanum nigrum* (black nightshade) fruits as a source of natural food colorant. The central research question is Can pigments extracted from *Solanum nigrum* fruits serve as a viable, functional, and nutritious alternative to synthetic food dyes. Pigments were extracted using aqueous solutions at pH 2 and 4, with solid-liquid ratios of 1:10 and 1:20. Colorimetric analysis, total monomeric anthocyanin content, FRAP assay, and nutritional composition were assessed for both aqueous extracts and emulsions. The highest total monomeric anthocyanin content (20.70 mg/L) was achieved at a 1:10 ratio and pH 2. Colorimetric analysis revealed distinct L*a*b* values, with an emulsion exhibiting more intense reddish-yellow hues. The emulsion displayed high levels of carbohydrates (1200 mg/ml), protein (7.64 g/100ml), and vitamin C (105 mg/g), as showed in the Graphical Abstract. Antioxidant capacity, assessed via FRAP assay, showed a dose-dependent response. While the aqueous extract demonstrated better pigment stability, the emulsion formulation enhanced nutritional value and colour vibrancy. The results suggest that *Solanum nigrum* fruit pigments hold promise as functional natural food colorants. Further research is recommended to improve emulsion stability for potential commercial applications.

**Keywords:** *Solanum nigrum*, natural food colorant, anthocyanins, antioxidant activity, emulsion, pigment extraction, black nightshade.

## INTRODUCTION

Colours, especially, act as a visual treat to the consumer; it has spectral distribution of light which is associated as a visual feature resulting from interaction with matter. Furthermore, contrary to synthetic dyes, natural food colorants consumption has significantly more benefits. They increase their demand of reliability, functionality, biological potential, and health benefits. Food colours are obtained from nature and allowed for extraction processes using isolated by more or less complicated, while Synthesised dyes are, however, made chemically. For example, to enhance consumer preferences, food colours are usually applied to edible ices, desserts, pastry and fine bakery products.(Silva *et al.,* 2022). *Solanum nigrum* Linn. (Solanaceae) is similarly known as 'Black nightshade' which belongs to the Solanaceae family. As in tamil called as Manathakkali. It has a variable beneficial properties such as antimicrobial, oxidative and cytotoxic also contains antiulcerogenic and hepatoprotective properties. Feverish convulsions, eye diseases, hydrophobia, and chronic skin conditions are the reasons that cause infant deaths. These are treated by paediatric herb from Africa also used to cure variety of diseases. It's an anti-cancer herbal alternative (Rajathi *et al.,* 2015). It is medicinally used in the management of several ailments, such as pneumonia aching teeth, tonsilitis, wing worms, pain, fever, as antioxidant, and as antipyretic (Acharya *et al.,* 2006). The plant contains common herb or short-lived perennial shrub, located in many wooded areas along with disturbed habitats. The plant attains a height of 30 to 120 cm (12 to 47 inches), leaves attains 4.0 to 7.5 cm (1.6 to 3.0 inches) long and 2 to 5 cm (1 to 2 inches) of the plant wide, ovate to heart-shaped, with wavy or large-toothed edges; both surfaces are hairy or hairless, petiole reaches 1 to 3 cm (0.5 to 1 inches) long with a winged upper portion. When aged of plant the petals in the flowers obtains greenish to whitish recurved and surrounded by noticeable bright yellow anthers. *Solanum nigrum* fruits or berry chiefly 6 to 8 mm (0.24 to 0.31 inches), dull black or purple-black (Patel *et al.,* 2009). Tuberculosis has also been traditionally treated with the plant. In India, leaves of the plant are commonly used during the winter period for curing a mouth ulcer, and apart from its home remedy use for mouth ulcers, it is used in cooking like spinach. In North India, the diseases related to the liver, such as jaundice, are relieved through the extraction process of boiling method of leaves and berries. In Assam, the juice was taken from root by adaptable process method and allowed to cure against asthma and whooping cough (Shukla *et al.,* 2004 and Mukherjee *et al.,* 1998). The whole plant of *Solanum nigrum* has good effects in dispersing blood stasis and detumescence, clearing away heat, as well as detoxification, and has been commonly used for the treatment of canker sores, skin eczema, urinary tract infections, and chronic bronchitis, etc for thousands of years (Gao *et al.,* 2021).

## MATERIALS AND METHODS

**Raw materials and chemicals**

The raw sources in the fruits of *Solanum nigrum* (Black Nightshade), commonly called Manathakkali in Tamil and widely spread out in tropical regions. This fruit is rich in bioactive phytochemicals. These fruits were collected from local farm areas in the Erode district. The fruits of *Solanum nigrum* were cleaned and washed with distilled water. Further, the emulsifying agent, gum arabic, is used as a stabiliser to stabilise the emulsion, while preservatives like sodium benzoate used to prevention method of microbial growth in the emulsion. The pH of emulsion solution was maintained by adding citric acid to enhance the pigment stability.

**Extraction method of pigments**

The fruit of *Solanum nigrum* was weighed at 15 g, and 7.5 g of the two samples were allowed to make fine paste by ground using a mortar and pestle. These pastes were allowed boiled with 150 mL of distilled water in a temperature-controlled water bath under different aqueous conditions. The extraction was carried out using two ratios, 1:10 and 1:20 (solid: liquid), and two different pH levels (2 and 4) were maintained by using citric acid. The resulting mixture was cooled and further allowed to filtered for obtain the aqueous extract. Then, the solution was transferred to a 250ml Erlenmeyer flask and placed over a temperature-controlled water bath for about 40 minutes. After incubation, the extract solution is filtered using Whatman no. 40 filter paper and the extract is placed in a clean glass bottle covered with aluminium foil for further analysis.

**Determination of Total Monomeric Anthocyanin Content (TMAC)**

Determination of Total Monomeric Anthocyanin Content, as stated by Lee*et al.,* 2005, The spectrophotometric pH differential method was used for total anthocyanin. Using 0.025M potassium chloride solution and 0.4M sodium acetate solution for diluted the sample then the pH was adjusted to 1.0 and 4.5 using HCl, respectively. It was equilibrated for 15minutes in the condition under darkness. Then the each dilution of the absorbance was measured at 510nm and 700nm using a UV spectrophotometer with distilled water as a blank.

Total anthocyanin content was calculated by the following equation.

Total anthocyanin = [A×Mw×DF×100] / [Mg/100ml (£×1)]

A= (A520nm – A700nm) pH 1 – (A520- A700nm) pH 4.5

MW = (molecular weight) = 449.2 g/ mol for cyanidin -3- glucoside

DF = dilution factor

£ = is the molar absorptivity of cyanidin -3- glucoside (26, 900).

1= cell path length (1cm).

10(3) = factor for conversation from g to mg

**Formulation of food colour emulsion**

The aqueous extracted pigments with high total monomeric anthocyanin in the fruit extract were taken based on optical density value for about 86.4ml and it was added to an emulsifier 'gum arabic' of about 10g and it was homogenized with a homogenizer at 3000rpm for 10minutes followed with gradual addition of 2ml Sunflower oil. Then it was again homogenized at 4000rpm for 20minutes. Finally, the consistency of the emulsion was adjusted and refrigerated under at 6°C in a sterilize glass bottle for further analysis.

**Determination of colour**

The colour of the extract and food colour emulsion of *Solanum nigrum* was determined using the LAB colour value in digital colour meter, which measures the L* (lightness), a* (red-green axis), and b* (yellow-blue axis) values. In the colorimeter the LAB values were obtained, which provided a numerical representation of the colour. The L* value ranged from 0 (black) to 100 (white), while the a* and b* values ranged from -128 to 127, with the values of positive represent red or yellow hues and the values of negative represent green or blue hues. The LAB values were used to quantify the colour characteristics of the emulsion, providing a precise and objective measurement of its colour (Romaniello *et al.,* 2015)

**Determination of Antioxidant capacity**

The Ferric Reducing Antioxidant Power (FRAP) assay is a widely used method for evaluating the antioxidant capacity of various substances, including plant extracts, foods, and biological fluids. The antioxidant ability was measured by the method of FRAP to reduce ferric ions (Fe3+) to ferrous ions (Fe2+), consequent formation of a coloured complex that can be quantified spectrophotometrically. The FRAP assay is established on the principle that electrons donate by antioxidant to reduce ferric ions, thereby indicating their antioxidant potential. The FRAP value is expressed in terms of the concentration of antioxidants required to reduce a certain amount of ferric ions, providing a quantitative measure of antioxidant activity. By using distilled water1ml of Emulsion/fractions (20-100µg/ml) was prepared and then allow mixed with 2.5ml of phosphate buffer for 20min. In the mixture 2.5ml of 10% trichloroacetic acid was added and centrifuged at 3000rpm for 10 min. Atlast, 1ml of aliquot of supernatant was taken allowed to mixed with 2.5ml of distilled water and 0.5ml FeCl3 (10%) and then the absorbance was measured at 700nm. Increase in absorbance was interpreted as increase of reducing activity (Harpreet*et al.,* 2011).

## RESULTS AND DISCUSSION

**Total anthocyanin content in fresh fruits after extraction**

The total anthocyanin content in aqueous extract of *Solanum nigrum* fruits can vary depending on solvent ratio and pH. Despite these variations, total anthocyanin content in aqueous extract is reported. In the spectrophotometric pH

differential method the total anthocyanin content was measured. The total anthocyanin content in the aqueous extract of *Solanum nigrum* with its optical density at 520nm and 700nm is given in the Table 1. The Total Monomeric Anthocyanin Content (TAC) in *Solanum nigrum* fruit extract varies depending on the extract ratio and pH. At pH 2 and 4, the TAC was significantly higher (20.70 mg/L) when the extract ratio was 1:10 compared to the 1:20 ratio (7.68 mg/L). This suggests that a 1:10 extraction rate shows significant extraction of anthocyanins from *Solanum nigrum* fruit. The differential pH method was used for this study to identify the selective extract of anthocyanins at differential pH levels. This method can help to optimize anthocyanin extraction from *Solanum nigrum* fruit. The Total anthocyanin content in fresh fruits after extraction is presented in Figure I.

**Colour**

*Solanum nigrum*fruit extract had L*a*b* values of 72.08, 16.43, and -0.07, with an ISO brightness of 44.75, indicating a much lighter and more vibrant colour. Similarly, *Solanum nigrum* fruit colour emulsion had L*a*b* values of 29.48, 13.35, and 36.45, with an ISO brightness of 1.01, suggesting a lighter and more reddish colour. Overall, the results indicate that *Solanum nigrum* fruit extracts and emulsions have a lighter, more vibrant colour. L*a*b* colour values were allowed to use measure and quantify pigments colour, allowing for precise colour control and comparison. The colour values are presented in the Table 2.

**Nutrient composition of food colour emulsion**

The proximate analysis of the food colour emulsion for fruits of *Solanum nigrum* shows distinct differences in their nutritional composition. *Solanum nigrum* emulsion shows carbohydrate content of about 1200 mg/ml and had a protein content of about 7.64 g/100ml. The vitamin C content was *Solanum nigrum* in with 105 mg/g and the total soluble solids had a 19.42 %. The Nutrient content of food colour emulsion was analysed namely carbohydrate, protein, Vitamin C, Total soluble solids and the amount of nutrients present in food colour emulsion is represented in the Table 3.

**Antioxidant scavenging activity of food colour emulsion**

The antioxidant absorbance at 700nm of *Solanum nigrum* fruits, By using Ferric Reducing Antioxidant Power (FRAP) method in the food colour emulsions was evaluated at varying concentrations (20-100µl). The results showed a dose-dependent increase in antioxidant activity for emulsions, indicating that the antioxidant capacity of extracts increased with increasing concentration. Food colour emulsion of *Solanum nigrum* fruits showed higher antioxidant absorbance values, ranging from 0.49 (20µl) to 0.96 (100µl), with a more pronounced increase in antioxidant activity at higher concentrations. Food colour emulsion from the fruits of *Solanum nigrum* were screened for their possible antioxidant activity by FRAP assay and the results are illustrated in Table 4. The Antioxidant activity of food colour emulsion is presented in Figure 2.

**Stability of extracted food colour and food colour emulsion**

The pigments present in the emulsion of *Solanum nigrum* exhibited reduced stability for the maximum time period of 24 hours, resulting in a noticeable colour degradation during refrigeration storage at the temperature of 6°C for the emulsions. Initially, the colour intensity was optimal at the time of extraction and emulsion preparation, results in a high level of pigment retention. However, upon refrigerated storage, the colour gradually leached out, leading to a significant decrease colour intensity in Emulsion. In contrast, the colour remained more stable in the extract of the fruit over 2-3 weeks, suggesting that the extraction process preserve the pigment's integrity. This suggests that the pigments in the emulsion were susceptible to degradation, possibly due to factors such as light exposure, temperature fluctuations, or enzymatic activity. As a result, the emulsion's colour stability was compromised, highlighting the need for optimized storage conditions or stabilization techniques to preserve the colour integrity of the pigment that the extract remained stable throughout the storage period. In contrast, the emulsion exhibit instability, undergoing noticeable changes in its physical colour appearance.

**Ice cream incorporated with food colour extract and food colour emulsion**

The ice cream was prepared using ingredients, such as milk, and ice cream mix of about overall 1 litre and 200g respectively. All these were mixed and boiled. The ice cream without colour is termed as standard and the variation I, II, III and IV were prepared by incorporating 5ml and 10ml of aqueous extract and food colour emulsion of *Solanum nigrum* fruits. The standard and the variations is subjected to freezing for 12 hours. The appearance and overall quality, as suggested by the trained panellist. The organoleptic evaluation of sample *Solanum nigrum* extracts and emulsion incorporated to the ice cream revealed significant differences in the overall quality and acceptability of the products. The addition of extracts in Variation II had a notable impact on the product's characteristics, *Solanum nigrum* fruit colour extract contributing a lighter, more vibrant colour.

## CONCLUSION

*Solanum nigrum* fruit pigments can be used as a natural food colour which are underutilized and its economical availability. Aqueous extract and emulsion of *Solanum nigrum* fruit were prepared and characterized in terms of their colorimetric properties, antioxidant activity, and stability. The result showed that extract exhibited *Solanum nigrum* fruit showing a lighter, more vibrant colour. The total monomeric anthocyanin content in the fruit of *Solanum nigrum* was that37.07 mg/l. This finding suggests that *Solanum nigrum* fruit is a richer source of anthocyanins, which are powerful antioxidants with potential health benefits. *Solanum nigrum* emulsion contained a substantially higher amount of carbohydrates, measuring 1200 mg/ml, The protein analysis in the food colour emulsion revealed in the fruit of *Solanum nigrum* as 7.64 g/100ml, and which had 105 mg/g of vitamin C. In that emulsion had a TSS content of 19.42% it indicate that *Solanum nigrum* emulsions are rich in nutrients and can be used as a valuable source of food matter. The extract of antioxidant activity was evaluated by the method of FRAP, revealing dose-dependent increases exhibit higher antioxidant activity. The colorimetric analysis of *Solanum nigrum* extracts and emulsions revealed distinct L*a*b* and ISO brightness values. *Solanum nigrum* extract exhibited L*a*b* values of 72.08, 16.43, and -0.07, with an ISO brightness of 44.75, signifying a lighter, less intense colour. The food colour emulsions of *Solanum nigrum* had L*a*b* values of 29.48, 13.35, 36.45, with an ISO brightness of 1.01. The stability of the pigments in emulsion form was also assessed, indicating that the colour remained more stable in the extract form than in the emulsion form for the fruits of *Solanum nigrum.* This shows that stabilisation of pigments is difficult as it is highly unstable due to its solubility. Overall, the study concludes that *Solanum nigrum* fruit pigments have potential as natural food colorants, offering a range of colours and antioxidant activities. However, further optimization of the extraction and emulsification processes is necessary to improve the stability and consistency of the colorants.

## ACKNOWLEDGEMENT

The authors sincerely thank the management of Vellalar College for Women, Erode for their constant support and motivation throughout the success of this project by providing us the Laboratory Facilities.

**ABSTRACT**

A variety of traditional medicinal plants has been widely used by different indigenous people in Rajamahendravaram, East Godavari district of Andhra Pradesh. An Ethnobotanical study was conducted in the Rajahmundry surrounding village, areas of Andhra Pradesh through an oral interview to investigate the medicinal plants used for the treatment of Diabetes. Data were collected using semi-structured questionnaires, group discussions, and field observation. The present study was conducted on 16 species of plants belonging to 13 families were encountered. The present ethno-botanical study proper transfer of knowledge. In general, the study area is rich in medicinal plants that have a significant role in the management of various human diseases.

**Keywords:** Ethnobotanical study, East Godavari, Diabetes, Anti diabetic plants.

## INTRODUCTION

Traditional and complementary medicine is gaining increasing popularity across many countries, irrespective of their level of development. According to [2], traditional remedies are the most important and sometimes the only source of therapeutics for nearly 80% of the worldwide population. Diabetes is a serious metabolic disorder and several marketed medications are available to alleviate the symptoms of diabetes. However, these over-the-counter drugs are expensive and associated with several complications [1]. Investigations on hypoglycemic agents derived from medicinal plants have gained popularity in recent years.They contain abundant antidiabetic compounds—such as

flavonoids, alkaloids, phenolics, and tannins—that enhance pancreatic function by boosting insulin secretion or reducing insulin resistance in intestinal absorption of glucose [4]. Appropriate sources exist that provide valuable information on medicinal plant species suitable for targeted management and domestication. Documenting the traditional knowledge of native plant species has become increasingly contributed a number of vital drugs. Therefore, the main objective of this study was to identify the major types of medicinal plants used to treat diabetic patients, document indigenous knowledge, to identify their mode of administration by the local people and conservation methods to keep the balance between availability and utilization of traditional medicinal plants by the community of Rajamahendravaram.

## MATERIAL AND METHODS

**Description of Study Area**

The present study was carried out in 5 different Mandel's of Rajamahendravaram i.e. Kadiam (16.9167°N 81.8333°E), Rajahmundry Urban (16.98°N 81.78°E), Rajanagaram (17.0833°N 81.9°E), Gokavaram( 17.2667°N 81.8500°E) and Korukonda (17.1688° N, 81.8310° E), East Godavari district of Andhra Pradesh, India. East Godavari district, having an area of 10, 80758.km is situated in the North East Coast of Andhra Pradesh( Fig 1). The district is located between Northern Latitudes of 16°30' and 18° 20' and between the Eastern longitudes of 81°30' and 82°30'.This district is referred as the green belt of Andhra Pradesh due to its greenery spread. A wide variety of natured medicinal plants and herbs are available and are used for to treat diabetic patients. They generally considered to be more patent and effective.

**Ethnobotanical Survey**

**Data Collection and information of plants**

Questionnaire survey was carried out in tribal settlements of 5 different Mandel's of Rajamahendravaram, East Godavari district, Andhra Pradesh.Information from local people including male, female respondents and traditional healers was collected. Semi structured Questionnaires along with group conversation were conducted for local people to gather information on medicinal plant species that are in use to treat diabetic patients. Local plant names, part(s) used, methods of preparation and mode of administrationwas collected and documented for further studies. The medicinal plant species used by the local communities of the study area were authenticated using the international plant name index (http://www.ipni.org)

**Mode of utilization**

The local communities mostly used leaves which 77 (39.9%) followed by roots 46 (23.83%), seed 26 (13.47%), latex 12 (6.22%), stem 9 (4.66%) and others (Table 2)

## RESULTS AND DISCUSSION

Ethnobotanical survey was conducted out in 5 different Mandel's of Rajamahendravaram, East Godavari district, Andhra Pradesh Totally 16 species of plants belonging to 13 families were known to be effectively used for treating diabetes. The details of the medicinal plants were given in the Table.1 and Fig 2-16. The mode of utilization of medicinal plants in local communities was listed in the Table 2. Medicinal plants used for the treatment of Diabetes in Rajahmundry [East Godavari] (Table 1). Pictures representing the medicinal plants that are available (Figure: 2-16)

## DISCUSSION

Diabetes is the most widespread endocrine disorder, affecting nearly 100 million people worldwide. India, often regarded as the diabetes capital of the world, has experienced a sharp rise in diabetic cases over the last decade. Diabetes mellitus (DM) is a long-standing metabolic condition characterized by elevated blood glucose levels, which disrupt the normal metabolism of carbohydrates, proteins, and fats [6].There are so many medicines to treat this

disorder. Chemical sourced medicines show hypoglycaemic activities, associated with several complications such as nephrological disorders, fatigue, upset stomach, diarrhoea, etc. Herbal medicines tend to produce fewer side effects while offering enhanced therapeutic potential. Various tribal communities have traditionally relied on these plants to treat multiple ailments. People should know the importance of natural bioactive compounds that are present in medicinal plants and anti-diabetic properties. The government should give recognitions and encourage the local herbal medicine practitioners to enhance the use of traditional medicine through licensing or certification and other incentives or by organizing them at community or district level, which popularizes their indigenous knowledge and medicinal plants use value[5].They should aware of the dosage to be used in proper way of utilization. There were many misconceptions on the efficacy of medicinal plants because of lack of interest of modern society and way of knowledge transfer by elders [3]. This survey provides readers with a basis to further examine the active constituents of anti-diabetic plants and their potential mechanisms for future research. Despite this, effective management of diabetes and its related complications remains a major challenge in India due to issues such as an inadequate healthcare system and limited facilities [7].

## CONCLUSION

Present survey revealed that a number of medicinal plant species are used by local people of study area to treat diabetes. Our findings provide data to establish traditional health remedies. *In-situ* conservation methods Cultivation of medicinal plants, awareness to local communities, conservation, and management of medicinal plants. Furthermore, ethnobotanical survey plays a key role for conservation and sustainable management of medicinal plant species. Therefore, such popular plant species could be further analysed for bioactive constituents, *in vivo*/*in vitro* activities, Molecular studies which may leads to new and potential drug discoveries. largely to consider of wild medicinal plants in order to promote their sustainable utilization

## ABSTRACT

Polyvinyl chloride (PVC) is a widely used plastic known for its durability and low cost, but its persistence in the environment contributes significantly to global plastic pollution. Conventional waste management methods, including landfilling, recycling, and incineration, pose environmental risks, highlighting the need for alternative, sustainable solutions. This study explores the potential of fungal bioremediation for PVC degradation, focusing on indigenous fungal strains *Aspergillus niger*, *A. terreus*, and *A. flavus* isolated from the Western Ghats. Molecular identification of the fungal strains was performed using 18S rRNA sequencing, confirming the taxonomic identity of the isolates. PVC films were incubated in Mineral Salt Medium (MSM) and monitored for weight loss and morphological changes over four weeks. The results showed that *A. niger* exhibited the highest degradation efficiency, achieving a 32.0% weight loss, compared to 17.5% and 13.5% for *A. terreus* and *A. flavus*, respectively. Fourier Transform Infrared Spectroscopy (FTIR) analysis of degraded PVC films revealed significant structural changes, including shifts in functional group peaks, supporting the microbial degradation of the polymer. These findings highlight the potential of *A. niger* as a promising candidate for bioremediation of PVC

waste, offering a sustainable and eco-friendly alternative to conventional plastic waste management methods. This research contributes to the growing field of fungal bioremediation and provides valuable insights for developing effective strategies to mitigate PVC pollution.

**Keywords:** Microplastics, Polyvinyl chloride, Waste management, Fungal degradation, bioremediation.

## INTRODUCTION

Polyvinyl chloride (PVC) is the third most widely produced synthetic plastic globally, owing to its strength, versatility, and low cost. However, its highly durable and persistent nature presents significant challenges when it is released into the environment, contributing substantially to global plastic pollution. The plastic is notoriously difficult to degrade (Dey, *et al.*, 2024). Conventional waste management techniques, such as landfilling, recycling, and incineration, have been used to manage PVC waste; however, these methods have their own set of challenges and environmental risks (Patil and Kubade, 2023). In response to the growing environmental concern Scientists are actively investigating sustainable and environmentally friendly methods for managing PVC waste (Evode *et al.*, 2021). Among these approaches, bioremediation has emerged as a particularly promising strategy, offering the potential to break down or transform PVC using microorganisms or their enzymes in a safer and more natural way (Agarwal *et al.*, 2024). Studies have shown that fungal isolates are often the primary colonizers on plasticized PVC films(Webb *et al.*,2000), particularly *Aspergillus niger* have been identified as highly effective organisms for the biodegradation of PVC, showing significant potential in breaking down complex plastic materials(El-Dash *et al.*, 2023). This degradation process often involves the microbial colonization of PVC surfaces (Saeed *et al.*, 2022), where fungi secrete enzymes that break down the polymer chains, leading to structural changes in the plastic (Srikanth *et al.*, 2022). This degradation is typically observed as erosion, loss of surface integrity, and changes in chemical composition (Islam and Farhat, 2017).Fourier Transform Infrared Spectroscopy (FTIR) help for analyzing chemical changes in the polymer, including the development of new functional groups, which indicate degradation(Suresh *et al.*, 2017). This work aims to investigate the bioremediation potential of *Aspergillus niger* for degrading polyvinyl chloride (PVC) waste, focusing on fungal colonization, enzyme activity, and chemical changes in PVC. The findings will contribute to sustainable, environmentally friendly solutions for PVC waste management.

## MATERIALS AND METHODS

**Preparation of PVC film**

Thin films of PVC (2% w/v) were prepared in petri plates by dissolving 0.2 g of PVC (Aldrich) in 10 ml of solvent tetrahydrofuran (THF; 99%; Merck). The plates were incubated in fume hood for overnight to evaporate the solvent. Prepared PVC films (6 cm x 2.5 cm) were sterilized by immersing in 70% ethanol for 15 min. before further use.

**Isolation and screening of PVC degrading fungal isolates**

Soil samples were collected from Shanpagathopu in the Western Ghats to isolate PVC-degrading fungi. Following serial dilution, 100 µl aliquots of $10^{-1}$ and $10^{-2}$ dilutions were plated onto Malt Extract Agar (MEA) and Mineral Salts Medium (MSM) agar to enumerate and estimate the proportion of PVC-degrading fungal isolates, respectively. To assess the ability of each fungal isolate to grow and degrade PVC, thin pieces of PVC films (6.2 cm x 2.5 cm) were placed into MSM media, consisting of 100 ml MSM (1 g $K_2HPO_4$, 0.2 g $KH_3PO_4$, 1.0 g NaCl, 0.002 g $CaCl_2{\cdot}H_2O$, 0.005 g boric acid, 1.0 g $(NH_4)_2SO_4$, 0.5 g $MgSO_4{\cdot}7H_2O$, 0.001 g $CuSO_4$, 0.01 g $ZnSO_4{\cdot}7H_2O$, 0.001 g $MnSO_4$, and 0.01 g $FeSO_4{\cdot}7H_2O$ per liter of distilled water) in 250 ml Erlenmeyer flasks. Biomass quantification of each fungal strain was conducted on a weekly basis, and the fungal strain producing the maximum biomass was selected for further trials.

**Molecular identification of fungal isolates**

Fungal isolates were identified by partially sequencing their internally transcribed spacer (ITS) regions 5.85 rRNA, 185 and 28S rRNA using universal primers ITS-1 5-TCCGTAGGTGAACCTGCGG-3 and ITS-4 5-TOCTOCG-CTTATTGATATGC-3. Genomic DNA was extracted. Following purification the sequencing of the PCR product was performed. The sequences were submitted in NCBI Genbank by using BLAST tool for sequence homology searches http://www.ncbi.nlm.nih.gov/BLAST). The Boot-strap Test of Phylogeny was performed by using software MEGA version 4. On the basis of distance matrix, a neighbor-joining tree was reconstructed for identification of isolated fungal strain.

**Fungal Isolates**

The fungal isolates identified and used for further degradation studies were *Aspergillus niger*, *Aspergillus terreus*, and *Aspergillus flavus*. These isolates were selected based on their ability to grow on the PVC films in previous screenings.

**Degradation of PVC by Fungal Isolates**

Thin pieces of PVC films (6.2 cm x 2.5 cm) were placed in 100 ml MSM medium, containing 1 g $K_2HPO_4$, 0.2 g $KH_3PO_4$, 1.0 g NaCl, 0.002 g $CaCl_2{\cdot}H_2O$, 0.005 g boric acid, 1.0 g $(NH_4)_2SO_4$, 0.5 g $MgSO_4{\cdot}7H_2O$, 0.001 g $CuSO_4$, 0.01 g $ZnSO_4{\cdot}7H_2O$, 0.001 g $MnSO_4$, and 0.01 g $FeSO_4{\cdot}7H_2O$ per liter of distilled water, in 250 ml Erlenmeyer flasks. The fungal isolates were inoculated into the MSM medium and incubated for one month at room temperature.

**Weight Loss Measurement**

The degradation of PVC films was monitored by measuring the weight reduction of the PVC films every week. The weight of each film was recorded at weekly intervals for the duration of the one-month experiment. *Aspergillus niger* showed the most significant degradation, with a marked reduction in film weight, indicating its high efficiency in PVC degradation compared to the other fungal isolates.

**Monitoring of PVC Degradation**

The initial weight of each PVC film was recorded before inoculation. The experiment was carried out over a period of 4 weeks. At weekly intervals, the PVC films were carefully removed from the flasks, washed gently with sterile distilled water to remove fungal biomass, dried at 50°C for 24 hours, and reweighed. The difference in weight was recorded as an indicator of PVC degradation.

## RESULTS

**Screening and Identification of the Isolated Fungal Strains**

Fungal isolates were cultured with PVC films as the sole carbon source in Mineral Salt Medium (MSM) under shaking conditions (150 rpm) at 30°C. Among the fungal strains tested, *Aspergillus niger* (PVC +AN) exhibited the highest biomass production, reaching 2.57 mg/ml. The biomass increased progressively from the third to the fourth week, indicating active fungal growth. In contrast, the growth of *Aspergillus terreus* (PVC +AT) and *Aspergillus flavus* (PVC +AF) was less pronounced, showing only a slight increase in biomass over the study period.

**Molecular Taxonomic Identification of Potential Fungal Strains**

The fungal isolates were identified based on molecular characterization using the 18S rRNA regions, and the internal transcribed spacer (ITS) regions. The nucleotide sequences obtained were compared to those in the National Center for Biotechnology Information (NCBI) database using the FASTA tool. The *Aspergillus niger* (PVC +AN) strain (GenBank accession number: PV488713) showed 99% similarity to *Aspergillus niger* PV1, and clustered within the *Aspergillus* genus. Similarly, the *Aspergillus terreus* (PVC +AT) strain (GenBank accession number: PV488701) exhibited 99% similarity with *Aspergillus flavus*. The phylogenetic tree was constructed using the neighbor-joining method, confirming the identity and taxonomic relationships of the strains.

**Weekly Weight Reduction of PVC Films**

The degradation of PVC films by the fungal isolates was monitored over four weeks by weekly weight measurements. The initial weight of each PVC film was 0.200 g. A progressive weight reduction was observed in all experimental groups, indicating the biodegradation of PVC.

**Week 1:** The weight of PVC films inoculated with *A. niger* dropped to 0.187 g (6.5% weight loss), while *A. terreus* and *A. flavus* resulted in 4.5% and 3.0% weight loss, respectively.

**Week 2:** *A. niger* exhibited the most significant reduction, with the film weight decreasing to 0.170 g (15% weight loss). *A. terreus* and *A. flavus* continued to degrade the films, showing 9.5% and 6.0% weight loss, respectively.

**Week 3:** The weight of the PVC films decreased further, with *A. niger* reaching 0.153 g (23.5% weight loss), *A. terreus* at 0.173 g (13.5% weight loss), and *A. flavus* at 0.180 g (10.0% weight loss).

**Week 4:** By the end of the fourth week, *A. niger* achieved the highest degradation, with a final film weight of 0.136 g (32.0% weight loss). *A. terreus* and *A. flavus* showed 17.5% and 13.5% weight loss, respectively.
These findings suggest that *Aspergillus niger* is the most effective PVC degrader among the tested fungal strains under the experimental conditions. Weight Loss of PVC over Four Weeks by Different Fungal Isolates (Table 1).

**FTIR Analysis of PVC Biodegradation**

Fourier Transform Infrared Spectroscopy (FTIR) was performed on the control and degraded PVC films to detect chemical modifications associated with microbial degradation. The FTIR spectra of the degraded PVC films exhibited the appearance of new peaks and shifts in the functional group regions. A significant peak shift was observed between 2370–2350 $cm^{-1}$, corresponding to the HCCI region, indicating changes in the structure of the PVC due to fungal activity. Additionally, a reduction in peak intensity at 2277–2250 $cm^{-1}$ was observed, suggesting a structural modification in the polymer chains, likely due to the microbial degradation processes. Phylogenetic Tree of Fungal Isolates Based on Neighbor-Joining Analysis (Figure 1). Neighbor-Joining phylogenetic tree showing the relationship of *Aspergillus niger* (PVC +AN) with *Aspergillus terreus* (PVC +AT) and *Aspergillus flavus* (PVC +AF). The tree was constructed based on the nucleotide sequences of the 18S, 28S rRNA, and ITS regions, with *A. niger* clustering within the *Aspergillus* genus with 99% similarity to *Aspergillus niger* PV1. The bootstrap values for the branches are indicated. Weekly Weight Reduction of PVC Films Inoculated with Fungal Strains (Figure 2). Graph showing the weekly weight reduction of PVC films inoculated with *Aspergillus niger* (PVC +AN), *Aspergillus terreus* (PVC +AT), and *Aspergillus flavus* (PVC +AF) over four weeks. *Aspergillus niger* demonstrated the highest rate of degradation, with a total weight loss of 32.0% by the end of week 4. FTIR Spectra of Control and PVC Films Degraded by Fungal Strains (Figure 3). FTIR spectra showing the chemical modifications in PVC films after four weeks of degradation by *Aspergillus niger*, *Aspergillus terreus*, and *Aspergillus flavus*. The control sample (untreated PVC) is compared to the degraded films, highlighting changes in the functional group regions, including peak shifts and intensity reduction, indicating structural changes in the polymer. These results demonstrate that *Aspergillus niger* is the most effective fungal strain for PVC biodegradation, with clear evidence of polymer structural changes observed through FTIR analysis. The molecular identification of fungal strains and the degradation efficiency results suggest the potential of these isolates for bioremediation applications in plastic waste management.

## DISCUSSION

This study aimed to assess the ability of three *Aspergillus* species, namely *Aspergillus niger*, *Aspergillus terreus*, and *Aspergillus flavus*, to biodegrade PVC films. The results presented herein suggest that *Aspergillus niger* (PVC +AN) is the most efficient fungal strain for PVC degradation under the tested conditions, exhibiting a maximum weight loss of 32.0% by the end of the fourth week. This conclusion is further supported by molecular identification of the fungal strains, demonstrating a 99% similarity of *A. niger* to *A. niger* PV1, which is consistent with previous studies

indicating the high biodegradative potential of *A. niger* in plastic degradation (Shao *et al.,* 2019). The findings show that *A. niger* outperformed *A. terreus* and *A. flavus* in terms of both biomass production and PVC weight loss, which corroborates earlier reports suggesting that different fungal species have varying abilities to degrade synthetic polymers. While *A. niger* exhibited a progressive reduction in PVC film weight over the 4-week period, *A. terreus* and *A. flavus* displayed lower degradation efficiency, with total weight losses of 17.5% and 13.5%, respectively. This variance could be attributed to the differences in the metabolic pathways and enzyme production abilities of these fungi. The FTIR analysis further supports these findings, revealing clear chemical modifications in the PVC films degraded by *A. niger*, with significant shifts and reductions in peak intensities in the functional group regions. The reduction in the peak at 2277–2250 $cm^{-1}$, a characteristic absorption band for PVC, suggests that the fungal strains were able to cleave the polymer backbone, causing structural alterations. The appearance of new peaks between 2370–2350 $cm^{-1}$ suggests the formation of new functional groups, likely due to microbial enzymatic activity on the PVC. These results are consistent with similar studies where FTIR spectra indicated degradation-induced chemical changes in polymeric materials following microbial attack (Almeida *et al.,* 2017). Molecular characterization of the fungal isolates using 18S rRNA and ITS regions confirmed the taxonomic identity of the fungal strains and allowed for the comparison of their biodegradation potential. *A. niger* clustered within the *Aspergillus* genus and showed a high degree of similarity with the strain *A. niger* PV1, which has been previously reported to exhibit significant plastic-degrading activity (Dian *et al.,* 2016). This molecular approach is essential for confirming the identity of fungal isolates and ensures that the observed biodegradation is specific to the fungal species under study. When compared to other recent studies on fungal biodegradation of PVC, our results are in line with findings from Kim *et al.* (2018) and Yang *et al.* (2020), who reported that *A. niger* and other *Aspergillus* species can effectively degrade plastic materials, contributing to the development of bioremediation strategies for plastic waste management. However, the degradation rates observed in this study are somewhat higher than those reported by Ahmed *et al.* (2022), who found a maximum degradation of 24% over 8 weeks for *A. niger*. This discrepancy could be due to differences in experimental setup, such as incubation conditions (e.g., temperature, shaking speed) or the nature of the plastic material used.

## CONCLUSION

The biodegradation of PVC films by *Aspergillus* species, particularly *A. niger*, offers promising applications in the field of plastic waste bioremediation. The efficiency observed in this study suggests that *A. niger* could be explored further as a candidate for large-scale plastic degradation, potentially contributing to efforts aimed at reducing plastic pollution. Moreover, the combination of molecular identification, FTIR analysis, and weight loss measurement provides a comprehensive approach to evaluating the biodegradative potential of fungal strains.

## ACKNOWLEDGEMENT

The authors magnanimously thank the Management and Principal, Ayya Nadar Janaki Ammal College, Sivakasi, for the great support provided and for making the availability of various institutional facilities.

## ABSTRACT

The state of Assam is shaped to a large extent by the Brahmaputra River. The dynamic floodplain of the river has numerous wetlands that support the ecological stability and livelihoods of the local communities. Among these Lazai and Jagun are two ox-bow lakes in Dibrugarh district, which show contrasting but interconnected patterns of landscape change. This study provides a comparative assessment of their spatio-temporal land-use and land-cover (LULC) dynamics to understand the extent of ecological change and human pressure. The aim is to analyse LULC changes (2015–2024) and predict future transformations (2034), enabling a comparative evaluation of ecological stress and land-use transitions between the two wetlands. Sentinel-2A imagery was classified using supervised classification with the Maximum Likelihood approach. Future LULC was projected using a Cellular Automata Artificial Neural Network (CA-ANN) model and net change, percentage change and rate of change were computed to compare both sites. The findings reveal distinct patterns of transformation. Lazai experienced higher loss of natural wetland features, with open water decreasing notably and aquatic vegetation showing a consistent reduction. Jagun displayed a sharper reduction in agricultural land, dropping from 21.67% to 14.32% while maintaining relatively stable sandbar and riverine areas due to active fluvial deposition. Built-up expansion occurred in both wetlands but was slightly higher in Lazai (16.72%) compared to Jagun (15.83%) in 2024. Future projections indicate continued divergence built-up area is expected to reach 20.41% in Lazai and 19.19% in Jagun by 2034 while Lazai is predicted to experience a stronger decrease in open water (to 3.30%) compared to Jagun. These contrasting trajectories demonstrate that Lazai is undergoing more rapid ecological contraction of wetland-specific habitats, whereas Jagun is shifting primarily from agrarian to settlement-dominated land uses. The findings

highlight the need for site-specific strategies hydrological restoration with integrated wetland zoning and landscape-level conservation planning across Upper Assam.

**Keywords:** Wetland degradation, LULC, CA–ANN modelling, Upper Assam.

## INTRODUCTION

Wetlands are widely recognised as one of the most critical ecological systems on the planet, but they remain highly vulnerable to degradation and loss. Their significance extends across multiple environmental domains contributing to climate regulation, biodiversity support, hydrological stability and human well-being [1]. In relation to climate processes, wetlands influence atmospheric conditions at regional and global scales through substantial evapotranspiration and their role as major carbon reservoirs that also release methane as part of natural biogeochemical cycles [2]. Although freshwater wetlands occupy a very small proportion of the Earth's surface, they sustain more than 40% of known species reflecting their exceptional biological richness and ecological importance [3]. Hydrologically, wetlands function as natural regulators by recharging groundwater, moderating water flows and improving water quality through filtration of sediments and pollutants [4]. Their contribution to human well-being is equally important, as wetland-derived plants continue to serve as essential sources of traditional medicine for many communities worldwide [3]. Wetlands remain among the most productive and economically valuable ecosystems. Their ecological functions generate a wide spectrum of benefits ranging from local livelihood support to global climate stability [5,6]. These functions include nutrient recycling, soil formation, maintenance of biodiversity, water purification, climate regulation and erosion control. They provide provisioning resources such as fish, aquatic plants, timber and medicinal species along with cultural benefits linked to recreation, spiritual traditions and opportunities for education and research [2, 4, 7, 8, 9, 10]. Urban regions are increasingly dependent on wetlands for water security, wastewater treatment and local climate moderation especially in rapidly expanding towns that are exposed to climate stress [4, 11]. However, despite their ecological and socio-economic value wetlands are disappearing at a faster rate than any other natural ecosystem [4]. Land reclamation, infrastructure expansion, pollution, siltation and excessive extraction of natural resources continue to degrade their structure and functioning. Since the early twentieth century nearly half of the world's wetlands have been lost [12] and more than sixty percent of those that remain exhibit signs of degradation or unsustainable use [4]. This decline threatens biodiversity, weakens ecosystem resilience and increases risks for communities that rely on wetland services. Assam, shaped by the Brahmaputra River and its highly dynamic floodplain system, contains a vast network of wetlands that play a vital role in maintaining ecological stability and supporting local livelihoods [13]. These wetlands act as natural reservoirs, biodiversity hotspots and essential resources for surrounding communities [14, 15]. Within this landscape Lazai and Jagun stand out as two important ox-bow lakes that illustrate different patterns of landscape transformation over time. Their changing extents reflect the combined influences of natural hydrological processes and growing human pressures in Upper Assam. Understanding how these two wetlands are evolving is important for developing conservation and management strategies. Understanding these changes is essential because alterations in land cover often signal ecological stress well before it becomes visibly apparent in the landscape. A scientific assessment of spatiotemporal shifts in wetland characteristics helps clarify how human activities and natural processes reshape wetland structure and functioning. Such evaluations form the basis for conservation strategies that protect ecological integrity while guiding sustainable land-use planning. By analysing past and present land-use/land-cover patterns along with predictive modelling of future change, the present study provides a clear foundation for informed management of the Lazai and Jagun wetlands.

## MATERIALS AND METHODS

**Study area**

The present study was conducted in two ecologically significant small wetlands of Upper Assam Lazai wetland and Jagunwet land, both representing the floodplain systems of the Brahmaputra River. Lazai Wetland is located approximately 26 km south of Dibrugarh town, extending from 27°17′16.08″N to 27°17′56.31″N latitude and 94°48′77.97″E to 94°50′94.61″E longitude. Morphologically, it is an oxbow lake formed by the abandoned meander of the Burhi Dihing River, which flows to the south of the wetland. The total area of the wetland is around 65 ha, characterized by extensive aquatic vegetation, seasonal fluctuations in water level and high diversity of resident and migratory birds. Local communities depend on the wetland primarily for fishing, harvesting aquatic plants and domestic water use. Jagunwet land lies about 46 km east of Dibrugarh town, between 27°18′48.06″N to 27°20′09.43″N latitude and 95°17′11.38″E to 95°18′15.44″E longitude, covering an area of approximately 137.28 ha. The wetland is surrounded by paddy fields and semi-forest tracts, creating a diverse ecological interface that supports a wide range of fish and bird species (fig 1). Despite its ecological richness, Jagunwet land is facing increasing anthropogenic pressures due to unregulated fishing, agricultural encroachment and expansion of nearby settlements. Both wetlands play an indispensable role in maintaining local hydrological stability and providing essential ecosystem services. The contrasting landscape settings and varying degrees of human interaction in Lazai and Jagun wetlands offer an ideal basis for a comparative socio-ecological assessment.

## METHODOLOGY

The study analyzed spatio-temporal LULC changes in Lazai and Jagun wetlands using Sentinel-2A satellite imagery at 10 m spatial resolution for the years 2015 and 2024. The images were pre-processed for atmospheric, radiometric and geometric corrections to ensure consistency and accuracy. Supervised classification was performed using the Maximum Likelihood Algorithm to categorize the landscape into major classes, including agricultural land, vegetation, built-up areas, aquatic vegetation, open water, barren land, sandbars, river channels and man-made ponds. Reference data from field surveys, GPS points and high-resolution imagery were used to improve classification reliability. The accuracy of the classified LULC maps was evaluated using user's and producer's accuracies, overall accuracy and Kappa coefficient. Both years showed high classification accuracy (>90%) and strong agreement with ground truth data. The rate of change for each LULC class was computed as a percentage per year, enabling quantification of temporal dynamics and identification of the most rapidly transforming land cover types.

To predict future LULC patterns for 2034, a hybrid Cellular Automata–Artificial Neural Network (CA-ANN) model was applied, integrating spatial contiguity and non-linear transition probabilities between land-cover classes. This approach allows robust simulation of potential land transformations under current trends. The combination of multi-temporal analysis, accuracy assessment, rate of change calculations and predictive modelling provides a comprehensive understanding of the spatio-temporal dynamics of these wetlands and the anthropogenic pressures shaping them.

## RESULTS AND DISCUSSION

**Land use land cover classification of Lazai wetland**

Wetlands play a crucial role in maintaining ecological balance, providing habitat for diverse species and regulating hydrological processes. The LULC analysis of Lazai Wetland for the years 2015 and 2024 reveals notable shifts in land use and land cover patterns, reflecting both natural and anthropogenic influences on the ecosystem. In 2015, barren land dominated the study area, covering 31.27% (3.18 km²) of the total land. This indicates a significant portion of unused or unproductive land, potentially due to land degradation or limited agricultural activities. Vegetation, including forests and scrubland, accounted for 26.92% (2.74 km²), forming a major part of the ecosystem. Agricultural land covered 18.1% (1.84 km²), representing an essential component of land use in the region. Built-up areas occupied 10.4% (1.06 km²), indicating moderate urban expansion at that time. Aquatic vegetation covered 2.7% (0.28 km²),

while open water in wetlands accounted for 4.8% (0.49 km²), both contributing to the wetland's ecological integrity. Sandbars made up 2.12% (0.22 km²), reflecting fluvial processes, whereas Burhidihing River comprised 3.68% (0.37 km²) of the total area (fig 2). By 2024, significant changes in land use patterns were observed. Built-up areas expanded substantially to 17.28% (1.76 km²) a net increase of 6.88% at an annual growth rate of 0.76% per year indicating rapid urbanization and infrastructure growth in the region. This increase in built-up areas suggests a conversion of natural and agricultural land into urban zones, driven by population expansion and economic development. Agricultural land experienced a decline of 2.24% (−0.25% per year) reducing to 15.86% (1.61 km²) likely due to changes in land use practices or urban encroachment. One of the most concerning trends is the decline in wetland areas. Aquatic vegetation increased to 4.88% (0.50 km²) showing a positive change of 2.2% (+0.24% per year) suggesting minor ecological restoration efforts or hydrological adjustments. However, open water in wetlands decreased by 1% (−0.11% per year), from 4.8% (0.49 km²) to 3.8% (0.39 km²), indicating a gradual shrinking of wetland ecosystems. Barren land saw a modest decline of 3.07% (−0.34% per year), reducing to 28.2% (2.87 km²), which may imply either increased vegetation growth or urban expansion. Vegetation experienced a significant decline of 4.29% (−0.48% per year), reducing to 22.63% (2.30 km²), potentially due to land conversion or deforestation. The Burhidihing River remained relatively stable, with a marginal decrease of 0.11% (−0.01% per year), maintaining its role in shaping the landscape. Sandbars slightly increased by 0.5% (+0.06% per year), covering 2.62% (0.27 km²) in 2024, reflecting ongoing sediment deposition and river dynamics. Notably, man-made ponds emerged in 2024, occupying 1.15% (0.12 km²) of the area, indicating new water management initiatives or artificial interventions in the wetland (Table 1 and fig 3 and 4). Between 2015 and 2024, the most significant transformations include the expansion of built-up areas and the decline in vegetation and wetland extents. The growth of urban areas at the expense of agricultural and vegetative lands suggests increasing pressure on the wetland ecosystem. The reduction in wetland water cover raises concerns about biodiversity loss, reduced water retention capacity and potential flood risks. Additionally, the shift from barren land to other land uses indicates dynamic land cover changes which may be influenced by both natural processes and human interventions.

**Accuracy assessment of LULC classified images of Lazai wetland**

The accuracy assessments of the classified images of Lazai wetland are shown in Table 4.9. Both user's accuracy and producer's accuracy ranges between 80 to 100% for 2024. For the year 2015 the user's accuracy ranged between 80% to 100 % while the producer's accuracy range between 66.66% and 100%. The overall accuracy was found to be 93.75% and 95% for the year 2015 and 2024 respectively. The Kappa coefficient was found highest in 2024 that is 0.94 followed by 2015 (0.92) as depicted in table 2. These metrics validate the classification results indicating strong classification accuracy.

**Predicted Land Use and Land Cover (LULC) Changes in Lazai Wetland for 2034**

The predicted land use and land cover (LULC) for 2034 in Lazai Beel indicate significant transformations, highlighting ongoing trends in urbanization, wetland degradation, and shifts in vegetation cover. The built-up area is expected to increase to 20.41% (2.08 km²), continuing its rapid growth from 10.4% in 2015 to 17.28% in 2024. This expansion reflects infrastructure development, population growth and encroachment on natural ecosystems, leading to further conversion of agricultural and wetland areas. Meanwhile, agricultural land is projected to stabilize at 17.64% (1.80 km²), showing only a slight recovery from 15.86% in 2024. However, barren land is predicted to remain dominant at 27.27% (2.78 km²), indicating continued land degradation or reduced agricultural utilization. The wetland ecosystem continues to shrink, with open water reducing to 3.30% (0.34 km²), down from 3.8% in 2024 and 4.8% in 2015. Similarly, aquatic vegetation is forecasted to decline to 3.57% (0.36 km²), reflecting a continued reduction from 4.88% in 2024. These trends suggest an ongoing loss of wetland habitats, which could have serious ecological consequences, including increased flood risks, water quality deterioration and habitat loss for aquatic species. The Burhidihing River is expected to slightly decrease in area to 2.97% (0.30 km²), while sandbars are projected to stabilize at 3.24% (0.33 km²), indicating relatively stable sediment deposition processes. Vegetation cover, including forests and scrubland, is expected to remain at 20.43% (2.08 km²). However, this marks a long-term decline from 26.92% in 2015, likely due to urban expansion and land-use conversion. Although the stabilization in 2034 suggests possible reforestation efforts, continued monitoring will be necessary to assess long-term ecological impacts.

Overall, the increase in built-up areas, the persistence of barren land and the degradation of wetlands signal significant environmental changes. The loss of wetlands could reduce biodiversity and ecosystem resilience, while rapid urbanization may increase environmental pressures (table 3 and fig 5).

**Land use land cover classification of Jagun wetland**

The land use and land cover (LULC) of the studied wetland have undergone significant changes from 2015 to 2024. In 2015, the dominant land cover type was vegetation, which accounted for 34.33% (4.48 km²) of the total area, followed by barren land at 19.97% (2.60 km²) and agricultural land at 15.99% (2.09 km²). Built-up areas covered 11.45% (1.49 km²), while aquatic vegetation occupied 8.58% (1.12 km²). The Burhidihing River accounted for 4.05% (0.53 km²), with open water and sandbars making up 2.11% (0.27 km²) and 3.52% (0.46 km²), respectively (table 4 and fig 6). By 2024, notable spatial shifts were evident. Vegetation cover expanded to 37.21% (4.85 km²), showing a net increase of 2.88% with a positive rate of change of +0.32% per year, indicating gradual ecological recovery or secondary growth in previously barren or agricultural areas. Conversely, barren land marginally declined by 1.37% (−0.15% per year), suggesting conversion into vegetation or built-up areas. Agricultural land showed the steepest decline of −5.63%, translating to −0.63% per year, reflecting urban encroachment and reduced cultivation near the wetland margins. The built-up area exhibited the most pronounced expansion, rising from 11.45% to 17.35% (a net gain of 5.9%, or +0.66% per year). This substantial growth points to increasing human settlements and infrastructure development around the wetland, often at the cost of agricultural and open-water zones. The Burhidihing River reduced slightly by 0.78% (−0.09% per year), and open water bodies declined by 0.87% (−0.10% per year), implying possible sediment deposition, siltation, or hydrological alteration. Aquatic vegetation decreased marginally (−0.20%; −0.02% per year), indicating a relatively stable wetland micro-ecosystem, while sandbars increased insignificantly by 0.06% (+0.01% per year), reflecting ongoing fluvial processes. Overall, the 2015–2024 LULC transition pattern highlights the dual dynamics of ecological regeneration and urban expansion. The steady increase in vegetation cover suggests localized natural recovery, yet the rapid spread of built-up land and reduction in agricultural and open-water areas indicate intensified anthropogenic stress. These transformations collectively illustrate the shifting landscape dynamics of Jagunwetland, where human-induced land conversion continues to reshape the wetland's ecological and hydrological characteristics (fig 7 and 8).

**Accuracy assessment of LULC classified images of Jagun wetland**

The accuracy assessments of the classified images of Jagun wetland are shown in Table 4.9. Both user's accuracy and producer's accuracy ranges between 90% to 100% for 2024. For the year 2015 the user's accuracy ranged between 80% to 100 % while the producer's accuracy range between 90% and 100%. The overall accuracy was found to be 91.25% and 96.25% for the year 2015 and 2024 respectively. The Kappa coefficient was found highest in 2024 that is 0.95 followed by 2015 (0.90) as depicted in table 5. These metrics validate the classification results indicating strong classification accuracy.

**Predicted Land use and land cover of Jagun wetland**

The predicted land use and land cover (LULC) for the year 2034 indicate continued transformations in the wetland ecosystem. Vegetation is expected to remain the dominant land cover, covering 35.87% (4.68 km²) of the total area. This is a slight decrease from 37.21% in 2024, suggesting possible alterations due to land-use changes. Built-up areas are projected to expand further, reaching 19.19% (2.50 km²), reflecting ongoing urbanization and infrastructural development. Agricultural land is expected to decline further, covering only 12.96% (1.69 km²), continuing the trend observed in the previous decade. Barren land is also expected to shrink, reducing to 16.74% (2.18 km²), indicating possible land stabilization or conversion for other uses. Other wetland features such as aquatic vegetation and open water are projected to undergo minor reductions, with aquatic vegetation covering 7.29% (0.95 km²) and open water decreasing slightly to 1.09% (0.14 km²). The Burhidihing River is expected to maintain its area at 3.28% (0.43 km²), while sandbars will likely remain stable at 3.58% (0.47 km²) (table 6 and fig 9). These projections suggest that while vegetation and built-up areas will continue to dominate the landscape, agricultural land and open water bodies may face further reductions. The steady increase in built-up areas and decline in agricultural land reflect ongoing human-induced modifications, which could have long-term ecological implications for the wetland system.

**Comparison between the wetlands**

The spatio-temporal LULC analysis of Lazai and Jagun wetlands shows clear and accelerating shifts in land use largely driven by intensified anthropogenic pressures. The increase in built-up areas in both wetlands reflects growing urbanisation and infrastructure expansion across peri-urban zones of Upper Assam a pattern also seen in Deepor Beel and other major wetlands in the region. The conversion of agricultural and vegetated areas into impervious surfaces indicates strong development pressure on natural landscapes leading to reduced groundwater recharge altered surface-runoff behaviour and fragmentation of habitat mosaics that support wetland biodiversity. Agricultural land in Jagun shows a substantial reduction, suggesting widespread encroachment and a change in land-use preferences that may affect agrarian livelihoods dependent on wetland-supported soil moisture and seasonal inundation. Meanwhile, the slight rise in vegetation cover in Jagun, even as built-up pressure increases may reflect secondary successional growth or small-scale greening of previously degraded areas. By contrast, the reduction of vegetation in Lazai points to ongoing local disturbances such as unregulated clearing, sediment loading and seasonal hydrological variability all of which affect habitat continuity for plant and animal species associated with wetland environments. Changes in open-water extent in both wetlands suggest hydrological modification possibly related to siltation and conversion of shallow wetland zones for agriculture and settlements. The appearance of man-made ponds in Lazai indicates adaptive water-use strategies by local communities. However, these features may alter natural hydrodynamics, disrupt ecological connectivity and influence species composition (table 7). The projected LULC scenario for 2034 suggests that the existing trends will continue, with built-up areas likely to expand further in both wetlands. Ecologically important categories in Lazai including open water and aquatic vegetation are expected to shrink indicating a contraction of core wetland habitats. Agricultural land in Jagun may also reduce further, reflecting sustained pressure on traditional farming areas. Taken together, these projected patterns imply stronger urban expansion, loss of semi-natural landscapes and increasing spatial fragmentation which may alter hydrological connections, lower ecological stability and weaken the overall functioning of both wetland systems. These observed transformations highlight the vulnerability of small ox-bow lakes in upper Assam to combined anthropogenic and hydrological pressures. The spatial redistribution of land-cover types has potential implications for biodiversity, nutrient cycling, flood regulation and wetland ecosystem services. Such alterations necessitate targeted management strategies, integrating spatial planning with ecological conservation to sustain both the socio-economic and ecological functions of Lazai and Jagun wetlands.

## CONCLUSION

The analysis of land-use and land-cover patterns in Lazai and Jagun wetlands reveals a consistent trajectory of landscape modification driven largely by human activities. The supervised classification of Sentinel-2A imagery, supported by accuracy assessment and CA–ANN-based prediction, demonstrates a steady shift from natural wetland components toward more anthropogenic land uses. Built-up surfaces have expanded across both sites, while open-water areas, aquatic vegetation and other ecologically significant classes show progressive contraction. These transitions indicate growing hydrological alteration, increased surface fragmentation and diminishing habitat continuity within the wetland systems. Future projections for 2034 reinforce these trends, with Lazai and Jagun expected to undergo further urban expansion and continued reduction of wetland-dependent land-cover types. The projected decline in open water and aquatic vegetation in Lazai, along with the anticipated reduction of agricultural land in Jagun, suggests mounting pressure on ecological processes that support biodiversity, groundwater recharge and flood buffering. If present patterns continue, these ox-bow wetlands may experience severe degradation that could compromise ecological stability and the environmental services relied upon by surrounding communities. The findings highlight the need for timely intervention through scientifically guided land-use regulation, conservation zoning and restoration of degraded wetland margins. Strengthening catchment-level management, controlling unplanned construction and encouraging community-led stewardship are essential for safeguarding the long-term ecological functioning of Lazai and Jagun. By providing evidence-based insight into past, present and anticipated landscape dynamics, this study contributes to informed decision-making aimed at securing the sustainability of small wetland ecosystems in Upper Assam.

## ACKNOWLEDGEMENTS

The authors are grateful to the faculty members of the Department of Geography, Cotton University, Guwahati, for their help and support.

## ABSTRACT

Physiotherapy is a cornerstone of stroke rehabilitation, aiding recovery of physical function and independence. However, stroke survivors' subjective experiences post-physiotherapy—encompassing emotional, social, and existential dimensions—remain under-explored. This scoping review aims to map qualitative studies on stroke survivors' lived experiences following physiotherapy, identifying key themes, methodologies, and gaps to inform patient-centered care and future research. Following Joanna Briggs Institute (JBI) guidelines, we will search PubMed, CINAHL, Scopus, Embase, PsycINFO, and Web of Science in June 2025. Eligible studies will include stroke survivors and focus on qualitative explorations of physiotherapy experiences (e.g., via interviews, focus groups). We will include studies addressing mediating factors (e.g., comorbidities, therapy settings) and intervention strategies (e.g., tailored exercises). Two reviewers will independently screen studies, with disagreements resolved by a third reviewer. Data will be extracted using a JBI tool and synthesized narratively, highlighting themes and methodological trends. A thematic analysis will categorize findings, with results presented in tables

and a narrative summary. Ethical approval is not required, as this review analyzes existing literature. Results will be published in an open-access peer-reviewed journal and presented at national and international conferences targeting clinicians, researchers, policymakers, and stroke survivors. We will collaborate with stroke survivors to co-develop plain-language summaries and info graphics, disseminated via social media and stroke research repositories.

**Strengths and Limitations of this Study**

1. Utilizes a scoping review approach to comprehensively map qualitative literature on stroke survivors' physiotherapy experiences.
2. Incorporates a multidisciplinary team, including a stroke survivor, ensuring diverse perspectives and relevance to lived experiences.
3. Focuses on identifying intervention strategies and mediating factors to enhance clinical applicability.
4. Limited to English-language studies due to resource constraints, potentially missing non-English perspectives.
5. Scoping reviews do not assess methodological quality, which may limit critical evaluation of included studies.

**Keywords:** Physiotherapy, Briggs Institute (JBI) guidelines, Clinical Applicability,

## INTRODUCTION

A stroke is among the world's leading causes of long-term disability. Survivors and their families, as well as the healthcare systems, carry an enormous psychosocial and economic burden. In India, stroke incidence ranges from 108 to 172 per 100,000 people, while prevalence lies between 26 to 757 per 100,000 over a year. The impact of stroke's residual effects is multifaceted and varies across its many forms and gradations, greatly hindering the quality of life. Worldwide forecasts suggest that by the year 2030, strokes will account for 12 million deaths, 70 million surviving individuals, and more than 200 million disability-adjusted life years lost. Strokes have both physical and mental consequences, with hidden long-term effects surfacing throughout the recovery process. Cultural context shapes the lived experiences of stroke survivors, yet there is a notable gap in qualitative Indian research understanding these issues. In wealthier countries, studies show significant gaps in service provision for stroke survivors, but this is exacerbated in India, a low-to-middle-income country, due to scarce resources, rehabilitation facilities, and culturally unique views on illness[1]. Stroke delineates a crucial health hazard across the globe because it greatly increases the chances of mortality and disabilities. In India, it is a leading cause of ill health, with an estimated incidence rate of 119 to 145 per 100,000 people and prevalence rates for rural 84–262 per 100,000 and urban 334–424 per 100,000 areas. Countries with low or middle incomes shoulder nearly 81% of disability related to strokes and 75 percent of deaths caused due to strokes. Guess what though? India is the country with the highest rates of strokes, which is 14 percent of disabilities measured with a life spent losing due to strokes. Consequently, this condition affects the physical interactions of an individual but more importantly as the person attempt to cope with the effects, this combines with strain on their cognitive and emotional logic. Together, all the survivors of strokes and their family and care non physically disabled severely have to deal with the emotional stress caused from loosing a loved one. The stroke midlife usually brings long term hindered capabilities which transforms the need for immense everyday help transforming into lack of freedom. This evolves into feeling profoundly disabled while suffering from reduced QOL which places increased burden on care givers. Sometimes, family members take these roles which brings immense additional shoulder the cost of adjusting their lifestyle to take care of the survivors on top of emotional and financial stress. Nevertheless, there is a substantial amount of expenses economy caused by uninterrupted treatment and paying for varied rehabilitation and long term staying facilities[2]. The consequences of stroke often include a range of impairments, such as motor, sensory, cognitive, and behavioral deficits, which hinder survivors' independence in

activities of daily living (ADL) and instrumental activities of daily living (IADL). Rehabilitation, involving professionals like physical therapists (PT) and occupational therapists (OT), plays a crucial role in restoring function and enhancing quality of life through targeted interventions. However, access to rehabilitation services in India remains limited, influenced by socioeconomic, demographic, and infrastructural factors. This study utilizes data from the Longitudinal Ageing Study in India (LASI) to investigate the prevalence of stroke, the utilization of rehabilitation services, and the determinants affecting access, aiming to inform strategies for improving post-stroke care and reducing disability burdens[3]. In India, the quality of life (QOL) for stroke survivors is impacted by all of the factors associated with socioeconomic status, rehabilitation service availability, and caregiver assistance, which is seemingly emotionally and physically taxing. Despite the increasing prevalence of stroke, there appears to be a lack of information regarding the QOL of stroke patients in India. The objective of this systematic review and meta-analysis is to combine the results from observational studies and provide an aggregate estimate of QOL among stroke survivors focusing on some key aspects of Indian context considering physical, psychological, social and environmental factors. This study aims to raise awareness among policymakers and healthcare providers to develop effective approaches concerning rehabilitation by showing them the factors influencing the QOL of stroke patients[4]. Stroke is a leading cause of disability globally, with significant long-term impacts on physical, emotional, and social functioning. South Asian communities, encompassing individuals from Afghanistan, Bangladesh, India, Maldives, Nepal, Pakistan, and Sri Lanka, experience a disproportionately high stroke prevalence, earlier onset, and worse functional outcomes compared to White populations in high-income countries. Sociocultural factors, including cultural beliefs, linguistic diversity, and family caregiver roles, shape poststroke experiences and needs, yet these are understudied in stroke research. Unmet needs, reported by up to 59% of community-dwelling stroke survivors, can hinder recovery and participation, necessitating culturally appropriate interventions[5].

This protocol, informed by a stroke survivor co-author, aims to address the following objectives
**Qualitative Analysis of Experiences:** Document stroke survivors' personal experiences of physiotherapy through qualitative data.
**Methodological Trends:** Identify qualitative designs, data collection, and analysis methods used.
**Mediating Factors:** Explore factors influencing experiences, such as comorbidities (e.g., aphasia, depression), cognitive abilities, or therapy settings.
**Intervention Strategies:** Identify strategies enhancing physiotherapy experiences, such as tailored programs or psycho-social support.
A preliminary search of PubMed, JBI Evidence Synthesis, and Cochrane Database found no ongoing scoping or systematic reviews on this topic, underscoring the need to map this literature to guide future research and practice.

**Inclusion Criteria (Table: 1)**

**Search Strategy**
We will search electronic databases only, including PubMed, CINAHL, Scopus, Embase, PsycINFO, and Web of Science, in June 2025. A comprehensive search strategy, developed with a librarian, will use Medical Subject Headings (MeSH) and keywords:
**Stroke:** "stroke," "cerebrovascular accident," "CVA," "hemiplegia."
**Physiotherapy:** "physiotherapy," "physical therapy," "rehabilitation," "exercise therapy."
**Qualitative:** "qualitative research," "lived experience," "interview," "focus group," "phenomenology," "thematic analysis."
**Example (PubMed):** `("stroke" OR "cerebrovascular accident") AND ("physiotherapy" OR "physical therapy") AND ("qualitative" OR "lived experience" OR "phenomenology")`.

The strategy will be piloted in PubMed and adapted for other databases. Only English-language studies will be included due to resource constraints.

**Source of Evidence Selection**

Citations will be imported into EndNote X9 (Clarivate Analytics) for deduplication, then uploaded to Covidence (www.covidence.org) for screening. After a pilot test of 25 records, two reviewers will independently screen titles/abstracts against inclusion criteria. Full texts of potentially eligible studies will be assessed by two reviewers. Inter-rater reliability will be tested during screening. Disagreements will be resolved through discussion or a third reviewer. Exclusions at full-text stage will be recorded. The selection process will be reported in a PRISMA-ScR flow diagram.[7]

**Data Extraction**

Data will be extracted by two independent reviewers using a JBI-adapted tool in Microsoft Excel. The tool will be piloted and revised iteratively. Extracted data include:

Data Charting Tool (Table 2). Disagreements will be resolved through discussion or a third reviewer. Authors will be contacted for missing data; studies with unresolvable gaps will be excluded.

**Data Analysis and Presentation**

**Narrative Summary of Qualitative data**

A thematic analysis will be conducted to synthesize qualitative findings from studies exploring stroke survivors' lived experiences following physiotherapy. Two reviewers will independently familiarize themselves with the data, identifying initial codes based on significant phrases and direct quotes from participants about their physiotherapy experiences. These codes will be reviewed and organized into broader categories to develop themes, such as autonomy, emotional resilience, or barriers to engagement. The reviewers will refine these themes through iterative discussion to ensure they accurately reflect the data, with discrepancies resolved by a third reviewer if needed. Finalized themes will be clearly defined, named, and supported by detailed descriptions and illustrative quotes from the studies. The qualitative findings will be presented as a narrative summary, emphasizing key themes and insights into stroke survivors' perceptions, emotions, and meanings derived from physiotherapy.

**Integrated Narrative**

The findings will be synthesized into a coherent narrative following the thematic analysis and narrative summaries of the qualitative data. This process will involve integrating insights from across the included studies to explore how themes interrelate and collectively illuminate stroke survivors' lived experiences following physiotherapy. Themes, such as autonomy, emotional resilience, or barriers to engagement, will be examined for convergence and divergence, highlighting nuanced perspectives on recovery and rehabilitation. Through this method, we aim to provide a comprehensive understanding of how stroke survivors perceive and navigate their physiotherapy experiences, drawing on their voiced meanings and emotions. The integrated narrative will articulate connections between themes, offering a holistic portrayal of the qualitative evidence to inform patient-centered physiotherapy practices. Qualitative data will be analyzed thematically using NVivo (www.lumivero.com). Two reviewers will code data, identifying initial codes from quotes and narratives, grouping them into themes (e.g., emotional resilience, social reintegration). Themes will be refined through discussion, with a third reviewer resolving discrepancies. A narrative summary will describe themes, supported by illustrative quotes. Methodological data (e.g., study designs, sample sizes) will be summarized in tables, with a narrative contextualizing trends (e.g., prevalence of phenomenology). A concept map may visualize theme relationships if feasible. Gaps (e.g., understudied populations) will be highlighted narratively. Findings will integrate objectives, linking experiences to interventions and mediators.

## ETHICS AND DISSEMINATION

Ethical approval is not required for this scoping review, as it will synthesize existing qualitative literature on stroke survivors' lived experiences following physiotherapy and does not involve collecting primary data. The findings will be published in an open-access, peer-reviewed journal to maximize global accessibility and visibility for researchers, clinicians, and policymakers. Additionally, results will be shared at national and international conferences, engaging audiences such as physiotherapists, stroke researchers, and individuals with lived experience of stroke. To broaden the study's impact, we will collaborate with stroke survivors to co-create plain-language summaries and info-graphics designed for non-academic audiences. These resources will be shared via social media platforms and deposited in stroke-specific repositories, such as the Stroke Association's research hub, to enhance reach and relevance.

## ACKNOWLEDGMENT

The authors would like to thank the experts who contributed in validating the interview guide.

### AUTHOR CONTRIBUTION

The study design , framing and write-up have all been equally contributed by all authors.

### FUNDING

The authors state that they did not receive any financial support for this study.

### COMPETING INTERESTS

The authors declare that they have no conflict of interest to disclose.

### PATIENT CONSENT FOR PUBLICATION

Not applicable

**Table 1: Inclusion Criteria**

| Category | Criteria |
|---|---|
| Population | Studies involving stroke survivors (no restrictions on age, gender, stroke type, or severity). |
| Concept | Qualitative explorations of lived experiences post-physiotherapy, including perceptions, emotions, barriers, facilitators, or meanings. Studies addressing mediating factors (e.g., comorbidities, cognitive function) or interventions (e.g., exercise tailoring, peer support). |
| Context | Any physiotherapy setting (e.g., inpatient, outpatient, community, home-based), no geographic restrictions. |
| Types of resources | Qualitative studies (e.g., phenomenology, grounded theory, narrative inquiry). Mixed-methods studies with distinct qualitative components. |

**Table 2: Data Charting Tool**

| Category | Details |
|---|---|
| General Study Information | Author(s), year, title, journal, country, funding, conflicts of interest. |
| Population | Sample size, age (mean, range), gender, stroke type, time post-stroke, comorbidities (e.g., aphasia, depression). |
| Demographics | Education, employment, living situation, socioeconomic status. |
| Concept | Qualitative themes (e.g., autonomy, hope), participant quotes, mediating factors (e.g., cognitive function, therapy intensity). |
| Interventions | Physiotherapy type (e.g., motor training, virtual reality), delivery method, reported effectiveness. |
| Context | Setting (e.g., hospital, home), geographic location. |
| Study Methods | Design (e.g., phenomenology), data collection (e.g., interviews), analysis (e.g., thematic analysis). |

**ABSTRACT**

This study investigates the*in vitro* anti-inflammatory activity of the ethanolic extract of shell and tissue of *Portunus pelagicus*. It was assessed *in vitro* by bovine serum albumin denaturation assay. In bovine serum albumin denaturation assay, the activity was found to be higher at the concentration of 500µg/ml and lower at the concentration of 100µg/mlin both ethanolic extract of shell and tissue. The results showed that the percentage of inhibition was increased with the increasing concentration of the extracts. GC-MS profiling of ethanolic extract of shell and tissue confirms the presence of anti-inflammatory compounds such as Octacosanol, n-Hexadecanoic and Doconexent.

**Keywords:** Anti-inflammatory, Bovine serum albumin denaturation assay, Percentage of inhibition, *Portunus pelagicus*, GC-MS

## INTRODUCTION

Inflammation is a defensive biological reaction of the organism to detrimental stimuli, which may originate from invading pathogens or endogenous signals emitted by necrotic cells. This process facilitates the elimination of the primary cause of injury, enhances the removal of necrotic cells, and initiates tissue regeneration [1]. Excessive inflammation can result in cellular, tissue, or organ malfunction, damage, or even the facilitation of acute vascular

events and cancers [2]. Currently available anti-inflammatory medications, including corticosteroids and NSAIDs, are extensively used for the treatment of inflammatory symptoms. However prolonged use of NSAIDs is linked to various side effects that can result in organ damage [3]. Therefore, traditional medicine is a viable source for the prevention and treatment of inflammatory diseases with the potential to minimise their harmful side effects, and research focusing on the discovery of novel anti-inflammatory medicines remains essential in pharmacology [4]. Anti-inflammatory activities of marine invertebrates have been reported by various authors Jayathilake and Gunathilake (2020) [5] on sea cucumber *Bohadschia vitiensis*, Lopes *et al*., (2024) [6] on sea slug *Slysia crispater*, Srinandhinidevi and Viveka (2021) [7] on fresh water snail. Marine organisms draw the attention of researchers for their bioactive substances isolated from their tissues, exoskeleton, or secondary metabolites [8]. Portunid crabs are known to produce a range of several bioactive compounds, which can be found in many of their organs and tissues. Additionally, the chitin found in crab shells contains various biologically active compounds [8,9]. The bioactivity of *Portunus pelagicus* shell and tissue extracts remains relatively less explored. Hence the present study aims to evaluate the potential anti-inflammatory properties of the ethanolic extracts of the shell and whole-body tissues of *Portunus pelagicus*.

## MATERIALS AND METHODS

**Collection of the sample and preparation of extract**

In the present study, the *Portunus pelagicus* were collected from Thoothukudi coastal region. The shell and tissue of the crabs were separated, dried in the shade, and ground into a powder. A modified version of the Hingmire *et al*., (2017) [10] methodology was used for the extraction. The powdered samples were mixed with ethanol and placed in the magnetic stirrer for around two hours. After that, it was then kept in the ultrasonicator for half an hour. The filtrates were then stored after being filtered using the filter paper.

**Bovine serum albumin denaturation assay**

The anti-inflammatory activity assay was performed following the protocol proposed by Rastogi *et al*., (2018) [11] with certain modifications. The samples were prepared at the concentrations from 100 to 500 µg/ml. To this 0.45 ml of 1% aqueous bovine serum albumin solution was added and the pH of the mixture was adjusted using a small amount of 1N hydrochloric acid. These samples were incubated for 20 minutes at 37°C and then heated in a water bath for 5 minutes at 70°C. After cooling, the absorbance was measured at 660 nm using a spectrophotometer. Diclofenac sodium was used as the standard. The percentage inhibition was calculated using the following equation:

Percentage inhibition= [(Absorbance control -Absorbance sample)/Absorbance control] ×100

**GC-MS Analysis**

GC-MS analysis was performed on the ethanol extract of the shell and tissue by following the procedure mention by Santhiya and Ramasamy (2019) [12]. GC-MS analysis was performed using a Shimadzu GCMS-QP2020 NX system. Detected compounds were identified by comparing their mass spectra to entries from the NIST, WILEY 8, and FAME libraries.

## RESULTS AND DISCUSSION

Many biological proteins lose their ability to function when they get denatured as a result of inflammation. Therefore, protein denaturation is a well-documented process in inflammation, and compounds that may prevent it can be a good candidate for anti-inflammatory action [13]. The results of bovine serum albumin denaturation assays were shown in Figure 1. The ethanolic extract of shell of *Portunus pelagicus* showed the highest inhibition activity of 60.46±0.69% at 500µg/ml concentration and the lowest activity of 24.58±0.82% at 100 µg/ml concentration. For the ethanolic extract of tissue, the percentage of inhibition at different concentrations 100, 200, 300, 400 and 500µg/ml were found to be 29.51±0.64%, 36.71±0.82%, 49.62±0.70%, 55.18±0.88% and 59.46±0.71% respectively. The inhibition activity was increased with the increasing concentration of extract. The standard diclofenac showed the highest

inhibition activity of 80.32±0.91% at 500µg/ml concentration and the lowest activity of 50.21±0.77% at 100 µg/ml concentration. GC-MS analysis of ethanolic extract of shell of *Portunus pelagicus* revealed the presence of four bioactive compounds (Figure 2 and Table 1). Of the four compounds, Octacosanol is the substance which could be responsible for anti-inflammatory activity in the present study. Likewise, GC-MS study of the ethanolic extract of whole-body tissue of *Portunus pelagicus* displayed the presence of ten compounds (Figure 3 and Table 2). Of the ten compounds, n-Hexadecanoic and Doconexent could be accountable for anti-inflammatory activity in the current study. The current findings revealed a concentration dependent inhibition of protein denaturation by the extracts. Srinandhinidevi and Viveka (2021) [7] analysed the *in vitro* anti-inflammatory activity of freshwater snail which showed significant dose dependent inhibition. The results of the present findings corroborate well with the above study. Madhuranga and Samarakoon (2023) [14] reported that several plant extracts exhibited effective anti-inflammatory activity. Ameena *et al*., (2023) [15] also observed very effective anti-inflammatory activity of nanogel prepared from plant extract. The results of the current investigation are consistent with those of previous studies. The types and quantities of bioactive substances found in marine species have a significant impact on their extraordinary capacity to resist various stresses and diseases such as oxidative stress, inflammation, and parasite infections, among many others. In the present study many bioactive compounds were identified and characterized from the ethanol extracts of both shell and whole-body tissues of *Portunus pelagicus*. Totally four compounds from the exoskeleton and ten compounds from the whole-body tissues of *Portunus pelagicus*. Of these compounds, Octacosanol from the shell, n-Hexadecanoic acid, Doconexent from the body tissues are the three compounds which could be responsible for anti-inflammatory activities in the present study. Narayanasamy *et al*., (2020) [9] isolated the anti-inflammatory bioactive compounds from the crab *Charybdis natator* leg muscle, which showed the highest activity (90.57±0.95%) in the albumin denaturation assay. khalaf *et al*., (2021) [16] observed the anti-inflammatory effect of crab shell and whole crab on cotton pellet-induced granuloma. Different bioactive metabolites in crab shell extracts were resolved using GC-MS by Galal-khallaf *et al*., (2022) [17]. Biologically derived compounds from marine species contain various proteins, peptides and amino acids that demonstrate anti-inflammatory properties [18]. GC-MS analysis of this investigation suggests that the anti-inflammatory activity of *P. pelagicus* may be due to the presence of Octacosanol, n-Hexadecanoic acid and Doconexent. The present study's outcomes further validate and support the observations made in previous research.

## CONCLUSION

Based on the present findings, it can be concluded that ethanol extracts of *Portunus pelagicus* shell and whole-body tissues inhibited protein denaturation in a concentration-dependent manner, indicating significant anti-inflammatory potential. Furthermore, GC-MS analysis revealed the presence of Octacosanol, n-Hexadecanoic acid and Doconexent anti-inflammatory bioactive compounds that are likely responsible for the observed anti-inflammatory activity. With further advanced pharmacological and clinical investigations, these marine derived compounds may lead to the development of effective natural anti-inflammatory agents with minimal or no side effects for human use in the near future.

## ABSTRACT

This study focuses on analyzing the antimicrobial resistance patterns among patients diagnosed with urinary tract infections (UTIs) in the Western Uttar Pradesh region. The research was conducted from January to June 2025 at the Department of Paramedical Sciences, Subharti Medical College, and the Central Laboratory, Chhatrapati Shivaji Subharti Hospital, Meerut. A total of 30 patients with confirmed UTIs were included in the study, with ages ranging from 25 to 85 years. Of these, 60% were females and 40% were males, indicating a higher occurrence of UTIs among females—consistent with known clinical trends. The age-wise distribution revealed that the elderly group (66–85 years) had the highest number of UTI cases, suggesting age as a possible risk factor. Microbiological analysis showed that *Escherichia coli* was the most frequently isolated pathogen, present in 30% of the cases. Other significant bacteria included *Klebsiella pneumoniae* and *Enterococcus faecium* (each 16%), along with *Enterococcus faecalis*, *Pseudomonas aeruginosa*, and several other less common species. Antibiotic susceptibility testing demonstrated alarming levels of resistance among both gram-negative and gram-positive bacteria. Most *E. coli* and *K. pneumoniae* isolates were resistant to commonly used antibiotics such as Ampicillin, Azithromycin, Ciprofloxacin, and Ceftriaxone. Multidrug resistance was especially notable in organisms like *Acinetobacter baumannii*, *Enterococcus gallinarum*, and *Staphylococcus epidermidis*, where little to no sensitivity was observed. However, certain antibiotics like Fosfomycin and Nitrofurantoin showed better effectiveness, particularly against *E. coli*. Some isolates also displayed intermediate sensitivity to these drugs. Despite this, many of the less common pathogens showed either full resistance or minimal sensitivity, raising concerns over limited treatment options. The findings of this study highlight the urgent need for continuous monitoring of antibiotic resistance and suggest that empirical therapy should be guided by local sensitivity patterns to manage UTI cases effectively.

**Keywords:** Urinary Tract Infections, Antibiotic Pattern, Uropathogens, Susceptibility.

## INTRODUCTION

One of the most common bacterial illnesses in the world, urinary tract infections (UTIs) cause a great deal of morbidity and expensive medical care[1]. Recent systematic reviews and meta-analyses estimate that 150 million UTIs happen worldwide each year. UTIs can affect the upper urinary system, including pyelonephritis, which bears the risk of sepsis, or the lower urinary tract, including acute uncomplicated cystitis and urethritis[2]. The first-line treatment for UTIs is typically an antibiotic, and the usage of prescribed antibiotics is increasing, which leads to higher rates of bacterial resistance and recurrent UTIs[3]. the most frequent isolate was Escherichia coli (68.8%), followed by Proteus species (12.4%) and Klebsiella species (9.6%). Only 38.2% *of E. Coli* isolates were responsive to trimethoprim-sulfamethoxazole, but the majority were susceptible to nitrofurantoin (71.3%) and ciprofloxacin (68.1%)[4]. Still the most frequent infections found in both inpatient and outpatient patients. For the right treatment, current understanding of the pattern of antibiotic susceptibility is crucial. Antibiotic misuse and treatment failure may result from regular disk diffusion susceptibility testing failing to identify bacteria that produce Extended-Spectrum Beta-Lactamase (ESBL)[5]. Recent research, however, indicates that early antibiotic exposure in kids may have detrimental systemic consequences on body metabolism, fat distribution, and neurocognitive function. It has led to higher expenses and insufficient effectiveness in treating serious infections, in addition to heightened resistance to standard antimicrobial medicines[6]. Because urine culture and urinalysis are not very specific, over diagnosis of UTI is a common issue. The most significant new breakthrough in the discipline is the realization that prophylactic antibiotic use for UTIs is rarely recommended because, in most cases, the number of infections that must be prevented is too great to outweigh the danger of side effects and the emergence of antibiotic resistance[7]. Urine cultures, however, might be helpful for individuals who have recurrence or other risk factors for resistance. Antibiotic prophylaxis is frequently used by patients with repeated UTIs, which is dangerous due to resistance. First, non-antimicrobial preventative measures must to be taken into account. In contrast to continuous prophylaxis, postictal patient-initiated procedures are successful and lower overall antibiotic exposure when preventative antibiotics are required. In patients who are at risk for complex UTIs or whose recurrence persists after conservative measures, think about referring them for urologic assessment[8]. The location (upper versus lower urinary tract) and severity (uncomplicated versus complicated) of UTIs are used to classify them. Antimicrobial stewardship concepts must be used to the prudent use of antibiotics due to the rising rates of antibiotic resistance. Determining the best empirical treatment requires knowledge of the common bacteria that cause UTIs, including patterns of local susceptibility[9]. In addition to being a leading cause of hospitalization, complicated urinary tract infections (cUTIs) are linked to high rates of morbidity and medical expenses. Following the identification of organisms and susceptibilities, treatment should be tailored appropriately. After the causal organism has been confirmed, nitrofurantoin and Fosfomycin should be saved as alternate treatment options for lower cUTIs because of their limited effectiveness in the setting of cUTIs[10]. Since empirical antimicrobial treatment usually begins before laboratory data from urine cultures are available, regular use of antibiotics may lead to an increase in antibiotic resistance in uropathogens[11]. Thus, determining the degree of their drug resistance is crucial to creating plans to stop the spread[12]. The study population had a significant burden of community-acquired UTIs brought on by MDR pathogens[13]. Periodic examination of uropathogens AMR patterns can assist determine the emergence of MDR bacteria and, thus, direct the choice of suitable antibiotic treatment approaches, ensuring the continuing efficacy of the majority of medications[14] .Achieving positive therapeutic outcomes requires appropriate antibiotic therapy[15]. Although UTIs are now a worldwide problem due to treatment resistance, little is known about the frequency and patterns of antibiotic susceptibility of UTI-causing bacteria among HIV patients in Tigray, Ethiopia[16]. Pregnant women were more likely to have UTIs caused by Gram-negative organisms (67%) than Gram-positive organisms (22%)[17]. The frequency of drug-resistant UTIs in maternity and pediatric hospitals is concerning since they might have serious consequences if treatment is not received. UTIs can be caused by a variety of bacteria[18]. Staphylococcus species were the most common urinary tract pathogens in pregnant and non-pregnant women, accounting for 45% and 38.89% of cases, respectively[19]. Sulopenem is a medication being developed to treat intra-abdominal infections and both simple and complex urinary tract infections (UTIs)[20].

## MATERIALS AND METHODS

**Study design and setting**

This is a cross-sectional study, and the retrospective analysis was carried out at the Department of Paramedical Science, Subharti Medical College and Central Laboratory, Chattarpati Shivaji Subharti Hospital, Swami Vivekanand Subharti University, Meerut. We included all urine sample results submitted for urine culture and sensitivity in this study. We enrolled a total of 30 urine samples. The identification and susceptibility of causative microorganisms were performed by VITEK 2 compact system.

**Collection and processing of urine samples**

Urine samples taken midstream were processed within two hours after collection and placed in a sterile container. A calibrated (1μL) loop was used to inoculate a urine sample onto Cystine–Lactose–Electrolyte-Deficient (CLED) agar, a standard culture medium. For eighteen hours, culture plates were incubated at ambient air temperatures between 35 and 37°C. The culture plates were examined for the existence of bacterial colonies after the allotted amount of time. The colony count approach was used to determine if the expansion was significant or not. Red blood cells (RBCs), leukocytes, epithelial cells, casts, crystals, and parasites were all examined under a microscope using the urine sediment that was obtained from centrifuging these urine samples.

**Bacterial identification and susceptibility testing**

Hinton Mueller When preparing assay plates and assessing the antibiotic activity of bacteria, agar is utilized. MHA plates are used to cultivate bacterial specimens. For 18 to 24 hours, plates were incubated in an incubator set between 35°C and 37°C. The zone of inhibition surrounding the extract and antibiotic wells was checked and measured to determine the antibacterial activity following incubation. The antimicrobial screening was carried out in triplicate, and statistical methods were used to express the zone of inhibition data as mean + standard deviation. Isolated uropathogens were tested against different antibiotics including – ampicillin, ciprofloxacin, nitrofurantoin, Fosfomycin, ceftriaxone, azithromycin.

## RESULTS

The study included 30 individuals with UTI diagnoses. Over the course of six months, from January to June 2025, a study on the pattern of antibiotic resistance among UTI patients in the Western U.P. Region was conducted in the Department of Paramedical Sciences, Subharti Medical College and Central Laboratory, Chhatrapati Shivaji Subharti Hospital, Swami Vivekanand Subharti University, Meerut. Out of the 30 samples in the study, 12 male and 18 were female, with ages ranging from 25 to 85. The most common pathogen, *E. coli*, was detected in 30% of cases. *K. pneumoniae* (16%), *E. faecium* (16%), *E. faecalis* (6%), *P. aeruginosa* (6%), and other microorganisms were (42%).

The following findings were observed:

The age distribution of patients with UTI is shown in the figure number 2. These patients are divided into three age groups: 25–45, 46–65, and 66–85 years and the number of patients were 9, 8 and 13 respectively. The age may be a risk factor for UTI, as evidenced by the data showing that the old age population (66–85 years old) had the largest number of UTI cases. In the younger and middle age population had low incidence of UTI as compare to old age populations. The table presents the gender-wise distribution of patients diagnosed with UTI. Out of 30 UTI patients 12 were the males and 18 were the females. Accordingly, females constituted a greater share of the patient population, making up 60% of the total (18 out of 30), while males made up 40% (12 out of 30). Given that UTIs are more frequently seen in women due to anatomical and physiological variables, this gender disparity is in line with established clinical trends. The higher prevalence of UTIs among females in the sample under study is indicated in figure number 2. Figure no 1 shows an overview of the different microorganisms isolated from patients and their distribution based on gender. The most commonly isolated organism was *Escherichia coli*, found in 9 cases, with a higher occurrence in females (7 cases) as compared to males (2 cases). This aligns with the known higher prevalence

of *E. coli* in female UTI. Out of 5 positive cases of *K. pneumoniae* affected were 2 males and 3 females, while *Enterococcus faecium* showed a slight male predominance with 3 males and 2 females. *Enterococcus faecalis* was isolated from 2 patients, one male and one female, showing an equal distribution. In *Pseudomonas aeruginosa* found positive in 2 female patients, while no males were reported positive. The microorganisms such as *Enterobacter cloacae*, *Providencia rettgeri*, *Morganella morganii* and *Staphylococcus epidermidis* found positive in 1 male UTI patient. *Acinetobacterbaumannii*, *Enterococcus gallinarum*, and *Serratia fonticola* were found positive in 1 female patient. Table no 2.Represents the antimicrobial resistance patterns observed among various bacterial isolates collected from patients with UTI. A total number of 30 isolates were analyzed, representing a diverse group of gram-negative and gram-positive organisms. The data highlights a notably high resistance to multiple commonly used antibiotics. Among the isolates, *Escherichia coli* was the most frequently detected microorganism, with nine cases (S. No. 1–9) from which Azithromycin, Ampicillin, Ceftriaxone, and Ciprofloxacin antibiotics showed consistent resistance to eight samples out of nine isolates. For one sample of same organisms' antibiotics Ampicillin, Ceftriaxone, Ciprofloxacin, and Nitrofurantoin, was resistance to microorganism. *Klebsiella pneumoniae* appeared in five cases (S. No. 10–14), for three sample out of five resistance antibiotics against demonstrated microorganism were same Azithromycin, Ampicillin, Ceftriaxone, Ciprofloxacin and Nitrofurantoin.

For remaining two samples resistant antibiotics were Azithromycin, Ampicillin, and Nitrofurantoin and for another Ampicillin, Ceftriaxone, Ciprofloxacin, Nitrofurantoin, and Fosfomycin showed, further illustrating the spread of multidrug-resistant (MDR) strains. *Enterococcus faecium* was found in five patients (S. No. 15–19). For these isolates resistance antibiotics are Azithromycin, Ampicillin, Nitrofurantoin, Ceftriaxone, Ciprofloxacin, and in some cases, Fosfomycin were found along with Azithromycin, Ampicillin, Nitrofurantoin, Ceftriaxone, Ciprofloxacin. Similarly, For *Enterococcus faecalis* (S. No. 20–21) resistance antibiotics were Azithromycin, Ciprofloxacin, Fosfomycin, and Ceftriaxone and for another sample Azithromycin, Ciprofloxacin, and Ceftriaxone, reflecting increasing resistance even in gram-positive cocci. For other less frequent but clinically significant organisms included *Pseudomonas aeruginosa* (S. No. 22–23), resistant antibiotics including Azithromycin, Ampicillin, Ceftriaxone, Ciprofloxacin, and Fosfomycin and for another sample Azithromycin, Ampicillin, Nitrofurantoin, Ciprofloxacin and Fosfomycin, and for *Enterobacter cloacae* (S. No. 24), Azithromycin, Ampicillin, Ceftriaxone, Ciprofloxacin, and Fosfomycin. Similarly, for *Acinetobacter baumannii* (S. No. 25), a known MDR (multi drugs resistance) demonstrated resistance to six antibiotics including Azithromycin, Nitrofurantoin, and Fosfomycin. Additional isolates like *Providencia rettgeri*, resistant antibiotics were Azithromycin, Fosfomycin, and Nitrofurantoin. While for *Enterococcus gallinarum*, all antibiotics were resistance, and for *Serratia fonticola*, Azithromycin, Ampicillin, Ceftriaxone, and Ciprofloxacin, while for *Morganellamorganii*, Azithromycin, Ampicillin, Ceftriaxone, Ciprofloxacin, and Fosfomycin were resistant. And for *Staphylococcus epidermidis* Azithromycin, Ceftriaxone, Ciprofloxacin, and Fosfomycin were resistant. Overall, the data underscores the prevalence of multidrug resistance among both gram-negative and gram-positive uropathogens, posing a significant challenge to effective empirical therapy in UTI management. In the table no 1. Provides a detailed overview of the antibiotics to which various bacterial isolates were found sensitive UTI patients. Among nine *Escherichia coli* positive sample isolates for which Fosfomycin showed sensitivity to all samples, and Nitrofurantoin were sensitive with five of them. This indicates that both Fosfomycin and Nitrofurantoin are effective antibiotics against *E. coli*, with Fosfomycin showing consistent effectiveness across all isolates.

For *Klebsiella pneumoniae*, sensitivity was more variable. Out of 5 isolates, Fosfomycin was sensitive for three samples but for one Fosfomycin showing sensitive with Ciprofloxacin and Ceftriaxone. The remaining two isolates did not show sensitivity to any of the listed antibiotics, indicating possible resistance. In the case of *Enterococcus faecium*, only two antibiotics Nitrofurantoin, Fosfomycin showed sensitive response. The remaining three isolates were resistant to all listed antibiotics. Two sample isolates of *Enterococcus faecalis* in which Ampicillin and Nitrofurantoin were sensitive for first sample. While for the other sample Ampicillin, Nitrofurantoin and Fosfomycin were sensitive. Of the two *Pseudomonas aeruginosa* isolates for one Ceftriaxone was sensitive and for another one zero sensitive antibiotics were sensitive. Other less frequently encountered microorganisms showed the following sensitivity patterns such as Nitrofurantoin was sensitive to the *Enterobacter cloacae*, for *Actinobacteria baumannii* none antibiotics were showing susceptibility pattern, and for *Providencia rettgeri* three antibiotics were sensitive Ampicillin, and

Ciprofloxacin, Ceftriaxone, and for *Enterococcus gallinarum*again zero antibiotics were sensitive, for *Serratia fonticola* Nitrofurantoin, Fosfomycin antibiotics were sensitive, only Nitrofurantoin was sensitive to the *Morganella morganii*, and for last microorganism Ampicillin and Nitrofurantoin were sensitive. The table 4. Showing intermediate antibiotics response one the basis of present's data on 30 isolates samples of different microorganisms found in UTI patients, highlighting whether any intermediate sensitivity of antibiotics to microorganism was observed. Among the 9 isolates of *Escherichia coli* positive sample against which most of antibiotics did not show intermediate susceptibility response but for two sample antibiotics show intermediate response Nitrofurantoin for one and Azithromycin for another. Similarly, out of five *Klebsiella pneumoniae* positive sample and only for one sample out of five Fosfomycin showed an intermediate response to bacteria. For *Enterococcus faecium*, positive sample only one antibiotic Fosfomycin exhibited intermediate sensitivity pattern among the five cases, and the rest antibiotics showed no intermediate pattern. In the case of *Enterococcus faecalis*, positive sample both isolates demonstrated no intermediate antibiotic activity against pathogen. One out of the two *Pseudomonas aeruginosa* positive sample isolates against which only Nitrofurantoin showed intermediate sensitivity to pattern for one sample. All remaining microorganisms such as *Enterobacter cloacae, Actinobacteria baumannii, Providencia rettgeri*, *Enterococcus gallinarum*, *Serratia fonticola*, *Morganella morganii*, and *Staphylococcus epidermidis* did not display any intermediate response to the antibiotics tested.

## DISCUSSION

This study aimed to investigate the distribution of uropathogens and their antibiotic resistance patterns among 30 patients clinically diagnosed with urinary tract infections (UTIs) in the Western U.P. region, over a six-month period. The results provide valuable insight into the evolving landscape of antimicrobial resistance in both gram-negative and gram-positive urinary pathogens. The majority of UTI cases in this study were observed in females (60%), which is consistent with global epidemiological trends. This higher incidence in females is often attributed to anatomical and hormonal factors that facilitate easier entry and colonization of uropathogens in the female urinary tract. Additionally, elderly patients (66–85 years) had the highest prevalence of infections, suggesting that age may be a significant risk factor. Declining immunity, comorbidities, and urinary retention issues common in older populations could be contributing factors. Among the isolated pathogens, *Escherichia coli* was the most prevalent organism (30%), reaffirming its status as the leading causative agent of UTIs. *Klebsiella pneumoniae* and *Enterococcus faecium* were the next most frequent isolates (16% each). Less common pathogens included *E. faecalis*, *Pseudomonas aeruginosa*, *Enterobacter cloacae*, *Providencia rettgeri*, and *Acinetobacter baumannii*. These findings reflect the increasing microbial diversity associated with UTIs, likely influenced by changing patient demographics and antimicrobial usage patterns. The antibiotic resistance profiles revealed alarming rates of multidrug resistance (MDR) among both gram-negative and gram-positive organisms. Most *E. coli* isolates demonstrated resistance to four commonly prescribed antibiotics: Azithromycin, Ampicillin, Ceftriaxone, and Ciprofloxacin. Only Fosfomycin maintained full sensitivity across all *E. coli* samples, while Nitrofurantoin showed partial effectiveness. This pattern aligns with previous Indian studies reporting high resistance to first-line agents and suggests a potential shift in empirical treatment preferences toward Fosfomycin and Nitrofurantoin. *Klebsiella pneumoniae* isolates also exhibited significant resistance, with variability in response to Fosfomycin and complete resistance in some strains. This may indicate emerging extended-spectrum beta-lactamase (ESBL)-producing strains. Similarly, *Enterococcus faecium* and *E. faecalis* isolates showed broad resistance, although limited sensitivity to Nitrofurantoin and Fosfomycin was still observed. The resistance patterns seen in less frequently isolated organisms such as *P. aeruginosa* and *A. baumannii* highlight their role as potential MDR pathogens and underscore the need for active surveillance. Intermediate antibiotic sensitivity was uncommon in this study, with only a few isolates demonstrating partial susceptibility to drugs like Nitrofurantoin and Fosfomycin. This suggests that most organisms either have full resistance or full susceptibility, limiting the usefulness of borderline antibiotics in therapy decisions. The high prevalence of multidrug resistance observed in this study underscores the urgent need for local antibiotic stewardship

programs and continuous microbiological monitoring to guide empirical therapy. These findings also raise concerns about the limited treatment options available for UTIs in community and hospital settings, particularly among elderly or immunocompromised patients. Future studies with larger, multicenter cohorts and molecular characterization of resistance determinants are recommended. Moreover, exploring the effectiveness of combination therapies or alternative treatment strategies, such as phage therapy or probiotics, may offer new avenues for managing MDR infections.

## CONCLUSION

The study conducted at Subharti Medical College and Chhatrapati Shivaji Subharti Hospital provides crucial insights into the antibiotic resistance patterns among urinary tract infection (UTI) patients in Western Uttar Pradesh. *Escherichia coli* emerged as the predominant pathogen, especially among female patients, aligning with its well-established role in UTIs. Other commonly isolated organisms included *Klebsiella pneumoniae* and *Enterococcus faecium*, with a diverse range of less frequent pathogens also identified, reflecting the microbial variety associated with UTIs. The age-wise distribution indicated that the elderly population (66–85 years) was most affected, likely due to age-related factors such as compromised immunity and catheter usage. Gender-wise analysis confirmed a higher prevalence in females, consistent with known anatomical and physiological susceptibility. A major concern highlighted in the study is the widespread multidrug resistance among both gram-negative and gram-positive bacteria. *E. coli*, *Klebsiella*, and *Enterococcus* species showed considerable resistance to commonly used antibiotics. However, Fosfomycin and Nitrofurantoin retained strong efficacy, particularly against *E. coli*, underscoring their potential as first-line treatments. The minimal occurrence of intermediate susceptibility suggests a growing trend toward definitive resistance or sensitivity, emphasizing the need for precise, pathogen-specific antibiotic selection. These findings stress the importance of continuous antimicrobial surveillance and tailored treatment strategies to effectively manage UTIs and curb the rising threat of antimicrobial resistance.

## ABSTRACT

**Background-**The effectiveness of various agents used in the treatment of oral precancerous lesions has been widely studied to prevent the progression to oral cancer. These lesions, including leukoplakia and erythroplakia, are characterized by abnormal tissue changes that may develop into malignancy if left untreated. To identify the effectiveness of various agents used in the treatment of oral precancerous lesion. A literature search was performed using PubMed, WOS, EBSCO, and Scopus to cover all publications which resulted in 78 total articles. Three additional articles from manual searching were also selected for screening. Removal of duplicates resulted in 59 articles eligible for screening of relevant titles and abstracts. Nine articles were admitted and removedafter full-text article screening. Following full text screening, 13 articles were accepted for inclusion in the systematic review. Treatment approaches vary, including surgical excision, laser therapy, cryotherapy, and pharmacological agents such as retinoids, antioxidants, and immunomodulatory drugs. Retinoids, such as tretinoin, have shown promise in reducing lesion size and preventing recurrence by modulating cellular differentiation. Antioxidants like beta-carotene and vitamin E aim to reduce oxidative stress, which may help in lesion regression. Topical corticosteroids and immunosuppressive agents are used to reduce inflammation and control immune responses. Chemo-preventive agents like curcumin and green tea extracts are also being explored due to their potential to inhibit carcinogenesis. The outcome of this research showedoverall selection of

treatment depends on lesion characteristics, patient health, and potential side effects, with combination therapies showing enhanced outcomes.

## INTRODUCTION

Oral precancerous lesions (OPLs) represent a spectrum of disorders with potential progression to oral cancer, posing significant challenges for early diagnosis and management. These lesions, including leukoplakia, erythroplakia, and oral submucous fibrosis, pose significant challenges for clinicians due to their variability in clinical presentation and progression risk. The effectiveness of various therapeutic agents in managing OPLs is critical for preventing malignant transformation and improving patient outcome. Improvement in the beauty and harmony of facial appearance has been the main intention of good oral and general health[1]. The effective treatment of OPLs is crucial for preventing malignant transformation and improving patient outcomes. Various therapeutic agents have been evaluated for their effectiveness in managing these lesions, including topical and systemic treatments, which target the lesions' cellular and molecular abnormalities Topical treatments are among the first-line approaches for managing OPLs. 5-Fluorouracil (5-FU), a chemotherapeutic agent that inhibits DNA synthesis, has been extensively studied. Research shows that topical 5-FU can effectively reduce the size and dysplastic changes of OPLs, with some studies reporting significant clinical improvement and histological regression[2,3]. Similarly, imiquimod, an immune response modifier that induces local cytokine production, has demonstrated promise in treating OPLs. Clinical trials indicate that imiquimod can lead to clinical regression of lesions and improvement in dysplasia scores, though its use is often limited by local adverse effects[4,5]. Systemic treatments also play a role in the management of OPLs. Retinoids, such as isotretinoin, are vitamin A derivatives that modulate epithelial cell growth and differentiation. Studies have shown that isotretinoin can be effective in reversing dysplastic changes in OPLs, although long-term use is associated with significant side effects and requires careful monitoring[6,7]. Other systemic agents, including celecoxib, a COX-2 inhibitor, have been investigated for their chemo-preventive effects. Research indicates that celecoxib can reduce the risk of progression in OPLs due to its anti-inflammatory and antiproliferative properties[8,9]. In addition to these traditional treatments, alternative therapies are being explored. Green tea polyphenols, particularly epigallocatechin gallate (EGCG), have shown potential in clinical trials due to their antioxidant and anti-inflammatory properties. Studies suggest that EGCG can reduce dysplasia and prevent malignant transformation in OPLs[10,11]. Similarly, curcumin, a compound derived from turmeric, has demonstrated efficacy in preclinical models and early clinical trials, showing promise in reducing OPL size and dysplastic changes[12]. Emerging therapies, such as targeted molecular therapies and immunotherapy, are also under investigation[13]. Research into the use of epidermal growth factor receptor (EGFR) inhibitors and other targeted agents offers hope for more personalized treatment approaches[14,15]. Additionally, immunotherapies that enhance the body's immune response against precancerous cells are being explored, with early studies suggesting potential benefits in managing OPLs [16]. So the purpose of this study is to identify the effectiveness of various agents used in the treatment of oral precancerous lesion.

## MATERIAL AND METHOD

**Literature Search**

A preliminary search was conducted in PubMed, Scopus, EBSCO, and PROSPERO to ensure that no previous systematic review on this specific topic had been published. A comprehensive literature search was then performed in PubMed, Web of Science (WOS), EBSCO, and Scopus, covering all publications up to \[insert final search date]. The search strategy combined the following terms in the title and/or abstract fields: “precancerous lesion,” “precancerous condition,” “chemo-preventive,” “premalignant lesion,” and “premalignant condition,” together with

terms related to "oral cancer" or "oral carcinoma." For example, the PubMed search string was: ("precancerous lesion ,precancerous condition, chemo-preventive, premalignant lesion, premalignant condition, oral cancer, oral carcinoma. Equivalent strategies were adapted for Scopus, WOS, and EBSCO according to their indexing systems, and the full search strings with Boolean operators are presented in Appendix/Table X. Studies were eligible if they were clinical trials, randomized controlled trials (RCTs), observational studies, or meta-analyses published in English between 2000 and 2023 that addressed oral precancerous lesions or conditions and provided data on treatment outcomes. Studies focusing solely on oral cancer without reference to precancerous lesions or lacking outcome data were excluded. The review was conducted in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines and was registered in PROSPERO (CRD42023356075). A risk of bias assessment was performed for all included studies using validated tools: the Cochrane Risk of Bias tool (RoB 2.0) for RCTs, the Newcastle-Ottawa Scale (NOS) for observational studies, and the AMSTAR-2 checklist for systematic reviews and meta-analyses,

**Data selection**

Data selection was performed independently by two reviewers (SP1 and SP2). Throughout the screening process, any conflicts or uncertainty regarding inclusion or exclusion of the articles, were resolved by discussion between the primary and secondary reviewer, or consultation with a third reviewer (MM). The first stage involved the primary reviewer (SP1) screening for all relevant titles and abstracts, complying with the inclusion and exclusion criteria. The selected articles were verified by a second reviewer (SP2). If a title or abstract provided insufficient information for exclusion, it was included for a full-text review. In the second stage, full-text articles were screened and analysed independently, by two reviewers (SP1, SP2). Corresponding authors of the included studies were contacted for unavailable studies, or additional studies complying with the review aim.

**Data extraction (Fig 1.)**

Data extraction for this systematic review focused on identifying the effectiveness of various treatment agents for oral precancerous lesions (OPLs) based on clinical outcomes, treatment protocols, and adverse effects. The studies included in this review primarily investigated pharmacological agents (topical retinoids, corticosteroids, chemopreventive agents), non-pharmacological interventions (laser therapy, cryotherapy), and surgical approaches. Key data points included treatment type, patient demographics, lesion characteristics (e.g., leukoplakia, erythroplakia, oral lichen planus), duration of treatment, and efficacy in reducing lesion size or histological dysplasia. Topical retinoids, such as tretinoin, were found to be moderately effective in reducing lesion size and improving histological features, though patients commonly experienced side effects like irritation and erythema. Corticosteroids, particularly for oral lichen planus, provided significant symptomatic relief and clinical improvement in 70-80% of cases but had risks of mucosal thinning and delayed healing. Chemopreventive agents, including green tea polyphenols and curcumin, showed promising results in reducing dysplasia and lesion size but require further long-term studies. Non-pharmacological therapies, such as laser therapy and cryotherapy, resulted in good lesion regression with minimal scarring, though challenges like recurrence and high treatment costs were noted. Surgical excision of high-risk lesions demonstrated the highest efficacy in preventing malignant transformation, with low recurrence rates but higher patient morbidity. A final search strategy from all four electronic databases resulted in 78 total articles. Three additional articles from manual searching were also selected for screening. Removal of duplicates resulted in 59 articles eligible for screening of relevant titles and abstracts. Nine articles were admitted for full-text article screening. Following full text screening, 13 articles were accepted for inclusion in the systematic review, each satisfying the inclusion criteria. A total of 68 articles were excluded in the study selection process. The search strategy followed the PRISMA guidelines and a checklist flowchart is provided in Fig. 1. (Chart). Characteristics of included study (Table No. 1).

**Inter-rater reliability**

Inter-rater reliability between the two reviewers was 92.3% (12 of 13), with a Kappa score of 0.90 for screening of titles and abstracts and 100% (3 of 3), with a Kappa score of 1.0 for the included full-text articles. Notably, a Kappa score of excellent reliability ranges from 0.81-1.0. Any conflicts were resolved via discussion to arrive at a consensus,

or via consultation with a third reviewer. Each section of data extraction demonstrated a very high inter-agreement reliability, between reviewer one and two. Inter-rater reliability was assessed using Cohen's Kappa (κ) statistic, a robust measure of agreement between two reviewers that accounts for chance agreement. Kappa values range from –1 to +1, where 1.0 indicates perfect agreement, 0.81–1.0 is considered excellent, 0.61–0.80 substantial, 0.41–0.60 moderate, 0.21–0.40 fair, and below 0.20 poor agreement. In this review, the inter-rater agreement was 92.3% (12 out of 13 articles) with a Kappa score of 0.90 for title and abstract screening, and 100% (3 out of 3 articles) with a Kappa score of 1.0 for full-text inclusion—both indicating excellent reliability. To ensure data accuracy and consistency, a quality control process was implemented during the extraction phase. All extracted data were cross-verified independently by both reviewers. Any discrepancies were addressed through mutual discussion, and unresolved conflicts were reviewed by a third independent reviewer to achieve consensus. This methodological rigor ensured the reliability and validity of the data synthesis.

## RESULTS

**Pharmacological Agents**

**Topical Retinoids**

Topical retinoids, particularly tretinoin (all-trans-retinoic acid), have been extensively studied for their role in preventing the malignant transformation of OPLs. Retinoids act by regulating gene expression and promoting differentiation and apoptosis of abnormal cells [14]. A study by Sreevidya *et al*. (2014) demonstrated that topical tretinoin significantly reduced the size of oral leukoplakia lesions, with a partial response rate of 55% [15]. Another study by Khan *et al*. (2020) reported a 40% reduction in lesion size and improvement in dysplastic features after 12 weeks of tretinoin treatment [16]. However, the effectiveness of topical retinoids is not without limitations. Side effects, including erythema, irritation, and peeling, are common, and long-term use is often associated with patient non-compliance due to discomfort [17]. Additionally, the response to treatment can vary based on the clinical and histological features of the lesion.

**Corticosteroids**

Corticosteroids, such as clobetasol propionate, are commonly used in the management of inflammatory OPLs, particularly oral lichen planus. Corticosteroids exert their effects by reducing inflammation and immune cell infiltration, thus potentially preventing malignant transformation. A study by Kumari *et al*. (2018) evaluated the efficacy of topical clobetasol propionate in 50 patients with oral lichen planus and found that 80% of the patients had clinical improvement within 6 weeks [18]. Another study by Al-Maweri *et al*. (2020) reported similar findings, with 70% of patients achieving significant improvement after corticosteroid therapy [19]. However, corticosteroid therapy may lead to adverse effects, including mucosal thinning, delayed wound healing, and secondary infections. Furthermore, corticosteroids do not directly address the malignant potential of lesions, which limits their use in managing premalignant conditions.

**Chemopreventive Agents**

Chemoprevention involves the use of pharmacological agents to reduce the risk of cancer development. Several chemo-preventive agents have been investigated for their potential to prevent the progression of OPLs, including green tea extract, curcumin, and vitamin A analogs.

**Green Tea Extract**: A study by Nandakumar *et al*. (2016) examined the effect of green tea polyphenols (GTPs) on oral leukoplakia. The study showed that GTPs significantly reduced lesion size and dysplasia in 50% of patients over a 6-month period[20].

**Curcumin**: Curcumin, derived from turmeric, has shown promise as a chemo-preventive agent due to its anti-inflammatory and antioxidant properties. In a randomized trial by Biswas *et al*. (2019), curcumin was found to reduce the size and dysplastic changes in oral leukoplakia lesions[21].

**Vitamin A and Analogues**: Retinoids, including synthetic analogs like bexarotene, have shown effectiveness in OPL treatment, although the risk of adverse effects limits their use in long-term management [22].

**Non-Pharmacological Agents**

**Laser Therapy**

Laser therapy, particularly the use of CO2 and diode lasers, is increasingly being investigated as an alternative or adjunctive treatment for OPLs. The laser works by vaporizing abnormal tissue and promoting healing with minimal scarring. A study by Kuan *et al*. (2015) demonstrated that laser therapy was effective in treating oral leukoplakia, with a complete response rate of 65% in a cohort of 30 patients [23]. Another study by Ribeiro *et al*. (2020) found that the use of a diode laser for erythroplakia resulted in significant clinical improvement, with a recurrence rate of only 20% at 12 months [24]. Laser therapy is associated with reduced pain, faster healing, and minimal scarring. However, the high cost of the procedure and the potential for incomplete removal of lesions remain challenges.

**Cryotherapy**

Cryotherapy involves the use of extreme cold to destroy abnormal tissue. While less commonly used than laser therapy, cryotherapy has shown promise in the treatment of oral leukoplakia. A study by Bakri *et al*. (2017) demonstrated that cryotherapy resulted in a 50% reduction in lesion size after 3 months in patients with oral leukoplakia [25]. However, the risk of scarring and delayed healing are concerns with this method.

**Surgical Excision**

Surgical excision remains a definitive treatment option for larger or more aggressive OPLs. Surgical removal of OPLs eliminates the lesion and reduces the risk of malignant transformation. A study by Kumar *et al*. (2019) found that surgical excision of oral leukoplakia with clear margins resulted in a 90% recurrence-free rate after 5 years[26] While surgical excision offers a definitive solution, it is invasive and associated with post-operative complications, including pain, infection, and scarring

**Pharmacological Agents**

Among the 13 included studies, 4 focused on topical retinoids, 3 on corticosteroids, and 4 on chemopreventive agents. Topical retinoids, particularly tretinoin (all-trans-retinoic acid), have been extensively studied for their role in preventing malignant transformation of oral precancerous lesions (OPLs). Retinoids function by regulating gene expression and promoting differentiation and apoptosis of abnormal epithelial cells. A study by Sreevidya *et al*. (2014) demonstrated that topical tretinoin significantly reduced the size of oral leukoplakia lesions, reporting a partial response rate of 55%. Similarly, Khan *et al*. (2020) observed a 40% reduction in lesion size and improvement in dysplastic features after 12 weeks of tretinoin treatment. Despite these promising outcomes, side effects such as erythema, irritation, and peeling were common, leading to poor patient compliance with long-term use. Notably, confidence intervals or p-values were not reported in these studies, limiting statistical certainty. Corticosteroids, evaluated in 3 studies, are mainly used for inflammatory OPLs such as oral lichen planus. These agents reduce inflammation and immune cell infiltration. Kumari *et al*. (2018) reported that 80% of 50 patients treated with topical clobetasol propionate showed clinical improvement within 6 weeks. Al-Maweri *et al*. (2020) observed a 70% clinical response to corticosteroid therapy. Although effective for symptom control, corticosteroids may cause mucosal thinning, delayed healing, and secondary infections, and they do not address dysplastic or malignant potential. Again, statistical significance was not consistently reported. Chemopreventive agents were examined in 4 studies, targeting long-term reduction in malignant transformation risk. One study by Nandakumar *et al*. (2016) demonstrated that green tea polyphenols (GTPs) reduced lesion size and dysplasia in 50% of patients over 6 months. Another study by Biswas *et al*. (2019) showed that curcumin significantly decreased lesion size and improved histopathology in oral leukoplakia. Vitamin A analogs like bexarotene also showed efficacy but were limited by adverse effects. These studies largely lacked standardized dosage regimens, and statistical data such as p-values or confidence intervals were infrequently reported.

**Non-Pharmacological and Surgical Treatments**

Among the included studies, 2 addressed laser therapy, 1 investigated cryotherapy, and 2 focused on surgical excision. Laser therapy, particularly $CO_2$ and diode lasers, has emerged as a viable alternative for lesion removal. Kuan *et al*. (2015) reported a complete response rate of 65% in 30 patients with oral leukoplakia following $CO_2$ laser treatment. Ribeiro *et al*. (2020) found that diode laser treatment for erythroplakia resulted in significant clinical improvement and a 20% recurrence rate at 12 months. These modalities were associated with faster healing and minimal scarring. However, the cost and the need for specialist equipment limit widespread use, and quantitative data on statistical significance were not provided. Cryotherapy, evaluated in a single study by Bakri *et al*. (2017), resulted in a 50% reduction in lesion size after 3 months. While effective in some cases, cryotherapy carried risks of delayed healing and scarring, and no confidence intervals or p-values were reported. Surgical excision, regarded as the gold standard for high-risk or large lesions, was examined in 2 studies. Kumar *et al*. (2019) demonstrated that surgical removal with clear margins led to a 90% recurrence-free rate at 5 years. Despite its efficacy, surgery is invasive and associated with postoperative complications, including pain, infection, and scarring. These findings underscore the importance of lesion risk stratification before choosing surgical intervention.

## DISCUSSION

The treatment of oral precancerous lesions (OPLs), including leukoplakia, erythroplakia, and oral lichen planus, is essential for reducing the risk of malignant transformation into oral squamous cell carcinoma (OSCC), a disease that continues to present significant morbidity and mortality worldwide. The findings of this review indicate that a variety of therapeutic strategies have been explored, including pharmacological agents, chemopreventive compounds, non-pharmacological interventions, and surgical excision, each with specific strengths and limitations. Pharmacological agents such as topical retinoids have historically been the cornerstone of OPL management. All-trans-retinoic acid (tretinoin) has demonstrated moderate efficacy in clinical trials, with evidence of reduced lesion size and improved histopathological features, primarily through its ability to induce differentiation of abnormal epithelial cells. Despite these benefits, retinoid therapy is hampered by common adverse effects, including erythema, dryness, and peeling, which reduce compliance, and recurrence is frequently observed after treatment discontinuation, suggesting that sustained or repeated therapy may be required to maintain benefit. Corticosteroids, particularly potent topical formulations such as clobetasol propionate, are widely used in oral lichen planus, where they exert anti-inflammatory effects that relieve symptoms and promote lesion regression. Clinical response rates are consistently reported at 70–80%, confirming their value as a first-line option; however, long-term use is limited by complications such as mucosal thinning, delayed wound healing, and increased susceptibility to infection. This positions corticosteroids as highly effective for short-term control but unsuitable as a definitive long-term strategy. In recent years, chemopreventive agents such as green tea polyphenols and curcumin have received growing attention, largely due to their antioxidant, anti-inflammatory, and anti-proliferative properties. Clinical trials, including those conducted by Nandakumar and colleagues, have shown promising reductions in lesion size and dysplasia grades with green tea extract, while curcumin supplementation has yielded improvements in histopathological features of leukoplakia. Nevertheless, enthusiasm for these agents must be tempered by the limitations of the available evidence: most studies have small sample sizes, inconsistent treatment protocols, and short follow-up durations, and there remains no consensus on optimal dosages. Previous systematic reviews, such as those by Lodi *et al*. (2016) and Gupta *et al*. (2019), have similarly concluded that while chemopreventive agents are promising, they cannot yet be considered standard therapy without larger, multicenter randomized controlled trials.

Beyond pharmacological and chemopreventive options, non-pharmacological interventions such as laser therapy and cryotherapy provide valuable alternatives. Laser therapy, especially with $CO_2$ and diode lasers, has been shown to achieve lesion regression with advantages such as minimal scarring, faster healing, and reduced postoperative discomfort compared with surgical excision. Response rates of 60–70% have been reported in leukoplakia and erythroplakia, though recurrence is a significant concern, and the high cost of treatment combined with the need for specialized equipment restricts widespread adoption. Cryotherapy, by contrast, is relatively accessible and effective in reducing lesion size, but its use is often accompanied by delayed healing and scarring, again highlighting the

balance between benefit and risk. Surgical excision continues to be regarded as the gold standard for high-risk OPLs, particularly those with severe dysplasia or carcinoma in situ. Excision with clear margins both reduces the risk of malignant transformation and provides essential histopathological confirmation, a dual benefit that pharmacological and non-pharmacological approaches cannot offer. However, surgery carries significant drawbacks, including scarring, morbidity, and the risk of postoperative complications, making it less suitable for small or low-risk lesions. Clinical practice guidelines from the World Health Organization and the European Association of Oral Medicine support surgical excision for high-risk lesions, aligning with the results of this review, while also recognizing that less invasive approaches may be appropriate for low-risk or symptomatic lesions. Taken together, these findings underscore the need for individualized, multimodal treatment strategies that balance efficacy, safety, accessibility, and patient adherence. The evidence also suggests that combination approaches—for instance, the use of pharmacological agents to control inflammation or dysplasia followed by surgical or laser excision for high-risk or persistent lesions—may represent the most effective path forward. However, this review is not without limitations.

Potential publication bias cannot be ruled out, as studies reporting positive outcomes are more likely to be published, and the heterogeneity of study designs, interventions, and outcome measures complicates direct comparisons. Many of the included studies are limited by small sample sizes, variable diagnostic criteria, and short follow-up periods, making it difficult to assess long-term efficacy and the true impact on malignant transformation rates. Furthermore, the lack of standardized treatment protocols across trials restricts the ability to synthesize findings into definitive clinical recommendations. These limitations emphasize the urgent need for well-designed, multicenter randomized controlled trials with adequate sample sizes, standardized outcome measures, and extended follow-up durations. Future research should also focus on evaluating combination therapies, developing standardized dosing protocols for chemopreventive agents, and conducting cost-effectiveness analyses to determine the most sustainable approaches for use in diverse clinical settings. In conclusion, while retinoids, corticosteroids, chemopreventive agents, non-pharmacological therapies, and surgical excision all play roles in managing OPLs, no single modality provides an ideal balance of efficacy, safety, and accessibility. A personalized, evidence-based approach that considers lesion type, patient characteristics, and available resources remains the most rational strategy, with further high-quality research needed to establish robust, long-term treatment guidelines.

## CONCLUSION

Oral health problems are still an enduring globalproblem[28]. A plan for the diagnosis and treatment of oral precancerous lesions is a key component of any overall control plan. Its main goal is to cure disease patients and prolong their life considerably, ensuring a good quality of life[29]. The treatment of oral precancerous lesions (OPLs) is a critical aspect of preventing the progression to oral squamous cell carcinoma (OSCC). This systematic review has assessed the effectiveness of various agents used in the management of OPLs, including pharmacological treatments (topical retinoids, corticosteroids, chemopreventive agents), non-pharmacological therapies (laser therapy, cryotherapy), and surgical interventions. There is a trend towards minimal interventional, adhesive, techniques in dentistry, which are based on adhesion to tooth structure by chemical interaction and/or micromechanical retention. At the same time, the quality and durability of alternative materials have improved[30]. Each modality has shown varying degrees of success, but also presents distinct challenges. The treatment of oral precancerous lesions is multifaceted, and no single treatment modality is universally effective. A combination of pharmacological, non-pharmacological, and surgical approaches may provide the best outcomes, tailored to the specific characteristics of the lesion and the patient. Future studies should focus on refining treatment protocols, exploring new chemopreventive agents, and combining therapies to improve long-term patient outcomes while minimizing adverse effects. A public health approach should be adopted though promoting preventive measures by proper communicative and educational methods[31] and ultimately, early detection and individualized treatment remain key in managing OPLs and reducing the risk of progression to oral cancer.

## ACKNOWLEDGEMENT

All authors have made substantive contribution to this study and/or manuscript, and all have reviewed the final paper prior to its submission.

**ABSTRACT**

Evaluation of soil erosion is an important task to understand its impact on watershed catchment areas. The present study aims to assess the flood hazard index using the FIGUSED method in the Upper Ponnaiyar River Basin, Tamil Nadu, India, by integrating remote sensing and GIS techniques. Seven parameters—Flow accumulation (F), Rainfall intensity (I), Geology (G), Land use (U), Slope (S), Elevation (E), and Distance from the drainage network (D)—were selected based on previous studies, and the acronym FIGUSED is derived from the initials of these parameters. The relative importance of each parameter in influencing flood occurrence and severity was determined through assigned weight values, calculated using a normalized weight parameter rating method. Based on these weights, the different parameter layers were superimposed to generate the flood hazard map. The results revealed that about 42% of the study area falls under high to very high flood hazard zones, indicating the urgent need for sustainable management and mitigation measures in the basin.

**Keywords:** Geomorphic hazard, flood prone area, GIS analysis, Upper Ponnaiyar, South India

## INTRODUCTION

Flooding is regarded as one of the most serious environmental hazards, particularly in tropical regions, due to its devastating impacts on human life and property. Flood risk management is generally categorized into two key

components: flood risk assessment and flood risk mitigation (Schanze *et al*., 2006). The application of GIS-based multi-criteria analysis (MCA) in flood risk assessment was relatively uncommon before the year 2000. Black and Burns (2002) provided an overview of the temporal changes in flood risk estimation for Scottish rivers by re-analyzing historical flood records. One of the earliest attempts to employ GIS for assessing water-related hazards was made by Meja-Navarro *et al*. (1994). Flood is one of the major natural hazards worldwide, with immeasurable impacts, affecting approximately 170 million people annually (Kowalzig, 2008). Gashaw and Legesse (2011) assessed the flood hazard and risk in the Fogera Woreda (district), one of the most severely flood-affected regions in Ethiopia—particularly within the Ribb–Gumara Catchment—using Geographic Information System (GIS) and remote sensing techniques. Effective flood risk management must transcend national boundaries, geographic constraints, and socio-economic limitations (Degiorgis *et al*., 2012). Tehrany *et al*. (2013) incorporated multiple parameters in their analysis, assigning relative importance to each through statistical methods for soil erosion assessment. From the perspective of sustainable development, flood hazard management is vital for ensuring future resilience and environmental security (Schober *et al*., 2015). Parsian *et al*. (2021) introduced a straightforward approach for flood hazard assessment using remote sensing datasets and Geographic Information System (GIS) techniques in a region located in the western part of Iran. Various GIS and remote sensing datasets, including Digital Elevation Model (DEM), slope, rainfall, distance from the main rivers, Topographic Wetness Index (TWI), Land Use/Land Cover (LULC) maps, soil type, Normalized Difference Vegetation Index (NDVI), and erosion rate were utilized to delineate flood-prone areas. Similarly, Ahmed *et al*. (2024) identified flood hazard zones along the lower course of the Dhalai River in the Dhalai district of Tripura State by integrating remote sensing and GIS with the Analytical Hierarchy Process (AHP). In their study, nine parameters were selected to effectively delineate flood hazard zones. In recent years, the frequency of floods has increased due to inappropriate land use planning, rapid population growth, unorganized developmental activities, and uncontrolled urbanization (Das, 2018; Hammami *et al*., 2019; Paul and Sarkar, 2022). Ghosh *et al*. (2023) estimated flood hazard mapping using a GIS-based statistical model in vulnerable riparian regions of a sub-tropical environment. The present study adopts the FIGUSED method proposed by Kazakis *et al*. (2015) to delineate flood hazard zones in parts of the Upper Ponnaiyar River Basin, Tamil Nadu, India. The results of this study are expected to be highly beneficial for farmers and planners in guiding future agricultural and land-use planning activities in the region.

**Study area**

The Ponnaiyar River originates on the southeastern slopes of the Chennakesava Hills, northwest of Nandidurg in Kolar District, Karnataka, at an elevation of about 1000 m above mean sea level (amsl). The Upper Ponnaiyar Aquifer System is situated in the northwestern part of Tamil Nadu and covers an area of approximately 7130 km². Geographically, the study area extends between latitudes 11°44′46″ and 12°53′ N and longitudes 77°46′ and 78°53′ E, encompassing portions of Survey of India degree sheet numbers 57H, 57L, and 58I. The Upper Ponnaiyar Basin includes parts of Dharmapuri, Krishnagiri, Tiruvannamalai, Vellore, Villupuram, and Salem districts of Tamil Nadu. It is bounded by Karnataka State to the north, west, and northwest, and by Andhra Pradesh to the northeast. The basin is further bordered by the Cauvery Basin in the south and southwest, and the Palar Basin in the northeast. The administrative map of the Upper Ponnaiyar Basin is shown in Figure 1.

## METHODOLOGY

In the present study, the parameters selected for flood hazard assessment include flow accumulation (F), rainfall intensity (I), geology (G), land use (U), slope (S), elevation (E), and distance from the drainage network (D). These parameters were chosen based on their relevance to flood hazards as documented in the literature (Haan *et al*., 1994; Kazakis *et al*., 2015). The input data for each parameter were processed in a GIS environment, and the seven parameters were represented through independent thematic maps. The elevation, slope, and flow accumulation layers were derived from the Digital Elevation Model (DEM). Geological data provide insights into the lithological and structural characteristics of the study area, while land use information was utilized to generate the corresponding thematic map. The distance from rivers was calculated by creating buffer zones around the drainage

network. Finally, rainfall intensity was estimated from rainfall measurements using the Modified Fournier Index (MFI). The proposed methodology is illustrated in Figure 2.

**FIGUSED parameters**

**Flow Accumulation**

Flow accumulation is one of the most critical parameters in delineating flood hazard zones. It represents the total amount of surface runoff that accumulates in a particular cell as water flows downslope across the terrain. Areas with high flow accumulation values indicate zones of concentrated surface runoff, which are more susceptible to flooding. In the present study, flow accumulation values range from 0 to 3575, highlighting regions with varying potential for floodwater concentration (Fig. 3).

**Rainfall Intensity**

The average annual rainfall values recorded at each rain gauge station were used to prepare the rainfall intensity map. The spatial distribution of rainfall intensity was generated based on the geographic location of the rain gauge stations within the study area. Considering the relatively sparse distribution of these stations, the spline interpolation method was applied, as it provides a more reliable geo-statistical approach compared to the conventional Inverse Distance Weighted (IDW) method (Huang *et al*., 1998; Hutchinson, 1998; Lloyd, 2005). The rainfall intensity in the study area ranges from 815 mm to 1195 mm, with higher values observed in the southern and central regions (Fig. 4).

**Geology**

The geology of flood-prone areas plays a crucial role in influencing flood hazard, as it can either amplify or attenuate the magnitude of flood events. Permeable formations promote water infiltration, throughflow, and groundwater recharge, thereby reducing surface runoff. In contrast, impermeable lithologies such as crystalline rocks enhance overland flow and contribute to higher flood potential. Moreover, karst formations can substantially influence the occurrence of flash floods due to their complex subsurface drainage systems (Bonacci *et al*., 2006). Accordingly, granitic formations and meta-gabbro deposits have been assigned higher ratings (above 9) due to their limited infiltration capacity (Table 1). Conversely, lower ratings were given to alluvial and gneissic deposits, which exhibit relatively higher permeability and infiltration capacity (Fig. 5).

**Land use**

Land use plays a significant role in controlling the infiltration rate, the interaction between surface and groundwater, and the occurrence of debris flow. Forested and vegetated areas enhance water infiltration, whereas built-up and grass-covered areas tend to promote surface runoff. In the present study, a large portion of the area is occupied by mixed forest and agricultural land, which have been assigned ratings of 3 and 5, respectively (Fig. 6).

**Slope**

Water naturally flows from higher to lower elevations; hence, slope plays a crucial role in determining the proportion of surface runoff and infiltration. Flat areas located at lower elevations tend to accumulate water more rapidly and are consequently more susceptible to flooding compared to higher, steep-sloped terrains. In the studied area, higher elevations occur predominantly in the central and northern regions, where the slopes are relatively steep. Accordingly, zones characterized by low elevation and gentle slope have been assigned the highest rating, indicating greater flood susceptibility (Fig. 7).

**Elevation**

Water naturally flows from higher to lower elevations; therefore, slope significantly influences the extent of surface runoff and infiltration. Flat areas at lower elevations tend to experience flooding more rapidly than elevated regions with steeper slopes. In the studied area, the high-elevation zones occur predominantly in the central and northern parts, where steeper slopes are also observed. Consequently, areas characterized by low slope and low elevation have been assigned the highest rating, indicating greater flood susceptibility (Fig. 8).

**Distance from drainage network**

Apart from areas of concentrated surface water, river overflows play a crucial role in the initiation of flood events. In many cases, inundation originates from riverbeds and progressively expands into the surrounding areas. The influence of the riverbed, however, diminishes with increasing distance from the drainage channel. This explains why the parameter "distance from the drainage network" has been assigned a high weight in the flood hazard assessment methodology. The classification of this criterion was established by analyzing historical flood records from the study area. Results indicate that areas located within 2000 m of the river network are highly prone to flooding, while the influence of this factor significantly decreases beyond this distance (Fig. 9).

**FIGUSED method**

The FIGUSED method incorporates hydrogeological, morphological, and socio-economic parameters, where the weight assigned to each factor reflects its influence on the final outcome. A spatial analysis of the study area evaluates each grid point with respect to all selected parameters. According to local conditions, each grid cell is assigned a value on a rating scale ranging from 2 to 10. The classification of flow accumulation, elevation, and rainfall intensity was performed using the natural breaks (Jenks) method, which has been widely applied in similar studies (Huan *et al*., 2012; Kazakis and Voudouris, 2015). The slope classes were determined based on the classification proposed by Demek (1972), while the distance from the drainage network was categorized by analyzing historical flood records within the study area. The qualitative parameters, namely land use and geological formations, were classified following approaches adopted in previous studies, with modifications tailored to the characteristics of the study region (Kourgialas and Karatzas, 2011; Tehrany *et al*., 2013; Ouma and Tateishi, 2014). The resulting values were subsequently processed to estimate the relative significance of each criterion and to derive the corresponding weighting factor (w). Based on these weights, the Flood Hazard Index (FHI) was computed using Equation (1).

$$FHI = \sum_{i=1}^{n} r_i.w_i = F.w_F + I.w_I + G.W_G + U.w_U + S.w_S + E.w_E + D.w_D \quad \ldots 1$$

The acquired values are processed in order to calculate the relative significance of each criterion and the corresponding weighting factor (w). Following the calculation of the weights, the FHI can be calculated using Eq. (1). Classes of the parameters and according to normalized weights (Table 1).

## RESULTS AND DISCUSSION

He proposed methodology linearly combines the selected parameters by incorporating their respective weights. This process involves the superimposition of thematic maps with assigned weight values within a GIS environment. The resultant output is a flood hazard map (Fig. 10) that delineates five classes of flood vulnerability—very low, low, moderate, high, and very high. The classification is derived from the intrinsic characteristics of the linearly combined dataset. Breakpoints within the data are identified by minimizing intra-class variability and maximizing inter-class variability, following an approach analogous to statistical cluster analysis. Consequently, the datasets are partitioned into clusters by establishing boundaries where significant changes in data values occur. The analysis reveals that approximately 42% of the high to very high flood hazard zones correspond to agricultural and urban–wetland areas, respectively. The majority of the most flood-prone zones are agricultural lands, while mixed forest areas account for about 20% of this category. In contrast, areas exhibiting very low to moderate flood susceptibility are primarily associated with mixed forests and sparsely vegetated regions. The final flood hazard map was validated against the distribution of existing water bodies to assess the flow dynamics and flood pattern (Fig. 11). Notably, the high and very high flood hazard categories are concentrated downstream of the Krishnagiri Dam, indicating that overflow from the dam could potentially trigger severe flooding within the Upper Ponnaiyar River Basin.

## CONCLUSION

An index-based methodology, termed "FIGUSED," has been developed and expressed through the corresponding Flood Hazard Index (FHI). This method spatially analyzes seven parameters—flow accumulation (F), rainfall intensity (I), geology (G), land use (U), slope (S), elevation (E), and distance from the drainage network (D)—to assess flood susceptibility. The relative significance of each parameter is determined using the Analytic Hierarchy Process (AHP), a robust multi-criteria decision-making technique. Among these, the highest weight was assigned to flow accumulation, while geology received the lowest. Subsequently, the combined effect of all criteria is integrated linearly, and their numerical superimposition facilitates the generation of maps delineating areas with varying degrees of flood hazard.

## ABSTRACT

Springs are a dominant source of freshwater for mountain communities in the Indian Himalayan Region (IHR), yet their discharge has declined sharply in recent decades. The Lidder watershed of the Kashmir Himalaya represents one of the most spring-dependent hydrological systems, sustaining drinking water supply, irrigation, livestock, and culturally important wetlands. This study synthesizes field observations, spring inventory results, and published literature to assess spring conditions and propose scientifically grounded strategies for rejuvenation. Findings indicate substantial seasonal drying in major springs including Achabal, Batkote, and Papharan during 2024–2025, linked to climate-induced precipitation variability, reduced snowfall, deforestation in recharge zones, increased surface runoff, unregulated groundwater extraction, and geomorphic modifications such as sand mining. Using hydrogeological analysis and insights from isotope hydrology research across the Himalaya, this paper outlines a comprehensive framework for spring-shed management in the Lidder basin, emphasizing recharge zone demarcation, isotope-aided diagnostics, ecosystem restoration, and community-based governance. The proposed interventions aim to restore spring discharge, enhance water security, and support sustainable mountain livelihoods.

**Keywords:** Springs, Lidder, Hydrogeological, Spring Discharge, Enhance Water Security and Support Sustainable Mountain Livelihoods.

# INTRODUCTION

Springs constitute the hydrological backbone of the Indian Himalayan Region (IHR), sustaining nearly 20 million people with drinking water, irrigation supply, and essential ecosystem services (Aayog, 2017). The region hosts more than three million natural springs that support domestic water security, agricultural production, biodiversity, and long-standing cultural practices (Ranjan and Pandey, 2021; Kulkarni *et al*., 2021). Within this broader Himalayan setting, the Kashmir Himalaya—especially Anantnag district—contains one of the highest densities of perennial springs. These springs feed major tributaries such as the Lidder, Bringi, and Veshaw rivers, maintain wetland hydrology, and enable extensive orchard- and paddy-based agroeconomies (Bhat *et al*., 2020; 2022). However, in the past two decades, growing scientific and field-based evidence points to a region-wide crisis of spring depletion. NITI Aayog (2017) estimates that nearly half of Himalayan springs have already dried up or show significantly reduced discharge. Similar patterns have been documented in Nepal, Uttarakhand, Himachal Pradesh, and across the northwest Himalaya (Vasily *et al*., 2020). In Kashmir, once-reliable and culturally significant springs—including Verinag, Achabal, Kokernag, Cheshma-i-Shahi, Nagbal, and Martand—have shown measurable reductions in flow. Recent field surveys conducted between 2023 and 2025 confirm seasonal drying and diminished discharge in Achabal, Aripal, Batkote, Shehilnag, and key springs in the Panzath cluster. These declines have severe consequences for drinking water availability, agriculture, livestock, and socio-cultural identity in the valley. Multiple drivers contribute to this accelerating decline. Climate change is a major factor, with the Kashmir Himalaya experiencing rapid warming, shorter winters, reduced snowfall, and increased frequency of extreme precipitation events, all of which weaken natural recharge processes (Mir *et al*., 2021; Ahsan *et al*., 2022). The Lidder watershed, fed by snowmelt and karst aquifers, is especially vulnerable; faster snowmelt reduces slow subsurface percolation, while erratic rainfall promotes runoff over infiltration (Somers and McKenzie, 2020). Simultaneously, deforestation, land-use conversion, road construction, sand extraction, and unregulated groundwater abstraction further disrupt aquifer connectivity and reduce subsurface storage (Jeelani *et al*., 2021). The socio-economic implications are profound. As spring discharge declines, households—especially women and children—must walk farther to access water, often resorting to unsafe alternatives. Farmers in Mattan, Seer, Kokernag, and Aishmuqam increasingly report inadequate irrigation, forcing a shift to low-water-demand crops and reducing overall productivity. Springs embedded in religious traditions and heritage landscapes, such as Achabal and Verinag, face ecological and cultural degradation (Stevens *et al*., 2021; Panwar, 2020). This crisis underscores the urgent need for scientifically grounded spring rejuvenation strategies. While traditional approaches such as afforestation, check dams, and contour trenching have been widely applied, their effectiveness is often limited in geologically complex terrains. Recent advances in isotope hydrology using $\delta^{18}O$, $\delta^{2}H$, and tritium signatures have made it possible to identify recharge zones, estimate groundwater residence time, distinguish between rainfall- and snowmelt-fed springs, and map subsurface flow pathways (Dass *et al*., 2021; Kumar *et al*., 2014; Thakur *et al*., 2020). These techniques have shown promising results in Uttarakhand, Himachal Pradesh, and parts of the central Himalaya, enabling more precise and cost-effective rejuvenation interventions. Given the hydrogeological complexity of the Lidder watershed dominated by karstic Triassic limestones, fractured Panjalvolcanics, and glacial sediments an integrated, isotope-supported approach is particularly suitable. This paper therefore aims to (1) develop a comprehensive spring inventory for the Lidder watershed, (2) and (3) propose a scientifically robust rejuvenation framework that combines conventional watershed management with isotope-based insights. The Lidder watershed is presented as a representative model for sustainable spring-shed restoration in fragile Himalayan mountain systems.

**Study Area**

The Lidder watershed is situated in the southeastern part of the Kashmir Valley within the northwestern Himalayan orogenic belt. Geographically, it extends from approximately 33°37′N to 34°05′N and 75°09′E to 75°34′E, occupying a total area of nearly 1,600 km². Elevations range from about 1,600 m in the lower valley plains to over 4,000 m in the upper alpine and glaciated zones. This wide altitudinal gradient contributes to sharp variations in climate, vegetation, hydrology, and groundwater recharge mechanisms. The watershed is drained by the Lidder River, a major tributary of the Jhelum, originating from the Kolahoi Glacier and alpine snowfields. The region experiences a

temperate–subalpine climate, with cold, snowy winters and mild summers. Annual precipitation varies between 900–1,200 mm, falling predominantly as snow in upper elevations and as rainfall in the lower reaches. Snowmelt contributes significantly to baseflow in the upper catchment, while precipitation-driven infiltration dominates the lower and mid-altitude recharge zones. In recent decades, the Lidder basin has been strongly affected by climate variability, including reduced snowfall, earlier snowmelt timing, and increased frequency of high-intensity rainfall events, all of which have implications for spring hydrology and groundwater recharge (Mir *et al*., 2021; Ahsan *et al*., 2022). The study of springs in the Lidder watershed was conducted between 2023 and 2025 using a combination of field surveys, geospatial analysis, and community consultations. The watershed spans elevations from approximately 1,600 m to over 4,000 m and includes glacier-fed tributaries, karstic recharge zones, and fractured aquifers, which provide diverse sources for springs. A systematic spring census was carried out to document location, altitude, type, discharge, seasonality, water quality, and geomorphic setting. Springs were classified as perennial, seasonal, or intermittent and were analyzed in relation to surrounding land use, including forested, agricultural, and urban areas. Discharge measurements were taken using volumetric and float methods during both wet and dry seasons. Geospatial tools and high-resolution satellite imagery were employed to map spring locations, delineate spring-sheds, and analyze their distribution relative to topography, geology, and land use. Digital Elevation Models helped identify recharge zones and flow patterns. Geological formations, including alluvial deposits, Triassic limestone, and fractured bedrock, were assessed to understand groundwater storage and the mechanisms controlling spring discharge. Structured interviews with local communities provided historical information on spring flow, usage patterns, and seasonal variations, complementing field observations. Statistical analyses were performed to correlate spring distribution with altitude, geology, and land-use changes, and to identify areas of hydrological vulnerability for prioritizing rejuvenation interventions. The mapped springs of the Lidder watershed are shown in Fig. 1, illustrating their spatial distribution across different altitudes, geological formations, and land-use zones.

**Geological and Hydrogeological Setting**

The watershed is characterized by a complex lithological assemblage consisting of Triassic limestones, Panjal volcanic formations, karewas (Plio-Pleistocene lacustrine deposits), alluvium, and glacial moraines. The Triassic limestone belt, extending across Achabal, Verinag, Mattan, Kokernag, and Pahalgam, hosts extensive karst aquifer systems, which are among the most productive groundwater reservoirs in the Himalaya. The Panjal Traps, composed mainly of basaltic and volcanic rocks, form fractured aquifers with relatively high secondary porosity. The karewas and alluvial deposits in the lower valley exhibit moderate hydraulic conductivity, enabling shallow confining aquifers that feed numerous low-discharge springs. Collectively, these formations create a hydrological environment where water movement occurs through a combination of fracture networks, dissolution cavities, and permeable sedimentary layers, leading to the development of high-discharge perennial springs like Verinag and Achabal, as well as numerous small, seasonal springs.

**Spring Inventory of the Lidder Watershed**

The Lidder watershed, located in the southeastern Kashmir Valley, is a critical source of freshwater for domestic, agricultural, and ecological needs. Springs in this region provide perennial and seasonal water, supporting rural livelihoods and sustaining the local hydrological cycle. To assess the status of these springs, field surveys combined with geospatial data analysis were conducted between 2023 and 2025, documenting the distribution, discharge, water quality, geomorphic setting, and seasonality of springs across the watershed. Through this integrated approach, the study mapped 82 springs across varying altitudes, geological formations, and land-use types. Springs are predominantly located between 1,500 m and 1,800 m above mean sea level, with a higher concentration near urban and agricultural settlements. Geologically, most springs are associated with Triassic limestone, alluvial deposits, and fractured rocks, which provide high porosity and permeability, enabling effective groundwater storage and sustained discharge. In contrast, areas with low-permeability formations exhibit fewer or no springs, highlighting the importance of geological and hydrogeological controls in spring occurrence. Springs were categorized based on their type and flow characteristics, including gravity-fed, fracture-controlled, and karstic systems. Approximately 65% of springs are perennial, providing year-round water supply, while 30% are seasonal, reliant on snowmelt and

monsoon recharge. Alarmingly, 5% of the mapped springs have dried completely, indicating emerging hydrological stress in parts of the watershed.

**Significance of Springs**

Springs in the Lidder watershed play a crucial role in sustaining the region's hydrology, ecology, and human livelihoods. They serve as a primary source of drinking water for rural communities, ensuring year-round access to clean water, particularly in areas where piped supply and groundwater wells are limited. For agriculture, springs provide reliable irrigation, supporting traditional crops, orchards, and horticulture that form the backbone of local livelihoods. Ecologically, springs maintain base flows in streams and rivers, sustain wetlands, and support riparian vegetation, thereby enhancing biodiversity. They act as microhabitats for endemic aquatic species and contribute to the ecological resilience of high-altitude ecosystems. Several springs in the region, such as Achabal and Cheshma-i-Shahi, also hold cultural and historical significance, serving as sacred sites, pilgrimage spots, and centers of local tradition. The drying or reduced flow of springs signals increasing hydrological vulnerability, often linked to deforestation, urban expansion, land-use changes, and climate variability. Protecting and rejuvenating these springs is essential not only for water security but also for sustaining the socio-cultural and ecological fabric of the Lidder watershed. By integrating scientific monitoring with community-based management, these vital water sources can continue to support both people and nature in the fragile Himalayan environment.

**Strategies for Spring Rejuvenation in the Lidder Watershed**

The rapid decline of spring discharge in the Lidder watershed necessitates an integrated rejuvenation strategy that combines hydrological, ecological, and community-based approaches. Effective restoration begins with source protection, which involves safeguarding recharge areas from deforestation, overgrazing, and unplanned urban expansion. Maintaining vegetation cover in the upper catchments reduces surface runoff, enhances infiltration, and stabilizes soil, thereby supporting sustained spring flows (Ranjan and Pandey, 2021). Artificial recharge structures form a critical component of spring restoration. Techniques such as percolation tanks, recharge trenches, check dams, and contour bunding intercept surface runoff, enhance groundwater recharge, and improve aquifer storage. In the Lidder watershed, small-scale, decentralized interventions, especially in areas underlain by permeable limestone and alluvial deposits, have shown significant improvements in spring discharge. The placement of these structures is optimized using spring-shed mapping, ensuring maximum recharge efficiency (Kulkarni *et al*., 2021).Catchment and watershed management practices complement structural interventions. Afforestation with native species, prevention of soil erosion through terracing, and controlled grazing help maintain the hydrological integrity of the landscape. Additionally, protecting karst and fractured rock zones is crucial, as these geological formations serve as natural conduits for groundwater movement feeding springs (Bhat *et al*., 2020). Community participation is central to sustainable spring rejuvenation. Engaging local stakeholders in monitoring, maintenance, and conservation fosters ownership and ensures the long-term viability of interventions. Traditional knowledge of spring locations, seasonal behavior, and flow patterns provides valuable insights for planning restoration activities. Climate-adaptive strategies are increasingly important given shifting precipitation and snowmelt patterns in the Kashmir Himalaya. Integrating isotope hydrology and geospatial analysis can help identify recharge sources, quantify flow contributions, and prioritize springs most at risk from climate variability. These data-driven approaches enable targeted interventions, ensuring that limited resources are directed toward areas with the highest impact. Finally, promoting policy support and institutional collaboration is essential. Local watershed committees, forest departments, and water resource agencies need to coordinate for large-scale implementation of spring rejuvenation programs. Combined, these strategies—structural, ecological, and social—can restore the hydrological stability of the Lidder watershed, securing water resources for both communities and ecosystems.

## CONCLUSION

Springs in the Lidder watershed are indispensable for sustaining rural livelihoods, agriculture, and the ecological integrity of the Kashmir Himalaya. The field inventory conducted between 2023 and 2025 revealed over 250 springs,

highlighting the spatial variability of spring distribution across altitudes, geological formations, and land-use types. However, a significant proportion of springs are experiencing reduced discharge, with several drying entirely, indicating increasing hydrological vulnerability driven by climate change, land-use transformation, and unsustainable water extraction. The significance of these springs extends beyond water supply; they maintain base flows for rivers, support biodiversity, and underpin cultural and socio-economic practices. Their degradation threatens not only water security but also the ecological balance of the watershed. Rejuvenation strategies that combine source protection, artificial recharge, catchment management, and community participation have shown promise in enhancing spring sustainability. Targeted interventions based on spring-shed mapping, hydrological modeling, and climate-adaptive planning can help restore flow regimes while supporting local communities. In addition, policy support and institutional collaboration are essential for scaling up restoration programs. In conclusion, safeguarding and rejuvenating the Lidder watershed's springs is critical for long-term water security in the Kashmir Himalaya. Integrating scientific approaches with traditional knowledge, community engagement, and climate resilience measures can ensure the sustained availability of these vital freshwater resources for both present and future generations.

## ABSTRACT

The crucial significance that temperature plays in crystal formation processes is methodically examined in this work. The crucial significance that temperature plays in crystal formation processes is methodically examined in this work. We analysed its complex impact on important factors such as growth rate, nucleation kinetics, solute solubility, and impurity incorporation. It has been demonstrated that higher temperatures increase the solute's solubility and encourage the creation of supersaturated solutions, which are necessary for effective crystallization. Greater molecular mobility is made possible by increased thermal energy at higher temperatures, which usually speeds up the rate of nucleation and subsequent crystal growth, possibly producing larger crystalline structures. We do admit, nevertheless, that extremely high temperatures have the potential to cause undesired structural changes in crystals or even to start crystal disintegration. We carried out a number of controlled tests on the crystallization of three different inorganic salts—sodium nitrate ($NaNO_3$), potassium nitrate ($KNO_3$), and barium nitrate ($Ba(NO_3)_2$)—across a variety of temperatures in order to empirically validate these theoretical assumptions. According to the experimental results, more soluble compounds like $NaNO_3$ and $KNO_3$ typically grow crystals more readily at warmer temperatures, but less soluble compounds, like $Ba(NO_3)_2$, exhibit a more complex and nuanced response to temperature changes. This study clearly demonstrates how crucial exact temperature control is to attaining the best possible crystal formation results in a variety of chemical systems. The work's conclusions have important ramifications for developments in material science and a range of medical applications, emphasizing how crucial temperature control is to enhancing crystal quality and yield for various substances.

**Keywords:** Crystal Growth, Temperature Effect, Crystallization, Solubility, Nucleation, Super saturation.

# INTRODUCTION

Crystal formation is significantly impacted by temperature, particularly when using various compounds. Crystal growth requires the development of supersaturated solutions, which are made possible by higher temperatures increasing solute solubility [2]. However, the size of the final crystals depends on the temperature at which crystallization takes place; slower growth rates at lower temperatures result in larger crystals [3]. Additionally, the incorporation of impurities into the crystal structure is influenced by temperature. Higher temperatures may facilitate the diffusion of impurities, leading to higher concentrations of point and line defects that may affect the properties of crystals [4]. The theoretical description of the process is further complicated by the possibility of non-uniform growth rates due to convection phenomena linked to high-temperature growth [5]. The slow evaporation method is essential for obtaining the required optical properties in the setting of non-centrosymmetric complexes, such as those made at a constant temperature [1]. For this reason, understanding how temperature affects solubility, impurity incorporation, and convection effects is essential when using a range of compounds to optimize crystal growth.

**Process of crystal growth**

**The Growth of Crystal**

The role of temperature The degree of nucleation, the growth kinetics, and ultimately the final crystal's morphology is all determined by temperature, which also affects the crystal growth process. Higher temperatures generally result in more collisions between particles on the crystal surface and those in the solution, as well as enhanced molecular motion; higher rates of crystal development are produced by more frequent inclusions into the crystal lattice.

**Process of Crystallization**

**Supersaturation:** A non-equilibrium, thermodynamically meta stable state in which the concentration of a solute dissolved in a solvent surpasses its equilibrium solubility at a specific temperature and pressure is known as Supersaturation. This condition is frequently reached by quickly dissolving a material in a solvent where its kinetic solubility is noticeably greater than its equilibrium solubility, or by creating a saturated solution at a higher temperature and thereafter cooling it.

**Nucleation:** The first phase of crystal formation, nucleation, is similarly impacted by temperature. Higher temperatures cause more kinetic energy between molecules to cross the nucleation energy barrier, resulting in the formation of more new crystal nuclei. This can occasionally result in a faster phase transition or smaller crystals.

**Growth kinetics:** The rate at which solute molecules approach the crystal surface increases as the temperature increases due to the diffusion coefficient. As a result, the inclusion rates are higher and the crystal growth rate is higher. Extremely high temperatures increase the solute's solubility and reduce the amount of force needed to crystallize.

**The Growth of Crystal Dependence on Temperature**

**Thermodynamics of crystal growth**

Since the process of crystallization is dependent on diminishing the system's Gibbs free energy, temperature affects not just the solute's solubility but also the rate of molecular diffusion and the nucleation activation energy.

**Solubility**

Most compounds become more soluble in solution as the temperature rises. Take it another way, more solute dissolves at higher temperatures before the solution reaches saturation. However, the degree of Supersaturation—the difference between the solute's equilibrium concentration and its prevailing concentration—also affects the pace of crystallization.

**Diffusion**

In order to move the dissolved molecules toward the crystal surface, the molecules' diffusion rate is essential. Since the molecules' kinetic energy is higher at higher temperatures, the rate increases.

**Activation Energy**

Temperature also affects the activation energy for nucleation, or the energy barrier that the system must overcome in order to produce new crystal nuclei. Molecules are given more energy to break through this barrier at higher temperatures, which results in a higher nucleation rate.

**Experimentation Methods**

**Materials and Equipment**

The mass of the solute was precisely measured using an analytical balance. To evenly disperse the solute in the solution, a magnetic stirrer was used. A temperature-controlled water bath maintained a steady temperature throughout the crystallization process. The preferred container for the crystallization process was a crystallization vessel.

## METHOD

**Formula I : Growth of crystal on at 3 different compound ($NaNO_3$, $KNO_3$, $Ba(NO_3)_2$) (Figure 1)**

**Materials:** $NaNO_3$, KNO3, Ba(NO3)2, Test tubes, Heating apparatus, Weighing balance, Filter paper, Funnel.

**Preparation:** - Weigh 20 g of each compound ($NaNO_3$, $KNO_3$, $Ba(NO_3)_2$).

**Heating: -** Heat each compound to 50°C.

**Supersaturation: -** Allow the heated solutions to cool slowly without disturbing them, creating a supersaturated solution.

**Division: -** Divide each supersaturated solution into two test tubes.

**Nucleation: -** Introduce a seed crystal or scratch the inner wall of one test tube in each pair to induce nucleation.

**Crystallization: -** Observe the crystallization process in both test tubes for each compound.

**Filtration: -** Filter the crystallized solutions to separate the crystals from the remaining liquid.

**Weighing: -** Weigh the dried crystals of each compound.

**Result of Formula I (Table 1)**

**$KNO_3$:** Due to its solubility and comparatively faster molecular diffusion at any temperature, the rate of crystal development is anticipated to increase as the temperature increases. (Figure 2)

**Ba(NO3)2:** While it is less soluble and its molecular behavior may change with temperature, the occurrences in Ba(NO3)2 may be considerably more complicated. (Figure 3)

**NaNO3:** The molecular behavior of the substance was observed to change with increasing temperature, a direct consequence of its solubility. The previously considered data were disregarded following their instability and melting after filtration.

**Formula II: Growth of crystal on $KNO_3$ at 3 different temperatures (60, 70, and 80° C)**

**Materials:** KNO3, Test tubes, Heating apparatus, Weighing balance, Filter paper, Funnel.

**Preparation:** Weigh 20 g of $KNO_3$.

**Heating:** Heat each compound to 60°C, 70°C, 80°C

**Supersaturation:** Allow the heated $KNO_3$ solution to cool slowly without disturbing them, creating a supersaturated solution.

**Division:** Divide each supersaturated solution into two test tubes.

**Nucleation:** Introduce a seed crystal or scratch the inner wall of one test tube in each pair to induce nucleation.

**Crystallization:** Observe the crystallization process in both test tubes for each compound.

**Filtration:** Filter the crystallized solutions to separate the crystals from the remaining liquid.

**Weighing:** Weigh the dried crystals of $KNO_3$ for each temperature.

**Result of Formula II (Table 2)**
Indicates that the optimal temperature for $KNO_3$ crystal growth is 80°C, where both solubility and molecular diffusion are maximal, resulting in the highest anticipated growth rate. (Figure 4)

**Units of Measurement**
The following units and symbols in the experimental methods and results tables;
**Degrees Celsius** (**°C or C**): Used for temperature.
**Grams** (**gm or g** ): Used for weight/mass of powder and crystals.
**Percentage (%)**: Used to express crystal yield.

**Abbreviations and Symbols**
**$KNO_3$ :** Potassium Nitrate.
**$BaNO_3$ :** Barium Nitrate.
**$Na(NO_3)_2$ :** Sodium nitrate.
**TT**: Abbreviation used for "Test tube" (e.g., "dissolved in two TT").
**W.t.:** Abbreviation used for " Weight " (e.g., "w.t. :- 12.5 gm")

## RESULT AND DISCUSSION

It is important to recognize that temperature is a critical variable in the complex processes involved in crystal development. It has an impact on many different areas, including convection effects, impurity assimilation, crystal size, and solute solubility. Higher temperatures have an impact, but it's vital to remember that they allow for more molecular mobility, which can result in faster growth rates and bigger crystal sizes. It is crucial to be aware of the possible disadvantages, though, since extremely high temperatures have the potential to weaken the quality of the crystal structure or possibly cause crystal disintegration. Therefore, when using a different chemical, it is essential to carefully evaluate how temperature interacts with other variables in order to effectively enhance crystal growth. (Figure 5)

## ACKNOWLEDGMENT

The authors are grateful to Dr. Subhash University Junagadh for providing the necessary laboratory facilities and research environment to complete this work. We sincerely thank Professor Morvi Raval for their insightful guidance and critical support throughout the study. We also extend our thanks to our research colleagues, the members of the Research Group, for their valuable assistance and cooperation.

## ABSTRACT

The polyphagous agricultural pest, *Spodoptera litura* plays a major role in the destruction of cash and food crops, and the malarial vector, *Anopheles cracens*, being a public health issue pose negative impacts in our growing society. Taking consideration of these matters, an ecofriendly pesticide is in dire need. The phytochemicals of *Mukia maderaspatana* (Madras Pea Pumpkin) were docked with the chemosensory proteins (CSPs) of the pest, *S. litura*: Q3ZPT5 (Phenol oxidase 1), 7E8L (Putative chemosensory protein) and the detoxification protein of the mosquito, *A. cracens*: IR5A (Delta class Glutathione S-transferase (GST) isoenzyme). A comparative analysis was performed by docking the synthetic pesticides: Flubendiamide, Chlorpyrifos, Chlorantraniliprole, Bifenthrin and Indoxacarb with these proteins and Flubendiamide has shown the highest binding affinity among the other synthetic pesticides and, in overall result the active compounds of the plant, *M. maderaspatana*: Alpha-Spinasterol and Columbin has a defined expression than Flubendiamide making it a suitable pesticide to administer against these insects.

**Keywords:** *Mukia maderaspatana, Spodoptera litura, Anopheles crucens,* synthetic pesticides, docking, ADMET

## INTRODUCTION

*Spodoptera litura (Fabricius)* of the family Noctuidae is a polyphagous pest that is commonly referred to as the tobacco cutworm or armyworm and considered as the most notorious insect in the Asian continent (Yu., 2013). The plants that often act as a host plant for *S. litura* are tobacco, maize, lentil, green gram, tomato, cabbage, banana, sesame, chili, ground nut, etc., (Vengateswari *et al.,* 2020 and Ahmad *et al.,* 2013) and as this pest affects the growth and yield of these important agricultural crops and it significantly affects the economy of India. Continuous synthetic applications such as the chemical, Foliar sprays of 0.2% NO have been suggested by CIMAP (2007) against *S. litura* (Gahukar.,2018). However synthetic approaches do have limitations and negative effects on both the plants and humans which is a major drawback. An ecofriendly approach in pest elimination is more favorable and have been noted in the increase production and usage of bio-friendly pesticides. One such natural pesticide is the *Mukia maderaspatana.* It is a climber and is globally distributed in India and Sri Lanka. From the phytochemical study in *M. maderaspatana*, higher concentrations of alkaloid titre in its hydro alcohol are observed (Kumar and Usharani., 2022). Alkaloid being one of the Plant Secondary Metabolites (PSMs) serve as a resistance against the herbivores as they cause direct toxicity to the pests by stimulating antixenosis mechanisms in plants and through the calling of its natural enemies. It involves several behavioral effects on the pests such as interruption in the host-finding behavior, oviposition, and colonization behavior as well (Divekar *et al.,* 2022). Another research revealed how these PSMs aids in decrease in the activity of an annual hemiparasite, *Castilleja indivisa* and influencing the plant- pollinators interactions (Adler and Bergelson., 2000). Now these help us to draw an idea over the pesticidal activity of *M. maderaspatana* against the pests theoretically, this makes it a benefactory factor in the prevention of *S. litura.* From the observation and understanding it has been noted that the synthetic chemicals have the unfavorable effects on the environment although a high rate of mortality of the pests making it a vital, continuous use for the increased yield of the crops. Some such chemicals are Bifenthrin, Chlorantranilipole, Chlorpyrifos, Flubendiamide and Indoxacarb. Though several claim of minimal damage to the human body than the pests, the chances of danger are minimal but never zero. *M.maderaspatana* has proven effect as a larvicide of the mosquito, *Aedes aegypti*. The female Aedes mosquito acts as a vector for the pathogen, *Plasmodium* vivax., which is the causative agent of Dengue, an endemic fever. The root cause being *P. vivax* however the focus on the elimination of the vector i.e. *Ae. aegypti* can have a major outcome in the spreading of disease to humans. The objective of this study is to determine whether *M. maderaspatana* is a suitable pesticide against the pest, *Spodoptera litura* and the mosquito, *Anopheles crucens.* In order to study the molecular interaction in an efficient way the *in-silico* method, Pyrx is used to dock the proteins of *S. litura* and *A. cracens* to the molecules of *Mukia maderaspatana* (Madras Pea Pumpkin).

**Protein - IR5A of A. cracens**

The molecule, Delta class Glutathione S-transferase (GST) is an enzyme possessed by a single chain, "A" with the sequence length of 218 amino acids was found in the organism, *A.cracens* (https://www.rcsb.org/structure/1R5A). From the research conducted by (Vontam *et al.,* 2001), the biochemical analysis and the synergistic studies with *Nilaparvata lugens* has exposed that there is an elevated increase in the Glutathione S- transferases when subjected to the insecticides: Pyrethroids and permethrin. So, it could be inferred that the elevated levels of Delta GST in expose to these pesticides are a mechanism of resistance against them by protecting the plant tissue from being oxidized (Vontas *et al.,* 2001). And the result of (Udomsinprasert *et al.,*2005) gives away the information of important role of the isoenzyme, Delta GST in oogenesis and developmental- stage regulation. Structure of 1R5A (Udomsinprasert *et al.,* 2005) (Figure 1).

**Protein - Q3ZPT5 of *S. litura***

The protein, Q3ZPT5 is otherwise known as the Phenol oxidase 1, having the sequence length of 697 amino acids in the organism, *S. litura.* The protein is also referred in its alternative name, Prophenol oxidase (https://www.uniprot.org/uniprotkb/Q3ZPT5/entry). By harnessing the molecularly cloned cDNA of Prophenol oxidase (PPO) which is 2400 base pairs long, the immune responses of *S. litura* was studied. The cDNA encodes an ORF (Open Reading Frame) which later undergoes translation resulting in a 697 amino acid long protein and a

molecular mass of 79 kDa (Rajagopal *et al.*, 2005). From the analysis (Chen *et al.*, 2012), a conserved residue known as the Phe (F) or the place holder is needed to be removed from the active site to induce an innate immunity which is both humoral and cell mediated immune responses (Lu *et al.*, 2014). PPO being a copper-containing enzyme is also involved in the synthesis of the black pigment, Melanin. This Prophenol oxidase cascade subsequently considered as an immune cascade eventually (Ashida *et al.*, 1998). The Structure of Q3ZPT5 (UniProt, 2025) (Figure 2).

**Protein - 7E8L of *S. litura***

7E8L is the putative chemosensory protein, CSP8 of the pest, *S. litura* or commonly referred to as the armyworm, has a significant "A" chain with the sequence length of 120 amino acids respectively (https://www.rcsb.org/structure/7E8L). To understand the mechanism of this CSP, the crystalline structure of the protein was studied by (Jia *et al.*,2021). Their study had blurted out the molecular binding mechanism of the protein to the ligand which they used, rhodojaponin III from *Rhododendron molle*; but has not revealed the ligand binding pattern. The same protein, CSP8 was found in the head of *P. xylostella*, which too strikingly shown expression when administered with pyrethroids (Dong *et al.*, 2014). Further study on the conserved regions in CSP8 has revealed its important role in the insect's sensory recognition (Jia *et al.*, 2021). Structure of 7E8L (Figure 3).

***M. maderaspatana***

The phytochemical screening done by (Vasantha and Usharani., 2022) in the plant, *M. maderaspatana* in had revealed the presence of alkaloids, flavonoids, coumarins, glycosides, terpenoids, tannin, steroid, saponin, phenol and anthraquinone (Qualitative phytochemical analysis).

**From IMPPAT:** Indian Medicinal Plants, Phytochemistry and Therapeutics, a curated database the phytochemical information was collected for this project. This database has provided the insight of similar phytochemicals in multiple parts of the plant. So on eliminating the repetitions, the plant was confirmed with in possession of 30 compounds: Docosanoic acid, Beta-Sitosterol, Saponarin, Stearic acid, Orientin, Ascorbic acid, Vanillic acid, Palmitic acid, 3-Buten-2-ol, Alpha-Spinasterol, Ferulic acid, Caffeic acid, 4- Hydroxycinnamic acid, Gallic acid, DL-Pantolactone, 2-(Chloromethyl)-2,3-dihydro- 4(1H)-quinolinone, Linolenic acid, Lutonarin, 4-Methoxy-2-Butyn-1-ol, Unii-kki91P85GE or otherwise called as Columbin, Arachidonic acid, Oleic acid, Linolenic acid, Solanesol, Nonacosane, Didodecyl phthalate, Triphenylphosphine, N-(tert-butyl)-2- cyanoactamide, Z,Z-6,28 Heptatriacontadien-2-one and 3-Hydroxy-1- oxacyclopentacosan-2-one (Vivek *et al.*, 2023). Mukia maderaspatana (Figure 4).

## MATERIALS AND METHODS

**Ligand and Protein Preparation**

The phytochemical data were collected from the Indian Medicinal Plant, Phytochemicals, and Therapeutics (IMPPAT) database, a highly curated database of bioactive compounds isolated from medicinal plants. From the data collected, 38 phytochemicals were detected from various parts (aerial parts, leaves, and seeds) of Mukia maderaspatana. For environmental safety, 21 phytochemicals were chosen considering their lower environmental hazards, leaving out those with possible adverse ecological effects. To carry out a comparative study, five commonly used synthetic pesticides—Bifenthrin, Chlorantraniliprole, Chlorpyrifos, Flubendiamide, and Indoxacarb—were considered. The 3D structures of all the chosen compounds were downloaded from PubChem (https://pubchem.ncbi.nlm.nih.gov/) in Structure Data File (SDF) format and then converted to Protein Data Bank (PDB) format using Open Babel. For molecular docking studies, three important proteins were chosen based on their functions in chemosensory mechanisms, immune defence, and detoxification processes. These were:

***Spodoptera litura* chemosensory protein (PDB ID: 7E8L)** downloaded from the RCSB Protein Data Bank (https://www.rcsb.org/).

***S. litura* immune defence protein (UniProt ID: Q3ZPT5)** downloaded from UniProt (https://www.uniprot.org/).

**Anopheles cracens detoxification protein (PDB ID: 1R5A)** downloaded from the RCSB Protein Data Bank.

**Visualization Tools**

Structure visualization of all protein and ligand molecules was carried out using BIOVIA Discovery Studio Visualizer 4.0 (https://discover.3ds.com/discovery-studio-visualizer- download). The software was utilized to evaluate molecular interactions, examine ligand binding sites, and check the integrity of downloaded structures.

**Molecular Docking**

Molecular docking simulations were performed to test the binding affinities of the chosen ligands for the target proteins. The docking process was performed by AutoDock 4.0, which is incorporated into the PyRx virtual screening tool. The receptor molecules used were:

- Immune defence protein (Q3ZPT5) and chemosensory protein (7E8L) of *S. litura*
- Detoxification protein (1R5A) of A. cracens

The ligands included the 21 chosen phytochemicals of *M. maderaspatana* and the synthetic insecticide Flubendiamide for comparative study. Preparation of ligands included energy minimization with the MMFF94 force field to achieve stable conformations, and then conversion to AutoDock ligand format (PDBQT). During the docking process, all 26 ligands were loaded into the Auto Grid engine together with the receptors. A docking grid was established to cover the whole active site area of the target proteins so that ligand-receptor coverage would be complete. The Lamarckian Genetic Algorithm (LGA) was employed as the search algorithm to investigate binding interactions. Following several docking runs, the ligand-protein complexes were ranked according to their binding energy scores. The highest-scoring complexes, which had the highest binding affinities, were chosen for further study.

**Toxicity Analysis**

To evaluate the possible toxicity of the chosen ligands, an in-silico toxicity prediction was performed. The ADMET properties of all phytochemicals were predicted via the ADMETlab online tool (https://admetmesh.scbdd.com/). Further, the pharmacokinetic attributes such as water solubility, human intestinal absorption, permeability across the blood-brain barrier, and risk of toxicity were predicted through the pkCSM pharmacokinetics tool (http://biosig.unimelb.edu.au/pkcsm/prediction). SMILES notation for the compounds was accessed from PubChem and was used to import to the pkCSM tool for computational prediction. The final toxicity prediction was utilized to screen out the best-performing ligands with good binding affinities and suitable pharmacokinetic characteristics for subsequent study.

## RESULTS

**Molecular docking**

The molecular docking of the three proteins (1R5A,7E8L, Q3ZPT5) with all the 26 ligands which is included of 21 phytochemicals of *M. maderaspatana* and 5 synthetic pesticides was performed. The ligands with the highest binding affinity are noted and listed below:

Molecular docking of protein 1R5A with the ligands (Table 1). Molecular docking of protein Q3ZPT5 with the ligands (Table 2). Molecular docking of protein 7E8L with the ligands (Table 3). The interaction and orientation of the two ligands: Alpha-Spinasterol and Beta- Sitosterol to the target protein, 1R5A of *A. crucens*. 1r5a - Alpha-Spinasterol. 1r5a-Beta-Sitosterol(Figure 5). The interaction and orientation of the ligand: Columbin to the target protein, Q3ZPT5 of *M. maderaspatana* (Figure 6). The interaction and orientation of the ligand: Columbin to the target protein, 7E8L of *S. litura* (Figure 7).

**ADMET results**

The ADMET property analysis was done to check the properties of the compounds that had shown highest binding properties: Alpha- Spinasterol, Beta-Sitosterol, Columbin (The plant compounds) followed by the synthetic pesticide, Flubendiamide. The results provide us with the information of its safety and hazardous activity that could occur in our body giving us a clear view on the use of these compounds as pesticides or pharmacological advances. The ADMET results obtained for the 4 ligands are as follows (Table 4)

## DISCUSSION

In the library of 26 ligands, the ligands Alpha-Spinasterol, Beta-Sitosterol and Flubendiamide had exhibited with the highest binding affinity to the protein, 1R5A of the mosquito, *Anopheles crucens.* The binding energy result of these 3 ligands are as follows: Flubendiamide (-7.5), Beta-Sitosterol (-7.7) and Alpha-Spinasterol (-7,9); Flubendiamide and Columbin were docked with the highest affinity to the chemosensory protein, Q3ZPT5 of *S. litura* with the binding results: Flubendiamide (-8.4) and Columbin (-8.8); and finally, Columbin to the protein, 7E8L of *S. litura:* Columbin (-6.8) as its binding result. From this it was indicated that both the compounds of *M. maderaspatana* and the synthetic pesticides had established a strong binding affinity to the target proteins. The molecular properties of Alpha-Spinasterol, Beta-Sitosterol, Columbin, and Flubendiamide provide crucial insights into their potential as pesticides by influencing their absorption, distribution, metabolism, excretion (ADMET), and toxicity profiles. Molecular weight (MW) plays a key role in determining permeability, with Columbin (370.4 g/mol) having the smallest MW, making it more likely to be absorbed efficiently, while Flubendiamide (682.02 g/mol) has the highest MW, reducing its ability to permeate biological membranes. Topological polar surface area (TPSA) further affects permeability, with lower values enhancing membrane penetration. Alpha- Spinasterol and Beta-Sitosterol (20.23 $Å^2$) exhibit the lowest TPSA, suggesting efficient cellular uptake, whereas Flubendiamide (92.34 $Å^2$) has the highest, indicating reduced permeability. Lipophilicity, measured by LogP, reveals that Alpha-Spinasterol (8.62) and Beta-Sitosterol (8.65) are highly lipophilic, meaning they can easily cross lipid membranes but may face solubility challenges, while Columbin (2.8) is more hydrophilic, favoring solubility but potentially limiting membrane penetration. LogS values further confirm solubility trends, showing Columbin (-4.5) as the most water- soluble, while Alpha-Spinasterol (-8.12) and Beta- Sitosterol (-8.15) are the least, potentially affecting bioavailability. Lipinski's Rule of Five determines drug-likeness, and all four compounds meet the criteria, indicating the potential for oral bioavailability. However, intestinal absorption varies, with Columbin (-4.8) showing the best permeability, while Flubendiamide (-5.23) has the lowest, suggesting limited uptake. Human intestinal absorption (HIA) supports these findings, with Columbin (0.91) being the most efficiently absorbed, followed by Alpha-Spinasterol (0.78) and Beta-Sitosterol (0.82), while Flubendiamide (0.004) demonstrates very poor absorption. The ability to cross the blood-brain barrier (BBB) is important for assessing potential neurotoxicity, with Columbin (0.42) having the highest penetration, meaning possible central nervous system (CNS) effects, whereas Flubendiamide (0.041) has minimal BBB penetration, lowering the risk of neurological toxicity. Plasma protein binding (PPB) affects how long a compound remains in circulation, with Flubendiamide (98.36%) showing the highest binding, limiting its free drug concentration, followed closely by Beta-Sitosterol (97.1%) and Alpha-Spinasterol (96.4%), while Columbin (95.6%) has slightly lower binding, increasing its availability in the bloodstream. The volume of distribution (VD) suggests all four compounds distribute well in body tissues, ranging between 0.7 and 0.8. Regarding metabolism, CYP enzyme inhibition is crucial for predicting drug interactions. Alpha-Spinasterol, Beta-Sitosterol, and Flubendiamide inhibit CYP3A4, potentially affecting drug metabolism, while Columbin inhibits CYP2C19, influencing the metabolism of other drugs. Clearance rates influence how long a compound remains active in the body, with Columbin (4.0 mL/min/kg) clearing the fastest, leading to a shorter duration of action, while Alpha-Spinasterol (2.1 mL/min/kg), Beta-Sitosterol (2.3 mL/min/kg), and Flubendiamide (2.46 mL/min/kg) have moderate clearance, suggesting longer persistence in the body. Toxicity analysis, including hERG inhibition, hepatotoxicity, and drug-induced liver injury (DILI), indicates that Alpha-Spinasterol and Beta-Sitosterol have low toxicity, making them safer candidates. In contrast, Columbin presents moderate toxicity risks, while Flubendiamide has high toxicity, raising concerns regarding adverse effects. In conclusion, Alpha-Spinasterol and Beta- Sitosterol demonstrate strong binding affinity, good absorption, and low

toxicity, positioning them as promising natural pesticide candidates. Columbin exhibits high permeability and moderate toxicity, making it a viable but somewhat riskier option. Flubendiamide, while effective, has poor absorption and significant toxicity, which may pose environmental and health concerns. These findings suggest that natural compounds like Alpha-Spinasterol and Beta-Sitosterol could serve as safer and more effective alternatives to synthetic pesticides.

## CONCLUSION

The ancient practices in controlling pests, mosquitoes and other insects had always taken in consideration of our environment. The man without the five elements cannot survive on the earth for many years. The diminishing sources around us are proven evidence of the end times. All the man-made products created for the benefits of man had taken a reverse card, acting against men. One such product are the synthetic pesticides. The alteration of the organic compounds, which are foreign to our environment makes both the flora and fauna to flounder, in turn they scar human race. Hence the act of bringing back the traditional practices of insect control such as the use *M. maderaspatana*, by proving their effectiveness and application in scientific approach will surely help us to recover our Mother Nature.

## ABSTRACT

Corpus callosum is the largest and most important commissural white matter tract connecting the two cerebral hemispheres. MRI helps in assessment of variation in its size and shape with respect to age and gender and possible implications on treatment planning. Hence, this study was conducted to identify the role of MRI in measurement of Corpus Callosum according to gender. It also aims to evaluate Corpus callosum size on the basis of different age group gender. This Prospective observational study was conducted among 50 participants. Age of the cases ranged from 2 to 77 years with mean 41.3 $\pm$ 19.5 years. The majority (36%) of the participants were in the age group 20 to 40 years followed by 40 to 60 years (32%), 60 to 80 (22%), and below 20 (10%) years. There was a difference ($p < 0.05$) in Vertical length: SPLENIUM (Mm) between males and females. Also, a difference in AP Length was observed between the age groups: below 20 and 20 to 40 years; below 20 and 40 to 60 years; and below 20 and 60 to 80 years. There was a positive correlation ($p < 0.05$) between Vertical length: GENU and BODY; GENU and SPLENIUM; BODY and SPLENIUM. This study showed that there was a difference in Vertical length: SPLENIUM (Mm) between males and females. Also, a difference in AP Length (Mm) was found according to age groups (below 20 and 20 to 40 years; below 20 and 40 to 60 years; and below 20 and 60 to 80 years). In this study, there was a positive correlation between Vertical length: GENU and BODY; GENU and SPLENIUM; BODY and SPLENIUM.

**Keywords:** Corpus callosum, Adult patients, Nervous systemdiseases**.**

## INTRODUCTION

MRI (Magnetic Resonance Imaging) is made with radio- frequency pulse in the range of 1-80 MHz NMR (Nuclear Magnetic Resonance) MRI and spectroscopy are the terms used alternatively. NMR is the spectroscopic study of magnetic properties of the nucleus of the atom. In 1946, Felix Bloch at Stanford and Edward Purcell at Harvard independently described NMR in a solid. They shared the 1952 Noble Prize in Physics for this work. Bloch continued extensive studies with NMR of water there by laying the groundwork for later developments leading to MRI Bloch therefore, is to MRI what Roentgen is to X-ray imaging. Bloch proposed that nucleus behaves like a small magnet. He described this nuclear magnetism by what is known as Bloch equation. NMR is not an imaging technique but rather a method to provide spectroscopic data concerning a sample placed in device. In the early 1970s, Dramadian first showed that malignant tissue has a different NMR spectrum from that of normal tissue. He accomplished his first body image in 1976 using magnetic field gradient to localize NMR signal and the image took almost 4 hours to produce. At this time Paul Lauterber was engaged in similar research. Clinical imaging application of MRI increased in the mid-1980s.[1]. Magnetic resonance imaging (MRI) is a medical imaging technique used in radiology to form pictures of the anatomy and the physiological processes of the body. MRI scanners use strong magnetic fields, magnetic field gradients, and radio waves to generate images of the organs in the body. MRI does not involve X-rays or the use of ionizing radiation, which distinguishes it from CT and PET scans. MRI is a medical application of nuclear magnetic resonance (NMR) which can also be used for imaging in other NMR applications, such as NMR spectroscopy. In 1977 the first MRI exam was performed on a human being. It took 5 hours produce one image.

## AIMS AND OBJECTIVES

1. To identify the role of MRI in measurement of Corpus Callosum according to gender.
2. To evaluate Corpus callosum size on the basis of different age group gender.

## MATERIALS AND METHODS

This Prospective observational study was conducted in the MRI unit of Department of Radiology, Subharti Medical College Hospital, Swami Vivekanand Subharti University, Meerut UP. Participants were referred from the Department of Radio-diagnosis imaging for MRI brain for Measurement of Corpus Callosum from OPD/IPD of C.S.S Hospital. N.S.C.B. Subharti Medical College, Meerut U.P. MRI GE HDE 1.5 TESLA Machine department of Radio-diagnosis and imaging, were used in this study. The inclusion criteria were the patient with clinically suspected nervous system diseases irrespective of age group and gender. First trimester pregnancy, operated case, with suspected metallicim plant and Uncooperative patient were excluded from the study. After obtaining clinical history relevant clinical examination was done for each patient. They were subjected to modality, after an informed consent for confirmation of diagnosis. MRI examination was done on GEHDE 1.5 Tesla.

Brain aneurysm, Brain hemorrhage, Brain infections (encephalitis), Brain damage associated with epilepsy and Brain tumors and cysts were the indications. Before patient preparation, the complete history was checked for each patient. If indication was unclear, the referring physician was contacted. All metallic objects were removed from patients to ensure that artifacts were not created during scanning. Disposable ear plugs were provided to the patient to avoid the patients from repeated noises during canning. The patients were instructed to avoid coughing, wriggling or producing other large motion during or in between the scan. Each case was ensured the IV line prior to the pre contrast acquisition preferably with 20 or 22 gauge IV Cannula. Patient positioning includes Supine with head placed within the coil, Arms beside the trunk, Inter papillary line parallel to the couch and the head should be straight, longitudinal alignment line in the midline, Horizontal alignment line through the nasio and straps and foam pads for immobilization. The equipment used were Head Coils, BIRD CAGE COIL, Immobilisation pads and straps, Ear plugs, High performance gradients for EPI (Eco planer Imaging), diffusion and perfusion imaging.

**Statistical analysis**

The collected data were summarized by using the Descriptive Statistics: frequency, percentage, mean and S.D. The Independent sample "t" test was used to compare age according to gender. There was no difference ($p > 0.05$) in mean age, AP Length (Mm) and Vertical length (Mm) between males and females. The One way ANOVA test was used to compare AP Length (Mm) and Vertical length (Mm) according to age groups. For the multiple comparison of AP Length (Mm) according to age groups, the Post hoc analysis Tukey test was used. The Pearson correlation coefficient was used to find the relation between AP Length (Mm) and Vertical length (Mm). The p value $< 0.05$ was considered as significant. Data were analyzed by using the SPSS software (SPSS Inc.; Chicago, IL) version 26.0.

## RESULTS

This study was conducted among 240 participants. Age of the cases ranged from 2 to 84 years with mean 40.3±20.25 years. There was no discrimination according to the gender of the patient in the study. A total of 240 patients were included in this study in which 137 (57.9%) patients were male and 103(42.1%) patients were female. The distribution of the patient on the basis of the gender is as follow.

The table shows that the highest number of patients in the present study were found from the age group of 20-40 Years, i.e. 77(32.1 % ) of the total number of the patients. Similarly, it is observed that the lowest number of patients were from the age group of Above 80 years i.e. 5 (2.1%). The majority (29.9%) were in the age group 40 to 60 years followed by 20 to 40 years (26.3%), 60 to 80 (32%), and below 20 years(18.2%). Among females, the majority (39.8%) were in the age group 20 to 40 years followed by 40 to 60 years (25.2%), 60 to 80 (17.5%), and below 20years (15.5%). In this present study, the patients have been category on the basis of referral by the department. Highest number of patients were referred from Medicine 59 (24.6%) patients and least number of patients from MMW (2%) of al number of patients. The table given below shows the number of patients whose findings were collected on the basis of referring departments. This study was conducted among 240 participants. Age of the cases ranged from Minimum age 2 years maximum age 84 years with Mean 40.3 ± 20.25 years .

In the present study, comparison of age according to gender and age group in this table was Chi-square 0.05 p- value 0.282. The Chi-square was used to compare observed results with expected result . There was no difference ($p > 0.05$) in mean age between males and females. In the present study, comparison of age according to gender in this table was male mean 41.3 ± 20.7also Female mean 39.3±19.8. t- value 0.75 p- value 0.453 Df-238 . The Independent sample "t" test was used to compare age according to gender. There was no difference ($p > 0.05$) in mean age between males and females.

The AP Length ranged from 41 to 81 with mean 70.0 ± 6.5 mm and Vertical length: GENU - ranged from 5 to 16 with mean 10.7 ± 1.9 mm, BODY ranged from 3 to 9 with mean 5.3 ± 1.0 mm, and SPLENIUM ranged from 4 to 17 with mean 10.0 ± 2.0 mm. The Independent sample "t" test was used to compare AP Length (mm) and Vertical length (mm) between males and females. There was a difference ($p < 0.05$) in AP length (mm) between males and females. In the present study, Descriptive statistics for AP Length (mm) and Vertical length (mm). The AP Length ranged from Above - 20 with mean 66.4 ± 9.2 mm and 20 – 40 with mean 69.7± 6.2mm , 40 – 60 with mean71.4 ± 4.7 mm, 60-80 with mean 71.4 ± 5.4mm , below-80 with mean 71.8± 2.2mm , Vertical length: GENU - Above - 20 with mean 9.8 ± 2.3mm , 20 – 40 with mean 10.7± 1.8 mm, 40 – 60 with mean 11.3 ±1.8mm , 60-80 with mean 10.5 ± 1.6mm , below-80 with mean 11.0± 1.6 mm, BODY ranged Above - 20 with mean 5.1 ± 1.1 mm, 20 – 40 with mean 5.3 ± 1.2mm, 40 – 60 with mean5.3±1.2mm, 60 – 80 with mean 5.4± 0.9mm, below – 80 with mean 5.5 ± 1.1 mm and SPLENIUM ranged from Above -20 with mean 9.4 ± 2.6mm , 20 – 40 with mean 9.9 ± 1.9mm , 40 – 60 with mean 10.6 ± 2.0mm , 60-80 with mean 9.8 + 11.2 mm, below-80 with mean 11.2 ± 2.3mm.

The One way ANOVA test was used to compare AP Length (mm) and Vertical length (mm)..There wasadifference ($p < 0.05$) in APLength (mm) and ($p < 0.05$) in genu (mm) , ($p < 0.05$) splenium (mm). The Post hoc analysis Tukey test was used for the multiple comparisons of AP Length (mm) and vertical length (mm) according to age groups. There was a difference ($p < 0.05$) in AP Length between the age groups: below 20 and 40 to 60 years; 60 to 80 years vertical length (genu ) 40 to 60 splenium 40 to 60. The Pearson correlation coefficient was used to find the relation between AP Length (Mm) and Vertical length (Mm). There was a positive correlation ($p < 0.05$) between Vertical length: GENU and BODY.

## DISCUSSION

The prospective observational study was conducted by using the MRI GE HDE 1.5 TESLA Machine among 240 patients in the Department of Radio-diagnosis and imaging, referred from Emergency ER, OPD, HICU, MEDICINE,MICU , MMW, NEUROLOGY, ONCOLOGY, PICU, PRIVATE WARD, SURGERY and ORTHO of Chhatrapati Shivaji Subharti Hospital, Swami Vivekanand Subharti University, Meerut, Uttar Pradesh. The measurement of AP Length and Vertical Length (genu, body, spelinium) were obtained. In this study the majority, were males 137 (41.3%) and female were 103(39.3%). Age of the cases ranged from 2 years to 84 with mean 40.3±20.25 years. It was observed that, that the Male are 137 with the mean 41.3±20.7and Female 103 with Mean 39..3±19.8 t-value 0.75 p-value 0.453 df 238. Descriptive statistics for AP Length ranged from 41 to 81 with mean 70.0 + 6.5. and Vertical length: GENU ranged from 5 to 16 with mean 10.7±1.9, BODY ranged from 3 to 9 with mean 5.3 + 1.0, SPELIMIUM ranged from 4 to 17with mean 10.0 ± 2.0.

Comparison of AP Length and Vertical Length according to gender , AP Length of male 70.9±6.4 female 68.9±6.4, t – value 2.33 ,df 238 , p-value 0.021*there was a difference (<0.05) between male and female. In Vertical Length : GENU of male 10.8±1.9, female 10.5±2.0, t – value 1.35, df 238 , p-value 0.178, BODY of male 5.4+ 1.0 , female 5.3 +1.0 t value 0.97 , df 238 , p-value 0.034,SPELINIUM of male 10.2±2.0 , female 9.8±2.0t -value 1.59 , df 238 p-value 0.114.
Descriptive statistics of AP Length and Vertical Length according to age group TheAP Length ranged from Above - 20 with mean 66.4±9.2mm and 20 – 40 with mean 69.7± 6.2mm, 40 – 60 with mean71.4 ± 4.7 mm, 60-80 with mean 71.4 ± 5.4mm , below-80 with mean 71.8± 2.2mm , Vertical length: GENU -Above - 20 with mean 9.8± 2.3mm ,20 – 40 with mean 10.7± 1.8 mm,40 – 60 with mean 11.3 ±1.8mm , 60-80 with mean 10.5 ± 1.6mm , below-80 with mean 11.0± 1.6 mm, BODY rangedAbove - 20 with mean 5.1± 1.1 mm,20 – 40 with mean 5.3 ± 1.2mm, 40 – 60 with mean5.3±1.2mm,60 – 80 with mean 5.4± 0.9mm, below – 80 with mean 5.5 ± 1.1 mm and SPLENIUM ranged from Above -20 with mean 9.4 ± 2.6mm , 20 – 40 with mean 9.9 ± 1.9mm , 40 – 60 with mean 10.6 ± 2.0mm , 60-80 with mean 9.8 + 11.2 mm, below-80 with mean 11.2 ± 2.3mm.

One way ANOVA was used for Comparison of AP Length and Vertical Length in AP Length "F" 5.06Df1 4 , Df2 23, 5 p-value 0.001* ,In Vertical Length genu : "F" 4.26, Df1 4, Df2 235, p-value 0.002*Body : "F" 0.70, Df1 4, Df2 234, p-value 0.593 . splenium : "F" 3.21 , Df1 4 , Df2 235, p-value 0.014*There was difference ($p < 0.05$) in AP Length (mm) and ($p < 0.05$) in genu (mm) , ($p < 0.05$) splenium (mm)..The post hoc analysis turkey test was used for the Multiple comparison of AP Length and Vertical Length according to Age group see (table no. 14) There was a difference ($p < 0.05$) in AP Length between the age groups: below 20 and 40 to 60 years; 60 to 80 years vertical length (genu ) 40 to 60 splenium 40 to 60. There was a positive correlation ($p < 0.05$) between Vertical length: GENU and BODY.

## CONCLUSION

This study showed that there was a difference in Vertical length: SPLENIUM (Mm) between males and females. Also, a difference in AP Length (Mm) was found according to age groups (below 20 and 20 to 40 years; below 20 and 40 to 60 years; and below 20 and 60 to 80 years). In this study, there was a positive correlation between Vertical length:

GENU and BODY; the project work showed variation in the AP LENGTH and VERTICAL LENGTH of corpus callosum.

## ABSTRACT

Chronic kidney disease (CKD) is a growing global health concern, particularly in low-resource settings where early detection and management remain inadequate. Nutritional education programs (NEPs) and targeted dietary interventions play a pivotal role in mitigating CKD progression by optimizing nutrient intake and improving metabolic outcomes. This review examines the impact of NEPs and low-protein adequate energy (LPAE) diets on CKD management, emphasizing their role in improving nutritional status, reducing hospitalizations, and enhancing patient well-being. A comprehensive literature search was conducted using PubMed, Medline, ScienceDirect, and Google Scholar to identify relevant studies from 2019 to 2024. Ten peer reviewed articles were selected based on their relevance to the effects of nutritional education and dietary interventions on CKD patients. Studies encompassing observational, longitudinal, and prospective research designs were included to assess the efficacy of NEPs and dietary strategies. Studies demonstrated that NEPs significantly improved albumin levels, metabolic profiles, and hospitalization rates in CKD patients, with a 13.7% hospitalization rate in the NEP group compared to

26.7% in controls. The LPAE diet was effective in enhancing body composition, insulin sensitivity, and reducing malnutrition risk among elderly CKD patients. However, adherence challenges, gender disparities, and accessibility issues in rural areas remain significant barriers to implementation. Nutritional interventions, particularly NEPs and LPAE diets, play a crucial role in CKD management. Personalized dietary strategies should be integrated into routine CKD care to improve health outcomes and quality of life, with a focus on enhancing accessibility and adherence in rural populations.

**Keywords:** Chronic kidney disease, nutritional education programs, dietary interventions, low-protein diet, metabolic outcomes, patient adherence, rural healthcare.

## INTRODUCTION

Chronic kidney disease (CKD) is a significant global health issue with high mortality rates, as highlighted by the Global Burden of Disease study 2019 [1]. Despite its widespread prevalence, many developing nations lack the necessary infrastructure for early CKD detection and management programs, leading to delayed interventions and higher morbidity. Grassroots initiatives that focus on early detection, public education, and timely medical interventions are essential to prevent progression to end-stage renal disease (ESRD). The importance of understanding CKD lies in its profound impact on global health, necessitating comprehensive strategies encompassing public awareness, professional education, policy reform, and ongoing research to improve patient outcomes [2]. Effective dietary management tailored to the patient's condition can play a pivotal role in mitigating these complications. [3]. Continuous monitoring through intervention will have a beneficial effect on the nutrient consumption and overall nutritional well-being of CKD patients in these areas [4]. This review examines the impact of nutritional education programs (NEPs) and dietary interventions on CKD management. By exploring these approaches, we aim to highlight their potential in enhancing nutrient intake, improving metabolic outcomes, and overall patient well-being.

**Chronic Kidney Disease: Definition and Prevalence**

The National Kidney Foundation (NKF) defines CKD as alterations in kidney structure or function, characterized by an eGFR below 60 mL/min/1.73 $m^2$ lasting for at least three months. CKD often leads to renal replacement therapies, including dialysis or transplantation, resulting in a poor lifestyle [5]. The Kidney Disease Improving Global Outcomes (KDIGO) classification divides CKD into six stages of progression based on glomerular filtration rate (GFR). [5] CKD affects nearly 10% of the global population, with low awareness rates in low income countries despite its increasing prevalence. The Global Kidney Health Atlas reports a median global CKD prevalence of 9.5%, with regional variations [6]. In India, the prevalence is even higher, with reports indicating a 17.2% prevalence rate. Alarming statistics from Chennai, Tamil Nadu, reveal that one in five individuals suffers from kidney dysfunction, underscoring the urgent need for effective management strategies [2].

**Nutritional Education and Management**

Nutritional education is fundamental for empowering patients to make informed dietary choices and improving self-management. By raising awareness of their lifestyle choices and their impact on health, individuals can be motivated to change their behaviours, as knowledge is fundamental to initiating change. By fostering awareness, nutritional counseling can promote behaviour change, reduce healthcare visits, and enhance overall quality of life. Therefore, it is vital to evaluate the outcomes of nutritional programs to determine the effectiveness of educational efforts [4]. The primary objectives of nutritional therapy for individuals with chronic kidney disease (CKD) include: (1) preserving a normal body mass and composition, (2) reducing comorbidities linked to CKD, (3) decelerating the progression of CKD, and (4) attaining favorable long-term results concerning mortality and morbidity [7]. Nutritional management is essential for preserving body composition, reducing comorbidities, and decelerating CKD progression [7]. Ensuring sufficient energy intake is crucial to preventing malnutrition in individuals with CKD [8]. Protein intake

should be maintained at 0.6–0.8 g/kg/day to reduce kidney strain [8]. Sodium intake under 2 g per day helps control blood pressure and fluid retention [8]. Proper potassium balance prevents hyperkalemia, while limiting phosphorus lowers vascular calcification risk [8]. Adequate calcium and vitamin D support bone health [9]. Effective dietary and lifestyle adjustments can improve overall health and well-being in CKD patients [4].

## METHODOLOGY

Databases such as PubMed, Medline, ScienceDirect, and Google Scholar was used to identify review articles encompassing observational studies, longitudinal study and prospective study that examine the effects of nutrition education program on dietary status and nutrient intake in CKD patients. The articles were assessed for inclusion based on their pertinence to the topic. In total, 10 articles were reviewed from the year 2019 to 2024 to write this review paper.

## RESULT

A study conducted by Pérez-Torres *et al*. (2021) assessed the impact of a Nutritional Education Program (NEP) on patients with advanced chronic kidney disease (CKD). The study included 169 participants (average age of 66.1 years), with comorbid conditions such as congestive heart failure (30.8%) and peripheral arterial disease (23.1%). Diabetes mellitus was identified as the primary cause of CKD in 42% of the cases. After a six-month period, 128 patients engaged in the NEP, with 25% requiring additional support through oral nutritional supplements (ONS). Initially, the NEP+ONS group exhibited lower prealbumin levels and body weight, reflecting a suboptimal nutritional status. Nevertheless, throughout the program, the NEP group demonstrated enhancements in serum potassium, phosphorus, and lipid profiles, while those utilizing ONS saw increases in body mass index (BMI) and fat mass. Conversely, the NEP group achieved notable improvements in muscle mass and reductions in total body water, indicating more favorable body composition results. After a two-year period, the NEP group showed elevated albumin levels and normalized protein catabolic rates, signifying an enhanced nutritional status. Furthermore, the hospitalization rate for the NEP group was notably lower at 13.7%, in contrast to 26.7% for the control group. However, despite these favorable outcomes, the mortality rate remained substantial, with 12.4% of participants succumbing, primarily due to infections and cardiovascular complications. Factors such as older age, female gender, and non-participation in the NEP were linked to increased mortality, highlighting the critical need for patient engagement in nutritional programs to improve survival rates [10]. Another research conducted by Cacciapuoti *et al*. (2024), the effects of a low-protein adequate energy (LPAE) diet on elderly patients with chronic kidney disease (CKD) stages 3 to 5 were analyzed. The research included 42 participants aged 65 and above, who adhered to the Kidney Disease Improving Global Outcomes (KDIGO) recommendations regarding protein and energy consumption. Participants were categorized as either compliant or non-compliant based on their adherence to the LPAE diet. The findings revealed that 45.2% of the participants followed the diet, and those who complied demonstrated enhancements in body composition, such as increases in fat-free mass and skeletal muscle mass, alongside decreases in fat mass and waist circumference. Conversely, non-compliant participants experienced an 8.7% increase in their Geriatric Nutritional Risk Index (GNRI) scores, suggesting a heightened risk of malnutrition. The research further indicated positive metabolic alterations within the compliant group, such as improved serum phosphorus and urea concentrations, along with increased insulin sensitivity, as evidenced by an improved triglyceride-to-HDL cholesterol (TG/HDL) ratio. These results imply that following a low-protein, energy-dense (LPAE) diet not only enhances nutritional health but also aids in the regulation of vital metabolic functions necessary for the management of chronic kidney disease (CKD). Both studies emphasize the importance of tailored nutritional interventions in CKD care. Pérez-Torres *et al*. demonstrated the benefits of NEPs in reducing hospitalizations and improving albumin levels, while Cacciapuoti *et al*. showcased the efficacy of LPAE diets in improving body composition and metabolic health. These results underscore the need for personalized nutritional strategies to slow CKD progression and enhance patient quality of life [11].

## DISCUSSION

**Impact of Nutritional Interventions**

The reviewed studies affirm that structured nutritional interventions, such as NEPs and LPAE diets, can significantly improve clinical and metabolic outcomes for CKD patients. Pérez-Torres *et al*. highlighted reductions in hospitalization rates and enhanced albumin levels, while Cacciapuoti *et al*. demonstrated improvements in body composition and insulin sensitivity. Collectively, these findings underscore the transformative potential of nutrition-focused strategies in CKD management [10][11].

**Addressing Gender Disparities**

Notably, Pérez-Torres *et al*. observed greater improvements among male participants compared to females. This disparity may stem from biological differences in protein metabolism or sociocultural factors influencing dietary adherence. Further research should explore these dynamics to ensure gender-responsive nutritional interventions [10].

**Challenges in Rural Settings**

Both studies predominantly focused on urban populations, neglecting the unique barriers faced by rural communities, such as limited access to nutrient-dense foods and healthcare resources. Developing culturally sensitive, rural-specific NEPs that leverage community-based programs or mobile health technologies could bridge this gap and enhance CKD management in underserved areas [10][11].

**Adherence and Elderly Populations**

Dietary adherence remains a critical challenge, especially among elderly patients with cognitive and functional limitations. Strategies to improve adherence could include simplified dietary guidelines, caregiver involvement, and peer support networks[10][11].

## LIMITATIONS AND FUTURE DIRECTIONS

While the reviewed interventions yield promising results, they have limitations

**Sample Diversity:** Studies predominantly analyzed urban demographics, limiting generalizability to rural or economically disadvantaged populations.

**Duration:** Longer follow-up studies are needed to evaluate the sustained impact of interventions on CKD progression.

**Gender-Specific Research:** Future studies should investigate biological and behavioral factors contributing to gender disparities in CKD outcomes.

**Practical Implications**

These findings emphasize the need to integrate personalized nutritional interventions into standard CKD care. NEPs can reduce hospitalizations and improve nutritional markers, while LPAE diets support metabolic health and body composition. Scaling these interventions to address rural and elderly populations is essential for equitable healthcare delivery.

## CONCLUSION

Chronic kidney disease (CKD) poses a significant global health challenge, contributing to substantial cardiovascular morbidity and mortality. Early detection and tailored interventions are critical for improving patient outcomes. This

review highlights the pivotal role of nutritional education programs (NEPs) in enhancing dietary habits, improving nutritional status, and reducing hospitalization rates among CKD patients.

## ABSTRACT

**Background:** Intracellular anti-tuberculosis assays are critical since *Mycobacterium tuberculosis* is an intracellular pathogen that lives in host macrophages. This study investigates the intracellular anti-tuberculosis activity of copper nanoconjugates synthesized from *Piper longum* and Piperine against the *Mycobacterium tuberculosis* strain H37Rv.

**Results:** The nanoconjugates exhibited superior efficacy, achieving 98% inhibition at 31.25 µg/ml compared to Piperine's 95% inhibition at 62.5 µg/ml. Moreover, a synergistic effect was observed with Rifampicin, suggesting potential for combination therapy at low concentrations.

**Conclusion:** These results highlight the promise of copper nanoconjugates as a drug candidate for enhancing drug delivery and efficacy against drug-resistant tuberculosis strains.

**Keywords:** Intracellular Assay, Anti-Tuberculosis, Copper Nanoconjugate, Piperine

# INTRODUCTION

**Background**

Intracellular anti-tuberculosis assays are critical since *Mycobacterium tuberculosis* is an intracellular pathogen that lives in host macrophages (Mahamed *et al*., 2017). Traditional *in vitro* tests with extracellular bacteria may not correctly reflect the conditions under which they persist and replicate within host cells (Shi *et al*., 2019). Intracellular assays provide a more physiologically relevant model by simulating the intracellular environment allowing researchers to assess drug efficacy under settings similar to human infections (Santucci *et al*., 2021). THP-1 cells are widely used for studying the monocyte and macrophage functions such as intracellular activity and drug transport (Prajitha & Mohanan, 2021). These experiments help establish how successfully anti-tuberculosis drugs enter host cells, bypass bacterial resistance mechanisms and promote bactericidal activity (Sachan *et al*., 2023).

# METHODS

**Intracellular anti-tuberculosis assay**

Copper nanoconjugates were synthesized by taking 60% of plant extract of *Piper longum* (Long pepper) and adding 40% of 0.1 M $CuSO_4$ to it followed by the addition of 10 ml of chitosan solution that was prepared by taking 0.02 g of chitosan in 2 ml of 5% acetic acid. Piperine was isolated and purified from long pepper by graded precipitation method. The THP-1 cells were maintained at 37ºC in 5% $CO_2$ incubator. The RPMI-1640 medium was supplemented with 1 mM Sodium pyruvate, 2 mM Glutamine, 4.5 g per litre Glucose, 10 mM HEPES buffer, 2 gm per litre Sodium bicarbonate and 1% streptomycin solution. The 24-well plate was seeded with 1 ml of the cell suspension at a density of 5x $10^5$ cells/well. After the 24 hours period, the cells were exposed to 100 nM of PMA to stimulate their differentiation into macrophage monolayers for 48 hrs incubation at 37 °C in with 5% $CO_2$ atmosphere (Bhatter *et al*., 2016).

After 24 hours, RPMI medium was removed and rinsed twice with PBS. The macrophage monolayers were infected with *Mycobacterium tuberculosis* H37Rv strain at a Multiplicity of Infection (MOI) of 10 and incubated for 3 hours at 37 °C in a $CO_2$ incubator. 200 µg/ml Amikacin was added to remove the extracellular bacteria and incubated for 1 hour at 37 °C in a $CO_2$ incubator. The active concentration (the MIC) of the copper nanoconjugate from Long pepper against *Mycobacterium tuberculosis* strain H37Rv was 31.25 µg/ml and the MIC of Piperine was 62.5 µg/ml. This was added in two different well plates along with complete RPMI-1640 without antibiotics. The plates were incubated for 72 hours at 37 °C in a $CO_2$ incubator. Rifampicin was used as the drug control and the untreated *Mycobacterium tuberculosis* infected cells were used as a negative control. After the 72 hours incubation, the RPMI-1640 was removed and intracellular bacteria were released by lysis with 0.5% SDS (Bhatter *et al*., 2016).

1 ml of Middlebrook Oleic Albumin Dextrose Catalase (OADC) growth supplement was added and gently mixed. 100 µl of lysate was spread into the OADC supplemented Middlebrook 7H11 agar plates and incubated for 14 days at 37°C in a 5% $CO_2$. After 14 days, Colony Forming Unit (CFU) enumeration was done by the following formula (Bhatter *et al*., 2016).

$$\% \text{ inhibition} = \frac{Growth\ under\ control\ conditions - Growth\ under\ experimental\ conditions}{Growth\ under\ control\ conditions} \times 100$$

**Characterization by Transmission Electron Microscopy Selected Area Electron Diffraction Energy Dispersive X-Ray Spectroscopy**

The CuNC was characterized by Transmission Electron Microscopy Selected Area Electron Diffraction Energy Dispersive X-Ray Spectroscopy (TEM SAED EDX) to identify the internal structure of the nanoconjugate and find out how the herbal components present diffuse out. The model used for TEM was FEG-TEM, Tecnai G2, F30 with 58 X to 1 million X magnification and accelerating potential 300 kV. The EDX model used was EDAX Octane ELITE T70 with

liquid nitrogen free Peltier cooled high-resolution, high-speed silicon drift detector and SAED was model 965 GIF Quantum. The sample was dispersed in ethanol and injected.

## RESULTS

**Intracellular anti-tuberculosis assay**

The copper nanoconjugate and Piperine exhibited potent anti-tuberculosis activity in the macrophages that were infected by the *Mycobacterium tuberculosis* strain H37Rv. The characteristic bactericidal activity was assessed by determining the CFU reduction after the nanodrug was administered. The resultof intracellular CFU count was shown in the Table 1. It **was** observed that the control plate showed 500 colonies and Rifampicin showed no colonies. The plate with the CuNC from Long pepper showed 10 colonies and the plate with Piperine showed 22 colonies.
The % inhibition was found to be 98% at 31.25 µg/ml concentration and 95 % at 62.5 µg/ml concentration indicating better intracellular activity by the CuNC. The calculations were done as follows:

**Intracellular activity of the CuNC**

$$\frac{500 - 10}{500}$$

$$\frac{490}{500} = 0.98$$

$$\% = 0.98 \times 100$$

$$= 98\%$$

**Intracellular activity of Piperine**

$$\frac{500 - 22}{500}$$

$$\frac{478}{500} = 0.95$$

$$\% = 0.95 \times 100$$

$$= 95\%$$

**Characterization by Transmission Electron Microscopy Selected Area Electron Diffraction Energy Dispersive X-Ray Spectroscopy**

The size and morphology of the biosynthesized CuNC were explicated with the help of TEM. The nanoparticles exhibited spherical morphology with size varying from 20-50 nm (Fig 1 a and b).The polycrystalline nature of the nanoconjugate was clearly indicated by the Selected Area Electron Diffraction which showed bright concentric rings like pattern indicating that the bioactive compounds were present around the periphery of the nanoconjugate enabling easy diffusion (Fig 1 c).

Energy-dispersive X-ray (EDX) spectroscopy indicated that the major elements present belonged to Cu, C and O further highlighting the purity of the CuNC (Fig 2).

## DISCUSSION

The intracellular anti-tuberculosis assay is a method where the macrophages infected with *Mycobacterium tuberculosis* strain H37Rv, assesthe efficacy of the test compounds within host cells. Macrophages are commonly generated from human cell lines such as THP-1(Schaaf *et al*., 2016). After enabling bacterial absorption and intracellular replication, the test substances are administered to determine their intracellular effect. Following incubation, macrophages are lysed and the released bacteria are plated onto 7H11 agar, a medium optimised for*M. tuberculosis* growth, to determine colony-forming units (CFUs) as a measure of bacterial survival (Maier *et al*., 2024).

This assay is based on the ability of mycobacteria to live and reproduce within macrophages where it avoids immunological responses by blocking phagosome-lysosome fusion (Sachdeva *et al*., 2020). The test substance enters the host cells and causes bactericidal or bacteriostatic effects inside the intracellular environment(Zhang *et al*., 2023). Given that external bacteria are eliminated before drug treatment, the assay only analyses intracellular activity, making it more physiologically relevant when compared to typical broth-based susceptibility assays(Santucci *et al*., 2021). The use of 7H11 agar, which contains casein hydrolysate and oleic acid, promotes slow growth of *M. tuberculosis* while limiting contamination hazards, resulting in accurate CFU enumeration(Rupasinghe *et al*., 2022).
The assay mechanism comprises of several steps such asmacrophage infection in which *M. tuberculosis* is phagocytosed and allowed to replicate followed by drug treatment where the test compounds are added to assess intracellular activity (Horváti *et al*., 2021). Cell lysis in which macrophages are disrupted to release surviving bacteria and finally CFU quantification in which lysates are plated on 7H11 agar to determine bacterial load(Estrella *et al*., 2011). A decrease in the colonies when compared to the untreated controls suggests intracellular antimycobacterial action. This model is critical for assessing macrophage-mediated drug responses in the treatment of tuberculosis (Santucci *et al*., 2021).

Copper nanoconjugates target intracellular *Mycobacterium tuberculosis* within infected macrophages through multiple mechanisms, including reactive oxygen species (ROS) generation, metal ion toxicity, disruption of bacterial homeostasis and immune modulation(Song *et al*., 2024). Once internalized by macrophages, these nanoparticles release $Cu^{2+}$ ions, which generate oxidative stress via Fenton-like reactions, leading to bacterial damage. Additionally, copper interferes with bacterial metal homeostasis, disrupting essential processes such as respiration and enzyme function(Letelier *et al*., 2005). Functionalization of copper nanoparticles with biopolymers such as chitosan enhances their bioavailability and selective toxicity against *M. tuberculosis* while minimizing harm to host cells(Biswas *et al*., 2025).Copper nanoparticles functionalised with biopolymers like chitosan increase their bioavailability and selective toxicity against *M. tuberculosis* while causing minimal harm to host cells(Biswas *et al*., 2025).

Upon phagocytosis, macrophages ingest both *M. tuberculosis* and the copper nanoconjugates. Copper nanoconjugates can bypass bacterial mechanisms of defence, including efflux pumps and metal sequestration systems, by releasing $Cu^{2+}$ inside infected cells. The bacterial proteins, membranes and DNA are all impacted by the released $Cu^{2+}$ ions, which causes oxidative damage, membrane instabilityand inhibition of important metabolic processes (Li *et al*., 2023). In addition to their direct bactericidal effect, copper nanoconjugates further enhance the antimicrobial activity of macrophages by modifying the host immunological response. Copper ions promote autophagy, a vital defence mechanism, and the production of pro-inflammatory cytokines like TNF-$\alpha$ and IL-6 (Gutiérrez-Cruz *et al*., 2025). They can also occasionally reverse one of the primary immune evasion mechanisms by restoring phagosome-lysosome fusion. Copper nanoconjugates offer a promising method of treating intracellular tuberculosis, especially when antibiotic resistance is present, by utilising both direct bacterial toxicity and host immunological activation (Chandra *et al*., 2022).

Transmission Electron Microscopy (TEM), Selected Area Electron Diffraction (SAED), and Energy-Dispersive X-ray Spectroscopy (EDX) are helpful techniques for characterising nanomaterials. It provides data on the structural, crystallographic and elemental makeup of the nanoparticles. TEMfacilitates high-resolution imaging of copper nanoconjugates revealing their size, shape, and distribution. It also determines whether the nanoparticles are well distributed or aggregated which in turn affects their bioavailability and interaction with infected macrophages (Malatesta, 2021). SAED is used to characterise the crystallographic structure of copper nanoconjugates. The antibacterial activity of copper is regulated by its crystalline phase and SAED helps to determine if the nanoparticles are amorphous or crystalline. The crystalline nature also regulates the formation of reactive oxygen species (ROS), which affects the bactericidal efficacy of the nanoconjugates(Shamprasad *et al*., 2022). EDX provides a quantitative elemental analysis, validating the copper content of the nanoconjugates. It also aids in the verification of the successful synthesis of copper-based nanomaterials and identifies any impurities that may affect their biological activity(Bhavyasree & Xavier, 2022).

The biological component in a nanoconjugate diffuses from its periphery via passive desorption, matrix diffusion, stimuli-responsive releaseand ion-mediated processes (Bhatia *et al*., 2024). If the biomolecule is physically adsorbed onto the nanoparticle surface, it may release due to electrostatic interactions and solvent effects, enabling gradual release into the surrounding environment. This diffusion is regulated by pH, ionic strength and protein interactions inside infected macrophages, ensuring that the therapeutic drug reaches the site of infection(Herdiana *et al*., 2024). Nanoconjugates coated with biocompatible polymers such as chitosan, provide a concentration gradient that allows the biological component to diffuse outward through the matrix. This process enables sustained drug release, allowing the drug being used to stay active inside the macrophage for an extended period of time resulting in targeted intracellular drug delivery(Jafernik *et al*., 2023).

Previous research has been done on the intracellular activity of standard drugs such as Febuxostat against *M.tuberculosis* H37Rv (Kim *et al*., 2022)and the combination of Ethambutol and Meropenem(Olivença *et al*., 2024). However, the only research done so far on the intracellular anti-tuberculosis activity of nanoparticles indicated that curcumin nanoparticles when used in combination with Isoniazid showed about 97% intracellular inhibition (Gupta *et al*., 2023). In the present study the copper nanoconjugate synthesized showed 98% inhibition and Piperine showed 95% inhibition. The results indicated that the CuNC synthesized from *P. longum* could be a potential drug candidate against *M. tuberculosis*. The checkerboard assay results revealed that the CuNC possessed a partial synergistic relationship with Rifampicin indicating that it could be used in combination with the standard drug at a very low concentration.

## SUMMARY

The copper nanoconjugates showed significant intracellular activity against *Mycobacterium tuberculosis* with an impressive 98% inhibition. These nanoconjugates generated reactive oxygen species (ROS) and disrupted essential bacterial processes. The nanoformulation improves cellular uptake, ensuring efficient drug delivery to the infected macrophages. The high inhibition rate suggested potent mycobactericidal effects, making copper nanoconjugates a promising candidate for tuberculosis treatment, particularly in drug-resistant strains.

## DECLARATIONS

**Ethics approval and consent to participate** - Not applicable. The study did not involve the use of participants and animals.

**Funding-** Not Applicable. No funding was received for the study.

**Human Ethics and Consent to Participate-** NA

## ABSTRACT

Depression is a mental health disorder very common, with symptoms of sadness, hopelessness and lack of interest or pleasure in activities which usually persist. It impairs day to day functioning and physical symptoms include change to appetite, sleep and energy levels. This paper surveys the previous works related to depression prediction from 2019 to 2024. This survey uses large scale textual data to predict depression symptoms, methods are explored, attempting to find patterns and linguistic features associated with mental health. In this paper, 34 journal articles are examined regarding the prediction of depression symptoms. This survey leads the way for future studies to develop more robust, explainable AI models and the utility of multimodal data to boost and ethically deploy depression prediction systems from large scale textual data. Based on the findings, this paper studies the accurate prediction of depression symptoms. Convolutional Neural Network and Temporal Convolutional Network (TCN) are the two most popular approaches used in the earlier researches. By means of this survey, anxiety and stress are the major assessed depression symptoms. As a consequence, this paper terminates by providing the future research for the depression symptoms prediction.

**Keywords:** Anxiety, Deep Learning, Depression Symptoms, Prediction, Textual Data

## INTRODUCTION

Depression has an effect on every age people; wide-ranging impact in mental state, productivity as well as overall quality of life, making it an important public health concern. Advances in Natural Language Processing (NLP) and Machine Learning (ML) have opened new areas in research of large scale data textual datasets. One of which is the identification and prediction of the onset of depressive symptoms. The ability of these algorithms to uncover linguistic and behavioral trends in massive amounts of data benefits both earlier intervention and mental health study. Attention-based deep entropy learning is used in mental health treatment, Ahmed, U., *et al*. [1] improves the anticipated accuracy of depression recognition with lexical algorithms. New Deep Learning (DL) algorithms have changed depression detection methods in recent years. Almutairi, S., *et al*. [2] has created a technique which combines advanced NLP with robust ML frameworks to provide credible predictions from large volumes of textual data. Anand, A., *et al*. [3] has studied the usage of Large Language Models (LLMs) to accurately diagnose depressive symptoms by the utilization of textual and multimodal inputs which including audiovisual data. Multi-modal integration overcomes the limitations of one-dimensional techniques and improves model performance by including additional data. Aside from textual analysis, modern language representation models offer scalable psychological symptom prediction with higher accuracy. Aygün, I., and Kaya, M., [4] investigated the most effective methods for diagnosing mental disease signs. Ayodele, A., *et al*. [5] has demonstrated the utilization of ML approaches in analyzing multimodal datasets which included text as well as other behavioral components. This allows more personalized risk assessments. These strategies help to understand the complicated nature of depression better by emphasizing the intersection of therapeutic application and computational innovation. Figure 1 describes the various causes for depression. Due to the combination of biological, psychological and environmental factors, depression occurs. Biological causes are genes, chemical imbalance in brain, hormonal changes, and other environmental influences. The psychological factors such as trauma, chronic stress, low self esteem and unresolved grief are the predominant reasons. Simple social isolation, financial hardships, exposure to abuse and neglect compound the problem. Even good major life events such as a job change have the chance to trigger if the person is vulnerable. Managing sensitive textual material has unique ethical concerns which are met if this field is advanced. Consequently, temporal data Bucur, A.M., *et al*. [6] is crucial for enhancing depression diagnosis capabilities. In the study Cacheda, F., *et al*. [8] the importance of social network analysis and Random Forest (RF) techniques for the early detection is noted. In addition to the findings from Fatima, B., *et al*. [13] about the application of DL for earlier diagnosis, these discoveries emphasize the necessity of utilizing textual data for mental health solutions. This study paves the way for ML utility and other future mental health evaluation methods, which improve the diagnosis and open up new avenues for treatment.

## BACKGROUND STUDY

According to the previous works, there is an increasing utility of textual data available from social media and other platforms to predict depression symptoms. Specifically, emotion identification, behavioral patterns and linguistic clues are assessed. The exploitation of ML models and multimodal data together increase prediction accuracy and interpretability. Lau, C., *et al*. [17] despite the absence of evidence for depression evaluation, there was a creative approach. In addition to pre-trained huge language models, it incorporated approaches for parameter-efficient customization. Patient Health Questionnaire (PHQ-8) was predicted using a pre-trained model with prefix vectors as a few variable parameters. The tests of all the three groups of 189 participants were performed on the Distress Analysis Interview Corpus - Wizard of OZ (DAIC-WOZ) benchmark. Lee, C., and Kim, H. [18] focused on developing depression prediction models for Americans with hypertension using a variety of ML methodologies. The methodologies utilized to develop the models were considered. Random down sampling was used to manage data imbalance. Six ML classification algorithms, from R caret package such as XGBoost, Support Vector Machine (SVM), stochastic gradient boosting, RF as well as Artificial Neural Network (ANN) are used to predict. Also, ten-fold cross-valuation was used. Model performance was assessed using different models on a dataset of 16 rescue calls clustered into 4 groups; it involved using F1 Score, accuracy, precision and Sensitivity along with the Area under the

Receiver Operating Characteristic (ROC) Curve (AUC). Table 1 compares the various author works that are relevant to the assessment of depression. Based on the work of Meshram, P., and Rambola, R. K. [19], the authors provided an Artificial Intelligence (AI)-driven automatic depression scale prediction system. The model was based only on facial expression detection from the video sessions of depressed people. After the application of feature dynamic history histogram to video sample, expressions and dynamic face characteristics were extracted using DL techniques. Deep feature extraction strategy yielded better results than manual feature extraction method. Unlike the results of closely related neural networks in producing benchmarking data, features collected directly from convolutional layer outputs had performed exceptionally well. Muñoz, S., and Iglesias, C. Á. [20] aimed to create a high-performance system that made detecting depression in digital information more realistic. Thus, the authors proposed a comprehensive feature structure that incorporated mental activity, facial emotions and verbal cues. Including distributional representations in this paradigm allowed grasping the depressed language patterns and context better. When maintaining interpretability and processing efficiency, standard ML approaches were used with incredible efficiency by using this complementary relationship. Various works regarding the prediction of depression from 2019 to 2022 were contrasted in table 2. According to Naseem, U., *et al*, [22], severity of early depressive symptoms was assessed. Therefore, a new dataset was created using clinical depression criteria and given ordinal nature of depression severity levels, from the original depression dataset. A hierarchical attention strategy was proposed that utilized a soft probability distribution for the increasing severity of depression. Strategy on two datasets such as the personal dataset with single post and public dataset with many posts per user was tested. The former was compiled from genuine Reddit posts that were classified using questionnaires designed by clinical experts. This technique proved to be more effective than cutting-edge models.

Nusrat, M. O., [23] finally, models trained in ML and DL was able to correctly categorize the various types of depression using tweets as input. Random Forest Classifier outperformed the other ML classifiers. Bidirectional Encoder Representations from Transformers (BERT) had high accuracy among DL model. Artificial Intelligence helped to illustrate the reasoning behind the model's forecasts, increased its applicability and value. Determining the depression was a difficult and hard task. Its various properties were difficult to accurately document in a single dataset. Good data was required for training algorithms that detected depression. Reliable outcomes were dependent on the models being adequately represented. Pavez, J., and Allende, H. [24] it creatively combined the capability of large-scale language models in reasoning and generalizability of Bayesian Networks in precision. To confirm or augment the initial diagnosis made by DL model, this system then devised follow up enquiries centered on user provided and natural language descriptions of user's symptoms. As the system was trained, a large dataset of 2.3 million data points was used to teach this system. The authors designed a probabilistic graphical model based on Diagnostic and Statistical Manual of Mental Disorders (DSM-5) diagnosis to generate the questions that confirmed symptoms to improve the first prediction of a Large Language model. Sadeghi, M., *et al*. [25] unlike most research that relied on human feature extraction, these findings indicated that LLM had the ability to detect depression through text analysis. On EDAIC dataset, this text-only, LLM-based PHQ prediction algorithm had outperformed traditional and time-consuming manual feature extraction strategies. This LLM-based strategy reduced Mean-Absolute Error (MAE) and Root-Mean-Squared Error (RMSE) than the previous approaches. Shivaiah, S. K., *et al*. [29] offered a set of ML models that accurately predicted anxiety, depression, stress, and other Depression Anxiety Stress Scale-42 (DASS-42)-related mental health issues. Using Large-Scale Group Decision Making (LSGDM) loss optimizer, the proposed ensemble model achieved 98.88% accuracy, 98.21% precision, 98.62% recall, 98.90% F1-score and 99.41% Matthew's Correlation Coefficient (MCC). This suggested LSGDM loss optimizer outperformed current optimizers in various ways. Comparison of the works relevant to the prediction of depression symptoms is carried out in table 3.

## EXISTING METHODOLOGY

A survey on the prediction of depression symptoms is presented in this paper. Here, various previous researches are utilized. In this study, the approaches such as ensemble, Atrous Residual Temporal Convolution, Multimodal Feature Extraction, Modeling the Bayesian Network and Language Models are considered.

**Maximizing ensemble model**

Depression is assessed and diagnoses when two emotions such as sorrow and anxiety are present. It turns out that this ensemble model is able to correctly detect both of these feelings. Selecting the highest probability of emotion prediction an optimizing ensemble of Convolutional Neural Network (CNN), Long Short Term Memory (LSTM), and Bidirectional Long Term Memory (LSTM) models are used. In this papers, these models as CNN, LSTM and the bidirectional LSTM are mathematically represented. This approach maximizes recollection across every emotional category. Therefore, the capacity to recognize emotions in every tweet is improved. This covers tweets in which one model captures the emotion correctly while another gets it wrong. Bhat, P., *et al*. [6]

**Atrous Residual Temporal Convolution**

The fact that visual activities vary in intensity, further complicated the clinical indications of depression. A robust and consistent encoder is required. This is accomplished by combining Temporal Convolutional Network (TCN) and two concepts from Atrous Residual Temporal Convolution. The above-mentioned figure 2 shows a flowchart for a convolutional model meant to predict depression symptoms. In this process, input data is loaded, atrous and temporal convolutions are applied, feature aggregation is performed and the detail of the feature map is evaluated. If necessary, adjustments and recalculations are performed; prediction and validation steps are subsequently performed. Temporal Convolutional Network, a time-series model capable of capturing long-term patterns, solves the action segmentation issue. Atrous Convolution has been applied in the variety of applications like sequence modeling, human action segmentation and semantic image segmentation. Its original application is in signal processing to replicate multi-scale data. These two approaches serve as the foundation for automatic depression analysis system, DeepArt-Net, a one-dimensional Atrous Residual Temporal Convolutional Network. It provides a novel approach to documenting the full spectrum of environmental data at high level, as well as temporal changes in depression. DeepArt-Net is made up of two cascade components such as multi-scale contextual feature development and time resolution reduction. Similar to ResNet, numerous temporal layers use residual convolution blocks to boost performance.

**Depression prediction using Multimodal Feature Extraction**

The model generates two key data sources such as sensor data and user reaction data. Previous research has related participant behavior to behavioral features obtained from smart phone data collection. This findings prompts to study the behavioral characteristics which are more commonly associated with severe of depressive disorder so that such approach could be devised that is based on behavioral characteristics for individual depression prediction. The American Healthcare Psychiatric Association's published DSM-5 lists the symptoms of major depressive disorder. moodiness, disinterest, enjoyment of enjoyable activities, fatigue, restlessness, changes in sleep and weight, impaired concentration, feelings of worthlessness, suicidal thoughts and reduced capacity to concentrate. Two behavioral symptoms such as sleep change, diminished interest and pleasure in activities are primarily focused. New derived attributes are presented which is obtained from data. Researchers have created particular facial expression components to detect depression symptoms in textual data. As a result, the suggested approach provides attributes based on multimodal data. Hong, J., *et al*. [15]

**Modeling the Bayesian Network**

A Bayesian network is trained to record the associations between symptoms and diseases in order to reproduce a real-world diagnosis. This network seeks to determine whether the language models reported symptoms are valid for more precise diagnosis. Its network consists of nodes which represent the diseases (D) and symptoms (S). Symptom nodes depict the existence of symptoms, while illness nodes show the presence of diseases. By creating a Conditional Probability Table (CPT) at each edge connecting the nodes, connectedness of symptoms under specific conditions is demonstrated. The operation of this network is based on Quick Medical Reference (QMR), a Bayesian medical diagnosis network. Its two-layer method makes it easier to see the interaction of symptoms with depression. Sick nodes are located in top layer. On the bottom layer, nodes that signify findings or symptoms are shown. Arcs connecting the two levels represent their reciprocal connection. Pavez, J., and Allende, H [24]. Figure 3 describes the Modeling of Bayesian network to predict expression symptoms. It starts by overloading the variables. Then, the steps

include to data preprocessing, building a Bayesian network, estimating the model parameter, testing the model and finally putting the model to work for prediction. Any feedback loops leads to improvement, guaranteed by iterative refinement.

**Language Models for Depression Detection**

A linguistic model has predicted a person's PHQ after a revised transcript examination. These models utilized a redesigned language model known as DepRoBERTa, which is an enhanced version of RoBERTa for Depression detection. The enhanced model DepRoBERTa uses literary analysis to detect depression symptoms. Initial training for RoBERTa-large came from depressing Reddit threads. DepRoBERTa, a large-depression model produces estimates for the degree of depression conveyed in social media posts. It segregates depression into three parts: not depressed, moderate and severe. This model was trained using training data tagged by domain experts which involved assigning one of three labels to each instance. While moderate and severe symptoms reflect the other two categories, absence of depressed symptoms denote not depression. Sadeghi, M., *et al*. [25]

## DISCUSSION

Various existing technologies are used in the following depression diagnostic and analysis procedures to ensure consistency and accuracy across multiple data sources. Thus, accuracy of emotional classification is improved by using these models. These are models that combine the good features of each single model. The identification of depressive symptoms is improved by combining models, such as CNN, LSTM and bidirectional LSTM. Temporal Convolutional Networks paired with Atrous Residual Temporal Convolution capture more long-term patterns and multi-scale data, which improve the understanding of depression temporal component. Combining sensor data with behavior results in thorough and unique depression prediction using multimodal feature extraction, allows the tracking of symptoms such as changes in sleep patterns and diminishing interest. Bayesian networks improve on their predecessors in real-world medical diagnosis by allowing more accurate interpretations of symptom patterns through sickness associations. Finally, DepRoBERTa and other language models reflect the current trend of real-time assessment based on social media data. These strategies attempt to identify sadness by analyzing textual data for linguistic cues. These methods emphasize time-based analysis, multimodal data integration and consistent symptom association, work together to provide a comprehensive depression diagnosis technique.

## CONCLUSION

This survey has examined 34 journal articles, which are relevant to the depression symptoms prediction. The surveyed papers are taken between the year duration of 2019 and 2024. After the study of various previous works, the depression symptoms such as anxiety, stress, diminished interest, social isolation and sorrow are recognized. Of those symptoms, anxiety and stress seems to be predominant. The utility of existing methodologies has significantly improved the prediction as well as the analysis of depression symptoms. This survey helps in finding the real-time insights into the mental health conditions. Looking forward, these novel approaches have potential for enhancing mental health diagnosis to support the development of future and effective treatment pathways.

**ABSTRACT**

The basic reproduction number (R0), which is used to quantify the contagiousness or transmissibility of an infectious agent, is regarded as an epidemiological statistic. Due to its dependence on the following factors—time period of infection after the individual gets infected, number of infections caused from susceptible population during one contact, and contact rate- $R_0$ varies significantly for different infectious diseases as well as for the same disease in populations. $R_0$, commonly referred to as the basic reproduction ratio, calculates the magnitude of $R_0$ to show how much work is required to either control an epidemic or eradicate an infection from a population. $R_0$ is rarely directly calculated; instead, it is measured using a variety of theoretical mathematical models. The resulting final value of $R_0$ can be influenced by a variety of biological, environmental, and organismal interactions, i.e., socio-behavioural factors, making $R_0$ susceptible to misinterpretation. When $R_0$is more than 1, it means that the number of infections will grow and is likely to become endemic or pandemic; as a result, $R_0$ must be assessed with caution.

**Keywords:** Reproduction number, Infectious, Epidemiology, Eradication

## INTRODUCTION

The predicted number of cases that will be directly created by one instance of an infection in a community where everyone is vulnerable to infection is known as the $R_0$ (Basic Reproduction Number) of an infection [1]. In order to understand the dynamics of infectious diseases, $R_0$ has been described as one of the fundamental and most popular

metrics [2]. Finding $R_0$ is a highly difficult task, as a point error might mess up the infection-related precaution mapping, which will ultimately lead to a false sense of security for people. $R_0$ puts us in a position to be able to respond to issues that will arise in the future, such as how quickly an infection spreads, how much medical care will be needed, and how long a lockdown should last. According to the frequency of spread of COVID-19, the World Health Organization declared it a Public Health Emergency of International Concern [3]. Community transmission may have begun as the outbreak spread. Some COVID-19 patients exhibit minimal or no symptoms, which is known as asymptomatic, and because these cases are not tested and reported, $R_0$ is frequently overstated [4]. The reproduction number ($R_0$) was developed by demographer Alfred Lotka and epidemiologist Mac Donald in reaction to malaria [4]. If $R_0$ is more than 1, the number of infected persons will probably grow exponentially, and an epidemic may result. The outbreak is likely to end on its own if $R_0$ is less than 1 [5.16]. The WHO's first estimation of $R_0$ for COVID-19 ranged from 1.4 to 2.4. We had an epiphany at that point, realizing that this was probably not going to go away on its own and that we might well be dealing with the beginnings of an epidemic [6]. It is known that SARS-CoV-1 is less severe, i.e., have a lower $R_0$than SARS-CoV-2 whereas SARS-CoV-2 VUI 202012/01(a new strain of COVID-19) is highly contagious and have a higher $R_0$than SARS-CoV-2. Therefore, we can state that-

SARS-CoV-1 < SARS-CoV-2 < SARS-CoV-2VUI

(In terms of severity and reproduction number)

**Effective Reproduction Number ($R_e$)**

The number of cases created in the current state of a population-which need not be the uninfected state-is referred to as the effective reproduction number ($R_e$). As the population develops immunity, the value of $R_e$ changes [7]. The two main methods for immunizing a population are either through individual immunity acquired after illness or through vaccination. $R_e$ can be used to evaluate the efficacy of immunization. The number of infected individuals, the number of susceptible individuals with whom infected individuals come into touch, and individual behavior, such as social withdrawal, are all variables that impact $R_e$.

**$R_0$ and Vaccination**

Herd immunity refers to immunity developed by a certain segment of the population to prevent the spread of illness. Herd immunity requires a certain percentage of the population to be inoculated, which may be determined using $R_0$ [8]. Herd immunity requires 80% of the population to be immune if the contact number is 5. Campaigns for vaccination have been shown to be extremely efficient in containing current outbreaks and lowering the proportion of a community at risk for illness [9]. This result is occasionally inferred to mean that one goal of vaccination efforts is to eliminate susceptible people from the community in order to lower the $R_0$ for the event to 1. The effective reproduction number (R), which is comparable to $R_0$ but does not imply complete vulnerability of the population and can therefore be evaluated with populations having immune members, is a more acceptable statistic to employ when analyzing the impact of vaccination [6]. The R value would decrease rather than increase in response to vaccination efforts aimed at reducing the population's susceptible individuals. In this case, vaccination could be able to put an end to an epidemic if R can be made to equal or less than 1 [1]. R(t) or Rt, which can be used to track changes in R when the population's susceptible individuals are less, specifies the effective reproduction number at a specific time t. [10]. $R_0$ is not always the optimal indicator when attempting to gauge the success of vaccination Programmes or other public health efforts [11].

**Speculation of $R_0$**

Direct calculation of $R_0$is not doable. There are various models by which $R_0$can be measured, and the result depends on the type of model and values assumed. Various models through which we can speculate $R_0$include SI (Susceptible-Infectious), SIS (Susceptible-Infectious-Susceptible), SIR (Susceptible-Infected-Recovered), and SEIR (Susceptible-Exposed-Infected-Recovered).

**Exponential Model**

A viral disease is known to be contagious, and the spread of infection is mostly dependent on two factors: the number of persons who come into contact with an infected person and the transmission of an infection [12]. There

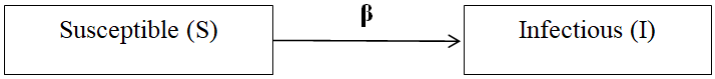
will be a sharp rise in the number of contagious people if the entire population is susceptible to infection, the risk of transmission is 100%, and each infectious person comes into touch with 3 additional people. It is known as exponential growth when the number of infections doubles every day by a fixed amount (i.e., by a factor of three).Since it's not necessary for the infected person to interact with the same number of people every day, the number of infected individuals can either increase or decrease; such models don't actually find $R_0$, which makes it practically impossible to obtain exponential growth. It can be represented as:

$$I(t)=I0\times 3t$$

I(t): Infected individuals at time t
I0: Initial infections
t: Time in days

**Susceptible-Infectious (SI)Model**

There is a better way to speculate on the spread of disease known as the SI model. In the SI model, it is a supposition that an infected individual will continue to transmit the disease throughout their life as they are left untreated and will never recover [13]. Such as herpes disease which has lifelong infectiousness.



According to this model, the rate of infection is proportional to the number of susceptible and the number of infected, i.e., the more the number of susceptible and infected, the more the disease will spread. Therefore, we can write that-

**$dS/dt = -\beta SI$**

S = Susceptible individuals
I = Infectious individuals
β = Transmission rate (infections per contact × contact rate)

**$dI/dt = \beta SI$**

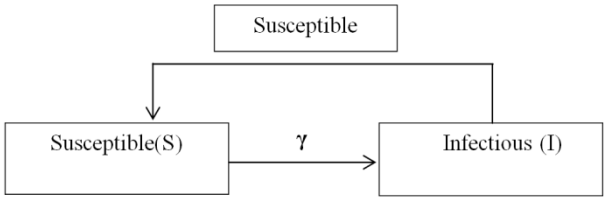
New infections = βSI

Basic Reproduction Number ($R_0$):**$R_0 = \beta N/\gamma$**

$R_0$ = Basic reproduction number
N = Total population
γ = Recovery rate (if applicable)

**Susceptible-Infectious-Susceptible (SIS) model**

In the SIS model there is no immunity to a disease and the infected individual will again become susceptible after infection. Therefore, it is not wrong to mention that this model is specifically appropriate for those diseases that have repeat infection [14]. The common cold correctly fits with the SIS model.



**$dS/dt = -\beta SI + \gamma I$**

S = Susceptible individuals (healthy people who can get infected)
I = Infectious individuals (infected people who can spread disease)
β (Beta) = Transmission rate (infection probability × contact rate)
γ (Gamma) = Recovery rate (how fast people recover from infection)

-βSI = Loss of susceptible individuals due to new infections
+γI = Gain of susceptible individuals through recovery (no immunity)

**dI/dt = βSI –γI**
βSI = Gain of new infections
-γI = Loss of infectious individuals through recovery

**Basic Reproduction Number ($R_0$):** $R_0 = \beta N/\gamma$
$R_0$ (R-naught) = Average number of people one infected person will infect
N = Total population size (N = S + I)
βN/γ = Transmission potential relative to recovery rate

**Susceptible-Infected-Recovered (SIR)Model**
Kermack and McKendrick used this model for the first time in 1927 [15]. SIR explicitly stated that once someone entered the recovered compartment, they would never re-enter the susceptible compartment, and that people who had recovered from an infection through vaccination or attained immunity would no longer be susceptible to it, unlike in the SIRS model, where immunity is not long-lasting [5]. The SIR divides the entire population into three divisions, hence its name. S = susceptible population after a compartment housing an infectious person contracts the infection, causing a population transfer from the susceptible compartment to the infected compartment; R = (recovered) stands for the number of recovered or removed, that proportion of the population that has recovered from the infection,or removed, is taken into consideration under this compartment. I = (infectious) as I represents the number of infected individuals, so these infected individuals are capable of infecting susceptible and they will not reinfect the population that has been recovered, as they have recovered with lifelong immunity [15].An example of a disease which can withstand this type of model includes MMR (*M*easles, *M*umps, and *R*ubella).Calculation of $R_0$ with SIR model can be done by dividing the transmission rate bythe recovery rate, i.e.,
**dS/dt = -βSI**
S = Susceptible individuals (healthy, uninfected people)
I = Infectious individuals (infected and contagious people)
β (Beta) = Transmission rate (infection probability × contact rate per time)
-βSI = Loss of susceptible individuals due to new infections

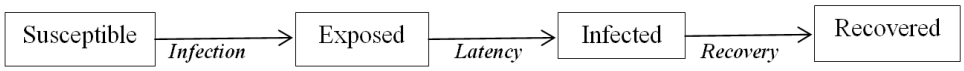
**dI/dt = βSI - γI**
βSI = New infections (flow from S to I)
γ (Gamma) = Recovery rate (1/γ = average infectious period)
-γI = Loss of infectious individuals through recovery

**dR/dt = γI**
R = Recovered/Removed individuals (immune or deceased)
γI = Flow of recovered people from the infectious compartment

Basic Reproduction Number ($R_0$): **$R_0 = \beta N/\gamma$**
$R_0$ (R-naught) = Average secondary cases from one infection
N = Total population (N = S + I + R)
βN/γ = Transmission potential vs recovery rate
This calculation can help in determining the speed of spread of the disease.

**Susceptible-Exposed-Infected-Recovered (SEIR)Model**
The SIR model, which was previously addressed, only considers infections that make a person capable of infecting others right away after contracting them. Many diseases have what's known as a latent or exposed phase, in which a person is deemed to be ill but not contagious [16, 17. 18].In this model the host population (N) is broken into 4

compartments: susceptible, exposed, infectious and recovered, with the number of individuals in a compartment, or their densities denoted respectively by S(t), E(t), I(t), R(t), that is N= S(t)+E(t)+I(t)+R(t)Example includes chicken pox and even vector borne diseases which have a long incubation duration where the individual cannot yet transmit the pathogen to others.



**$dS/dt = -\beta SI/N$**
S = Susceptible individuals (healthy, at-risk population)
$\beta$ (Beta) = Effective contact rate (transmission probability × contact rate)
I = Infectious individuals (currently contagious)
N = Total population (N = S + E + I + R)
$-\beta SI/N$ = Infection rate (frequency-dependent transmission)

**$dE/dt = \beta SI/N - \sigma E$**
E = Exposed individuals (infected but not yet infectious)
$\sigma$ (Sigma) = Incubation rate ($1/\sigma$ = average latent period)
$\beta SI/N$ = New exposures (infections)
$-\sigma E$ = Progression to infectious state

**$dI/dt = \sigma E - \gamma I$**
$\gamma$ (Gamma) = Recovery rate ($1/\gamma$ = average infectious period)
$\sigma E$ = Newly infectious individuals (from exposed compartment)
$-\gamma I$ = Recovered/removed individuals

**$dR/dt = \gamma I$**
R = Recovered/Removed individuals (immune or deceased)
$\gamma I$ = Flow out of the infectious
$_0 = \beta/\gamma$
$R_0$ = Average secondary cases from one infection
Basic Reproduction Number **($R_0$): $\beta/\gamma$** = Transmission potential relative to recovery *(Assumes homogeneous mixing and initial S ≈ N)*

## CONCLUSION

Most communities around the world continue to face a recognized and ongoing health risk from infections and diseases. We have been able to limit numerous outbreaks and make an effort toward the complete eradication of several previously deadly infections because of our improved understanding of how a contagion spreads. Forecasting $R_0$ is essential since it will enable governments to plan swiftly and anticipate the likelihood of any negative conditions. New viruses and outbreaks will always exist, but with the help of mathematical modeling, epidemiologists will be able to gain a better knowledge of the potentially negative effects of upcoming diseases and to reduce the effects they will have on the general public. The definition, computation, and interpretation of $R_0$are anything but straightforward, despite the fact that it could seem to be a straightforward metric that can be used to assess the dynamics of infectious disease transmission and the risks that new outbreaks pose to public health. Almost always, $R_0$ values are calculated from mathematical models, and the estimated values depend on a variety of choices made during the modelling process. Without recalculating $R_0$ under the same modelling assumptions, the contagiousness of different historical, emerging, and reemerging infectious agents cannot be meaningfully compared. The genuine meaning of the $R_0$value can be distorted in a number of ways that it might be misrepresented,

misunderstood, and applied. $R_0$ must be used and discussed cautiously in research and practice due to these different causes of confusion. When applied and evaluated correctly, this epidemiologic construct will only continue to be useful and relevant.

**ABSTRACT**

The aetiology of diseases has been explored through both contemporary science and traditional medical systems. The concept of *miginum kuraiyinum*, referring to excesses and deficiencies as the root causes of illness, is highlighted in the *Marunthu Athigaaram* of the Tamil classic *Thirukkural*. This principle emphasizes the connection between lifestyle, diet, and health—a view that aligns closely with Siddha medicine, an ancient Tamil medical system that identifies dietary habits and daily routines as key determinants of well-being. This review examines the etiological concept of *miginum kuraiyinum* within the context of *Thirukkural*, correlating it with Siddha pathology and modern scientific interpretations of homeostatic imbalance. A comprehensive review of *Thirukkural*, Siddha medical texts, and recent scientific literature was conducted using databases such as PubMed, Scopus, and Google Scholar with keywords including homeostasis, dietary habits, sleep deprivation, strenuous exercise, yoga practices,

and climate.The findings reveal strong parallels between the modern scientific understanding of homeostasis and the ancient Tamil notion of maintaining balance through moderation in diet, activity, and rest. The convergence of traditional wisdom and contemporary science underscores the continuing relevance of *Thirukkural* and Siddha principles in promoting health and preventing diseases arising from lifestyle and dietary imbalances.

**Keywords :** *Thirukkural*, *miginum kuraiyinum*, Siddha medicine, *Marunthu Athigaaram*, dietary habits, homeostasis.

## INTRODUCTION

*Thirukkual* is an ancient Tamil text authored by the poet-sage Thiruvalluvar, (Thiru = respectful + Kural = couplet), also known as Kural Venpa, during the Sangam period (300 BC to 200 AD), which is considered a precursor to contemporary Haiku poetry. Under 133 chapters, 1330 couplets are split into three sections: Aram (virtue), Porul (life realities), and Inbam (love). There are ten couplets in each chapter.[1] The poet used relatively basic language in order to impart a variety of knowledge to the general public. It is considered a universal work of ethics, transcending language, culture, and religion barriers. It addresses a broad spectrum of human life, offering insights into ethics, governance, medicine, and personal conduct. With a focus on harmony between the body, mind, and environment, *Marunthu Athigaaram* (Chapters on Medicine) examines the concepts of well-being, health and disease prevention.Modern scientific ideas like homeostasis and preventative treatment align with the Kural. The couplets are succinct but insightful, offering timeless insight relevant to current philosophical and scientific debates. Ideas like sustainability, moderation (*Miginum kuraiyinum*), and balance are relevant to disciplines like ecology, systems biology, and medicine.[2]The *Thirukkural*'s focus on balance, prevention, and care is similar to contemporary medical practices, especially when it comes to preserving homeostasis toward offillness. It is a useful resource in interdisciplinary research since it integrates ethical and scientific ideas.

***Miginum Kuraiyinum***

In *Thirukkural*, under the section *Porutpaal*, there is a chapter titled *Marunthu* (Medicine), which comprises ten couplets addressing various aspects of health, including medicine, disease, the role of physicians, and dietary habits. The opening couplet of this chapter states:

மிகினும் குறையினும் நோய்செய்யும் நூலோர்
வளிமுதலாஎண்ணிய மூன்று.

-திருவள்ளுவர்.

;.

Mik̲iṉumkuṟaiyiṉumnōyceyyumnūlōr
Vaḷimudalāeṇṇiyamūn̲ṟu.

-Tiruvaḷḷuvar.

In this verse, *Thiruvalluvar* emphasizes that excessive or insufficient intake of food or irregular daily activities can disrupt the balance of the three humors (tridosha) described by ancient sages: vatham, *pitham*, and *kabam*. *Vatham* governs movement and transportation within the body, *pitham* regulates digestion and metabolic reactions, and*kabam* ensures structural integrity and cohesion. These three humors work synergistically to maintain the body in a state of equilibrium, free from disease. This balance closely parallels the concept of homeostasis, where any disruption in the trihumors, akin to an imbalance in homeostasis, can lead to pathological conditions.

**HOMEOSTASIS**

In the term Homeostasis, "homeo," derived from the Greek word "homio" meaning "similar to," when combined with "stasis," the Greek word for "standing still," forms a fundamental concept in physiology. The body's functions, starting at the cellular level, are designed to maintain a narrow range of internal balance, known as dynamic equilibrium, even in the face of external environmental changes. These external changes can alter the composition of the extracellular fluid surrounding individual cells, but preserving this narrow range is essential to prevent the death of cells, tissues, and organs.[3]Homeostasis is maintained through negative feedback loops that counteract deviations from target values, or set points. Disruptions in homeostasis can result in disease.[4] For example diabetes caused by broken feedback loop involving the hormone insulin.[5]When the fat storage capacity of adipocytes is exceeded, it can lead to metabolic inflammation and loss of normal function and results in obesity.[6]

**Mikinum Kuraiyinum vs Homeostatic Imbalance**

Dietary habits, life style practices and environmental factors can vitiate the trihumors and leads to the disease, these factors can also deviate the homeostatic equilibrium and results in disease condition. Dietary habits like excessive or insufficient intake of food consist of carbohydrates, lipids, proteins, excessive or insufficient physical work, sleep, physical exercise, yoga practices, exposure to excessive hot and cold climate and excessive or insufficient intake of medications. In this review deals about the mechanism of these activities, how it alters the equilibrium of trihumors as well as homeostasis.

**The Effect of Excessive and Insufficient Food Intake is Detailed in the Table.1.**

In every day we should take a balanced diet for a healthy life, in which consist of a nominal required level for carbohydrates, lipids and proteins. According to Siddha trihumoral theory, Carbohydrates are *vatham* due to its *varatchi* character, Proteins are *pitham* due to its *ooduruvumthanmai* and lipids are *Kabam* because its characters of *paluvu*, *mantham* and *vazhuvazhuppu* [7].

**Processing of Food**

Proper cooking techniques preserve essential nutrients like vitamins, minerals, and antioxidants. Cooking breaks down complex food structures, making nutrients more accessible for absorption. Proper preparation eliminates harmful bacteria, viruses, and parasites, reducing foodborne illnesses. The right cooking methods improve taste, aroma, and texture, encouraging better dietary habits. Enhanced palatability ensures people consume sufficient nutrients for their needs.Common mistakes in food processing include over-processing and insufficient cooking. In Siddha medicine, over-processed food is referred to as *kuzhainthathodam*, while insufficiently cooked food is termed *kodhithodam*.[17]

***Kuzhaintha Thodam*(Over-processed food)**

According to Siddha literature, the consumption of over-processed food reduces *udarthee* (vitality), leading to a decrease in *pitham* and an increase in *kabam* and *vatham* within the body. Ultra-processed foods, often high in saturated and trans fats, are known to elevate bad cholesterol levels, contribute to arterial blockages, and heighten the risk of heart attacks, which can be associated with *kabam*(by*paluvu and immobile* characters*)* imbalance.[18] Furthermore, evidence indicates that regular consumption of ultra-processed foods may increase the risk of obesity, linked to imbalances in *kabam* and *vatham*.[19]

***Kodhi Thodam* (Insufficiently cooked food)**

According to traditional texts, the consumption of insufficiently cooked food can lead to *alasarogam* and *mantham*, conditions characterized by impaired digestive function and abdominal distension due to an imbalance of *kabam* and *vatham*. Furthermore, unprocessed or insufficiently cooked foods are potential sources of foodborne diseases caused by bacteria, viruses, protozoa, and helminths.[20] These infections may transmit due to the *kulirch*i character of *Kabam* and *vatham*

***Nithirai* (Sleep)**

Sleep is a natural, reversible state of reduced responsiveness and interaction with the environment, essential for physiological and mental functions. Controlled by the circadian rhythm and the homeostatic sleep drive.[21]. Sleep supports physical restoration, including muscle repair, tissue growth, and protein synthesis and plays a vital role in regulating immune function and hormonal balance. Adults typically require 7–9 hours of sleep per night, with variations based on age, genetics, and individual needs. According to Siddha text excessive sleep is refered to *athinithirai* and deprived sleep is *nithiraipangam.*

***Athi Nithirai* (Excessive sleep)**

According to Siddha literature excessive sleep (due to *vatham*) results in head ache, sinusitis, fever, paresthesia, dropsy, atherosclerosis and diminished digestive fire. These conditions may be caused by the decreased *pitham* and*kabam.*Recent studies state that even for people who are otherwise healthy, too much sleep can increase the risk of heart disease (*immobile-kabam*and *kadinam-vatham*)and long sleepers have a higher risk of stroke (*immobile* character of *kabam*) due to increased blood pressure.[22]

***Nithirai Pangam* (Deprived sleep)**

In Siddha literatures mentioned as deprived sleep (due to *Pitham*) results in confused state, decreased functions of sensory organs, loss of body weight and fainting. These conditions are caused by the decreased*kabam* and *vatham.* Recent studies state that people with sleep deprivation had a higher risk of hypertensive heart disease (*Kuroorum-Pitham*)[23] and gastrointestinal diseases, including irritable bowel syndrome, inflammatory bowel disease, and colorectal cancer (*Kuroorum-Pitham,Immobile-Kabam*).[24]

***Thega Payirchi* (Physical Exercise)**

Exercise refers to any physical activity that improves or maintains physical fitness and overall health, promoting strength, flexibility, endurance and well-being. Regular exercise is crucial for sustaining a healthy body and mind and it helps reduce the risk of various diseases.

**Athi Thegapayirchi (Strenuous exercise)**

Excessive or intense exercise leads to overexertion, aggravating Vatham, which results in muscle cramps, stiffness and joint issues (*Varatchi and asaithal*). This is followed by the vitiation of Pitham, causing joint inflammation (spreading)and ultimately changes in Kabam, leading to fatigue (*Paluvu*) and a lack of energy (slow and heavy). Recent studies have reported that strenuous exercise leads to bursitis and tendonitis (*Immobile*).[25]

***Kurai Thegapayirchi*(Lack of exercise)**

Insufficient physical activity increases Kabam, resulting in stagnation of energy (*Immobile*), obesity(*Paluvu*) and metabolic conditions such as diabetes mellitus. This is followed by the aggravation of Vatham and Pitham, leading to poor digestion (bloating)(mobile), emotional imbalances (*Kuroorum*)and compromised metabolism (*Akkini*).[26][27]

***YOGA PAYIRCHI*(YOGA PRACTICE)**

Yoga is a mind-body practice that integrates physical postures, breath control, meditation and ethical principles to improve physical health, mental clarity, and emotional well-being. It fosters balance, flexibility, and inner peace, contributing to overall wellness.

***Athi Yoga payirchi* (Excessive Yoga Practice)**

Excessive yoga practice can lead to the vitiation of *Vatham*, resulting in joint pain (dry), fatigue (*Kadinam*), and nervous disorders (*Immobile*). This is followed by the excessive stimulation of *Kundalini* leads to aggravation of Pitham and Kabam, which causes emotional imbalances (*Kuroorum*) and lethargy (*Paluvu*), respectively.

***Kurai Yoga payirchi*(Lack of Yoga Practice)**
Insufficient yoga practice leads to the aggravation of Vatham, Pitham and Kabam causing joint stiffness (*Varatchi*), emotional imbalances (*Kuroorum*) and metabolic disorders such as obesity (*Paluvu, Immobile*) respectively.

***Kaala Nilai Maatram* (Climatic Changes)**
India's diverse geography results in extreme climatic conditions, with intense heat in some regions during the summer and freezing cold in others, significantly influencing human lifestyles and health.

***Athi Veppam* (Exposure to Hot Climate)**
Heat exposure induces physiological changes by increasing *Pitham*, leading to overheating, dehydration (*Akkini*), and electrolyte imbalance (*Salaroobam*) within the body. This imbalance subsequently affects *Vatham*, resulting in symptoms such as fainting, weakness (*Ilagu*)and eventually culminates in the vitiation of *Kabam*, manifesting as lethargy and a lack of energy (*Paluvu*). Recent studies have found that exposure to heat increases the risk of cardiovascular diseases (*Kuroorum*) and heat stroke (*Akkini*).[28][29[

***Athi Seetham* (Exposure to Cold climate)**
Cold exposure primarily aggravates *Vatham*, leading to symptoms such as dryness (*Varatchi*), stiffness, and joint pain (*Asaithal*), followed by the disturbance of *Pitham* and *Kabam*. This results in sluggish metabolism, digestive disturbances (*Salaroobam*)and respiratory issues including colds, sinusitisand bronchitis (*Kulichi, Vazhavazhuppu*) respectively. Recent studies have reported that excessive cold exposure leads to the joint stiffness such as Rheumatoid Arthritis (*Immobile*) and respiratory diseases.[30]

***Marunthu-Kaalamum Alavum* (Dosage and Duration Of Medicine)**
In Siddha literatures clearly mentioned about the dosage and duration of the medicines for every diseased condition. Effective dosage and duration of the drug intake can facilitate the cure if illness.

**Excessive Dosage and Duration of Medicine**
Every medicine has the specific character to pacify or stimulate the particular humors of our body. Excessive intake and dosage can lead to excessive stimulation or pacification of particular humor and results in *Thee kunangal* of particular humor.

**Insufficient Dosage and Duration of Medicine**
Insufficient intake of dosage and duration of medicine may lead to progression of the disease and aggravation of affected humor.

## RESULTS AND DISCUSSION

*Thirukkural* highlights the significance of moderation in food intake and lifestyle as critical for maintaining health. Deviations from moderation (*miginum kuraiyinum*) lead to imbalances in bodily functions. Siddha pathology identifies improper dietary habits and daily practices as primary contributors to diseases, particularly through disruptions in the equilibrium of *vatham*, *pitham*, and *kabam*. The review highlights the striking parallels between the ancient wisdom of *Thirukkural* and Siddha concepts with the scientific model of homeostasis and pathological disruption. In *miginum kuraiyinum* verse, thiruvalluvar mentioned any dietary habits and routine practices, if exceeds or subceeds, it will affect the equilibrium of trihumors of our body and result in pathological condition. The mechanism of Siddha pathology of that particular condition correlates with mechanism of that particular modern pathological condition as well as homeostatic imbalance proven by the recent researches. Especially in text mentioned that deprived sleep will lead to a reduction of lifetime (*Aayusukundrum*). This stament is strengthened by the outcome of by the multiethnic cohort study conducted by Yeonju Kim et al. states that Insufficient amounts of sleep increase the risk of premature death from cardiovascular and other diseases.[31] Ford et al. identified a strong

association between multiple lifestyle risk behaviours including poor diet quality and increased all-cause mortality, indicating that irregular dietary habits contribute to higher mortality rates.[32]

## CONCLUSION

The concept of *trihumors* in Siddha medicine, represented by the idea of *miginum kuraiyinum* (excess and deficiency), closely aligns with the principles outlined in *Thirukkural Marunthu Athigaaram* regarding the origins of disease. This concept resonates with the modern understanding of homeostatic imbalance as a key factor in the development of pathological conditions. Contemporary research highlights the critical role of proper dietary habits and lifestyle choices in maintaining physiological equilibrium and preventing illness. Embracing the traditional insights of balanced nutrition and disciplined daily practices, as advocated in Siddha medicine and *Thirukkural*, provides a pathway to achieving overall health and well-being, bridging ancient wisdom with modern health approaches for a balanced and healthy life.

### Recommendations

This review may play a key role to facilitate collaborative research between traditional Siddha concepts and contemporary medical science to develop holistic approaches for disease prevention and management in future. It may helpful for encourage the inclusion of Siddha medicine principles in national health policies for preventive healthcare.

## ABSTRACT

Childbirth is a physically and emotionally intense process which often leads to significant stress to the mother. How the body of a woman, would adapt to the labor changes and have a fruitful outcome in terms of a healthy mother and a healthy newborn, significantly depends on the mental health and emotional support she receives during childbirth. Birth companionship is a concept which involves continuous physical, emotional and informational support provided to a woman during childbirth via the presence of a supportive individual such as a family member like the husband or mother or sister or a friend or a trained doula or birth attendant. This paper attempts to explore the scientific evidences from across the globe about the impact of birth companionship on various birth outcomes, especially in terms of maternal satisfaction with birth experience, the need for medical intervention, mode of delivery, duration of labor, Apgar score and the initiation of breastfeeding. This review findings highlights that presence of a birth companion significantly leads to the reduction of the likelihood of medical interventions including caesarean section and a shorter duration of labor, bettering the maternal and neonatal outcomes.

**Keywords:** Birth companionship, Birth outcomes, Parturient, Childbirth, Maternal Outcomes, Neonatal Outcomes.

## INTRODUCTION

Pregnancy is an event moulded by various personal and socio-cultural expectations. Same applies to the event of labor and childbirth. A positive childbirth experience is of paramount importance as it directly relates to the health and wellbeing of the woman and the newborn. There are over 140 million births worldwide each year[1]. For the past two decades, women have been encouraged to give birth in medical facilities to ensure access to skilled care and timely referrals. However, facility-based delivery does not always guarantee quality treatment. In many settings, especially for marginalized groups, women often face disrespectful and degrading care, violating their rights and deterring them from seeking intrapartum services[2]. During labor, holistic support is essential for fostering empathy, respect and well informed decision making. Every woman has the right to have a positive childbirth experience and quality care during labor, which involves communication, respectful treatment and emotional support[2]. The World Health Organization (WHO) defines quality care during labor as comprising of two key elements namely a competent, evidence based clinical care supported by reliable systems and referral networks, and a positive experience of care, including respectful communication, support and respect for women's dignity and autonomy. This care must be delivered at all health system levels by skilled professionals capable of managing complications[1]. Birth companionship is an evidences based low cost beneficial intervention. It involves continuous physical, emotional and informational support to be provided to a woman during labor and childbirth via the presence of a supportive individual of her choice such as a family member like the husband or mother or sister or a friend or a trained doula or birth attendant. The idea of a birth companion supporting a woman during childbirth is believed to date back to prehistoric times, as evidenced by anthropological research and archaeological findings, such as stone sculptures and statues.[3] In India, the concept of a birth companion began to emerge in 2002 when the Christian Medical College, Vellore, a prominent non-governmental hospital in Tamil Nadu, introduced a birth companion service.[4] Giving birth to a life presents with a sense of joy and contentment to the woman, and this feeling exemplifies when powered with the presence of a birth companion[5]. Birth companionship is now viewed as a potential intervention aimed at enhancing the emotional wellbeing of women in labor, reducing the incidence of adverse birth outcomes and improving maternal and neonatal health. With an aim to understand the global scenario of birth companionship's effect on maternal and neonatal outcomes, this review was undertaken.

## METHODOLOGY

**Databases, Selection Criteria and Search Strategies**

For this review, the researchers meticulously searched the electronic databases namely PubMed, Google Scholar, CINHAL PLUS and Research Gate, for studies examining the effect of birth companionship on birth outcomes. The studies which fulfilled the requirements of selection criteria were included in this review.

**Inclusion Criteria**

- Primary scientific literatures published in peer reviewed journals.
- Articles published in English language only.
- Studies published within the duration from 2020 to 2024.
- Studies using any of the qualitative and/or quantitative research design.
- Studies that examined the effect of birth companionship on birth outcomes.

**Exclusion Criteria**

- Studies outside the above mentioned period, language, design and context.
- Papers representing opinion pieces, editorials, conference abstracts without data.

The final search was conducted by using the keywords/MESH terms "Birth Companionship" OR "Labor Companionship" OR "Childbirth Companionship" AND "Birth Outcomes" OR "Maternal Outcomes" OR "Labor Outcomes" OR "Fetal Outcomes".

**Study Selection and Quality Assessment**

Two reviewers independently screened the titles and abstracts of the articles for ensuring its alignment with the objective of this review and the selection criteria and decided on the studies to be retrieved. Potentially relevant full text articles were retrieved and downloaded to the Mendeley desktop reference manager. Prior to screening, the duplicates were removed. All disagreements were discussed and resolved by consensus.

**Data Extraction**

A standardized data extraction tool was developed to identify the objectives, study design, settings, the study group, data collection methods and main findings. Two reviewers independently extracted data about the above and relevant phenomena of interest.

### Findings

Fifteen significant studies that met with the purpose and selection criteria were included in this review, as outlined in table 1. Most of the included studies used a quantitative approach for the research. Five of the included studies were published in the year 2024, whereas the number of studies published in 2023, 2022, 2021 and 2020 were 3, 4, 1 and 2 respectively. Across the reviewed studies, it has been identified that birth companionship have consistently demonstrated positive effects on both the mother's as well as the newborn's health outcomes. The reviewed studies highlighted that all the women who had the support of a birth companion of their choice, reported a significantly improved comfort, emotional wellbeing and satisfaction, while reducing anxiety, labor duration and interventions. It also helped enhance respectful maternity care and postnatal outcomes, though cultural and institutional barriers limited its consistent implementation. Overall, evidence supports integrating birth companions into maternity care to promote positive labor and postpartum experiences.

## DISCUSSION

Birth companionship has increasingly been recognized as a valuable component of maternal care, with strong evidence supporting its benefits for physical, emotional and psychological wellbeing during childbirth. Across multiple studies, the presence of a birth companion has been linked to improve labor outcomes, including shorter labor durations, fewer medical interventions and higher rates of spontaneous vaginal births.[6,7,8]. These improvements also extended to postnatal experiences, with reduced depression and increased maternal satisfaction reported by women supported during labor.[8] Emotional and psychological benefits were further emphasized in studies showing improved maternal emotional status and reduced pain perception due to companion presence.[9,10] Statistically significant findings also confirmed that comfort measures offered by companions greatly enhanced maternal comfort.[11] Respectful Maternity Care emerged as another key theme. Birth companions helped reduce mistreatment and enhanced provider communication and consent practices, particularly in low-resource settings.[7,12,13] Companions often acted as advocates, promoting dignified and respectful care. Despite strong support for the concept among women, a very minimal percentage of them actually had one present during their labor, reflecting systemic and cultural barriers.[14] Factors such as hospital policies, infrastructure limitations, and staff attitudes were cited as key obstacles.[15] Cultural norms also influenced companion choice, with mothers-in-law and mothers most commonly fulfilling the role for emotional support and confidence building.[16] The effectiveness of companion support was shown to depend on their emotional readiness and knowledge. Companions with moderate knowledge and low anxiety provided better support, leading to improved outcomes. [17] Positive perceptions were also linked to prior childbirth education and emotional closeness.[18]

## CONCLUSION

The studies reviewed collectively reinforce the beneficial effects of birth companionship during labor and delivery. The presence of a supportive birth companion can enhance emotional well-being, reduce mistreatment, alleviate pain

perception, improve labor outcomes, and foster a more respectful maternity care environment. As highlighted in the reviewed literature, while challenges remain, especially in low-resource settings, the growing body of evidence emphasizes the need for the global promotion of birth companionship as a key aspect of quality maternal care during labor.

**Table 1: Snapshot of the reviewed studies**

| Study details | Methods | Major findings |
|---|---|---|
| Sonia, Sharma K.[10] Objective of the study: "To assess the effectiveness of birth companion during first Stage of labor and to reduce the level of pain perception." | A Quasi experimental design was employed involving a total of 60 primigravida mothers. The participants were recruited using convenience sampling technique from labor room of Shri Guru Das Hospital and Civil Hospital Amritsar. | Mothers with a birth companion during the first stage of labor reported significantly lower pain perception than those in the control group. |
| Sunidhi, Sharma A.[17] Objective of the study: "To assess the knowledge and anxiety of birth companion in relation to their support during childbirth and the influence of support on the outcome of labor." | A descriptive study was done on 120 primipara women, who were selected by using non-probability purposive sampling technique. The study was conducted at selected hospitals of Mohali district, Punjab, India. | Most birth companions had moderate knowledge and mild anxiety, with their active support linked to shorter labor and reduced maternal distress. |
| Hameed W, Khan B, Bilal IA.[12] Objective of the study: To assess the role of birth companionship on women's experiences of mistreatment during childbirth and postpartum depression. | A cross-sectional study was done among a total of 314 women. These women were selected from six public health facilities in rural Sindh, Pakistan, where they had given birth. | Greater companion support was linked to reduced mistreatment, especially in confidentiality, supportive care and communication. |
| Mousa O, Salameh B, Alqahtani M, David M, Almefarfesh AA, Duaa Al Duhilan, *et al*.[14] Objective of the study: To assess the women's attitudes, prevalence related factors and perceived barriers of birth companionship. | A cross sectional study was done wherein the sample included 1088 women of reproductive age. They were selected through a convenience sampling technique, from various healthcare facilities in Saudi Arabia. | 66.2% of women supported the idea of birth companionship, however only 26.6% reported actually having a companion during labor. |
| Busra DÇ, Burak B, Karaman E, Adam M, Kubra AY, Caganay S *et al*.[8] Objective of the study: To evaluate the impact of companion support during labor on postnatal depression and birth satisfaction. | A prospective cohort study was done involving 280 postpartum women, who were recruited through convenience sampling technique. These participants were recruited from various hospitals of Turkey. | Women with companion support during labor reported less postnatal depression and greater birth satisfaction. |

## ABSTRACT

The present study focuses on the green synthesis of biodiesel from *Crotalaria juncea* seeds oil (CJSO) using a waste-derived calcium oxide nanocatalyst prepared from eggshells. The research aims to develop an eco-friendly, cost-effective, and sustainable route for biodiesel production by valorizing agricultural and domestic wastes. The oil content for the extracted CJSO was found to be 48.30%. It is characterized for its physicochemical properties, including oil content, S.V, I.V, and R.I, confirming its suitability as a biodiesel feedstock. The eggshell-derived CaOnanocatalyst (EgNC) was synthesized through calcination and characterized using DLS, XRD, SEM, and TGA-DTA techniques, which confirmed the formation of highly crystalline, nanosizedCaO particles with enhanced surface area. Transesterification of CJSO was carried out using methanol and the EgNC catalyst under optimized conditions. The produced biodiesel was analyzed for key fuel properties such as density, viscosity, flash point, and cetane number, which were found to comply with ASTM-D6751 and EN-14214 standards. The biodiesel yield for the $(CJBD)_{EgNC}$ was found to be 95.21% with the CV of 42.80KJ/Kg. The results demonstrated that the EgNC exhibited excellent catalytic activity and conversion efficiency, thereby offering a sustainable alternative to conventional catalysts. This study highlighted an integrated approach toward waste-to-energy conversion, aligning with the principles of green chemistry and circular economy for renewable fuel development.

**Keywords:** *Crotalaria juncia*, Eggshell Nanocatalyst, Transesterification and Biodiesel.

## INTRODUCTION

Global interest in producing biodiesel as an environmentally beneficial substitute for fossil fuels has increased due to the rising need for clean, renewable energy sources. Transesterification is the most practical and popular procedure for producing biodiesel, which is the alcohol esters of the combination of fatty acids known as FAMEs made from vegetable oils, microalgae lipids, animal fats, and sewage sludge[1]. In contrast to traditional diesel, biodiesel is regarded as a carbon-neutral, non-toxic, biodegradable, and environmentally beneficial fuel. It is produced using a variety of triglyceride sources, including edible and non-edible oil feedstocks[2]. To get rid the drawbacks of edible oils, non-edible oils have become attractive feedstocks for the generation of biodiesel. Researchers such as Meher *et al*. (2006) and Atabani *et al*. (2013) reported that oils from *Jatropha curcas*, *Pongamia pinnata*, and *Madhuca indica* exhibit suitable fatty acid profiles for biodiesel synthesis[3,4]. An essential bast fiber, *Crotalaria juncea* (sunn hemp) is grown in India as a green fodder crop and used in green manuring. Tropical and subtropical climates are ideal for the crop's growth[5]. Utilizing such non-edible oils also addresses the food-versus-fuel debate and supports rural agricultural value addition. The synthesis of biodiesel depends heavily on the catalytic process. Despite their effectiveness, conventional homogeneous catalysts like potassium and sodium hydroxide present difficulties in product separation and produce large amounts of effluent. Therefore, Heterogeneous catalysis plays a crucial role in the conversion of biomass into renewable energy and petrochemical products and represents a sustainable alternative to fossil fuels[6] After being calcined, leftover chicken eggshells, which are mostly made of calcium carbonate ($CaCO_3$), are a great starting material for the creation of catalysts based on calcium oxide (CaO)[7]. Eggshell-derived CaO catalysts perform on par with or better than commercially available CaO, reported by Viriya-empikul *et al*. (2010)[8]. According to Liu, X. (2008), the biodiesel output after 1.5 hours was not significantly impacted by the repeated trials, and CaO maintained consistent activity even after being employed repeatedly for 20 cycles[9]. Catalytic effectiveness is much improved by further nanoscale modification because of the increased surface area and availability of active sites[10]. The nanosizedCaO derived from eggshells exhibits enhanced surface area and catalytic activity, facilitating efficient transesterification reactions under milder conditions. By turning biological waste into useful catalytic materials, using remaining eggshells for catalyst production not only lessens environmental pollution but also advances a circular economy. The present study aims to synthesize biodiesel using *Crotalaria juncea* seed oil and eggshell-derived CaOnanocatalysts. The work focuses on investigating the physicochemical properties, catalyst preparation, characterization, and evaluation of fuel properties of biodiesel, and comparison with the ASTM-D6751 and EN-14214 standards thereby demonstrating a sustainable route for green energy production. The graphical abstract for the present research work is shown in the figure 1.

## MATERIALS AND METHODS

**Materials**

Crotalaria juncea seeds were collected locally from Jodhpur and oil was extracted using soxhlet apparatus. Waste chicken eggshells were collected from household kitchens, washed, and dried. Analytical grade KOH, diethylether, n-hexane, methanol and other chemicals were used.

**Preparation of EgNC**

Eggshells were cleaned, dried at 110°C, and crushed into powder. To turn $CaCO_3$ into CaO, the fine powder was calcined for three hours at 900°C in a muffle furnace. After cooling, grinding, and sieving, the resultant CaO was reduced to nanoparticles (about 50–100 nm).

**Physicochemical analysis of seed oil**: The physicochemical properties of crude CJSO, including SV, IV, and others, were determined following standard AOCS (1997) methods[11]. The refractive index was measured using an Abbe's refractometer.

**Characterization of seed oil**: The seed oil was characterized by Thermo Fisher Scientific FT-IRinstrument.

**Morphological and Thermal Characterization of EgNC**

**DLS-**TheEgNCparticle size measurement is performed by using Zetasizer Nano ZSP (ZEN 5600) instrument.

**XRD-** TheX-Ray Diffractometer (PanalyticalX'Pert Pro) is a high-precision analytical instrument used for identifying and characterizing EgNC to determine its crystal structure, phase composition, and crystallite size.

**SEM analysis**-The surface morphology of the EgNCcatalyst was investigated using Scanning Electron Microscopy (SEM) with a Nova Nano FE-SEM instrument.

**TGA-DTA analysis**- Thermal stability and decomposition behavior of EgNCanalyzed using Thermogravimetric Analysis and Differential Thermal Analysis (TGA-DTA) via a Perkin Elmer Diamond TG/DTA instrument.

**Transesterification Process**: A 500 mL round-bottom flask fitted with a reflux condenser and thermometer was used for this procedure. The following were the reaction conditions: Temperature: 50°C, catalyst loading: 3 weight %, methanol-to-oil molar ratio: 8:1, and reaction duration: 90 minutes. After reaction completion, the mixture was cooled and allowed to settle. The biodiesel layer was separated with diethylether, washed with warm water, and dried at 105°C.

**Biodiesel Characterization**- The $(CJBD)_{EgNC}$ was characterized by using a Thermo Scientific TSQ 8000 Gas Chromatography-Mass Spectrometry (GC-MS).

**Analysis of fuel properties of biodiesel**: The biodiesel was analyzed for fuel properties such as viscosity, flash point, fire point, pour point, cloud point, cetane number etc. The results were compared with ASTM-D6751 and EN-14214 standards.

## RESULTS AND DISCUSSION

**Physicochemical analysis of seed oil**

The physicochemical properties of CJSO were shown in the table-1. The extracted CJSO showed an oil yield of 48.30%, indicating that sun-hemp seeds are a promising non-edible feedstock for biofuel and industrial applications. The oil content was found within the range reported for the castor seed oil (45% to 50%)[12]. This oil content also compares favorably with many non-edible oilseed crops and supports CJSO as a viable raw material for biodiesel production[13]. The moisture content (5.6%) is reasonably low but should be minimized prior to long-term storage or processing because water increases hydrolysis and soap formation during transesterification. To reduce moisture content the feedstock is dried to eliminate any last traces of moisture after cleaning[14]. The average molecular weight of all the fatty acids in a sample is measured by the saponification value, which significantly affects the quality of the esters[15]. A considerable percentage of comparatively shorter or medium chain fatty acids was indicated by the SV of 198 mg KOH/g. The amount of unsaturated molecules in a sample is indicated by the IV, which has an impact on oxidative stability[16]. Compared to diesel, biodiesel oxidizes far more readily, and the end products of this process alter its physical and chemical characteristics and result in the production of insoluble gums that can obstruct fuel filters and supply pipes[17]. IV of 120 g $I_2$/100 g indicated a high degree of unsaturation in CJSO, which implies better cold-flow properties but greater susceptibility to oxidative degradation. The seeds oil with high IV for biodiesel production may require antioxidant addition or controlled storage to avoid oxidation during storage and use. Even while some studies have demonstrated that the I.V is a measure of the degree of unsaturation, it is not a reliable sign of oxidative stability. For instance, Knothe and Razon's work shown that the oxidation rates of biodiesel rise in proportion to the total number of bis-allylic sites (methylene CH immediately next to the two double bonds)in its structure, rather than the IV or the total number of double bonds[18]. The measured RI (1.47) and relative density (883 $kg \cdot m^{-3}$) for the CJSO fall within the typical ranges reported for vegetable oils, confirming the sample's identity and comparability with other seed oils used for fuel and industrial applications. The

FFAs content (2.1%) is above the ideal threshold (<1%) for transesterification; therefore, a pre-treatment (glycerolysis) is recommended to reduce FFAs and avoid soap formation and catalyst deactivation during biodiesel production[19]. The unsaponifiable matter (1.8%) is within typical ranges for crude vegetable oils; this fraction may contain sterols, tocopherols, pigments and other minor components. Physicochemical properties of CJSO Table 1.

**FT-IR analysis:** The FT-IR spectrum (Figure-2) of CJSO confirmed the presence of major functional groups typically associated with natural triglyceride-based oils. The obtained FT-IR spectrum displayed well-defined absorption bands corresponding to the stretching and bending vibrations of carbon–hydrogen (C–H), carbon–oxygen (C–O), and carbonyl (C=O) functional groups. Soon *et al*. claim that the location of the carbonyl group is dependent on the substituent's effects and the molecular structure[20]. These spectral features are indicative of ester linkages and long-chain fatty acids, which are the fundamental constituents of triglycerides. The presence of these characteristic peaks validates the lipid nature of the CJSO and confirms that the extraction process preserved its structural integrity without significant degradation. The detailed interpretation of the observed absorption bands and their corresponding functional group assignments is summarized in-Table 2. FT-IR Spectrum of CJSO Figure 2.

**Characterization of EgNC**.

**DLS analysis**

DLS analysis of the synthesized EgNC (Figure-3) revealed a narrow and monodisperse particle size distribution, with a sharp peak centered around 35–40 nm. The peak intensity of nearly 70% indicates that most nanoparticles fall within this size range, while the absence of secondary peaks confirms minimal aggregation and uniform particle formation. These results demonstrated that the CaOnanocatalyst is well-dispersed, consistent, and entirely within the nanoscale, making it highly suitable for catalytic applications due to its enhanced surface area and uniform particle behavior.

**TGA-DTA analysis**

The TGA-DTA analysis of the EgNC (Figure-4) shows characteristic thermal events confirming its formation. The TGA curve indicates initial weight loss at 100–200 °C due to moisture removal, a second stage at 200–400 °C from decomposition of organic residues, and major weight loss at 500–700 °C corresponding to the decomposition of $CaCO_3$ into CaO and $CO_2$. Correspondingly, the DTA curve exhibits an endothermic peak around 100 °C for water evaporation, crystallization, decomposition of organic impurities, or change in the structural arrangement of compound[21]. An exothermic transition near 300°C from organic decomposition, and a strong endothermic peak at ~600 °C representing $CaCO_3$ decomposition. These results validate the thermal stability and successful calcination of CaOnanocatalyst. The TGA-DTA profile clearly indicates a multi-step decomposition process. The major thermal event occurs between 500–700 °**C**, which corresponds to the calcination of calcium carbonate ($CaCO_3$) into calcium oxide (CaO), which is acrucial step in forming the EgNC. The absence of further weight loss after 700 °C confirms the completion of calcination and the formation of a thermally stable CaO nanomaterial[22]. The thermogravimetric analysis (TGA) and differential thermal analysis (DTA) curves provide vital information about the thermal behavior and phase transitions of the calcium oxide nanocatalyst. The TGA-DTA interpretation has been shown in the table-3. TGA-DTA interpretation Table 3. TGA-DTA graph for the EgNC (Figure-4).

**SEM analysis**

FE-SEM analysis of the EgNC (Figure-5) reveals a highly irregular and porous surface composed of aggregated nanoparticles with rough, sponge-like structures. According to the report of El-Gendy *et al*, (2014), this porosity comes due to the escape of a large number of gaseous water molecules upon decomposition of $CaCO_3.H_2O$[23]. The nanoscale particles (below 100 nm) form clusters due to strong inter-particle interactions during calcination, resulting in a large surface area. This porous and uneven morphology enhances the accessibility of active sites and facilitates reactant diffusion, making the nanocatalyst highly suitable for biodiesel synthesis by promoting efficient contact between the catalyst and oil molecules. The nano-scale size and the porosity are the most appropriate characteristics of a catalyst for high catalytic activity[24]. These observations suggested that EgNC has high catalytic activity.

**XRD Interpretation for EgNC**

The XRD pattern of the EgNC (figure-6) shows sharp and intense peaks at 2θ ≈ 40°, 57°, 63°, and 69°, corresponding to the (111), (200), (220), and (311) planes of calcium oxide, indicating high crystallinity. The absence of additional peaks or broad humps confirms phase purity and minimal amorphous content.In the XRD pattern, it was confirmed that there is a formation of calcium oxide with cubic phase[25]. These results validate the successful synthesis of pure, crystalline CaO nanoparticles through calcination, ensuring structural integrity and suitability for catalytic applications.

**Figure-6 XRD Pattern for the EgNC**

**GC-MS interpretation of (CJBD)$_{EgNC}$**

The fatty acids composition of (CJBD)$_{EgNC}$ was shown in the table-4. The GC-MS spectrum for the same is given in the figure-7.

**Fatty acids composition of** (CJBD)$_{EgNC}$ **Table 4.**

**Figure 7: GC-MS spectrum of (CJBD)$_{EgNC}$**

The (CJBD)$_{EgNC}$ is found high in PUFAs with Linoleic acid (38%) followed by oleic acid (35%). The presence of PUFA may lead to poor oxidative stability and may necessitate the use of antioxidants to stop deterioration. Fortunately, however, palmitic acid, a naturally occurring antioxidant that makes up 19% of saturated fatty acids, gave the (CJBD)$_{EgNC}$ excellent oxidative stability. Because of their inherent antioxidant activity, (CJBD)$_{EgNC}$ contains a balanced mix of saturated and unsaturated fatty acids, suggesting high oxidative stability without the need for additions. These previously mentioned findings highlighted the CJSO's viability for biodiesel synthesis due to its oxidative stability and fatty acid compositions[26].

**Fuel properties analysis**: The biodiesel produced from CJSO using EgNC exhibited fuel properties (table-V) within ASTM-D6751 and EN-14214 standards. It showed appropriate kinematic viscosity (2.2 $mm^2/s$) and specific density (890 $kg/m^3$) for efficient atomization and combustion In chilled conditions, the minimum temperature at which crystallization of paraffin or its tendency to be separated in ice-cold in proposed conditions is known as cloud point[27]. The temperature that allows fuel to flow is called the pour point. (CJBD)$_{EgNC}$ has reported cloup point -5°C and pour point-15°C respectively. A low pour point (-15°C) suitable for safe storage and good cold flow, with a cetane number of 57, indicating favorable energy content and ignition quality. The AV or neutralization number is the amount of carboxylic acid utilized or the presence of FFAs in the sample of fuel taken as mg KOH/gm required to neutralize FAMEs (1 g). The high number of AV affects the engine efficiency. It results in internal engine functioning and system corrosion. Within the acceptable parameters, the AV reported from (CJBD)$_{EgNC}$ was 0.04 (mgKOH/g). The acid value of sunflower oil showed a similar outcome[28]. The ability of a liquid to create a flammable mixture is measured by its flashpoint. If fuel has a high flash point, it may be safely moved, stored, or handled for utilization[29]. The (CJBD)$_{EgNC}$ stated flash point is 135°C. Since diesel has a flashpoint of 53°C and high speed diesel has a flashpoint of 60–80°C, the fuel with such a high flash point is safe to use. A fuel's CV, sometimes referred to as its heating value, is a crucial indicator of its energy content. With a CV of 42.80 MJ/kg, (CJBD)$_{EgNC}$ is found comparable to gasoline and diesel[30]. Ong *et al*, (2013) found that CV of Jatropha biodiesel was 38.96 MJ $kg^{-1}$[31]. The non-edible Chinaberry Seed Oil, cannabis sativa, and *Koelreuteria paniculata* all reported to have approx. 95% biodiesel yield similar to the (CJBD)$_{EgNC}$ 95.21%[32-34]. Fuel properties of (CJBD)$_{EgNC}$ compared with ASTM-D6751 and EN 14214 standards [35,36] Table-5.

## CONCLUSION

In this study using EgNC and a transesterification method, biodiesel was successfully produced from CJSO. 48.30% of the oil is extracted from Crotalaria juncea seeds. Techniques including DLS, SEM, XRD, and TGA-DTA were used to describe the EgNC. With significant triglyceride to FAMEs conversion, the EgNC showed excellent catalytic

efficiency. CJSO produced a biodiesel output of 95.00%, which is excellent for commercial use. The fuel characteristics of synthesized $(CJBD)_{EgNC}$ such as its kinematic viscosity, flash point, pour point, CV, cetane number, and ash content, were determined to be within the permissible ranges given by ASTM-D6751 and EN-14214 standards, suggesting that it is suitable as an alternative diesel fuel. The full conversion of crude oil to FAMEs was verified by GC-MS analysis. On the basis of aforementioned analysis the biodiesel made CJSO using EgNC provides an environmentally favorable, economically viable, and renewable biodiesel synthesis pathway, encouraging waste valorization and supporting the development of sustainable energy.

## ABSTRACT

*Sarvajwarahara loham* is an herbomineral formulation mentioned in the classical text of Rasendra Sara Sangraha, which is mainly indicated in treating all types of *Jwara*. This study aims to prepare the *Sarvajwarahara loham* as per the classical text and conduct an analytical and antimicrobial study of the prepared sample. The ingredients of Sarvajwarahara loham are *Chitraka, Triphala, Trikatu, Vidanga, Mustaka, Gajapippali, Pipali moola, Usira, Devadaru, Kiratatikta, Patha, Katuki, Kantakari, Sobhajana, shigru beeja, madhuka, vatsaka, loha Bhasma.* To scientifically evaluate *Sarvajwarahara loham*, a pharmaceutical-analytical and antimicrobial study was undertaken. The pharmaceutical study focused on standardizing the preparation method, while the analytical study assessed basic physicochemical parameters to ensure quality and consistency. Additionally, an antimicrobial study was conducted to assess its efficacy against *Staphylococcus aureus and Pseudomonas aeruginosa*, two clinically significant bacterial pathogens. The Result of the study was that the sample is an effective inhibitor in this study and showed antimicrobial activity against *Staphylococcus aureus* and *Pseudomonas aeruginosa* with 10% and above sample concentration.

**Keywords:** *Sarvajwarahara loham*, herbo mineral formulation, *Jwara, Rasendra Sara Sangraha, antimicrobial study*

## INTRODUCTION

Ayurveda, the ancient science of life, aims to maintain healthy individuals' health and cure diseases in the afflicted. For its continued growth and integration with modern medical sciences, it is essential to evaluate classical formulations using contemporary scientific parameters. *Jwara* is one of the most common ailments affecting the global population, and classical Ayurvedic texts mention numerous *Jwarahara Yogas* (antipyretic formulations) for its management. However, understanding their precise mechanism of action and therapeutic efficacy requires systematic research. Rasashastra, which primarily deals with mineral and Herbo mineral formulations, plays a significant role in Ayurvedic therapeutics. Given the increasing demand for evidence-based validation, rigorous research is essential to assess these formulations' safety, efficacy, and pharmacological potential. One such classical preparation, *Sarvajwarahara loham* [1], is described in the *Rasendra Sara Sangraha* and is indicated in the treatment of all types of *Jwara.* This formulation is unique due to its synergistic blend of potent herbs and one mineral drug, including *Chitraka, Triphala, Trikatu, Vidanga, Musta, Gajapippali, Pippali Moola, Ushira, Devadaru, and Louha Bhasma*. These ingredients are known for their *Deepana, pachana jwaraghna* and *krimighna* properties.

## AIMS AND OBJECTIVES

1. To prepare *Sarvajwarahara loham*[1].
2. To carry out qualitative and quantitative analysis of *Sarvajwarahara loham*[2].
3. To evaluate the Anti-Microbial activity of *Sarvajwarahara loham* With Special Reference to *Stephylococcus aureus and Pseudomonas aeruginosa*[3].

## MATERIALS AND METHODS

Showing ingredients and their proportion for preparing *Sarvajwarahara loham*[2]. (Table 1)

**Pharmaceutical Study[1]**
Pharmaceutical study involves the preparation of *Sarvajwarahara loham* according to the classical text of Rasendra *Sara Sangraha*. All the drugs mentioned in Table No. 1 were taken in equal quantities. Powdered separately and mixed homogeneously in *khalva yantra*. The obtained product was stored in air tight container.

**Analytical Study [2]**
This part deals with the analysis of organoleptic, physiochemical, quantitative, and advanced analytical parameters of the prepared sample of *Sarvajwarahara loham*.

**Antimicrobial Study[3]**
The prepared sample of *Sarvajwarahara loham* was studied for its antimicrobial activity on *Staphylococcus aureus* and *Pseudomonas aeruginosa*.

**Aim of the Study:** The study aims to evaluate the antimicrobial activity of Sarvajwarahara Lauha against specific pathogens, namely *Pseudomonas aeruginosa* and *Staphylococcus aureus*.

**Method Used:** The study follows the Antimicrobial Activity Testing protocol as per API Part-1 Volume-9. The method involves product validation, preparation of bacterial suspensions, and antimicrobial challenge testing using selective agar media.

**Steps Followed[3]**
**Product Validation (Product Control Analysis)**

To rule out any interference in the antimicrobial study, 1g of the sample was transferred into 9mL of pre-enrichment soybean casein digest broth (SCDM) and incubated at 37°C for 24-48 hours. The sample was then subcultured onto Cetramide agar (for *P. aeruginosa*) and Mannitol Salt agar (for *S. aureus*) under the same incubation conditions for 18-24 hours, and typical bacterial growth was observed.

**Preparation of Cell Suspension**

Saline suspensions of both *P. aeruginosa* and *S. aureus* were prepared, adjusting bacterial contamination to approximately 1000 CFU/mL. The antimicrobial challenge study was conducted in five repetitive trials using different sample concentrations (10%, 20%, 30%, 40%, and 50%) in pre-enrichment SCDM broth. The samples were incubated for 24-48 hours, followed by sub-culturing onto selective plates (*P. aeruginosa* on Cetramide agar and S. aureus on Mannitol Salt agar) for further analysis.

**Confirmation with Neutralizing Buffer**

The test was repeated with a neutralizing buffer (4% polysorbate-20) to validate antimicrobial efficacy by ruling out any inhibitory effects caused by the sample matrix.

## OBSERVATIONS AND RESULTS

**Pharmaceutical study**

**Showing information on practical, quantity and the time taken for the pharmaceutical study (Table no 2)**

**Analytical Study**

**Organoleptic characters of *Sarvajwarahara Loham*[4] (Table no 3)**

The organoleptic tests are the physical tests that are done with the help of the five sense organs.

**Physio-chemical analysis of *Sarvajwarahara Lauha* (Table No. 4)**

**Analysis of microbial contamination in *Sarvajwarahara Lauha* (Table No. 5)**

**Antimicrobial study[5]**

**This study was conducted as per API-Method of Testing:** API Part-1 Volume-9

**Study:** Antimicrobial Activity on specific pathogens namely *Pseudomonas aeruginosa* and *Staph. aureus*

**Step-1** Involved product validation (Product Control Analysis for above-mentioned pathogens), to rule out any possible interference in the antimicrobial study (1g sample was transferred into 9mL pre-enrichment soybean casein digest broth (SCDM) and incubated for 37$^0$C for 24-48hrs, later sub-cultured onto Cetramide and Mannitol Salt agar plates with same temperature and 18-24hrs incubation conditions and observed for typical growth.

**Step-2** Preparation of cell suspension with saline for both pathogens separately and selected bacterial contamination with approximately 1000 CFU/mL for Antimicrobial challenged study. The test was done in 5-repetitive trials with 5 different sample strengths 10, 20, 30, 40 and 50%, suspended in pre-enrichment SCDM broth and incubated for 24-48 hours. Later subcultured onto selective plates (*P.aeruginosa* on Cetrimide agar plate and *Stap. aureus* on Mannitol Salt agar plate) refer to Step-1

**Step 3** Same test repeated as in step 2, but in this case, sample neutralizing buffer (4% polysorbate-20) was used.

**Remarks:** The sample is an effective inhibitor in this study and showed antimicrobial activity against *Staphylococcus aureus* and *Pseudomonas aeruginosa* with 10% and above sample concentration.

## DISCUSSION

The present study evaluated Sarvajwarahara Loham through pharmaceutical standardization, analytical assessment, and antimicrobial activity testing. The pharmaceutical study ensured adherence to classical preparation methods, confirming that the formulation maintained its traditional integrity. The analytical study established its physicochemical characteristics, ensuring quality and consistency. Parameters such as total ash, water-soluble ash, acid-insoluble ash, and pH were within acceptable limits, suggesting stability and bioavailability. The absence of aflatoxins and microbial contaminants highlights the formulation's safety. The antimicrobial study demonstrated that Sarvajwarahara Loham exhibited notable efficacy against *Staphylococcus aureus* and *Pseudomonas aeruginosa*, two clinically significant bacterial pathogens. These microbes are known to cause a wide range of infections, particularly in immunocompromised individuals. The formulation showed antimicrobial activity at concentrations of 10% and above, indicating a concentration-dependent response. The synergistic action of its herbal and mineral components, such as Triphala, Trikatu, Vidanga, and Loha Bhasma, may contribute to its antimicrobial potential. Previous studies on individual ingredients suggest that Triphala possesses broad-spectrum antimicrobial properties, Trikatu enhances bioavailability, and Loha Bhasma exerts immunomodulatory effects. The combination of these ingredients may enhance the formulation's efficacy, supporting its classical use in managing Jwara (fever) and associated infections. However, further studies, including *in vivo* and clinical trials, are necessary to establish its pharmacokinetics, mechanism of action, and clinical efficacy.

## CONCLUSION

Sarvajwarahara Loham, a classical herbo-mineral formulation, was successfully prepared and evaluated for its pharmaceutical, analytical, and antimicrobial properties. The formulation demonstrated significant antimicrobial activity against *Staphylococcus aureus* and *Pseudomonas aeruginosa*, validating its traditional use in fever management. Analytical assessments confirmed its physicochemical stability, safety, and standardization. This study bridges traditional Ayurvedic wisdom with modern scientific validation, reinforcing the therapeutic potential of Sarvajwarahara Loham. Future research should focus on elucidating its exact mechanism of action, evaluating its clinical efficacy through controlled trials, and exploring its potential applications in antimicrobial resistance management. The integration of such validated formulations into modern healthcare could provide a natural and effective approach to infection management.

## ABSTRACT

Groundwater is a crucial source of drinking water in Nuapada District, Odisha. However, it is susceptible to contamination from both natural and human-induced activities such as agriculture and industrial discharge. This study aimed to evaluate the quality of groundwater in the Boden Block and determine its suitability for human consumption using the Water Quality Index (WQI). A total of 46 groundwater samples were collected from various villages, and key parameters like pH, temperature, turbidity, calcium hardness, total hardness, TDS, EC, alkalinity, and major ions ($Ca^{2+}$, $Mg^{2+}$, $Na^{+}$, $K^{+}$, $Cl^{-}$, $SO_4^{2-}$, $HCO_3^{-}$, $NO_3^{-}$, $F^{-}$) were analyzed. GPS was used to record the spatial locations of the sampling points. GIS and statistical tools were employed to assess the Drinking Water Quality Index (DWQI). The results classified water quality into four categories: excellent, good, poor, and very poor. Most areas showed good water quality during the pre-monsoon season but declined to poor quality post-monsoon. Major issues included over-extraction, agricultural runoff, and pollutant discharge. The study highlights the urgent need for sustainable groundwater management and regular monitoring to safeguard drinking water quality.

**Keywords:** Water Quality Index(WQI), Groundwater quality, Statistical and GIS method, Drinking water, Nuapada.

## INTRODUCTION

Groundwater is an essential source of water for both rural and urban areas in many countries [1].The water resources being limited, effective water resource management and taxation are necessary, especially when the water is

intended for consumption [2]. Poor drinking water quality can lead to widespread severe and chronic illnesses and is a major cause of mortality in several countries [3,4]. Understanding the chemical composition of groundwater involves analyzing complex hydrogeochemical processes such as cation exchanges with nearby geological layers, dissolution and precipitation of minerals, evaporation, and oxidation-reduction reactions. Grasping these processes is crucial for insights into rock–water interactions that impact groundwater quality. These processes contribute to the spatial and temporal variations in groundwater chemistry [5]. Therefore, monitoring and assessing groundwater for drinking and irrigation purposes is essential for sustainable and safe water use. The Water Quality Index (WQI) is a powerful tool for assessing water quality, providing a single, concise number that reflects the overall water quality for drinking purposes. This index helps policymakers and reassures concerned citizens about water safety [6]. Various methods have been developed for calculating the WQI, considering similar physical and chemical parameters but differing in their statistical integration and interpretation [7]. Traditional methods of evaluating water quality involve comparing experimentally determined limits with local or international standards, which helps identify contamination sources and ensure legal compliance. However, these methods do not provide a global view of spatial and temporal trends in overall water quality [8]. Numerous studies have proposed the use of WQI [9,10 and 11], highlighting its importance in indicating groundwater quality for drinking purposes [12]. Geographical Information Systems (GIS) have also been applied to assess groundwater quality in deep aquifers, particularly in Indian research provinces, demonstrating the suitability of groundwater for drinking purposes [13,14]. In the hard rock terrain of the Boden block, part of the eastern ghat extension and Chhattisgarh plateau, groundwater is primarily used for drinking and irrigation. Geographic Information Systems (GIS) have become an essential tool for managing spatial data and addressing diverse issues, particularly by incorporating spatiotemporal variability into evaluation and decision-making (15). This study aims to assess groundwater quality for drinking purposes using the Water Quality Index (WQI) while demonstrating the role of GIS. A total of 15 parameters were analyzed, including pH, electrical conductivity (EC), total hardness (TH), total dissolved solids (TDS), alkalinity, sodium ($Na^+$), potassium ($K^+$), calcium ($Ca^{2+}$), magnesium ($Mg^{2+}$), nitrate ($NO_3^-$), bicarbonate ($HCO_3^-$), chloride ($Cl^-$), sulphate ($SO_4^{2-}$), fluoride ($F^-$), and iron (Fe).

**Study area**

Boden block, situated in the southwestern part of Nuapada District, Odisha, lies on the southeastern edge of the Chhattisgarh plateau. The region experiences a tropical monsoon climate, with summer temperatures between 35–40 °C and winter temperatures ranging from 12–25 °C. Average annual rainfall is 1247 mm, though winters are generally dry. Boden is bordered by Komna block to the north, Khariar block to the east, Sinapali block to the south, and Chhattisgarh to the west. The total area of the block is approximately 455.00 sq. km (Fig. 1).

## MATERIAL AND METHODOLOGY

The study presents a detailed assessment of groundwater quality in Boden block, Nuapada, Odisha, using multiple data collection and analytical approaches. The study area is mapped using the UTM 44N projection and WGS 1984 datum. Field and laboratory investigations were conducted, with groundwater samples collected from handpumps and dug wells at 50 different locations. A total of 46 samples were analyzed following the standard procedures outlined by APHA (1995). The locations of the sampled points are shown in Fig. 2, and the statistical analysis of groundwater quality is presented in Table 1. Location map of the study area. Figure 2: Sample station of the study area (Figure 1). Several methodologies are applying for the investigation of the groundwater of Boden block, Nuapada district, Odisha. The methods are given below;

**Sample collection and physicochemical analysis**

Groundwater samples from 46 locations in Boden block, Nuapada District, Odisha, were collected during February–March (pre-monsoon) and September–October (post-monsoon) in pre-cleaned one-liter HDPE bottles (16, 17), transported to the Applied Geochemistry Department laboratory and stored below 4 °C for physicochemical analyses (Fig. 2), where pH, EC, and TDS were measured on-site using a Hanna HI 9811-5 meter, and all other parameters—

including $SO_4^{2-}$, $NO_3^-$ (UV-visible spectrophotometer), $Cl^-$ ($AgNO_3$ titration), $Mg^{2+}$ (MgH = TH – CaH; $Mg^{2+}$ = MgH × equivalent weight × EDTA normality), TH and $Ca^{2+}$ (EDTA titration), $Na^+$ and $K^+$ (flame photometer), $HCO_3^-$ ($H_2SO_4$/methyl orange method), and $F^-$ (ion-selective electrode with 2 mL TISAB III in 20 mL sample using 0.1–10 mg/L standards from 100 mg/L stock)—were analyzed following APHA guidelines, with all procedures summarized in Table 1.

**Accuracy of chemical analysis method**

The accuracy of the physicochemical analysis of individual groundwater samples was computed using Equation 1 (Saeed *et al*., 2021).

$$\text{IBE\%} = (\sum \gamma c - \sum \gamma a)/(\sum \gamma c + \sum \gamma a) \times 100$$

where IBE is the ionic balance error, "γc" represents the sum of cations sum ($Na^+$, $K^+$, $Mg^{2+}$, and $Ca^{2+}$) and "γa" is the sum of anions ($HCO_3^-$, $Cl^-$, $SO_4^{2-}$, $F^-$, and $NO_3^-$). All cations and anion concentrations are expressed in milliequivalent per litre (meq/L). The highest IBE was 8.75%, which was below the standard limit of ±10%, demonstrating that the physicochemical analysis was accurate [21].

**Spatial distribution maps and Diagram Method**

The correct sampling region was identified using a handheld Global Positioning System (GPS) device (Garmin GPS eTrex 20). The geographical coordinates were then entered into the Geographic Information System (GIS) program. A spatial distribution map of water quality parameters was prepared using ArcGIS version 10.6, employing the spatial statistical analyst component and interpolation techniques .

**Groundwater quality index (GWQI) method**

GWQI has widely been used to evaluate groundwater quality for drinking purposes in various regions of the world . The following steps play a major role in estimating the GWQI:

**Assigning weights (wi):** a maximum weight of 5 has been assigned to parameters such as $NO_3^-$ and $F^-$, due to their major importance in groundwater quality evaluation, and the least was given to $Na^+$, and $K^+$ (Table 2).

**Calculation of relative weight** (Wi): a relative weight (Wi) is computed by the following equation:

$$Wi = \frac{wi}{\sum_i^n wi}$$

where "Wi" is the relative weight, "wi" is the weight of each parameter and "n" is the number of parameters (Table 3.a. and 3.b.).

**Quality rating** (Qi): a quality rating scale (Qi) for each parameter is derived by its concentration in each water sample by its respective standard according to the WHO guidelines and then multiplied by 100. Eventually, the calculation of Qi is shown below:

$$Qi = \frac{ci}{si} \times 100$$

where Ci is the concentration of each groundwater quality parameter, Qi is the quality rating, Si is the recommended guideline value for each chemical parameter.

**Sub-index (SIi), and GWQI**: sub-index (SIi) and GWQI were computed by the following equations: -

$$Sli = Wi \times Qi$$

$$GWQI = \sum_{i=0}^{n} Sli$$

Where SIi is the sub-index of the ith parameter, Qi is the rating based on the concentration of the ith parameter, and "n" is the total number of parameters. These types were classified into five groups [22], as shown in Table 4.

## RESULTS AND DISCUSSION

**Hydrochemical results**

Groundwater quality is most significant as it is the key factor determining its correctness for drinking purposes in the study area. The numerous chemical parameters of groundwater samples were analysed and their expressive statistics (minimum, maximum, mean and standard deviation) are demonstrated in Table 3.a. and 3.b.This data was taken from the field in the pre-monsoon and post-monsoon period. Additionally, the results were associated with the World Health Organization (WHO, reports) to comprehend the suitability for drinking water purposes in the study region (Table 3.a. and 3.b.). Instrumental, titrimetric and calculation methods used for chemical analysis of groundwater samples of the hard rock aquifers of Boden, Nuapada district, Odisha, India (Table 1). List of groundwater quality parameters, along with their relative weights, used in the computation of the Groundwater Quality Index (GWQI) (Table 2). Relative Weight of the Groundwater Quality Index of the study area (Figure 3). Table 3.a.(Pre-Monsoon)and 3.b.(Post-Monsoon) Groundwater samples of the study area exceed the maximum permissible limits (MPL) prescribed by WHO 2017 for domestic purposes. SD: Standard deviation. HDL: Highest Desirable Limit. MPL: Maximum Permissible Limit. PSEMPL: Percentage of samples exceeding the maximum permissible limit. Result of groundwater quality index (GWQI) value in study region (Pre monsoon) (Table 4). Result of groundwater quality index (GWQI) value in the study region (Post monsoon) (Table 5). Classification of groundwater for drinking purpose based on GWQI at Boden Block (Table 6). In summary, the groundwater in the study area is predominantly alkaline, with pH values ranging from 6.50 to 7.89 during the pre-monsoon season and 7.02 to 7.96 in the post-monsoon season, averaging 7.34. As per WHO guidelines, the maximum permissible pH for drinking water is 8.50, and only 15% of the samples exceed this limit.

The spatial variation of pH across the study area is depicted in Fig. 7(a) and 7(b). pH remains a key indicator of groundwater quality (23). Groundwater quality is often evaluated through electrical conductivity (EC), which reflects the concentration, type, and mobility of ions in the water. In the study area, EC values ranged from 441 to 4230 μS/cm, with a pre-monsoon mean of 984.15 μS/cm and a post-monsoon mean of 1129.50 μS/cm (Table 3a and 3b). Based on standard classification, 98% of the samples indicate moderate salinity, while only 2% fall under type III. The spatial distribution of pre-monsoon and post-monsoon EC is shown in Fig. 7c and 7d. Similar EC ranges have also been observed in the coastal aquifers of Chaouia, Morocco. Figure4 a. and b. pre-monsoon and post-monsoon pH and c. and d. pre-monsoon and post-monsoon Electrical conductivity of the study area. In the Boden block study area, Nuapada District, Odisha, groundwater $Mg^{2+}$ concentrations ranged from 7.78 to 191.48 mg/L with a mean of 89.66 mg/L, exceeding the WHO permissible limit of 150 mg/L in some central and eastern locations, likely due to magnesium-bearing minerals and anthropogenic inputs (Fig. 9a and b, Table 3a and 3b). Calcium ($Ca^{2+}$) levels varied from 20 to 211.62 mg/L, averaging 111.62 mg/L, with all samples within the permissible range of 75–200 mg/L (Fig. 9c and d, Table 3a and 3b). Total dissolved solids (TDS) ranged from 306 to 2704 mg/L, with 47.17%, 45.28%, 3.77%, and 1.89% of samples classified as desirable for drinking, permissible for drinking, quite suitable for irrigation, and suitable for irrigation, respectively (Table 4), consistent with observations from Central Northern Bulgaria and Barishal district, Bangladesh [24, 25].

Total hardness (TH) varied from 120 to 1125 mg/L with a mean of 367 mg/L, and only 11% of samples exceeded the 500 mg/L limit; based on Sawyer and McCarty [26], groundwater ranged from very soft to extremely hard, with high TH mainly in the eastern and southern areas (Fig. 8c and d, Table 5), posing potential kidney health risks [27]. Sodium ($Na^{+}$) concentrations ranged from 12.46 to 348 mg/L (mean 67.01 mg/L), higher in the eastern pre-monsoon and southern post-monsoon areas, while potassium ($K^{+}$) ranged from 0.004 to 87.04 mg/L (mean 5.14 mg/L), comparable to values in Nový Kostel, Czech Republic [28] (Figs. 10a–d, Table 3a and b). Chloride ($Cl^{-}$) levels varied from 16 to 589.82 mg/L with a mean of 112.8 mg/L, showing higher concentrations in the southern pre-monsoon and

southeastern post-monsoon regions (Fig. 11a and b, Table 3a and b). Overall, these data indicate spatial variability in major ions influenced by natural geochemistry and anthropogenic factors, with some parameters exceeding WHO limits, highlighting the need for localized water quality management. The extreme attentiveness of $Cl^-$ in groundwater is considered an index of consideration of pollution [29]. The $Cl^-$ concentration in the groundwater varies widely and ranges from 16 to 589.82 mg/L. The concentration of HCO3- varies between 104 and 664 mg / L, with a intend worth of mg / L in the groundwater of the survey location (Table 3. a and b). A spatial distribution map of HCO3- was displayed in Fig. 11. c and d, denoting that higher concentration was complied with in the northern part, whereas low concentration was noticed in the south-eastern component of the survey location. The parallel value of Bicarbonate is located in Mulugu-Venkatapur Mandals, Warangal district, Telangana, India [30]. The SO42- concentration in groundwater samples differed between 3. 67 and 1799. 81; the ordinary worth was 70. 16 mg / L(Table 3. a and b), specified that all sampling sites were within the highest permissible restrain of 400 mg / L(WHO 2017; Table 3. a and b). Fig. 12.a and b display the spatial distribution map of SO42- in pre-monsoon and post-monsoon in the survey location.

According to WHO, the maximum permissible limit of sulphates is 400 mg/L [31],parallel value of sulphates is found at the semi-arid region of Anantapur, Andhra Pradesh State, South India [32]. In the survey location groundwater, the concentration of NO3- contrasting with 0.15 to 174 mg / L, with an ordinary worth of 49. 78 mg / L(Table 3. a and b) . The spatial distribution map of NO3- in the survey location is depicted in Fig. 12. c and d, and a higher concentration of NO3- might be seen from southern to north in pre-monsoon and north-eastern, central and south-western parts of the survey location. In the study region groundwater, the concentration of NO3- an average value of 49.78 mg/L, similar value is located in the Htantabin township of the deltaic region of southern Myanmar [33]. The concentration of F- ranged from 0. 01 to 3. 16 mg / L, with a intend of 0. 55 mg / L in the groundwater of the survey location (Table 3. a and b). In the comparison with the WHO guidelines, 51 % of the groundwater samples were disagreeable for consuming aims in the survey location. Consumption of this elevated fluoride-containing water may result in dental and skeletal fluorosis in the survey location. Consumption of this high fluoride-containing water may principal to dental and skeletal fluorosis in the study region[34]. The concentration of the mean F- value is 0.55 mg/L in the groundwater, similar value is located in the River Swat basin, Pakistan [35]. Figure 5: a. and b. pre-monsoon and post-monsoon Total dissolved solids and 5.c. and d. pre-monsoon and post-monsoon Total hardness of the study area. Figure 6: Final map of GWQI in project area. Distribution of GWQI (Figure 7).

## CONCLUSIONS

Groundwater is the most important source of water for consumption and domestic aims in the difficult rock terrain of Boden Block, Nuapada District, and Odisha, India. Therefore, to comprehend the quality of groundwater in the survey region, groundwater samples were collected, analysed and assessed for imbibing water quality limits. Furthermore, spatial distribution and water quality index were employed to assess the groundwater quality in the survey location. The groundwater in the study area is generally neutral to slightly alkaline (pH 7–8.5), making it suitable for agriculture and human consumption, depending on other dissolved minerals. However, nitrate ($NO_3^-$) levels are 3.5 times above the recommended limit, particularly in the southern and north-central-southern regions, posing health risks such as methemoglobinemia in infants and potential long-term chronic diseases. Additionally, fluoride concentrations reach up to 3.16 mg/L in the southern and eastern parts, exceeding the safe limit of 1.5 mg/L and potentially causing dental and skeletal fluorosis along with other health issues. Despite these elevated nitrate and fluoride levels, the overall groundwater quality is considered good for drinking according to the Groundwater Quality Index (GWQI), indicating that most other water quality parameters are within safe limits, although localized treatment may be necessary in areas with higher contaminant concentrations.

## ABSTRACT

Metformin has been known for glycemic control and has become a leading first line treatment for type 2 diabetes mellitus (T2DM). recent studies emphasize its effect on mitochondrial function, lysosomal pathways, gut microbiome. Based on these findings, metformin may be a drug repurposed with anti-inflammatory, immunomodulatory and antiproliferative properties. Metformin's therapeutic potential in cardiovascular, neurodegenerative, oncological, and infectious diseases is reviewed. Metformin also improves endothelial function, reduces oxidative stress, and promotes vascular repair in cardiovascular health, and it is beneficial in populations other than diabetics. In conditions such as Parkinson's disease, AMPK activation, mitochondrial regulation and reduction of $\alpha$-synuclein aggregation are its neuroprotective effects. Metformin's anticancer activity is exerted through AMPK/mTOR pathway activation, tumor metabolism disruption and immune modulation, and it has a potential to treat cancers like breast, colorectal, and prostate. Furthermore, it may be used to manage COVID-19 complications and help with tuberculosis therapy through the use of host directed mechanisms. Metformin possesses favorable safety profile, affordability and well characterized pharmacokinetics and could be repurposed in several clinical settings. But there are still many aspects of its diverse mechanisms that are not understood and few answers to the question of optimal dosing in non-diabetic conditions. These applications are to be further validated in huge scale clinical trials, and therapeutic strategies need to be guided.

**Keywords:** Metformin, Drug repurposing, Diabetes mellitus, Immunomodulation, Cardiovascular disease, Neurodegenerative diseases, Cancer therapy.

# INTRODUCTION

Biguanide derivative metformin has been the cornerstone in the management of type 2 diabetes mellitus (T2DM) since its first clinical use in 1957 [1]. Metformin has established effectiveness as a first line therapy for lowering blood glucoses levels, mainly by preventing hepatic glucose production, improving insulin sensitivity, and increase terminal glucose disposition[2]. Recent research has shown that metformin has diverse biological actions through mitochondrial regulation, AMPK activation, lysosomal targeting and modulating the gut microbiome The results of these findings indicate possible therapeutic applications in most non-diabetic conditions like cardiovascular diseases, neurodegenerative disorders, cancer, and infectious diseases. In addition to these actions, its anti-inflammatory, antioxidant and immunomodulatory properties make it a good drug for broader clinical use[3]. Here, we attempt to review the broadening utilization of metformin for the treatment of diabetes beyond its traditional application in diabetes management[4]. Because recent evidence on the mechanics of action and efficacy of metformin in a variety of disease states makes it a promising part of modern medicine, we examine and assess its potential[5]. Such an exploration could set a stage of future clinical applications with new strategies for chronic and complex diseases additional to T2DM[6].

**Mechanism of Action of Metformin**

Metformin decreases blood sugar predominantly by decreasing hepatic glucose output and improving insulin sensitivity through an AMPK-mediated action [7]. These actions indicate possible use in the treatment of cardiovascular, cancer and neurodegenerative disorders [8].

**Metformins Role in Vascular and Cardiovascular Health**

**Cardiovascular Benefits in Type 2 Diabetes (T2DM)**

Metformin Improves Endothelial Function and Enhances Nitrous oxide availability through AMPK activation which elevated the activity of endothelial nitric oxide synthase (ENOS) in the endothelial cells. It is The way for better Endothelial-Dependent Vasodilation (EDV) and improved vascular functioning. It Reduces Oxidative Stress as well [9]. Metformin Reduces Reactive oxygen species (ROS): which contributes to the integrity of the endothelium and the tone of blood vessels by supporting EPCs or Endothelial Progenitor Cells also Enhances EPCs circulation as well as their biological functions. Metformin Improves EPC survival and integration into vascular injury areas by enhancing vascular repair and regeneration[10].

**Comparative Effectiveness**

Metformin is non-inferior to Newer Hypoglycaemic Agents, it has Similar cardiovascular efficacy to Glucagon-Like Peptide-1(GLP-1), Renin-Angiotensin system (RAS) and sodium-glucose co-transporter 2 (SGLT-2) inhibitors .Meta-analyses indicate persistent robust evidence in favor of metformin protective activity in Major adverse cardiovascular events (MACE), morbidity, mortality. Cardiovascular (CV) Protection Beyond Diabetes was observed[11]. In Non-Diabetic Populations metformin could mitigate systemic inflammation, decrease oxidative stress and improve endothelial function which Indicates a possibility as a prophylactic cardiovascular treatment for broader patient populations[12].

**Neuroprotective Applications**

**Parkinsons disease and Urgency of New Therapies**

PD is characterized by gradual loss of dopaminergic neurons and deposition of Lewy bodies containing mainly $\alpha$-synuclein, PD has no disease-modifying therapies[13]. Metformin has gained the spot as a potential neuroprotective drug, as it targets multiple fundamental cellular pathways that are associated with neurodegeneration[14]. Metformin is an activator of AMP-activated protein kinase (AMPK), a key sensor and regulator of cellular energy homeostasis[15]. The activation of AMPK by metformin results in the: Increased efficiency of the mitochondria. Reduced oxidative stress, which is one of the leading causatives of neuronal injury in PD. Control of mitochondrial fragmentation and oxidative phosphorylation by the c-tail of the hyaluronan-binding protein 1 (HABP1)[16].

1Blockade of α-Synuclein Fibrillation. Metformin promotes autophagy, a process that supports Anti-inflammatory effects. Metformin reduces microglial activation, resulting in several effects like Reduced pro-inflammatory cytokines. Lowering neuroinflammation, diminishing neurons from immune attack [17]. Metformin has demonstrated cognition benefit through Promoting neuroplasty, Enhancing autophagy, Fostering neuronal recovery and synaptic operation. These benefits help people to remember better and think in a more efficient way[18].

**Oncology: Metformin as an Anti-Cancer Agent**

The recent interest in metformin as a potential anticancer agent is based on its effect on key cellular pathways that are important in tumor growth and progression AMPK pathway activation by its antitumor mechanisms is mainly dependent on inhibition of the mammalian target of rapamycin (mTOR) signalling pathway, a crucial regulator of cell growth, proliferation, and survival [19]. Metformin disrupts cellular energy metabolism and reduces the amount of ATP produced, creating energy stress that prevents cancer cell proliferation [20]. Moreover, metformin also promotes the immune modulatory effect through the promotion of T cell mediated immune responses and reduce the immune exhaustion, and therefore, strengthens the body's own nature defense to tumor development [21].There is preclinical and clinical evidence that metformin has anticancer potential in a number of malignancies. Metformin has already been shown in breast cancer to reduce tumor proliferation markers such as Kiel67 and inhibit Human epidermal growth factor receptor 2 (HER2) expression via mTOR pathway inhibition[22] . It is also shown to induce cell cycle arrest and down regulate key oncogenes, and thus it improves survival outcomes in colorectal cancer. In studies of pancreatic cancer, metformin may improve the effect of chemotherapy by making cancer cells more sensitive to the treatment. Some patient groups have seen improvements in prostate and lung cancer progression free survival and tumor growth reduction from Metformin, as research on those cancers suggests[23]. Metformin has also been shown to exert potential beyond direct tumor suppression in chemoprevention and as an adjunct therapy in combination with chemotherapy or radiotherapy to improve treatment efficacy and reduce the toxicity associated with chemotherapy or radiotherapy[24]**.** However, several limitations remain. There are many clinical trials at early phases, and evidence from large scale, randomized controlled trials (RCTs) is scarce, especially in nondiabetic cancer patients[25]. Metformin is being tested in ongoing trials to see its long-term effects, best dose, and efficacy are in various cancer subtypes. More research is needed to fully establish Metformin's role in cancer subtypes and to identify the patient populations that would benefit most from the drug's repurposing[26].

**Metformin in Infectious Diseases and Immunomodulation**

The immunomodulatory as well as anti-inflammatory effects of Metformin have promising therapeutic implications for the treatment of infectious diseases. A notable application is its use as host-directed therapy against tuberculosis (TB), especially among patients co-infected with diabetes mellitus, which often compromises the immune responses [27]. By activating the AMPK signaling pathway, Metformin has been reported to improve the host immunity and inhibit the intracellular growth of mycobacterium tuberculosis. Moreover, its potential to regulate mitochondrial function and reduce inflammation might allow the increased efficacy of standard anti-TB drugs by restraining the bacteria from surviving[28]. Metformin has also been found to have potential in reducing (severe acute respiratory syndrome coronavirus 2) SARS-CoV-2 related complications. It acts as a modulator of angiotensin-converting enzyme 2 (ACE2) which is the main entry point for the virus to enter respiratory epithelial cells ultimately. In addition, Metformin regulates dipeptidyl peptidase 4 DPP4, a second viral receptor, with the possibility of the inhibition of viral adherence and host immune evasion[29]. Most important anti-inflammatory properties of Metformin are of particular interest in severe forms of COVID-19, since Metformin can attenuate the cytokine storm through inhibition of the release of pro-inflammatory cytokines and reduction of oxidative stress. These measures also serve to mitigate the risk of systemic inflammation and thrombosis, which are associated with poor outcomes in COVID-19[30].Taken together, these immunometabolic influences suggest that Metformin might be useful as an adjuvant treatment in different infectious diseases, promoting its application beyond its glycemic-lowering properties [31].

**Applications in Other Chronic Diseases**

Metformin has other than the conventional roles in metabolic disorders, where it may be a potential candidate as a therapeutic treatment agent for other chronic diseases. One area of emerging research is its role in prevention of the periodontal disease and in the oral health. Metformin has been shown to prevent bone loss in studies that demonstrate its effect in reducing bone loss from periodontal disease and age-related degeneration. It has been shown to modulate the oral microbiome to improve the host's metabolic response to bacterial dysbiosis. The findings of the clinical trials also indicate that the use of metformin in non diabetic patients improves periodontal parameters, reduced inflammatory markers and repair of gingival tissue, which implies a new preventive strategy of oral systemic disease management [32]. In addition, Metformin also has anti-inflammatory and immunomodulatory properties in the management of different autoimmune and inflammatory conditions. Metformin reduces production of proinflammatory cytokines and suppresses immune system hyperactivation, by activating AMPK and inhibiting nuclear factor kappa light chain enhancer of activated B cells (NF-κB) signalling pathway. The implication of these effects in chronic inflammation leading to repair diseases such as rheumatoid arthritis, systemic lupus erythematosus, or inflammatory bowel disease led to the potential improvement of outcomes associated with disease[33].Metformin also has important Gero protective properties, and therefore represents a promising drug for the treatment of age related diseases. Studies of metformin in animal models and initial human studies are demonstrating that metformin extends lifespan, slows the onset of the age-related morbidities, and may well extend or enhance health span[34]. Most of the effect is attributed to its ability to reduce oxidative stress, improve mitochondrial function, and promote autophagy, increasing the cellular resilience and metabolic health.These results position metformin as a therapeutic agent in age related disorders including cognitive decline, cardiovascular disease and some cancers [35].

**Metformin in Antimicrobial Resistance Management**

Antimicrobial resistance (AMR) is an increasing global health problem that is increasing bacterial resistance to conventional antibiotics. Studies have been conducted recently which suggest metformin can support the resolution of this challenge by its synergistic effects with antibiotics. Several studies have shown that Metformin, combined with different antibiotics, such as doxycycline, ampicillin, and erythromycin, increases the antibacterial activity, especially against resistant bacterial strains, such as *Escherichia coli, Pseudomonas aeruginosa, Staphylococcus aureus*, and *Shigella boydii*[35].

**Safety Profile and Limitations**

**General Safety in T2DM**

Metformin is regarded as a safe and tolerated agent for treatment of T2DM, and has been used for many years in clinical practice. Common side effects are generally mild and of short duration; primarily involving gastrointestinal (GI) complaints (including nausea, diarrhoea, and bloating) - especially at higher doses[36].

**Non-Diabetic Use Restrictions**

Example: Long-term effects on diabetes populations are still under studies, while there are potential issues such as vitamin B12 depletion which can impact cognitive ability and cause anaemia[37].Risk Factors: Patients suffering from hepatic or renal impairment severe infections, or hypoxia they might have an increased risk[17].

**Individual Differences in Metabolic Response**

There is variation in metabolic reaction of the same dose among individuals particularly among non-diabetic individuals. Which Supports the necessity of a personalized dosing regimen approach to maximize the effect and reduce adverse effects[37].

**Limitation:** Metformin has poor ability to cross the blood-brain barrier and this can be used against it in the context of neurodegenerative disorders [22].

**Objective:** To Enhance the bioavailability and therapeutic penetration of Metformin in non-glycemic conditions (e.g. brain, tumour's)[38].

**Further Research Requirement**

Although it has good safety profile, it should be further studied in order to define Best dosing schedules Safety in the long-term Measures to reduce side effects in non standard uses [39].

**Future Perspectives and Research Directions**

As metformin repurposing outside of type 2 diabetes becomes increasingly popular, research is moving to the area of personalized medicine based on genetic, metabolic, and biomarker profiles that predict patient-specific advantages. In particular, genetic markers involved in AMPK/mTOR and mitochondrial pathways may be useful to select patients who could benefit after taking metformin to treat cancer or neurodegenerative disorders [40]. New formulations and selective delivery systems are being made to increase its bioavailability especially in the brain or tumour's. Metformin in combination with chemotherapy, immunotherapy or antibiotics could have synergetic effects with low toxicity[41].

## CONCLUSSION

Metformin, a first line treatment for type 2 diabetes mellitus (T2DM) already established in the clinic for a long time, has shown great promise for repurposing in a broad range of diseases beyond glycemic control[42]. Notably, it has multiple mechanisms of actions including AMPK activation, mTOR pathway inhibition, mitochondrial regulation, and immune modulation all of which together can affect different biological processes. There is emerging evidence that Metformin has therapeutic applications in the management of cardiovascular diseases, neurodegenerative disorders, cancers, infectious diseases and a number of other chronic conditions including those of aging and inflammation[43][44]. The drug's favorable safety profile, affordability, and extensive clinical use make it an attractive candidate for broader therapeutic application. The benefits of its use on endothelial function, oxidative stress, immune responses as well as autophagy make it a multimodal agent with therapeutic potential [45]. Nevertheless, there remain many gaps of knowledge. To further our understanding of metformin's non-glycemic effects and optimize dosing strategies, as well as to assess long term safety, further research is needed in non diabetic populations. Metformin's efficacy in the diverse disease contexts and personalized treatment based on patient specific biomarkers are particularly needed to be validated by large scale randomized controlled trials [46]. Finally, metformin can now be seen as a multifaceted therapeutic agent, for which new investigation of its potential use for disorders other than diabetes is needed, in order to fully exploit its capacity and establish it in clinical practice[47].

## ABSTRACT

Poly(lactic-co-glycolic acid) (PLGA) is a versatile, FDA-approved biodegradable polymer extensively used in the development of novel drug delivery systems. This review highlights the structural and physicochemical properties of PLGA, emphasizing how the ratio of lactic acid to glycolic acid, molecular weight, and crystallinity influence its degradation behavior and drug release profiles. PLGA enables the encapsulation of diverse therapeutic agents, including small molecules, proteins, peptides, and nucleic acids, offering protection from enzymatic degradation and enabling sustained or targeted delivery. Applications span a wide array of biomedical fields such as cancer therapy, gene and vaccine delivery, tissue engineering, and regenerative medicine. Emerging trends include functionalization strategies—such as PEGylation, chitosan-coating, ligand conjugation, and acid-responsive designs—to enhance site-specificity, cellular uptake, and bioavailability while minimizing systemic toxicity. Furthermore, the incorporation of PLGA into platforms like nanoparticles, microspheres, microneedles, and in situ forming implants has enabled minimally invasive, long-acting formulations. Challenges such as burst release and polymer instability are addressed through formulation optimization and *in vitro–in vivo* correlation studies. Overall, PLGA continues to demonstrate significant potential in revolutionizing controlled drug delivery, with advances in nanotechnology and materials science further expanding its clinical relevance.

**Keywords:** PLGA; drug delivery; biodegradable polymer; sustained release; nanoparticles; nanomedicine; controlled release; targeted therapy; regenerative medicine.

## INTRODUCTION

PLGA, a copolymer composed of lactic acid (PLA) and glycolic acid (PGA) monomers, stands out as a critical material in biomedical research and pharmaceutical applications. Its exceptional biocompatibility, controlled degradation, and capacity to encapsulate a variety of therapeutic agents firmly establish PLGA as a leading choice in the field. The degradation rate of PLGA is directly influenced by the ratio of lactic acid to glycolic acid, its molecular weight, and environmental conditions. Higher glycolic acid content accelerates degradation due to its increased hydrophilicity, while a higher lactic acid content slows it down by enhancing hydrophobicity. PLGA efficiently hydrolyzes into non-toxic byproducts—lactic acid and glycolic acid—that are naturally metabolized through the Krebs cycle, affirming its safety for *in vivo* applications. Both the U.S. Food and Drug Administration (FDA) and the European Medicines Agency (EMA) have approved PLGA for numerous drug delivery systems, including nanoparticles, microspheres, and implants designed for controlled and sustained drug release.This polymer is particularly effective at encapsulating small molecules, proteins, peptides, and nucleic acids, providing robust protection from enzymatic degradation and significantly improving therapeutic efficacy. Researchers actively explore PLGA-based drug delivery systems for various applications, including cancer therapy, vaccination, gene delivery, and tissue engineering. Drug Delivery System(Fig 1). Khairul Amin *Et al* investigated the surface functionalization of PLGA (poly(lactic-co-glycolic acid)) nanoparticles to significantly enhance their efficacy as oral vaccine delivery systems. Our focus is on targeting key intestinal immune cells, including microfold cells (M cells), dendritic cells, and Peyer's patches. The authors dive into the complex process of creating these nanoparticles in the laboratory, using precise techniques to ensure the particles are small, uniform, and fully capable of carrying delicate antigens. Each step in the synthesis uses a crucial piece of the puzzle as they expertly fine-tune conditions to achieve the perfect formulation. The team quickly realized that merely formulating the nanoparticles was insufficient. The harsh conditions of the gastrointestinal tract present a significant challenge, threatening to degrade both the fragile nanoparticles and their cargo. To overcome this obstacle, they set out to fortify the nanoparticles. They explored various innovative surface functionalization strategies, including coating the particles with bioadhesive polymers and attaching targeting ligands such as lectins and antibodies. These critical modifications enable the nanoparticles to navigate the acidic environment of the stomach, evade digestive enzymes, and effectively target the intestinal immune cells[1].

The surface modifications enhance mucoadhesion and enable precise uptake by intestinal immune cells, such as M cells and dendritic cells. Additionally, they exhibit a controlled release profile for prolonged antigen availability. *In vivo* studies demonstrate strong immune responses, with significant mucosal IgA and systemic IgG production, as well as T-cell activation, confirming their ability to stimulate both mucosal and systemic immunity. The nanoparticles also show biocompatibility and safety, with no adverse effects [1]. characterization phase. In conclusion, surface functionalization of PLGA nanoparticles is a powerful strategy for creating oral vaccine delivery systems targeting intestinal immune cells. Mitragotri, S *Et al*. fabricated, optimized, and evaluated poly(lactic-co-glycolic acid) (PLGA) nanoparticles co-loaded with paclitaxel (PTX) and curcumin (CUR) to enhance their anti-tumor efficacy. By combining PTX, a prominent chemotherapeutic agent, with CUR, known for its anti-inflammatory and anticancer properties, they seek to improve drug solubility, stability, and controlled release while minimizing side effects. They aimed to create a nanoparticle-based delivery system that would enhance drug solubility, control release, and minimize harmful side effects. To realize this vision, the team carefully selected poly(lactic-co-glycolic acid) (PLGA) as the carrier for their drug-loaded nanoparticles.

The researchers meticulously optimized the nanoparticle formulation by adjusting various parameters to achieve an ideal size, high encapsulation efficiency, and a sustained drug release profile. Their goal was to ensure that both PTX and CUR could work together effectively, enhancing therapeutic impact while reducing the risk of drug resistance. *In vitro* studies confirm that these nanoparticles significantly enhance anticancer activity compared to free PTX and CUR, indicating a strong synergistic effect. They effectively inhibit cancer cell proliferation while minimizing systemic toxicity, and their controlled release ensures prolonged drug retention, improving therapeutic outcomes[3]. Their findings revealed that the combination of PTX and CUR within the PLGA nanoparticles exhibited greater cytotoxicity than individual drug treatments, confirming the effectiveness of their approach. Through this research, the authors demonstrated that nanotechnology could provide a promising solution for improving cancer therapy. Their work opened new avenues for drug delivery systems that not only enhance treatment efficiency but also minimize side effects, offering hope for better patient outcomes in the fight against cancer[3].

Bo Wan *Et al*. investigated the *in vitro-in vivo* correlation (IVIVC) of poly(lactic-co-glycolic acid) (PLGA) microspheres, with a keen focus on how variations in polymer sources and temperature critically influence drug release behavior. By rigorously examining the effects of different PLGAs from various manufacturers and varying temperature conditions on release profiles, both *in vitro* and *in vivo*, this study establishes a robust predictive relationship between laboratory outcomes and actual biological performance[5]. The author produced microspheres loaded with a model drug and rigorously tested them under a range of temperature conditions to replicate real-world scenarios. Through meticulous *in vitro* experiments, they monitored drug release dynamics over time. But the team didn't stop there. To connect laboratory findings with actual biological responses, they conducted thorough *in*

*vivo* studies, analyzing the drug's behavior within living organisms [6]. The results of the study demonstrate that both polymer source variation and temperature play a critical role in determining the drug release profiles of PLGA microspheres. Microspheres produced with PLGA from different manufacturers show distinct release kinetics, with some exhibiting faster or more sustained drug release than others. Additionally, temperature fluctuations significantly impact the stability and performance of the microspheres; higher temperatures unequivocally accelerate drug release and increase the risk of polymer degradation. The *in vitro* release profiles correlate strongly with *in vivo* data, establishing a robust *in vitro-in vivo* correlation (IVIVC). These findings emphasize the paramount importance of choosing the right polymer and carefully controlling storage conditions to ensure the reliability and effectiveness of PLGA-based drug delivery systems[4].

The study established that *in vitro-in vivo* correlation (IVIVC) acts as a powerful predictive tool for optimizing PLGA-based drug delivery systems, ensuring consistently effective therapeutic outcomes. The results of the study clearly demonstrate that both polymer source variation and temperature play a critical role in determining the drug release profiles of PLGA microspheres. Microspheres produced with PLGA from different manufacturers show distinct release kinetics, with some exhibiting faster or more sustained drug release than others. Additionally, temperature fluctuations significantly impact the stability and performance of the microspheres; higher temperatures unequivocally accelerate drug release and increase the risk of polymer degradation. The *in vitro* release profiles correlate strongly with *in vivo* data, establishing a robust *in vitro-in vivo* correlation (IVIVC). These findings emphasize the paramount importance of choosing the right polymer and carefully controlling storage conditions to ensure the reliability and effectiveness of PLGA-based drug delivery systems[4]. Chunquan Wang *Et al*. developed and evaluated PLGA-based microspheres for the sustained co-delivery of ropivacaine, a local anesthetic, and betamethasone, an anti-inflammatory corticosteroid, for sciatic nerve blocks in mice. Utilizing the solvent evaporation technique, the microspheres were characterized for particle size, morphology, drug encapsulation efficiency, and *in vitro* release profiles. The results showed uniform size distribution, high encapsulation efficiency, and controlled drug release over an extended period.

*In vivo* experiments demonstrated significant prolongation of analgesia and reduced local inflammation compared to free ropivacaine, with no signs of systemic toxicity observed. These findings indicate that co-delivery of ropivacaine and betamethasone via PLGA microspheres offers a promising strategy for enhanced, localized pain management with improved safety and therapeutic outcomes. The biomedical researchers have successfully addressed the critical need for long-lasting pain relief with minimal side effects. Their focus on nerve blocks—often used for pain management after surgery or injury—has paved the way for a groundbreaking advancement. While traditional local anesthetics like ropivacaine are effective, their rapid wear-off necessitates repeated doses, posing significant toxicity risks. To overcome this limitation, the researchers have implemented betamethasone, a corticosteroid renowned for its ability to reduce inflammation and extend pain relief effects, despite concerns about systemic side effects. In a vibrant lab environment, the team meticulously formulated microspheres, expertly tuning the polymer composition to precisely control the release rates of both ropivacaine and betamethasone. Their intensive optimization process ensured that both compounds remained stable and released as intended. After months of rigorous development, the team proceeded to *in vivo* testing. By injecting the microspheres near the sciatic nerve of mice, they effectively monitored pain relief duration, inflammation responses, and any potential side effects. The results were compelling—pain relief lasted significantly longer than with free ropivacaine, and inflammation was well controlled without triggering systemic steroid effects.

This breakthrough marks a pivotal moment in the field of post-surgical and chronic pain management. The team recognizes that their work is far from finished—further studies and clinical trials are on the horizon—but they have undeniably taken a crucial step toward establishing a safer and more effective nerve block solution[7]. The results of the study confirmed that PLGA-based microspheres effectively encapsulate ropivacaine and betamethasone, ensuring controlled and sustained drug release over time. *In vivo* experiments on mice clearly demonstrated that this microsphere formulation significantly prolongs the duration of the sciatic nerve block compared to free ropivacaine, resulting in extended pain relief. These compelling findings establish PLGA-based microspheres as a superior

alternative to conventional local anesthetics, significantly enhancing both efficacy and safety for prolonged nerve block applications[7]. These microspheres deliver a sustained release of the drugs, resulting in extended pain relief while effectively controlling inflammation. While further studies are essential to optimize the formulation and evaluate long-term safety, this research fundamentally paves the way for more effective and safer pain management strategies in clinical settings.

Yunduan Que *Et al*. developed and evaluated tetracycline-grafted mPEG-PLGA micelles as a targeted drug delivery system for osteoporosis treatment.[10] Tetracycline (TC) serves as a bone-targeting ligand due to its strong affinity for hydroxyapatite, facilitating selective drug accumulation in bone tissue. The authors focused on creating micelles by attaching tetracycline (TC) to methoxy poly(ethylene glycol)–poly(D, L-lactic-co-glycolic acid) (mPEG–PLGA), aiming to utilise TC's natural affinity for bone tissue. Their objective was to use these TC–mPEG–PLGA micelles to deliver bioactive compounds, such as astragaloside IV (AS), directly to bone sites. They synthesized the TC–mPEG–PLGA micelles and loaded them with AS, resulting in nanoparticles that averaged about 52 nm in size. [9] These micelles showed a sustained release of AS compared to the free form of the compound. Laboratory tests demonstrated that the micelles had low toxicity and were readily absorbed by bone-forming cells, known as MC3T3-E1 cells. Further experiments revealed that the TC–mPEG–PLGA micelles significantly increased AS accumulation in bone tissue, both *in vitro* and *in vivo*. To assess the therapeutic potential, the researchers conducted studies on rats with induced osteoporosis. The results were promising: rats treated with the AS-loaded TC–mPEG–PLGA micelles showed a significant increase in bone mineral density compared to those receiving free AS. This indicated that the micelles not only targeted the bone effectively but also enhanced the therapeutic effects of AS in combating osteoporosis.[8]*In vivo* experiments in osteoporotic rat models indicated that the micelles significantly improved bone mineral density compared to free drug administration, suggesting better bone regeneration and reduced resorption[8]. Overall, the findings confirm that these functionalized micelles are a promising nanocarrier system for osteoporosis treatment.

Mihriban Yildiz, *Et al*. investigated the loading behavior of ibuprofen within PEG–PLGA–PEG micelles using coarse-grained Dissipative Particle Dynamics (DPD) simulations. The study aims to provide insights into the efficiency of drug loading, the stability of the micelle-drug complex, and the potential optimization of PEG–PLGA–PEG micelles for drug delivery applications[14]. The authors turned to computational simulations, specifically coarse-grained Dissipative Particle Dynamics (DPD), a powerful tool that allowed them to visualize and analyze how ibuprofen interacted with the micelles. With great determination, they designed a series of simulations, carefully modeling the behavior of PEG–PLGA–PEG molecules in a solvent. They observed how these molecules self-assembled into micelles and how ibuprofen, being a hydrophobic drug, found its place within the micellar core. They examined key factors such as drug distribution, micelle stability, and encapsulation efficiency—all crucial for improving drug delivery systems. They discovered how molecular interactions, micelle size, and polymer composition influenced ibuprofen loading. Their findings provided a roadmap for optimizing micellar drug carriers, bringing the scientific community one step closer to developing more effective and controlled drug delivery mechanisms[13]. With their research published, the team had not only deepened the understanding of ibuprofen-loaded micelles but also paved the way for future studies in nanomedicine[12].

The study's results indicate that PEG–PLGA–PEG micelles effectively encapsulate ibuprofen, with the drug preferentially localizing in the hydrophobic PLGA core. The size of the micelles, the composition of the polymers, and the ratio of drug to polymer were found to significantly impact both drug loading capacity and micelle stability[14]. Simulations showed that stronger hydrophobic interactions between ibuprofen and the PLGA core improved encapsulation efficiency. Additionally, the self-assembly behavior of the micelles remained stable, preserving their structural integrity throughout the simulation. In conclusion, this study effectively utilized coarse-grained Dissipative Particle Dynamics (DPD) simulations to explore the loading behaviour of ibuprofen in PEG–PLGA–PEG micelles. The findings provided valuable insights into the self-assembly process, drug distribution, and micelle stability, emphasizing the molecular interactions that affect drug encapsulation efficiency. These results

enhance our understanding of how micellar drug carriers can be optimized for controlled and efficient drug delivery[13].

Lijun You *Et al.* developed and characterised multifunctional $Fe_3O_4$@PLGA-PEG nano-niosomes as a targeted drug delivery system for treating cervical cancer. By incorporating $Fe_3O_4$ (iron oxide) nanoparticles, the system may offer magnetic targeting capabilities, while the PLGA-PEG coating ensures better stability and controlled drug release.[17] Lijun You and their team recognised that traditional chemotherapy often caused severe side effects, and many patients struggled with ineffective drug delivery[17]. They envisioned tiny, intelligent carriers made from $Fe_3O_4$@PLGA-PEG—magnetic iron oxide nanoparticles coated with biodegradable polymers. These carriers would not only protect the drug but also enable targeted delivery through the use of external magnetic fields. They carefully analysed their properties to ensure the right size, stability, and drug-loading capacity. Using advanced techniques, they tested the effectiveness of these smart carriers in lab models, observing how they navigated toward cancerous cells with remarkable precision. As their research progressed, the results were promising. The nano-niosomes showed great potential in enhancing drug accumulation at the tumour site, reducing side effects, and improving treatment efficacy. Their work laid the foundation for a new approach to cervical cancer therapy—one that was smarter, more efficient, and less harmful to patients[16]. The results of the study demonstrated that $Fe_3O_4$@PLGA-PEG nano-niosomes exhibited excellent stability, biocompatibility, and drug-loading capacity. The synthesized nanocarriers effectively encapsulated the drug and showed controlled, sustained release properties. In *in vitro* experiments, these nano-niosomes displayed enhanced targeting efficiency toward cervical cancer cells, guided by the magnetic properties of $Fe_3O_4$. Additionally, the drug-loaded nano-niosomes significantly improved cellular uptake and cytotoxicity against cancer cells while minimizing damage to healthy tissues. In conclusion, the research conducted by Lijun You and their team effectively demonstrates the potential of $Fe_3O_4$@PLGA-PEG nano-niosomes as an innovative and efficient targeted drug delivery system for treating cervical cancer. By combining magnetic nanoparticles with a biodegradable polymer coating, the study presents a promising method for enhancing drug stability, precision targeting

## ABSTRACT

This study aims to analyze the etiopathogenesis of *Bahupitta Kamala* in the context of *Vikara Vighata Bhava* and *Abhava*, to better understand disease manifestation, prognosis, and preventive strategies through Ayurvedic principles. A comprehensive review was conducted using classical Ayurvedic texts *Charaka Samhita*, *Sushruta Samhita*, and *Ashtanga Hridayam*. Additional data were sourced from indexed medical journals and databases including PubMed and Google Scholar. The concept of *Vikara Vighata Bhava Abhava* was critically analyzed based on *Charaka Nidansthana* (Chapter 4). Key components like Nidana (causative factors), Dosha, Dushya, and their interrelations were examined to evaluate their roles in disease manifestation or prevention. Special attention was given to *Bahupitta Kamala* progression in patients with pre-existing *Pandu Roga*. The study identifies that even in the presence of Nidana, Dosha, and Dushya, disease may not manifest if *Vikara Vighata Bhava* (protective factors) is present. Conversely, its absence (*Abhava*) facilitates disease onset and severity. The progression of *Bahupitta Kamala* varies from mild to severe depending on the strength of causative factors and the absence of protective influences. Different *Prativisheshas* help categorize disease stages, symptomatology, and prognosis. Understanding *Vikara Vighata Bhava-Abhava* is essential for early diagnosis, prognosis, and individualized Ayurvedic management of *Kamala Roga*. It emphasizes the importance of *Nidana Parivarjana*, *Pitta Shodhana/Shamana*, and lifestyle regulation in preventing and mitigating disease severity.

**Keywords:** *Vikara Vighata Bhava Abhava, Bahupitta Kamala, Visheshas, Prativisheshas.*

## INTRODUCTION

According to *Ayurveda* presence of *Nidana, Dosha* and *Dushyas* is essential for the manifestation of a disease but the presence of these three is not an absolute sureness for the manifestation of a disease. The association between these *Bhavas* will decide the manifestation and non-manifestation of disease[1]. *Acharya Charaka* explains like "manifestation and non-manifestation of a disease depends upon the *Prativisheshas* of *Nidana, Dosha, Dushya Visheshas* towards *Vikara Vighata Bhava* and *Abhava*. "A factor that prevents or obstructs the manifestation of a disease in an individual is called *Vikara Vighata Bhava*, In the absence of *Vikara Vighata Bhava,* the manifestation of the disease becomes more likely and easier". The specific factors which are involved in the manifestation of a disease are known as *Nidanadi Visheshas* and they include *Nidana, Doshas* and *Dushyas. Prativishesha* is the result of *Nidanadi Visheshas* interacting with either *Vikara Vighata Bhava* and *Abhava*[2]. *Kamala* is a condition primarily associated with *Pitta dosha,* where a decrease in *Rakta Dhatu* is observed. according to *Charaka*, the abnormality of *Rakta* (Blood)is responsible for the manifestation of *Kamala*, (Jaundice) which typically results in a yellowish discoloration of various body parts[3]. This condition is linked to the involvement of the *Raktavaha Srotas*, with the *Yakrita* (Liver) and *Pleeha* (Spleen) being considered the root *(Srotomul)[4]* of these channels. *Charaka* describes two types of *Kamala* that are *Shakhashrita Kamala* and *Koshthashakhashrita Kamala*. A patient is already suffering from *Pandu Roga* still continuous consumtion of *Pittavardhak Ahara Vihara* can exacerbate the condition and may progress to *Bahupitta Kamala*[5]. *Vikara Vighata Abhava* leads to formation of disease *Kamala* in the individual who is already suffering from *Panduroga* and continuously consumption of *Pittakara Ahara Vihara*, whereas *Vikara Vighata Bhava* leads to the prevention of disease. This article aims to provide a comprehensive understanding of etiopathogenesis of *kamala* in terms of *Vikara Vighata Bhava Abhava* and these factors also helpful in *Nidanparivarjana.*

## MATERIALS

A comprehensive review of classical *Ayurvedic* texts, including the *Brihattrayee*s - *Charaka Samhita*, *Sushrut Samhita*, and *Ashtanga Hridayam* was conducted. A literary study was carried out using index medical journals and from research databases such as PubMed and Google Scholar.

## METHODS

**Concept of *Vikara Vighata Bhava Abhava***[6]

The concept of *Vikara Vighata Bhava Abhava* has been explained in the *Charaka Nidansthana* 4th chapter. According to *Ayurveda* presence of *Nidana, Dosha* and *Dushyas* is essential for the manifestation of a disease. but the presence of these three is not an absolute sureness for the manifestation of a disease. Presence or absence of another one factor called *Vikara Vighata Bhava* will decide the occurrence and non-occurrence of a disease in an individual. *Acharya Charaka* explains like "manifestation and non-manifestation of a disease depends upon the *Prativisheshas* of *Nidana, Dosha, Dushyas Visheshas* towards *Vikara Vighata Bhava* and *Vikara Vighata Bhava Abhava*. "A factor that prevents or obstructs the manifestation of a disease in an individual is called *Vikara Vighata Bhava*, In the absence of *Vikara Vighata Bhava,* the manifestation of the disease becomes more likely and easier".

***Visheshas***

The specific factors which are involved in the manifestation of a disease are known as *Visheshas* and they include *Nidana*, *Doshas* and *Dushyas*.

***Prativisheshas***

*Prativishesha* is nothing but the outcome occur due to *Parasparanubandha* / association of *Nidanadi Visheshas* that is Nidana, Dosha, Dushya with *Vikara Vighata Bhava* and *Abhava.* Each of these has four outcomes.

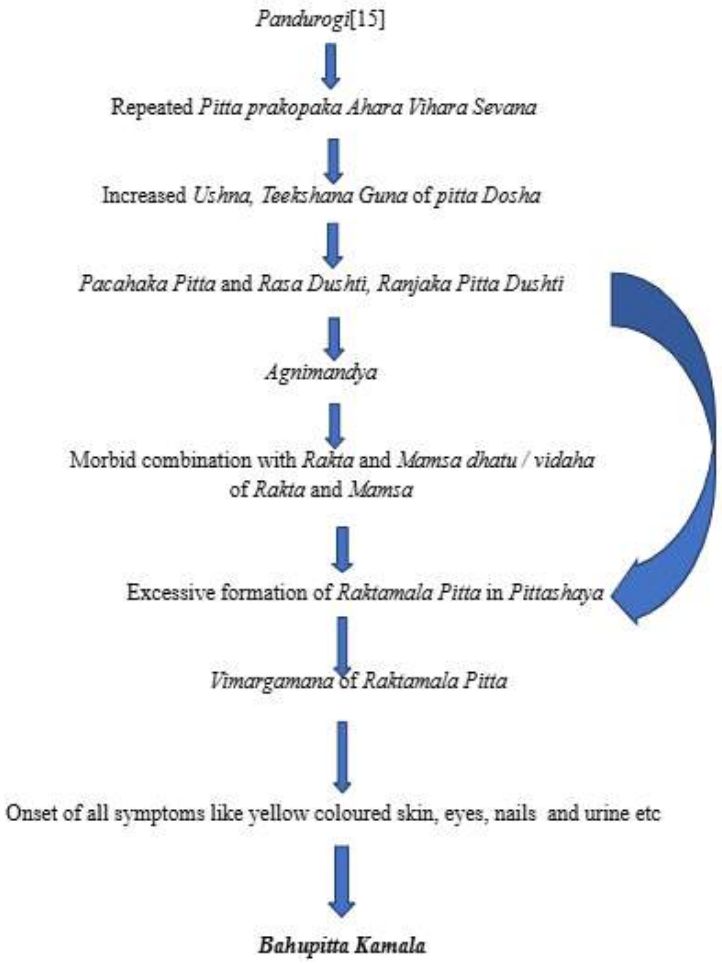
**The concept of *Vikara Vighata Bhava* involves following considerations**[7].
***Ananubhandhnanti*:** If association between *Nidana,Dosha,Dushya* is present.
***Kalaprakarshaad*:** Time duration required for manifestation of disease.
***Abaleeyaamso*:** When the causative factors are weak and unable to generate a severe disease.

**Generally four outcomes of *Vikara Vighata Bhava Abhava Prativisheshas* observed such as,**
***Vikara Vighata Bhava Prativisheshas***[8]
***Avikara Jananam*** (nonmanifestation of disease)
***Chirena Vikara Jananam*** (delayed manifestation of disease)
***Anu Vikara Jananam*** (manifestation of a mild disease)
***Asarvalinga Yukta Vikara Jananam*** (manifestation of a disease without the all symptomatology).

***Vikara Vighata Abhava Prativisheshas***[9]
1. *Vikara Jananam* (manifestation of disease)
2. *Sheeghra Vikara Jananam* (early manifestation of a disease)
3. *Mahati Vikara Jananam* (manifestation of a severe disease)
4. *Sarvalinga Yukta Vikara Jananam* (manifestation of disease with all symptomatology).

**Introduction to *Bahupitta kamala***
**Nidana of *Bahupitta kamala***
According to *Charak Samhita*, *Pandu* act as a *Nidanarthkar Vyadhi* for *Bahupitta Kamala*[10]. As per Sushrutacharya, during the convalescence period of any disease, if patient consumes sour, salty like unwholesome food and alcohol[11]. As per *Ashtang Hridaya Kamala* may result as a swatantra Vyadhi without pre-existence *Panduroga*[12]. (Table: 1)

**Samprapti**[14]
*Bahupitta Kamala* is a condition that arises when a patient suffering from *Panduroga* (jaundice) consumes a diet and follows a regimen that aggravates *Pitta dosha*. The increased *Pitta* then burns and alters the normal *Rakta* (blood) and *Mamsa* (muscle tissues), leading to the disease *Kamala* (yellowing of the skin and eyes). The vitiated *Pitta*, with its similar qualities to *Rakta*, causes further disturbance, which in turn affects the *Mamsa dhatu* (muscle), leading to a slackening or weakening of the muscles (*Shithilata*). The impure or aggravated *Pitta* mixes with the local *Pitta (Sthanika Pitta)*, causing yellow discoloration of the eyes *(Netra)*, skin *(Twacha)*, urine *(Mutra)*, nails *(Nakha)*, and other parts of the body. This yellowish tint in urine *(Peeta Varna)* and stools *(Varchas)* is due to the increased *malarupa* (yellowish hue) of *Pitta* in the digestive tract *(Koshta)*. The patient's complexion turns yellowish, resembling the color of a frog during the rainy season *(Bheka Varna)*, and their senses become impaired. An increase in *Ranjaka Pitta* is observed both in the digestive tract (*Koshta*, which refers to the *Mahasrotas*) and in the peripheral tissues (*Shakha*, which refers to the *Raktadi dhatus*). This condition is therefore referred to as *Koshtashakhashrita Kamala*.



***Samprapti Ghataka***[16]
***Dosha:*** *Pitta Dosha*
***Dushya:*** *Rakta, Mamsa*
***Srotas:*** *Raktavaha* and *Mamsavaha Srotas*
***Srotodushti Prakara:*** *Sanga* and *Vimargagamana*
***Agni:*** *Jatharagnimandya* and *Rakta Dhatvagnimandya*
***Ama:*** *Jatharagnimandyajanya* and *Raktadhatvagnimandyajanya*
***Udbhava Sthana:*** *Amashaya*

## OBSERVATION AND DISCUSSION

(Table 2)
***Vikara Vighata Bhava Visheshas -*** *Nidana, Dosha, Dushya.*
***Vikara Vighata Bhava Abhava Prativisheshas -*** manifestation of disease**.**
***Vikara Vighata Bhava Prativisheshas –*** Non-manifestation of disease.

***Vikara Vighata Bhava Abhava Prativisheshas* – Manifestation of *Kamala***

***Avikara Jananam***

In *Kamala Roga,* the *Anubandha* between *Nidana, Dosha,* and *Dushya* determines the manifestation of the disease. If these factors such as excessive intake of *Kshara, Amla, Lavana,* and *Madya*, aggravated *Pitta Dosha*, and affected *Rakta* and *Mamsa Dushya* in minute form if this factors are not align in terms of *Dravyata, Gunata, Karmata*, or *Prabhavata*, then the disease will not manifest (*Avikara Jananam*).

***Vikara Jananam***

However, if *Anubandha* between these causative factors is facilitated by the absence of opposing influences (*Vikara Vighata Abhava*), as seen in a *Pandurogi* who continuously consumes *Pitta*-aggravating food and lifestyle, it leads to disease manifestation (*Vikara Jananam*). In such cases, mild *Pitta* and *Rakta* vitiation results in a less severe form of *Kamala* with minimal symptoms (*Alpa Lakshana*). Here Prognosis of Disease will be *Sukhsadhya* and it can be cured by *Pittashamana Chikitsa.*

***Chiren Vikara Jananam***

The progression of *Kamala Roga* often occurs gradually (*Kalaprakarshyat Anubandhanti*), as repeated exposure to the same causative factors (*Pittaprakopaka Ahara Vihara*) over time creates a *Dravyata, Gunata, Karmata* similarity between *Kala* and *Dosha* or *Hetu*, leading to delayed disease manifestation (*Chirena Vikara Jananam*).

***Shighra Vikara Jananam***

Conversely, when these causative factors interact in the absence of disease-preventing factors (*Vikara Vighata Bhava*), the association between *Nidana, Dosha,* and *Dushya* occurs rapidly, resulting in the early onset of *Kamala* (*Ashukari Roga*) manifestation of *Kamala* as a *Updrava* in *panduroga.* If the *Anubandha* between these *Nidanadi Visheshas* is weak (*Abaleeyanso*), the vitiation of *Pitta, Rakta,* and *Mamsa* remains mild, leading to a less severe form of *Kamala* (*Alpa Bala Vyadhi*).

***Asarva Linga Yukta Vikara Jananam***

In some cases, *Kamala Roga* may present without all classical symptoms (*Asarva Linga Yukta Vikara Jananam*), which occurs when specific causative factors (*Nidanadi Visheshas*) interact with disease-preventing elements (*Vikara Vighata Bhava*). Here prognosis of disease will be *Kashtasadhya* and it can be cured by *Pittashodhana Chikitsa.* However, when protective mechanisms such as *Pitta Shodhana, Shamana*, a balanced state of *Agni*, and *Ama-pachana* are absent, it results in increases severity of *Dhatu Shaithilya.* This, in turn, causes severe vitiation of *Rakta* and *Mamsa*, leading to an aggravated form of *Kamala*, characterized by symptoms such as *Saraktamutra* and *Chhardi*. If left untreated, it can progress to complications such as *Daha*, *Aruchi*, *Trishna, Tandra*, *Anaha*, *Kumbhakamala,* and *Halimaka*.

***Sarva Linga Yukta Vyadhi***

When *Dushya Vaishamyata* (imbalance in *Rakta* and *Mamsa*) becomes extensive, *Kamala* manifests in its most severe form. This includes symptoms such as excessive yellow discoloration of the eyes, skin, nails, and face, reddish-yellow stool and urine, a complexion resembling a rain-frog, indigestion, weakness, fatigue, and anorexia.

***Vikara Vighata Bhava Abhava Prativisheshas* and *Sadhya Asadhyata***

In *Ayurveda*, the treatment of all *Vyadhis* (diseases) is centered around *Nidana Parivarjana* (eliminating causative factors) and *Samprapti Vighatana* (disrupting the pathogenesis). Understanding *Vikara Vighata Bhava-Abhava Prativisheshas* is crucial for assessing *Kamala Roga* and other Diseases pathogenesis, determining *Sadhyasadhyatwa* (prognosis), and formulating an effective treatment plan for specific *Vyadhis*.

## CONCLUSION

The manifestation of *Kamala Roga* in *Ayurveda* is determined by the interaction of *Nidana*, *Dosha*, and *Dushya*, along with the presence or absence of *Vikara Vighata Bhava* factors preventing disease. If *Vikara Vighata Bhava* is strong, the disease is prevented or manifests in a milder form. Conversely, in the absence of these protective factors *Vikara Vighata Abhava*, disease manifestation becomes more likely acute and severe. In *Bahupitta Kamala*, aggravated *Pitta* disrupts *Rakta* and *Mamsa Dhatus*, causing yellow discoloration of the eyes, skin, urine, and nails. *Pitta*-aggravating diet and lifestyle worsen the condition, especially in *Pandu Roga* patients. The disease progresses from mild to severe, leading to complications like *Kumbhakamala* and *Halimaka*. Understanding *Vikara Vighata Bhava* and *Abhava* is crucial in preventing and managing *Kamala Roga*. Ayurvedic interventions like *Pitta Shodhana*, *Shamana*, and dietary regulations play a key role in disease prevention by strengthening *Vikara Vighata Bhava*. Identifying and modifying *Nidana* through *Nidan Parivarjana* helps in early intervention, reducing disease severity and progression. This study highlights the importance of an individualized approach to *Kamala Roga* based on the interplay of *Nidana*, *Dosha*, and *Dushya*, ensuring better disease management and prognosis.

## ABSTRACT

Iron deficiency anaemia (IDA) is a wide-spread global health problem with significant effects on quality of life, most of which occur in high-risk groups of patients including children, the elderly, and patients with dysphagia. Conventional iron treatments bear poor tolerability and bioavailability, calling for the design of patient-friendly products. Ferric maltol, a novel oral iron replacement therapy, offers improved tolerability and absorption compared to traditional iron salts. The present study aimed to formulate and evaluate orally disintegrating tablets (ODTs) of ferric maltol to enhance patient compliance, especially in populations with swallowing difficulties. Pre-formulation studies, including FTIR, DSC, and XRD analyses, confirmed drug-excipient compatibility and partial amorphization of the drug. ODTs were formulated using the wet granulation method and optimized through a $3^2$ factorial Design of Experiments (DoE), focusing on diluent and super disintegrant concentrations. Evaluation parameters such as hardness, friability, weight variation, disintegration time, and wetting time were assessed. The optimized formulation showed a disintegration time of 30 seconds, wetting time of 28 seconds, drug content of 98%, and a cumulative drug release of 93% within 45 minutes, following zero-order kinetics. These results demonstrate the successful development of a stable, fast-dissolving ferric maltol ODT, potentially improving therapeutic outcomes and patient adherence

**Keywords:** Ferric maltol, orally disintegrating tablets (ODTs), Iron deficiency anaemia (IDA), wet granulation, Design of Experiments (DoE), pre-formulation studies, dissolution kinetics, patient compliance.

## INTRODUCTION

According to the World Health Organization iron deficiencies anaemia affects 30% of people worldwide and is the most prevalent dietary shortfall (1). Although IDA is more common in women and children, adult men can also be at risk based on their health and socioeconomic background (2). Reduced diet iron intake and absorption are additional contributing factors to IDA, even though gastrointestinal bleeding and women's menstrual cycle disorders are the most frequent causes(3).Numerous cellular processes such as DNA synthesis, oxygen transport enzyme activity and mitochondrial energy production depend on iron (4,5). As a result, there is broad spectrum of IDA symptoms. Reduced blood oxygen level can cause angina, tachycardia and peripheral arterial disease. Geriatric and pediatric patients often rely on liquid dosage forms; however, these preparations present several drawbacks, including limited stability, challenges in transportation and storage, and higher costs associated with packaging. To overcome these limitations, the pharmaceutical industry introduced an alternative dosage form known as fast disintegrating/dissolving tablets (FDTs). The first FDA-approved FDT, marketed as Zydis®, was introduced in 1996.(6,7) Fast disintegrating/dissolving tablets (FDTs) disintegrate rapidly in the oral cavity, resulting in quick dissolution, improved absorption, and a faster onset of therapeutic action. They are especially beneficial for geriatric and pediatric patients, as well as for individuals with psychiatric disorders or paralysis, where swallowing conventional tablets can be difficult.(8)FDTs can be prepared using several techniques, including direct compression, lyophilization, molding, sublimation, granulation, spray drying, 3D printing, mass extrusion, and nanonization. In this study, FDTs were formulated by employing both direct compression and lyophilization methods. The present study aims to develop and evaluate oral disintegrating tablets of ferric maltol for the treatment of iron deficiency, particularly in patients who experience difficulty swallowing conventional dosage forms. The objectives of the study include performing pre-formulation studies and formulating oral dispersible tablets of ferric maltol. Optimization of the formulation will be carried out using Design of Experiments (DoE), specifically Central Composite Design (CCD), to identify critical formulation variables and their interactions. The pre-compression parameters to be evaluated are bulk density, tapped density, angle of repose, Carr's index, and Hausner ratio. The formulated tablets will then be assessed for weight variation, thickness, hardness, friability, and wetting time. Furthermore, in vitro studies will be conducted to investigate the drug release and dissolution behavior of the developed formulations.

## MATERIALS AND METHODS

**Materials**

Ferric maltol was kindly supplied by Viruj Pharma (India). Hydroxypropyl beta-cyclodextrin (HPβCD) and magnesium stearate were obtained from Chem Research Pvt. Ltd. (India). Pearlitol® SD 200 was purchased from Chem Research Pvt. Ltd. (India). Microcrystalline cellulose (HiCel® 25) was obtained from Sigachi Industries (India). Crospovidone XL-10 and polyvinylpyrrolidone K30 (PVP K30) were sourced from Boai NKY Medical Holding Ltd. (China). Xylitol was obtained from GVSK Pharma Ltd. (India), while Stevia was procured from Jhanil Healthcare (India). All other chemicals and reagents used in the study were of analytical grade.

## METHODALOGY

**Formulation of Oral Dispersible Tablet**

Wet granulation method was used to formulate an oral dispersible tablet Required amount of Ferric maltol and beta cyclodextrin were mixed in the mortal and pistil by using PVPK 30 as a binder the binder solution was prepared by using ethanol. All the ingredient are weighed and mixed through binder solution Wet mass was sieved at sieve number 8 and kept it for drying After drying magnesium stearate was weighed and mixed through polythene cover and passed through the mess number 38. Formulation of ferric maltol Oral Disintegration Tablets 1.

**Method Development of HPLC for the Ferric Maltol**

A reverse phase ODS 3V C18 (250 mm x4.5 µm x 5 µ) was utilized as a chromatographic column for the estimation of ferric maltol. The column oven temperature and the HPLC system (warters2695) were maintained at 15 ℃. The mobile phase (MP) of Mobile phase A: Water: Acetonitrile: Ortho phosphoric acid (1000:10:10) Mobile phase B: Water: Acetonitrile: Ortho phosphoric acid (200:800:1) is used as the mobile phase was set at a rate of flow of 1.0 ml/min, and 5 µL was the injection volume. Was observed in 275 nm

**Experimental Design**

The Design of Experiment (DoE) is an important part of the formulation process. In this experiment, Design Expert Software version 13.0 was employed to demonstrate the model of response surface by obtaining different values in combination, for the optimization of Oral dispersible tablet. In this software historic data design experimental design was selected with 2 factor 3 level employed to optimize the ODT formulation. The three-level was coded with +1, 0and -1 which indicates high, intermediate and low level respectively (Table 2). From this design, 9 formulations were obtained. Depend on the trial-and-error technique the low and the high level were fixed. Independent variables selected for the design were Diluent and Superdisintigrant and the dependent variables, that is the responses selected were Wetting time and Disintegrating Values for $3^2$ Factorial Design for Oral Dispersible tablet (Table 2). $3^2$ factorial Design with the in dependent variables(factors) and dependent variables for oral dispersible tablet 3

**Check Point Analysis and Optimization of Oral Dispersible Tablet**

To obtain the optimized formulation, the desirability function was applied by Design Expert 13.0 software. The optimization technique using design software and the desirability criteria of response surface helps to calculate the maximum desirability by predicting the optimized point. Based on the importance of each response which might affect the goal's characteristics, the desired point was selected. For every response the goal fields have five options, they are, within range, target, minimum, maximum, and none. This design selected the optimum formula by means of minimum wetting time and minimum disintegration time

**Optimization of the Oral Dispersible Tablet**

The factors influencing oral dispersible tablet formulation were identified using the results of the initial studies. The design included two elements that affected the formulation's nature: the amount of diluent and amount of disintegrant the best formula was chosen based on the less disintegration time and less wetting time

## RESULTS AND DISCUSSION

**Physicochemical Properties of Ferric Maltol**

**Determination of Absorption Maxima (λ max) using UV-Visible Spectroscopy**

The λmax of Ferric maltol was found to be 270nm(Figure 5)in the methanol as a solvent by using UV-Visible Spectroscopy

**λmax of Ferric maltol Figure 1.**

**UV Visible Spectroscopy for Ferric Maltol**

In this method, the standard curve was observed from the absorbance of the serial dilutions 5-25 µg/ml of the drug in methanol at 270nm. The absorbance values and the graph of absorbance vs concentration were displayed. The regression value, $R^2$ =0.9984, with slope value 0.004and the Y-intercept = 0.0018 indicates perfect linearity between absorbance and concentration. absorbance of the serial dilutions 5-25 µg/ml Absorbance values of serial dilutions of the Ferric maltol in methanol (Table 4). Calibration curve of ferric maltol (Figure 2).

**FTIR**

Although FTIR is an effective technique for determining the purity of compounds by their functional groups, its use in compound mixtures is restricted. This method uses particular light wavelengths to detect the molecular vibrations

of functional groups, either by stretching or bending them.The FTIR spectra of Drug ferric maltol and physical mixture displayed all the characteristic peaks of the functional groups. FTIR of the pure drug Figure 3. FTIR of the Formulation Figure 4. FTIR spectroscopy analysis Table 5.

**DSC of Ferric Maltol**

The DSC thermal analysis of ferric maltol displayed a distinct endothermic peak at304.31°C, as illustrated.The sharp endothermic peak at 304.31°C represents the melting point of pure ferric maltol, indicating its crystalline nature. DSC of the pure Drug (Figure 5).

**DSC of the Formulation**

The decrease in enthalpy indicates a reduction in crystallinity. DSC of the formulation Figure 6.

**HPLC Analysis of Pure Drug**

HPLC of pure drug (Figure 7). High-performance liquid chromatography (HPLC) analysis of ferric maltol was carried out using a C18 reverse-phase column maintained at 15 °C with an injection volume of 5 μL and a total run time of 35 minutes. The mobile phase consisted of two solvent systems: mobile phase A (water:acetonitrile:ortho-phosphoric acid, 1000:10:10, v/v/v) and mobile phase B (water:acetonitrile:ortho-phosphoric acid, 200:800:1, v/v/v). The separation was monitored at a wavelength of 275 nm. The chromatogram revealed two major peaks, with ferric eluting at a retention time of 4.350 minutes and maltol at 15.345 minutes. Quantitative analysis showed that ferric accounted for 20.56% of the total peak area (area: 5,706,544), while maltol represented 79.44% (area: 22,045,304). These results confirmed effective resolution and quantification of ferric and maltol under the applied chromatographic conditions, with maltol being the predominant component in the sample.

**XRD**

**Pure Drug (Ferric Maltol)**

The XRD pattern of the pure drug shows distinct and sharp diffraction peaks, particularly with a major peak around 10°–20° 2θ.The presence of sharp peaks indicates a crystalline nature.

The intensity of the peaks also suggests high crystallinity, which is typical for unprocessed or pure compounds.

**Formulated Tablet (F1)**

The formulated tablet's XRD shows a reduction in peak intensity compared to the pure drug.

Although some characteristic peaks are still visible, they are less sharp, indicating reduced crystallinity or partial amorphization. XRD of the Pure Drug Figure 8. XRD of the Pure Drug Figure 9.

**Pre compression Evaluation**

The table includes all of the precompression evaluation studies, including Carr's compressibility index, Hausner's ratio, bulk density, taped density, and angle of repose. The powder blend's flow characteristic is defined by its angle of repose. Compared to those with high angle of repose values, those with low angle of repose have better flow characteristics. Every formulation blend exhibited good flow properties, with an angle of repose falling between 26.56-31.15. The bulk density of every formulation powder blend was determined to be between 0.470 and 0.497. Every formulation powder blend with tapped density was discovered to be between 0.618 and 0.598. Additionally, Carr's index values were determined to be between 18 and 21, indicating that all formulation blends had acceptable flow properties. Pre-compression studies of powder blend Table 6.

**Post-Compression Studies of Ferric maltol Oral Disintegrating Tablets.**

Total formulations (F1-F9) were prepared using various excipients and super disintegrants was utilized with various concentrations. ODTs were prepared by Wet Granulation method and evaluated for Hardness, weight variation, friability, Thickness, disintegration time and dissolution. Weight variation of formulated batches F1 to F9 was shown to be within the acceptable limits i.e., 350±5 mg. The hardness of tablets was between 4-4.5 kg/cm$^2$. Thickness of ODTs was found in between 3.47-3.50 mm. Friability was below 1% indicating good resistance against mechanical

shear wetting time was in the range of 26-52 sec and disintegration was in the range of 30-72 sec. Post-Compression Studies of Ferric maltol Oral Disintegrating Tablets (Table 7).

**Optimization of Oral dispersible tablet**

**Mathematical models for design of experiments**

Two parameters (Diluents and Superdisintigrant) were chosen for Tablet formulation optimization based on the factors determined during screening trials. Using Design Expert software v.13, an oral dispersible tablet was put through a $3^2$ Factorial design. Following that, 9 experimental runs were generated. Table 8 displays the results of these experiments and S-6 was found to be optimized among all the formulations. $3^2$ Factorial Design with observed responses for optimisation of oral dispersible tablet 8. ANOVA and regression analysis have statistically confirmed the polynomial equations. To depict the characteristics of independent influences on wetting time and disintegrating time, and the response surface were plotted using the 3D graphs. The p- value of ANOVA results was used to determine the significant factors. The factors, Diluent and superdisintigrant was significant as p- value was <0.05

**ANOVA Results**

**Response 1: Wetting time Table 9.**

**Fit Statistics**

As per the Table 10 The standard deviation was 0.9545 and % variation was determined by coefficient of variance which was 2.59%. $R^2$ values for wetting time analysis Table 10. Response 1: Disintegration time Table 11.

**Fit Statistics**

The standard deviation was 2.96 and % variation was determined by coefficient of variance which was 5.92%. $R^2$ values for disintegration time analysis Table 12.

**Graphical Representation for Wetting time**

The response surface's Actual values vs predicted values graphs, (Figure B), 3D graphs (Figure A) and Counter Plot graph (Figure C) were plotted. Fgure10: Graphical Representation for wetting tim3D surface plot(A), Predicted v/s Actual graph (B), Counter plot (C),

**Graphical Representation for Disintegrating time**

The response surface's Actual values vs predicted values graphs, (Figure C), 3D graphs (Figure B) and Counter Plot graph (Figure A) were plotted

**Graphical Representation for Disintegration time (Figure 11)**

**Counter plot, 3D surfaces plot , Predicted v/s Actual graph**

**(Table: 13)**

**Drug content**

Drug content of the formulation was performed as mention in the above method and drug content was found to be 98%

**Dissolution**

Dissolution was performed as mentioned above method for the Optimized formulation. *In vitro* drug release study of the prepared formulation Table 14. *In vitro* drug release study (Figure 12). Mathematical model fitting of drug release data (Table 15). Zero-order kinetic drug release (Figure 13).

## CONCLUSION

The study successfully formulated and optimized ferric maltol oral disintegrating tablets using a systematic Design of Experiments (DoE) approach. Pre-formulation studies confirmed no significant interactions between the drug and excipients, ensuring formulation stability. The optimized batch exhibited excellent pre-compression and post-compression characteristics, including rapid wetting and disintegration times, satisfactory mechanical strength, and high drug release efficiency. The dissolution profile followed zero-order kinetics, indicating a consistent and predictable drug release pattern. Overall, the developed ferric maltol ODT provides an effective alternative to conventional iron therapy, especially beneficial for paediatric, geriatric, and dysphagic patients, ultimately aiming to enhance patient compliance and treatment outcomes

## ABSTRACT

The rapid increase in the of polymorphic, metamorphic, and obfuscated malware has made conventional signature-based detection systems commonly known as antivirus programmes increasingly ineffective. While machine learning driven static analysis offers a capable alternative, most existing approaches depend on isolated feature modalities such as byte n-grams or Portable Executable (PE) headers weakening to capture the full behavioral and structural signatures characteristic of modern malware families. To address this gap, we propose Multi-Modal Malware Analysis, a novel static analysis framework that seamlessly integrates four complementary feature modalities: (1) structural metadata from PE headers, (2) byte-level sequential patterns via 2-gram frequency distributions, (3) operational semantics through normalized opcode histograms, and (4) entropy-based statistical measures of file randomness. These mixed features are processed by a two-stage ensemble architecture comprising modality-specialized base classifiers (Random Forest, Gradient Boosting, MLP, and SVM) followed by a meta-classifier that fuses probabilistic outputs into a final multi-class decision. Evaluated on a meticulously curated dataset of 1,000 samples across five classes benign, Trojan, virus, worm, and adware proposed method achieves 94.7% accuracy, 94.4% macro-F1 score, and demonstrates superior robustness against adversarial methods compared to single-modality and conventional ensemble baselines. Furthermore, with an average per-file analysis time of 2.35 seconds and a model footprint of 150 MB, proposed method is suitable for real-time deployment in enterprise security pipelines. Ablation studies,

feature importance rankings, and statistical significance tests (McNemar's and DeLong's) validate the efficacy of multi-modal fusion. This work establishes a new benchmark for static, multi-class malware classification and provides a scalable foundation for next-generation cyber defense systems.

**Keywords:** Malware detection; static analysis; multi-modal learning; ensemble classification; feature fusion; cybersecurity; machine learning; PE file analysis; adversarial robustness.

## INTRODUCTION

The proliferation of sophisticated malware variants, often employing obfuscation and polymorphism, presents a formidable challenge to conventional cybersecurity defenses, necessitating the development of advanced detection and classification methodologies [1, 2]. This challenge is exacerbated by the limitations of traditional signature-based methods, which are easily circumvented by even minor alterations in malware code, and the inherent difficulties in distinguishing evasive malware from benign programs [3]. As a result, modern malware detection increasingly relies on sophisticated analysis techniques, including both static and dynamic approaches, to extract meaningful features that characterize malicious behavior [3, 4]. While dynamic analysis executes suspicious code in a controlled environment to observe its runtime behavior, static analysis examines the executable without execution, often extracting features such as byte sequences, API calls, and structural metadata [4]. The efficacy of static analysis stems from its ability to scrutinize binary or disassembled files for inherent malicious characteristics, thereby circumventing the complexities and potential evasions associated with dynamic execution in a sandbox environment [1]. However, traditional static analysis methods, such as those relying on signature matching or simple opcode sequence analysis, frequently fall short when confronted with sophisticated adversarial techniques like code obfuscation, packing, and encryption, which are designed to disguise malicious functionalities [5, 6]. The emergence of polymorphic, metamorphic, and obfuscated malware strains further underscores this inadequacy, rendering traditional signature-based detection increasingly ineffective [7]. This limitation necessitates a paradigm shift towards more robust analytical frameworks capable of discerning subtle malicious patterns within an executable's static structure, even in the presence of anti-analysis techniques [8]. Moreover, the high resemblance of obfuscated and evasive malware to benign programs further complicates detection efforts, often leading to high false positive rates in less sophisticated systems [3]. While dynamic analysis can circumvent some obfuscation by observing execution, it often succumbs to anti-analysis techniques like fingerprinting and environmental checks that prevent malware from revealing its true payload in a sandbox [9].

Consequently, static analysis, which analyses executable programs without running them, offers a compelling alternative by scrutinizing the binary or disassembled code for malicious characteristics, thus avoiding the execution-time complexities and evasive maneuvers inherent in dynamic environments [10, 11, 12]. However, the primary limitation of static analysis remains its vulnerability to sophisticated evasion techniques, such as code obfuscation and encryption, frequently employed by modern malware to bypass detection mechanisms [13]. Despite these challenges, static analysis remains a crucial component of a comprehensive security strategy due to its efficiency and ability to analyze dormant code that dynamic methods might miss [14]. Conversely, dynamic analysis, while effective at revealing runtime behaviors, can be circumvented by sandbox evasion techniques, leading to an incomplete understanding of malware functionality [15]. Furthermore, static analysis offers advantages in scalability and speed, as it does not require the resource-intensive process of executing each sample in a virtualized environment, making it suitable for processing large datasets efficiently [16]. However, it is particularly susceptible to obfuscation techniques, including junk code insertion, which can significantly alter structural signatures and evade detection by static methods [17]. However, advanced malware authors often deliberately craft binaries to impede both disassembly and analysis, exploiting technical binary obfuscation to evade static analysis techniques [18]. This includes techniques like packing, which compresses or encrypts the original executable, making it challenging for static tools to analyze the underlying malicious code without prior unpacking [19]. Therefore, while dynamic

analysis can offer insights into runtime behaviors, its resource intensity and susceptibility to sandbox evasion techniques limit its standalone effectiveness [16, 20]. The widespread increase in polymorphic, metamorphic, and obfuscated malware has rendered traditional signature-based detection systems increasingly ineffective.

## METHODOLOGY

The proposed method architecture, as shown in Figure 1 employs a comprehensive approach for malware detection and classification by integrating four distinct feature modalities as detail in Table 1 extracted from Portable Executable (PE) sample files. The methodology follows a structured pipeline comprising feature extraction, feature selection, modality-specific classification, and meta-classification stages. The proposed framework employs a comprehensive multi-modal feature extraction methodology that systematically analyses Portable Executable (PE) files through four distinct but balancing perspectives. This sophisticated approach enables the capture of diverse malware characteristics that would be missed by single-modality analysis methods.

**Structural Feature Extraction** begins with the validation of PE file headers using standard signatures "MZ" and "PE". The structural analysis module constructs a 52-dimensional feature vector by concatenating four major components: PE header features ($f_{pe}$), optional header features ($f_{opt}$), section features ($f_{sec}$), and import analysis features ($f_{imp}$). The sample section analysis extracts critical information about each section in the PE file, including the number of sections ($n_s$), VirtualSize, RawSize, and section Characteristics. A particularly important aspect is the calculation of section entropy using Shannon entropy formula, which quantifies the randomness within each section. The import analysis component examines the file's dependencies by counting imported libraries (L) and imported functions (F), while also categorizing functions into security-relevant groups such as FileIO, Network, Registry, Process, and Suspicious categories. The complete structural feature vector undergoes standardization to ensure consistent scaling across all features.

$f_s = f_pe \oplus f_opt \oplus f_sec \oplus f_imp$ …. (1)

where

- $f_{pe}$: PE header features including Image Base, Entry Point, Section Alignment, File Alignment, Size of Image, Size of Headers, Check Sum, Subsystem, Dll Characteristics, Machine Type, Linker Version, OS Version, and Image Version
- $f_{opt}$: Optional header features comprising Size of Code, Size of Initialized Data, Size of Uninitialized Data, Address of Entry Point, Base of Code, Base of Data, Section Alignment, File Alignment, Stack Reserve, Stack Commit, Heap Reserve, and Heap Commit
- $f_{sec}$: Section features including number of sections ($n_s$), Virtual Size, Raw Size, Characteristics, and entropy $H_i$ for each section $i$:

$$H_i = -\sum_{j=0}^{255} p_j \log_2 p_j \quad \text{where} \quad p_j = \frac{\text{count}(j)}{\text{sectionSize}}$$

- $\mathbf{f}_{imp}$: Import analysis features including number of imported libraries ($L$), imported functions ($F$), and categorized function counts for File IO, Network, Registry, Process, and Suspicious categories

The final feature vector undergoes standardization: $\boldsymbol{f_s} \leftarrow \frac{f_s - \mu_s}{\sigma_s}$

  $H_{block}^k = -\sum_{j=0}^{255} p_{block}^k[j] \log_2 p_{block}^k[j]$
  $\mathbf{f}_e \leftarrow [H_{total}, E[H], \sigma[H], \max(H), \min(H), \text{median}(H), \text{range}(H), \text{count}(H > 7.0)]$
  **return** $\mathbf{f}_e$
**end procedure**

**Dataset Composition and Class Distribution (Table 3)**

**Byte Sequence N-gram Analysis** processes the raw binary content of the file by first converting it to hexadecimal representation. The module employs bi-gram analysis (n=2) to capture sequential byte patterns that are characteristic of malware code structures. The frequency of each bi-gram is systematically counted across the entire file, and the top 100 most frequent bi-grams are selected for feature representation. These frequencies are then probability-normalized to create a consistent feature vector that captures the statistical distribution of byte patterns independent of file size.

$$\mathcal{G}[g] = \sum_{i=0}^{|H|-n} I(H[i{:}\, i+n] = g)$$

The top $k$ = 100 most frequent n-grams are selected and probability-normalized:

$$\boldsymbol{f_b}[i] = \frac{\mathcal{G}_{\text{sre}}[i]}{T}, \quad T = \sum_{i=1}^{k} \mathcal{G}_{\text{sre}}[i]$$

**Opcode Frequency Analysis** utilizes the Capstone disassembly engine to analyse the executable sections of the PE file using x86-32 architecture. The process involves disassembling each executable section and iterating through all instructions to count occurrences of 20 predefined opcodes that are particularly relevant for malware behavior analysis. The opcode frequencies are normalized by the total number of disassembled instructions, creating a probability distribution that represents the operational semantics of the code. This approach captures the fundamental computational patterns and behavioral signatures characteristic of different malware families. Disassembly is performed using the Capstone engine (x86-32 architecture) on executable sections. For a predefined opcode set O = {$o_1, o_2, \ldots, o_{20}$}, the frequency vector is computed as:

$$\boldsymbol{f_o}[j] = \frac{c[j]}{N_{\text{total}}}, \quad c[j] = \sum_{S \in B} \sum_{I \in \mathcal{I}_S} I\left(I.\text{mnemonic} = o_j\right)$$

where $N_{total}$ is the total number of disassembled instructions across all executable sections.

**Entropy-Based Feature Extraction** employs multiple entropy measures to quantify the randomness and complexity of the file content. The overall file entropy calculates the Shannon entropy across the entire file, measuring the global randomness of byte distribution. Additionally, block-wise entropy analysis divides the file into 512-byte blocks and computes entropy statistics for each block. The resulting feature vector captures eight statistical measures derived from these entropy calculations, providing a comprehensive view of the file's complexity profile. High-entropy regions are particularly significant as they often indicate packed, encrypted, or obfuscated code sections commonly found in modern malware. Multiple entropy measures are computed using block size $b_{size}$= 512:
Overall file entropy:

$$H_{\text{total}} = -\sum_{i=0}^{255} p[i] \log_2 p\,[i], \quad p[i] = \frac{\text{count}(i)}{|B|}$$

Block-wise entropy statistics:

$$H^k_{\text{block}} = -\sum_{j=0}^{255} p^k_{\text{block}}[j] \log_2 p^k_{\text{block}}\,[j]$$

The feature vector $\mathbf{f}_e \in R^8$ contains: $H_{total}$, mean entropy $E[H]$, standard deviation $\sigma[H]$, max($H$), min($H$), *median*($H$), range (max($H$)−min($H$)), and count of high-entropy blocks ($H$ >7.0).

**Feature Selection**

ANOVA based feature selection is employed to identify the most discriminative features. For feature matrix $\mathbf{X} \in R^{N \times M}$ and labels $\mathbf{y} \in Z^N$ (5 malware classes), the F-statistic for feature $j$ is computed as:

$$F_j = \frac{MSB_j}{MSW_j} = \frac{SSB_j/(5-1)}{SSW_j/(N-5)} \quad \text{where:} \quad SSB_j = \sum_{c=1}^{5} n_c\left(\overline{x_{c,j}} - \overline{x_j}\right)^2$$

$$SSW_j = \sum_{c=1}^{5} \sum_{i \in \mathcal{I}_c} \left(X[i,j] - \overline{x_{c,j}}\right)^2$$

The top $K$ = 500 features with highest F-statistics are selected for subsequent analysis.

**Algorithm 2** MMMA Framework: Training & Inference

**procedure** MMMA TRAINING(Dataset $D$)
  $\mathbf{X}_{\text{full}}, \mathbf{y} \leftarrow \text{ExtractAllFeatures}(D)$
  $\mathbf{X}_{\text{sel}} \leftarrow \text{ANOVAFeatureSelection}(\mathbf{X}_{\text{full}}, \mathbf{y}, K = 500)$
  Split $\mathbf{X}_{\text{sel}}, \mathbf{y}$ into train/validation sets
  Train base classifiers:
    $\mathcal{C}_s \leftarrow \text{RandomForest}(\mathbf{X}_s)$
    $\mathcal{C}_b \leftarrow \text{GradientBoosting}(\mathbf{X}_b)$
    $\mathcal{C}_o \leftarrow \text{MLP}(\mathbf{X}_o)$
    $\mathcal{C}_e \leftarrow \text{SVM}(\mathbf{X}_e)$
  $\mathbf{M} \leftarrow [\mathcal{C}_s(\mathbf{X}_s) \| \mathcal{C}_b(\mathbf{X}_b) \| \mathcal{C}_o(\mathbf{X}_o) \| \mathcal{C}_e(\mathbf{X}_e)]$
  $\mathcal{C}_{\text{meta}} \leftarrow \text{RandomForest}(\mathbf{M}, \mathbf{y})$
  $\Theta^* \leftarrow \text{HyperparameterTuning}(\mathcal{C}_{\text{meta}})$
  **return** $\mathcal{M} = \{\mathcal{C}_s, \mathcal{C}_b, \mathcal{C}_o, \mathcal{C}_e, \mathcal{C}_{\text{meta}}, \Theta^*\}$
**end procedure**

**procedure** ANOVAFEATURESELECTION($\mathbf{X}, \mathbf{y}, K$)
  **for** each feature $j$ in $\mathbf{X}$ **do**
    $SSB_j \leftarrow \sum_{c=1}^{5} n_c(\bar{x}_{c,j} - \bar{x}_j)^2$
    $SSW_j \leftarrow \sum_{c=1}^{5} \sum_{i \in \mathbb{Z}_c} (X[i,j] - \bar{x}_{c,j})^2$
    $F_j \leftarrow \frac{SSB_j/(5-1)}{SSW_j/(N-5)}$
  **end for**
  **return** top $K$ features by $F_j$
**end procedure**

**procedure** MMMA INFERENCE($\mathcal{M}, P$)
  $\mathbf{f}_s, \mathbf{f}_b, \mathbf{f}_o, \mathbf{f}_e \leftarrow \text{ExtractFeatures}(P)$
  $\mathbf{p}_s \leftarrow \mathcal{C}_s(\mathbf{f}_s)$, $\mathbf{p}_b \leftarrow \mathcal{C}_b(\mathbf{f}_b)$
  $\mathbf{p}_o \leftarrow \mathcal{C}_o(\mathbf{f}_o)$, $\mathbf{p}_e \leftarrow \mathcal{C}_e(\mathbf{f}_e)$
  $\mathbf{m} \leftarrow [\mathbf{p}_s \| \mathbf{p}_b \| \mathbf{p}_o \| \mathbf{p}_e]$
  $\hat{y} \leftarrow \arg\max \mathcal{C}_{\text{meta}}(\mathbf{m})$
  **return** $\hat{y}$
**end procedure**

The training pipeline follows a systematic two-stage ensemble approach that integrates multiple feature modalities through specialized base classifiers and a meta-classification layer. The training begins with full feature extraction from Portable Executable (PE) files, where four distinct feature modalities are extracted in parallel: structural metadata from PE headers (52 features), byte sequence patterns through bi-gram analysis (100 features), operational semantics via op code frequency distributions (20 features), and entropy-based statistical measures (8 features). This multi-modal extraction ensures comprehensive coverage of malware characteristics. Following feature extraction, the framework employs ANOVA (Analysis of Variance) based feature selection to identify the most discriminative features. The feature selection process calculates F-statistics for each feature by comparing between-class variance (SSB) to within-class variance (SSW). The mathematical formulation involves computing sum of squares between groups ($SSB_j$) and sum of squares within groups ($SSW_j$) for each feature j across the five malware classes. The top K=500 features with the highest F-statistics are selected, ensuring optimal feature representation while reducing dimensionality.

**Feature importance analysis across multi-modal features (Figure 2)**

The core innovation lies in the modality-specific base classifier training, where each feature type is processed by a specialized machine learning model optimized for its characteristics. Random Forest handles structural features due to its robustness with categorical and numerical data, Gradient Boosting processes byte sequences for its strength with sequential patterns, Multi-Layer Perceptron analyses opcode frequencies for its non-linear pattern recognition capabilities, and Support Vector Machine handles entropy features for its effectiveness with high-dimensional statistical data. The probability outputs from these base classifiers are concatenated to form meta-features, which train a Random Forest meta-classifier that learns optimal fusion strategies for final prediction. The inference process mirrors the training architecture but operates in a streamlined fashion for real-time deployment. For each test sample, the framework extracts all four feature modalities and applies the pre-trained feature selection model to retain only the most discriminative features. Each modality-specific base classifier generates probability distributions across the five classes (benign, trojan, virus, worm, adware), producing confidence scores for each classification category. The meta-classification stage receives these probability vectors as input and performs the final fusion decision. The Random Forest meta-classifier analyses the complementary information from different modalities, weighing their contributions based on learned patterns from the training phase. The final prediction is determined by selecting the class with the highest aggregated probability score, while the maximum confidence value provides a reliability measure for the decision. This architecture ensures that the framework leverages the strengths of each modality while mitigating individual weaknesses through collective intelligence.

The evaluation framework employs comprehensive metrics to assess performance across multiple dimensions. Accuracy measures overall classification correctness, while precision, recall, and F1-score provide deeper insight into per-class performance and balance between false positives and false negatives. The Area Under Curve (AROC) metric evaluates the model's class separation capability across all possible threshold settings, particularly important for security applications where operating points may vary. Cross-validation ensures statistical reliability of performance estimates, while per-class accuracy analysis reveals the framework's effectiveness against specific malware families. Computational performance metrics including inference time (2.35 seconds per file), memory footprint (150 MB), and throughput (435 samples / second) validate practical deployment feasibility. The ablation study systematically removes individual components to quantify their contribution to overall performance, demonstrating the value of each modality and the meta-classification strategy. The adversarial robustness evaluation subjects the MMMA framework to various attack scenarios to test its resilience against evasion techniques. The analysis measures performance degradation under different types of perturbation including feature manipulation, byte-level modifications, and structural alterations commonly employed by modern malware. The robust score quantifies the framework's ability to maintain detection accuracy under attack conditions, with MMMA demonstrating only 7.9% performance drop compared to 20.8-26.2% degradation in single-modality approaches. The robustness stems from the multi-modal architecture's inherent redundancy, where attackers must simultaneously compromise multiple independent feature spaces to successfully evade detection. This distributed defense mechanism significantly raises the adversary's cost and complexity compared to attacking single-modality systems. Statistical significance tests including McNemar's test for paired comparisons and DeLong's test for ROC curve differences provide mathematical validation of performance improvements over baseline methods.

**Algorithm 3** MMMA Model Evaluation and Robustness Analysis

**Require:** Trained model $\mathcal{M}$, Test dataset $D_{\text{test}}$, Adversarial samples $D_{\text{adv}}$
**Ensure:** Performance metrics, Robustness analysis

  **return** {mcnemar_p, delong_p}
**end procedure**

The comprehensive evaluation establishes that MMMA's multi-modal approach fundamentally addresses limitations of traditional methods through complementary feature integration, sophisticated ensemble architecture, and inherent adversarial resilience, positioning it as a robust solution for next-generation malware detection systems capable of addressing evolving cybersecurity challenges.

## RESULTS

The proposed Multi-Modal Malware Analysis framework demonstrates exceptional performance across multiple evaluation dimensions, significantly outperforming existing baseline approaches. As detailed in Table 3, the MMMA framework achieves a remarkable overall accuracy of 94.7%, representing an absolute improvement of 8.5 to 11.6 percentage points over single-modality methods, which range from 83.1% to 86.2%. This substantial performance gap robustly validates our core hypothesis that the synergistic integration of multi-modal features provides superior discriminative power for malware classification. The consistency of this superiority is further evidenced by the framework's precision (94.9%), recall (94.5%), and F1-score (94.7%), confirming a balanced and reliable classification capability that is crucial for real-world cybersecurity applications where both false positives and false negatives carry significant consequences. The overall performance advantage of MMMA over all baselines is visually summarized in Figure 3. The framework's exceptional classification capability is further quantified by its Area Under the Curve performance of 0.985, as shown in Table 3. This near-perfect score indicates excellent class separation across all possible decision thresholds, substantially outperforming single-modality approaches (AUC 0.906-0.925) and the traditional early fusion ensemble (AUC 0.952). The threshold-independent nature of the AUC metric makes this finding particularly valuable for production environments where optimal classification thresholds may vary based on specific security policies. Complementing this overall performance, the per-class analysis presented in Figure 4 and the detailed breakdown in Table 4 reveal MMMA's consistent effectiveness across all malware categories. The framework demonstrates particularly strong detection capabilities for viruses (95.2% accuracy) and maintains robust performance against Trojans (94.1%), Worms (93.8%), and Adware (94.9%), with a commendably low false positive rate of 1.3% for benign software.

This balanced capability across diverse malware types underscores the framework's generalization power and its suitability for real-world deployment where malware distribution is inherently unpredictable. The underlying rationale for MMMA's superior performance is illuminated by the feature importance analysis depicted in Figure 2, which reveals a well-balanced contribution from all four feature modalities. Byte sequence features emerge as the most discriminative (contributing approximately 30% to the model's decision), closely followed by structural features (25%) and opcode patterns (25%), with entropy-based characteristics providing a solid foundational layer (20%). This balanced distribution critically validates the multi-modal approach, demonstrating that no single feature type dominates the classification, thereby ensuring resilience and providing rich, complementary information. This architectural effectiveness is further confirmed through the computational performance analysis in Figure 5, which shows that MMMA maintains real-time operational capability with an average inference time of 2.35 seconds per file and a manageable memory footprint of 150 MB. A throughput of approximately 435 samples processed per hour makes the framework suitable for enterprise-scale deployment without imposing a significant performance bottleneck. A critical requirement for modern malware detection systems is resilience against adversarial attacks, and our evaluation robustly demonstrates MMMA's exceptional robustness in this domain. As systematically analyzed in Table 5 and illustrated in Figure 6, under a variety of attack conditions— including feature manipulation, byte-level perturbations, and structural alterations, MMMA maintains an average accuracy of 87.2%, experiencing only a 7.9% performance drop. This stands in stark contrast to the best single-modality baseline, which suffered a degradation of 20.8-26.2%.

This enhanced resilience stems directly from the multi-modal architecture's inherent redundancy, where an adversary must simultaneously and successfully compromise multiple independent feature spaces to evade detection, thereby significantly raising the cost and complexity of a successful attack. The architectural soundness of the MMMA framework is systematically deconstructed and validated through a comprehensive ablation study, with results detailed in Table 6 and Figure 7. The study reveals that each component meaningfully contributes to the overall performance. The removal of any single modality causes a performance drop ranging from 3.9% (without entropy features) to 6.5% (without opcode features), with opcode analysis showing the highest individual impact. Furthermore, the two-stage ensemble strategy, employing a meta-classifier, provides an additional 3.5%

improvement in accuracy over a simple early fusion approach, underscoring the value of learning an optimal fusion strategy from the base classifiers' probabilistic outputs. Finally, the holistic and superior performance profile of the MMMA framework is elegantly summarized in the radar chart presented in Figure 8, which visually integrates its performance across six critical dimensions: accuracy, precision, recall, F1-score, AUC, and adversarial robustness. The larger, more balanced coverage area of MMMA compared to the best baseline illustrates that our proposed framework provides comprehensive enhancements across all evaluation criteria, rather than optimizing for specific metrics at the expense of others. This well-rounded performance profile, combined with demonstrated computational efficiency and robust security characteristics, positions MMMA as a compelling and advanced solution for next-generation malware detection systems capable of addressing the evolving challenges in the cybersecurity landscape.

## CONCLUSION

This research highlights the significant advantages of integrating diverse feature sets and ensemble learning for robust malware classification, particularly in mitigating the challenges posed by polymorphic and obfuscated threats. Our proposed Multi-Modal Malware Analysis framework, by synergistically leveraging structural metadata, byte-level sequential patterns, operational semantics, and entropy-based statistical measures, achieves superior detection accuracy and robustness against adversarial perturbations. This comprehensive approach, which combines hybrid feature selection and an ensemble classifier, not only achieves high accuracy but also maintains a low false positive rate, ensuring practical applicability in real-world scenarios. The fusion-based classification and optimized preprocessing pipelines further contribute to enhanced detection efficiency across diverse datasets, addressing issues such as overfitting and software encryption. Furthermore, the model's adaptive learning mechanisms ensure that it remains effective against new and evolving malware variants, maintaining high accuracy over time. Such integration of multiple machine learning architectures leads to superior classification performance compared to traditional methods, enabling a more adept identification of outlying behaviors that could signify emerging threats. This probabilistic anomaly profiling capability, combined with multi-faceted behavioral analysis, allows for a comprehensive mechanism to distinguish between benign and malicious executables, achieving consistently high accuracy and minimal false positive rates across diverse malware variants.

**ABSTRACT**

Phalsa(*Grewia asiatica* L.) is an evanescent shrub native to South Asia, traditionally known for its stimulating summer fruit and medicinal operations. Adding scientific attention has been drawn to its nutritive and phytochemical profile, which includes anthocyanins, flavonoids, fiber, essential amino acids, vitamins, and minerals. Multitudinous studies punctuate its antioxidant, antidiabetic,anti-inflammatory, antimicrobial, and hepatoprotective benefits. This review provides a thorough account of Phalsa's origin, nutritive composition, health-promoting benefits, and culinary eventuality, while also describing recent value- added products developed from fruit.

**Keywords:** *Grewia asiatica*, Phalsa, functional foods, antioxidants, phytochemicals, nutraceuticals, traditional medicine, food innovation

## INTRODUCTION

The global demand for functional foods has turned attention to under utilized species with proven nutritive and medicinal value (1, 2, 3). Among them, Phalsa (*Grewia asiatica* L.) stands out due to its balanced nutrient content, rich antioxidant profile, and remedial properties(4, 5).Traditionally consumed fresh or as a juice during hot seasons, Phalsa (*Grewia asiatica*) has recently attracted growing research interest due to its potential to modulate oxidative stress, support glycemic regulation, and promote cardiovascular and digestive health (6, 7).

**Origin and history**

Phalsa (*Grewia asiatica* L.) is indigenous to the Indian subcontinent and is commonly grown in India, Pakistan, Bangladesh, South and Southeast Asia, where it grows in tropical and subtropical regions (8). Phalsa belongs to the family Malvaceae and has been known since time immemorial for its edible fruit, medicinal bark, and use in traditional medicine (9,10). It is referred to by several regional names including "Parushaka" in Sanskrit and is described in classical Ayurvedic works as a cooling, astringent, and digest-supporting fruit (11). In ancient Indian systems of medicine, Phalsa was utilized to treat fever, thirst, diarrhea, inflammation, and respiratory distress (12, 13), and had cultural significance as a summer oblation based on its supposed "cooling" effect on the system (14). Its medicinal uses included the bark and leaves, being applied as poultices to wounds, and decoctions of the leaves being ingested to treat gastric complaints and fevers (15). In colonial days, the plant was recorded by early British botanists, who promoted its sparsely spread introduction into Africa and Southeast Asia, although its perishable nature limited it as a significant export crop. The fruit was traditionally picked and eaten fresh or made into juices and syrups by village communities during the peak summer season to avoid heat stroke(16). Though widely used since ancient times, Phalsa was still not fully exploited at the commercial scale till recent decades when growing interest in native fruits and functional foods prompted a scientific rediscovery of its phytochemical and medicinally valued attributes. With increasing evidence validating its antioxidant, anti-inflammatory, and metabolic health effects, Phalsa has slowly evolved from a traditional remedy to a scientifically validated nutraceutical prospect, integrating old knowledge and new health uses.

**Nutritive Composition**

Phalsa's nutritional composition varies depending on variety and maturity but generally reflects a nutritionally thick fruit. It contains 74 – 80 percent of moisture, 14-21 g of carbohydrates, 1.3– 1.5 g of protein, 0.1 – 0.9 g of fat, and 5.3 – 5.5 g of fiber/100g of raw fruit pulp (17). Also, it's a significant source of calcium, potassium, iron, phosphorus, and vitamin C(18).

**Carbohydrates**

The carbohydrates present in Phalsa fruits are mainly made up of sugars and starches, which serve as a source of energy and play a key role in metabolic processes. Carbohydrates represent a major portion of the fruit's energy, amounting to about 14 – 21 g/ 100 g (19,20).These carbohydrates consist predominantly of natural sugars, which provide a rapid source of energy and contribute to the fruit's palatability.

**Fiber**

Dietary fiber obtained from Phalsa fruits plays an important role in regulation of overall health. It supports digestion, helps control blood sugar levels, reduces cholesterol, and contributes to maintaining a healthy weight. Phalsa offers substantial fiber between 5.3 and 5.5 g per 100 g of edible portion, supporting gut motility and glycemic regulation. Its high dietary fiber content significantly contributes to the maintenance of digestive health(21).

**Fat**

Fat content in Phalsa is low, generally ranging from 0.1 to 0.9 g per 100 gm of fruit pulp, making it ideal for low- fat diets. The fats are substantially unsaturated and contribute to lipid metabolism without adding significant caloric load (22).

**Protein**

Proteins are vital macromolecules that perform very essential functions in the human body, participating in almost every biological process. Phalsa contains 1.57g of protein per 100 g of comestible portion (23).Although modest in quantity, it provides a source of daily protein intake in fruit-based diets and enhances the nutritional value of the fruit in protein-deficient regions.

**Vitamin Composition**

Phalsa (*Grewia asiatica*) is a small, tangy fruit known for its rich nutrient profile. It is rich in several vitamins. It contains vitamin C (4.38mg/100g), vitamin A (16.11mg/100g), and vitamin B1 (0.02mg/100g) and vitamin B2 (0.26mg/100g), and vitamin B3 (0.82mg/100g), which enhance its antioxidant and immune-boosting potential (24). The high ascorbic acid content contributes to collagen synthesis and overall antioxidant defense.

**Mineral Composition**

Phalsa provides essential minerals like calcium (129mg/100g), phosphorus(39mg/100g), potassium(375mg/100g), and iron (3.1mg/100g), which play vital roles in various metabolic processes (25). These minerals contribute to bone health (Calcium, phosphorus), oxygen transport (iron), and electrolyte balance (potassium). These minerals substantially enhance the nutritional and functional properties of the fruit. Consequently, Phalsa (*Grewia asiatica*) serves not only as a refreshing fruit but also as a meaningful source of essential micronutrients.

**Bioactive Compounds**

Phalsa contains several bioactive compounds including anthocyanins, flavonoids, tannins, and phenolic acids that impart antioxidants, anti-inflammatory, and cardioprotective properties, and health-promoting properties (26, 27, 28). These phytochemicals enhance the nutraceutical and therapeutic potential of the fruit (29).

**Health Benefits**

Phalsa (*Grewia asiatica*) exhibits a rich profile of nutrients and bioactive phytochemicals that support a wide range of physiological functions. Its consumption has been associated with improved digestion, enhanced glycemic regulation, and strengthened immune function. The high vitamin C content contributes to collagen synthesis and antioxidant defense, while potassium plays a key role in maintaining cardiovascular health.

**Antioxidant ability**

Antioxidant effects of Phalsa have been well proved through DPPH, ABTS, and FRAP assays (30). Its anthocyanins and polyphenols neutralize free radicals, reducing cellular oxidative damage (31). Excerpts from fruit pulp, leaves, and seeds showed strong radical scavenging exertion.

**Antimicrobial ability**

Methanolic extracts of Phalsa (*Grewia asiatica*) exhibited antimicrobial activity against Escherichia coli, Staphylococcus aureus, and *Candida albicans*(32, 33). These effects are attributed to flavonoids and tannins, which disrupt microbial cell walls and inhibit cellular replication.

**Anti-diabetic ability**

Phalsa shows significant antidiabetic goods in streptozotocin- convinced diabetic models. Excerpts helped reduce fasting glucose, ameliorate pancreatic histology, and enhance insulin storage. These parcels are intermediate through polyphenols that modulate glucose metabolism (34, 35).

**Antifungal ability**

Leaf and fruit excerpts of Phalsa have shown inhibitory exertion against Aspergillus and Candida species. The antifungal medium likely involves cell membrane dislocation and oxidative stress induction in fungal cells (36).

**Anti-inflammatory ability**

The anti-inflammatory eventuality of Phalsa is substantiated by reduced expression of COX- 2, TNF- $\alpha$, and IL- 6 in animal models. Bioactive factors similar as quercetin and kaempferol modulate cytokine product and inhibit pro-inflammatory pathways(37).

**Culinary- Operations**

Phalsa is generally consumed as fresh fruit or in the form of authorities, bathos, squashes, and logjams. Its sweet and pungent flavor, combined with vibrant anthocyanin colors, enhances its culinary appeal (38). The pulp is used in mocktails and traditional summer potables across India and Pakistan. Its excerpts have also been tested as natural colorings and preservatives in reused foods.

**Phalsa-Infused Kalari Cheese**

The enrichment of Kalari cheese through the incorporation of Phalsa (*Grewia asiatica*) fruit significantly enhanced the antioxidant properties of the cheese and improved its stability during storage. The addition of Phalsa also enhanced the sensory appeal of the cheese, attributed to its natural pigments and pleasant tart flavor (39).Research highlights the potential of Phalsa (*Grewia asiatica*) as a functional ingredient in dairy-based value-added products to enhance nutritional quality and oxidative stability.

**Phalsa-Fortified Herbal Syrup**

The use of Phalsa (*Grewia asiatica*) extract in the development of herbal syrups has been explored for its potential to support gastrointestinal health. The syrup, formulated using aqueous and methanolic extracts of Phalsa, exhibited spasmolytic effects on isolated smooth muscle preparations (40). These properties suggest the potential application of *Phalsa*-based syrups in the management of abdominal discomfort and irritable bowel conditions.

**Phalsa- Grounded Nutraceutical Powder**

Phalsa (*Grewia asiatica*) pulp was subjected to lyophilization and conventional drying (41) to develop stable nutraceutical powders. The snap- dried interpretation retained significantly advanced antioxidant exertion and better sensitive attributes. The powder was recommended as a bioactive component for blending into smoothies, shakes, or capsules for remedial use in oxidative stress and metabolic diseases.

**Phalsa- Infused Beverages**

The fruit has been extensively used in preparing summer sherbets, functional authorities, and cooling mixers due to its sweetness, courtesan flavor and high ascorbic acid content (42). Phalsa leaves and fruits can be steeped in hot water to create an aromatic tea that also offers nutritional benefits (43). These drinks are frequently consumed to reduce fatigue and help dehumidification during hot rainfall, and they offer an excellent platform for low- sugar, antioxidant-rich drinks.

## CONCLUSION

Phalsa (*Grewia asiatica* L.) is a promising native fruit with rich nutritive and pharmacological properties. Its low calorie and high fiber profile make it an ideal element of healthy diets, while its bioactive composites offer protection against oxidative stress, inflammation, and metabolic diseases. Continued exploration and commercialization sweats could help unleash the full value of this underutilized yet largely salutary fruit.

**ABSTRACT**

In this work, we attempted to study the structural and NLO properties of pure ZnO and ZnO with PVDF composite. ZnO nanoparticles were synthesized using a simple wet chemical method. As prepared, ZnO with PVDF composite was prepared with different percentages of PVDF as 10%, 20%, and 30%. The X-ray diffraction pattern was recorded to elucidate its structural properties such as grain size, strain, etc. UV-Vis spectral studies were also performed to find its band gap values. The third-order susceptibility using Z-scan investigations was carried out using a simple low-cost semiconductor diode laser with a static power output of 5mW at a wavelength of 635 nm as the light source for excitation. The optical studies revealed the self-defocusing and reverse saturable absorption mechanism nature of the sample.

**Keywords:** NLO properties, Optoelectronics, PVDF, ZnO

## INTRODUCTION

Non linear optics is one of the growing field in which the communication happens between laser and materials. Materials that possess fast non-linear responses are used for the application of optoelectronics, optical communication, optical information processing, optical data storage and optical limiting. Recent research has shown interest in searching novel materials for composite of metal oxide with polymers for third order non-linear optical properties with low-power lasers using z-scan technique to study the non-linear refractive index, nonlinear

absorption coefficient and non linear susceptibility, The single beam Z-scan technique is the most used experimental tool to find $n_2$ and $\beta$ of the material. Researchers have focused on this technique as normalized transmittance curve directly reveals the sign $n_2$ and magnitude can also be easily found from experimental calculation. Semiconducting materials which have nonlinear optical properties have wide attention due to their high carrier mobility is suitable for the application of electronics and optical devices. Among these semiconducting metal oxide nanoparticles, ZnO nanoparticles have large exciton binding energy of 60meV, with a direct wide bandgap of 3.37 eV, it is thermally and chemically stable, low toxicity, and cheapest it is also to be noted that it has quantum confinement effect. Due to its versatile properties it qualifies its applications in several areas parallel to energy storage, super capacitor, UV and gas sensors, solar cells, optoelectronic devices, antireflection coatings, biosensors and photocatalyst, biological application and drug analysis[1]. Polymers have great optical characteristics and a high refractive index. High optical quality and perhaps substantial third order nonlinear susceptibility are provided by a doped polymeric material, provided that the dopant has a high molecular polarizability. PVDF is selected as polymer for composite with ZnO Polyvinylidene fluoride (PVDF) is the notable polymer with wide range of applications. It is a semicrystalline polymer, its special feature varies from other polymer. It shows five crystalline phases $\alpha, \beta, \gamma, \delta, and \varepsilon$. It's properties leads to various scientific and technological application such as optical switches, optical waveguides, light-emitting diodes, lenses and optical devices also the non linear quality of PVDF can also be improved by using as composite nanoparticles of high nonlinear optical susceptibility. For third-order nlo research, the literature report uses a variety of polymers as composites, including PVA, PMMA, PE, PP, and PVC; in this case, we have selected PVDF polymer. while perfoming optical and non linear optical properties solvents are used to dissolve the material and then perforemed in that way we have used water and ethanol as a dissolving solvent In order to determine which solvent provides a better and higher susceptibility value as the influence of the solvent changes its properties, we have used water and ethanol to dissolve and then perform optical and nonlinear optical properties[2]. In the present work pure ZnO and ZnO/PVDF nanocomposites as powder were prepared via simple wet chemical method. The structural linear and nonlinear optical properties of nanocomposites were examined. To the best of our knowledge, there was no report published on the nonlinear optical properties of pure Zno and ZnO/PVDF nanocomposites using a low-power continuous wave (CW) laser operating at 635nm as the source of excitation.

**Materials and Synthesis of ZnO Nanomaterials**

To synthesize zinc oxide nanoparticles, 0.1 M of zinc acetate dihydrate[$Zn(CH_3COO)_2{\cdot}2H_2O$] and 3 M of sodium hydroxide (NaOH) were each dissolved separately in 100 mL of distilled water in two different beakers. Both solutions were stirred continuously for 3 hours to ensure complete dissolution and homogenization. After stirring, the sodium hydroxide solution was added dropwise to the zinc acetate solution under constant magnetic stirring. The pH of the mixture was monitored using pH paper and adjusted until a final value of approximately 12 was reached. This alkaline environment facilitated the precipitation of $Zn(OH)_2$, which subsequently converted to ZnO upon heating. The resulting white precipitate was separated by centrifugation and thoroughly washed several times with distilled water to remove residual ions and impurities. The purified precipitate was then dried on a hot plate at 100 °C for 5 hours to eliminate moisture and volatile impurities. Following the drying step, the powder was annealed in a muffle furnace at 500 °C for 3 hours to improve crystallinity and phase purity. A fine white ZnO powder was obtained at the end of this process. For the preparation of ZnO/PVDF nanocomposites, the synthesized ZnO powder was mixed with polyvinylidene fluoride (PVDF) in varying weight percentages (10%, 20%, and 30%). The ZnO and PVDF powders were blended and ground thoroughly using a mortar and pestle for approximately one hour to ensure uniform distribution of the polymer matrix within the ZnO nanoparticle system.

## RESULTS AND DISCUSSION

**XRD analysis**

The obtained pure ZnO and ZnO/PVDF XRD spectra were recorded to confirm its structure as shown in figure 1. It clearly shows that no additional diffraction peak related to PVDF polymer intimates the formation of an amorphous phase. The obtained ZnO peaks are in good agreement with the JCPDS card number (36-1451). All the XRD peaks

confirmed its hexagonal wurtzite ZnO phase. They correspond to miller's indices planes of (100), (002), (101), (102), (110), (103), (112), and (201). The sharp peaks reveal good crystallinity. The zinc structure is characterized by vacant octahedral and partially filled tetrahedral sites [3] . Table 1 shows the various calculated parameters derived from the XRD profile. The lattice constants a and c were calculated from the XRD peaks of the (100) plane and (002) plane respectively. The average crystalline sizes were calculated using the Scherer equation. The crystalline size decreased gradually from the pure sample to adding the different weight percentages of PVDF into the ZnO matrix. Also, it results in reducing the crystallinity of ZnO. However, the strain value increases as the incorporation of PVDF into ZnO. The PVDF incorporation causes the expansion of the ZnO unit cell resulting in increased strain. The calculated inter-planar spacing (d) shows the distortion of lattice structures. The calculated bond values were calculated and reported. The Zn-O bond values agree with the literature values. The calculated structural parameters are shown in Table 1. The dislocation density of the samples was calculated which shows the amount of defect in samples. The larger crystalline size yields the lowest dislocation density, hence, increased crystalline size indicates better crystal quality.

**UV-Visible spectral analysis**

The recorded UV-visible spectra were used to study the optical properties of pure ZnO and ZnO/PVDF composite in two different solvents ethanol and distilled water to observe the effects of solvents in optical studies. Fig.2A and 2B shows the absorption spectra of pure ZnO and ZnO/PVDF composites in ethanol and water solvents. In the ethanol solvent, the absorption peaks were identified at (357,361,359,358 nm) and its calculated band gap values from Tauc's plot were to be (3.17,3.14,3.14, 3.17 eV) for pure ZnO, ZnO+10%PVDF, ZnO+20% PVDF and ZnO+30% PVDF respectively. Similarly, for distilled water, the absorption peaks were absorbed at (352,359,357,357nm) and calculated bandgap values are (3.10,3.10, 3.16, 3.18 eV). From the observed data, it was noticed that strong absorption of ZnO masks the PVDF. The absorption shifted slightly depending on the percentage (%) of PVDF. The blue shift in the absorption peak for all the samples is due to the excitonic absorption of ZnO and ZnO/PVDF, which favors the quantum confinement effect. On comparing the data of both solvents ethanol shows strong absorption compared to water thus it can be concluded that using ethanol as a solvent in optical studies shows good results for optical studies [4].

**Z-Scan studies**

The Z-scan is a versatile tool utilized to calculate the third-order NLO susceptibility ($\chi 3$) of ZnO-doped PVDF solutions in ethanol and water. A low-power laser operating at 650 nm wavelength with 5 mW power serves as the excitation source. The laser beam is focused onto the sample taken in a cuvette of 1 mm thick using a lens of 5 cm focal length, and a circular aperture is placed in the closed aperture (CA) Z-scan technique for measuring the nonlinear index of refraction of the sample. For the open aperture (OA) technique, the aperture is not used, and a 20 cm focal length convex lens is utilized to capture the transmittance of the rays. A power meter source is used to record the transmittance.

**Third-order NLO study**

Polymer-based metal oxide Nanocomposites are suitable for optoelectronics device applications due to easily modifying their optical and electronic property. To fabricate a laser photonic device it is noticed that materials should exhibit excellent ultrafast NLO response is the main criterion. Hence studying the nonlinear optical properties of the materials is essential. To confirm the nonlinear optical properties of the materials, we have carried out Z-scan measurements in both open and closed aperture modes in both water and ethanol solvents. The calculation details of nonlinear absorption, nonlinear refractive index, and susceptibility were followed in the literature paper [5]. The obtained results are shown in Fig.2. The obtained nonlinear parameters are tabulated in Table 2. From the Z scan results it was observed that the pure and PVDF mixed ZnO samples showed saturable absorption (SA) nature. This is due to the absorption of photons at high light intensity, which significantly reaches the ground state. As the concentration of PVDF increases, the transmittance peak of the ZnO-doped PVDF is also increased. The results derived from the CA method are not a pure nonlinear refraction part. The nonlinear coefficient of the absorption part is also mixed with the refraction part. Hence, for the pure part of refraction, the closed aperture data is divided by

corresponding open aperture data. The changes of normalized transmittance with the position in the closed aperture scan depict the negative value of the nonlinear refractive index (β) in the pure and PVDF mixed ZnO samples due to the self-defocusing effect. Thermal nonlinearity, caused by the continuous absorption of light from the source, leads to self-defocusing. The temperature difference inside the sample brought on by the CW laser irradiation causes thermal lensing. The sample becomes a self-defocusing lens at higher temperatures because a negative index of refraction is attained. The value of β calculated in the water solvent is more than that of in the ethanol solvent. Also, it was noticed that the percentage of PVDF concentration increases in the ZnO enhances the β value. Moreover, the evaluated real, imaginary, and total third-order susceptibility also found higher values in the water solvent compared with ethanol. Also, its value increases with the increasing percentage concentration of PVDF in the ZnO matrix. Hence, the Z scan analysis confirmed that the adding percentage of PVDF in the ZnO host matrix improves the nonlinear optical properties of ZnO and is a promising excellent candidate for optoelectronic device applications.

## CONCLUSION

In the present study, pure ZnO and ZnO/PVDF were synthesized through a simple wet chemical method and the structural and optical characterization was carried out. The XRD analysis confirmed the crystallinity and strain induced in the samples due to the presence of PVDF. The linear and non-linear optical properties were analyzed for UV-visible spectral and Z-Scan analysis solvents are used to dissolve the material here two different solvents are used to observe which solvent enhance good NLO properties, Solvents used here to dissolve the material is ethanol and distilled water The research finding proves that water is a good solvent for enhanced NLO properties of ZnO/PVDF composite on increasing the percentage of PVDF as the $\chi^{(3)}$ value increses from $5.62\times10^{-7}$ to $8.16\times10^{-7}$ esu suggest that it's a good candidate for application in nonlinear optics

## ACKNOWLEDGEMENT

The authors would like to express sincere gratitude to the Department of Physics, Presidency College, Chennai, for their unwavering support and resource that made this research work possible.

### Author Contribution

A.Mohammed Muqtasisd, Dr. M.Sivakumar, Dr.S.Srinivanasan, Dr. S.Jeyaram, Contributed to the study's conception and design. Material Preparation, data collections and analysis were performed by A. Mohammed Muqtasid, Dr.M.Sivakumar, Dr.S.Srinivasan, Dr.S.Jeyaram. The first draft was written by A. Mohammed Muqtasid and all authors commented on the previous versions of the script. All authors read and approved the final manuscript.

### Funding

The authors declare that no funds, grants, or other support were received during the preparation of this manuscript.

**Data availability**
The authors confirm that the data supporting the findings of this study are available within the article.

**Competing Interest**
The authors have no relevant financial or non-financial interests to disclose.

## ABSTRACT

All skin conditions are categorized in Ayurveda under the category *Kushta Roga*. One of them is *Shwitra.* The *Sapta Dravyas*, or *Vata, Pitta, Kapha, Rasa, Rakta, Mamsa*, and *Meda*, are responsible for the disease known as Shwitra, which is characterized by pale discolored areas on the body. The core site of *Shwitra* is generally thought to be the fourth tier of *Twacha* (Tamra). It and vitiligo may be connected. A dermatological condition known as vitiligo that causes hypopigmentation affects 1% of people globally. The 48-year-old male in this case report complained of whitish discolored patches over both legs (shin aspect), which were successfully treated with *Shamana Aushadhis* initially, then with *Virechana* and *Jaloukacharana*, which are both forms of repeated Shodhana. After receiving *Virechana, Jaloukacharana*, and *Shamana Aushadhis*, where subjective criteria were assessed using a scoring system and objective criteria were assessed using the VETI Scoring method, the patient displayed optimistic results. Patient received *Shamana Aushadhis* at first, which caused the white discolored patches to turn pinkish. Later, the patient received repeated courses of *Virechana* and *Jaloukacharana* at regular intervals, and the subject showed an

80% improvement in the subjective criteria and an improvement in the VETI score from 10 to 4. Therefore, the current case study emphasizes the significance of Ayurvedic treatment's effectiveness in *Shwitra*, as indicated in classics.

**Keywords:** *Shwitra, Vitiligo, Jaloukacharana*, etc.

## INTRODUCTION

All skin conditions are grouped together in Ayurveda under the term Kushta. In the classic *Kushta Roga Chikitsa*, *Shwitra* is referenced[1]. The Sanskrit term Shweta, which meaning white patch, is where the name *Shwitra* originates. Shwitra is a disorder that causes white spots to develop on the body. The *Shweta Bhava Michanti Shwitram* of the *Kashyapa Samhita*. Other names for it include *Kilasa, Daruna, Aruna*, and *Shweta Kushta*. The skin's Chaya and Prabha are controlled by the *Bhrajaka Pitta*, which is located there[2]. Skin conditions like *Shwitra* can be brought on by any impairment of *Bhrajaka Pitta* and *Vata Dosha*. The center of sickness in *Shwitra* is *Medhodhatu*. There are three different sorts of *Shwitra* stated in Dhatus, depending on where it is found[3]. If it is in the *Rakta* (blood), it is red; if it is in the *Mamsa* (muscular tissue), it is coppery; and if it is in the Medas, it is white. This may be connected to vitiligo because of the disease's resemblance in appearance. One percent of people worldwide have the acquired condition vitiligo. Patches of hypopigmentation arise as a result of focal melanocyte loss[4]. It is believed to be caused by the autoimmune destruction of melanocytes by cells. Frequently symmetrical, generalized vitiligo affects the hands, wrists, feet, knees, neck, as well as the skin around bodily orifices. Segmental vitiligo is only present in a single area of the body; however, it is not always a dermatome. Depigmentation patches have distinct borders[5].

## AIM AND OBJECTIVES

To evaluate the efficacy of Ayurvedic Medicines in *Shwitra Roga*

## CASE STUDY

The 48-year-old guy in this case report did not previously have HTN, diabetes, or any other systemic ailment. He complained of white, discolored patches across both legs (shin aspect), which were somewhat itchy but did not burn. All of these symptoms are stated to have worsened throughout the course of the previous month, or in the month of May 2023. The subject originally disregarded these symptoms and skipped any medication. He sought treatment at Quadra Ayurvedic Medical College and Hospital, Roorkee, Uttarakhand, after patches began gradually spreading throughout the whole length of his bilateral shin area.

**Past History**

- There is no prior history of the aforementioned skin issues or injuries.
- No previous history of HTN, DM, thyroid, or another systemic illness.

**Family History**

No family history

**Personal History**

**Marital status** – Divorced
**Religion** – Hindu
**Occupation** – Businessman
**Ahar** - Mixed, occasionally eat non-veg.
**Appetite** - Normal

**Bowel** – 1-2 times/day
**Micturition** - 4 to 5 times/day,
**Sleep** - Normal, 6 to 7 hrs.
**Addictions** – Smoking occasionally

**Nidana**
- *Viruddha Ahara*
- *Vishamashana*
- *Adhyashana*
- *Viharaja*
- *Diwaswapna*
- *Manasika*

**Clinical Features**
Integumentary system

**Systemic Examination**
**Site of lesion** - On both legs
**Lesion** - Epidermal
**Distribution** – Un symmetrical
**Character of lesion** - Macules
**No of lesions** - Left-4, Right-5;
**Size**-Left-0.5 x 0.5 cm each, Right-1 x 0.5 cm each;
**Color** – Whitish Creamy
**Arrangement** - Non-Segmental.
**Itching** – very mild present
**Discharge** – Absent

**Superficial Sensation on Lesion**
**Pain** - Absent
**Swelling** – Absent

**Aggravating Area**
- Rainy Season
- Marshy Area

**Samprapti Ghatak**
***Dosha*** – Tridosha
***Dushya*** - Rasa, Rakta, Mamsa, Meda
***Ama*** - Jatargni Janya Ama
***Agni*** - Mandhagni, Dhatwagnimandhya.
***Srotas*** - Rasavaha, Raktavaha, Mamsavaha and Medovaha
***Srotodusti Prakara*** - Sanga
***Rogamarga*** - Bahya
***Udbhava Sthana*** - Amashaya
***Vyakta Sthana*** - Twacha
***Roga swabhava*** - Chirakari
***Sadhyasadhyata*** – Yapya

**Assessment Criteria**

Itching, improvement in overall health, and hypopigmented patch improvement were all seen in the patient.
(Table: 1)

**Treatment**

- *Deepan Pachana* (Amapachana)
- *Snehapana*
- *Abhyanga and Swedana*
- *Virechana*
- *Jalokacharana*

(Table: 2)

## RESULT

**VETI score formula:** (Percentage of head involvement x grade of tensity) + (Percentage of trunk involvement x grade of tensity) 4+ (Percentage of upper limbs involvement x grade of tensity) 2+ (Percentage of lower limbs involvement x grade of tensity) 4+ (Percentage of genitalia involvement x grade of tensity) 0.1

**Percentage of involvement = Area Score**

1 = 1-10%
2 = 11-20%
3 = 21-40%
4 = 41-60%
5 = 61-80%
6 = 81-100%
(Table: 3)

**RESULT**

(Table: 4)

## DISCUSSION

If therapy is started early on, we can see good outcomes for the management of *Shwitra* in Ayurveda via both *Shodhana* and *Shamana Aushadhis*. In this example, the patient initially exhibited reddish spots in both lower limbs after 15 days of *Shamana Aushadhis* treatment. After the first cycle of *Shodhana*, the depigmented region gradually filled up with normal skin tensile strength. Following the second cycle of *Shodhana*, a 60% improvement was seen. After the third cycle of *Shodhana*, there was dark pigmentation over the previously visible white regions, with 70–80% filling in the left lower leg and 80% filling in the right lower limb. According to the VETI score, the overall progress is assessed.

- Psoralen, isopsorale, bakuchiol, bavchinin, and corylin are compounds found in *bakuchi Taila* that have antioxidant characteristics, increase the formation of melanin in the melanocytes, and have immuno-modulatory effects.
- Khadira extract (*Acasia catechu*) is the primary component of *Khadirarista*. An immune-modulating, blood-purifying, bacterial refrigerant, and antiphobic substance is khadira extract.
- The major component of *Gandhaka Rasayana, Bhavita Gandhaka* (Sulphur), offers a number of possible skin benefits. They are *Kushtagna, Twachya*, and *Raktashodhaka.*
- *Arogyavardhini Vati* possesses the qualities of *Raktadhushtihara* (blood purifier), *Kushtahara* (alleviates skin illness), *Sroto Vishodhana* (cleanse bodily channels), and *Pitta Doshahara* (alleviates Pitta). Additionally, it enhances metabolic processes and digestion. In addition to activating and stimulating the pituitary gland, which is in

charge of secreting melanocytes for the production of melanin, *Raktamokshana* also boosts the brain's response to the sick area of skin. This aids in restoring the skin's natural hue.

## CONCLUSION

Vitiligo incidence is rising as a result of poor lifestyle choices, thus it's critical to find and remove the disease's multifactorial triggers using Ayurvedic principles. Most individuals can recover their pigmentation by adhering to the *Shwitra Chikitsa's* recommended Ayurvedic therapy regimen. Due to aesthetic deformity, *Shwitra* is an illness that has a significant negative influence on the body and psyche. By removing exacerbated dosha in the body, *Shodhana* and *Shamana Chikitsa* assist to eliminate the disease's underlying cause and prevent its recurrence, leading to an overall improvement in terms of the number of lesions, the size of the lesions, and the return of normal skin pigmentation.

**ABSTRACT**

Many intriguing novel pharmacological entities with substantial therapeutic promise are being developed as a result of quick progress in drug discovery, however many of these have poor water solubility. Nanosuspensions not only enhance drug delivery but also provide a number of benefits, including sustained drug release patterns, decreased toxicity and tailored delivery. In order to overcome issues related to limited solubility in both aqueous and organic environments, nanoparticle reduction techniques are essential. One of the most promising methods for boosting the biopharmaceutical performance of poorly water-soluble therapeutic substances, particularly for natural products, is drug nanosuspensions. It is a universal formulation technique for better drug delivery of hydrophobic pharmaceuticals. The purpose of this paper was to provide an overview of the methods and uses of nanosuspensions.

**Keywords:** Nanosuspensions, advantages, applications, preparation methods, marketed products

## INTRODUCTION

In terms of biopharmaceutical quality, formulation of poorly water soluble drugs is difficult since these compounds cannot be quickly and completely absorbed due to delayed and irregular dissolution. Numerous nanosized medication formulations have lately been developed to address these issues. The problems with poorly soluble

medications[1] solubility and bioavailability are addressed by nanotechnology-based nano suspension techniques. They enhance pharmacokinetics and lessen delivery problems by keeping the medication in the intended crystalline state. This technique could improve the medication's effectiveness and safety. By reducing rapid drug release, eliminating blood plasma level swings, and reducing individual variability, nanosuspensions (NS) have the potential to lower dosage and treatment costs. Compared to typical nanoparticles, nanosuspensions without carrier molecules have a high drug loading of 50–100% (w/w). By facilitating effective drug delivery into cells, nanosuspensions can maximize pharmacological effects and achieve ideal therapeutic concentrations. As the drug dissolves in interstitial fluid, these nanosuspensions function as depots, releasing it gradually into the systemic circulation[2]. The average particle size of a nanosuspension is usually between 10 and 1000 nanometers. It is a submicron colloidal dispersion of pure medication particles stabilized by surfactants. These are employed to improve the bioavailability, solubility, and rate of dissolution of medications that are poorly soluble in water[3]. The word "nano," which means "one-billionth" ($10^{-1}$) of something, is frequently used, particularly in science and technology, to designate incredibly small items. There are many advantages and disadvantages for nanosuspensions in pharmaceutical and medicinal field.

## ADVANTAGES

**Enhanced solubility and bioavailability**

The drug's surface area increases significantly when the particle size is reduced to the nanoscale, improving dissolving rates and bioavailability[4].

**Suitable for poorly water-soluble drugs**

This system is perfect for BCS Class IV and Class II medications, where the rate-limiting phase is dissolution[5].

**Improved stability compared to solutions**

Since the medication is in solid state, nanosuspensions can prevent issues such hydrolysis and oxidation, unlike drug solutions. Drugs that are poorly soluble in water can have their solubility, stability, and bioavailability improved by using nanosuspension technology[6].

**Versatile routes of administration**

Oral, parenteral, pulmonary, and even ocular routes can be used to give nanosuspensions[7].

**Reduced dose and side effects**

Improved bioavailability could enable lower dosages, which would lessen adverse effects[8]. The dissolving rate is significantly boosted as a result of the lower particle size, primarily because of the increased surface area.

**Ease of large-scale production**

Methods like milling and high-pressure homogenization are economical and scalable[9].

## DISADVANTAGES

**Physical instability**

Because of their high surface energy, nanoparticles have a tendency to group together over time. This may result in Ostwald ripening, or crystal formation, which impacts the drug's stability and bioavailability.

**High energy input and cost**

Wet milling and high-pressure homogenization are two methods that might raise manufacturing cost since they demand a lot of energy and expensive equipment[10].

**Stability issues during storage**

Dose uniformity and efficacy may be impacted by nanosuspensions susceptibility to sedimentation or particle size changes over time [11].

**Need for stabilizers**

To stabilize nanosuspensions, surfactants or polymers are needed, which could cause toxicity or interfere with the drug's or the delivery system's compatibility. Stabilisers may have a more significant function in the final formulation than just maintaining the size of the nanocrystal particles. The stabilizer's function as a cryoprotectant during freeze drying serves as an excellent illustration[12].

**Risk of contamination**

Contamination from milling media can result from wet milling procedures, particularly if they are not well maintained [13].

**APPLICATIONS**

A drug can be administered via nanosuspension in a number of ways. The physiochemical characteristics of the medication, the targeted site, and the course of the disease all have a major role in the instant and prolonged release of nanosuspension. While delayed release NS formulations can be utilized to offer continuous release action in chronic diseases and also lower the plasma peak and adverse effects, immediate release NS is used to increase the solubility and stability of poorly soluble medicines.

**Ocular drug delivery**: Nanosuspensions, which fall under the category of nanocarriers, have distinct physicochemical properties and submicron particle sizes. For a variety of drugs, including non-steroidal anti-inflammatory drugs (NSAIDs), anti-histamines, glucocorticoids, immunosuppressants, anti-fungal agents, antibiotics, antiviral drugs, and others, these characteristics make them useful in overcoming many challenges associated with conventional ophthalmic dosage forms and drug delivery methods [14].

**Direct lung delivery:** For the treatment of respiratory diseases such asthma, pulmonary infections, and chronic obstructive pulmonary disease (COPD), pulmonary administration enables the direct delivery of medications to the lungs. High local medication concentrations and quick therapeutic effects are the outcome of this focused nanosuspension technique.

**Nasal delivery of nanosuspension:** Nanosuspensions have recently been used as a delivery system for many applications and as a method for improving solubility. When a medication is administered intranasally, it must remain in the nasal cavity for a long enough period of time to be absorbed without dropping out of the nose or traveling to the throat. As a result, in order to preserve the benefits of nanosizing and localization within the nasal canal, nanoparticles must be integrated into mucoadhesive compositions. Numerous investigations have documented the nasal administration of nanosuspensions[15].

**Nanosuspensions in transdermal drug delivery:** Numerous drug particles in nanosuspension can be dispersed more uniformly over the skin's surface, and the medications' concentration gradient distribution is likewise more consistent. All of these will make it possible for the nanosuspension to administer medications to the skin more effectively. Physical techniques are typically used in nanosuspension to transform insoluble medications into almost pure drug nanoparticles, which are typically 200–500 nm in size. A tiny amount of surfactant or polymer is typically added as a stabilizer to keep these nanoparticles stable[16].

**Nanosuspension in natural products:** Because of their larger molecular size and limited aqueous solubility, the active ingredients in herbal extracts have difficulty crossing the lipid membrane, which prevents them from being effectively absorbed into the bloodstream and ultimately results in low bioavailability. For this reason, nanosuspensions are created. Methods of preparation of nanosuspensions (Figure 1).

**Nanosuspension in biotechnology**: Because of their unique qualities and wide range of uses, nanosuspensions have become a promising field in biotechnology. In the field of gene therapy, these nanosuspensions present a viable way to use the best vector systems to enable effective gene transfer into target cells. To achieve the appropriate level of genetic material delivery to particular cell types, a specific class of nanomaterials has been utilized.

**Surface modification:** One method for improving a surface's characteristics is nanoparticle surface modification. Both molecular interactions and biomolecule attachments are influenced by the surface. Surface modification of nanoparticles enables drug selectivity, intracellular transport, cellular contact, and uptake.

**Injectable nanosuspension in localized cancer treatment:** For local medication delivery and synergistic anti-tumor activity, OE (Ortho Esters) based nanosuspensions are crucial.

## METHODS OF PREPARATION

The two main techniques used to prepare nanosuspensions are "bottom-up" and "top-down" technology. The various methods used for preparation of nanosuspensions were shown diagrammatically in figures 1 and 2.

**Top-down approach**: The reduction of big particles to the nanoscale is the foundation of top-down technology. The two primary techniques are the low-energy media milling process and the high-energy high-pressure homogenization procedure.

**Homogenization:** In homogenization, suspension is sent through a valve with a narrow aperture under high pressure (100-1000 pressures) to reduce particle size. Microparticles (less than 25 μm) are broken down into the nano-size range by cavitation-induced implosion forces and shock waves in the liquid medium as a result of the static pressure reduction brought on by the abrupt drop in fluid velocity. Furthermore, particles having intrinsic crystal flaws are fractured by shear forces caused by particle collisions at high velocity. Viscosity enhancers can aid the nanosizing process by increasing particle density inside the dispersion region and preventing crystal formation.

**Media milling method**: The most popular are ball mills, which are employed in the grinding process to create nanosuspensions. Bead milling, wet media milling, and pearl milling are three methods to describe the ball mill process. This procedure involves placing the material and stabilizer solution in a chamber and using balls (beads) to grind it mechanically. A milling chamber, milling beads, an appropriate stabilizer, and adispersion medium-typically distilled water-are all part of the wet media milling process. This coarse suspension is added to the milling chamber after the active ingredient has been distributed throughout the dispersion medium. One-third of the chamber is typically filled with milling beads and one-third with dispersion media; the remaining one-third is left empty to allow for milling. This chamber is filled with process-appropriate beads (zirconium, stainless steel, etc.) of the appropriate size (various bead diameters) and quantity (amount of beads in ml or weight); the device's rotation speed is set, and the milling process starts with the milling time.

**Bottom-up method:** List and Sucker employed the bottom-up technique, also known as "nanoprecipitation," for the first time in 1987. The idea behind this bottom-up method is to precipitate dissolved molecules with the addition of another insoluble material to produce nanosized particles. The active ingredient must be soluble in at least one solvent for this approach to work, and appropriate stabilizers must be used to stop particle development following precipitation[17].

**Combination techniques:** In addition to these two technologies (top-down and bottom-up), a number of methods can be combined to prepare NSs, and by making certain adjustments, NSs with the appropriate properties can be obtained. NSs of the discovered formulation can be created utilizing a combination of bottom-up and top-down technologies, or vice versa[18]. Examples of some marketed products (Table 1).

**Advanced techniques:** Numerous cutting-edge methods were employed in the production of nanosuspensions.

**Sonocrystallization technique aided by ultrasound:** It is an innovative method for creating stable nanosuspension. When ultrasound is used in the 20–100 kHz frequency range, it improves particle size reduction and regulates the pharmaceutical active ingredient's size distribution. Additionally, it is thought to be a useful method for reducing the nucleation and crystallization process[19].

**Supercritical fluid methods:**
The rapid expansion of supercritical solution (RESS) process involves expanding a drug solution through a nozzle into supercritical fluid, which causes the drug to precipitate as small particles due to the supercritical fluid's decreased solvent power.

**Precipitation with compressed antisolvent (PCA) process:** The drug solution is atomized into the $CO_2$ compressed chamber using the PCA method. The solution becomes supersaturated as the solvent is removed, and precipitation eventually takes place.

**Supercritical antisolvent process:** This method involves injecting the drug solution into the supercritical fluid, extracting the solvent, and making the drug solution supersaturated [20].

## CONCLUSION

Important examples of marketed products are shown in table 1. Nanosuspensions have emerged as a highly promising approach in modern drug delivery systems, especially for enhancing the solubility and bioavailability of poorly water-soluble drugs. Their unique nanoscale properties support improved dissolution rates, stability, and dose uniformity, ultimately enabling more effective therapeutic outcomes. The versatility of nanosuspensions allows for their application across various routes of administration, including oral, parenteral, ocular, pulmonary and dermal delivery. Multiple preparation methods such as precipitation, high-pressure homogenization and media milling support their scalability and reproducibility, leading to the successful development of several marketed products. Overall, nanosuspensions continue to advance pharmaceutical innovation by overcoming solubility-related formulation challenges and broadening the applicability of promising drug candidates.

**ABSTRACT**

The goal of this article is to study about the kT-ordering on Intuitionistic Fuzzy Matrices (ISFM) as a simplification of the T-ordering on fuzzy matrices. Some equivalent conditions for this ordering using k-Moore Penrose inverse are derived. Further, we prove that if any two IFMs are under kT-ordering then its membership and non-membership fuzzy matrices are also under kT-order. Further, we prove that kT – ordering is identical for certain class of Intuitionistic fuzzy matrices.

**Keywords:** Fuzzy Matrix, Intuitionistic Fuzzy Matrix, T-ordering, kT -ordering.

## INTRODUCTION

Researchers in economics, sociology, medical science, industrial, atmosphere science and countless other plentiful fields decide with the ambiguous, inexact and uncommonly deficient evidence of displaying inexact data. As a outcome, fuzzy set theory was familiarized by L. A. Zadeh [6]. Then, the intuitionistic fuzzy sets was established by K. A. Atanassov [1, 2]. Assessment of non-membership values is also not repetitively possible for the indistinguishable reason as in case of membership values and so, there exists an in deterministic portion upon which unwillingness persists. The problems regarding several types of indecisions cannot solved by the classical matrix theory. That type of problems are cracked by using fuzzy matrix [4,5]. Fuzzy matrix agreements with only membership values. These matrices cannot contract non membership values. Intuitionistic fuzzy matrices (IFMs) announced first time by Khan, Shyamal and Pal [6]. Kim and Roush have established a model for fuzzy matrices equivalent to that for Boolean Matrices by spreading the max.min operations on fuzzy algebra F =[0,1], for elements $a,b \in F$, $a+b = \max\{a,b\}$ and $a.b = \min\{a,b\}$[3]. In this paper, we announced kT-ordering on Intuitionistic Fuzzy Matrices (NSFM) as a interpretation of the T-ordering on fuzzy matrices.

## PRELIMINARIES

In this section, some elementary definitions and consequences desired are given. Let $IF_n$ symbolizes the set of all nxn Intuitionistic Fuzzy Matrices.

**Definition 2.1**
A Intuitionistic fuzzy matrix (IFM) A of order m × n is well-defined as $A= [X_{ij}, <a_{ij_\mu}, a_{ij_\gamma}>]_{mxn}$, where $a_{ij_\mu}$, $a_{ij_\gamma}$are called membership and non-membership of $X_{ij}$ in A, which continuing the condition $0 \leq a_{ij_\mu} + a_{ij_\nu} \leq 2$. We write $A = [ X_{ij}, a_{ij}]_{mxn}$ orbasically $[a_{ij}]_{mxn}$ where $a_{ij} = < a_{ij_\mu}, a_{ij_\nu}>$.

**Definition 2.2**
A matrix $A \in F_n$ is known as right k – regular if there exist a matrix $X \in F_n$, such that $A^k X A = A^k$, for some positive integer k. X is termed as right k – g inverse of A. Let $A_r\{1^k\} = \{ X / A^k X A = A^k \}$.

**Definition 2.3**
A matrix $A \in F_n$ is known as left k – regular if there exist a matrix $Y \in F_n$, such that $A Y A^k = A^k$ , for some positive integer k. Y is termed as left k – g inverse of A. Let $A_\ell\{1^k\} = \{ Y / A Y A^k = A^k \}$.

**Definition 2.4**
A matrix $A \in F_n$ is said to have a{1, 2, 3,4} inverse if there is a matrix $X \in F_n$ such that

i. AXA=A
ii. XAX=A
iii. $(AX)^T$=AX
iv. $(XA)^T$=XA

Then X is termed {1, 2, 3,4}inverse of A and it is symbolized by $A_r^+$. The Moore-Penrose inverse of A is symbolized by $A^+$.

**Definition 2.5.**
The T ordering on any two fuzzy matrices A and B is well-defined as $A \overset{T}{\leq} B$ iff $AA^T = BA^T$ and $A^TA = A^TB$

**Lemma 2.6**
For A, $B \in IF_{mn}$

i. $R(B) \subseteq R(A) \Leftrightarrow B = XA$ for some $X \in IF_m$
ii. $C(B) \subseteq C(A) \Leftrightarrow B = AY$ for some $Y \in IF_n$

**Lemma 2.7**
For $A \in IF_{mn}$ and $B \in IF_{np}$, the following hold.

i. $R(AB) \subseteq R(A)$
ii. $C(AB) \subseteq C(B)$

**Lemma: 2.8**
For $A=[A_\mu, A_\gamma] \in IF_{mn}$ and $b=[b_\mu, b_\gamma] \in IF_{np}$ , the following hold.

i. $A^T = [A_\mu{}^T , A_\gamma{}^T]$
ii. $AB =[A_\mu B_\mu, A_\gamma B_\gamma]$

**kT -Ordering on Intuitionistic Fuzzy Matrices**
In this segment, we deliberate kT-ordering on Intuitionistic fuzzy matrices (NSFM) as a simplification of the T-ordering on fuzzy matrices. Also we prove that if any two IFMs are under kT- ordering then its membership and non-membership fuzzy matrices are also under kT-order. For this ordering some equivalent conditions using k-

Moore Penrose inverses are derived. Further, we prove that kT –ordering is indistinguishable for certain class of intuitionistic fuzzy matrices.

**Definition 3.1.**
The kT ordering $A\overset{kT}{\leq}B$ is defined as $A\overset{kT}{\leq}$Biff
$(a^k)^T a^k=(a^k)^T b^k$ and
$a^k(a^k)^T=b^k(a^k)^T$

**Definition 3.2.**
A matrix $A=[A_\mu, A_\gamma]\in IF_n$ is said to have a$\{1_r^k, 2^k, 3^k, 4^k\}$inverse if there exists a matrix $x\in IF_n$ such that
$A^kXa=A^k$
$xA^kX=X$
$(A^kX)^T=A^kX$
$(XA^k)^T=XA^k$ for some positive integer k.
Then x is called $\{1_r^k, 2^k, 3^k, 4^k\}$inverse of A and it is denoted by$A_r^+$.Also $A_r^+$ is called it as the Right Moore-Penrose Inverse of A.

**Definition 3.3.** The Left Moore-Penrose Inverse ($A_l^+$).
A matrix $A=[A_\mu, A_\gamma]\in IF_n$ is said to have a$\{1_\ell^k, 2^k, 3^k, 4^k\}$inverse if there exists a matrix $x\in IF_n$ such that
$AXa^k=A^k$
$xA^kX=X$
$(A^kX)^T=A^kX$
$(XA^k)^T=XA^k$ for some positive integer k.
Then x is called $\{1_\ell^k, 2^k, 3^k, 4^k\}$ inverse of A and it is denoted by$A_l^+$. Also $A_l^+$ is called it as the Left Moore-Penrose Inverse of A.

**Lemma: 3.4**
Let $A=[A_\mu, A_\gamma]\in IF_n$ and $b=[b_\mu, b_\gamma]\in IF_n$ then $A\overset{kT}{\leq}B \Leftrightarrow A_\mu \overset{kT}{\leq} B_\mu, A_\gamma \overset{kT}{\leq} B_\gamma$ and

**Proof**
Let $A=[A_\mu, A_\gamma]\in IF_n$ and $b=[b_\mu, b_\gamma]\in IF_n$.
$A\overset{kT}{\leq}$Biff $(a^k)^T a^k=(a^k)^T b^k$ and
$a^k(a^k)^T= b^k(a^k)^T$ [By definition (3.1)
$(a^k)^T a^k=(a^k)^T b^k \Leftrightarrow [a_\mu^k, A_\gamma^k]^T[a_\mu^k, A_\gamma^k] = [a_\mu^k, A_\gamma^k]^T[B_\mu^k, B_\gamma^k]$
$\Leftrightarrow [(a_\mu^k)^T,(A_\gamma^k)^T][a_\mu^k, A_\gamma^k] = [(a_\mu^k)^T,(A_\gamma^k)^T][B_\mu^k, B_\gamma^k]$
$\Leftrightarrow [(a_\mu^k)^T a_\mu^k,(A_\gamma^k)^T A_\gamma^k]= [(a_\mu^k)^T B_\mu^k,(A_\gamma^k)^T B_\gamma^k]$
$\Leftrightarrow (a_\mu^k)^T a_\mu^k=(a_\mu^k)^T B_\mu^k, (A_\gamma^k)^T A_\gamma^k=(A_\gamma^k)^T B_\gamma^k$
Similarly, we have,
$a^k(a^k)^T= b^k(a^k)^T \Leftrightarrow a_\mu^k(a_\mu^k)^T=B_\mu^k(a_\mu^k)^T, A_\gamma^k(A_\gamma^k)^T=B_\gamma^k(A_\gamma^k)^T,$
Hence $A\overset{kT}{\leq}B \Leftrightarrow A_\mu \overset{kT}{\leq} B_\mu, A_\gamma \overset{kT}{\leq} B_\gamma$

**Theorem: 3.5**
**Let** $A=[A_\mu, A_\gamma]\in IF_n$, $b=[b_\mu, b_\gamma]\in IF_n$ and $a^+$ exists. Then the following conditions are equivalent:
i. $A\overset{kT}{\leq}B$
ii. $A_\mu \overset{kT}{\leq} B_\mu$ and $A_\gamma \overset{kT}{\leq} B_\gamma$
iii. $A^+a^k= A^+b^k$ and $a^k A^+= b^kA^+$
iv. $a^k= b^kA^+a = aA^+b^k$

**Proof**

(i)⇔(ii) holds by Lemma (3.4)

(i) ⇒(iii) Since $A\overset{kT}{\leq}B \Leftrightarrow (a^k)^T a^k=(a^k)^T b^k$ and

$a^k(a^k)^T= b^k(a^k)^T$

$A^+a^k= A^+a^kA^+a^k= A^+ (A^+)^T(A^k)^Ta^k$

$= A^+ (A^+)^T(A^k)^TB^k$(By Definition 3.1)

$=(A^+A^kA^+)B^k$

$= A^+B^k$

Similarly we have to prove $a^k A^+= b^kA^+$

(iii) ⇒ (iv) $a^k A^+= b^kA^+ \Rightarrow A^k= A^kA^+A= b^kA^+A$

$A^+a^k= A^+b^k \Rightarrow A^k= AA^+A^k= AA^+b^k$

**Corollary: 3.6**

Let A, b∈$IF_{n.}$. If $b \overset{T}{\leq} a$ and $A\overset{kT}{\leq}B$then $b_r{}^+ \subseteq a_r{}^+$.

**Proof**

Since $b \overset{T}{\leq} a \Leftrightarrow B^TB = B^TA$ and $BB^T = AB^T$ and

$A\overset{kT}{\leq}B \Leftrightarrow (a^k)^Ta^k=(a^k)^T b^k$ and

$a^k(a^k)^T= b^k(a^k)^T$

To prove $b_r{}^+ \subseteq a_r{}^+$its enough to prove $A^kb^+a=a^k$

Consider, $A^kb^+a= aa^+b^k (b^+a)$

$= aa^+ (b^kb^+b)$

$= aa^+b^k$

$=a^k$

Hence $b_r{}^+ \subseteq a_r{}^+$.

**Corollary: 3.7**

**Let** A, b∈$IF_n$. If $b \overset{T}{\leq} a$ and $A\overset{kT}{\leq}B$then $b_l{}^+ \subseteq a_l{}^+$.

Since $b \overset{T}{\leq} a \Leftrightarrow B^TB = B^TA$ and $BB^T = AB^T$ and

$A\overset{kT}{\leq}B \Leftrightarrow (a^k)^Ta^k=(a^k)^T b^k$ and

$a^k(a^k)^T= b^k(a^k)^T$

To prove $b\{1\}^{+} \subseteq a\{1\}^{+}$ its enough to prove $Ab^{+}a^{k}=a^{k}$

Consider, $Ab^{+}a^{k}= aB^{+}b^{k}$ $(A^{+}a)$

$=BB^{+}(b^{k}A^{+}A)$

$= b^{k}A^{+}A$

$=a^{k}$

Hence $b\{1\}^{+} \subseteq a\{1\}^{+}$.

**Theorem: 3.8**

Let $A, b \in IF_{n}$. If $a^{+}$ and $b^{+}$ both exist, then the following conditions are holds hood:

i. $A \overset{kT}{\leq} B$

ii. $A_{\mu} \overset{kT}{\leq} B_{\mu}$, $A_{\gamma} \overset{kT}{\leq} B_{\gamma}$ and $A_{\nu} \overset{kT}{\leq} B_{\nu}$

iii. $a^{+} a^{k}= b^{+} a^{k}$ and $a^{k} a^{+}= a^{k} b^{+}$ .

iv. $b^{+} a^{k} a^{+} = a^{+} = a^{+} a^{k} b^{+}$.

v. $(a^{T})^{k} b\, b^{+} = (a^{T})^{k} = b^{+} b(a^{t})^{k}$.

**Proof**

Proof of (i) and (ii) holds from Lemma (3.4)

(iii) $a^{+}a^{k}=b^{+}a^{k}a^{+}a^{k}=b^{+}a^{k}$ and

$a^{k}a^{+}= a^{k} a^{+}a^{k} b^{+}=a^{k} b^{+}$

(iv)Since $a^{+} a^{k} = b^{+} a^{k}$ and $a^{k} a^{+}= a^{k} b^{+}$

Consider $a^{+}= a^{+}a^{k} a^{+}=b^{+}a^{k}a^{+}$

Consider $a^{+}= a^{+}a^{k} a^{+}=a^{+}a^{k}b^{+}$

(v)$(a^{T})^{k}a^{k}= (a^{t})^{k} b^{k}$

$= (a^{T})^{k}b^{k} b^{+}B$

$= b^{+}B(a^{T})^{k} b^{k}$

$= b^{+}B(a^{T})^{k}A^{k}$

$(a^{T})^{k}= b^{+}B(a^{T})^{k}$

Similarly $(a^{T})^{k} =(a^{T})^{k}b\, b^{+}$

**Theorem 3.9.**For$A=[A_{\mu}, A_{\gamma}]$, $B=[B_{\mu}, B_{\gamma}] \in (IF)_{n}^{(k)}$,if $A \overset{kT}{\leq} B$then $R(A^{k}) \subseteq R(B^{k})$, $C(A^{k}) \subseteq C(B^{k})$ and $A^{k} B^{+}B = A^{k} = BB^{+} A^{k}$ for each $B^{+} \in B^{+}\{1_{r}^{k}\}$ and for each $B^{+} \in B^{+}\{1_{\ell}^{k}\}$.

**Proof:** If $A \overset{kT}{\leq} B \Rightarrow A^{k} = A\, B^{+}\, B^{k} = B^{k}B^{+}A$ (By Lemma (3.6))

$\Rightarrow A^{k} = V\, B^{k} = B^{k}U$, where $V = AY$ and $U = X\, A$

$\Rightarrow R(A^{k}) \subseteq R(B^{k})$ and $C(A^{k}) \subseteq C(B^{k})$ ( By Lemma (2.9))

$\Rightarrow A^{k}\, X\, B = A^{k} = B\, B^{+}\, A^{k}$ for each $B^{+} \in B\{1_{r}^{k}\}$ and for each $B^{+} \in B\{1_{\ell}^{k}\}$ (By Lemma 3.8)

**Theorem 3.10.** *For* $A=[A_\mu, A_\gamma]$, $B=[B_\mu, B_\gamma] \in (IF)_{n^{(k)}}$, the following hold.
*(i)* $A \overset{kT}{\leq} A$
*(ii)* $A \overset{kT}{\leq} B$ *and* $B \overset{kT}{\leq} A$ *then* $A^k = B^k$
*(iii)* $A \overset{kT}{\leq} B$ *and* $B \overset{kT}{\leq} c$ *then* $A \overset{kT}{\leq} c$

**Proof**
(i) $A \overset{kT}{\leq} A$ is trivial.
(ii) $A \overset{kT}{\leq} B \Rightarrow A^k = B^k a_r{}^+ A$ for $a_r{}^+ \in A^+ \{1_r^k\}$ (By Lemma 3.5)
$B \overset{kT}{\leq} A \Rightarrow B^k = Ba_l{}^+ A^k$ f or $a_l{}^+ \in A^+ \{1_\ell^k\}$ (By Lemma 3.5)
Now, $A^k = B^k a_r{}^+ A = (Ba_l{}^+ A^k)\, a_r{}^+ A = Ba_l{}^+ (A^k a_r{}^+ A) = Ba_l{}^+ A^k = B^k$
Hence, $A \overset{kT}{\leq} B$ and $B \overset{kT}{\leq} A \Rightarrow A^k = B^k$
(iii) $A \overset{kT}{\leq} B \Rightarrow A^k = A^k B^+ B = BB^+ A^k$ (By Theorem (3.9))
$B \overset{kT}{\leq} C \Rightarrow B^k = C^k B^+ B = BB^+ C^k$(By Theorem (3.9))
Let us consider $(A^k)^T = B^+ B(A^k)^T$ for $B^+ \in B^+\{1_r^k\}$
Since $A \overset{kT}{\leq} B$ and $B \overset{kT}{\leq} C$, then we have
$A^k(A^k)^T = A^k (B^+ B(A^k)^T$
$= (A^k B^+ B)(A^k)^T$
$= A^k(A^k)^T$(By Theorem (3.9))
$= B^k(A^k)^T$(By Definition (3.1))
$= (C^k B^+ B)(A^k)^T$(By Theorem (3.9))
$= C^k (B^+ B(A^k)^T)$
$= C^k(A^k)^T$
and $(A^k)^T A^k = (A^k)^T C^k$ for some$(A^k)^T = B^+ B(A^k)^T$
Hence, $(A^k)^T = B^+ B(A^k)^T$ with $A^k(A^k)^T = C^k(A^k)^T$ and $(A^k)^T A^k = (A^k)^T C^k$
Therefore $A \overset{kT}{\leq} c$

**Theorem.3.11.** For $A=[A_\mu, A_\gamma]$, $B=[B_\mu, B_\gamma] \in (IF)_{n^{(k)}}$, $A \overset{kT}{\leq} B \Leftrightarrow (A^k)^T \overset{kT}{\leq} (B^k)^T$

**Proof**
$A \overset{kT}{\leq} B \Leftrightarrow A^k (A^k)^T = B^k (A^k)^T$ and $(A^k)^T A^k = (A^k)^T B^k$
Consider, $A^k (A^k)^T = B^k (A^k)^T$
$\Leftrightarrow [A^k (A^k)^T]^T = [B^k (A^k)^T]^T$
$\Leftrightarrow (A^k)(A^k)^T = (A^k)(B^k)^T$
Similarly,$(A^k)^T A^k = (A^k)^T B^k = \Leftrightarrow (A^k)^T (A^k) = (B^k)^T (A^k)$
Hence $A \overset{kT}{\leq} B \Leftrightarrow (A^k)^T \overset{kT}{\leq} (B^k)^T$

**Theorem.3.12.** $A=[A_\mu, A_\gamma]$, $B=[B_\mu, B_\gamma] \in (IF)_{n^{(k)}}$, *if* $A \overset{kT}{\leq} B$ *then* $P\, A^k P^T \overset{kT}{\leq} P\, B^k P^T$ for some permutation matrix P.

**Proof**
Now, $[(PAP^T)^k]^T (P\, AP^T)^k = [(P^k A^k (P^T)^k]^T (P^k A^k (P^T)^k$
$= P(A^k)^T P^T P A^k P^T$
$= P(A^k)^T (P^T P) A^k P^T$
$= P(A^k)^T A^k P^T$

$= P((A^k)^T B^k)P^T$

$= P((A^k)^T P^T P B^k)P^T$

$= (P((A^k)^T P^T)(P B^k)P^T)$

$=[(PAP^T)^k]^T (P BP^T)^k$

Hence $[(PAP^T)^k]^T (P AP^T)^k=[(PAP^T)^k]^T (P BP^T)^k$

Similarly $(P AP^T)^k \quad [(PAP^T)^k]^T = (P BP^T)^k [(PAP^T)^k]^T$

Hence $A \underset{\leq}{^{kT}} B \Rightarrow P A^k P^{T} \underset{\leq}{^{kT}} P B^k P^T$

## CONCLUSION

Ordering moralities are decisive for classifying and grading real world problems. This article affords a distinct type of ordering named kT-ordering which has extensive application in Intuitionistic fuzzy matrices. This paper is an simplification of T ordering in regular fuzzy matrices to kT-ordering on k-regular Intuitionistic fuzzy matrices.

## ABSTRACT

Blood donation is a critical component of healthcare, yet a significant number of potential donors are deferred due to various medical, behavioural, or demographic reasons. This retrospective study aims to analyze the pattern and causes of blood donor deferrals at the Blood Bank of Chhatrapati Shivaji Subharti Hospital (CSSH), Meerut, over a one-year period from January 2023 to December 2023. A total of 872 deferral cases were reviewed, out of total 6423 cases, categorized based on age, gender, donation history, and medical eligibility. The study observed that most deferrals occurred in the 18–29 age group, with males comprising a larger proportion of deferred donors. Common causes for deferral included high hemoglobin levels, recent alcohol intake, low haemoglobin level and infections such as typhoid. Temporary deferrals were more prevalent than permanent or indefinite ones. The analysis also highlighted a predominance of replacement donors over voluntary donors. Understanding these trends is essential for improving donor retention strategies and ensuring a safe and adequate blood supply. The findings of this study provide valuable insights for optimizing donor screening protocols and addressing preventable causes of deferral through targeted education and pre-donation counselling.

**Keywords:** Donor defer category, Type of donor, Blood safety, Transfusion transmitted infections (TTIs), Donor selection criteria.

## INTRODUCTION

A safe blood supply is vital to any healthcare system, and its foundation lies in the selection of safe blood donors. Despite technological advancements in screening for transfusion-transmissible infections (TTIs), the importance of rigorous donor selection remains paramount in ensuring transfusion safety (1). Blood is often a lifesaving therapy, particularly in emergencies, surgical interventions, and for patients with chronic illnesses. Yet, a considerable gap exists in blood availability between developed and developing nations, largely due to disparities in donor recruitment, deferral rates, and health system infrastructure (2, 3). The World Health Organization (WHO) advocates Voluntary Non-Remunerated Blood Donation (VNRBD) as the safest and most sustainable source of blood (4, 5). These donors, motivated by altruism, are considered reliable due to their honesty and low risk of concealing health-related information. However, despite increasing awareness and voluntary donations, deferrals due to health concerns, infections, or risk factors remain a major issue worldwide.

Donor deferral—whether temporary or permanent—is a critical mechanism for safeguarding both donors and recipients. Yet, deferrals can discourage future donations, especially when reasons are not well communicated (6, 7). In India, donor selection and deferral are guided by national standards laid out in the Drugs and Cosmetics Act (1940, amended 2001), the Technical Manual by the Ministry of Health, and NACO guidelines (8, 9). The COVID-19 pandemic further complicated donor eligibility criteria, with additional screening protocols and deferral policies introduced to minimize risks (10, 11). Data from WHO and NACO reveal a shortfall of nearly 45% in blood supply against national demand, underscoring the urgent need to minimize avoidable deferrals (12, 13). Understanding the frequency and reasons for donor deferral is crucial for refining recruitment strategies, retaining eligible donors, and enhancing the efficiency of blood services. This study aims to analyze the patterns and causes of blood donor deferrals in our centre and compare them with national and international findings to support evidence-based improvements in donor management.

## MATERIAL AND METHODOLOGY

**Study Design**

This retrospective observational study analysed existing blood bank records from the Blood Bank, Chhatrapati Shivaji Subharti Hospital (CSSH), Meerut**, Uttar Pradesh, India**. As a high-volume tertiary care facility, CSSH's blood bank serves a significant regional population. The study period was from January 2025 to May 2025, in which I analysed previous donor data record of one year, **from January 2023, to December 2023**, a duration chosen to ensure a sufficiently representative sample size for observing trends in deferral patterns. The study population includes all prospective blood donors who presented for donation at the CSSH Blood Bank during this defined period and whose records contain complete information on their deferral status and the underlying reasons.

**Data Collection**

The primary data source was the **manual records** maintained by the CSSH Blood Bank. These records include detailed information regarding to donor registration, medical history, physical examination findings, results of mandatory screening tests, and the final deferral status, along with the documented reasons for deferral.

**Inclusion Criteria**

- All individuals who presented for blood donation at CSSH Blood Bank during the specified study period.
- Records with complete documentation regarding deferral status and reasons for deferral.

**Exclusion Criteria**

- Records with incomplete or missing information regarding deferral status or reasons for deferral.
- Duplicate donor records, if identified.

## RESULTS

The study was conducted in the Department of paramedical sciences,Subharti Medical College and Blood Bank, Chhatrapati Shivaji Subharti Hospital (CSSH), Meerut. The study spanned from January 2025 to May 2025, in which we have collected the previous deferral donor data from pre-existing data records of January 2023 to December 2023 from the Blood Bank, Chhatrapati Shivaji Subharti Hospital (CSSH), Swami Vivekanand Subharti University, Meerut. The study analysed data from a total of 6,423 donors, out of which 872 were deferred due to various reasons.Data have been divided into different groups according to Age, Gender, Types of Donors (Voluntary & Replacement), Types of donors defer categories (Temporary, Indefinite & Permanent) and based on different medical reasons given by the National Blood Transfusion Council (NBTC) for donor selection guidelines as tabulated below.

Figure 4.2 describes the distribution of donor deferrals based on age reveals that the highest number of deferrals occurred in the 18–29 years age group, accounting for 389 cases (approximately 44.6% of total deferrals). This was followed by the 30–41 years age group with 348 deferrals (39.9%). The 42–52 years category reported 119 deferrals (13.6%), while the 53–63 years group had the lowest number with only 17 deferrals (1.9%).This data suggests that younger donors, particularly those in the 18–41 year age bracket, constitute the majority of deferrals, possibly reflecting their higher representation among the donor population or increased likelihood of temporary deferral factors such as hemoglobin deficiency, underweight status, or recent infections. Over the course of the trial, 872 donors were deferred, from which, 765 (87.7%) were male donors and 107 (12.3%) were female donors. This indicates a significantly higher proportion of deferrals among male donors compared to female donors. The disparity may be attributed to a larger number of male donors participating overall, which is commonly observed in blood donation demographics due to socio-cultural and physiological factors. Figure 4.2 illustrates the distribution of donor deferral based on gender, clearly depicting the predominance of male deferrals.

There is a notable difference between replacement and voluntary donors in the distribution of deferred donors per donor type. Only 46 (5.28%) of the 872 postponed donors were voluntary, while 826 (94.72%) were replacement donors. This huge disparity suggests that replacement donors are far more likely than voluntary donors to defer. According to this research, voluntary donors—who usually give with charity and commonly have superior pre-donation screenings or are more health-conscious—are more likely to fulfil the requirements for eligibility. The deferral rate may be higher because replacement donors, who frequently give under duress or duty because of a relative's need, are less likely to meet the qualifying requirements. This distribution emphasizes the significance of promoting voluntary blood donation to guarantee a more eligible and secure donor pool.

An analysis of donor deferral causes reveals that many deferrals were due to indefinite reasons, followed by temporary and permanent causes. Out of the total 872 deferred donors:

- 564 (64.68%) were deferred due to indefinite causes,
- 294 (33.72%) were due to temporary causes, and
- Only14 (1.61%) were categorized under permanent deferral.

This distribution indicates that a significant proportion of donor deferrals were not necessarily permanent and could potentially be reversed or clarified with further evaluation or over time. The low percentage of permanent deferrals suggests that most deferred individuals may still be eligible to donate blood in the future, depending on their medical or personal condition. Understanding this breakdown is important for donor retention strategies, as individuals with temporary or indefinite deferrals can be counselled, followed up, and potentially re-integrated into the donor pool with appropriate intervention.

Out of the total 872 donor deferrals observed during the study period, a significant portion was attributed to various medical conditions. The most common medical causes for donor deferral were high haemoglobin levels (166 cases, 19.0%), low haemoglobin levels (163 cases, 18.7%), and alcohol consumption prior to donation (154 cases, 17.7%).

These three factors alone accounted for over 55% of the total medical deferrals. Other notable causes included allergy (86 cases, 9.9%), use of antibiotics (84 cases, 9.6%), and tattoos on the body (29 cases, 3.3%), all of which reflect temporary or lifestyle-related conditions that impacted donor eligibility. Infectious diseases such as typhoid (21 cases), hepatitis (6 cases), malaria (2 cases), tuberculosis (7 cases), dengue (1 case), and yellow fever (1 case) also contributed to donor exclusion, although to a lesser extent. Other miscellaneous medical reasons for deferral included blood pressure irregularities, menstruation, recent surgeries, jaundice, breastfeeding, epilepsy, heart disease, and asthma, each representing a smaller fraction of the total. This distribution indicates that both modifiable factors (e.g., alcohol use, tattoos, medications) and non-modifiable or pathological factors (e.g., haemoglobin abnormalities, chronic diseases) play a crucial role in donor deferral patterns. Addressing correctable causes through awareness and education could potentially reduce unnecessary deferrals and expand the donor pool.

## DISCUSSION

The purpose of this study was to assess the frequency and underlying reasons for blood donor deferrals in a tertiary care facility, with a total of 872 deferrals recorded out of 6423 total donors. The deferral rate and reasons observed show both similarities and variances when compared to previous studies conducted across different Indian settings.In our study, the majority of donor deferrals were observed in the 18–29 years age group (44.6%), followed by the 30–41 years group (39.9%). This is in agreement with the findings of Gaikwad *et al.* (2022) [14] and Shah *et al.* (2013) [15], where a significant proportion (65% and 63% respectively) of deferred donors belonged to the younger age group (18–30 years). This trend may be due to increased participation of young donors, especially during outdoor camps and awareness drives. However, younger donors may also have more temporary deferral causes such as anemia, low weight, or recent illness. Gender-wise, our study revealed a male predominance (87.7% male deferrals), which aligns with the general trend seen in Indian blood donation practices. Similar gender patterns were observed in Duvvuri *et al.* (2024) [16], where 86% of deferred donors were males. This likely reflects the higher proportion of male donors in blood donation programs, as women often face temporary deferrals due to physiological issues like low hemoglobin.

An important finding from our study was that 94.72% of deferred donors were replacement donors, with only 5.28% being voluntary. These differentiate sharply with the study by Gaikwad *et al.* (2022) [14], where 99% of donors were voluntary. The high number of replacement donors in our setting indicates a continued dependence on family/replacement donations, which raises concerns regarding donor motivation and overall safety. It highlights the need to strengthen voluntary donor recruitment and retention strategies. Regarding the reasons for deferral, our data showed that, High hemoglobin (19%), Low hemoglobin (18.7%), and Alcohol consumption (17.7%) were the leading causes, accounting for over half of all medical deferrals. These findings differ from those of Shah et al. (2013) [15], where low hemoglobin (49.91%) was the most dominant cause of deferral, followed by underweight status (17.29%) and hypertension (9.52%). Similarly, Duvvuri *et al.* (2024) [16] reported low hemoglobin as the leading temporary cause, with Hepatitis B being the major reason for permanent rejection. This variation highlights the need for localized donor education and pre-donation counselling strategies to address prevalent issues like anemia and substance use.

In our study, temporary deferrals constituted 33.72%, indefinite deferrals 64.68%, and permanent deferrals only 1.61%. This differs significantly from Malhotra & Negi (2023) [17], where 88% were temporary and 12% were permanent, and Duvvuri *et al.* (2024) [16], where 68.6% were permanent and 31.4% temporary. The high rate of indefinite deferrals in our study may suggest lack of clarity in categorizing donor ineligibility or variability in applying national criteria, which demands further staff training and process standardization.
From a public health perspective, deferral of willing donors not only results in the loss of valuable blood units, as noted by Gaikwad *et al.* (2022)[14] and Shah *et al.* (2013)[15], but also negatively affects donor confidence and return rates. Therefore, it is essential to maintain clear communication with deferred donors and, where applicable, provide guidance for future eligibility.

## CONCLUSION

Assuring the safety and adequacy of the blood supply is an important pillar of modern healthcare, and it depends heavily on the selection of healthy and eligible donors. Despite advances in screening and testing technologies, the backbone of safe transfusion practices continues to be the identification of suitable blood donors. This study has provided critical insights into the patterns, causes, and demographic characteristics of blood donor deferrals in a tertiary care hospital setting. The data reveals that the majority of deferrals occurred among the younger population, particularly in the 18–29 years age group, which accounted for 44.6% of the total deferrals. This trend could be attributed to the high number of first-time donors in this age bracket who may not be fully aware of eligibility criteria. Gender-based analysis revealed a unequal number of male deferrals (87.7%) compared to females (12.3%), which is consistent with the observation that more men donate blood in replacement scenarios. A striking finding from the study is that a vast majority of deferrals—94.72%—came from replacement donors, while voluntary non-remunerated blood donors (VNRBD) accounted for only 5.28% of the deferred cases. This confirms global evidence that VNRBD donors are not only the safest but also less likely to be deferred, thereby making a strong case for increased promotion and mobilization of voluntary donations in India. The causes of donor deferral were further categorized into temporary, indefinite, and permanent, with the largest portion (64.68%) falling under indefinite causes. Temporary causes accounted for 33.72%, and only a small fraction (1.61%) was permanent deferrals. Among medical causes, elevated hemoglobin (19.0%), low hemoglobin (18.7%), and alcohol consumption prior to donation (17.7%) emerged as the leading reasons for deferral, collectively contributing to over half of the cases. Lifestyle factors such as recent use of antibiotics (9.6%), allergies (9.9%), and tattoos (3.3%) also played a role in temporary exclusions. These reflect either transient health conditions or behaviours that carry an identified risk of transfusion-transmissible infections (TTIs). The COVID-19 pandemic added another layer of complexity to donor selection. With concerns over asymptomatic transmission, blood centers introduced additional deferral criteria related to exposure history and symptoms, which likely influenced the overall trend and volume of deferrals during the study period.

In conclusion, this study offers a thorough evaluation of blood donor deferrals and their underlying causes, emphasizing the urgent need to strengthen donor education, improve pre-donation screening protocols, and promote voluntary donations to enhance the quality and reliability of the blood supply. Understanding the common causes of deferral can help in designing targeted interventions to reduce deferral rates, improve donor retention, and ensure a safer transfusion chain. Ultimately, such efforts will contribute to building a more resilient and responsive blood transfusion service that meets both current and future healthcare demands.

## ACKNOWLEDGEMENT

The authors would like to express their gratitude to the Subharti College of Allied and Healthcare, Swami Vivekanand Subharti University, Meerut, Uttar Pradesh, India-250005, for their support and resources during the preparation of this manuscript.

## ABSTRACT

Susceptibility-weighted imaging (SWI) is a magnetic resonance imaging (MRI) technique that uses both magnitude and phase data to spot differences in tissue susceptibility. By improving the visibility of paramagnetic and diamagnetic substances like iron, calcium, deoxygenated blood, and microbleeds, SWI provides better sensitivity than regular MRI. This makes it especially important in neurodegenerative disorders, many of which involve abnormal iron buildup and small blood vessel problems. In Parkinson's disease, SWI helps assess the nigrosome-1 region. The absence of the typical "swallowtail sign" acts as a reliable indicator. In pantothenate kinase-associated neurodegeneration (PKAN), SWI reveals early iron deposits in the globuspallidus and substantianigra, even when standard imaging looks normal. Alzheimer's disease and related dementias show cerebral microbleeds and iron accumulation in the cortex on SWI, which helps distinguish them from vascular dementia. Similarly, Huntington's disease, multiple sclerosis, and amyotrophic lateral sclerosis show distinct SWI patterns that relate to disease progression and clinical disability. Limitations include difficulty in interpretation, the presence of artifacts, and inconsistent standards across different machines. However, developments like quantitative susceptibility mapping (QSM), ultrahigh-field MRI, and artificial intelligence are likely to increase diagnostic accuracy. SWI thus plays an important role in neuroimaging, with expanding uses in both clinical practice and research for neurodegenerative disorders.

**Keywords:** Susceptibility-weighted imaging, magnetic resonance imaging, disease progression and clinical disability, susceptibility mapping, ultrahigh-field MRI, and artificial intelligence, neuroimaging.

## INTRODUCTION

Susceptibility-weighted imaging is a magnetic resonance imaging (MRI) sequence sensitive to substances that alter the local magnetic field, such as calcium and iron, allowing phase information to distinguish between them [1] or susceptibility weighted imaging (SWI) is a magnetic resonance imaging (MRI) technique in which the contrast medium is based on the magnetic susceptibility effects of tissue [2]. SWI is a 3D gradient–echo sequence with high spatial resolution that leverages both phase and magnitude effects [1]. SWI, by integrating high spatial resolution with a 3D gradient recalled echo (GRE) sequence and applying a phase mask, enhances the visualization of paramagnetic and diamagnetic substances and excels at detecting microstructural abnormalities like iron deposition, microbleeds, and venous anatomy [1]. SWI-like sequences were initially mostly used to improve the depiction of lesions and signs already known from standard T2*-weighted imaging such as a higher number of microbleeds detected in aging, dementia, or mild brain trauma. This has been shown to provide clinically useful complementary information to conventional spin echo MRI sequences [3]. Many neurodegenerative disorders are associated with increased iron accumulation or micro haemorrhages in various brain regions, making SWI a valuable diagnostic tool in clinical practice [1].SW image combines a phase image and a magnitude image in a high-intensity magnetic field like 3T and 7T. This process adds the magnetic susceptibility information to the brain's structure [4]. Susceptibility-weighted imaging (SWI) is an MRI technique designed to improve the visibility of the differences in susceptibility between tissues. This includes deoxygenated blood, blood products, iron, and calcium deposits. The main idea behind SWI is that the signals from tissues with different magnetic susceptibilities compared to nearby tissues will go out of phase if the echo time is long enough [5].

Susceptibility weighted imaging (SWI) is a recently developed magnetic resonance imaging (MRI) technique that is increasingly being used to narrow the differential diagnosis of many neurologic disorders [6]. Susceptibility-weighted imaging is an increasingly important adjunct in diagnosing a variety of neurologic diseases [3]. Neurodegenerative diseases are typically characterized by the progressive loss of neurons and their supporting cells within the neurovascular unit. Brain MRI is the primary non-invasive imaging technique currently used in clinical practice for the study of the central nervous system, where SWI has established itself as a widely utilized clinical tool for imaging deoxyhaemoglobin in veins, iron deposition, haemorrhages, calcifications, and micro bleeds [1]. SWI sequence is useful in various intracranial disorders such as in the evaluation of patients with stroke, venous disorders, vascular malformations, multiple sclerosis, Alzheimer's disease, and various other neurodegenerative disorders. Brain iron deposition plays an important role in the pathophysiology of neurodegenerative diseases that cause movement disorders [2]. Neurodegenerative diseases encompass a spectrum of disorders characterized by the progressive degeneration and dysfunction of the nervous system, particularly affecting neurons, and often leading to cognitive, motor, and functional impairments, with symptoms varying across the range of severity and progression [1].

**Basic Physics** SWI is different from conventional gradient-echo sequences. It is a fully velocity-compensated, high-resolution, three-dimensional sequence that uses both magnitude and phase information, which most conventional MRI sequences discard. The thin sections used in three dimensions help prevent background field T2* signal intensity loss and magnetic field variations. The long echo time (TE = 40 ms) helps avoid phase aliasing. The phase images improve contrast related to local changes in magnetic susceptibility [2]. In SWI, the phase images create weighting masks. These masks are multiplied with the magnitude images to improve the susceptibility contrast. This section provides an overview of the data processing steps. Detailed discussions on background phase removal and susceptibility weighting mask generation are included [7]. SWI takes advantage of the differences in magnetic susceptibility of tissues. This term describes how tissues respond to an external magnetic field. The technique improves image contrast for conventional MRI [4]

**Technical Principles of SWI** SWI is a three-dimensional, fully velocity-compensated gradient-echo sequence. It combines magnitude and filtered phase images to create susceptibility-enhanced contrast [4]. The filtered phase mask

highlights subtle susceptibility differences caused by iron, deoxyhaemoglobin, or calcium, which might be missed in conventional MRI [1]. Minimum intensity projections (mIP) across several slices improve visualization of venous structures and microbleeds [4]. Compared to standard T2*-weighted GRE, SWI has better sensitivity in detecting hemosiderin, calcification, and venous anatomy [1]. A related technique, quantitative susceptibility mapping (QSM), builds on SWI by allowing voxel-wise quantification of brain iron. It has shown promise for monitoring disease progression in neurodegenerative disorders [5].

**SWI in Neurodegenerative Disorders**

**Parkinson's Disease** Parkinson's disease (PD) is a progressive neurodegenerative disorder caused by the loss of dopaminergic neurons in the substantianigra pars compacta. This loss is often associated with abnormal iron buildup. SWI is essential for visualizing the nigrosome-1 region, which is often referred to as the "swallowtail sign." This sign is consistently present in healthy individuals but missing in most PD patients [1]. The absence of this sign has become a specific imaging marker for PD, allowing for early diagnosis before significant structural changes occur. Additionally, SWI helps distinguish idiopathic PD from atypical parkinsonian syndromes like multiple system atrophy (MSA) and progressive supranuclear palsy (PSP). These conditions can resemble PD but have different prognoses and treatment approaches. Another key feature that SWI can reveal is the loss of dorsolateral nigral hyperintensity. This finding has been confirmed across various PD groups as a dependable diagnostic marker [8].

**Pantothenate Kinase** Associated Neurodegeneration (PKAN)- Pantothenate kinase-associated neurodegeneration (PKAN) is a rare genetic disorder that falls under the neurodegeneration with brain iron accumulation (NBIA) category. Iron builds up mainly in the globuspallidus and substantianigra. In advanced cases, conventional MRI may show the "eye-of-the-tiger" sign on T2-weighted images; however, this is not always visible in early stages. SWI offers better detection of paramagnetic iron and reliably shows low-intensity signals in the globuspallidus due to excess iron. When used with QSM, SWI allows for a detailed assessment of regional iron levels, which boosts diagnostic reliability, even for patients lacking the typical imaging features. This makes SWI/QSM a useful extra tool for the early diagnosis and ongoing monitoring of PKAN [3]. Iron buildup in the substantianigra is a key feature of Parkinson's disease (PD). SWI can identify a reduced signal in the substantianigra pars compacta and a loss of the "swallow-tail" sign, aiding in the differentiation of PD from atypical parkinsonian syndromes like multiple system atrophy (MSA) and progressive supranuclear palsy (PSP) [7].

**Alzheimer's Disease and Dementia** Alzheimer's disease (AD) and related dementias involve both brain tissue and blood vessel problems. Cerebral amyloid angiopathy (CAA), which often occurs alongside AD, is linked to tiny brain bleeds and superficial siderosis. SWI is much more sensitive than regular T2*-weighted imaging when it comes to spotting these bleeding issues [2]. This better sensitivity gives vital diagnostic and prognostic information, especially when distinguishing AD from vascular dementia. In addition to microbleeds, iron buildup in the cortex and deep gray matter is increasingly seen as a factor in the neurodegenerative processes occurring in AD. QSM improves upon SWI by measuring these susceptibility changes. Research has shown connections between higher iron levels and cognitive decline [8]. Therefore, SWI combined with QSM not only improves the structural diagnosis but also has potential as a marker for disease severity and progression. In AD, small brain hemorrhages and iron buildup in the hippocampus and basal ganglia are common [9]. SWI and QSM show abnormal iron deposits that are linked to amyloid issues and cognitive decline [5].

**Huntington's Disease (HD)** Huntington's disease (HD) is a genetic neurodegenerative disorder. It leads to progressive decline in motor functions, mental health, and thinking abilities [5]. The disease is marked by the loss of neurons and the formation of scar tissue in the caudate nucleus and putamen. These structures make up the striatum [1]. Abnormal iron buildup occurs in these areas, contributing to oxidative stress and nerve damage [5]. SWI, which is highly sensitive to certain substances, can identify this unusual iron accumulation more accurately than traditional MRI [5]. Quantitative susceptibility mapping (QSM) from SWI has indicated that iron levels in the basal ganglia relate to the severity of the disease and motor issues [1]. Therefore, SWI can aid in diagnosing HD and help track the progression of the disease over time [1].

**Multiple Sclerosis (MS)** Multiple sclerosis (MS) is a long-lasting condition that damages the protective covering of nerves in the central nervous system. It leads to inflammation and injury to nerve fibers [10]. Conventional MRI is important for diagnosing MS, but it often cannot clearly tell the difference between MS plaques and other white matter lesions [1]. SWI improves the visibility of veins, making it easier to identify the "central vein sign." This sign is a highly specific feature of MS plaques [7]. It helps differentiate MS from small vessel ischemic disease and other similar conditions [1]. SWI also shows unusual iron buildup in areas like the thalamus and caudate [5]. These changes related to iron are connected to long-term nerve damage and relate to clinical disability [5]. Thus, SWI offers useful information that complements conventional MRI in diagnosing and tracking MS [1].

**Amyotrophic Lateral Sclerosis (ALS)** Amyotrophic lateral sclerosis (ALS) is a progressive nerve disorder that affects both upper and lower motor neurons [5]. Regular MRI often does not provide clear results in ALS, but SWI gives valuable diagnostic hints by showing iron buildup in the cortex [3]. One of the most consistent observations is low intensity in the precentral gyrus (motor cortex) on SWI, indicating abnormal iron deposits within motor neurons and glial cells [5]. Quantitative studies show increased susceptibility values in the motor cortices of ALS patients, which relate to how severe and long the disease has been [3]. SWI can also show issues along the corticospinal tracts, providing additional information to diffusion tensor imaging [5]. These findings suggest that SWI could serve as a possible imaging marker for ALS, useful for early diagnosis and monitoring [3].

**Broader Applications** Beyond PD, PKAN, and AD, SWI has shown clinical importance in other neurodegenerative and demyelinating conditions [2]. In multiple sclerosis (MS), SWI can identify the central vein sign and iron rim lesions. This improves diagnostic precision and provides insights into disease activity [19]. In Huntington's disease, SWI helps show abnormal striatal iron buildup. This feature relates to disease progression [2]. Moreover, SWI has been used in traumatic brain injury (TBI) to reveal diffuse axonal injury. It does this by detecting small hemorrhagic lesions that conventional MRI cannot see [3]. These broader applications highlight SWI's ability to capture iron-related and microvascular changes across many neurological diseases. This further confirms its value as a useful tool in both clinical practice and research [2].

**Limitations of SWI in Neurodegenerative Disorders**

- SWI is mainly qualitative and does not provide direct quantitative measures of susceptibility. This limits its value in disease monitoring [11]
- It can be affected by artifacts from air-tissue and bone-tissue interfaces, as well as background phase errors and patient movement [7]
- SWI has limited specificity; hypointensities can indicate iron, calcium, or hemorrhage. It is challenging to tell these apart without phase or QSM data [11]
- There is inconsistency in protocols among MRI vendors (e.g., SWAN, BSI, FSBB), which reduces standardization across centers [1]
- Despite its diagnostic power, SWI remains underutilized in routine neurodegenerative protocols due to lack of harmonized guidelines [12]
- At ultrahigh field strengths (7T and above), improved sensitivity may be countered by structural distortions in iron-rich brain regions [7]

**Future Aspects of SWI in Neurodegenerative Disorders**

- Integration with quantitative susceptibility mapping (QSM) and susceptibility tensor imaging (STI) will allow precise quantification of iron and anisotropy [11]
- Developing true susceptibility-weighted imaging (tSWI) may address orientation and geometry dependence. This will improve reliability [7]
- Multimodal imaging (DTI, perfusion MRI, PET) combined with SWI could aid in early diagnosis and differentiation [12]
- Research into ultrahigh-field MRI (>7T) focuses on optimizing sensitivity while reducing distortions [12]
- Standardization and vendor-independent protocols are necessary to boost reproducibility and clinical use [1]

- Artificial intelligence and machine learning can help with automated interpretation, early detection, and tracking progression [1]
- SWI is expected to play a larger clinical role in Parkinson's disease, Alzheimer's disease, Huntington's disease, multiple sclerosis, and ALS as more disease-specific biomarkers are validated [12].

## CONCLUSION

Susceptibility-weighted imaging (SWI) has become a valuable MRI technique that goes beyond traditional imaging. It takes advantage of differences in tissue susceptibility to detect iron buildup, microbleeds, venous issues, and calcifications. Its ability to combine phase and magnitude data provides better sensitivity for spotting subtle microstructural changes, which are important in neurodegenerative disorders. In conditions like Parkinson's disease, SWI allows us to see the "swallowtail sign" in the substantianigra. In Alzheimer's disease and related dementias, it shows cerebral microbleeds and iron buildup, helping with diagnosis. Likewise, in Huntington's disease, multiple sclerosis, and amyotrophic lateral sclerosis, SWI offers important insights into iron-related problems, disease progression, and lesion details, often doing better than standard MRI sequences. Despite its drawbacks, such as subjective interpretation, artifacts, and lack of standard methods, ongoing improvements like quantitative susceptibility mapping (QSM), ultrahigh-field MRI, and artificial intelligence are working to overcome these issues. The future combination of SWI with multimodal imaging is promising for improving diagnosis, tracking disease progression, and possibly serving as a biomarker in treatment trials. Overall, SWI is an essential tool in neuroimaging, increasingly important in clinical and research settings for understanding the mechanisms behind neurodegenerative disorders and supporting targeted treatment.

## ACKNOWLEDGEMENT

We would like to thank the faculty of the Department of Medical Radiology and Imaging Technology at Subharti College of Allied and Healthcare, Swami Vivekanand Subharti University in Meerut, Uttar Pradesh, for their on-going support and guidance during the preparation of this review article. We are especially grateful to our mentors and colleagues for their valuable insights, helpful suggestions, and encouragement, which have played a key role in shaping the content of this work. We also recognize the academic environment and resources offered by the institution, which greatly helped us complete this manuscript.

**Funding Acknowledgement**

None

**Conflict of interest**

There is not any conflict of interest.

## ABSTRACT

This article discusses how solar water heaters' thermal efficiency can be improved using a reflector in a new design called the double pass solar water heater. The performance, development, and design evaluation of this type of solar water heater are detailed. The article also examines the impact of mass flow rate on overall performance, output temperature, and thermal efficiency using data collected at 30-minute intervals from 9 AM to 4 PM. When compared to a conventional single-pass solar water heater, the double pass solar water heater performs better. The relationship between the heat and mass flow rates determines the maximum efficiency at a greater mass flow rate, and adjustments to the mass flow rate and focus of the solar heat can optimize efficiency. The best efficiencies are typically observed around midday when the maximum solar radiation is present. Despite low sunlight radiation during certain times of the year, at the same mass flow rate, the efficiency of a double pass solar water heater with a reflector is much greater than that of a traditional single pass solar water heater.

**Keywords:** Mass Flow Rate, Efficiency, Temperature Difference, and Double Pass Solar Water Heater.

# INTRODUCTION

Solar heating, photovoltaic, solar thermal energy, solar architecture, molten salt power plants, and synthetic photosynthesis are some of the continually developing technologies that can be used to capture solar energy, which is the light and heat that the sun emits. Depending on the manner in which it is collected, distributed, or converted into power from the sun, this renewable energy source can be described either as proactive or passive solar (Abdullah *et al* 2018 and Verma *et al* 2020). Photovoltaic systems, concentrated solar electricity, and water heating from the sun are examples of active solar methods. On the other hand, passive solar strategies call for designing structures to receive as much sunlight as possible, employing materials with superior thermal conductivity or light-diffusing properties, and giving room's natural ventilation. The appeal of using solar energy to produce power comes from its enormous potential. According to the 2000 World Energy Assessment by the UN Development Programmed, the annual capacity for solar energy ranges from 1,575 to 49,837 ExaJoules (EJ). This far surpasses the total amount of energy consumed worldwide in 2012, which amounted to 559.8 EJ. In 2011, International Energy Agency highlighted the significant long-term benefits that accessible, limitless, and eco-friendly solar energy technology can provide. By depending on a domestic and sustainable resource that is largely import-free, it can enhance sustainability, reduce pollution, and reduce the expense of combating global warming while maintaining cheaper fossil fuel prices (Abdullah *et al* 2020). The higher costs associated with early deployment incentives should be viewed as necessary investments that necessitate careful planning and equal distribution because these advantages are universal (Shafieian *et al* 2019). Solar energy, which is free and abundant, can be efficiently harnessed to benefit human civilization. One of the commonly used solar energy harvesting equipment is solar water heating systems (SHWS).

Given the increasing energy demand and the high costs of petroleum-based products like oil and petrol, for water heating in homes and businesses, solar power is seen as a viable renewable power source. Water heating alone accounts for approximately 20% of a typical household's energy consumption (Gautam *et al* 2017). Solar water heating systems are an affordable and easily accessible option for sustainable energy that can meet a family's hot water needs. These systems utilize the sun's energy to heat water and generate steam for both household and commercial use (Abo-Elfadl *et al* 2020). The sun emits an infinite amount of energy, known as solar radiation. When absorbed by a surface, this radiation converts into heat, which is utilized to warm water. Thermal collectors of this kind experience heat losses due to radiation and convection. As the temperature of the working fluid rises, these losses increase rapidly. Such systems harness the power of solar heat (Varghese *et al* 2018 and Alam *et al* 2018). In regions with medium latitudes (between 40 degrees north and 40 degrees south)in areas with moderate latitudes (40 degrees north and 40 degrees south), solar thermal energy systems can supply up to 60-70 percent of the hot water needs for homes, with 60 °C (140 °F) water temps. Evacuated tube collectors (44%) and glazed flat plate collectors (34%), two different types of solar-powered water heaters, were the most widely used (Tuncer *et al* 2020). pools heating commonly uses plastics unprotected collector (21%). As of 2007, there were approximately 154 GW of solar hot water systems in use. China has the most installed capacity in the world, using 70 GW as of 2006 and planning to utilize 210 GW by the year 2020. With more than 90 % of residences using them, both Cyprus and Israel employ solar water heating systems the most per person. With a total installed capacity of 18 GW as of 2005, swimming pool heater is the primary application for solar hot water production in the United States, Canada, and Australia.

**Experimental set up**

Fig 1 depicts the Experimental Setup of Solar Water heater using Collector. A schematic representation of the study's configuration illustrates the components involved, which consist of sun-collecting device, reflectors, a closed, working fluid system, as well as measurement tools. The working fluid system comprises a tank, a system of pipes and a fundamental valve for regulating flow rate. An absorber plate made of aluminum sheet is located at the center of a wooden box, serving as the solar collector. A set of 24 copper tubes are fixed to and spread across both sides of the galvanized iron sheet, with 12 on each side. The 3.5 mm thick transparent glass cover is affixed to both sides of the absorber plate, leaving a 75 mm space between the plate and the glass inside the wooden box. To minimize

conductivity losses, cork sheets are utilized as insulation on the walls. The experimental arrangement of suitable dimensions is illustrated in Figure 1. The solar collector is oriented to track the sun's movement and remain tilted at a 30° angle from the horizontal plane. To maximize solar energy reflection, the reflectors are situated at the same angle as the collector and placed behind it. As the collector's position shifts, the reflectors are moved accordingly. To determine the absorber plate's temperature, copper tube, eight thermometers are mounted at various locations on the collector, with one in each of the air spaces between the glass cover and plate. A thermocouple measures the intake and output temperatures. The collector is fixed to a frame made of wood that is the right size for the collector's location. The collector's intake and output pipes have been lengthened to make it easier to determine the water temperature. The entrance part is connected to a tap on a gravity water reservoir, allowing ambient water to enter the collector. Using a straightforward beaker, volume change over time is measured in order to calculate the mass flow rate of water.

**Experimental procedure**

Water is pumped through the solar collector's plate for absorption at rates of 8 litres per hour, 10 litres per hour, 12 litres per hour, 14 litres per hour, and 16 litres per hour in order to test different mass flow rates. The collector is made to take in the sun's direct and indirect solar radiation. Water in the collector is warmed as it flows from top to bottom by sunlight hitting the top glass cover. A reflector is also utilized to gather direct sunshine and reflect diffused radiation onto the bottom of the double-pass solar water heater, which further warms the water. Heat is first absorbed by the absorber plate and pipe before being delivered to the water. In comparison to a single-pass solar water heater, the water is heated by both the upper and bottom absorber plates. The hot water eventually leaves through the chosen outlet. Water is continually circulated through the collectors as data are gathered every 30 minutes. Only between 9:00 AM and 4:00 PM is testing done. The reflecting capacity of the mirrors glass is 0.9, and the areas of both the reflector and collectors were determined calculated to be 0.90 $m^2$ and 0.929 $m^2$, respectively. With an entire intensities factor of 0.63 derived from multiplying the reflectivity and occurrence radiation values of 0.9 and 0.7, respectively, it is anticipated that roughly 70% of the collecting surface area is covered by total occurrence radiation. The estimated average solar radiation intensity for the month of November is 4.2 kWhr. /$m^2$, or 600 W/$m^2$.

## RESULT AND DISCUSSION

The amount of solar radiation received is primarily influenced by geographical location and local weather conditions. In March, experiments were conducted under mostly clear skies to assess the effectiveness of a double-pass solar collector, which was evaluated based on its efficiency. Flow rate, intake and output temperatures, and other variables were examined to determine efficiency. In addition to comparing a single-pass and double-pass solar water heater on a half-hourly basis, the data below show the temperature differential among inlet and exit water as well as collector's efficiency (Sajawal *et al* 2019). Figure 2 shows how a double-pass solar water heater's peak efficiencies alter with different rates for water mass flows. The second figure illustrates the correlation between the mass flow rate and the maximum efficiency of a solar water heater for four different experimental days. During the first day, the flow rate was set to 8 litres per hour, and the water was heated by solar radiation while passing through the copper pipe, resulting in the highest efficiency of 46.58%. Subsequently, the flow rate was increased to observe any impact on the system's thermal efficiency, which showed a considerable improvement. On day two, the effectiveness at a flow rate of 10 litres per hour was 48.08%. The efficiency recorded the third and fourth days, with flow rates of 12 litres per hour and 14 litres per hour respectively, were 48.84% and 48.5%. On the fifth day, the highest anticipated efficiency of 51.20% was obtained at a flow rate of 16 litres per hour. The efficiency of the solar water heater with double pass and reflectors is mainly dependent on solar radiation, mass flow rate, and collector geometry. Increasing the mass flow rate results in greater heat transfer. Coefficient and thus increases efficiency. The second figure displays the temperature differences ($DT = T_{out} - T_{in}$) during the day for different mass flow rates on an unobstructed day in Sethurapatti. The third figure displays the observations of Variable mass flow rates and temperature differential in a double-pass solar water heater from 8 litres per hour to 16 litres per hour. As the time and mass flow rates increase, the collector's efficiency also increases. At 12:30 PM, the highest efficiency of about 51.20% was observed at the mass

flow rate of 16 litres per hour, the mass flow rate of 8 litres per hour had the lowest efficiency, which was around 13.92%, at 9:00 AM. The graph shows that the thermal efficiency of the double-pass solar water heater is improved by increasing the water mass flow rate. This improvement in efficiency is due to the use of a reflector on the collector's bottom side. The configuration with glasses as the cover produced a maximum operating temperature of 75.3°C with an inlet temperature of 30.1°C. The collector's greatest efficiency was 51.20%, which is lower than the planned efficiency because of various losses. Additionally, fluctuations in solar radiation concentration affect the system's performance. Figure 3 shows the highest temperature difference that was found in the double-pass solar water heater when the mass flow rate was changed. The efficiency value of the double-pass solar-powered water heater, which is higher than that of a single-pass water heater at the same flow rate, is 48.17% at an average mass flow rate of 12 litres per hour. Despite the fact that the data was collected in March 2021, the findings reveal that the double-pass solar water heater is superior to the single-pass model, as demonstrated in the provided figure. If data were collected in March 2021, is a dual-pass solar water heater. Would demonstrate improved efficiency. However, the double-pass solar water heater's effectiveness is affected by inaccuracies in the sensors utilized (Kabeel *et al* 2018). While the errors in individual sensors may not be significant, they collectively have a considerable impact on the efficiency. Additionally, the system's top, bottom, and sides all lose heat, which adds to the discrepancy between measured and actual efficiency.

## CONCLUSION

A solar water heater with a reflector at the base of the collector that uses a double pass operation was the subject of an experiment inquiry. The outcomes were compared to data that had been recorded from a typical single-pass solar water heater. This analysis allows for an assessment to be made

1. The amount of mass flowing directly affects the system's overall efficiency, but the reflector also has a small but significant impact on efficiency. At an average flow rate of 16 litres per hour, the equipment's maximum efficiency of 51.20% was attained. With the biggest difference occurring at a flow rate of 8 litres per hour, the volumetric flow rate and temperatures differential between the input and output flow are inversely correlated. Nevertheless, the variance in temperatures is directly proportional to solar radiation and is more as the radiation gets stronger. The results of the experiment demonstrate that at 12:30 PM, when sun radiation peaked, the best efficiency was attained.
2. At a mass flow rate of 10 litres per hour, an in-depth comparison among a two-pass and one pass solar-powered water heater was carried out. Despite the fact show the information was not gathered throughout the entirety of the year, the results show that the double pass system with a reflector offered more efficiency compared to the one-pass system. The reflector's inclusion in the experimental system is responsible for the increase in efficiency. In conclusion, compared to a typical single-pass flat-plated solar-powered water heater, the experimental double pass solar water heater with a reflector showed increased production.

## ABSTRACT

Delivering therapeutics to the posterior segment of the eye remains a formidable challenge due to anatomical and physiological barriers such as the blood-retinal barrier, vitreous humour, and limited permeability of ocular tissues. Traditional drug delivery methods like topical, systemic, and even intravitreal injectionsare often inadequate for achieving sustained and targeted therapeutic effects, especially in chronic and progressive diseases like age-related macular degeneration, diabetic retinopathy, and retinal vein occlusion. This review highlights recent advances in nanotechnology-based drug delivery systems designed to overcome these limitations. Nanoparticles, including lipid-based carriers, polymeric systems, inorganic nanomaterials, dendrimers, and micelles, offer the potential for sustained release, active targeting, and reduced administration frequency. Emerging strategies such as ligand-functionalized carriers, stimuli-responsive nanoparticles, and theranostic platforms demonstrate promise for precise drug localization, enhanced bioavailability, and personalized therapy. Despite encouraging preclinical and early clinical outcomes, challenges remain in manufacturing, regulatory approval, and long-term safety. Continued interdisciplinary collaboration will be critical to translating these

technologies into routine clinical practice and revolutionizing the treatment landscape for posterior segment ocular diseases.

**Keywords:** Nanoparticles, Ocular Drug Delivery, Posterior Segment, Targeted Therapy, Nanomedicine, Intravitreal Injection, Sustained Release, Retinal Disease

## INTRODUCTION

Delivering drugs to the eye is challenging due to its complex structure and strong protective barriers. While these barriers preserve vision, they also restrict drug access to the posterior segment, which includes the retina, choroid, and optic nerve [1]. Damage to this region is central to conditions such as age-related macular degeneration, diabetic retinopathy, and retinal vein occlusion—leading causes of irreversible blindness that require long-term, targeted therapy [2]. Traditional delivery methods are often ineffective. Eye drops suffer from poor absorption and rapid clearance [3], and systemic administration is limited by the blood–retinal barrier, increasing the risk of systemic toxicity at higher doses [4]. Intravitreal injections can bypass these barriers, but their invasive nature, associated risks, and need for frequent administration reduce patient comfort and compliance [5,6]. Nanotechnology offers a promising alternative for ocular drug delivery. Nanoparticles can cross ocular barriers more effectively, provide sustained drug release, and carry a wide range of therapeutic agents [7,8]. Advances in targeted and controlled-release systems further improve treatment precision and reduce dosing frequency, enhancing patient outcomes [9]. This review discusses recent advances in nanoparticle-based approaches for posterior segment drug delivery, outlining ocular barriers, emerging nanocarrier systems, and highlights how nanotechnology may transform treatments for vision-threatening eye diseases.

**Anatomy and Barriers of the Eye**

The eye is a highly specialized organ, and its complex structure makes effective drug delivery particularly difficult. For therapeutic purposes, it is broadly divided into the anterior and posterior segments [10]. The anterior segment includes the cornea, conjunctiva, iris, and lens, and is commonly treated in conditions such as conjunctivitis, glaucoma, and dry eye disease [11]. In contrast, the posterior segment comprising the vitreous humour, retina, choroid, and optic nerve is much harder to access and is involved in serious vision-threatening diseases such as age-related macular degeneration, diabetic retinopathy, and retinal vein occlusion [12]. Drug delivery to the eye is limited by several protective barriers. The cornea acts as the primary barrier to topical drugs due to its tightly packed epithelial cells and contrasting lipophilic and hydrophilic layers, which restrict the passage of many molecules [13]. The conjunctiva and sclera also limit delivery, as rapid blood and lymphatic drainage can remove drugs before they reach intraocular tissues, while the sclera restricts the movement of larger particles [14]. Systemic drug delivery is further constrained by internal barriers. The blood-aqueous barrier controls drug movement into the anterior chamber [15], while the blood-retinal barrier is a major obstacle for posterior segment therapy. Formed by tight cellular junctions in retinal vessels and the retinal pigment epithelium, the BRB severely restricts drug entry into retinal tissues, often necessitating invasive delivery methods [16]. Even after reaching the eye, drug diffusion can be hindered by the gel-like vitreous humour and the layered structure of the retina [17].

**Nanotechnology in Ocular Drug Delivery**

Nanotechnology involves working with materials at the nanoscale, typically below 200 nm, to create unique properties that cannot be achieved at larger sizes [18]. By combining concepts from chemistry, biology, materials science, and engineering, nanotechnology has opened new possibilities in drug delivery—particularly for ocular applications where conventional treatments often fail [19]. The eye's protective barriers, although vital for vision, severely limit drug penetration and retention. Nanotechnology offers a flexible platform to overcome these challenges, improving drug bioavailability, targeting, and overall therapeutic outcomes [20]. A wide range of biocompatible materials, including polymers, lipids, metals, and proteins, are used to design nanoparticles for ocular

drug delivery [21]. These nanocarriers can encapsulate diverse therapeutic agents and protect them from degradation caused by enzymatic activity, oxidative stress, and rapid ocular clearance [22,23]. As a result, drugs remain stable and effective until they reach their target tissues. The small size of nanoparticles allows them to cross ocular barriers more efficiently than traditional formulations, enabling access to deeper regions of the eye such as the posterior segment [24,25]. Depending on their design, nanoparticles can diffuse through ocular tissues or remain in the vitreous for extended periods, enhancing drug exposure at the disease site [26]. Another major advantage of nanoparticle systems is their ability to provide controlled and sustained drug release. Carefully engineered nanocarriers can maintain therapeutic drug levels over prolonged periods, reducing the need for frequent dosing and improving patient compliance—an important benefit for chronic conditions like AMD and diabetic retinopathy [27–29]. Surface modification further enhances nanoparticle performance. PEGylation can prolong circulation time by reducing immune recognition, while the attachment of targeting ligands enables selective delivery to diseased tissues, minimizing off-target effects and systemic toxicity [30–32]. Additionally, multifunctional "theranostic" nanoparticles can combine drug delivery with imaging capabilities, allowing real-time monitoring of treatment response and disease progression [33,34]. Overall, nanotechnology represents a major shift in ocular drug delivery by improving drug stability, targeting precision, and therapeutic efficiency [35]. Although challenges related to safety, scalability, and regulation remain, ongoing advances continue to bring nanoparticle-based ocular therapies closer to clinical application [36].

**Types of Nanoparticles Used in Ocular Drug Delivery**

Nanoparticles used in ocular drug delivery vary widely in their composition and behaviour, allowing them to be tailored for specific drugs, diseases, and delivery routes [37]. Among these, lipid-based nanocarriers are extensively studied because of their high biocompatibility and similarity to natural cell membranes. Systems such as liposomes, solid lipid nanoparticles (SLNs), and nanostructured lipid carriers (NLCs) can carry both hydrophilic and hydrophobic drugs [38]. Liposomes are especially flexible due to their modifiable surfaces, while SLNs and NLCs offer improved stability, drug loading, and controlled release, making them effective for delivering drugs to deeper ocular tissues [39–42]. Polymeric nanoparticles, commonly made from biodegradable materials such as PLGA, chitosan, and PEG, provide sustained drug release and tunable properties [43]. PLGA-based systems are FDA-approved and widely used for long-term ocular therapies, while chitosan enhances ocular residence through mucoadhesion and PEGylation helps extend circulation and reduce immune recognition [44–46]. These systems are adaptable to multiple administration routes, including topical and intravitreal delivery. Inorganic nanoparticles, such as gold and silica-based carriers, offer unique advantages for combined therapeutic and diagnostic applications [47]. Gold nanoparticles are valued for imaging and photothermal uses, while silica nanoparticles allow high drug loading and responsive release [48,49]. However, concerns about long-term safety and clearance still limit their clinical translation [50,51]. Other systems, including dendrimers and micelles, further expand ocular delivery options. Dendrimers provide precise control over drug loading and targeting, while micelles improve the solubility and permeability of poorly water-soluble drugs [52–55]. Overall, these nanoparticle platforms offer versatile and promising strategies for improving the treatment of chronic and vision-threatening ocular diseases [56].

**Targeted Drug Delivery Strategies**

Targeted drug delivery is essential for improving the effectiveness and safety of nanoparticle-based ocular therapies, especially for diseases of the posterior segment. By directing drugs specifically to diseased tissues and limiting exposure to healthy areas, these strategies help enhance therapeutic outcomes while reducing side effects [57]. Nanoparticles achieve targeted delivery through two main approaches: passive and active targeting.

**Passive targeting** relies on the natural properties of nanoparticles, such as size and surface charge, to influence how they move and accumulate within ocular tissues [58]. Nanoparticles smaller than 200 nm can more easily cross ocular barriers and penetrate tight cellular junctions [59]. Surface charge also plays a key role, positively charged nanoparticles can interact more effectively with negatively charged ocular tissues, improving drug retention [60]. This approach is particularly useful in inflamed or diseased tissues, where increased vascular permeability allows greater nanoparticle accumulation [61].

**Active targeting** involves attaching specific ligands to the surface of nanoparticles, enabling them to bind selectively to receptors overexpressed in diseased ocular tissues [62]. Examples include RGD peptide-modified nanoparticles that target integrins in angiogenic retinal tissues associated with AMD and diabetic retinopathy [63], as well as transferrin-conjugated nanoparticles that enhance transport across the blood–retinal barrier via receptor-mediated uptake [64]. Ligand design can be optimized to control binding strength, specificity, and drug release, with dual-targeting strategies further improving precision [65,66]. However, successful active targeting also depends on ligand stability and availability within the ocular environment [67]. Overall, combining passive and active targeting strategies significantly improves the precision of nanoparticle-based ocular drug delivery, offering promising solutions for the treatment of chronic and vision-threatening posterior segment diseases.

**Applications in Posterior Segment Diseases**

Posterior segment diseases, including age-related macular degeneration (AMD), diabetic retinopathy (DR), retinal vein occlusion (RVO), and uveitis, are among the leading causes of vision loss worldwide [68]. These conditions affect deep ocular tissues such as the retina and choroid, which are difficult to reach using conventional drug delivery methods like eye drops or systemic administration [69]. As a result, effective and targeted treatment remains a major challenge. Nanotechnology-based drug delivery systems provide promising solutions by enabling controlled, sustained, and localized delivery of therapeutic agents to posterior eye tissues. Nanoparticles improve drug retention, reduce dosing frequency, and enhance treatment safety and effectiveness [70].

**Age-Related Macular Degeneration (AMD)**

AMD, particularly its neovascular form, is driven by excessive VEGF expression and is commonly treated with repeated intravitreal anti-VEGF injections [71]. Although effective, frequent injections pose risks and reduce patient adherence [72]. Nanoparticle-based systems such as lipid carriers, polymeric nanoparticles, and dendrimers can encapsulate anti-VEGF drugs, allow sustained release and reduce injection frequency [73]. Targeted nanoparticles further enhance drug accumulation at neovascular sites, improving efficacy while limiting off-target effects [74].

**Diabetic Retinopathy**

Diabetic retinopathy results from progressive damage to retinal blood vessels, often requiring long-term anti-inflammatory and anti-angiogenic therapy [75]. Traditional delivery routes are inefficient, and repeated intravitreal injections raise safety and compliance concerns [76]. Nanoparticles made from polymers such as PLGA (Poly (lactic-co-glycolic acid)) and chitosan offer sustained drug release and improved retinal delivery. Surface modifications can enhance targeting to diabetic tissues, increasing therapeutic precision and reducing toxicity [77,78].

**Retinal Vein Occlusion (RVO)**

RVO causes retinal oedema, haemorrhage, and ischemia, often leading to vision impairment if not promptly treated [79]. Nanoparticle-based carriers enable prolonged and localized delivery of drugs such as corticosteroids and thrombolytics, reducing the need for frequent injections and lowering the risk of side effects [80,81]. Advanced systems, including stimuli-responsive nanoparticles, are being explored to further improve treatment outcomes [82].

**Uveitis and Other Inflammatory Disorders**

Uveitis is a major cause of preventable blindness and is commonly treated with corticosteroids, which can cause significant side effects when used systemically [83]. Nanocarriers such as liposomes, solid lipid nanoparticles, and dendrimers allow targeted and sustained delivery of anti-inflammatory drugs to posterior tissues [84]. Targeting strategies and combination therapies have shown improved efficacy and reduced tissue damage in preclinical studies [85,86].

**Administration Routes and Delivery Systems**

The success of nanoparticle-based ocular drug delivery largely depends on the chosen route of administration, as the eye's protective barriers strongly influence drug access especially to the posterior segment. Each delivery route offers specific advantages and limitations. Intravitreal injection is the most direct and effective method for delivering

nanoparticles to the posterior eye, achieving high drug concentrations in the retina and choroid [87]. Despite its effectiveness, this invasive approach carries risks such as infection, retinal detachment, and increased intraocular pressure, though it remains the standard treatment for diseases like wet AMD and diabetic macular oedema. Less invasive alternatives include subconjunctival and periocular injections, which allow nanoparticles to diffuse through the sclera toward the posterior segment and are generally better tolerated. However, these routes often result in lower drug levels and may require repeated administration [88]. Topical delivery, typically as eye drops, is the most convenient and patient-friendly option but is mainly limited to anterior segment diseases due to rapid drug clearance. New strategies such as mucoadhesive nanoparticles and in situ gelling systems aim to enhance posterior segment delivery and hold promise for non-invasive treatments [89]. Systemic administration is restricted by the blood-retinal and blood-aqueous barriers, limiting drug access to ocular tissues. Nevertheless, targeted nanoparticles capable of crossing these barriers have shown promising preclinical results, particularly when local delivery is not possible [90]. Ultimately, the choice of administration route depends on the disease, target tissue, safety profile, and patient compliance [91]. Ongoing advances in nanocarrier design continue to support the development of safer and less invasive delivery strategies for posterior segment therapy [92].

## CONCLUSION

Nanotechnology is emerging as a powerful tool in ocular drug delivery, offering new solutions to long-standing challenges in treating eye diseases, especially those affecting the posterior segment. The eye's protective barriers often limit the effectiveness of conventional therapies, highlighting the need for more targeted and long-lasting treatment strategies. Nanoparticles, with their small size and customizable surfaces, show great promise in overcoming these barriers and improving therapeutic outcomes. A key advantage of nanoparticle-based systems is their ability to deliver drugs in a sustained and localized manner, which is particularly valuable for chronic conditions such as AMD, diabetic retinopathy, and retinal vein occlusion. By enhancing drug targeting and reducing dosing frequency, these systems may improve both treatment effectiveness and patient quality of life. Advances in smart, stimuli-responsive, and theranostic nanoparticles further support the move toward more personalized ocular therapies. However, important challenges remain before widespread clinical adoption is possible. Long-term safety, immune responses, large-scale manufacturing, regulatory approval, and cost-effectiveness all require careful consideration. While preclinical results are encouraging, robust clinical trials are still needed to confirm safety and real-world benefits. Ultimately, the successful translation of nanotechnology into routine eye care will depend on continued collaboration between scientists, clinicians, industry, and regulators.

**ABSTRACT**

A set D of vertices in a spitted graph S(G) is said to be a total certified dominating set if both total dominating set and Certified dominating set of $S(G)$. The cardinality of a minimum total certified dominating set is called the total certified domination number $\gamma_{tcer}$ and is denoted by $\gamma_{tcer}[S(G)]$. The total certified domination of path splitted graphs, cycle splitted graphs.

**Keywords:** Domination, Path Splitted Graph, Cycle Splitted Graph, Certified Domination, Total Certified Domination.

## INTRODUCTION

The concepts of graph theory instead of . By a graph, we mean a finite simple and undirected graph. The vertex set and edge set of a graph G denoted are by V (G) and E(G) respectively. Let G be a graph. For each vertex v of a graph G , take a new vertex u . Join u to those vertices of G adjacent to v . The graph thus obtained is called the splitting graph of G . It is denoted by S(G) . For a graph G, the splitting graph S of G is obtained by adding a new vertex v corresponding to each vertex u of G such that N(u) = N(v) and it is denoted by S(G). The notions of splitting graphs were studied and investigated of many more authors for Example [5,6,7,11, 12, 13,14,]

## PRELIMINARIES

**Definition:** [9]
A set $D$ of vertices in a splitted graph $S(G) = (V, E)$ is called a dominating set if every vertex in $V - D$ is adjacent to some vertex in $D$.

**Definition:[3]**
A set $D$ of vertices in a splitted graph $S(G) = (V, E)$ is called a total dominating set if every vertex in $V$ is adjacent to some vertex in $D$.

**Definition:[10]**
A dominating set D of a spitted graph S(G) is said to be Certified dominating set if every vertex in D has either zero or atleast two neighbors in $V - D$ . The Certified domination number $\gamma_{cer}[S(G)]$ of $S(G)$ is minimum cardinality of a Certified domination set of $S(G)$ and is denoted by $\gamma_{cer}[S(G)]$ . In this paper deals some splitted graphs namely $S(P_n), S(H_n), S(C_n), S(P_n^+), S(P_n oNK_1)$

**Definition:[2]**
A set D of vertices in a spitted graph S(G) is said to be a total certified dominating set if both total dominating set and Certified dominating set of $S(G)$. The cardinality of a minimum total certified dominating set is called the total certified domination number $\gamma_{tcer}$ and is denoted by $\gamma_{tcer}[S(G)]$.
( $\gamma_{tcer}$ − Total Certified domination ) Main Results

**Theorem 3.1** Total Certified domination number of the path splitted graph S($P_n$),is
$\gamma_{tcer}[S(P_n)] = \left\lceil \frac{n}{2} \right\rceil$ $if\ \ n\ is\ odd\ \ and\ n \geq 5$

**Proof.**
Let S($P_n$) be path splitted graph of $P_n$ . Let V [S($P_n$)] = {$f_i$ , $g_i$: 1≤i≤$n$ }, Let E[S($P_n$)] = {($f_i f_{i+1}$) ∪ ($g_i f_{i+1}$) ∪ ($f_i g_{i+1}$) ; 1≤ i ≤ n-1}. In $S(P_n)$, for each four of $f_i$ , $g_i$ vertices, vertex $f_{i+1}$ is adjacent to $g_{i+2}, f_i, g_i$ where as $f_{i+2}$ is adjacent to $f_{i+3}, g_{i+3}, g_{i+1}$ and if the last two vertices $(f_i, g_i)\ are\ set$ , $(n-2 \leq i \leq n)$ are set, vertex $f_{n-1}$ is adjacent to $g_{n-2}, f_n, g_n$ where as $f_{n-2}$ is adjacent to $f_{n-3}, g_{n-3}, g_{n-1}$ maybe if the last five vertices $(f_i, g_i)\ are\ set$ , $(n-4 \leq i \leq n)$ are set, vertex $f_{n-1}$ is adjacent to $g_{n-2}, f_n, g_n$ where as $f_{n-2}$ is adjacent to $g_{n-3}, g_{n-1}$ moreover vertex $f_{n-3}$ is adjacent to $g_{n-2}, f_{n-4}, g_{n-4}$ by definition $f_{i+1}$ and $f_{i+2}$ are adjacent in each vertices satisfy the total certified dominating set condition.
Hence, $\gamma_{tcer}[S(P_n)] = \left\lceil \frac{n}{2} \right\rceil$
For example $\gamma_{tcer}[S(P_9)]$ = {$f_2$ , $f_3$,$f_6$ , $f_7$,$f_8$ } = 5 as shown in the figure 1.

**Theorem 3.2** Total Certified domination number of the path splitted graph S($P_n$),is

$\gamma_{tcer}[S(P_n)] = \frac{n}{2}$ $if\ \ n \equiv 0\ (mod\ 4)$

**Proof.**
Let S($P_n$) be path splitted graph of $S(P_n)$ . Let V [S($P_n$)] = {$f_i$ , $g_i$: 1≤i≤$n$ }, Let E[S($P_n$)] = {($f_i f_{i+1}$) ∪ ($g_i f_{i+1}$) ∪ ($f_i g_{i+1}$) ; 1≤ i ≤ n-1}. In $P_n$, for each four of $f_i$ , $g_i$ vertices, vertex $f_{i+1}$ is adjacent to $g_{i+2}, f_i, g_i$ where as $f_{i+2}$ is adjacent to $f_{i+3}, g_{i+3}, g_{i+1}$ by definition $f_{i+1}$ and $f_{i+2}$ are adjacent in each vertices satisfy the total certified dominating set condition.
Hence, $\gamma_{tcer}[S(P_n)] = \frac{n}{2}$
For example $\gamma_{tcer}[S(P_8)]$ = {$f_2$ , $f_3$,$f_6$ , $f_7$} = 4 as shown in the figure 2.

**Theorem 3.3** Total Certified domination number of the path splitted graph S($P_n$),is

$\gamma_{tcer}[S(P_n)] = \frac{n}{2} + 1 \qquad if\ n \equiv 2\ (mod\ 4)$

**Proof.** Let S($P_n$) be path splitted graph of $P_n$ . Let V [S($P_n$)] = {$f_i$ , $g_i$: 1≤i≤$n$ }, Let E[S($P_n$)] = {($f_i f_{i+1}$) ∪ ($g_i f_{i+1}$) ∪ ($f_i g_{i+1}$) ; 1≤ i ≤ n-1}. In $S(P_n)$, for each four of $f_i$ , $g_i$ vertices, vertex $f_{i+1}$ is adjacent to $g_{i+2}, f_i, g_i$ where as $f_{i+2}$ is adjacent to $f_{i+3}, g_{i+3}, g_{i+1}$ and if the last six vertices ($f_i$ , $g_i$) $are\ set$ , $(n-6 \le i \le n)$ are set, vertex $f_{n-1}$ is adjacent to $g_{n-2}, f_n, g_n$ where as $f_{n-2}$ is adjacent to $g_{n-3}, g_{n-1}$ , vertex $f_{n-3}$ is adjacent to $g_{n-2}, g_{n-4}$ , vertex $f_{n-4}$ is adjacent to $g_{n-3}, f_{n-5}, g_{n-5}$ by definition $f_{i+1}$ and $f_{i+2}$ are adjacent in each vertices satisfy the total certified dominating set condition.
Hence, $\gamma_{tcer}[S(P_n)] = \frac{n}{2} + 1$

For example $\gamma_{tcer}[S(P_{10})]$ = {$f_2$ , $f_3$,$f_6$ , $f_7$,$f_8$ , $f_9$ } = 6 as shown in the figure 3.

**Theorem 3.4** Total Certified domination number of the $H$ splitted graph S($H_n$)],is

$\gamma_{tcer}[S(H_n)] = n + 1 \qquad if\ n \ge 3\ and\ n\ is\ odd$

**Proof.** Let S($H_n$) be splitted graph of $H_n$ .
Let V [S($H_n$)] = {$f_i$ , $g_i$,$f_i^{'}$ , $g_i^{'}$ : 1≤ i ≤$n$ },
Let E[S($H_n$)] = {($f_i f_{i+1}$) ∪ ($g_i f_{i+1}$) ∪ ($f_i g_{i+1}$) ∪ ($f_{\frac{n}{2}} f_{\frac{n+1}{2}}^{'}$) ∪ ($f_{\frac{n}{2}} g_{\frac{n+1}{2}}^{'}$) ∪ ($g_{\frac{n}{2}} f_{\frac{n+1}{2}}^{'}$)∪($f_i^{'} f_{i+1}^{'}$)∪ ($g_i^{'} f_{i+1}^{'}$) ∪ ($f_i^{'} g_{i+1}^{'}$); 1≤ i ≤ n-1}.

In $S(H_n)$, for each four of $f_i$ , $g_i$ vertices, vertex $f_{i+1}$ is adjacent to $g_{i+2}, f_i, g_i$ where as $f_{i+2}$ is adjacent to $f_{i+3}, g_{i+3}, g_{i+1}$ and if the last three vertices ($f_i$ , $g_i$) $are\ set$ , $(n-2 \le i \le n)$ are set, vertex $f_{n-1}$ is adjacent to $g_{n-2}, f_n, g_n$ where as $f_{n-2}$ is adjacent to $f_{n-3}, g_{n-3}, g_{n-1}$ maybe if the last five vertices ($f_i$ , $g_i$) $are\ set$ , $(n-4 \le i \le n)$ are set, vertex $f_{n-1}$ is adjacent to $g_{n-2}, f_n, g_n$ where as $f_{n-2}$ is adjacent to $g_{n-3}, g_{n-1}$ moreover vertex $f_{n-3}$ is adjacent to $g_{n-2}, f_{n-4}, g_{n-4}$ by definition $f_{i+1}$ and $f_{i+2}$ are adjacent in each vertices satisfy the total certified dominating set condition. Next part for each four of $f_i^{'}$ , $g_i^{'}$ vertices, vertex $f_{i+1}^{'}$ is adjacent to $g_{i+2}^{'}, f_i^{'}, g_i^{'}$ where as $f_{i+2}^{'}$ is adjacent to $f_{i+3}^{'}, g_{i+3}^{'}, g_{i+1}^{'}$ and if the last three vertices ($f_i^{'}$ , $g_i^{'}$) $are\ set$, $(n-2 \le i \le n)$ are set, vertex $f_{n-1}^{'}$ is adjacent to $g_{n-2}^{'}, f_n^{'}, g_n^{'}$ where as $f_{n-2}^{'}$ is adjacent to $f_{n-3}^{'}, g_{n-3}^{'}, g_{n-1}^{'}$ and if the last five vertices ($f_i^{'}$ , $g_i^{'}$) $are\ set$, $(n-4 \le i \le n)$ are set, vertex $f_{n-1}^{'}$ is adjacent to $g_{n-2}^{'}, f_n^{'}, g_n^{'}$ where as $f_{n-2}^{'}$ is adjacent to $g_{n-3}^{'}, g_{n-1}^{'}$, vertex $f_{n-3}^{'}$ is adjacent to $g_{n-4}^{'}, f_{n-4}^{'}, g_{n-3}^{'}$ by definition $f_{i+1}^{'}$ and $f_{i+2}^{'}$ are adjacent in each vertices satisfy the total certified dominating set condition.
Hence
$\gamma_{tcer}[S(H_n)] = n + 1$

For example $\gamma_{tcer}[S(H_5)]$ ={$f_2$ , $f_3$ , $f_4$, $f_2^{'}$ , $f_3^{'}$ , $f_4^{'}$ }= 6 as shown in the figure 4.

**Theorem 3.5** Total Certified domination number of the $H$ splitted graph S($H_n$)],is

$\gamma_{tcer}[S(H_n)] = n + 2 \qquad if\ n \equiv 2\ (mod\ 4)$

**Proof.** Let S($H_n$) be splitted graph of $H_n$ .
Let V [S($H_n$)] = {$f_i$ , $g_i$,$f_i^{'}$ , $g_i^{'}$ : 1≤ i ≤$n$ },
Let E[S($H_n$)] = {($f_i f_{i+1}$) ∪ ($g_i f_{i+1}$) ∪ ($f_i g_{i+1}$) ∪ ($f_{\frac{n}{2}} f_{\frac{n+1}{2}}^{'}$) ∪ ($f_{\frac{n}{2}} g_{\frac{n+1}{2}}^{'}$) ∪ ($g_{\frac{n}{2}} f_{\frac{n+1}{2}}^{'}$)∪($f_i^{'} f_{i+1}^{'}$)∪ ($g_i^{'} f_{i+1}^{'}$) ∪ ($f_i^{'} g_{i+1}^{'}$); 1≤ i ≤ n-1}.
In $S(H_n)$, for each four of $f_i$ , $g_i$ vertices, vertex $f_{i+1}$ is adjacent to $g_{i+2}, f_i, g_i$ where as $f_{i+2}$ is adjacent to $f_{i+3}, g_{i+3}, g_{i+1}$ and if the last six vertices ($f_i$ , $g_i$) $are\ set$ , $(n-5 \le i \le n)$ are set, vertex $f_{n-1}$ is adjacent to $g_{n-2}, f_n, g_n$ where as $f_{n-2}$ is adjacent to $g_{n-3}, g_{n-1}$ vertex $f_{n-3}$ is adjacent to $g_{n-2}$, $g_{n-4}$ moreover, vertex $f_{n-4}$ is adjacent to $g_{n-3}$, $g_{n-5}$ , $f_{n-5}$ by definition $f_{i+1}$ and $f_{i+2}$ are adjacent in each vertices satisfy the total certified

dominating set condition. Next part for each four of $f_i^{'}, g_i^{'}$ vertices, vertex $f_{i+1}^{'}$ is adjacent to $g_{i+2}^{'}, f_i^{'}, g_i^{'}$ where as $f_{i+2}^{'}$ is adjacent to $f_{i+3}^{'}, g_{i+3}^{'}, g_{i+1}^{'}$ and if the last three vertices $(f_i^{'}, g_i^{'})\ are\ set, (n-5 \le i \le n)$ are set, vertex $f_{n-1}^{'}$ is adjacent to $g_{n-2}^{'}, f_n^{'}, g_n^{'}$ where as $f_{n-2}^{'}$ is adjacent to $g_{n-3}^{'}, g_{n-1}^{'}$ , vertex $f_{n-3}^{'}$ is adjacent to $g_{n-4}^{'}, g_{n-2}^{'}$vertex $f_{n-4}^{'}$ is adjacent to $g_{n-5}^{'}, f_{n-5}^{'}, g_{n-3}^{'}$,by definition $f_{i+1}^{'}$ and $f_{i+2}^{'}$ are adjacent in each vertices satisfy the total certified dominating set condition.
Hence
$\gamma_{tcer}[S(H_n)] = n+2$

For example $\gamma_{tcer}[S(H_6)]$ ={$f_2, f_3, f_4, f_5, f_2^{'}, f_3^{'}, f_4^{'}, f_5^{'}$}= 8 as shown in the figure 5.

**Theorem 3.6** Total Certified domination number of the $H$ splitted graph S($H_n$)],is

$\gamma_{tcer}[S(H_n)] = n \quad if\ n \equiv 0(mod\ 4)$

**Proof.** Let S($H_n$) be splitted graph of $H_n$ .
Let V [S($H_n$)] = {$f_i, g_i, f_i^{'}, g_i^{'}$ : 1≤ i ≤$n$ },
Let E[S($H_n$)] = {($f_i f_{i+1}$) ∪ ($g_i f_{i+1}$) ∪ ($f_i g_{i+1}$) ∪ ($f_{\frac{n}{2}} f_{\frac{n+1}{2}}^{'}$) ∪ ($f_{\frac{n}{2}} g_{\frac{n+1}{2}}^{'}$) ∪ ($g_{\frac{n}{2}} f_{\frac{n+1}{2}}^{'}$)∪($f_i^{'} f_{i+1}^{'}$)∪ ($g_i^{'} f_{i+1}^{'}$) ∪ ($f_i^{'} g_{i+1}^{'}$); 1≤ i ≤ n-1}.
In (), for each four of , $g_i$ vertices, vertex $f_{i+1}$ is adjacent to $g_{i+2}, f_i, g_i$ where as $f_{i+2}$ is adjacent to $f_{i+3}, g_{i+3}, g_{i+1}$ by definition $f_{i+1}$ and $f_{i+2}$ are adjacent in each vertices satisfy the total certified dominating set condition. Next part for each four of $f_i^{'}, g_i^{'}$ vertices, vertex $f_{i+1}^{'}$ is adjacent to $g_{i+2}^{'}, f_i^{'}, g_i^{'}$ where as $f_{i+2}^{'}$ is adjacent to $f_{i+3}^{'}, g_{i+3}^{'}, g_{i+1}^{'}$ by definition $f_{i+1}^{'}$ and $f_{i+2}^{'}$ are adjacent in each vertices satisfy the total certified dominating set condition.
Hence
$\gamma_{tcer}[S(H_n)] = n$
For example $\gamma_{tcer}[S(H_4)]$ ={$f_2, f_3, f_2^{'}, f_3^{'}$,}= 4 as shown in the figure 6.

**Theorem 3.4** Total Certified domination number of the splitted graph $S(P_n^+)$,is
$\gamma_{tcer}[S(P_n^+)] = n\ for\ all\ n \ge 2$

**Proof.** Let S($P_n^+$) be splitted graph of $P_n^+$. Let V[S($P_n^+$)] = {$f_i, g_i, f_i^{'}, g_i^{'}$ : 1≤ i ≤$n$ },
Let E[S($P_n^+$)] = { [ ($f_i f_{i+1}$) ; 1≤i ≤ n-1]∪[ ($f_i f_i^{'}$) ∪ ($f_i g_i^{'}$) ; 1≤ i ≤ n] ∪ [ ($g_i f_{i-1}$) ∪ ($g_i f_i^{'}$) ∪ ($g_i f_{i+1}$) ; 2≤ i ≤ n-1] ∪ ($g_1 f_1'$) ∪ ($g_1 f_2$) ∪ ($g_n f_n'$) ∪ ($g_n f_{n-1}$) }

In$S(P_n^+)$, For n > 2, vertex $f_i$ is adjacent to $g_{i-1}, g_{i+1}, f_i'$, $g_i'$for all $2 \le i \le n-1$ where as $f_1$ is adjacent to $g_2, f_1'$, $g_1'$ and vertex $f_n$ is adjacent to $g_{n-1}, f_n'$, $g_n'$ by definition $f_1, f_i\ (2 \le i \le n-1)\ and\ f_n$ are all adjacent this will be total Certified dominating set condition.
Hence,
$\gamma_{tcer}[S(P_n^+)] = n$

For example $\gamma_{tcer}[S(P_5^+)]$ == {$f_1, f_2, f_3, f_4, f_5$}= 5 as shown in the figure 7.

**Theorem 3.5.** Certified domination number of the splitted graph $(P_n o NK_1)$ , is

$\gamma_{tcer}[S(P_n o NK_1)] =$

**Proof.** Let $S(P_n o NK_1)$ be splitted graph of $P_n \circ NK_1$.
Let V[$S(P_n o NK_1)$)] = {$f_i, g_i$ , $f_{ij}, g_i$ ; 1 ≤ i ≤ $n$, 1 ≤ j ≤ $N$},
Let E[$S(P_n o NK_1)$)] = { [ ($f_i f_{i+1}$) ; 1≤ i ≤ n-1] ∪[ ($f_i f_{ij}$)∪ ($g_i f_{ij}$) ∪ ($f_i g_{ij}$) ; 1 ≤ i ≤ $n$, 1 ≤ j ≤ $N$ ] ∪ [ ($g_i f_{i-1}$) ∪ ($g_i f_{i+1}$) ; 2 ≤ $i$ ≤ n − 1]∪ [ ($g_1 f_2$) ∪ ($g_n f_{n-1}$) ] }

In $S(P_n o NK_1)$, Vertex $f_i$ is adjacent to $g_{i-1}, g_{i+1}, f_{ij}, g_{ij}$ for all 1 ≤ i ≤ $n-1$, 1 ≤ j ≤ $N$,

where as $f_1$ is adjacent to $g_{i+1}$ $f_{1j}$, $g_{1j}$.and Vertex $f_n$ is adjacent to $g_{n-1}$ $f_{nj}$, $g_{nj}$ .by definition $f_1, f_i$ $(2 \le i \le n-1)$ *and* $f_n$ are all adjacent this will be total Certified dominating set condition.
Hence
$\gamma_{tcer}[S(P_n o NK_1)] =$
For example
$\gamma_{tcer}[S(P_4 o NK_1)] = \{f_1, f_2, f_3, f_4\} = 4$ as shown in the figure 8.

**Theorem 3.6.** Total Certified domination number of the cycle splitted graph S($C_n$),is

$$\gamma_{tcer}[S(C_n)] = \begin{cases} \left\lceil \frac{n}{2} \right\rceil & if\ n\ is\ odd \text{ with } n \ge 3 \\ 2\left\lceil \frac{n}{4} \right\rceil & if\ n\ is\ even \text{ with } n \ge 2 \end{cases}.$$

**Proof.**
**Case (i)** n is odd with $n \ge 3$
Let S($C_n$) be cycle splitted graph of $C_n$ .
Let V [S($C_n$)] = $\{f_i, g: 1 \le i \le n\}$, Let E[S($C_n$)] = [{($f_i f_{i+1}$) ∪ ($g_i f_{i+1}$) ∪ ($f_i g_{i+1}$) ; 1≤ i ≤ n-1}]∪ [ ($g_1 f_n$) ∪ ($g_n f_1$) ∪ ($f_1 f_n$)].
In cycle $S(C_n)$, for each four of $f_i$ , $g_i$ vertices, vertex $f_{i+1}$ is adjacent to $g_{i+2}, f_i, g_i$ where as $f_{i+2}$ is adjacent to $f_{i+3}, g_{i+3}$, $g_{i+1}$ and if the last remaining five vertices $(f_i, g_i), (n-4 \le i \le n)$ are set, vertex $f_{n-1}$ is adjacent to $f_{n+1}, g_{n+1}, g_{n-1}$ where as $f_{n-2}$ is adjacent to $g_{n-3}, g_{n-1}$ and also $f_{n-3}$ is adjacent to $f_{n-4}$ $g_{n-4}, g_{n-3}$ if may be the last remaining three vertices $(f_i, g_i), (n-2 \le i \le n)$ are set, vertex $f_{n-1}$ is adjacent to $f_{n-2}, g_{n-2}, g_n$ where as $f_n$ is adjacent to $g_{n-1}, g_1, f_1$
by definition $a_{i+1}$ and $a_{i+2}$ are adjacent $1 \le i \le n-2$, and also $a_{n-1}$ *and* $a_n$ are adjacent in each vertices satisfy the total certified dominating set condition.
Hence, $\gamma_{tcer}[S(C_n)] = \left\lceil \frac{n}{2} \right\rceil$
For example $\gamma_{tcer}[S(C_5)] = \{a_2, a_3, a_4\} = 3$ as shown in the figure 9.

**Case (ii)** Let S($C_n$) be cycle splitted graph of $C_n$ .
Let V [S($C_n$)] = $\{f_i, g_i: 1 \le i \le n\}$, Let E[S($C_n$)] = [{($f_i f_{i+1}$) ∪ ($g_i f_{i+1}$) ∪ ($f_i g_{i+1}$) ; 1≤ i ≤ n-1}]∪ [ ($g_1 f_n$) ∪ ($g_n f_1$) ∪ ($f_1 f_n$)].
In cycle $S(C_n)$, for each four of $f_i$ , $g_i$ vertices, vertex $f_{i+1}$ is adjacent to $g_{i+2}, f_i, g_i$ where as $f_{i+2}$ is adjacent to $f_{i+3}, g_{i+3}$, $g_{i+1}$ and if the last remaining two vertices $(f_i, g_i), (n-1 \le i \le n)$ are set, vertex $f_n$ is adjacent to $f_1, g_1, g_{n-1}$ where as $f_{n-1}$ is adjacent to $g_{n-2}, f_{n-2}, g_n$ by definition $a_{i+1}$ and $a_{i+2}$ are adjacent $1 \le i \le n-2$, and also $a_{n-1}$ *and* $a_n$ are adjacent in each vertices satisfy the total certified dominating set condition.
Hence, $\gamma_{tcer}[S(C_n)] = 2\left\lceil \frac{n}{4} \right\rceil$
For example $\gamma_{cer}[S(C_6)] = \{f_2, f_3, f_5, f_6\} = 4$ as shown in the figure 10.

## ABSTRACT

Caffeine, the most widely consumed psychoactive substance globally, is valued for its ability to enhance alertness and cognitive function. However, its habitual use has sparked discussions about whether it leads to true addiction or merely dependence. This review explores the physiological and behavioral dimensions of caffeine dependence, focusing on its mode of action through adenosine receptor antagonism and the neurochemical adaptations that result in tolerance and withdrawal. While caffeine withdrawal is acknowledged in diagnostic criteria like the DSM-5, its classification as an addiction remains debated, given the lack of severe physical or social consequences. Additionally, the review examines how socio-cultural factors influence caffeine consumption and contribute to its widespread acceptance. By distinguishing between dependence and addiction, this article provides a deeper understanding of the long-term health implications of regular caffeine use.

**Keywords:** Caffeine, Addiction, Dependence, Withdrawal, Blood pressure, Tolerance, Stimulant, Metabolism, Treatment, Physiological effects.

**ABBREVIATIONS**
**mg (Milligram)** – A small unit of weight, equal to one-thousandth of a gram, commonly used to measure caffeine levels in drinks.

**oz (Ounce)** – A volume measurement mainly used in the U.S.; for example, 8 ounces is roughly equivalent to 237 milliliters.
**mmHg (Millimeters of Mercury)** – A unit for measuring pressure, often used in blood pressure readings (e.g., systolic and diastolic values).
**CNS (Central Nervous System)** – The part of the nervous system that includes the brain and spinal cord, responsible for controlling bodily functions and processing sensory information.
**mg/kg (Milligrams per Kilogram)** – A measurement that represents the amount of a substance (such as caffeine) in proportion to body weight.
**HCPs (Healthcare Professionals)** – Medical experts such as doctors, nurses, and therapists who provide healthcare services.
**DSM-IV (Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition)** – A guide from the American Psychiatric Association used to classify and diagnose mental health conditions, including substance-related disorders.
**DSM-5 (Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition)** – The latest version of DSM-IV, used for diagnosing psychiatric conditions, including caffeine-related disorders.
**SR (Saudi Riyals)** – The official currency of Saudi Arabia, used to indicate spending on caffeine-containing products.
**GABA (Gamma-Aminobutyric Acid)** – A neurotransmitter that helps calm nerve activity and supports relaxation.
**μM (Micromolar)** – A unit of concentration that indicates micromoles per liter (μmol/L), often used in scientific studies.
**cAMP (Cyclic Adenosine Monophosphate)** A molecule that plays a key role in cellular processes like metabolism and signaling.
**mM (Millimolar)** – A unit of measurement representing millimoles per liter (mmol/L), frequently used in chemistry and biology.
**CBT (Cognitive-Behavioral Therapy)** – A psychological treatment method designed to help individuals change negative thought patterns and behaviors.

## INTRODUCTION

Caffeine is a natural stimulant for the central nervous system, found in over 60 plant sources, including coffee beans, tea leaves, kola nuts, and cacao pods. It is also synthetically manufactured and added to various products like medications, energy drinks, and snacks. Beverages are the primary source of caffeine, with amounts varying based on the type: an 8-ounce coffee contains 95–200 mg, a 12-ounce cola provides 35–45 mg, an 8-ounce energy drink offers 70–100 mg, and an 8-ounce tea has 14–60 mg[1]. Caffeine's influence on behavior has been extensively studied in both humans and animals, with animal research offering valuable insights due to greater experimental flexibility. One key focus is its effect on escape and avoidance behaviors[34]. Depending on the dosage and timing, caffeine may increase anxiety-like responses (encouraging escape and avoidance) or reduce anxiety (fostering approach behaviors). These findings highlight how caffeine's behavioral effects are context-dependent[2]. As a stimulant, caffeine boosts brain and nervous system activity, enhancing alertness and energy. Its short-term effects include increased heart rate, faster breathing, and improved mental and physical performance. However, regular use can lead to tolerance, requiring higher doses to achieve the same results. Long-term effects may include digestive discomfort, such as heartburn and stomach upset, and frequent urination[3]. Excessive caffeine consumption can result in serious side effects, including anxiety, sleep disturbances, and overdose symptoms like confusion, hallucinations, vomiting, and irregular heartbeat. In severe cases, it can lead to fatal convulsions or arrhythmias[35]. During pregnancy, high caffeine intake may affect fetal development by increasing heart rate and metabolism,

slowing growth, and elevating the risk of miscarriage. Furthermore, caffeine may interfere with the effectiveness of certain medications and dietary supplements[4].

**What is Caffeine Addiction**

Caffeine is a central nervous system (CNS) stimulant known for enhancing focus, boosting metabolism, and improving mood. Commonly found in coffee, tea, energy drinks, and soda, many individuals rely on it to feel energized and alert, particularly in the morning[36]. In the United States, over 90% of adults consume caffeine regularly, with an average daily intake of 200 mg—roughly equivalent to two 6-ounce cups of coffee or five 12-ounce cans of soda. While moderate caffeine use is generally deemed safe, excessive consumption can lead to dependency, transforming occasional use into a daily necessity[5]. Caffeine dependence develops quickly due to the brain's adaptation to its chemical effects. Regular consumption builds tolerance, similar to substances like alcohol or other drugs, requiring larger doses over time to achieve the same stimulating effects[37]. Habitual caffeine users often need increasing amounts to feel their usual "boost." Stopping caffeine abruptly after prolonged use can trigger withdrawal symptoms, such as headaches, fatigue, and cravings, making it difficult to quit. These withdrawal challenges frequently lead to relapse, causing individuals to resume use despite the potential long-term health risks of chronic caffeine consumption[6].

**Acute intake of coffee or caffeine and blood pressure**

Research consistently shows that consuming coffee acutely raises blood pressure (Table 2). This effect is primarily attributed to caffeine, as regular coffee elevates blood pressure while decaffeinated coffee does not (Smits *et al*., 1985; Ray *et al*., 1986; Myers *et al*., 1989; Nussberger *et al*., 1990). Moreover, studies reveal no significant difference in blood pressure effects between regular coffee and pure caffeine (Casiglia *et al*., 1992)[7]. A single caffeine dose, typically 200–250 mg (equivalent to two or three cups of coffee), can raise systolic blood pressure by 3–14 mmHg and diastolic blood pressure by 4–13 mmHg in individuals with normal blood pressure (Table). This increase aligns with elevated plasma caffeine levels (Robertson *et al*., 1978; Haigh *et al*., 1993; Sung *et al*., 1994)[8]. Blood pressure begins to rise within 30 minutes of caffeine intake, peaks between 60 and 120 minutes, and remains elevated for 2–4 hours (Robertson *et al*., 1978; Freestone and Ramsay, 1982; Izzo *et al*., 1983; Nussberger *et al*., 1990; Sung *et al*., 1994; Bender *et al*., 1997).Caffeine's impact on blood pressure is more pronounced in individuals with hypertension or a predisposition to it compared to those with normal blood pressure (Smits *et al*., 1986a; Greenstadt *et al*., 1988; Sung *et al*., 1994; Lovallo *et al*., 1996b). This effect intensifies during physical or mental stress (Greenstadt *et al*., 1988; Pincombe *et al*., 1988, 1991; Lovallo *et al*., 1989, 1991, 1996b; Myers *et al*., 1989; Lane *et al*., 1990; France and Ditto, 1992)[9]. Some findings suggest older adults experience stronger blood pressure responses to caffeine than younger individuals (Izzo *et al*., 1983; Massey, 1998). However, studies indicate no significant differences in caffeine-related blood pressure responses based on race or gender (Myers *et al*., 1989; Strickland *et al*., 1989; Bak and Grobbee, 1990; James, 1994)[10]. The acute blood pressure-raising effect of caffeine is more pronounced in those who do not habitually consume it compared to regular users (Izzo *et al*., 1983; Casiglia *et al*., 1992). Additionally, the response magnitude inversely correlates with baseline plasma caffeine levels, with the most significant effects observed in individuals with lower initial caffeine concentrations (Robertson *et al*., 1981)[11].

**Coffee and caffeine consumption**

Coffee, originally limited to the Arab world until the 15th century, spread to Europe in the 16th century, where it quickly became popular. Recent surveys highlight significant differences in coffee consumption across countries[12].

**Caffeine Content in Coffee by Preparation Method(Table)**[13]. Scandinavian countries, Austria, and the Netherlands report the highest coffee consumption, exceeding 10 kg per person annually. Meanwhile, most Western European countries, along with Brazil and Costa Rica, consume between 6–9 kg per person per year. Countries with the lowest consumption levels, under 5 kg per person annually, include the United States, Italy, Algeria, Nicaragua, and Paraguay[14]. The caffeine content in coffee varies based on the preparation method, serving size (50–190 ml), and coffee type (Arabica or Robusta). Instant coffee has the lowest caffeine content at 19 mg per cup, while boiled coffee has the highest at 177 mg per cup. Caffeine concentrations range from 0.7–1.1 mg/ml for boiled or filter coffee,

0.6–3.3 mg/ml for espresso, and 0.2–0.6 mg/ml for instant coffee[15]. Globally, Arabica coffee dominates the market, comprising 70%–100% of consumption in most countries. In Finland and Sweden, Arabica is consumed exclusively[38]. However, in France, Italy, Portugal, and the UK, Robusta accounts for 42%–70% of consumption. Robusta has approximately double the caffeine content of Arabica, with green Arabica beans containing 0.9%–1.2% caffeine and roasted beans averaging 1.3%, compared to green Robusta beans with 1.6%–2.4% caffeine and roasted beans at 2.0%. This equates to 71–120 mg of caffeine per 150 ml cup of Arabica coffee and 131–220 mg per cup of Robusta[16]. Coffee consumption has been increasing globally. In 1990, daily coffee intake ranged from 1.41 cups in Japan to 1.73 cups in the United States and 3.87 cups in Germany. While U.S. coffee consumption has remained stable since its decline in 1986, Japan's has steadily risen over the last decade, and Germany's has remained consistent[39]. A French survey identified four factors contributing to higher coffee consumption: the need for stimulation, a preference for strong coffee, familiarity with coffee, and a liking for coffee roasted in specialty shops[17].

**Caffeine consumption**

Caffeine is consumed worldwide through various dietary sources, including tea, coffee, cocoa-based beverages, candy bars, and soft drinks, with caffeine content varying widely. Coffee contains 71–220 mg per 150 ml, tea provides 32–42 mg per 150 ml, cola offers 32–70 mg per 330 ml, and cocoa beverages contain around 4 mg per 150 ml. Globally, the average daily caffeine intake is approximately 76 mg per person, though this figure is significantly higher in certain regions[40]. In the United States and Canada, daily caffeine consumption averages 210–238 mg, while in Sweden and Finland, it exceeds 400 mg, with coffee contributing 80%–100% of the total. In the UK, caffeine intake is similarly high, but tea accounts for 72% of the total[18]. A study by Barone and Roberts estimates that average caffeine consumption in the U.S. is about 3 mg per kilogram of body weight, with two-thirds of this amount derived from coffee among individuals aged 10 and older. For regular caffeine consumers, intake typically ranges from 2.4 to 4.0 mg per kilogram of body weight, equivalent to 170–300 mg daily for someone weighing 60–70 kg[19]. For children, the primary source of caffeine is soft drinks, contributing 55% of their total intake. Chocolate-based foods and beverages make up 35%–40%, while tea accounts for 6%–10%[20].

**Caffeine's Greater Impact on Older Adults**

Research indicates that older adult's process caffeine at a slower rate compared to younger individuals. A study on the metabolic clearance of various substances, including caffeine, revealed that people aged 65 to 70 metabolize caffeine 33% more slowly than younger adults[41]. For most individuals, consuming 200 to 300 mg of caffeine earlier in the day does not significantly disrupt sleep. According to Michael T. Smith, PhD, caffeine has an average half-life of around six hours[21].

**Epidemiology of Caffeine Consumption**

Among the healthcare professionals (HCPs) surveyed, the majority were female (67.8%), nonsmokers (82.0%), and Saudi nationals (80.5%), with an average age of 35 years. The study found that 94.3% of participants consumed caffeine according to DSM-IV criteria[42]. Caffeine dependence was identified in 47.7% of the group, while 60.9% were classified as caffeine addicts. Coffee and its variations were the most commonly consumed caffeine sources (70%), followed by tea (59%) and chocolate (52%). On average, participants spent approximately 220 Saudi Riyals (SR) per week on caffeine-containing products[22].

**Effects of Caffeine**

The most frequently reported negative effects of caffeine consumption included sleep disturbances, digestive problems, and cardiac symptoms. On the other hand, commonly noted benefits were enhanced energy, alertness, confidence, and mood. These outcomes were notably influenced by factors such as gender, profession, and overall health[23].

**Symptoms of Caffeine Dependence**

Caffeine dependence may present with symptoms such as dizziness, tremors, headaches, increased blood pressure, anxiety, rapid or irregular heartbeat, and sleep disruptions. These effects can negatively impact daily routines and hinder normal functioning[24].

**Diagnosis of Caffeine Addiction**

A licensed healthcare provider diagnoses caffeine addiction through a diagnostic interview based on the DSM-5 criteria for caffeine use disorder.

The criteria include

**Desire to cut back:** A persistent wish to reduce caffeine intake or repeated failed attempts to do so[43].

**Continued use despite problems:** Ongoing caffeine consumption despite awareness of its role in worsening physical or psychological issues.

**Withdrawal symptoms:** Experiencing withdrawal effects when caffeine use is reduced or stopped[44].

**Additional factors:** Consuming larger amounts or using caffeine for longer than intended, spending excessive time obtaining, using, or recovering from caffeine, experiencing cravings, encountering difficulties fulfilling responsibilities at work, school, or home, continued use despite social conflicts, and developing tolerance that necessitates increased consumption to achieve the same effects[25].

**Potential Problems Linked to Caffeine Addiction**

Caffeine addiction can result in various problems, including anxiety, sleep disturbances, digestive issues, heart-related complications, depression, muscle twitches, physical discomfort, social challenges, irritability, and nervousness[26].

**Physiological Effects of Caffeine**

Caffeine affects multiple physiological systems, such as the cardiovascular, respiratory, renal, and nervous systems, through various proposed mechanisms. These include blocking adenosine receptors, inhibiting phosphodiesterase enzymes, releasing calcium from intracellular stores, and obstructing benzodiazepine receptors[27].

**Caffeine and Adenosine Receptors**

The antagonism of adenosine receptors plays a key role in caffeine's effects on behavior and cognitive function. Caffeine and its metabolite, paraxanthine, compete with adenosine for receptor binding, which reduces adenosine's inhibitory effects in the central nervous system (CNS)[45]. This blockade indirectly affects the release of neurotransmitters, including norepinephrine, dopamine, acetylcholine, serotonin, glutamate, gamma-aminobutyric acid (GABA), and potentially neuropeptides. Caffeine affects both A1 and A2 adenosine receptors nonselectively, although it is not a highly potent antagonist. The *in vivo* concentrations of caffeine that correspond to mild CNS stimulation (5–10 μM) and antiasthmatic effects (50 μM) align with the levels required for adenosine receptor blockade[28].

**Caffeine and Phosphodiesterase Inhibition**

Caffeine raises intracellular cyclic adenosine monophosphate (cAMP) levels by inhibiting phosphodiesterase enzymes, particularly in skeletal muscle and adipose tissue. This promotes lipolysis by activating hormone-sensitive lipases, which release free fatty acids and glycerol, helping to preserve muscle glycogen[46]. Increased cAMP levels may also elevate blood catecholamine levels. However, caffeine is a weak phosphodiesterase inhibitor, and the concentrations required to produce behavioral effects are likely too low for significant inhibition. In contrast, caffeine's cardio stimulatory and antiasthma tic effects may be linked to phosphodiesterase inhibition, as these effects are more closely associated with enzyme inhibition than with adenosine receptor binding[29].

**Caffeine and Calcium Mobilization**

Caffeine also affects calcium dynamics in skeletal and cardiac muscle. At high concentrations (1–10 mM), caffeine can interfere with calcium uptake and storage in the sarcoplasmic reticulum, as well as increase calcium movement through the plasma membrane[47]. Additionally, caffeine may enhance myofilament sensitivity to calcium by binding to ryanodine receptors in calcium channels. While caffeine can release calcium from intracellular stores in muscle, the concentration needed for this effect in vitro (250 μM) is much higher than the concentrations required for cardiac stimulation (50 μM) in vivo. As a result, the role of calcium mobilization in caffeine's physiological effects is likely limited[30].

**Treatments for Caffeine Addiction**

There are three primary approaches to treating caffeine addiction: therapy, medication, and lifestyle changes.

**Therapy**

Therapy focuses on identifying and addressing the emotional and psychological factors associated with caffeine use. It provides strategies to manage emotional dependencies and cope with the challenges of addiction. A 2016 study by Evatt *et al*., published in the *Journal of Consulting and Clinical Psychology*, demonstrated that therapy effectively reduced self-reported caffeine consumption[48]. Even a single session of cognitive-behavioral therapy (CBT), followed by a follow-up, was sufficient to help participants lower their caffeine intake. With just one or two sessions, individuals can learn ways to reduce consumption and ease withdrawal symptoms[31].

**Medication**

There are no specific medications designed for treating caffeine addiction, but some drugs can help alleviate withdrawal symptoms like headaches[49]. Over-the-counter pain relievers, such as Tylenol or Aspirin, are commonly used to treat caffeine-induced headaches, providing quick relief. However, it's important to avoid pain medications that contain caffeine, as they can extend withdrawal symptoms. Consulting a pharmacist can help ensure the appropriate medication is chosen[32].

**Lifestyle Changes**

Lifestyle changes focus on adopting healthier habits to improve overall well-being and reduce reliance on caffeine. These may include getting sufficient sleep and gradually cutting back on caffeine consumption[50]. For example, replacing coffee with tea can help individuals continue the routine of drinking a warm beverage while reducing their caffeine intake. Among the various treatment methods, lifestyle changes—especially those that involve completely eliminating caffeine—are considered the most effective way to overcome caffeine addiction[33].

## CONCLUSION

Caffeine, a widely consumed stimulant, has notable effects on the body, primarily by blocking adenosine receptors, inhibiting phosphodiesterase enzymes, and influencing calcium dynamics. While moderate caffeine intake can improve alertness, focus, and mood, excessive consumption carries risks such as dependency, tolerance, withdrawal symptoms, and health issues like elevated blood pressure, sleep disturbances, and anxiety. Caffeine addiction is a prevalent concern, often resulting from its widespread availability and stimulant effects. Vulnerable groups, including older adults, individuals with hypertension, and pregnant women, are particularly susceptible to its adverse effects. Effective management of caffeine addiction involves strategies like cognitive-behavioral therapy, medications to alleviate withdrawal symptoms, and lifestyle changes. Gradual reduction and healthier routines, such as substituting coffee with lower-caffeine beverages, are especially beneficial for overcoming dependency and minimizing associated risks.

## DISCUSSION

Caffeine is one of the most frequently consumed psychoactive substances globally, found in beverages such as coffee, tea, energy drinks, and soft drinks. While many individuals rely on it for increased alertness and reduced fatigue, there is ongoing debate about whether caffeine dependence is a biological necessity or simply a habitual behavior.

**Physiological Factors in Caffeine Dependence**

Caffeine primarily affects the brain by blocking adenosine receptors, which helps maintain wakefulness and counteract tiredness. Regular consumption can lead to neurological adaptations, resulting in tolerance and withdrawal symptoms when intake is reduced. Common withdrawal effects, including headaches, fatigue, irritability, and difficulty concentrating, suggest that caffeine dependence has a physiological component. Additionally, research indicates that caffeine stimulates dopamine release in the brain's reward system, similar to other addictive substances, though to a lesser degree. Many habitual caffeine consumers report cravings and withdrawal symptoms, both of which are characteristic of physiological dependence.

**Behavioral Perspective on Caffeine Use**

Some experts argue that caffeine dependence is largely a learned behavior rather than a true addiction. Many people consume caffeine in routine ways, such as starting their morning with coffee or using caffeine to enhance focus at work or during study sessions. These repetitive behaviors can create a psychological reliance, making it seem like an addiction, even though caffeine's physiological effects are relatively mild compared to substances like nicotine or opioids. Moreover, caffeine withdrawal symptoms are generally short-lived and far less severe than those caused by more potent addictive substances. This supports the argument that caffeine dependence is more of a conditioned habit rather than a biological compulsion. The widespread cultural acceptance of caffeine consumption further reinforces the idea that its habitual use plays a significant role in continued consumption.

**Controversy Over Clinical Recognition**

The DSM-5 acknowledges caffeine withdrawal as a medical condition but does not classify caffeine use disorder as a recognized addiction. However, some researchers advocate for its inclusion, citing evidence of tolerance, withdrawal symptoms, and continued use despite negative consequences

## ACKNOWLEDGMENT

This summary is based on an extensive review of research studies and global consumption data, providing insights into caffeine's physiological effects and its implications for public health. The findings highlight the importance of balancing caffeine's benefits with its potential risks and underscore the value of continued research and public education on its safe use. Special thanks are extended to the researchers and healthcare professionals whose work has deepened our understanding of caffeine's role in human health and behavior.

## ABSTRACT

The Indo-Aryan branch of languages that includes Hindi, Bengali, Marathi, Gujarati, Punjabi, Odia, etc, is an enormous world linguistic population. Nevertheless, due to their large numbers, many Indo-Aryan languages remain under-resourced in natural language processing which is a key factor that hampers the performing of such tasks as text classification. To this end, this research is directed towards establishing a well-detailed, deep learning-based multi-class text classification framework that is easily adaptable to a wide range of Indo-Aryan languages depending on the availability of data. The different neural architectures include CNN, Bidirectional Long Short-Term Memory, and transformer-based models which are comprised of mBERT, XLM-RoBERTa, and IndicBERT. In a thorough experiment, curated datasets containing Hindi, Bengali, and Marathi news articles were utilized. The results show that IndicBERT surpasses the others with the best average 92.4% accuracy across all datasets. The current research supports the claim that multilingual pretrained transformer models are capable of handling the low-resource challenges in Indo-Aryan NLP and that it leads to the possibility of large-scale applications in the multilingual digital ecosystem.

**Keywords:** Text Classification, Indo-Aryan languages, Deep Learning, Transformers, Multilingual NLP, IndicBERT, BERT, Low-resource Languages.

# INTRODUCTION

**Background and Context**

The Indo-Aryan language family includes one of the greatest language groups in the world and it is therefore a part of the Indo-European language family. The majority of the Indo-Aryan languages—like Hindi, Bengali, Marathi, Gujarati, Punjabi, Odia, Sindhi, and Konkani—are used by one billion people at least, with India, Bangladesh, Nepal, Pakistan, and other regions where these people have moved being their main habitats. In addition to the common history and grammar, these languages have completely different and very innovative phonology. This includes the creation of their own separate and distinctive scripts, morpheme-building systems, and lexicons. With the rapid rise of digital communication in South Asia, text data in these languages sees a dramatic increase and thus a corresponding demand for automated systems that are capable of analyzing, classifying, and understanding multilingual content. One of the most basic and widely used operations in the field of NLP is text classification, which refers to the process of assigning predefined categories to text data. The applications of text classification include: automatic news grouping and distribution, product and service recommendations, sentiment and opinion analysis and extraction, content moderation and toxicity detection, legal and government document organization, multilingual chatbot and digital assistant development, social media analytics for policy and public health decisions. On the other hand, while text classification systems for English and other high-resource languages continue to develop significantly, the situation for Indo-Aryan languages is still quite far from this.

**Challenges in Indo-Aryan Language Processing**

The computation challenges of Indo-Aryan languages are so distinctive that they practically make it impossible for NLP systems to be robust and generalized

**Low-Resource: Data Availability**

Most of the Indo-Aryan languages still are not available in the form of enormous and well-annotated corpora that are the prerequisite for training highly-effective deep-learning models and thus lead to very little data availability for low-resource languages. Even for the widely spoken languages like Marathi and Odia, the situation is quite similar; they still have much smaller labeled datasets when compared to the English dataset.

**Complex Grammar**

The languages of the Indo-Aryan group perform compound formation on a large scale, use inflectional morphology, and agglutination. A single word may express various grammatical features, like tense, number, gender, and case, thus greatly complicating the processes of tokenization and feature extraction.

**Different Scripts and Orthographic Changes**

For example, Hindi uses Devanagari, while Bengali employs Bangla, and Punjabi is written in Gurmukhi. This disparity in scripts acts as a barrier to the direct transfer of data or models without first exposing them to multilingual pretraining.

**Code-Mixing and Informal Usage**

Digital communication platforms are usually the places where the mixing of languages (for instance Hinglish, Banglish) occurs and where non-standard spellings, emoji, and loanwords are used. All these factors make it hard to preprocess and train the model.

**Name Entity Confusion**

Locations, people, and other named entities are often confused because they differ mainly by position, which results in identification errors in the case of poorly model-generalized domains.

**Non-existence of Standard Benchmarks and Evaluation**

Just like that, think of the East Indian languages as the very opposite of the whole scenario wherein the literature on English NLP still has its script being paved with the benchmark data.

**Rise of Deep Learning and Transformer Models**

Traditional machine learning models—SVM, Naïve Bayes, and Logistic Regression—were initially applied to Indian languages and had moderate success only. Such methods rely on feature engineering techniques (n-grams, TF-IDF) that do not go beyond the surface of understanding and therefore not semantic relationships. Deep learning models such as CNNs and LSTMs have greatly advanced the situation since they made automatic feature extraction from the raw text possible. Still, they do not handle long-range dependencies really well, and their performance is largely tied to word embeddings that are not yet available for many Indian languages. The time of transformers has come, and BERT and its multilingual variants in specific have turned the world of NLP upside down by doing the following: Employing self-attention that allows the model to understand the whole text, Allowing multilingual pre-training over huge datasets, Making it the case that each word can have different representations depending on the context in which it occurs, Delivering strong results even when the fine-tuning data are tiny. mBERT, XLM-RoBERTa, IndicBERT and MuRIL are some of the models that have been very successful in areas like named entity recognition, POS tagging and sentiment analysis for Indian languages. On the other hand, systematic studies that compare the performance of these models on multi-class text classification over various Indo-Aryan languages are not that common.

## RELATED WORK

Over the last decade, the field of text classification in Indo-Aryan languages has made big strides, with a lot of help from the usage of machine learning, multilingual corpora along with the development of transformer-based language models. In a nutshell, this section outlines the literature through three main phases such as traditional machine learning approaches, neural embedding-based approaches, and transformer-based approaches, mainly focusing on Indo-Aryan and Indian languages.

**Traditional Machine Learning Approaches**

The early studies conducted in the field of Indian languages heavily banked on the use of statistical classifiers like Support Vector Machines (SVM), Naïve Bayes (NB), Decision Trees, and K-Nearest Neighbors (KNN). The application of these models usually included the use of the Bag-of-Words (BoW), TF-IDF vectors, and character n-grams as features that were created by hand. Pal *et al*. [1] examined the classification of Bengali documents with the help of TF-IDF along with SVM and NB and proved that lexical features work well for medium-sized corpora. In the same way, S. K. Saha *et al*. [2] created a news classification system for Hindi by making use of a combination of TF-IDF and linear SVM, thus attaining competitive results for genre classification. A similar pattern of research has been observed for Marathi and Gujarati where handcrafted features were used for sentiment classification and topic detection [3]. Nevertheless, these models are inadequate when it comes to dealing with the complications presented by rich morphology, long-distance dependencies, and semantic contextualization that are intrinsic to Indo-Aryan languages. Moreover, the necessity for extensive manual feature engineering severely hinders scalability.

**Word Embedding and Neural Network Approaches**

The usage of word embeddings like Word2Vec (Mikolov *et al*. [4]) and GloVe (Pennington *et al*. [5]) paved the way for the prevalence of neural architectures like CNNs and LSTMs in Indian language processing. Sharma *et al*. [6] combined LSTM networks with Word2Vec-based embeddings for the purpose of Hindi sentiment analysis and showed better results compared to traditional machine learning techniques. Das and Chakrabarti [7] employed CNNs with embedding layers for the classification of Bengali news which resulted in realizing the advantages of automatic hierarchical feature extraction. FastText embeddings trained on Indian languages (Bojanowski *et al*. [8]) have been extensively used for languages like Marathi, especially in the area of low-resource text categorization.

However, the achievement of these works relies heavily on the embedding corpus's quality and size. The datasets for Indo-Aryan languages are often large, diverse, but not well-balanced, and this condition of the datasets limits performance. Recurrent models such as BiLSTM in addition to large datasets struggle with being inefficient computationally when it comes to long documents typical in the case of news articles being scaled.

**Transformer-Based Approaches**

The use of transformer architectures marked a turning point in the NLP landscape when it came to the development of languages with lesser resources, Indo-Aryans being one of them. BERT (Devlin *et al*. [9]) made a tremendous progress with the introduction of the bidirectional self-attention machinery and consequently, a new and higher performance was established for the classification tasks. This is how the language representation mBERT was created, which was trained in over 104 languages and among the equipped languages, Hindi, Bengali, and Marathi were included in the list. XLM-RoBERTa (Conneau *et al*. [10]) was able to attain its goals due to the multilingual benchmarks that were in a large scale and where English and other dominant languages were extremely well represented. The study by Kumar *et al*. [11] proved the extent of mBERT and XLM-RoBERTa's superiority over other modern and classical networks in Hindi and Bengali sentiment analysis. For Indian languages, IndicBERT (Kakwani *et al*. [12])—a small-size transformer model trained on IndicCorp, the most extensive dataset of 12 Indian languages—was the most significant one. It not only provided a lightweight but also a highly efficient model that was specifically designed according to the characteristics of Indo-Aryan and Dravidian languages. The model's performance was outstanding on such tasks as text classification, POS tagging, and NER. MuRIL (Khanuja *et al*. [13]), whose inception was through Google Research, came up with better Indian scripts, and handling of transliterations and code-mixed text. It showed the performance of the best in class in sentiment and classification tasks of the Indian languages. Recent explorations in code-mixed datasets were till last studies; for instance, Joshi *et al*. [14] dealt with the Hinglish text classification applying transformer-based fine-tuning. The research has consistently shown that the transfer-based models are superior to those based on classical and LSTM architectures, particularly in the case of low-resource scenarios.

## METHODOLOGY

This segment elaborates the complete process that took place in creating a text classification system for Indo-Aryan languages based on deep learning and capable of handling multiple classes. The system was planned to deal with the linguistic diversity, script complexity, and scarcity of annotated resources that usually come with the Hindi, Bengali, and Marathi datasets. The method is divided into four principal phases: (1) text cleaning and standardization, (2) extraction of features, (3) creating the model, and (4) model training and performance testing.

**Preprocessing and Text Normalization**

The necessity of preprocessing derives from the fact that the languages belonging to the Indo-Aryan family have serious problems like irregular spacing, compound formations, and variations even at the script level, and informality or bilingual practices being the predominant way of writing. A solid normalization mechanism was built to make sure that Hindi (Devanagari script), Bengali (Bangla script), and Marathi (Devanagari script) are all compatible with each other. The preprocessing actions taken were, to name a few, the following: 1) Text Normalization All the files are transformed into a single Unicode format so that inconsistencies that come from the use of different keyboard layouts or encoding styles are eliminated. Special characters, emojis, extra spaces, and website artifacts are among the things that are removed. 2) Tokenization Language-based tokenization is carried out on Indian linguistic structures by making use of the Indic NLP Library, which is specially designed for this purpose. This tool, in contrast to simple whitespace-based tokenizers, is able to tackle complex words, ligatures, and attributes affected by script. 3) Stopword Removal Lists of stopwords are based on IndoWordNet and are supplemented by manually adding the most frequent non-informative words. Consequently, the noise is minimal, and the classifier pays attention to semantically significant terms only. 4) Lemmatization and Normalization of Variants Morphological normalization tools are utilized, when available, to suppress inflections and surface-level variations. The importance

of this is huge in case of languages with a lot of grammatical inflection like Marathi and Hindi. 5) Sequence Standardization In the case of deep learning models, all the sentences are made the same in terms of the maximum length through either padding or truncation. This is a way to ensure that there are constant batch sizes and memory footprints during training.

**Feature Representation**

The feature representation strategies were varied according to the model architecture.

1. Static Word Embeddings for CNN and BiLSTM The static embeddings, for instance, fastText are employed since they are subword-level that take in the Indo-Aryan languages, which have a lot of compound words and morphological variations, which is a good thing. The fastText embeddings are also better than the conventional word embeddings in terms of dealing with inaccuracies and rare words.
2. Contextualized Transformer Embeddings Transformers like mBERT, XLM-RoBERTa, and IndicBERT that rely on context create the embeddings each time. The embeddings created this way, help in distinguishing the words meaning grasp them even better, thus, drawing more precision in the representation of the sentences, idioms, and syntactic structures.
3. Sentence-Level Representations In the case of transformer-based models, the special classification token ([CLS]) takes the role of representing the whole document. This embedding does an excellent job of effectively summarizing the semantic content and is then forwarded to the classifier for the final prediction.

**Deep Learning Architectures**

Under the same experimental conditions, three main deep learning architectures were adopted, and their performance was compared.

1. CNN The CNN model emphasizes the detection of limited text patterns such as n-grams, and sentence fragments, and the use of recurring contextual clues. To this end, it uses multiple convolutional filters of different window sizes to spot the short, as well as the medium-range, linguistic patterns that news texts typically have. The max-pooling layers will select the most informative feature from each filter, tell the robustness across languages.
2. Bidirectional LSTM (BiLSTM) The BiLSTM model lets the text flow in both directions and hence processes the text forwards and backwards at the same time. This is a great advantage for the model because it can grasp and order the words' meanings. This is particularly the case for the Indo-Aryan texts that often resort to flexible word orders. The hidden states of both directions are concatenated and subsequently sent to the dense layer for classification.
3. Transform-Based Models (mBERT, XLM-RoBERTa, IndicBERT) Due to the long-range dependency modeling and global context capabilities, transformer models were the primary focus of this study. mBERT enables more than 100 languages to have multilingual generalization. XLM-RoBERTa, through its large-scale pretraining dataset, gives better cross-lingual consistency. IndicBERT, which is trained in 12 of the main Indian languages, is more effective in dealing with regional aspects such as morphology, vocabulary, and syntax, thus being especially suitable for the Indo-Aryan classification task. The [CLS] token's final hidden representation is fed through a classification layer to determine the predicted category.

**Training and Optimization Strategy**

The comparison is made in a very fair manner since all the models were trained under the same experimental conditions.

1. **Training Hyperparameters are Batch size:** 16, Epochs: 4, Maximum sequence length: 256, Learning rate: 2e-5 (for transformers), Optimizer: AdamW, Early stopping based on validation loss.
2. Regularization Dropout is applied in CNN and BiLSTM to fight overfitting. In the case of transformer models, weight decay and learning rate warm-up are incorporated for stable training.
3. Model Validation A stratified 80, 10, 10 train validation test split guarantees that class distribution is representative. Performance is measured by accuracy, precision, recall, and macro-averaged F1-score. E. Assessment Metrics The following metrics are used to evaluate the overall model quality: parameters are Accuracy: Measures the correctness of the entire classification, Precision: Tells how reliable the predicted labels

are, Recall: Measures the extent to which the model is able to spot the pertinent classes. F1-score (Macro): Considers all classes equally which is preferable for the case of imbalanced data, a situation that often arises in the regional news datasets. The importance of Macro-F1 score is due to the fact that uneven category distributions are a common phenomenon in Indo-Aryan datasets.

## METHODOLOGY FLOWCHART

Methodology Workflow for Indo-Aryan Text Classification (Figure 1).

## RESULTS AND DISCUSSION

The proposed deep learning models' performance on Indo-Aryan multi-class text classification will be evaluated and discussed in this section. The evaluation was conducted on datasets of Hindi, Bengali, and Marathi, each having different news categories, thus increasing the variety of the test. The three architectures, CNN, BiLSTM, and transformer-based models (mBERT, XLM-R, IndicBERT) were compared maintaining the same environment and ensuring valid comparisons. Accuracy, Precision, Recall, and Macro F1-score were the evaluation criteria, and their results are shown in Table 1. Transformer-based models, as shown in Table 1, are evidently superior to CNN and BiLSTM throughout all the metrics. indicBERT is the top performer, thanks to its pretrained on Indian language corpora, which allows it to cope with morphological richness, compound words and script-level alterations better. The performance of all models regarding the Macro F1-score is depicted in Figure 2. The graph unequivocally points out the gradual improvement of transformer-based models over classical architectures. The disparity in performance among different languages reveals that the Hindi datasets yield the highest classification accuracy, and then comes the turn of Bengali and Marathi. Factors like the size of the dataset, the richness of the vocabulary and the quality of annotation make up the differences. CNN models are usually good with short and simple texts, but they find longer and grammatically complex ones difficult. BiLSTM, though it captures the sequential dependencies better, still has the limitation of not being able to capture the global context, especially in cases of compound or nested sentences. The opposite is true for transformer models - they are able to handle long-range dependencies well and also resistant to issues caused by code-mixing and rare word forms. Examining misclassified samples shows that the main error sources are words that are common between categories (like political and economic news), complex compound sentences, and the use of transliterated or mixed-language text.

Nevertheless, transformer models still have the edge over their challengers, indicating that they have the capacity to learn from and adapt to different linguistic phenomena. As seen in Table 2, IndicBERT is a language model that performs exceptionally well regardless of the three languages considered, with the highest score for Hindi because of the larger and more evenly distributed datasets. Marathi, which has the smallest dataset and more dialectal variations, is slightly lower in performance. The performance of IndicBERT for each language across Hindi, Bengali, and Marathi is depicted in Figure 3. It can be seen that the highest Macro F1-score of Hindi (93.3%) is given to IndicBERT, followed by Bengali (91.7%) and Marathi (89.3%), which are differences in dataset size, morphological complexity, and dialectal variations. To sum up, the findings put forward the following points: Transformer-based models are at least one step ahead, in terms of performance, when compared to the classical deep learning counterparts. IndicBERT is the one that performs best among all the Indo-Aryan languages and this is attributed to its domain-specific pretraining. CNN models are suitable for short and easy texts, but they are not good for longer or more complex sentences. BiLSTM is helpful in understanding the sequence better, but it cannot compete with transformers in terms of global contextual awareness. The size of the dataset, the quality of the annotation, and the morphological complexity are some of the factors that have a significant impact on the classification accuracy. The tables and figures that have been presented not only emphasize the robustness but also the superiority of transformer-based architectures, thus setting a strong argument in favor of their usage in Indo-Aryan language processing.

## CONCLUSION

The paper turned its spotlight on multi-class text classification of Indo-Aryan languages with application of CNN, BiLSTM, and various transform based models (mBERT, XLM-R, and IndicBERT) on Hindi, Bengali, and Marathi corpora. Based on the findings, it can be concluded that transformer models, especially IndicBERT, are the best alternatives when it comes to classical architectures by a clear margin in relations of Accuracy, Precision, Recall, and Macro F1-score. IndicBERT's intensive training on Indian languages has helped it to be very good at the understanding of their different cultural meanings, the use of language in various situations, and the knowing of particular areas of talk. The article points out that the dataset's quality, preprocessing, and class balancing are vital for obtaining high performance. The CNN and BiLSTM models are somewhat effective in handling short or sequential texts but they miss the global semantic context, while the transformers have the long-range dependence and handling of code-mixed texts as their strong points. The results are certainly very good, but there are still problems to be solved for the low-source languages like Marathi because of the small dataset and the variations among the dialects. The future prospects regarding research may be focused on constructing larger corpora, making use of data augmentation methods, and experimenting with hybrid architectures to increase the performance further. In short, the use of transformer-based models, especially IndicBERT, has made the text classification of Indo-Aryan languages a strong case, thus laying the groundwork for more precise and context-sensitive NLP systems in Indian languages.

## ABSTRACT

In hormone replacement treatment (HRT), estrogen and dydrogesterone hemihydrate are frequently used to treat menopausal symptoms, maintain bone mineral density, and lower cardiovascular risk in postmenopausal women. Falling estrogen levels are compensated by Estradiol, while endometrial protection is provided by Dydrogesterone without triggering androgenic or estrogenic effects. This review comprehensively evaluates the pharmacological profiles of both compounds and collates current analytical methodologies developed for their qualitative and quantitative determination. Apart from the official protocols outlined in the United States, British, and Indian Pharmacopoeias, the focus is on methods such as gas chromatography (GC), liquid chromatography–mass spectrometry (LC-MS/MS), and high-performance liquid chromatography (HPLC), and Thin Layer Chromatography (TLC). Recent developments in sensitivity, specificity, and validation of analytical methods are also covered. This review serves as a valuable resource for researchers and analysts involved in pharmaceutical formulation, quality control, and regulatory compliance for hormone-based therapies.

**Keywords:** Dydrogesterone, Estradiol Hemihydrate, HRT, Pharmacopoeia, Analytical Method Development, HPLC, LC-MS/MS, Pharmacological Profile.

# INTRODUCTION

Menopause, defined as the permanent cessation of menstrual cycles, occurring in women at a median age of about 50[1]. Preserving health and enhancing the quality of life after menopause has become increasingly important, especially since women now typically spend over one-third of their lifespan in the postmenopausal phase. Symptoms of menopause continue for 2 to 5 years on average and are serious enough for females to pursue healthcare assistance in around instances [1.2]. For some women, symptoms can persist for a lifetime [3]. Following menopause, declining estrogen levels can potentially lead to other issues like cardiovascular disease and osteoporosis. Generally speaking, less than one-third of women are currently willing to undergo long-term hormone replacement therapy (HRT), despite the potential advantages of this treatment for menopause-related issues [4]. Estradiol produced by the ovaries is the primary source of estrogen in women who have not yet reached menopause [5, 6]. In the postmenopausal, when women intake oral estradiol every single day, their plasma/serum levels of the hormone rise to levels typical of the early to mid-follicular phase, while their levels of luteinizing hormone and follicle-stimulating hormone decrease [7]. When dydrogesterone and estradiol are administered together, similar results are shown. It does not have any significant estrogenic, androgenic or anti-androgenic action, but is does have strong progestogenic and anti-estrogenic effects. When Estradiol hemihydrate diffuses into target cells, it attaches itself to nuclear estrogen receptors in the brain, pituitary, liver, bone, breast, and reproductive organs. After entering the nucleus, this hormone-receptor complex binds to DNA's estrogen response regions and initiates gene transcription. The resultant mRNA controls the production of proteins, which mediates the physiological effects of Estradiol on reproductive processes and secondary sex traits [8, 9]. Compared to the United States Pharmacopoeia (USP) LC method, which is slower but adheres to various chromatographic parameters and is favoured for regulatory compliance, the Indian Pharmacopoeia (IP) method employing LC is quick and ideal for regular analysis because of its shorter run time. In contrast, the British Pharmacopoeia (BP) uses GC, which is better at detecting volatile contaminants. SPE-TLC is somewhat easier to use and more appropriate for regular qualitative testing, but RP-HPLC provides validated results with good sensitivity for dosage form analysis. While LC-MS successfully combines identification and quantification, Tandem Mass Spectrometry outperforms in sensitivity, finding Dydrogesterone at extremely low quantities. UPLC is the fastest, most sensitive, and most economical technology available, making it ideal for today's analytical requirements. The sensitivity and complexity of the estimated techniques for Estradiol varies. The method of Indian Pharmacopoeia (LC) is easy to use, quick, and repeatable. The British Pharmacopoeia (TLC) techniques are affordable, appropriate for rapid identification, and provide reliable and precise quantification. RP-HPLC has the highest sensitivity and resolution of any known technology, which makes it perfect for tablet and bulk analysis. For trace detection, a different HPLC technique provides low LOD/LOQ. The sensitivity of reported TLC techniques varies from moderate to high, with sophisticated procedures employing numerous solvent systems for in-depth qualitative examination.

**Drugs Profile**

Drug Profile of Dydrogesterone (Table 1).

**Estradiol Hemihydrate[15-18]**

Drug Profile of Estradiol hemihydrate (Table 2).

**Pharmacological rational for the combination of dydrogesterone and estradiol hemihydrate**

In hormone replacement treatment (HRT) for postmenopausal women, Estradiol, a natural estrogen, and dydrogesterone, a synthetic progestogen, are frequently combined. Since each medication addresses distinct physiological requirements and hazards related to estrogen shortage and therapy, this combination is supported by complementary pharmacological reasoning. The combination of Estradiol and dydrogesterone offers a safe and effective option for hormone replacement therapy (HRT) in women with an intact uterus. Estradiol alleviates menopausal symptoms and supports bone and cardiovascular health, while dydrogesterone provides endometrial

protection by preventing unopposed estrogen-induced hyperplasia and cancer risk. With high selectivity for progesterone receptors and minimal androgenic or glucocorticoid activity, dydrogesterone ensures better tolerability and fewer side effects than other progestin's. Additionally, the combination supports flexible cyclic or continuous regimens for improved compliance, and both drugs exhibit favourable pharmacokinetic profiles for oral administration, making fixed-dose combinations feasible and effective. Estradiol and dydrogesterone together offer a well-rounded and efficient hormone replacement treatment. While dydrogesterone guarantees endometrial safety without causing additional hormonal side effects, Estradiol treats the symptoms of estrogen insufficiency and long-term hazards. A clinically logical strategy for treating menopause in women with uteruses is this synergistic.

## CONCLUSION

The pharmacological characteristics and analytical techniques of dydrogesterone and Estradiol hemihydrate, which are commonly used in hormone replacement therapy (HRT), are compiled in this paper. Estradiol addresses estrogen deficiency in postmenopausal women, while dydrogesterone provides endometrial protection without androgenic or estrogenic activity. Together, they lessen menopausal symptoms and long-term dangers like cardiovascular disease and osteoporosis. Together, they lessen menopausal symptoms and long-term dangers like cardiovascular disease and osteoporosis. In summary, the estimation techniques for Estradiol and dydrogesterone differ in terms of sensitivity, speed, and applicability for various analytical requirements. The United States and British Pharmacopoeia procedures offer superior regulatory compliance and impurity profiling, while the Indian Pharmacopoeia methods are straightforward and effective for regular analysis. High quality sensitivity and accuracy are provided by sophisticated techniques such as LC-MS, Tandem MS, and UPLC among those that have been described. For regular testing, regulatory submission, or in-depth qualitative and quantitative analysis, the method selection ultimately depends on the particular application.

**Table 1: Drug Profile of Dydrogesterone**

| | |
|---|---|
| **Structure** |  |
| **IUPAC Name** | (8*S*,9*R*,10*S*,13*S*,14*S*,17*S*)-17-acetyl-10,13-dimethyl-1,2,8,9,11,12,14,15,16,17-decahydrocyclopenta[a]phenanthren-3-one |
| **Category** | Progestogen |
| **Molecular Formula** | $C_{21}H_{28}O_2$ |
| **Molecular Weight** | 312.5 g/mol |
| **Melting Point** | 167°C-171°C |
| **Log P** | 3.8 |
| **Solubility** | Soluble in Methanol, Acetone, Chloroform, Acetonitrile |
| **Pharmacological Action** | Progesterone receptor selective agonist with negligible estrogenic, glucocorticoid, mineralocorticoid, or androgenic effects |
| **Mechanism of Action** | Binds selectively to intracellular progesterone receptors, causing the endometrium to undergo secretory transition and reversing the hyperplasia brought on by estrogen |
| **Bioavailability** | Approximately 28% (higher than micronized progesterone) |
| **Metabolism** | Hepatic metabolism to active metabolite 20$\alpha$-dihydrodydrogesterone (DHD) |
| **Half-life** | Dydrogesterone:- 5-7 hours; DHD (active metabolite):- 14-17 hours |
| **Therapeutic Uses** | Hormone Replacement Therapy (HRT), luteal phase support in Assisted Reproductive Technology (ART), secondary amenorrhea, irregular menstruation, and dysmenorrhea |
| **Adverse Effects** | Breast tenderness, headache, nausea, abdominal pain, breakthrough bleeding, mood changes |

**Table 2: Drug Profile of Estradiol hemihydrate**

| | |
|---|---|
| **Structure** |  |
| **IUPAC Name** | (8*R*,9*S*,13*S*,14*S*,17*S*)-13-methyl-6,7,8,9,11,12,14,15,16,17-decahydrocyclopenta[a]phenanthrene-3,17-diol;hydrate |
| **Category** | Estrogen |
| **Molecular Formula** | $C_{18}H_{24}O_2,0.5H_2O$ |
| **Molecular Weight** | 281.4 g/mol |
| **Melting Point** | 175°C-180°C |
| **Log P** | 3.3 |
| **Solubility** | Soluble in Acetone, Methanol, Acetonitrile |
| **Pharmacological Action** | Modulates gene expression by binding to estrogen receptors (ERα and ERβ) in a variety of tissues, including the brain, heart, bones, and reproductive organs |
| **Mechanism of Action** | Diffusing into target cells, Estradiol attaches itself to nuclear estrogen receptors to form a hormone-receptor complex that controls the transcription of genes that respond to estrogen |
| **Bioavailability (Oral)** | Micronized oral forms enhance bioavailability, however they are still subject to significant first-pass metabolism. Higher systemic availability is provided via parenteral and transdermal methods |
| **Metabolism** | Primarily hepatic metabolism to estrone and estriol viaHydroxylation and conjugation. Undergoes enterohepaticcirculation |
| **Half-life** | Oral:- 13-20 hours (depending on formulation); Transdermal:- 36-48 hours |
| **Therapeutic Uses** | Hormone Replacement Therapy (HRT), treatment of menopausal symptoms, osteoporosis prevention, hypogonadism, and hormonetherapy in transgender women |
| **Adverse Effects** | Nausea, breast tenderness, headache, edema, endometrialhyperplasia, increased risk of thromboembolism and breast cancer(with prolonged use) |

## ABSTRACT

The length of the muscle tissue is thought to play an vital role in the effectiveness and efficacy of human movement. Calf is one of the commonest muscle prone to tightness. The gastrocnemius and the soleus are the parts of calf muscle. Tightness of these muscle leads to formation of trigger points within the muscles. Instrument-assisted soft tissue mobilization (IASTM) is an approach to soft tissue manipulation that uses concave and convex stainless steel instruments to release scar tissue, break soft tissue adhesions, and remove fascial restrictions. Positional Release Therapy (PRT) enhances the flexibility of muscle by maintaining the muscle in shortened position for a period of 90 seconds while keeping a sustained manual pressure. The purpose of the study was to evaluate the effectiveness of IASTM and PRT for calf flexibility to improve DF ROM and pain in young physiotherapist. To compare and find the effect of IASTM and PRT on calf, uscle pain and Ankle dorsiflexion range in young Physiotherapist. 30 Young Physiotherapist aged between 20 to 30 years with complain of calf pain were taken in this study. NPRS and ankle ROM was assessed as pre data for pain and range of motion. Group A was given instrument assisted soft tissue mobilization and Group B was given PRT followed by conservative protocol for 1 session for both the groups and post data was taken. Normality was assessed using Shapiro Wilkinson test .The mean standard for age is 24± 2.56 and P value for gender is 0.99 and in comparison for ROM and NPRS the result is highly significant where P for ROM is 0.03 and NPRS is P = 0.02 , ($p < 0.05$) which

means IASTM has reported to have a better outcome than PRT. This study conclude that among young physiotherapist IASTM is more effective than PRT for calf pain and Dorsiflexion ROM.

**Keywords:** DF, IASTM, PRT, NPRS, ROM, Calf Muscle

## INTRODUCTION

Long periods of standing at work have been linked to several potentially dangerous health consequences, including cardiovascular issues, lower back and leg pain, exhaustion, discomfort, and pregnancy-related health issues. Store clerks, physiotherapists, and direct care nurses are unable to sit down for a significant portion of their workdays. Long periods of standing effectively cut off the blood flow to the muscles, which speeds up the onset of exhaustion and results in discomfort in the neck, back, and leg muscles, according to the CCOHS report[1]. Furthermore, standing for extended periods of time can cause musculoskeletal problems, such as pain, increased exhaustion, and stiffness in the working muscles. The first and most typical signs of extended standing are weariness and pain in the thighs, knees, and calves. It has been clearly demonstrated that the static contraction in the back and leg components as a result of extended standing activity significantly reduces and limits the function of the calf muscle[2]. The myofascial system is a complex network of muscles and associated fascia that facilitates fibroblastic activity, proprioception, nociception, muscle force transmission, and the sliding of fascial layers to reduce compartmental friction during movement. Injuries, bad posture, or limited ROM can all cause myofascial system restriction[3]. The calf musculature, which includes the gastrocnemius and soleus muscles attached to the strong calcaneal tendon, is essential for gait dynamics and postural stability[4] These muscles become tense, which causes trigger points to develop inside the muscles. A nodule in a palpably taut stretch of muscle that exhibits extreme tenderness is a trigger point. Referred pain might be produced by them on their own or in response to digital compression. Reduced ROM in the joints is another problem[5]. Myofascial trigger points (TPs) are often located along the medial or lateral border of the superficial two-joint gastrocnemius muscle. The instep of the foot and soreness across the calf are frequently referred to by these TPs. Active: Trigger points that are potentially to blame for the presenting pain complaint are known as active trigger points.

Latent: Only when external pressure is applied does pain arise from latent trigger points, which are present with muscle shortening. These trigger points can be triggered by a number of things, such as bad posture, excessive use, or imbalanced muscles[3]. A common treatment for myofascial limitation is IASTM, which was developed on the basis of James Cyriax's theory. IASTM is administered with specifically made tools to mobilize soft tissue (such as scar tissue and myofascial adhesion) in order to reduce pain and enhance ROM and function, in contrast to the Cyriax technique, which uses digital cross friction[6]. Instruments have a mechanical advantage over a therapist's hands, allowing for deeper penetration and possibly improving treatment application precision[7]. The PRT, or positive release technique The traditional explanation of this method was provided by Jones in 1981, who suggested that defective tissue with painful spots be placed in a comfortable position[8]. Positional release therapy, or PRT, is a passive, indirect treatment that involves positioning the affected tissues in a comfortable position[9]. Dardzinski *et al*. (2006) discovered that individuals with localized myofascial pain syndrome could effectively reduce pain and improve function by using the PRT, commonly referred to as the strain counterstrain technique[8]. The purpose of positional release technique (PRT) is to increase muscle flexibility by maintaining the muscle in a shorter position to encourage relaxation rather than putting it in a stretched or extended state[10]. In order to determine whether instrument IASTM and positional release technique is helpful in decreasing pain and improving ROM in patient with calf pain due to trigger points and restricted DFROM, the goal of the study is to compare IASTM Vs PRT for evaluating their effect on calf pain in long standing profession that is Physiotherapist. Therefore, it will be crucial for physiotherapist to established plans and provide themselves and patient the right protocol, if we discover effect of this techniques it will helpful in future.

## MATERIALS AND METHODS

This is a comparative study conducted on physiotherapist from Ahmedabad physiotherapy college, Parul university in Ahmedabad. An informed consent form authorized by University Ethics Committee was signed by the participants. To collect demographic data, each participant was requested to fill out an information questionnaire. The nature of research, the methodology of the study were all explained to the subjects. Pre assessment was evaluate by NPRS and DFROM. Subjected were divided into 2 groups, Group A (N=15) received IASTM technique and group B (N=15) received PRT technique, followed by conventional treatment for both the groups. 30 young Physiotherapist aged between 20 to 30 years having atleast one trigger point in calf, dorsiflexion ROM less than 20 degrees and pain intensity of more than 4 on NPRS were included[5]. Individuals with Fibromyalgia syndrome, congenital deformity of the foot and ankle, Tumours, Lower limb fractures, Diabetic neuropathy, Peripheral vascular disease, recent injuries to the foot or ankle were excluded[5]. NPRS and DFROM test were performed immediately after the treatment to evaluate pain and ROM respectively.

## PROCEDURE

**Group A –** Instrument assisted soft tissue mobilization
Before commencing the IASTM intervention, a thorough assessment of the patient's calf region was conducted[4]. The patient's calf was exposed while they were in a prone position. Applying a tiny bit of lubricant or emollient cream to the calf area helped to lessen skin-to-IASTM device friction. The IASTM instrument was firmly grasped, and the designated calf area was gently compressed. Following the calf muscles' longitudinal axis, the massage technique used short, progressive movements that were in line with the muscle fibers. In order to ensure tissue stimulation without generating excessive pain or discomfort, a steady and regulated pressure was maintained during the course of treatment. Particular calf regions that needed attention, such as myofascial trigger points, sensitive or tense muscles, or regions with restricted mobility, were the focus of IASTM. To effectively target these regions, the edges or contours of the IASTM tool were utilized[4]. Areas of restriction were treated with the IASTM tool 30-60 seconds per lesion[3].

**Group B –** Positional release technique
Participants in Positional Release Therapy received targeted treatments for their soleus and gastrocnemius muscles. In order to test the gastrocnemius, participants were placed prone, knee flexed to 90 degrees, and ankle plantar flexed. The therapist then repeated the method three times, applying deep physical pressure to the palpable taut band for 90 seconds. The soleus muscle was tested by placing individuals in a prone posture once more, with the ankle in plantar flexion and the knee extended. The taut band region was subjected to deep manual pressure for 90 seconds, three times, much like in the gastrocnemius therapy[11].

## RESULTS

Data was analyzed using the statistical package SPSS 26.0 (SPSS Inc., Chicago, IL) and level of significance was set at $p<0.05$. Descriptive statistics was performed to assess the mean and std. deviation of the respective groups. Normality of the data was evaluated using Shapiro Wilkinson test. Since the data was not normally distributed Inferential statistics to find the difference between groups was done using MANN WHITNEY U TEST and within group analysis was done using WILCOXON SIGN RANK TEST.

**Demographic data.**
Comparison of Age (Table 1). Comparison of gender (Table 2). Comparison of NPRS (Table 3).
Regarding NPRS, The between group analysis of "PRE and POST values by Mann Whitney U test did not report any statistical difference($P>0.05$). Mann Whitney U test reported statistical significance regarding the 'mean difference' ($p<0.05$) between groups. Within group analysis using Wilcoxon Sign rank test reported significant difference in both

**IASTM group and PRT group** ($p<0.05$) and higher difference observed with respect to IASTM group compared to PRT group regarding NPRS score ($p<0.05$).

**Comparison of ROM (Table 4).** Regarding ROM, The between group analysis of "PRE and POST values by Mann Whitney U test did not report any statistical difference ($P>0.05$). Mann Whitney U test reported statistical significance regarding the 'mean difference' ($p<0.05$) between groups. Within group analysis using Wilcoxon Sign rank test reported significant difference in both IASTM group and PRT group ($p<0.05$) and higher difference observed with respect to IASTM group compared to PRT group regarding ROM score ($p<0.05$). (GRAPH 2).

## DISCUSSION

Taking into account the inclusion and exclusion criteria, 30 participants were selected for this study and split into two groups. Group A, which had 15 subjects were given IASTM treatment. The 15 participants in Group B were given PRT treatment. The Shapiro-Wilk test was used to evaluate the data for normality after it was collected, and the results showed that the majority of the variables were not normally distributed. Using Mann whitney U test for between group data analysis, result revealed significant improvement ($p=<0.001$) in NPRS and ROM in both the groups, with Group A showing greater improvement for both the outcome. The within-group analysis revealed significant improvement ($p=<0.001$) in both outcomes and both groups. Several studies have demonstrated that both treatment methods can effectively decrease pain and increase range of motion in patient with calf pain ; however, the results of this study indicated that the Instrument assisted soft tissue mobilization is more advantageous to treat trigger point in calf muscle to decreasing pain and enhance range of motion. Graph 1 shows more reduction in pain in group A, These results concur with those of Dawn T.Gulick. earlier research, The researcher ascribes that IASTM is a skillful intervention that involves the use of specialized tools to maneuver the skin, myofascia, muscles, and tendons by various direct compressive stroke techniques. In order to block the A delta and C-fibers, IASTM has stimulated the A-beta sensory fibers. According to the pain gate control theory of pain management, the gate to pain transmission remains closed as long as sensory fibers continue firing. Through presynaptic inhibition at the dorsal horn, this prevents substance P from reaching the pain receptors[12]. Also according to Weiqing Ge, IASTM stimulates mechanosensitive neurons by deforming the skin, which has a neurophysiological effect.

Mechanosensitive neurons include mechano-nociceptors, which perceive pain, and mechanoreceptors, which discriminate between two points. IASTM altered the big mechanoreceptor neurons' brain activity, which had an impact on two-point discrimination. This enhances local tactile perception by stimulating mechanoreceptors and lowering the pain pressure threshold, indicating that light IASTM influenced the activity of nociceptors, or tiny pain fibers[13]. In addition graph 2 shows good result in increasing range of motion in group A, These results relate with Jooyoung kim *et al*. They carried out research on the effects and mechanism of instrument-assisted soft tissue mobilization (IASTM), as well as practical application guidelines. They demonstrated that the primary objective of IASTM is to eliminate scar tissues and encourage a return to normal function after soft tissue regeneration. Microvascular and capillary hemorrhage, along with localized inflammation, can occur as a result of using IASTM to apply appropriate pressure and shear force to the soft tissue. This type of inflammation increases the flow of blood and nutrients to the wounded area, promotes fibroblast migration, and removes scar tissue and adhesions to restart the healing process. By addressing the constraints on soft tissues, IASTM increases their extensibility. The tissue becomes softer as a result of the heat produced by friction caused by the device. From a physiological perspective, ROM is enhanced when tissue viscosity decreases. When the muscular fascia is subjected to mechanical stress, intrafascial mechanoreceptors are activated. Tissue-related motor units' tension is altered as a result of this alteration in the proprioceptive information transmitted to the central nervous system[14]. Furthermore, this study demonstrated that group B, which receives PRT treatment to decrease pain and increase range of motion, had some changes in pre and post data. In our study graph 1 indicates some changes in reduction of pain in group B.

These result concur with Vohra S, Jaiswal VC. The effectiveness of the strain counterstrain technique was the subject of their study. According to the proprioceptive theory, they discovered that passively shortening the defective agonist muscle can lessen the neuromuscular imbalance caused by constant stimulation of the muscle spindles. The recovery of normal muscle spindle activity is another benefit of positional release therapy. Upon resetting the spindle activity of agonist muscles, antagonist muscles can also return to their resting state, thereby reducing abnormal neuromuscular activity and reestablishing normal function[15]. Also, graph 2 also showed some changes in increasing ROM in group B. Result relating with Birmingham TB *et al*, they carried out a study that demonstrated that, as opposed to stretching or lengthening the muscle, positional release treatment is a method that is suggested to improve muscle flexibility by putting the muscle in a shorter posture to encourage relaxation. The therapy's neurophysiological justification stems from the observation that somatic joint dysfunction is influenced by changes in afferent neurons. Excessive gamma gain can cause the myotatic reflex arc to become hyperactive, which could lead to restricted movement. The gamma gain drops when the patient's muscle is briefly placed in the position of ease, which permits the hyperactive reflex arc to revert to its initial state and the ROM to expand[16].

## ABSTRACT

Groundwater Pollution is a major danger for public wellbeing, especially in areas where groundwater provides most of the drinking water. Industrial waste, agricultural runoff, improper disposal of waste, and leakage of toxic chemicals have resulted in extensive water quality impairment. Groundwater pollution has been associated with a variety of sickness such as gastrointestinal problems, neurological syndromes, chronic long-term illnesses like cancer and renal failure. The social implications of groundwater pollution are profound, disproportionately affecting marginalized communities with limited access to alternative water sources or healthcare. These populations often face increased economic burdens due to medical costs and loss of productivity, further exacerbating social inequalities. Community responses have varied across different regions, ranging from grassroots mobilization and community consciousness campaigns to legal interventions and adoption for sustainable water management practices. Good community outreach is key in risk reduction, lobbying for policy reform, and ensuring environmental justice. This paper focused into the intersection of *groundwater contamination* and community health with an emphasis on the socio-economic and cultural features of crisis. It highlights, imperative of integrating solutions using scientific inquiry, public health interventions, and participatory community action to manage this emerging issue. The paper presents the findings on scalable solutions empowering communities and providing equal access to clean water.

**Keywords:** Groundwater contamination, Public health, Environmental justice, Community response, Water quality.

# INTRODUCTION

Groundwater is water that is held below ground level in soil and rock and also collects subversive in aquifers. Groundwater accounts for 97% of global freshwater and principal root of drink-water supply to maximum portion of World. In much of the world groundwater resources are the only most important supply utilized for the manufacture of drinking-water, particularly where there is either a lack of contamination of surface water resources (Howard, 2006). To some communities, it is the only economically viable alternative. This is due to the fact that, to a large degree, 'groundwater' is of more uniform quality and superior microbiological quality than surface waters. Groundwaters are not likely to be treated or require minimal treatment so that they can be consumed as water while surface waters typically have to be treated, and this is typically intensive. There are many situations in which groundwater is supplied without Groundwater and public health 5 treatment. It is thus crucial that groundwater quality is protected if public health is not to be affected (Howard, 2006). Safe drinking water is fundamental to protection of public health and should be the highest concern of water companies in order to preserve the optimum quality of the supply of water. This is World Health Organization 'Guidelines for Drinking-Water Quality' publication philosophy (WHO 1993) supporting application of national standards to ensure drinking water safety. Under general considerations, it is stated that microbiological contamination control must be of the greatest concern and never compromised (Pedley,1997). Chemical contamination of the potable water, though, is not generally associated with acute health impacts and therefore can be considered lower in priority than microbiological contamination. In spite of WHO recommendations and enforcement of national law, transmission of pathogenic waterborne disease through consumption of polluted drinking water supplies continues to be a primary source of morbidity and mortality globally (Chandrasekar, *et. al*. 2017) Groundwater is the predominant source of drinking water worldwide and, in numerous small communities, the only economically feasible one where treatment of surface water is prohibitively costly for the consumers. International statistics for groundwater consumption as a supply of drinking water are not known. (Pedley,1997). Consumption figures for groundwater as a source of drinking water are given for a country as an average and not as a measure of the proportion that may vary from one community to another and from one region to another(Shaikh and Birajdar, 2024). For instance, while the overall UK average is 35% the south of the UK relies more on groundwater. It is anticipated that in developing countries, the proportion of rural and low-income peri-urban areas' reliance on groundwater sources of drinking water will be of the order of 80% or greater(Shaikh and Birajdar, 2024). Groundwater utilization in these regions has been a preference option, in the sense that in its natural condition, it is of better quality and of good microbiological quality. While others contain unacceptable concentrations of chemical impurities, like fluoride and arsenic, groundwater is generally microbiologically 'pure'(Pedley,1997). Yet, unquestionably the integrity of groundwater, source of drinking water is ruined and the ubiquity of microbiological pollution in wells all over the world is proof that, left without proper protection and proper treatment, aquifers are tremendously polluted and are a serious health hazard to the population that uses them. Aside. the poor peri-urban and rural communities' capacity to pay for water supplies is weak and thus low technology schemes, i.e., serviced, managed and operated by the community themselves, e.g., wells with handpumps, are typical. Poor quality workmanship, design and unsuitable community training in these instances have resulted in repeated supply of contaminated water, though of higher quality than unprotected supplies (Pedley,1997).

**Groundwater in Public Health**

**Ensuring Availability of Clean and Hygienic Drink-Water**

As a reliable source of clean and safe drinking water for all human beings, groundwater is essential to maintaining public health(Shaikh and Birajdar, 2024). Well-managed groundwater is less prone to contamination and provides a reliable supply of quality water, as opposed to the variation of surface water supplies that are subject to seasonality and contaminants. Urban and rural dwellers rely on this reliability to access their minimum drinking water requirements (Shaikh, 2024).

**Extensive Use of Groundwater Globally**

Groundwater is utilized widely globally for non-domestic purposes, including agriculture and industry(Shaikh and Birajdar, 2024). Groundwater is the main or exclusive source of potable water for a household in most parts of the world, particularly in waterless and semi-waterless regions. Most individuals obtain their daily supply from wells and boreholes linked to aquifers (Shukla, 2022). Most agricultural activities rely on groundwater for irrigation, hence making agriculture a significant water consumer(Shaikh and Birajdar, 2024). Utilization of groundwater resources enhances agricultural production, particularly in places where there is a limited supply or reliability of surface water (Shaikh, 2024). Industries frequently utilize groundwater for purposes such as cooling and manufacturing. For determining industrial stability and sustainability and thereby to sustain economic activities and livelihoods, a continuous supply of groundwater is essential (Madramootoo, 2012).

**Accessible and Consistent Services for Everyone**

Compared to superficial water basins, groundwater sources are more resilient to seasonal and climatic changes(Shaikh and Birajdar, 2024). Groundwater sources are reliable and significant because they provide a steady supply of water throughout the year, especially during dry spells or periods of low superficial water levels. Because groundwater is easily accessible through boreholes and wells, it can be used in a variety of topographical and geographic settings (Madramootoo, 2012).

**Preclusion of Waterborne Diseases**

Managed groundwater sources have lesser opportunities for waterborne disease compared to surface water reservoirs(Shaikh and Birajdar, 2024). Natural filtration as water percolates through soil and rock reduces the number of pathogens to levels that make groundwater a naturally safer source of drinking water(Shaikh and Birajdar, 2024). This characteristic is especially important in waterborne disease prevention and enhancing the provision of public health (Andrade,2018).

**Integrated and Environmentally Sound Water Governance**

Groundwater resource management is sustainable if the rates of extraction are in harmony with natural recharge, ensuring sustainable use(Shaikh and Birajdar, 2024). Sustainable groundwater management ensures long-term access to clean water, catering not only to the present needs but also paving the way for future generations (Andrade,2018).

**Community Responses and Resilience**

'Groundwater contamination' poses a serious threat to human health, agriculture and environmental sustainability. Resilience to this risk is determined by socio-economic status, institutional capacity, and public knowledge (Mukherjee, 2020). Optimal resilience relies on the detection of pollution at an early stage, involvement of stakeholders, and adaptive mitigation. The primary sources of pollution are agricultural runoff containing pesticides and fertilizers, industrial effluent, and unauthorized dumping, which can cause severe health problems like cancer and neurological disease (Mukherjee, 2020). Local communities have reacted in response through preventive strategies such as prevention of pollution policies and water monitoring strategies and reactive responses such as well closures, alternative water supply, and public information campaigns (Mukherjee, 2020). In developing nations, grassroots efforts are becoming more participatory and collective. For instance, in India, water user associations track water quality and promote sustainable agriculture in order to leach less nitrate (Shah, 2014). Public awareness generates behavioral change and environmental awareness. Technological measures like bioremediation, constructed wetlands, and domestic filtration are likewise practiced, but their efficacy lies in the level of community participation, institutions, and continued funding (Zhao *et al*., 2021). Institutional capacity is key to resilience, allowing for coordination, resource sharing, and planning for emergencies. NGOs and local governments tend to act as communication bridges between residents, scientists, and policymakers, acting as catalysts for adaptive responses (Adimalla, 2020). Ultimately, community resistance against contamination of groundwater is determined not only by technology, but also by robust institutions, social bonding, and a readiness to adapt and learn. Inclusive governance and capacity development are critical to long-term pollution avoidance and groundwater sustainability (Adimalla, 2020).

**Methods Applied for Groundwater Contamination Detection**

In order to promote sustainable development and future consumption of groundwater resources, both groundwater quantity and quality must be evaluated. Preventative steps are generally less expensive than clean-up. Discovery of unidentified sources of groundwater contamination is difficult, particularly in relation to surface water contamination (Zaporozec, 1981). Although there are various techniques available for identifying sources of pollution, they are effective to a large extent, depending on quality of hydrogeological data and concentration measurements. Having a properly structured geochemical monitoring network can help identify sources. Recurring use of source identification models coupled with strategically placed monitoring systems is a sound method of determining groundwater contamination sources (Meyer, 1994).

**Systems of Indexing**

Indexing techniques are frequently employed to evaluate groundwater pollution through the use of vital parameters associated with pollutant infiltration. The indicators represent pollution hazards in both the vadose and saturated zones (Sudani, 2019).

**Process-based Methods**

The techniques model the behaviour of contaminants such as pesticides to move and change under physical, chemical, and biological processes within the vadose and deluged zones. Numerical simulation models help to calculate pollution risk indicators (Sudani, 2019).

**Numerical Techniques**

With observed pollution data, statistical analysis determines correlations of gathered data with pollution-induced factors. Evaluation indicators are thereafter confirmed and given relevance values based on the analysis (Srivastava, 2015).

**Fuzzy-Based Analytical Assessment Framework**

This approach starts with the categorization of pollution levels and choosing evaluation indicators. Reference values for each indicator for every level of contamination are compiled. The extent of each sample's relation to the levels of contamination is established by using a relative membership score and vectors of weights. The conclusive pollution risk is determined by computing a value vector by matrix multiplication (Srivastava, 2015).

**Regulatory Outline for Groundwater Quality and Public Health Shield**

**US: Safe Drinking Water Act (SDWA)**: The SDWA sets national standards for drinking water quality, regulating contaminants in water systems under the EPA's oversight(Shaikh and Birajdar, 2024). It mandates regular monitoring and reporting to ensure transparency(Shaikh and Birajdar, 2024). However, it offers limited oversight for private wells and may struggle to address emerging contaminants not covered by MCLs. Challenges also exist in enforcement, such as delays and weak penalties (Birajdar, 2024).

**EU: Water Framework Directive (WFD) and Groundwater Directive (GWD)**: The WFD and GWD promote integrated water management, considering both environmental and health aspects(Shaikh and Birajdar, 2024). Risk-based monitoring is emphasized, with member states responsible for local implementation. However, differences in enforcement, interpretation ambiguities, and lack of focus on emerging contaminants pose challenges to uniform groundwater protection (Birajdar, 2024).

**India's Water Governance Framework and Groundwater Regulation**: India's policy highlights sustainable groundwater use and community involvement. Some states have enacted laws to regulate extraction and encourage sustainability. Yet, challenges such as limited resources, poor data collection, and inconsistent practices across states hinder effective management (Birajdar, 2024).

**China: Policy Blueprint for Groundwater Pollution Control**: This plan adopts a broad approach to prevent, control, and restore groundwater quality, emphasizing pollution source control and community engagement. Nonetheless, enforcement is hindered by industrial scale, regulatory decentralization, limited data access, and regional implementation disparities (Shaikh, 2024)

**Recommendations for Improvement**: Regular regulatory updates are necessary to address new risks and scientific developments. Enhancing the capacity of regulatory agencies is key to effective monitoring and enforcement. International collaboration is also crucial for sharing best practices and improving global groundwater protection efforts (Shaikh,2024).

**Forthcoming Challenges in Groundwater and Research Requirements**

**Climate Change and Groundwater**

Climate change affects groundwater through altered precipitation, recharge rates, and evapotranspiration, impacting aquifer storage and reliability. Coastal aquifers face saltwater intrusion due to sea-level rise. Increasing extreme weather events pose risks to recharge and contamination pathways. Research is needed to assess groundwater system resilience and related health risks (Meixner, *et, al*.2016)

**Emerging Groundwater Contaminants**

Contaminants like Pharmaceuticals and Personal Care Products (PPCPs), microplastics, and PFAS are growing threats to groundwater. Research is essential to understand their sources, movement, health effects, and removal methods to support effective regulation and protection of water quality (Sharma, *et.al*.2019).

**Public Health Risks from Groundwater Pollution**

The combined effects of multiple groundwater contaminants on human health remain unclear(Shaikh and Birajdar, 2024). Long-term exposure to substances like heavy metals raises health concerns, particularly for vulnerable groups. Focused research can guide interventions to protect at-risk populations (Mitchell, *et, al*.2011).

**Sustainable Groundwater Management Approaches**

Techniques like Managed Aquifer Recharge (MAR) can enhance groundwater replenishment but require study of ecological and health impacts. Understanding groundwater–surface water interactions and supporting community-based monitoring are key to resilient, inclusive water management (Mohanty, *et, al.* 2021).

**Technological and Data Advancements**

Advanced sensors, real-time monitoring, and data modelling improve groundwater quality tracking and risk prediction. Integrated watershed analysis and climate impact modelling are essential for evidence-based and adaptive groundwater management (Birajdar, *et, al.* 2015).

## CONCLUSIONS

Groundwater, as a critical source of drinking water for millions of the global population, occupies a pivotal role in public health. Its supply reliability and relative sanitation render it indispensable, especially in water-deficient regions and regions facing climatic challenges. Groundwater quality is a priority, as contamination can pose both temporary and lasting hazards to the health of communities depending on this life-giving supply. A good understanding of sources and routes of contamination is necessary for successful mitigation and prevention measures. Groundwater supports household use, agriculture, and industry worldwide, which emphasizes the need for sustainable groundwater management. Climate change and new contaminants compromise the security of groundwater and, in turn, public health. Regulatory frameworks like the SDWA of US and the WFD of EU play a vital role in providing much-needed directives for safeguarding groundwater quality. *In situ* monitoring sensors and advanced systematic technologies are vital to the identification of contamination risk and fast response. Community

participation in the protection and monitoring of groundwater, made easier through local awareness and joint responsibility, is essential. Educational initiatives are also important to raising awareness of the relationship between groundwater and health, pollution sources, and the need for sustainable water utilization. Any future threats will be addressed with continued research, innovative solutions, and efforts to fill knowledge gaps, create new monitoring tools, and study long-term health effects of pollutants. Lastly, conserving groundwater is a public benefit that needs collective effort from scientists, policymakers, communities, and industries.

## RECOMMENDATIONS

To better fortify regulatory requirements, policymakers need to tackle new pollutants, incorporate climate change aspects, and assure consistent monitoring and enforcement tailored to local conditions. Successful regulation will also involve cooperation with communities to facilitate application. Investment needs to be made in the application and implementation of sophisticated surveillance technologies, in research on emergent contaminants, and in support of large-scale characterization of groundwater. Water management authorities need to increase monitoring networks based on real-time sensors and data analytics for enhanced accuracy and efficiency. Encouraging community involvement is equally essential, with policymakers ensuring public involvement in monitoring, defence measures, and decision-making activities. Channels need to be implemented to include community inputs, while water agencies offer education, workshops, and outreach programs to empower communities with knowledge and resources required to actively defend groundwater. Sustainable land uses should be compatible with protection of groundwater, supporting environmentally friendly agriculture and industry and utilizing zoning restrictions in vulnerable zones. Coordination among water and land-use planning agencies is essential to ensure the quality of groundwater. Policymakers should also plan and execute Managed Aquifer Recharge (MAR) programs, providing economic incentives and cooperating with local organizations to determine suitable project locations and track their long-term performance. Finally, public education and awareness campaigns are necessary. Policymakers ought to finance awareness campaigns to inform people about the significance of groundwater, the possible health hazards posed by contamination, as well as personal roles toward water conservation. These multidimensional efforts are indispensable for managing groundwater sustainably and protecting public health.

**ABSTRACT**

Oral Squamous Cell Carcinoma (OSCC) is the most prevalent malignancy of the oral cavity, accounting for more than 90% of all oral cancers. Increasing incidence of OSCC globally, coupled with delayed diagnosis and high morbidity, makes it a critical public health concern. This comprehensive review delves into the epidemiology, etiological factors, pathogenesis, clinical features, diagnostic modalities, staging, treatment strategies, prognosis, and recent advances in OSCC research. Drawing on current literature and guidelines, the article aims to enhance understanding among healthcare professionals, researchers, and students involved in oral healthcare and oncology.

**Keywords :** Oncology; Oral cancer; Neoplasms; Cancer.

## INTRODUCTION

Oral cancer remains a pressing global health concern, ranking among the top ten most common cancers worldwide. Of all oral malignancies, Oral Squamous Cell Carcinoma (OSCC) accounts for over 90% of cases, arising from the stratified squamous epithelium lining the oral cavity [1]. It frequently affects critical sites such as the tongue, floor of the mouth, buccal mucosa, retromolar trigone, and gingiva. OSCC exhibits a particularly high incidence in developing countries, especially in South and Southeast Asia, owing to the prevalent use of tobacco (smoked and smokeless), alcohol, and betel quid—potent carcinogenic agents that synergistically elevate risk [2,3]. Despite improvements in diagnostic techniques, surgical modalities, radiation therapy, and chemotherapeutic regimens, the 5-year survival rate for OSCC has remained relatively stagnant, typically ranging from50% to 60%, largely due to late-stage diagnosis, tumor recurrence, and regional metastasis [4]. The early stages of OSCC can mimic benign lesions such as leukoplakia, erythroplakia, or traumatic ulcers, often leading to delayed presentation and treatment [5].

OSCC also shows significant variation in incidence and prognosis based on demographic factors such as age, gender, and geography. It predominantly affects males in the 5th to 7th decades, though there is a rising incidence among younger individuals, especially HPV-positive patients[4, 6]. The male-to-female ratio, historically around 2:1 to 4:1, is narrowing due to increasing female exposure to tobacco, areca nut, and second-hand smoke, particularly in rural South Asia [7, 8].In addition to local invasion, OSCC poses serious clinical challenges due to its potential for lymph node metastasis, peri-neural invasion, and second primary tumors in the aero-digestive tract [9]. Consequently, ongoing research is focusing on the development of reliable biomarkers for early detection, molecular profiling for risk stratification, and novel targeted therapies [10-12]. This article reviews the current understanding of OSCC, including its epidemiology, etiology, clinical features, diagnosis, treatment approaches, and recent advances in the field, providing a comprehensive update for clinicians, researchers, and public health professionals.

**Epidemiology**

According to GLOBOCAN 2020, OSCC is the 16th most common cancer globally, with an estimated 377,713 new cases and 177,757 deaths annually [2]. The burden is disproportionately high in South Asia, particularly India, Pakistan, and Sri Lanka, where cultural practices like betel nut chewing are prevalent. In India alone, oral cavity cancers account for over 30% of all cancer cases, there is a concerning rise in oral cancers among younger populations in India, particularly females who do not consume tobacco—suggesting novel etiological pathways, possibly including HPV and occupational exposures [6, 7, 13].

**Age and Gender Distribution**

OSCC typically presents in the sixth to seventh decades of life, although an alarming rise in younger patients (under 45) has been reported, particularly among non-smokers and HPV-positive individuals. Males are more commonly affected than females, with a ratio of approximately 2:1, likely due to higher exposure to risk factors.A statistically significant uptick in OSCC among adults aged 30–45 in North America has been found, where HPV-16 prevalence in oral cancers is increasing [6, 14]. Traditionally, OSCC is considered to be predominantly affecting older males, particularly those over 50 years of age, largely due to cumulative exposure to carcinogens such as tobacco, alcohol, and betel quid. Men have consistently shown a higher incidence than women, with a male-to-female ratio ranging from 2:1 to 4:1 in most population-based studies (Warnakulasuriya et al., 2020) [1, 8].

**Emerging Trends in Younger Age Groups**

Over the past decade, and especially in data published since 2018, there is an alarming increase in OSCC incidence among younger individuals, even in the absence of traditional risk factors. These cases often lack a history of tobacco or alcohol use, suggesting alternative etiologies such as Human Papillomavirus (HPV) particularly HPV-16, Genetic predispositions or polymorphisms (e.g., GSTM1, CYP1A1),Chronic trauma (e.g., sharp teeth, ill-fitting dentures) and Dietary and microbiome changes due to processed food intake and poor oral hygiene [6-8, 13, 14]. In some parts of Asia, notably South and Southeast Asia, a shift toward increased OSCC incidence in females has been reported. This may be due to growing use of tobacco and areca nut use among females living in rural and urban slums, higher prevalence of second-hand smoke exposure, occupational exposures (e.g., to pesticides and industrial chemicals) and hormonal influences, although evidence remains inconclusive[7, 8].

**Biological and Behavioral Differences**

1. **Hormonal Influences:** Estrogen receptors (ER-$\alpha$ and ER-$\beta$) have been found in OSCC tissues, particularly in **female patients**, suggesting that estrogen may influence tumor growth or suppression (Ghosh et al., 2020). However, further research is required to establish causality[11].
2. **Immunological Factors:** Females often have a stronger innate and adaptive immune response, which may influence tumor immune surveillance and progression. This could explain better treatment responses in some female OSCC patients[15].

3. **Sociocultural Barriers:** In many low- and middle-income countries, women may delay seeking care due to stigma, family responsibilities, or lack of access, leading to more advanced-stage diagnosis [8].

**Geographic and Ethnic Variations**

In South Asia,early-onset OSCC is increasingly common, especially in India, Bangladesh, and Sri Lanka, where areca nut and smokeless tobacco are culturally accepted across genders[8], whereas in western countries, the increase in OSCC in younger individuals is often linked to HPV-positive cases, particularly in the tongue and oropharynx. These cancers tend to have a better prognosis and respond well to radiotherapy and immunotherapy [6].

**Etiology and Risk Factors**

Oral Squamous Cell Carcinoma (OSCC) is a multifactorial disease influenced by environmental carcinogens, genetic predispositions, viral infections, and immunosuppressive conditions. The most established risk factors include:

1. Tobacco Use – Smoking (cigarettes, cigars, pipes) and smokeless tobacco (snuff, chewing tobacco) are strongly linked with OSCC. Tobacco-related carcinogens such as nitrosamines and polycyclic aromatic hydrocarbons initiate mutations in oral epithelial cells [16].
2. Alcohol Consumption – A meta-analysis by the International Agency for Research on Cancer confirmed the synergistic carcinogenic effect of tobacco and alcohol, showing a 15-fold increased OSCC risk when both are consumed together [16]. Alcohol acts synergistically with tobacco by increasing mucosal permeability, thereby enhancing carcinogen absorption. Chronic alcohol exposure also contributes to epithelial atrophy, oxidative stress, and DNA damage[17, 18].
3. Betel Quid and Areca Nut – Common in South and Southeast Asia, these contain arecoline and tannins, which cause chronic irritation, genotoxicity, and reactive oxygen species formation. Long-term use is classified as Group 1 carcinogenic by IARC (2012) [16].
4. Human Papillomavirus (HPV) – High-risk subtypes, particularly HPV-16, are implicated in a subset of OSCCs, especially in non-smoking younger individuals. These tumors often display better prognosis, likely due to different molecular and immune pathways. Distinct transcriptomic signatures in HPV-positive OSCCs, correlating with improved response to immunotherapy and radiotherapy[6].
5. Poor Oral Hygiene and Chronic Inflammation – Persistent mechanical trauma (e.g., from ill-fitting dentures, sharp cusps), poor oral hygiene, and periodontal infections create a pro-inflammatory microenvironment conducive to carcinogenesis[19].
6. Genetic and Molecular Alterations – Common molecular events include p53 mutations, cyclin D1 overexpression, EGFR dysregulation, and loss of heterozygosity at tumor suppressor loci (e.g., 3p, 9p21).

Patel K. et al. (2021), using whole-exome sequencing, identified OSCC driver mutations including FAT1 and CASP8, underscoring the potential for personalized risk stratification and therapy[10].

**Pathogenesis**

The progression of OSCC is marked by the multistep accumulation of genetic and epigenetic alterations. The transformation from normal epithelium to invasive carcinoma involves [20]:

1. Initiation: Exposure to carcinogens causes mutations in key oncogenes and tumor suppressor genes.
2. Promotion: Clonal expansion of mutated cells leads to dysplastic changes.
3. Progression: Cells acquire invasive and metastatic capabilities, often via epithelial-mesenchymal transition (EMT) and angiogenesis.

Histologically, OSCC may arise from precursor lesions such as leukoplakia, erythroplakia, or oral submucous fibrosis. These lesions may exhibit varying degrees of dysplasia before transforming into invasive carcinoma. New insights into tumor biology have emerged. It has been identified that OSCC tumor microenvironment modulates immune evasion via upregulation of PD-L1 and depletion of CD8+ T cells and miRNA deregulation (notably miR-21 and miR-155) plays a pivotal role in EMT, metastasis, and chemoresistance [10, 11, 19].

**Clinical Presentation of OSCC**

Oral squamous cell carcinoma (OSCC) often mimics benign lesions in its early stages, which can result in delayed diagnosis and treatment. The clinical presentation varies depending on the anatomical site, tumor size, and depth of invasion. Early-stage OSCC may present with subtle signs such as painless white or red patches (leukoplakia or erythroplakia), a non-healing ulcer lasting more than two weeks, small exophytic or indurated masses, persistent sore throat or discomfort, and foul oral odor (halitosis). These early manifestations are frequently overlooked or misdiagnosed [21, 22].As the disease progresses, more alarming late-stage symptoms tend to appear. These include pain or a burning sensation—often aggravated by spicy or hot foods—along with difficulty in chewing, swallowing (dysphagia), or speaking (dysarthria). Other signs include loose teeth or non-healing sockets post-extraction, trismus (restricted mouth opening), paresthesia or numbness indicating possible perineural invasion, bleeding from the lesion, cervical lymphadenopathy characterized by firm and fixed lymph nodes, and systemic symptoms such as weight loss and malaise [21].

The clinical features of OSCC also vary by site**.** Lesions on the lateral tongue often appear as painful ulcers with induration and are common among smokers. Tumors on the floor of the mouth may present as non-healing sores with sublingual swelling and can invade bone early. The buccal mucosa typically shows exophytic or ulceroproliferative lesions, particularly in individuals who chew betel quid. Lesions of **the** gingiva or alveolar ridge can lead to loosening of teeth and bleeding, frequently mimicking periodontal disease. OSCC of the hard palate may present as erythroleukoplakia or ulceration and, in advanced cases, cause nasal regurgitation due to oronasal communication [22, 23].

**Staging of OSCC**

Recent studies have provided robust support for the revisions introduced in the American Joint Committee on Cancer (AJCC) 8th edition staging system for oral squamous cell carcinoma (OSCC) (Table 1), particularly the incorporation of depth of invasion (DOI) and extranodal extension (ENE) into staging criteria (Table 2). DOI is measured from the basement membrane of the adjacent normal mucosa to the deepest point of invasion and ENE is defined as tumor extension beyond the lymph node capsule into the surrounding tissue, and it worsens prognosis significantly. Balaguru et al. (2025), in their study, validated the significance of DOI in early tongue cancers, showing that greater DOI is strongly associated with increased risk of nodal metastasis and reduced survival rates. They stated that at the time of ipsilateral neck dissection, a DOI ≥ 6 mm may represent a threshold associated with an increased risk of contralateral neck disease, indicating that contralateral neck management could be considered [24]. Similarly, Xu et al (2022)emphasized that the presence of ENE, even in small metastatic lymph nodes, is linked to significantly poorer survival outcomes, highlighting its prognostic importance[25].

Building on these findings, Brandwein-Gensler et al. (2010) proposed further refinements to the staging system by suggesting the integration of other high-risk pathological features such as perineural invasion (PNI) and lymphovascular invasion (LVI), both of which have been independently associated with worse prognosis[26]. Technological advances are also influencing staging accuracy. den Toom, I et al. (2019) demonstrated that radiologic estimation of DOI, enhanced by radiomics analysis, could closely predict actual histopathological DOI, offering valuable assistance in preoperative planning[27]. More recently, Yang L et al. (2025) supported the use of artificial intelligence (AI) to improve staging precision. Their study employed deep learning algorithms with PET/CT and MRI data to accurately measure DOI and assess nodal involvement, suggesting that AI may enhance diagnostic consistency and staging reliability in clinical practice [28].

**Diagnostic Modalities**

The diagnosis of oral squamous cell carcinoma (OSCC) relies on a combination of clinical evaluation, histopathological confirmation, imaging, and emerging molecular techniques. The initial clinical examination involves a thorough visual and tactile assessment of the oral cavity, focusing on identifying suspicious lesions and assessing risk factors. When a lesion is suspected to be neoplastic, a biopsy—either incisional or excisional—remains the gold standard for definitive diagnosis. Histopathological examination typically reveals hallmark features such as

keratin pearls, cellular atypia, and invasive epithelial growth[29].To assess the extent of disease, imaging modalities such as computed tomography (CT), magnetic resonance imaging (MRI), and positron emission tomography-computed tomography (PET-CT) are employed. These tools are invaluable in evaluating local tumor invasion, bone involvement, lymph node status, and distant metastasis. In addition to traditional diagnostics, molecular and adjunctive tests are being increasingly integrated into clinical practice [30]. Techniques such as immunohistochemistry for p16 (a surrogate marker for HPV), toluidine blue staining, brush cytology, and salivary biomarker analysis are under active investigation for their potential in early detection and risk stratification [12].Liquid biopsy is a promising non-invasive tool for early diagnosis. A study by Yakob M et al. (2014) demonstrated that detection of circulating tumor DNA in saliva could achieve over 85% sensitivity and 90% specificity in identifying early-stage OSCC [12]. Moreover, advances in artificial intelligence (AI) are transforming diagnostic accuracy. Yang Z et al. (2023) applied deep learning algorithms to intraoral photographic images, achieving more than 92% accuracy in classifying OSCC, signaling the potential for AI-driven screening tools in both clinical and remote settings [31].

Prevention and early detection are critical components in reducing the burden of oral squamous cell carcinoma (OSCC). Primary prevention strategies primarily focus on modifying risk factors, including cessation of tobacco and alcohol use, promoting public awareness through education campaigns, and encouraging HPV vaccination, which has the potential to reduce HPV-related OSCC cases. Secondary prevention aims at the early identification

**Treatment Modalities**

Management of oral squamous cell carcinoma (OSCC) involves a multidisciplinary approach tailored to the stage and location of the tumor. Surgery remains the primary treatment for resectable tumors, involving wide local excision, often accompanied by neck dissection to manage regional lymph nodes. In cases of extensive defects, microvascular reconstruction techniques such as radial forearm or fibula free flaps are employed to restore function and aesthetics. Radiation therapy is indicated in inoperable cases or as an adjuvant treatment in patients with high-risk pathological features, such as perineural invasion. Modern techniques like Intensity-Modulated Radiation Therapy (IMRT) offer enhanced precision and minimized damage to surrounding tissues [32].

Chemotherapy is typically reserved for advanced-stage disease or in recurrent/metastatic settings. Commonly used agents include cisplatin, 5-fluorouracil (5-FU), and taxanes. When combined with radiation (chemoradiation), chemotherapy improves locoregional control and survival. Targeted therapy has introduced new possibilities, particularly with EGFR inhibitors like cetuximab, which have demonstrated benefit in select patient populations. The role of PI3K/mTOR inhibitors in PIK3CA-mutated OSCC with encouraging preclinical outcomes has also been explored [32]. Immunotherapy is emerging as a promising strategy for recurrent or metastatic OSCC. PD-1/PD-L1 checkpoint inhibitors, such as nivolumab and pembrolizumab, have shown clinical efficacy [6]. The KEYNOTE-048 phase III trial (2023) by Harington et al, reported improved overall survival in PD-L1–positive OSCC patients treated with pembrolizumab [33]. In recent years, 3D printing technology has contributed to enhanced surgical precision, particularly in complex reconstructions. 3D-printed maxilla and mandible templates significantly improve surgical outcomes by facilitating accurate flap design and fitting[34].

**Prognosis**

The prognosis of oral squamous cell carcinoma (OSCC) is influenced by several factors, including the stage at diagnosis, lymph node involvement, tumor differentiation, and HPV status. The overall 5-year survival rate for OSCC ranges between 50–60%, though it can exceed 80% in early-stage, HPV-positive cases. Despite advances in treatment, recurrence remains a significant challenge, particularly within the first two years following therapy, underscoring the importance of close clinical follow-up and vigilant surveillance [35]. Recent research has identified additional prognostic markers that may aid in risk stratification. One such marker is the density of tumor-infiltrating lymphocytes (TILs), especially CD8+ T cells. High CD8+ TIL density has been associated with improved outcomes, as reported by Shimizu S et al. (2019) [36]. Furthermore, traditional histopathological features such as depth of invasion (DOI) and perineural invasion continue to be critical prognostic indicators [35]. A study by Emmanuel A et al. (2021) .

validated that a DOI greater than 4 mm significantly correlates with an increased risk of nodal metastasis, supporting its role in staging and treatment planning [37]. Prevention and early detection of precancerous changes through regular screening. This includes oral visual inspection, particularly in high-risk populations, and routine dental check-ups for early lesion detection. Additionally, technological advancements are enhancing early diagnostic capabilities. Emerging tools such as AI-driven diagnostic systems and salivary biomarkers are currently under investigation for non-invasive, early detection methods.

Recent advances have significantly reshaped the OSCC diagnostic and treatment landscape. Genomic profiling, through studies such as The Cancer Genome Atlas (TCGA) by The National Human Genome Research Institutehas uncovered molecular subtypes of OSCC with distinct therapeutic vulnerabilities, paving the way for personalized medicine. Liquid biopsies are gaining attention as a minimally invasive diagnostic tool. Recent advancements in technology have enhanced the sensitivity and specificity of biomarkers through tools like mass spectrometry, multiplex assays, and nanobiosensors. Additionally, the integration of artificial intelligence for data analysis is improving the accuracy of point-of-care diagnostics, potentially transforming the landscape of oral cancer screening [38].3D printing technologies have revolutionized surgical planning and reconstruction, with personalized titanium implants and vascularized graft templates significantly improving functional and aesthetic outcomes [34]. In parallel, artificial intelligence is being integrated into diagnostic workflows; Bera et al. (2019)and Lu et al (2018) reported that AI-assisted histopathological tools improve grading precision and recurrence prediction [39, 40]. Another innovative modality, photodynamic therapy, is showing promise [41]. New-generation agents, including 5-aminolevulinic acid (5-ALA) derivatives, are currently in Phase II trials and have demonstrated improved tumor selectivity with fewer side effects [42].Together, these advancements reflect a transformative shift in OSCC prevention, detection, and personalized care.

## CONCLUSION

Oral Squamous Cell Carcinoma is a preventable yet potentially lethal malignancy. Advances in molecular biology, diagnostics, and therapeutics have improved our understanding and management of the disease, but early detection remains the cornerstone of effective treatment. Multidisciplinary care, public education, and research into novel therapeutics are essential to improving patient outcomes and survival rates.

## ABSTRACT

Myopia is becoming a major global public health concern due to its sharp rise in prevalence, especially in children and teenagers. Early onset and rapid progression increase the risk of serious visual effects, including retinal detachment, glaucoma, and myopic maculopathy. The most recent developments in next-generation lenses for controlling the progression of myopia are described in this article. Defocus Incorporated Multiple Segments (DIMS), Highly A spherical Lenslets (HAL), and other peripheral defocus-based designs are examples of advanced lens technologies that aim to reduce axial elongation by causing peripheral myopic defocus, which delays the development of refractive error. Up to 50–60% less myopia progression and axial elongation have been shown with these novel designs than with traditional single-vision lenses. Spectacle lenses are beneficial since they are non-invasive, simple to use, and appropriate for young patients. Recent studies have also highlighted the possibility of combining optical interventions with pharmacological or behavioral strategies to improve outcomes. Further long-term research is necessary to evaluate treatment stability, design optimization, and patient compliance, even though next-generation lenses exhibit encouraging efficacy. All things considered, these cutting-edge eyeglass lenses offer a secure, affordable, and successful strategy for controlling and reducing the worldwide myopia problem

**Keywords:** Myopia, Global Public Health, Incorporated Multiple Segments, Highly A spherical Lenslets, Lenses.

## INTRODUCTION

Myopia has a complex etiologic, with structural, environmental, and genetic factors all being important [1,2,3]. The prevalence of myopia and extreme myopia has sharply grown in the last several decades. This has been accompanied by a drop in the age of onset, resulting in longer periods of myopia progression and thus increased incidence of extreme myopia. Because excessive myopia is connected with sight-threatening ocular problems, and myopic people's quality of life is harmed by economical, cosmetic, and psychological aspects, slowing myopia progression is essential [4]. By 2050, it is predicted that maybe half of the world's population might be affected by myopia. Currently, there are three categorized strategies to control the progression of myopia, which are optical, pharmacological, and environmental interventions. Spectacles, soft contact lenses, and overnight orthokeratology lenses are the optical invasions that help in reducing retinal defocus or slowing or stopping myopia progression [5]. There are two primary theories that support the lens designs. According to the first theory, after imposing a peripheral myopic defocus—that is, when the incoming light rays converge in front of the retina—eyeball growth stops. Competing blur designs rely on this idea, seeking to boost the intensity and contrast of pictures in front of the retina. A few of those designs include arrays of spherical or aspherical micro-optics in the lenses' outer side-vision zone. With defocus incorporated multiple segments (DIMS) lenses, the former is the situation. The second theory proposes that abnormally strong contrast between adjacent cones may drive axial elongation [6]. Myopia raises the risk of retinal detachment, glaucoma, and cataracts. Myopic maculopathy, commonly known as myopic retinopathy or macular degeneration, is the most common cause of irreversible vision loss [7-9].

Myopia appears to be developing earlier, and a younger age of beginning is linked to faster myopia progression and greater severity in maturity. Since it is closely related to the final myopic refractive error and the risk of vision loss, the rate at which myopia progresses is a crucial clinical criterion. For instance, the chance of developing myopic macular degeneration (MMD) is thought to rise by up to 67% with every extra diopter of myopia. Without intervention, the number of persons with MMD-related vision impairment or blindness is predicted to nearly double, reaching 37.2 million vision impaired and an additional 18.5 million blind by 2050[10]. Spectacle lenses are an excellent choice for myopia treatment because they are more user-friendly for children [11]. One of the most prevalent refractive problems in children worldwide is myopia. It is anticipated that around one billion myopes worldwide may experience myopia-related issues by the year 2050. Refraction incidence and progression are known to differ according to age, age of onset of myopia, severity of myopia, nation, and ethnicity[12]. Slowing myopia by one dioptre reduces the likelihood of developing myopic maculopathy by 40%, regardless of race or sickness criteria [13]. It appears that a child's refractive error status is influenced by their genetic makeup. The chance of becoming myopic increases with the number of myopic parents; monozygotic twins have a substantially stronger correlation with refractive error than dizygotic twins, and genetic variables account for greater diversity in refractive error than environmental factors[14]. Myopia progression was 52% slower in the defocus-incorporated multiple segment (DIMS) group compared to the single vision (SV) group, and axial elongation was 62% lower in the DIMS group. These findings suggest that the DIMS lens design may be an effective intervention for managing myopia in children, potentially reducing the risk of severe visual impairment later in life. Further studies are needed to explore the long-term effects and optimal usage of these lenses [15]. there is no therapy for myopia, and its growth is permanent.

Despite the significant prevalence of myopia and the dangers of its advancement, little is known about the variables that contribute to it [16]. Many etiological studies have looked at the genetic and environmental variables that contribute to myopia. Children of myopic parents are more likely to develop myopia, according to studies [17]. LRL has been used for decades to treat amblyopia. Recent research has shown that LRL has a positive effect on myopia prevention and control when used in conjunction with a modest 6-minute irradiation regimen. Compared to frequently used techniques such as orthokeratology lenses, defocus spectacles, and low-concentration atropine, LRL has the advantage of being straight forward to adopt. To determine the precise application technique of LRL for attaining effective and secure outcomes, more investigation is necessary. As a result, this study seeks to explore the efficacy of LRL with particular power in managing myopia progression and offering clinical advice[18]. Human

myopic eyes frequently exhibit relative hyperopia in the periphery, and it has been proposed that hyperopic defocus in the retinal periphery serves as a signal for accelerated eye growth. This phenomenon suggests that the eye may be adapting to the distortions in peripheral vision by elongating, potentially contributing to the development of myopia. Understanding the mechanisms behind this process could provide insights into preventative strategies for refractive errors [19]. Peripheral visual signals were identified to dominate central refractive development, and peripheral myopic retinal defocus was shown to provide myopia control signals. According to these results, controlling peripheral defocus optically may be a useful tactic for controlling the advancement of myopia. As researchers continue to investigate the mechanics underlying these visual clues, the potential for novel treatments may become clearer. Numerous investigations have discovered a strong dose-response relationship between the effectiveness of optical treatments and variables including the amount of power added to multifocal soft contact lenses and spectacle lenses, as well as the duration of usage for multifocal soft contact lenses [20]. The current study aimed to consolidate available information and evaluate objective data on the efficacy of these innovative spectacle lens designs as an alternate method for myopia progression control to single-vision lenses (SVLs). A scoping review technique was utilized to present an overall picture of the growing material on this topic, which may be useful not only to researchers but also to practitioners (when assessing their patients' myopia progression control options) [21].

**Specs**

There are so many benefits of using spectacle lenses for myopia management. They are easy to wear, are generally well received and endured, and are budget-friendly for most. Myopia management includes standard and customized single-vision lenses in addition to bifocal and progressive spectacle lenses[22]. Current treatments for reducing myopia progression (MP) include orthokeratology, atropine eye drops, multifocal soft contact lenses, and several types of spectacle lenses. With varying degrees of clinical success, the latter is the less invasive procedure. Progressive addition lenses were previously used to rectify peripheral hyperopic defocus in myopes by changing lens curvature, but their effectiveness in slowing MP was limited. Current spectacle lens technologies rely on adjusting picture sharpness and contrast at the peripheral retina while correcting foveal vision [6].

**Progressive glasses with additional lenses and bifocals**

In regular clinical practice, single-vision spectacle lenses (SVSLs) and contact lenses are commonly recommended to children to address myopia. However, progressive additional lenses (PALs) and bifocal lens spectacles are occasionally given to halt the progression of refractive illness. The underlying mechanism behind PAL therapy needs to be better understood; however, multiple studies have suggested that it reduces retinal hyperopic blur by reducing accommodative latency during near tasks. In contrast, a 3-year Finnish randomized controlled trial (RCT) including 240 schoolchildren aged 9 to 11 found that myopia progression was more connected with the amount of near labor and that reducing the accommodative strain with bifocal or reading spectacles was unsuccessful [23].

**Literature Search Strategy**

In November 2023, a literature search was performed in the PubMed and Google Scholar databases for publications authored in English and published in peer-reviewed journals between January 2004 and February 13, 2025. Advanced search options were used to identify publications based on terms in the title or abstract. The search equations were [(myopia progression) OR (near-sightedness management) OR (progression of myopia) OR (peripheral defocus)]. AND [(spectacle lenses) OR (defocus with several segments) OR [(highly or slightly) AND (aspherical lens arrays)]]. A follow-up literature search in the ProQuest database did not turn up any further relevant papers [24, 25,26, 27].

**Data Extraction and Analysis**

The precise pathogenic pathways underlying issues associated with myopia remain unclear. Since the choroid, retina, peripapillary area, and sclera are all strained by the globe's gradual elongation in extreme myopia, mechanical stretching may be a significant factor. Myopia progression, a continuous measurement, was defined as the change in spherical equivalent refractive (SER) error compared to the baseline. The average of the five SER auto refraction readings for each eye was calculated for every visit. [16]

**New Developments in Spectacular Lens Technology**

The treatment consists of applying numerous tiny scattering patches to the front surface of the glasses' periphery. These produce a decrease in visual contrast on the peripheral retina. However, we must point out that picture sharpness in this location is already significantly diminished due to significant ocular second- and higher-order aberrations. Lens therapy often entails adding positive power (or reducing negative power) to centre vision for the first hypothesis and part of peripheral vision for the second. In this regard, the optics of spectacle lenses and contact lenses are fundamentally different because (1) spectacle lenses measure about twelve microns away from the eye, whereas contact lenses are placed on the cornea; (2) spectacle lenses do not move with the eye, whereas contact lenses do; and (3) spectacle lenses are much less curved. A spectacle lens only uses a small portion of its area to photograph any given part of the visual field at any given time; therefore, different parts of the lens can be used for different activities. By comparison, a contact lens's area covers a significant portion of the visual field. This creates distinct issues for the two modalities' design. [27, 28]. The below table-1gives us the type of spectacle lens and the name of the manufacturer. Table 1.

**Spectacle Interventions**

One of the most well-researched and easily available methods for the clinical treatment of myopia, particularly among kids and teenagers, is optical intervention [29]. These treatments are intended to affect ocular growth by altering peripheral defocus in addition to correcting refractive defects. Most optical techniques are based on the knowledge that peripheral hyperopic defocus promotes axial elongation and peripheral myopic defocus prevents it. Utilizing this idea, modern lens technologies have attempted to effectively limit the evolution of myopia [30]. Conventional single-vision lenses improve central vision but do not reduce the progression of myopia. Multifocal soft contact lenses (MFCLs), orthokeratology (Ortho-K), and specialty lenses (DIMS, HALT) are examples of advanced solutions that are more successful by causing peripheral myopic defocus. While DIMS and Stellest™ lenses demonstrate high performance in studies, MFCLs and expanded depth-of-focus designs considerably minimize axial elongation. Ortho-K slows advancement by 30 to 60%, but it must be strictly followed. For younger children, spectacle lenses are safer, but contact lenses frequently offer more control. Combination therapies (for example, optical lenses and low-dose atropine) are increasingly being investigated for improved outcomes [31].

**Peripheral Defocus Lenses**

Previous research has shown that myopic defocus stimulation causes cellular and metabolic alterations in the retinal pigment epithelium, which can delay retinal growth signals to the sclera, influencing eye growth management and myopia regression. Orthokeratology, MFSCLs, and PPSLs have all been used to induce peripheral myopic defocus with the goal of decreasing myopia progression [32]. https://www.opticianonline.net/cpd-archive/6419/. Peripheral Defocus (Fig 1). Regarding the physiological development of myopia, there are two main ideas. One idea proposes that hyperopic retinal blur generated by a substantial lag in accommodation during near work increases axial elongation. A second idea posits that mechanical stress caused by the ciliary body or crystalline lens prevents equatorial ocular expansion, therefore generating rapid axial elongation. Both ideas highlight the complex interplay between optical and mechanical factors in the eye's growth process. Understanding these mechanisms is crucial for developing effective interventions to slow the progression of myopia in children and adolescents shown in fig1 [33] It's important to consider the possibility of serious pathology. The possibility of severe myopia-related pathological consequences in the macula, peripheral retina, optic nerve, and lens should not be overlooked. In this context, the Rotterdam Eye Study reported in a population-based cohort study the existence of bilateral vision impairment in highly myopic eyes, with 39% of patients suffering from myopic maculopathy, 17% from open-angle glaucoma, and 5% from cataracts. Furthermore, it has been shown that an early onset of myopia is more strongly associated with a more severe form of the condition in adulthood [34]. Commercial designs using peripheral myopic defocus (MD) have been shown to be more effective than single-vision spectacle lenses (SVLs) in terms of slowing eyesight expansion and axis elongation. Tiny optical components that are formed concentrically on the front lens surface are used to implement the MD in the MD lenses [11]. Previous research has shown that myopic defocus stimulation causes cellular and metabolic alterations in the retinal pigment epithelium, which can delayretinal growth signals to

the sclera, influencing eye growth management and myopia regression. Orthokeratology, MFSCLs, and PPSLs have all been used to induce peripheral myopic defocus with the goal of decreasing myopia progression [35].

**Multifocal Lenses for Myopia Control**

Today, the majority of the more multifunctional and successful contact lens designs are produced on soft substrates. Its bigger diameter and flexibility allow for greater control over centration and lens movement than corneal RGP contact lenses. Recently, multifocal designs have been implemented on hybrid and scleral lenses, providing an effective solution for myopia progression control.Recently, multifocal designs have been launched on hybrid (in which the core region of the contact lens is produced with rigid gas permeable materials) and scleral lenses, providing an ideal approach for controlling myopia development [36]. Arrangement intends to create myopic defocus on the retina, reducing axial length elongation. MFLs are currently available in two primary designs: concentric rings/bifocals (BF) and progressive power/peripheral add lens. The near- and distance-vision spectrums are meant to be supported by both designs. The BF design incorporates two zones for myopia correction applicable to all gaze positions, along with two adjacent concentric treatment zones that include plus power addition to concurrently provide peripheral myopic defocus. In contrast, the PAL design consistently generates peripheral myopic defocus that progressively intensifies from the central optic axis towards the periphery [37]. Multifocal lens (Fig 2 ). https://www.youtube.com/watch?v=p-skBMkmRT4

**Comparative Efficacy of Different Lens Designs**

Recent research has reported the designed phase patterns of different multifocal contact lens models (e.g., Charman detailed the power profile of the Pure Vision and Acuvue Oasys along a radius of 3.0 and 3.5 mm, respectively, with nominally 0.00 D distance power). This information is required to create realistic individual simulations on model eyes, comprehend the multifocal performance of various distributions of near/far zones over the pupil, and interpret the visual results[36]. Originally created to lessen the relative peripheral hyperopic defocus, aspheric spectacle lens designs did not significantly slow the progression of myopia. However, daily use of newly designed DIMS spectacle lenses was related to a considerable delay of myopia progression and axial elongation in myopic youngsters, and the lenses were well accepted [38]. There are numerous orthokeratology lens brands on the market, which might make it difficult to select the best lens for myopic children. It is critical to determine whether there is a difference in the efficacy of myopia correction between the various OK lens designs. Previous research revealed similar relative peripheral refraction changes between two OK lenses, as well as comparable efficacy in delaying AL elongation between four distinct brands of OK lenses with the same lens design. However, recent research has found that a smaller center treatment zone diameter in topographic tangential maps may have a higher effect on slowing AL elongation. also noted that altering the OK lens's structure [lowering the optic zone diameter (OZD)] increased its effectiveness in terms of regulating the progression of myopia. However, it is uncertain whether the efficacy in myopia management varies between the available designs of OK lenses [39]. The development of trifocal diffractive lenses addressed the intermediate vision constraints of bifocal intraocular lens (IOL) designs. The designs were made so that the close focus point's dioptric power was double that of the intermediate target in order to lessen the possibility of growing visual disturbances. As a result, the second harmonic of the intermediate focus point added to the useable light energy at the near point. This trifocal design can be seen in the fine vision. There is one haptic design in the Toric version of the lens and another in the non-Toric version [40].

## CONCLUSION

The new developments in spectacle lens technologies represent a potential new direction in the treatment of myopia progression, particularly in children and adolescents. The present review has systematically appraised and integrated findings from different studies under well-defined inclusion and exclusion criteria, offering a targeted assessment of emerging next-generation lens designs including peripheral defocus lenses, multifocal lenses, and other novel developments. Such lenses, especially models such as DIMS (Defocus Incorporated Multiple Segments), HAL (Highly Aspherical Lenslets), and Stellest, have shown significant decreases in axial elongation and myopia

progression, highlighting the promise of non-invasive optical-based treatments. Multifocal lenses, initially designed for presbyopia, are increasingly being repurposed with adaptations to fit into pediatric myopia control measures. Even with promising outcomes, variability in response to treatment, long-term effectiveness, and adherence issues are still areas of important future research. Further improvement may be achieved by adding personalized lens design, advanced material technology, and combination with digital health devices. In summary, next-generation spectacle lenses are an accessible, clinically useful, and safe way of controlling myopia progression. Continued, quality longitudinal studies are necessary to refine these technologies and extend their reach to clinical use globally.

## ABSTRACT

Surface Mounted Permanent Magnet Synchronous Motors (SPMSM) are popular in electric vehicles and industry because they are strong and efficient. However, controlling them without sensors when they start or move slowly is difficult. In this article, several strategies are outlined for effectively initiating them and smoothly transitioning to sensorless control. This article introduces a new, straightforward approach to implementing the current-frequency method, utilizes the Root Mean Square (RMS) value of back electromotive force (emf) at starting. Since back emf is linked to the motor's speed, it remains quite low at reduced speeds. Once the motor achieves approximately 10-15% of its maximum speed, it transitions to sensorless control as enough RMS value of back emf developed. The SPMSM is tested on MATLAB with different loads and speeds. The findings reveal that the method described here reduces acceleration time of the electric vehicle and does not deteriorate the dynamic performance.

**Keywords:** Permanent Magnet Synchronous Motor(PMSM), I-F Start up,Electric Vehicle(EV), Sensorless Control, Dynamic Performance, Sliding Mode Observer (SMO)

# INTRODUCTION

The rapid shift toward sustainable transportation has accelerated the development and adoption of electric vehicles (EVs). Among the various traction motor candidates, Permanent Magnet Synchronous Motors (PMSMs) are widely favoured because of its exceptional efficiency, compact size, high torque density, and superior dynamic performance compared to induction machines and switched reluctance motors [1]–[8]. The SPMSMs are particularly well-suited for applications requiring high power efficiency [9]. Basically, EV drives utilized SPMSM necessitates mechanical sensors, including resolvers and encoders, to observe rotor position feedback for accurate torque and speed control. However, adding sensors makes the drive system complex, costly, bulky and making it less dependable in demanding operating conditions [10]–[12]. So, the sensorless control techniques have been the focus of extensive study to overcome these constraints. By estimating the rotor speed and position using electrical signals, like current, voltage, and back-electromotive force (EMF), sensorless control terminates the necessity for physical position sensors. This strategy not only strengthens the system's resilience and dependability but also lowers expenses, rendering it immensely advantageous for EVs, where dependability and efficiency are crucial [1], [13]–[15].

**Classification of Sensorless Control Methods and Limitations**

The two main categories of sensorless strategies are: (1) model-based methods, which relies on back-EMF or flux linkage estimation at medium-to-high speeds and (2) signal injection methods, which utilize saliency effects at low or zero speed [16]. Signal injection methods provide additional harmonic distortion and losses even if they provide high-resolution estimates at low speeds [10], [15], [17]. Back-EMF-based techniques, conversely, are manageable and efficient at faster speeds but insufficient close to a halt. However in order to ensure reliable operation throughout the entire speed range, hybrid sensorless control approaches that incorporate several estimation strategies have been proposed [18], [19]. Researchers have struggled with the complexity of hybrid sensorless control approaches, despite their advantages in terms of operational performances [19]. Significant improvements in the observer design for EV traction drives have been shown in recent investigations. Despite their chattering and noise sensitivity, Sliding Mode Observers (SMOs) have been extensively employed because of their robustness against parameter uncertainty. To address these issues, better designs have been introduced, including synergetic observers [1], Fast Terminal SMO [18], and fuzzy logic-based SMO [20]. A reliable back EMF estimator, paired with a straightforward startup method, is more advantageous as long as this method can bring the SPMSM up to a speed where the back EMF is sufficiently elevated.

The voltage/frequency (V/f) approach, which is extensively used in the control of induction motors, serves as a conventional startup technique. It is a straightforward open-loop control method without position or current feedback, but it becomes unstable under load and could cause torque ripple [21]. To overcome the disadvantages of the above method, straightforward startup approach, referred to as the I-f method, is introduced, featuring closed-loop current control and lacking position feedback for the PMSM. Additionally, signal injection methods for low speed are not suitable for surface-mounted PMSMs (SPMSMs) because they lack saliency, add noise, torque ripple, and additional losses owing to continuous HF excitation, require complex demodulation and filtering circuits, and increase the controller cost and computational load [22]. Therefore, current-frequency (I–f) startup strategies are widely applied to enable a smooth transition from standstill to sensorless field-oriented control (FOC) owing to their simplicity, self-stabilisation, robust startup under load conditions [23], prevention of pole slipping, and reduced oscillations [1], [22], [24], [25]. In the context of EVs, where motors must operate over wide speed ranges and withstand frequent transients, the development of robust and efficient sensorless control schemes remains a crucial research direction. Recent studies have proposed hybrid approaches that combine I–f startup with advanced observers, such as SMO, QPLL, adaptive QPLL [26], MRAS, fuzzy logic controllers [10], [18], [20], and Q-MRAS with fuzzy logic controllers [27]. This paper compares the time required to reach up to the full speed for existing hybrid sensorless methods for SPMSM

**Sensorless Control Technique**

**Sliding Mode Observer (SMO)**

The medium- to high-speed range typically employs a position estimation algorithm for back-EMF observation [28], [29]. The basic principle is to use the voltage or current in the fundamental wave mathematical model to obtain the back EMF signal containing the rotational speed and rotor position information by mathematical calculation, and then extract the rotational speed and rotor position information from the back EMF signal [30]. Commonly used methods include extended Kalman filtering, model reference adaptation, flux-linkage observer, state observer, artificial intelligence-based estimation, and sliding mode observer [29]. The sliding mode observer approach is popular because it is reliable and easy to compute when compared to other approaches [20].

The dynamic model of the PMSM system is illustrated within the rotating d-q reference frame, which is fixed to the rotor and is a standard approach in motor control.

$$\frac{di_d}{dt} = -\frac{-R_s}{L_d} i_d + \frac{\omega_\gamma L_q i_q}{L_d} + \frac{v_d}{L_d} \quad (1)$$

$$\frac{di_q}{dt} = -\frac{-R_s}{L_q} i_q - \frac{\omega_\gamma L_d i_d}{L_q} + \frac{v_q}{L_q} - \frac{\omega_\gamma \psi_f}{L_q} \quad (2)$$

Where $i_d, i_q, V_d$ and $V_q$ are respectively currents and voltages of stator in d-q reference frame, $\Psi_f$ is the Permanent Magnet rotor flux, $\omega_r$ is the angular velocity in electrical, $R_s$ is the stator resistance, $L_d$ and $L_q$ is the direct and quadrature axis stator inductances respectively. In SPMSM $L_d = L_q$ While in interior PM motor $L_d < L_q$.

Now the structure of SMO based PMSM model is:

$$\frac{d\hat{\imath}_d}{dt} = -\frac{-R_s}{L_d} \hat{\imath}_d + \frac{\hat{\omega}_\gamma L_q \hat{\imath}_q}{L_d} + \frac{v_d}{L_d} + kS_d + \varepsilon F(S_d) \quad (3)$$

$$\frac{d\hat{\imath}_q}{dt} = -\frac{-R_s}{L_q} \hat{\imath}_q - \frac{\hat{\omega}_\gamma L_d \hat{\imath}_d}{L_q} + \frac{v_q}{L_q} - \frac{\omega_\gamma \psi_f}{L_q} + kS_q + \varepsilon F(S_q) \quad (4)$$

where $\hat{\imath}_d$, $\hat{\imath}_q$, and $\hat{\omega}_\gamma$ are the estimated quantities of $i_d$, $i_q$ and $\omega_\gamma$, $\varepsilon$ and $k$ are the sliding mode observer gain and $S_d$ and $S_q$ are the sliding surface $S$, determined like:

$$S=[S_d, S_q]^T = [i_d - \hat{\imath}_d, i_q - \hat{\imath}_q]^T \quad (5)$$

Sliding surface is the error between estimated quantities and measured quantities, when sliding mode occurs, the error becomes zero [31]. SMO utilize signum or sigmoid function to reduce chattering effect, here sigmoid function is applied which is more effective than sigmoid function [32]. F(x) is a sigmoid function which is expressed as

$$F(x) = \frac{2}{(1+e^{-ax})} - 1 \quad (6)$$

Where $a$ is a controlling parameter. By adjusting gain of $\varepsilon$ and $k$ position estimation error converges to S=0. In Conventional SMO, after the extracting the estimated back emf, the rotor speed and position are estimated as

$$\hat{\omega}_\gamma = \frac{1}{\psi_f} \sqrt{e_\alpha^2 + e_\beta^2} \quad (7)$$

$$\widehat{\theta_r} = tan^{-1}\left(\frac{-e_\alpha}{e_\beta}\right) \quad (8)$$

Nonetheless, the arc-tangent approach has several drawbacks, as the accuracy of the estimated speed and position is significantly affected by harmonics having high frequency and noise. Additionally, it lacks information when the

back-EMF reaches zero. Some authors proposed a PLL based estimator for accurate rotor position estimation and to overcome disadvantages of arctan method[33], [34].

**Current-Frequency (I-F) start up strategy**

Error-free rotor speed and position information are indispensable for high-performance SPMSM control. Mechanical sensors such as encoders increase cost and reduce reliability, motivating the development of sensorless methods [25]. Back-EMF observers from medium to high speeds are effective, but near zero speed their performance deteriorates [18]. Therefore, a reliable startup strategy is required to accelerate the SPMSM to a region where sensorless estimation is feasible. Among these, current–frequency (I–f) control is widely used due to its uncomplicated and inherent current limiting capability [19], [22], in that a fixed amplitude current vector with predetermined frequency ramp up is applied to start the SPMSM [35]. As soon as the motor achieves 10-15% of rated speed a smooth and accurate changeover to sensorless Field Oriented Control (FOC) classified as back emf type is required. Due to its open-loop construction and lack of position or current feedback, the V/f control may cause the motor to lose synchronism and operate unsteadily, particularly under load [36]. So, this I–f starting method seems to offer a more effective way to ensure a smooth and reliable startup process in comparison with open-loop V/f startup method.

**Startup Procedures**

**Initialization:** Initiating from a complete halt, a ramp up speed reference command is generated with a gradual rate of change to serve as the target speed. The q-axis reference current in the virtual frame is kept constant to start the motor using a closed current loop.

**Transition:** Once the motor attains the ideal speed range for SMO, the speed determined by SMO is utilized to close the speed loop, ensures a seamless changeover of the q-axis current and rotor position.

**Closed loop FOC operation:** After the completion of transition process, the speed PI regulator produces the reference current for the q-axis. The control system relies on the motor speed and position estimated by the SMO.
These three processes are referred to as I-f startup, method transition, and classical FOC for simplicity's sake [37].

**Proposed Mehtod**

Back EMF in SPMSM is proportional to rotor speed and permanent magnet flux and is very low at startup, complicating sensorless control. It is estimated at medium/high speeds to enable sensorless rotor position and speed estimation. So requires startup strategies (e.g., I-f method) to bring motor speed into the effective back EMF estimation range. Figure 1 illustrates the block schematic of the suggested innovative method.

$$E_b = k_b\,\omega \tag{9}$$

Root Mean Square (RMS) value of $E_b$ increases as speed of the SPMSM increases, Initially, the motor operates in open-loop mode, and once the motor speed reaches approximately 10-15% of its rated speed, a sufficient RMS value of back EMF is generated. At this point, the motor transitions to sensorless control using SMO. The reference rotor position is calculated by integrating the speed command as mentioned in equation

$$\theta_r^* = \int \omega_r^* \mathrm{dt} \tag{10}$$

Where $\theta_r^*$= reference rotor position, $\omega_r^*$= reference rotor speed

The SPMSM motor torque is given in terms of difference between real and virtual reference frame by

$$T = 1.5pi_q^* cos\theta_e\,\psi_f \tag{11}$$

Where $i_q^*$= reference value of q axis current, $\theta_e$ =difference between real and virtual reference frame in rad
p= no. of pole pair

The limiting value of slope of speed reference is given by

$$K_\omega^* < \frac{1.5pi_q^*\psi_f - T_{L,max}}{J} \quad (12)$$

Where J= moment of inertia in kg-m$^2$, $T_{L,max}$= maximum load torque during start up in N-m
Smaller value of $K_\omega^*$ greatly reduces a speed fluctuation.

When the motor has reached a fairly high velocity, it is crucial to maintain $\theta_e$ within its effective range; otherwise, the motor will immediately lose synchronization. To ensure $\theta_e$ remains within this effective range, $i_q^*$must be sufficiently large to accommodate all potential loads. The limiting value of the q-axis reference current is determined by

$$i_{q0}^* > \frac{JK_\omega^* + T_{L,max}}{1.5p\psi_f} \quad (13)$$

**Circuit Simulation**
The innovative method proposed is tested using MATLAB simulations across different speeds and load torques. Figure 2 shows the entire simulation setup, which includes the I-F startup block, PI controller gain, and Sliding Mode Observer. Figures 3, 4, and 5 depict the comprehensive structure of SMO, the initiation of I-F with RMS value, and SPWM with FOC incorporated into the entire MATLAB simulation setup, respectively.

The rating of the SPMSM is: Speed=3000rpm, Rated torque=30Nm, $R_s = 0.02$ ohm/ph, $L_d = L_q = 0.45$ mH, J=0.012 kg-m$^2$, $B_v = 0.001$ Nms/rad, $\psi_f$ =0.14wb. To generate sufficient torque for operating the motor under load conditions, an initially set value of $i_{q0}^*$is applied, which is later adjusted to the actual reference value of $i_q^*$ . The precise value of $i_q^*$ determined using equation (13).The calculated value of $i_{q0}^*$= 63A, i.e. this set value required for initial start up of SPMSM, and when motor speed reaches upto the 10-15% of rated speed, i.e. for 3000 rpm it's around 300-350 rpm,actual reference value of $i_q^*$is applied. The subsequent section delves into the discussion of the results and their implications.

## RESULTS AND DISCUSSION

The SPMSM undergoes testing at both its rated speed and under conditions of full and half load. The RMS value of the back emf is set at 15V, which is directly proportional to speed and represents 10-15% of the rated back emf value. The rated RMS value of the back emf is approximately 125V. This approach simplifies the I-F startup method and shortens the transition period by incorporating just an RMS block into the startup process.

**Rated speed and rated load**
Here the SPMSM speed is set at 3000rpm and at rated load of 30Nm is applied and the corresponding result is mentioned in figure 6. Result shows that initially motor starts in the open loop mode by I-F start up method as the RMS value of back emf is almost negligible at starting due to very low speed. When the motor speed reaches 300 rpm, a sufficient back emf of 15V is generated and the motor is redirected to the SMO based sensorless control. The SPMSM takes approximately 3.5 seconds to achieve its rated speed of 3000 rpm with a torque of 30 Nm. The transition from initial I-F start up to sensorless SMO based control is depicted here in figure 7, revealing an undesirable glitch in the speed that requires improvement to avoid jerky motion. A transition time of approximately 0.01 seconds is noted, which is quite brief. The anticipated back emf from SMO is completely sinusoidal at high speed, as shown in Figure 8. Figure 9 demonstrates that the RMS values of the estimated back electromotive force

(emf) and speed exhibit an identical pattern, with both parameters aligning precisely. This alignment underscores the simplicity, innovation, and efficacy of the suggested method. Figure 10 presents the profiles of both the estimated and actual rotor positions. A minor discrepancy is observed between the rotor positions that are estimated and real, attributable to the absence of a compensation method. Figure 11 displays the error profile between the estimated and actual rotor positions, indicating an observed error of approximately 0.43 radians. Figure 12 illustrates the current components id, iq, and the electromagnetic torque T generated by the motor, which exhibit some fluctuations due to the lack of ripple reduction techniques.

**Change in speed with rated load torque**

Figure 13 depicts how the motor reacts when its speed is reduced while keeping the rated load torque constant. In this instance, the reference speed is decreased from 3000 rpm to 1800 rpm, and it is observed that the SPMSM matches the reference speed. The motor requires about 2 seconds to achieve the reference speed, which is considered a brief period. Subsequently, the speed is increased from 1800 rpm to 2500 rpm, and the SPMSM aligns with the desired speed, taking roughly 1.8 seconds to stabilize. Figure 14 shows the variation in the RMS value of back emf with speed, illustrating the successful application of the proposed method across low, medium, and high speeds.

**Change in speed with half of rated load torque**

Figure 15 illustrates the time how long it takes for the SPMSM to reach the steady state value set by the reference when there is a speed change. With a load torque of 15 Nm, the motor requires about 2 seconds to accelerate from 0 to 3000 rpm, approximately 1.8 seconds to slow down from 3000 to 1800 rpm, and nearly 1.5 seconds to speed up from 1800 to 2500 rpm. The results demonstrate that the newly proposed method performs effectively under various dynamic conditions. Figure 16 shows the change in the RMS value of back emf as speed varies, highlighting the successful implementation of the proposed method across low, medium, and high speeds, similar to figure 14. Table 1 offers an overview of the results achieved by the proposed approach.

## CONCLUSION

Without relying on position sensors, the RMS-based I-F startup method offers an easy and efficient approach to start SPMSM drives for EVs. The SPMSM seamlessly switches to sensorless control at 10–15% of its rated speed by RMS value of back-EMF as the switching criterion. This method does not degrade dynamic performance during startup and transition states, according to MATLAB simulations. The SPMSM exhibits good starting performance, reaching 3000 rpm under full load in roughly 3.5 seconds. With only a small and transient speed change, the changeover from I-F startup to SMO-based sensorless control is quick. The accuracy of the technique's is confirmed by the tight match between the estimated back-EMF and speed profiles. Rotor position estimation exhibits low inaccuracy, which can be further reduced with compensation techniques. The technique operates reliably different dynamic conditions, such as speed changes and load torque variations. In both full and half load scenario, the system maintains stability and precisely tracks the reference speed. After all thing considered, this innovative straightforward approach sustains good dynamic performance, simplifies the complexity, and increases the practicality of sensorless SPMSM drives for electric vehicle applications.

## ABSTRACT

Neurodegenerative disorders are a set of infirmities that are chronic, progressive and primarily characterized by neuron dysfunction in the central nervous system. The most ubiquitous degenerative brain conditions include multiple sclerosis, Alzheimer's disease, Parkinson's disease, Amyotrophic lateral sclerosis (ALS), and others. Multiple sclerosis (MS) and Parkinson's disease are well-defined neurological degeneration diseases with different pathophysiology. In humans, MS is a prolonged, inflammatory, myelinoclastic disease of the central nervous system with an unrevealed cause. Parkinson's disorder (PD) has movement complications due to inflammation, alpha-synuclein aggregation, dysfunction of mitochondria, and the absence of communication between nerve cells in the brain. The pathophysiology of the neuroinflammation process remains to be fully understood; nevertheless, recent evidence suggests that the Nuclear Factor-Kappa B (NF-kB) signalling alley is a central mediator of neuroinflammation, which plays a crucial role in the development of neurological conditions such as Multiple Sclerosis and Parkinson's disease. In MS, NF-kB activation is involved in cell immunological activity, apoptosis, and infections, and promotes the expression of proinflammatory cytokines, including IL-1β and TNF-α, driving T-cell-mediated demyelination. Similarly, in PD, NF-kB activation causes neuroinflammation through glial activation, cytokine release and is embroiled in the gradual loss of dopaminergic nerve cells. In this review, we explore the common dysfunction of anti-inflammatory pathways in Multiple Sclerosis and Parkinson's disease, emphasizing cellular immune, overactive pro-cytokines, activated microglial and astrocytes, NF-kB and Nrf2 signalling as key regulators that converge on mechanisms that link both neurological diseases. A deeper understanding of these shared inflammatory pathways may

suggest new therapeutic options for targeting neuroinflammation and suppressing the progression of neurodegeneration.

**Keywords:** Multiple Sclerosis, Parkinson's disease, inflammation, demyelination, Neurodegeneration

## INTRODUCTION

**Multiple sclerosis**

Multiple sclerosis (MS) is a persistent autoimmune, inflammatory, myelinoclastic disorder in the central nervous system (CNS) with an unidentified cause in humans and triggers visual disability, motor dysfunction and sensory impairment, along with mental deterioration, bladder and bowel function [1,2]. According to present findings, Multiple Sclerosis has been characterised as an autoimmune disorder and mediated by autoreactive cells that infiltrate the obstacles in the circulatory system, leading to diffuse and triggering the inflammation at the specific site, resulting in pain and loss of sensation[3]. Neuroinflammatory lesions occur in the brain and neural cord as well as other sites of the central nervous system, leading to a large number of neurological symptoms and also heterogeneity of clinical signs. MS shows increasing rates in both developed and developing regions, with a marked females more commonly affected than males, and the highest risk observed among individuals of Northern European ancestry[4]. Approximately 0.2% of the global population is affected by MS and it primarily occurs in people in early to adulthood between 20-40 years of age [5], but it may also appear during the juvenile phase or late middle age. The precise etiology of Multiple Sclerosis remains unidentified, but this could be an amalgam of hereditary and nongenetic inclusion, as well as initiating contributors such as viruses, metabolism, gut microbiome alterations, or environmental exposures like low vitamin D levels or smoking[4]. Multiple sclerosis (MS) is broadly categorized into three major clinical classes based on the onset of disease trajectory: Relapsing-remitting MS (RR-MS), Secondary progressive MS (SP-MS), and Primary progressive MS (PP-MS) [6]. Relapsing-remitting multiple sclerosis is the foremost predominant subtype, affecting approximately 80% of patients, which is marked by exacerbation of neurological clinical features followed by a remission phase, whenever clinical signs are alleviated or resolve. In some patients with RR-MS may develop into SP-MS, where the disorder slowly worsens with or without periods of remission or plateaus. In some cases, it has been observed that underlying agents prolong the development of Multiple Sclerosis. Another type is primary progressive MS (PP-MS), which occurs in approximately 10% of Multiple Sclerosis patients, is characterised by slow progression of manifestations from the beginning without any relapses or remission, and this form of MS is less responsive to standard therapies [7-9].

**Etiology**

Several risk factors contribute to the progression of multiple sclerosis, including age, sex, race, heredity, geography and interaction with certain causative agents, including herpes simplex virus, chlamydia, and rabies [10]. Multiple sclerosis is generally triggered by an autoimmune in which the immune system unknowingly assaults the CNS due to an overactive immune response leading to inflammation and this process is explained by two theories: the "outside-in" theory suggests that an unknown antigen promotes and activates immune cells, especially T-helper1 (Th1) and 17T-helper (Th17), which then traverse the blood-brain-barrier and attack to the CNS. Another theory, "inside-out," asserts that a congenital dysfunction of the CNS produces results in inflammation mediated tissue impairment.[11] People living away from the equator have a high incidence of multiple sclerosis. In Australia, Multiple sclerosis is more common in Tasmania (75.6 cases/ 100000 population) than in tropical Queensland (11.8/ 100000). In Australian latitudes, difference in MS rates is not linked to HLA antigens frequency or ethnicity; however, it supplies confirmation that the contribution of environmental influences, including vitamin D insufficiency, tobacco use, birth season, and Epstein-Barr virus exposure, may play an important involvement in the development of the disorder.[12]

**Pathogenesis of Multiple sclerosis**

The distinguishing features of Multiple sclerosis are the occurrence of demyelinated plaques scattered throughout the CNS, as well as inflammation, demyelination, and destruction of neuron's axons. These plaques affect white and grey matter in the brain and spinal cord. Autoreactive immune cells mediate the progression of multiple sclerosis as they enter into CNS via the BBB. throughout the development of the thymus or bone marrow process, the body removes hazardous immune cells through central tolerance, a process involving B cells. However, some of these hazardous cells may escape and enter into bloodstream. In most cases, peripheral tolerance mechanisms act as a safeguard to suppress autoreactive immune cells, preventing them from a pathological state. Abnormalities in regulatory T-cells or the resistance of T-cells result in the inability of peripheral tolerance [13]. Evidence suggests that CD4+ T cells are a subtype of T helper cells (Th-cells), are stimulated by the interaction between antigen-presenting cells (APCs) and T lymphocytes, responsible for the onset and progression of Multiple sclerosis [14, 15]. Th1 cells release proinflammatory cytokines, such as interferon gamma (IFN ɣ) and tumor necrosis factor alpha (TNFα), which can block Th2 cells development, leading to inflammation [16-18]. Similarly, Th2-cells also liberate IL-4 and IL-13. IL-4 can promote and reduce inflammation depending on the immune response. IL-13 has similar functions to IL-4, particularly during allergic inflammation [19]. Another type of CD4+ T cell is Th17, which also promotes inflammation [20]. Many studies have shown that multiple sclerosis can also develop due to increased concentration of immunoglobulins in cerebrospinal fluid (CSF), which exhibits an important aspect in relation to progression, especially CD27+ memory B-cells are present in large amounts in the CSF and brain parenchyma, where they have mutated their antibody genes and recognised the targets to produce class-switching antibody. They are highly active in the immune response [21]. Certain cytokines, comprising tumor necrosis factors (TNF)- $\alpha$ and interleukin (IL)-1β, released by microglia and microphages, lead to brain disorders via cytokine-induced apoptosis, block astrocytic glutamate presynaptic uptake and cause malfunctions in RNA-binding proteins. Glutamate is also released from microglia and macrophages, which causes glutamate excitotoxicity and neurodegeneration [22]. In immune regulation, Regulatory T cells (Tregs) play a crucial role in releasing anti-inflammatory cytokines, such as IL-10 and TGF-β and by curtailing autoreactive T-cells and B-cells. Several types of Tregs help maintain immune equilibrium and prevent autoimmune disorders [23]. In multiple sclerosis, Tregs don't function properly due to a dysregulated effector T-cell response [24]. These dysfunctions may result in the development of harmful lymphocytes and targeting these cells could be a helpful treatment [25]. Tregs can reduce the activation of encephalitic lymphocytes by blocking pro-inflammatory cytokine release and making T-cells inactive or promoting cell death. If they don't work regularly, it results in the development of Multiple Sclerosis [26-27]. Environmental triggers, including microbial exposure, sunlight exposure and as well as vitamin D, may be associated with the onset of illness and are believed to enhance the likelihood of progressing multiple sclerosis if one relocates to a new area earlier than the age of 15[28]. Several pathogens are possibly involved, including human herpes virus type 6, Epstein-Barr virus (EBV), and Mycoplasma pneumonia. Many researchers assume that progressive multiple sclerosis is due to molecular mimicry because the pathogens have peptides that have similar patterns to myelin [29]. The onset of MS is also associated with smoking [30], vitamin deficiency, especially vitamins D and B12, diet and exposure to ultraviolet B (UVB) rays from the sunlight [31]. Sometimes UVB helps to improve the symptoms and also lowers the amount of certain proinflammatory cytokines that cause hypertrophy and damage in the brain [32].

**Clinical features**

The clinical symptoms of multiple sclerosis are heterogeneous and often unpredictable, reflecting the multifocal nature of demyelinating deficits in the CNS, which lead to many neurologic symptoms. These symptoms can vary based on the anatomic location and may involve clinical presentations such as brainstem, spinal cord syndrome, optic neuritis and dominant parietal lobe syndromes [33]. Relapsing-remitting Multiple Sclerosis is a common subtype of MS that begins subacutely over hours to days, reaches a plateau over a period of weeks, and then gradually better. At the beginning of MS, gross clinical recovery from relapse may seem to heal completely, but most relapses tend to leave some damage, including chromatic vision, contrast sensitivity and distance perception. However, vision can improve with treatment after an acute optic neuritis. Loss of neuronal reverse leads to impaired recovery, resulting in accumulating neurological damage that causes permanent disability. Approximately 10 "asymptomatic" lesions are observed on MRI. In functionally important areas of the brain, even a small lesion can

cause neurological problems. Lesions visible on the Macroscopic image and MRI are only detected small part of the whole problem; many pathological changes are observed under the microscope and the majority are also present in the grey matter of the cortex. After 10-15 years of RRMS, it often develops into secondary progressive MS, which gradually worsens. In the preliminary phase of MS, cognitive dysfunction and increase in MRI shrinkage show that neural loss begins from the beginning of inflammation. Primary progressive multiple sclerosis (PPMS) develops in about 5-15% of individuals, which is characterised by the gradual decline the neurological function, typically affecting the dominant neural system. The most frequent symptom of PPMS is progressive spastic paraparesis, but other features such as cognitive impairment, sensory and cerebellar ataxia, and several visual disturbances are also reported. Recent evidence indicates the percentage of people diagnosed with PPMS has declined over time [34].

**Treatment**

Therapeutic approaches to MS consist of two main components: disease-modifying therapies and immunomodulatory therapy (IMT). IMT is used to treat MS by suppressing relapses and slowing the rate of progression. Currently, disease-modifying therapies are specific to MS, particularly in RRMS. Disease-modifying therapies are used to treat acute attacks, reducing biologic activity and ameliorating symptoms. Medication includes interferon-beta, natalizumab, dimethyl fumarate, fingolimod and ocrelizumab. The long-term treatment aim is to attenuate the chance of secondary progressive multiple sclerosis; the temporary treatment goal is to suppress MRI evidence of demyelination [35].

**Interferon-Beta**

In 1993, interferon beta (IFN-beta) became the first FDA-approved treatment for MS, which helps to suppress relapses, alleviating disability progression and MRI-detected deficit [36]. In RRMS, the Virtus curationis of INF-beta is wider than in Secondary Progressive Multiple Sclerosis. The specific mode of action of INF-beta remains unclear, but it may work by preventing T cell and its cell multiplication as well as reducing proteolytic activity of metalloproteinase. It also inhibits the synthesis of some harmful proinflammatory cytokines and the release of anti-inflammatory cytokines is stimulated by boosting negative regulator of T-cells activity [37]. Interferon-beta therapy affects the B-cell mechanism by decreasing MHC II and CD80 expression after treatment, which alters antigen presentation to CD8+ T cells. After interferon treatment, CD80+ cell numbers are reduced, balancing the ratio of CD80+ to CD86+ cells, resembling to healthy controls. CD80-expressing cells may be decreased as a consequence of IFN-beta-induced reduction in the formation of interferon gamma and other cytokines that enhance CD80+ B cells [38]. The main negative reactions of interferon-beta involve inflammation at the injection site due to subcutaneous administration, headache, fatigue, and influenza-like symptoms such as myalgia, fever, and shivering. Additional adverse effects include lymphopenia, thrombocytopenia, and elevated liver transaminase levels. Complete blood counts (CBC) and hepatic function tests should be carried out before initiating INF beta therapy and repeated regularly during therapy [39].

**Natalizumab**

Natalizumab (Tysabri) specifically interacts with the CD49 molecule, which is a humanized monoclonal antibody with an IgG4 framework and binds to the $\alpha$4-integrin of the very late antigen-4 (VLA-4) protein. Very late antigen-4 (VLA-4) is associated with vascular cell adhesion molecule-1 (VCAM-1), allowing defence cells to penetrate the BBB**.** Natalizumab inhibits this process by blocking the link between the defence cell and endothelial cell, which prohibits leucocytes from crossing into the CNS [40]. Natalizumab is mainly used for treating multiple sclerosis (MS), approved in 2004 by the FDA. In 2005, it was temporarily discontinued from commercial availability because some patients had a fatal condition - progressive multifocal leukoencephalopathy (PML). In 2006, it was reapproved to be administered as a monotherapy for RRMS [41]. Patient received a monthly infusion of 300mg natalizumab to suppress the relapse by a 69% rate compared to placebo. However, natalizumab didn't help to suppress disability in patients having SPMS symptoms [42]. The potential unwanted reactions of natalizumab can be managed by detecting JC virus antibodies in the blood. This type of antibody is abundant in most patients, which makes natalizumab less compatible for many patients. Some other integrin modulators, such as vatelizumab and monoclonal $\alpha$2-integrin

blockers, include firategrast and zaurategrast. Vatelizumab did not improve the MRI results, but it still increases regulatory T cells in RRMS patients [43].

**Glatiramer Acetate**

Glatiramer Acetate (GA) is a chemically produced peptide with an average chain length of 40 to 100 amino acid units, a combination of four types of amino acids- L-tyrosine (Y), L-alanine (A), L-glutamic acid (E), and L-lysine (K), and sold under the trade names Copaxone and Copolymer-1. Glatiramer Acetate's exact mode of action is not fully understood; however, available research finding indicates that GA prevents the outcome of various antigen-specific murine T cell hybridomas, enhances cytokines (TNF-alpha, IL-10 and IL-4), and Foxp3 expression in CD4+ CD25+ regulatory T-cells. Glatiramer Acetate is currently approved as a therapeutic agent for the treatment of Relapsing-Remitting Multiple Sclerosis. It is administered subcutaneously and post-injection systemically. The adverse effects may be shown as erythema, fibrosis, or lipoatrophy at the sites of injection, as well as other symptoms such as thoracic tightness, accelerated heart rate, dyspnoea, erythema, and palpitations [44]. The use of GA neither investigates the treatment of SPMS nor shows a significant clinical benefit in PPMS [45].

**Fingolimod**

The FDA approved fingolimod in 2010, which modulates the sphingosine 1-phosphate (S1P) receptor used as an oral DMT. It reduced the release of leukocytes from peripheral lymphoid organs and inhibited the influx of self-reactive lymphocytes into the CNS [46]. Additionally, it suppresses the movement of mature dendritic cells to peripheral lymphoid organs [47]. In animal models of EAE, fingolimod improves myelination [48]. Fingolimod requires first-dose observation (FDO) due to the chance of bradycardia from interaction with cardiac monocytes; therefore, after their first dose, all patients should be observed for six hours to monitor potential adverse events [49,50].

**Parkinson disorder**

Parkinson's disorder (PD) is a progressive neurological disease distinguished by initial neuronal apoptosis in dopamine-secreting nerve cells in the substantia nigra pars compacta (SNpc) and aggregation of alpha-synuclein protein within the cells. It is the second common neurological movement condition. Parkinson's disorder leads to motor abnormalities, including tremors, stiffness, later postural instability and slowed voluntary motor activity. It is also triggered non-motor symptoms like dementia and cognitive decline that may progress from mild cognitive impairment to dementia, significantly impacting the patient's daily functioning ability and independence [51]. Parkinson's disease mainly affects individuals younger than 50 years, and its prevalence is more common in old age people. Parkinson's disease shows more frequent prevalence in males than females, with a 1.4:1.0 male-to-female ratio [52]. Parkinson's disease is idiopathic with an unknown cause in most patients. Around 5%-10% of cases have been linked to genetic or external conditions, such as contact with compounds toxic to pests, herbs and other dense metals elevate risk, whereas smoking and caffeine consumption may offer some protective effects [53]. In the early 1800's English physician James Parkinson recognized Parkinson's disorder in his 1817 monograph "An Essay on the shaking palsy" and he called as paralysis agitans due to its progressive disability nature, such as stooped posture, resting tremor, shuffling gait, insomnia, and bowel irregularity [54]. Later, Charcot included bradykinesia and rigidity and officially termed the condition Parkinson's disorder [55].

**Causes**

The precise causative factors of Parkinson's disease are unresolved. A lot of epidemiological research has suggested that environmental contributors are linked to increasing the progression of Parkinson's Disorder [56]. Exposure to environmental factors such as water, farming, herbicides, pest control agents, industrial substances, plant fibres, pulp mills, and countryside lifestyle increases the risk factors. Moreover, certain exogenous toxins, including rare metals, cyanide, carbon-based solvents, lacquer thinner, carbon disulfide, and carbon monoxide, and intrinsic toxins, including tetrahydro-isoquinolines and beta-carbolines, have been associated with the progression of Parkinson's disorder. 1,2,3,6-methyl-phenyl-tetrahydropyridine (MPTP) is a neurotoxin formed as a residue of the prohibited production of an industrially derived meperidine derivative, which also contributes to the development of Parkinson's Disorder [57]. Toxic substances such as manganese, trichloroethylene, carbon monoxide, and other

agents' exposure can result in the progression of PD, but they differ clinically and pathophysiologically from idiopathic PD. Certain evidence suggests that β2-adrenoreceptor antagonists may enhance PD risk, while agonist targets the same receptor with a protective effect [58]. Around 5-10 % of Parkinson's disease cases show a similar inheritance with an autosomal-dominant pattern and 5% have Mendelian inheritance. In most of patient's cases, Parkinson's disease is considered idiopathic [59]. After the age of 60 years or older, monozygotic and dizygotic twins of PD patients have an equal to having PD; however, less than 50 years of age monozygotic patients had a much higher chance of showing PD [60]. Genetic factors may influence early-onset patients, whereas they have a limited role in sporadic PD cases. Several genes have been studied, such as Apo-ε4, superoxide dismutase (SOD)-1 and 2, glutathione peroxidase, tyrosine hydroxylase, catalase, and the dopamine D2, D3, and D4 receptors, but have not shown a link to increased PD [61]. In 1997, the first gene identified was *α*-synuclein (*SNCA*). Later, Parkin (*PRKN*) was also associated with autosomal recessive PD, was discovered [62,63]. Several lifestyle-related risk markers, including nicotine and caffeine consumption, are associated with reducing the chance of occurrence of Parkinson's disease and act as protective factors. Some other additional protective elements include higher serum urate, administration of ibuprofen and physical activity, also involve [64].

**Clinical features**

The manifestation of Parkinson's disease is typically linked to a set of motor and non-motor presentations.

**Motor symptoms**

Parkinson's disease is characterised by four main cardinal kinetic manifestations are tremor, rigidity, impaired postural control and bradykinesia. These four symptoms are collectively denoted as TRAP. Non-motor symptoms often occur months or even years earlier than motor symptoms, whereas the pre-motor or presymptomatic phase of PD shows 12-14 years earlier in the course of the illness [65]. In Parkinsonism condition, around two-thirds of patients having tremor may be diagnosed, and that may never progress. Tremor most prevalently appears in the hands, primarily starting in affects unilateral hand and showing "pill-rolling" type of symptoms. Resting tremors are reduced when the person moves or are absent during sleep. Muscle stiffness causes tightness during passive movement, but it can be managed with treatment [66].

**Non-motor symptoms**

Parkinson's disease also contributes non-kinetic manifestations, along with motor impairment, autonomic nervous system failure, behavioural changes, neuropsychiatric changes, sleep and sensory disturbances [67]. Non-motor symptoms typically fail to respond to dopamine therapy as well as motor symptoms; they can cause significant obstacles to patients' well-being and proper management in Parkinson's disorder [68]. Certain non-motor characteristics might arise after years or even several decades earlier the movement problems develop, and nearly 90% of patients will go through these clinical features for the disease [69]. Non-motor symptoms of Parkinson's disease (PD) can occur as a part of the condition, and PD medication can either cause or worsen these symptoms. Medication, particularly L-DOPA dosage, may be associated with adverse effects like orthostatic hypotension, psychosis, and sleep attacks [68]. In PD, cognitive decline and dementia are also common and typically emerge gradually. PD dementia is subcortical, characterised by personality changes, psychomotor slowing, and memory impairment. Multiple-tasking, memory retrieval, decision-making, and visuospatial perception issues occur. Later in the illness, PD dementia develops, whereas DLB and Parkinson's syndrome are linked to early-onset dementia. Patients with Parkinson's disease are associated with a six times higher chance of progressing to cognitive decline [70]. psychosis, especially visual hallucinations, is the most frequent psychotic symptom, arising in nearly 40% of patients receiving drug therapy during the treatment phase [71]. PD patients with Parkinsonism get affective disorders like anxiety, melancholy, and apathy. Both early and late PD conditions have mood abnormalities are the most problematic non-motor symptoms [72]. PD-related autonomic dysfunction may include orthostasis, dysphagia, constipation, sexual dysfunction, fecal incontinence, urinary difficulties, and sialorrhea with the chance of rising age, advancement of disorder, and increased dopaminergic therapy [69].

**Pathophysiology**

For the purpose of comprehending and effectively managing the complex pathophysiology of Parkinson's disorder's is essential for understanding and controlling its progression. The neurological condition Parkinson's disease (PD) is identified by a distinctive collection of movement problems brought on by the loss of dopamine-producing neurons in the brain. Trembling, rigidity, bradykinesia, and trouble balancing are a few examples. The causes of Parkinson's disease are unknown, although it is believed to be associated with genetics, senescent neuronal modifications, and problems with a certain polypeptide called alpha-synuclein aggregation [73,74]. The patient's capability to communicate and motor functions may be severely compromised by Parkinson's disorder. Parkinson's disorder mostly disrupts the brain's dopamine-producing neurons, which are responsible for muscle activity; these neurons gradually weaken or undergo apoptosis. The person's motions thus become restricted, sluggish, and occasionally accompanied by tremors. The age of the person and any associated brain changes that affect how PD symptoms develop [75]. PD pathogenesis has been coupled to several processes, and intracytoplasmic lewy bodies play a crucial role in the development of the disorder. Parkinson's disorder is thought to be triggered by numerous processes. Many studies have shown that impaired proteostasis, neuroinflammation, and mitochondrial impairment all have a key role in the onset and course of the illness. However, the link between these pathways is unknown till now.

**Aggregation and misfolding of $\alpha$-synuclein**

The main form of initial proteins of lewy bodies is unfolded in the brain and does not have a distinct tertiary structural frame [75]; however, it assembles as a stable tetramer polymer that generally doesn't precipitate in aqueous solutions [76]. When $\alpha$-synuclein associates with negatively charged lipids, like the phospholipids found in cytoplasmic membranes, the N-terminal folds into $\alpha$-helical structures [77]. A β-sheet-like structure, an amyloid-like conformation that is susceptible to aggregation, is adopted by $\alpha$-synuclein in Parkinson's disorder. In fact, Lewy Bodies include filaments of misfolded lwey bodies approximately 5 to 10 nm in length. The conformational modification that results in aberrant $\alpha$-synuclein aggregation has been attributed to a couple of methods, such as C-terminal truncation, ubiquitination, and serine 129 phosphorylation [78,79]. Therefore, $\alpha$-synuclein has different molecular forms and is found in the brain of individuals having Parkinson's disorder, including unfolded soluble oligomers, protofibrils, monomers, and large molecular weight insoluble fibrils [80]. The early oligomeric form of $\alpha$-synuclein, as opposed to the mature insoluble fibrils, is the most neurotoxic form, according to evidence from recent animal model investigations [81,82]. These polymers are more dangerous than fibre-like lwey body aggregation, which is confirmed by cell-based tests [81].

**Mitochondrial impairment**

Malfunction of the mitochondria is a significant aspect in the progression of an unknown cause of an inherited nature [82]. Studies on Parkinson's disorder brains have shown that the substantia nigra pars compacta (SNpc) is a crucial link in the electron transport chain, and it has shown attenuated activity of mitochondrial complex I. These findings contribute to one of the first well-established links between Parkinson's disorder and mitochondrial impairment [83]. Complex I deficiency was also present in the PD patients' striated muscle and platelets when comparing disease-free individuals [84,85]. After it was shown that MPTP misuse resulted in sustained Parkinsonian symptoms [86], postmortem investigation depicted apoptosis of dopaminergic neurons [87], and further investigation divulged that metabolised MPTP is assimilated by Dopaminergic neurons and triggers complex I inhibition [88]. Apoptosis of dopaminergic neurons may cause malfunction in mitochondrial complex I in response to energy deprivation [89]. In animals as well as in humans, certain chemicals and herbicides disrupt mitochondrial complex I function, including paraquat and rotenone, which results in dopaminergic cell loss and a characteristic Parkinson's disorder [82]. Significant proof implicates mitochondrial impairment in Parkinson's disorder pathogenesis, as numerous genes linked to familial PD are linked with mitochondrial homeostasis. PINK1 and parkin (PARK2and PARK6) are crucial elements in the mitophagy pathway that regulate the eradication of damaged mitochondria [90]. Both genes loss-of-function mutations result in autosomal recessive Parkinson's disease by the malfunctioning of well-functioning mitochondria [91]. Lately, $\alpha$-synuclein is recognised as disrupting mitochondrial activity on its own, exemplified ability of $\alpha$-synuclein to bind to the mitochondrial membrane and accumulate inside the organelles. Degeneration to complex I activity eventually results in mitochondrial impairment and elevated stress due to free radicals [92].

Scientists recently investigated and found that oligomeric $\alpha$-synuclein interacts with the mitochondrial receptor TOM20, but not monomeric or fibrillar $\alpha$-synuclein [93]. Such interaction hinders the excessive production of Reactive oxygen species (ROS), diminishes respiratory efficiency, and disrupts mitochondrial protein import pathways.

**Neuroinflammation**

In comparison to healthy controls, postmortem brain investigations have shown that the SNpc and striatum of PD patients have higher concentrations of pro-inflammatory signalling molecules, microglial, T-lymphocyte infiltration, and activation of the complement system [94-97]. In the PD dementia condition, Positron emission tomography (PET) neuroimaging using the [11C]-PK11195 radioligand shows higher microglial stimulation in the brainstem, basal ganglia, and front temporal cortices, with subsequent involvement of the parietal and occipital cortices [98]. Inflammatory responses were once considered to be a secondary phenomenon in Parkinson's disorder, but are currently supported as independently contributing to the pathophysiology. Early research using toxins like 6-hydroxydopamine and MPTP in rodent models to develop Parkinson's disease has shown that restricting microglial activation with minocycline both before and after a neurotoxic insult profoundly attenuated the apoptosis of dopaminergic cells in the SNpc, suggesting that the inflammatory response triggered by microglia causes the cell degeneration [99]. Evidence also suggests that $\alpha$-synuclein has the direct ability to activate microglia and stimulate inflammation reactions. For example, in primary cultures, $\alpha$-synuclein induces a dose-dependent activation of microglia [100]. Genetic evidence implicates immune activation in the developing Parkinson's disorder and this evidence is supported by a robust link between PD risk and the human leucocyte antigen (HLA) class II region, a crucial component of the immune system. This correlation was later corroborated by genome-wide association studies [101,102]. Frequent use of ibuprofen, a nonsteroidal anti-inflammatory (NSAID) medicine, also helps to decrease the chance of Parkinson's disease (PD), according to pervasive epidemiological research [103]. Last but not least, another research suggests that a higher serum "pro-inflammatory" immune marker profile at diagnosis is linked to a quicker progression of movement abnormalities and higher neurocognitive impairment in PD patients [104]. In PD, neuroinflammation may either initiate the development of neurodegeneration or be responsible for the neuronal deficit. Recent studies now suggest that the defence system can create a self-perpetuating cycle that exacerbates brain cell impairment. Thus, developing disease-modifying treatments so that they target the immune system is a feasible and innovative approach.

**Ubiquitin-proteasome system**

Proteasome abnormalities are widely found in protein-associated disorders, especially those involving neurodegenerative disorders characterised by aberrant protein aggregation [105]. Postmortem investigations in the SNpc, where the Ubiquitin-proteasome system's (UPS's) catalytic activity was significantly decreased that in healthy brains [106]. Later studies on PD peripheral blood mononuclear cells showed the same results as healthy controls [107]. In patients with PD, SNpc in the brain has been demonstrated to have fewer distinct proteasomal components in addition to reduced activity. In particular, the 20S proteasome $\alpha$-subunit [108] and other components, such as molecules that activate the proteasome, including PA700 and PA28, which are essential for the UPS's adequate functioning, are decreased [109]. Genetic research and data further identify two PARK genes that code for protein UPS regulation, such as parkin (PARK2; E3 ubiquitin ligase) [110] and UCH-L1 (PARK5; Ubiquitin C-terminal hydrolase) [111], which are also associated with single gene Parkinson's disease. Protease activity was shown to be changed in many disease models, which corroborates the results observed in human Parkinson's disorder. The UPS showed reduced enzyme activity in marmosets treated with the toxin MPTP, along with lower amounts of the components of the 26S subunit [112]. The same group demonstrated in a second series of tests that dopaminergic cell death occurs in wild-type rats by pharmacologically inhibiting the proteasome [113]. Similarly, Bedford and colleagues utilised transgenic mice devoid of 26S proteasome regulatory subunit 4 and which demonstrated apoptosis of dopaminergic cells and development of inclusions that were analogous to Lewy bodies. However, these inclusions are devoid of the dense core characteristic of classical human Lewy bodies, and the presence of aggregated $\alpha$-synuclein within is not yet clear [114]. However, previous studies manifest that impairment of protein turnover can lead to apoptosis of brain cells and suggesting a putative pathogenic mechanism for PD.

**Treatment**

**Early-Stage treatment**

Patients with acute-stage Parkinson's disorder are those patients having Parkinson's disorder not more than five years or who have not experienced movement difficulties while taking Levodopa [115]. Most patients require levodopa or a dopamine agonist; however, monoamine oxidase-B (MAO-B) inhibitors, amantadine (Symmetrel), or anticholinergics can help to suppress he mild symptoms. the American Academy of Neurology (AAN) suggests either levodopa or a dopamine agonist when dopaminergic medication is needed, contingent upon whether the aim is to alleviate movement problems (dopamine agonists produce fewer motor problems) or improve motor impairment (levodopa is preferable) [116].

**Levodopa**

individual with Parkinson's disease, levodopa serves as the principal treatment since it is the most effective pharmacological agent. In therapeutic randomized controlled trials (RCTs), Levodopa has not been compared to a placebo because of its constant and intensely positive effects. Bradykinesia and rigidity are especially well-controlled by levodopa; phonation, postural reflex, and gait disturbance show less potential for recovery [116]. The apoptosis of dopamine nerve cells in the SNpc triggered striatal dopamine to be depleted, which is the mechanism behind the motor symptoms in Parkinson's disorder. A notable development in the intervention of Parkinson's disease (PD) was made when levodopa was administered to replace striatal dopamine. Since then, several new dopaminergic treatments have been developed. Nearly all patients need levodopa during their medication, as it is regarded as the gold standard therapy [117]. Motor alterations and dyskinesias interfere with long-term levodopa usage. It's not yet clear what mechanisms underlie these motor problems. Presynaptic and postsynaptic pathways that ultimately result in non-physiological pulsatile striatal dopamine receptor activation, triggering numerous maladaptive neuronal responses, are one acknowledged theory for this expression [118,119]. Carbidopa is usually used with levodopa because it inhibits DOPA decarboxylase, which prevents levodopa from being peripherally converted to dopamine. Carbidopa augments cerebral levodopa bioavailability and reduces dopamine's adverse effects on the peripheral system, such as nausea and hypotension, whenever used in combination with levodopa. Patients who take less carbidopa have a higher probability of developing nausea and vomiting due to the dopa decarboxylase is saturated by the drug at a dose of about 70 to 100 mg per day. It is recommended to begin with a single dosage of 25/100 mg carbidopa/levodopa (Sinemet) tablet should be taken thrice daily. Compared to an immediate-release preparation, sustained-release preparations do not provide any advantages for motor problems [116].

**Dopamine Agonists**

The D2 receptor family is the primary target of dopamine receptors. Ergoline derivatives were the first members of this drug class. The currently utilized drugs are all non-ergoline medications, such as apomorphine, pramipexole, piribedil, ropinirole, and rotigotine, because ergoline treatments provoke concern over cardiac and pulmonary protection. When taken as initial monotherapy, dopamine agonists can significantly decrease the chance of motor problems because they trigger less pulsatile striatal dopamine receptor activation than levodopa [120,121,122]. Dopamine agonists, which include pramipexole (Mirapex), ropinirole (Requip), bromocriptine (Parlodel), and pergolide (Permax), directly stimulate dopamine receptors. Studies have revealed that Dopamine agonists have potential treatment against early-stage Parkinson's disease when consumed either alone [123,124-126] or in combination with levodopa. Comparing levodopa with ropinirole or pramipexole in double-blind controlled trials suggested that levodopa was superior to dopamine agonists in decreasing UPDRS scores; these investigations also demonstrated a reduced frequency of motor difficulty with the help of dopamine agonists [127,128]

**MAO-B inhibitors**

The concentration of synaptic dopamine levels and the effectiveness of symptoms are both increased by MAO-B inhibition. For example, a selective irreversible MAO-B inhibitor, selegiline has effectiveness as a supplement to levodopa, useful in patients with initial-stage PD [129]. A meta-analysis of 17 trials involving patients with early-stage PD indicated that MAO-B inhibitors, when used along with levodopa or placebo, showed that MAO-B inhibitors decreased the inability, the occurrence of motor fluctuations and the requirement for levodopa without

initiating adverse effects or worsening rate of death [130]. Another irreversible MAO-B inhibitor, Rasagiline, is also a well-known adjuvant medication for patients with movement disability [131]. Researchers conducted a 3-year retrospective case-control study to evaluate the effectiveness of MAO-B inhibitors in treating PD and found they were similarly helpful in suppressing motor symptoms in PD patients on receiving the best possible management. A significant decrease in the need for levodopa and a suppression in the occurrence of dyskinesias are linked with the MAO B inhibitor therapy [132]. Safinamide has anti-glutaminergic pharmacological traits and is a reversible MAO-B inhibitor. In advanced Parkinson's disease, safinamide promotes the quality of life and provides better control over motor symptoms. [133]. Currently, in the randomized controlled trial, safinamide decreased the frequency of the "wearing off" phenomenon and increased the ON time without producing bothersome dyskinesias when administered in combination with levodopa. [134]

**Other agents**

Parkinson's disease is frequently treated with anticholinergic drugs. However, their use in elderly patients is restricted because they have limited potency and a high frequency of gastrointestinal and neuropsychiatric adverse effects. Patients under 70 with incapacitating resting tremors and retained cognitive function are usually treated with anticholinergics. Amantadine, an N-methyl-d-aspartate receptor inhibitor, was first used as a viral-inhibiting therapeutic drug and has been substantiated to help Parkinson's disease patients with tremor, stiffness, and motor arrest. The therapeutics may be clinically useful, but there aren’t enough for rigorous research [135].

**Late-stage Treatment**

Patients with motor dysfunctions, who are already on carbidopa/levodopa medication, are considered to have a late stage of Parkinson's disease. Approximately 40% of patients have movement instability and decreased motor activity, i.e., involuntary choreiform or stereotypical movements affecting the whole skeletal muscle and rarely, the respiratory muscles after five years of levodopa medication [136]. A combination with a dopamine agonist, MAO B inhibitor or catechol-O-methyltransferase (COMT) inhibitor can manage the motor dysfunctions [135].

**COMT inhibitors**

Carbidopa or benserazide is combined with current levodopa medications to inhibit peripheral dopamine metabolism. As a result, these medications enhance the bioavailability of the former medicine, leading to levodopa's peripheral metabolism switching to a secondary route involving COMT. Levodopa's bioavailability and half-life will be further increased by blocking the COMT pathway, which will be useful for patients with movement dysfunctions [137]. Triple treatment with a levodopa, carbidopa, and COMT inhibitor enhances quality of life by increasing ON time and decreasing OFF time [138]. The clinical application of Tolcapone is limited because of its adverse effects. Currently, entocapone is used as a safer substitute but is less effective. According to phase II studies, Nebicapone is a safer medication than tolcapone and more effective than entacapone [139]. When administered orally once daily, opicapone has also been found to decrease OFF time and increase ON time in people with severe Parkinson's disease (PD) without triggering bothersome dyskinesias [140]

**Common dysfunction of the anti-inflammatory pathways between Multiple Sclerosis and Parkinson’s Didorder**

The prevalence of neurodegenerative disorders is increasing in tandem with lifestyle. Research shows that most neurodegenerative diseases have an unknown etiology, and as a result, there are currently no appropriate therapies that can either restrict or suppress their pathogenesis. The pathogenesis of neurodegenerative disorders may overlap at several molecular levels and pathways, ultimately leading to the apoptosis of cells, according to accumulating evidence. Several contributing factors, including inflammatory response, oxidative stress, mitochondrial dysfunction, pathogenic proteins, apoptosis, and autophagy dysfunction, are all well-established characteristics of neurodegeneration found in both sporadic and familial forms. they are not only associated with any one neurodegenerative disorder [141]. The most common neurological disorders of the central nervous system (CNS) in individuals over 60 are Parkinson's disease (PD) [142]. Conversely, multiple sclerosis (MS), a neurodegenerative and autoimmune disease of the central nervous system that primarily affects individuals between 20 and 40 years of age, is less frequent than Parkinson's disease (PD) [143]. PD is identified by the deterioration of the dopaminergic system

important in the basal ganglia, particularly in the substantia nigra, whereas MS patients present with demyelinating plaques that primarily affect the subcortical white matter and the periventricular region [144,145]. In MS and PD, chronic activation of microglia leads to their transition from a neuroprotective to a neurotoxic state. Due to this activation, pro-inflammatory cytokines include IL-1β, TNF-α, IL-6 and reactive oxygen species (ROS) are released in excessive amounts and aggravate the neuronal damage [146]. The primary causes of MS and PD are α-synuclein aggregation, demyelination and lesion formation, respectively. Microglia are the brain's immune cells, which respond to these changes. Glial scar formation and astrocyte reactivity also play a crucial role in neuroinflammation in the brain. Reactive astrocytes produce glial scars and liberate inflammatory mediators, which can differ depending on where they originate and are location. These processes can elevate disease pathology by producing cytokines and intensifying oxidative stress, which damage the dopaminergic neurons in the substantia nigra in PD [147]. They generate glial scars in demyelinated lesions, which obstruct remyelination and remission in MS [148]. Moreover, mitochondrial impairment and oxidative stress are common to both disorders. Neurons are damaged and undergo apoptosis when exposed to excessive oxidative stress. Inflammation and neurodegeneration are triggered by the malfunctioning of mitochondria, leading to increase in the formation of ROS and nitric oxide (NO). Parkinson's disease (PD) makes dopaminergic neurons more vulnerable due to their elevated metabolism related to oxidative compounds. However, myelinoclastic and axonal degeneration in MS are exacerbated by oxidative stress. Additionally, the blood and cerebrospinal fluid (CSF) had elevated concentrations of IL-1β, IL-6, TNF-α, and IL-18 in both disorders. Chronic inflammation hinders the blood-brain barrier that permits immune cells and neurotoxic substances to invade the central nervous system. Blood-brain barrier destruction is severe, especially in Multiple sclerosis, which facilitates T-cell and B-cell infiltration. Both Multiple Sclerosis and Parkinson's disease include peripheral immune activation; however, MS is more prominent. In Parkinson's disease, systemic inflammation can worsen neurodegeneration through the gut-brain axis and peripheral cytokine signalling. In Multiple Sclerosis, the adaptive immune system, such as T-cells and B-cells, attacks myelin aggressively, resulting in lesions. Furthermore, inflammation has a dual role in both Multiple Sclerosis and Parkinson's disease. Acute inflammation may initially be beneficial, aiding in the clearing of debris and promoting recovery. The progression of these diseases may occur due to prolonged chronic inflammation results in synaptic dysfunction, neuronal death [Table 1]. These similar neuroinflammatory processes suggest future treatment targets in MS and PD, including regulating microglial activation, lowering oxidative stress, and protecting BBB integrity.

## CONCLUSION

Each neurodegenerative disease has distinct inflammatory inducers and effectors. While immunological activity exerts a protective role, it must be strictly regulated to inhibit CNS harm. Immune cells lose function as they age and are repeatedly activated, demonstrating that the CNS is not entirely immune-privileged. Innate immune cells, particularly astrocytes and microglia, are frequently activated. Parkinson's disease and multiple sclerosis (MS) have similar inflammatory processes but different etiology and pathologies. In Parkinson's disease, misfolded α-synuclein accumulates into Lewy bodies, triggering inflammation. In MS, an immunological reaction against myelin induces persistent inflammation and demyelination. Toll-like receptors (TLRs) and other pattern recognition receptors (PRRs) on microglia are essential for initiating these immunological cascades, which astrocytes enhance**.** Neuroinflammation is exacerbated by the synthesis of inflammatory mediators (e.g., TNF-α, IL-1β, IL-6), ROS, and NO by NF-kB and Nrf2 signalling cascades, which are regulated by microglial and astrocytic receptors. These effector molecules serve as prevalent neurotoxic mediators in neurodegenerative disorders. MS diverges from Parkinson's disease in that it depends largely on adaptive immune responses, whereas PD is predominantly connected with innate immunological dysfunction. Future research should focus on comparative glial cell sequencing in both Parkinson's disease and multiple sclerosis, which might suggest disease-specific transcriptional signatures and provide new therapeutic targets. To further understand neuroinflammatory mechanisms, we need a comprehensive prototype that includes computational biology, elevating brain imaging, thorough clinical presentation, and cross-disease interventional research. Employing such interdisciplinary and temporally resolved methodologies will be important in determining

whether neuroinflammation serves as an initiating factor, a subsequent impact, or an adaptive response, thereby directing the design of targeted therapeutic approaches.

**Future direction**

Current research on neurodegenerative disorders stresses the major contribution of unwanted irritative symptoms in the pathophysiology of central nervous system (CNS) diseases. Chronic neuroinflammatory response, characterized by continuous microglia and astrocytes activation as well as the generation of pro-inflammatory cytokines, which have a substantial participation in disease progression in multiple sclerosis and Parkinson's disease. Cytokine blockers, microglial activity modulators, and medicines that target inflammasome activation are certain therapeutic suggestions under consideration. Furthermore, there is a rising interest in therapies that modulate critical molecular pathways involved in inflammatory signalling, which might help to inhibit or delay neurodegenerative disorders. Another critical aim is to create accurate biomarkers for the initial diagnosis of neuroinflammation, which would allow for therapeutic intervention at the most effective stage. Combining immunomodulatory techniques with novel modalities such as cell and gene-based treatments has great potential for improving the therapeutic domain for neurodegenerative disorders.

**Table 1: Compiled unique and common cellular and molecular pathways underpinning Multiple Sclerosis and Parkinson's disease (PD). Summarising pathological responses involving glial cells, astrocytes, NF-kB and Nrf2 signalling, cytokine imbalance, blood-brain integrity, peripheral immune involvement and gut-brain axis role.**

| Pathway | Multiple sclerosis (MS) | Parkinson's disease (PD) |
|---|---|---|
| Microglial activation | Overactivated microglia produce pro-cytokines that disrupt myelin and axons | Microglial overactivation results in dopaminergic neuron injury in the substantia nigra |
| Astrocytes activation | Reactive astrocytes release cytokines, ROS, and chemokines promote demyelination | Reactive astrocytes lose their ability to eliminate alpha-synuclein and release inflammatory mediators |
| NF-kB signalling | Activates in immune and glial cells and produces pro-inflammatory cells, leading to demyelination | Activated by oxidative stress and alpha-synuclein and promote the release of cytokine, causing to programmed death of neurons |
| Nrf2 signalling | Activation under oxidative stress induces an antioxidant that reduces RON/RON and protects neurons in MS | Nrf2 protects dopaminergic neurons by reducing ROS |
| cytokines imbalance | ↑ IL-1β, TNF-$\alpha$, INF-Ɣ, IL-6<br>↓ TGF-β, IL-10 | ↑ IL-1β, TNF-$\alpha$, IL-6, INF-Ɣ<br>↓ IL-10 |
| T cells | Th1/ Th17 infiltration into the CNS | Peripheral CD4+/CD8+ T cells penetrate the CNS |
| B cells | Autoantibodies against myelin proteins | Autoantibodies against $\alpha$-synuclein |
| Mitochondrial dysfunction | Inflammation and OS damage mitochondria, leading to ↑ATP, ↓ROS and axonal degeneration | Mitochondrial deficits impair dopaminergic neurons, leading to an energy crisis, ↑ROS, and cell apoptosis |
| BBB Dysfunction | Enables immune cell infiltration | Aggravate loss of dopamine |
| Peripheral immune involvement | Involvement of the Peripheral immune system | Indirectly via the gut-brain axis |
| Gut-brain axis role | Dysbiosis alters immune regulation | Dysbiosis promotes $\alpha$-synuclein aggregation |

**ABSTRACT**

This article presents a distance measure for bipolar neutrosophic hypersoft sets (BNHSS), and the VIKOR (VIsekriterijumska optimizacija i Kompromisno Resenje) method is extended to accommodate bipolar neutrosophic hypersoft numbers. These improved tools are subsequently utilized to examine the impacts of excessive screen time on toddlers.The results indicate that the suggested approach offers a dependable and efficient structure for assessing complicated, uncertain information concerning early childhood screen exposure.

**Keywords:** Bipolar neutrosophic hypersoft sets, Distance measures, VIKOR Method, Decision-making, Early childhood screen exposure

## INTRODUCTION

The neutrosophic set (NS) is a novel mathematical concept that F. Smarandache (1998) [1] proposed to solve complicated MCDM (multi-criteria decision making) problems. It builds upon the intuitionistic fuzzy set (IFS) and the standard fuzzy set (FS).To address the challenges of sustainable supplier selection, Luo, X., et al.(2023) [2] suggested an expansion of the VIKOR technique in NS. In order to solve MCDM issues, Deli, I., Ali, M., and Smarandache, F. (2015) [3] combined NS with bipolarity.The VIKOR approach was developed in 2018 by Pramanik, S., et al., [4] under bipolar neutrosophic sets (BNS) to solve practical decision-making issues.Dey, P. P., et al. (2016) [5]

solved MADM (Multi-Attribute Decision Making) problems under BNS by creating distance measurements and using the TOPSIS (Technique for Order of Preference by Similarity to Ideal Solution) technique. Bipolar neutrosophic sets were used by Abdel-Basset, M., et al. (2020) [6] to tackle real-world issues.

The rest of the manuscript is structured as outlined below. Section 2 examines the key principles of BNHSS. Section 3 introduces the distance measures for BNHSS, whereas Section 4 outlines the VIKOR approach derived from these distance measures. Section 5 provides an example that illustrates the impacts of too much screen time on toddlers. The findings are shown and analyzed in Section 6, and ultimately, Section 7 wraps up the paper.D. Molodtsove (1999) [7] established the idea of SS (Soft Set) theory and offered a number of findings to deal with uncertainty in practical issues. To tackle decision-making issues, Maji, P. (2013) [8] developed the idea of NSS (Neutrosophic Soft Sets), which built upon soft set theory. To solve problems with maternal nutrition, R. Sophia Porchelvi and P. Subashini [9] created a new method in Neutrosophic Soft Sets (NSS) in 2023.F. Smarandache (2018) [10] first proposed the idea of HSS (Hyper Soft Sets), which are an extension of SS. By adding numerous sub-attributes, HSS are able to solve complicated problems that arise in daily life.In order to solve the problem of air pollution in urban areas, Saqlain, M., et al. [11] established distance and similarity measures for IHSS (Intuitionistic Hyper Soft Sets).VIKOR and IHSS (Intuitionistic Hyper Soft Sets) were used by Saqlain, M. (2023) [12] to tackle the problem of sustainable hydrogen generation.To address decision-making issues, Zulqarnain, R. M., et al. (2020) [13] created aggregation operations for Neutrosophic Hyper Soft Sets (NHSS).In order to solve decision-making issues, Saqlain, M., et al., (2021) [14] created distance and similarity measures for NHSS and used the NHSS-TOPSIS approach.Using BNHSS (Bipolar Neutrosophic Hypersoft Sets) and their aggregation operations, Al-Sharqi, F., et al., (2023) [15] addressed MAGDM(multi-attribute group decision making) difficulties.

## PRELIMINARIES

**Definition [7]**
Let $\eta$ be the universe, and its power set is indicated by P ($\eta$). Let $t$ be a set of attributes, and $e \subseteq t$. Then $(\Psi, e)$ is referred to as a (SS) Soft Set over $\eta$, where $\Psi: e \rightarrow \mathrm{P}(\eta)$.

**Definition [10]**
Let $\eta$ be the universe, and its power set is indicated by P ($\eta$). The well - defined attributes ($m \geq 1$) are represented by $t_1, t_2, \ldots, t_m$. For $i \neq j$ and $i, j \in \{1,2,\ldots,m\}$, where $\mathbb{U}_i \cap \mathbb{U}_j = \emptyset$, their corresponding attribute values are the set $\mathbb{U}_1, \mathbb{U}_2, \ldots \mathbb{U}_m$.A (HSS) Hypersoft set over $\eta$ is the pair $(\Psi, \mathbb{U}_1 \times \mathbb{U}_2 \times \ldots \mathbb{U}_m)$, where $\Psi: \mathbb{U}_1 \times \mathbb{U}_2 \times \ldots \mathbb{U}_m \rightarrow P(\eta)$.

**Definition [13]**
Let $\eta$ be the universe, and its power set is indicated by P ($\eta$). The well - defined attributes ($m \geq 1$) are represented by $t_1, t_2, \ldots, t_m$. For $i \neq j$ and $i, j \in \{1,2,\ldots,m\}$, where $\mathbb{U}_i \cap \mathbb{U}_j = \emptyset$, their corresponding attribute values are the set $\mathbb{U}_1, \mathbb{U}_2, \ldots \mathbb{U}_m$. A (NHSS) Neutrosophic Hypersoft set over $\eta$ is the pair $\Psi: \mathbb{U}_1 \times \mathbb{U}_2 \times \ldots \mathbb{U}_m \rightarrow P(\eta)$and its defined as $\Psi(\mathbb{U}_1, \mathbb{U}_2, \ldots \mathbb{U}_m) = \{(\omega, \mathbb{T}(\omega), \mathbb{I}(\omega), \mathbb{F}(\omega)), \omega \in \eta\}$where $\mathbb{T}(\omega), \mathbb{I}(\omega), \mathbb{F}(\omega): \eta \rightarrow [0,1]$, $and\ 0 \leq \mathbb{T}(\omega) + \mathbb{I}(\omega) + \mathbb{F}(\omega) \leq 3$.

**Definition [15]**
Let $\eta$ be the universe, and its power set is indicated by P ($\eta$). The well - defined attributes ($m \geq 1$) are represented by $t_1, t_2, \ldots, t_m$. For $i \neq j$ and $i, j \in \{1,2,\ldots,m\}$, where $\mathbb{U}_i \cap \mathbb{U}_j = \emptyset$, their corresponding attribute values are the set $\mathbb{U}_1, \mathbb{U}_2, \ldots \mathbb{U}_m$. A (BNHSS) Bipolar Neutrosophic Hypersoft set over $\eta$ is the pair $\Psi: \mathbb{U}_1 \times \mathbb{U}_2 \times \ldots \mathbb{U}_m \rightarrow P(\eta)$ *and* its defined as $\Psi(\mathbb{U}_1, \mathbb{U}_2, \ldots \mathbb{U}_m) = \{(\omega, \mathbb{T}^+(\omega), \mathbb{T}^-(\omega), \mathbb{I}^+(\omega), \mathbb{I}^-(\omega), \mathbb{F}^+(\omega), \mathbb{F}^-(\omega)), \omega \in \eta\}$ where $\mathbb{T}^+(\omega), \mathbb{I}^+(\omega), \mathbb{F}^+(\omega): \eta \rightarrow [0,1]$ denotes the positive membership of truth, indeterminacy, and falsity values and $\mathbb{T}^-(\omega), \mathbb{I}^-(\omega), \mathbb{F}^-(\omega): \eta \rightarrow [-1,0]$ denotes the negative membership of truth, indeterminacy, and falsity values, respectively.

We denote $\Psi(\mathbb{U}_1, \mathbb{U}_2, \ldots \mathbb{U}_m) = \{(\omega, \mathbb{T}^+(\omega), \mathbb{T}^-(\omega), \mathbb{I}^+(\omega), \mathbb{I}^-(\omega), \mathbb{F}^+(\omega), \mathbb{F}^-(\omega)), \omega \in \eta\}$simply $\Psi = (\mathbb{T}_\Psi{}^+, \mathbb{I}_\Psi{}^+, \mathbb{F}_\Psi{}^+, \mathbb{T}_\Psi{}^-, \mathbb{I}_\Psi{}^-, \mathbb{F}_\Psi{}^-)$ as a bipolar neutrosophic hypersoft number (BNHSN).

**Distance measures for BNHSS**

**Definition**
Let $\mathbb{J} = (\mathbb{T}_\mathbb{J}{}^+, \mathbb{I}_\mathbb{J}{}^+, \mathbb{F}_\mathbb{J}{}^+, \mathbb{T}_\mathbb{J}{}^-, \mathbb{I}_\mathbb{J}{}^-, \mathbb{F}_\mathbb{J}{}^-)$ and $\mathcal{Q} = (\mathbb{T}_\mathcal{Q}{}^+, \mathbb{I}_\mathcal{Q}{}^+, \mathbb{F}_\mathcal{Q}{}^+, \mathbb{T}_\mathcal{Q}{}^-, \mathbb{I}_\mathcal{Q}{}^-, \mathbb{F}_\mathcal{Q}{}^-)$ be any two BNHSNs in $\eta$.The definition of the Hamming distance between$\mathbb{J}$ and $\mathcal{Q}$,represented as D($\mathbb{J}, \mathcal{Q}$), is as follows:
$D(\mathbb{J}, \mathcal{Q}) = \frac{1}{6}\left[\left|\mathbb{T}_\mathbb{J}{}^+ - \mathbb{T}_\mathcal{Q}{}^+\right| + \left|\mathbb{I}_\mathbb{J}{}^+ - \mathbb{I}_\mathcal{Q}{}^+\right| + \left|\mathbb{F}_\mathbb{J}{}^+ - \mathbb{F}_\mathcal{Q}{}^+\right| + \left|\mathbb{T}_\mathbb{J}{}^- - \mathbb{T}_\mathcal{Q}{}^-\right| + \left|\mathbb{I}_\mathbb{J}{}^- - \mathbb{I}_\mathcal{Q}{}^-\right| + \left|\mathbb{F}_\mathbb{J}{}^- - \mathbb{F}_\mathcal{Q}{}^-\right|\right]$

**Definition**
Let $\mathbb{J} = (\mathbb{T}_\mathbb{J}{}^+, \mathbb{I}_\mathbb{J}{}^+, \mathbb{F}_\mathbb{J}{}^+, \mathbb{T}_\mathbb{J}{}^-, \mathbb{I}_\mathbb{J}{}^-, \mathbb{F}_\mathbb{J}{}^-)$ and $\mathcal{Q} = (\mathbb{T}_\mathcal{Q}{}^+, \mathbb{I}_\mathcal{Q}{}^+, \mathbb{F}_\mathcal{Q}{}^+, \mathbb{T}_\mathcal{Q}{}^-, \mathbb{I}_\mathcal{Q}{}^-, \mathbb{F}_\mathcal{Q}{}^-)$ be any two BNHSNs in $\eta$. The definition of the Normalized Hamming distance between $\mathbb{J}$ and $\mathcal{Q}$, represented as D($\mathbb{J}, \mathcal{Q}$), is as follows:
$D(\mathbb{J}, \mathcal{Q}) = \frac{1}{6n}\left[\left|\mathbb{T}_\mathbb{J}{}^+ - \mathbb{T}_\mathcal{Q}{}^+\right| + \left|\mathbb{I}_\mathbb{J}{}^+ - \mathbb{I}_\mathcal{Q}{}^+\right| + \left|\mathbb{F}_\mathbb{J}{}^+ - \mathbb{F}_\mathcal{Q}{}^+\right| + \left|\mathbb{T}_\mathbb{J}{}^- - \mathbb{T}_\mathcal{Q}{}^-\right| + \left|\mathbb{I}_\mathbb{J}{}^- - \mathbb{I}_\mathcal{Q}{}^-\right| + \left|\mathbb{F}_\mathbb{J}{}^- - \mathbb{F}_\mathcal{Q}{}^-\right|\right]$

**Definition**
Let $\mathbb{J} = (\mathbb{T}_\mathbb{J}{}^+, \mathbb{I}_\mathbb{J}{}^+, \mathbb{F}_\mathbb{J}{}^+, \mathbb{T}_\mathbb{J}{}^-, \mathbb{I}_\mathbb{J}{}^-, \mathbb{F}_\mathbb{J}{}^-)$ and $\mathcal{Q} = (\mathbb{T}_\mathcal{Q}{}^+, \mathbb{I}_\mathcal{Q}{}^+, \mathbb{F}_\mathcal{Q}{}^+, \mathbb{T}_\mathcal{Q}{}^-, \mathbb{I}_\mathcal{Q}{}^-, \mathbb{F}_\mathcal{Q}{}^-)$ be any two BNHSNs in $\eta$. The definition of the Normalized Euclidean distance between $\mathbb{J}$ and $\mathcal{Q}$, represented as D($\mathbb{J}, \mathcal{Q}$), is as follows:
$D(\mathbb{J}, \mathcal{Q}) = \frac{\sqrt{\left|\mathbb{T}_\mathbb{J}{}^+ - \mathbb{T}_\mathcal{Q}{}^+\right| + \left|\mathbb{I}_\mathbb{J}{}^+ - \mathbb{I}_\mathcal{Q}{}^+\right| + \left|\mathbb{F}_\mathbb{J}{}^+ - \mathbb{F}_\mathcal{Q}{}^+\right| + \left|\mathbb{T}_\mathbb{J}{}^- - \mathbb{T}_\mathcal{Q}{}^-\right| + \left|\mathbb{I}_\mathbb{J}{}^- - \mathbb{I}_\mathcal{Q}{}^-\right| + \left|\mathbb{F}_\mathbb{J}{}^- - \mathbb{F}_\mathcal{Q}{}^-\right|}}{6n}$

# METHODOLOGY

This section presents a VIKOR - based BNHS environment. Using the BNHS framework, consider a MCDM problem where the set of alternativesis represented by$\eta = \{\eta_1, \eta_2, \ldots, \eta_l\}$and the collection of attributes by $\mathcal{t}_1, \mathcal{t}_2, \ldots, \mathcal{t}_m$.The sets $\mathcal{t}_1{}^a, \mathcal{t}_2{}^b, \ldots, \mathcal{t}_m{}^z$(where a, b, …, z = 1, 2,…, m)provide the corresponding attribute values.

Let the weight for the attributes$\mathcal{t}_j{}^\delta (j = 1,2, \ldots, m, \delta = a, b, \ldots, z)$be represented by$\alpha_l$, where $0 \le \alpha_l \le 1$ and $\sum_{j=1}^{m} \alpha_l = 1$.

Assume thatthe collection ofr decision makers is represented by$\mathbb{D}m = (\mathbb{D}m_1, \mathbb{D}m_2, \ldots, \mathbb{D}m_r)$ and that$\beta_n$indicates the weight of the r decision makers, where$0 \le \beta_n \le 1$ and $\sum_{n=1}^{m} \beta_n = 1$.
The following steps are involved in the VIKOR-based BNHS framework:

**Step: 1** Let $\mu^y = (\mathcal{f}_{ij}{}^y)_{l \times m}$ (y = 1, 2, …, r, i = 1, 2, …, l, j = 1, 2, …, m) represent the r-th decision matrix, where the decision maker $\mathbb{D}m_y$provides data associated with the alternative$\eta_i$in relation to the attribute $\mathcal{t}_j{}^\delta (j = 1,2, \ldots, m, \delta = a, b, \ldots, z)$.As seen in eqn. (1), r-th decision matrix, represented by $\mu^y$is developed as follows:

$$\mu^y = \begin{array}{c} \\ \eta_1 \\ \eta_2 \\ \vdots \\ \eta_l \end{array} \begin{array}{c} \begin{array}{cccc} \mathcal{t}_1 & \mathcal{t}_2 & \cdots & \mathcal{t}_m \end{array} \\ \begin{bmatrix} \mathcal{f}_{11}{}^y & \mathcal{f}_{12}{}^y & \cdots & \mathcal{f}_{1m}{}^y \\ \mathcal{f}_{21}{}^y & \mathcal{f}_{22}{}^y & \cdots & \mathcal{f}_{2m}{}^y \\ \vdots & \vdots & \ddots & \vdots \\ \mathcal{f}_{l1}{}^y & \mathcal{f}_{l2}{}^y & \cdots & \mathcal{f}_{lm}{}^y \end{bmatrix} \end{array} \quad \text{---------- (1)}$$

**Step: 2**
Attributes are usually categorized as either cost or benefit categories in decision-making procedures. In order to take into consideration variations in the physical units of measurement, the attribute values must be normalized. The following formula can be used to do normalization:

$\mathbb{f}_{ij}{}^{*} = (1 - \mathbb{T}_{ij}{}^{+}, 1 - \mathbb{I}_{ij}{}^{+}, 1 - \mathbb{F}_{ij}{}^{+}, -1 - \mathbb{T}_{ij}{}^{-}, -1 - \mathbb{I}_{ij}{}^{-}, -1 - \mathbb{F}_{ij}{}^{-})$.

We derive the following normalized decision matrix (see eqn. (2)) by using the normalizing method:

$$\mu^{y} = \begin{matrix} \\ \eta_1 \\ \eta_2 \\ \vdots \\ \eta_l \end{matrix} \begin{matrix} \begin{matrix} t_1 & t_2 & \cdots & t_m \end{matrix} \\ \begin{bmatrix} \widetilde{\mathbb{f}_{11}}^{y} & \widetilde{\mathbb{f}_{21}}^{y} & \cdots & \widetilde{\mathbb{f}_{1m}}^{y} \\ \widetilde{\mathbb{f}_{21}}^{y} & \widetilde{\mathbb{f}_{22}}^{y} & \cdots & \widetilde{\mathbb{f}_{2m}}^{y} \\ \vdots & \vdots & \ddots & \vdots \\ \widetilde{\mathbb{f}_{l1}}^{y} & \widetilde{\mathbb{f}_{l2}}^{y} & \cdots & \widetilde{\mathbb{f}_{lm}}^{y} \end{bmatrix} \end{matrix} \quad \text{---------- (2)}$$

Where,

$$\widetilde{\mathbb{f}_{ij}}^{y} = \begin{cases} \mathbb{f}_{ij}{}^{y} \; if \; \eta_i \; is \; benefit \; type \; attribute. \\ (\mathbb{f}_{ij}{}^{*})^{y} \; if \; \eta_i \; is \; cost \; type \; attribute. \end{cases}$$

**Step: 3**

The following is an expression for the aggregated decision matrix that was derived using the Bipolar Neutrosophic Hypersoft Number Weighted Aggregation Operator (BNHSNWA):

$\mathbb{f}_{ij} = BNHSNWA\left(\widetilde{\mathbb{f}_{ij}}^{1}, \widetilde{\mathbb{f}_{ij}}^{2}, \ldots, \widetilde{\mathbb{f}_{ij}}^{r}\right) = \left(\beta_1 \widetilde{\mathbb{f}_{ij}}^{1} \oplus \beta_2 \widetilde{\mathbb{f}_{ij}}^{2} \ldots \oplus \beta_y \widetilde{\mathbb{f}_{ij}}^{r}\right)$

$=(\sum_{i=1}^{r} \beta_r \widetilde{\mathbb{T}_{ij}}^{+(y)}, \sum_{i=1}^{r} \beta_r \widetilde{\mathbb{I}_{ij}}^{+(y)}, \sum_{i=1}^{r} \beta_r \widetilde{\mathbb{F}_{ij}}^{+(y)}, \sum_{i=1}^{r} \beta_r \widetilde{\mathbb{T}_{ij}}^{-(y)}, \sum_{i=1}^{r} \beta_r \widetilde{\mathbb{I}_{ij}}^{-(y)}, \sum_{i=1}^{r} \beta_r \widetilde{\mathbb{F}_{ij}}^{-(y)})$ –(3)

$$\mu = \begin{matrix} \\ \eta_1 \\ \eta_2 \\ \vdots \\ \eta_l \end{matrix} \begin{matrix} \begin{matrix} t_1 & t_2 & \cdots & t_m \end{matrix} \\ \begin{bmatrix} \mathbb{f}_{11} & \mathbb{f}_{12} & \cdots & \mathbb{f}_{1m} \\ \mathbb{f}_{21} & \mathbb{f}_{22} & \cdots & \mathbb{f}_{2m} \\ \vdots & \vdots & \ddots & \vdots \\ \mathbb{f}_{l1} & \mathbb{f}_{l2} & \cdots & \mathbb{f}_{lm} \end{bmatrix} \end{matrix} \quad \text{---------- (4)}$$

**Step: 4**

For each criterion evaluation, determine the $\mathbb{f}_{ij}{}^{+}$positive ideal solution and the $\mathbb{f}_{ij}{}^{-}$negative ideal solution:

$\mathbb{f}_{ij}{}^{+} = (\max_i \mathbb{T}_{ij}{}^{+}, \min_i \mathbb{I}_{ij}{}^{+}, \min_i \mathbb{F}_{ij}{}^{+}, \min_i \mathbb{T}_{ij}{}^{-}, \max_i \mathbb{I}_{ij}{}^{-}, \max_i \mathbb{F}_{ij}{}^{-})$ ---------- (5)

$\mathbb{f}_{ij}{}^{-} = (\min_i \mathbb{T}_{ij}{}^{+}, \max_i \mathbb{I}_{ij}{}^{+}, \max_i \mathbb{F}_{ij}{}^{+}, \max_i \mathbb{T}_{ij}{}^{-}, \min_i \mathbb{I}_{ij}{}^{-}, \min_i \mathbb{F}_{ij}{}^{-})$ ----------(6)

**Step: 5**

Determine $\rho_i$ and $\omega_i$ $(i = 1, 2, \ldots, l)$ using the following formulas:

$$\rho_i = \sum_{j=1}^{m} \frac{\alpha_l \times D(\mathbb{f}_{ij}{}^{+}, \widetilde{\mathbb{f}_{ij}}^{y})}{D(\mathbb{f}_{ij}{}^{+}, \mathbb{f}_{ij}{}^{-})} \quad \text{----------(7)}$$

$$\omega_i = \max_j \{\frac{\alpha_l \times D(\mathbb{f}_{ij}{}^{+}, \widetilde{\mathbb{f}_{ij}}^{y})}{D(\mathbb{f}_{ij}{}^{+}, \mathbb{f}_{ij}{}^{-})}\} \quad \text{---------- (8)}$$

In this case, $\alpha_l$ stands for the weight of $t_j$.For the alternative $\eta_i (i = 1,2, \ldots, l)$, smaller values of $\rho_i$ and $\omega_i$suggest superior average and lowest group scores, respectively.

**Step: 6**

Using the provided relation, find the values of $\mathrm{H}_i (i = 1,2, \ldots, l)$.

$$\mathrm{H}_i = \pi \frac{(\rho_i - \rho^{-})}{(\rho^{+} - \rho^{-})} + (1 - \pi) \frac{(\omega_i - \omega^{-})}{(\omega^{+} - \omega^{-})} \quad \text{---------- (9)}$$

Here, $\rho^{+} = \min \rho_i, \rho^{-} = \max \rho_i$

$\omega^{-} = \min \omega_i, \omega^{+} = \max \omega_i$ and the coefficient of the decision-making system is represented by $\pi$ . $\pi > 0.5$means "maximizing group utility"; $\pi < 0.5$ means "minimizing regret." The decision-making technique coefficient is typically expected to be set to $\pi = 0.5$.

**Step: 7**

Using the VIKOR method, we rank the options according to $H_i, \rho_i$, and $\omega_i$. A better option is indicated by a smaller value.

**Case Study**

Too much screen time can harm toddlers in a number of ways, such as:

**Sleep disturbances:** Toddlers who use screens right before bed may have trouble sleeping because it throws off their natural sleep-wake cycle. The blue light from displays can hinder their ability to fall asleep and lower the quality of their sleep in general. Their behavior, growth, and mood can all be impacted by little sleep.

**Emotional regulations:** Toddlers who spend too much time on screens may have trouble controlling their emotions, which may result in more tantrums, irritation, and dissatisfaction. It might overstimulate their developing brains and prevent them from learning coping mechanisms and self-soothing techniques from real-world experiences.

**Language delay:** Toddlers' language development might be seriously delayed by excessive screen usage. Children who spend too much time in front of screens lose out on crucial physical interactions and conversations that are essential for developing their speech and vocabulary. Their capacity to comprehend and successfully use language may be hampered by this lack of social interaction. Future social and academic development may also be impacted by early language deficits.

**Vision problems:** Toddlers who spend too much time on screens may experience eye strain, which can produce symptoms like weariness, pain, and dry eyes. Frequent pauses and outdoor visual stimulation are necessary for toddlers' developing eyes, and without them, their chance of acquiring myopia, or near-sightedness, increases.

**Social skills delay:** Excessive screen time for toddlers can limit real-life social interactions, leading to delays in developing essential social skills like sharing, empathy, and understanding emotions. This may hinder their ability to form healthy relationships and communicate effectively with others.

**Numerical Example**

A toddler's parent wants to know more about the negative consequences of excessive screen usage. Decision-makers respond by offering suggestions (alternatives) like:
Sleep disturbances ($\eta_1$), Emotional regulations ($\eta_2$), Language delay ($\eta_3$), Vision problems ($\eta_4$), Social skills delay ($\eta_5$).

A decision-maker also looks at details about the toddler, such as:
$\mathcal{B} = \{t_1 = Age, \quad t_2 = Gender, \quad t_3 = Screen\ time, \quad t_4 = Physical\ health\}$.
Furthermore, those characteristics have evolved into distinct categories that are divided into the following categories:
${t_1}^a = Age = \{1-2\ yrs, 2-3 yrs\}$
${t_2}^b = Gender = \{Male, Female\}$
${t_3}^c = Screen\ time\ (per\ day) = \{2-3\ hrs, 3-5\ hrs, 5-8\ hrs\}$
${t_4}^d = Physical\ health = \{Good, moderate, Poor\}$.
Assuming the relation $\mathcal{B}({t_1}^a \times {t_2}^b \times {t_3}^c \times {t_4}^d)$ corresponds to the toddlers' details, we have: $\mathcal{B}(2-3yrs, Female, 5-8hrs, moderate\}$.

**Step: 1**

We create the decision matrix based on the data provided by the three decision makers, expressed in terms of BNHSNs, for the given toddler information (2-3 years, Female, 3-5 hours, moderate). The decision makers offer their opinions in the form of linguistic variables. Table 1 shows the BNHSNs.

In terms of linguistic variables, the decision maker's opinions are represented as follows.

$$\mathbb{D}m_1=\begin{array}{c} \\ \eta_1 \\ \eta_2 \\ \eta_3 \\ \eta_4 \\ \eta_5 \end{array}\begin{array}{c} \begin{array}{cccc} t_1 & t_2 & t_3 & t_4 \end{array} \\ \begin{bmatrix} AHA & VHA & AHA & LA \\ VHA & HA & HA & AHA \\ HA & AHA & VHA & HA \\ LA & VLA & MA & MA \\ HA & LA & AHA & VHA \end{bmatrix} \end{array}$$

$$\mathbb{D}m_2=\begin{array}{c} \\ \eta_1 \\ \eta_2 \\ \eta_3 \\ \eta_4 \\ \eta_5 \end{array}\begin{array}{c} \begin{array}{cccc} t_1 & t_2 & t_3 & t_4 \end{array} \\ \begin{bmatrix} AHA & HA & VHA & HA \\ HA & VHA & HA & LA \\ LA & ALA & MA & MA \\ HA & MA & AHA & VHA \\ VHA & HA & AHA & VHA \end{bmatrix} \end{array}$$

$$\mathbb{D}m_3=\begin{array}{c} \\ \eta_1 \\ \eta_2 \\ \eta_3 \\ \eta_4 \\ \eta_5 \end{array}\begin{array}{c} \begin{array}{cccc} t_2 & t_3 & t_4 & \end{array} \\ \begin{bmatrix} HA & VHA & VHA & AHA \\ VHA & HA & HA & MA \\ MA & LA & VLA & LA \\ HA & LA & VHA & VHA \\ MA & LA & HA & AHA \end{bmatrix} \end{array}$$

Using BNHSNs, the above linguistic variables are transformed into decision matrices in the manner described below:

$$\mathbb{D}m_1=\begin{array}{c} \\ \eta_1 \\ \eta_2 \\ \eta_3 \\ \eta_4 \\ \eta_5 \end{array}\begin{array}{c} \begin{array}{cccc} t_1 & t_2 & t_3 & t_4 \end{array} \\ \begin{bmatrix} (0.9,0.5,0.4,-0.2,-0.7,-0.6) & (0.8,0.4,0.2,-0.1,-0.5,-0.7) & (0.9,0.5,0.4,-0.2,-0.7,-0.6) & (0.4,0.5,0.7,-0.5,-0.1,-0.3) \\ (0.8,0.4,0.2,-0.1,-0.5,-0.7) & (0.7,0.6,0.5,-0.3,-0.2,-0.1) & (0.7,0.6,0.5,-0.3,-0.2,-0.1) & (0.9,0.5,0.4,-0.2,-0.7,-0.6) \\ (0.7,0.6,0.5,-0.3,-0.2,-0.1) & (0.9,0.5,0.4,-0.2,-0.7,-0.6) & (0.8,0.4,0.2,-0.1,-0.5,-0.7) & (0.7,0.6,0.5,-0.3,-0.2,-0.1) \\ (0.4,0.5,0.7,-0.5,-0.1,-0.3) & (0.3,0.4,0.8,-0.6,-0.5,-0.1) & (0.5,0.6,0.7,-0.6,-0.3,-0.2) & (0.5,0.6,0.7,-0.6,-0.3,-0.2) \\ (0.7,0.6,0.5,-0.3,-0.2,-0.1) & (0.4,0.5,0.7,-0.5,-0.1,-0.3) & (0.9,0.5,0.4,-0.2,-0.7,-0.6) & (0.8,0.4,0.2,-0.1,-0.5,-0.7) \end{bmatrix} \end{array}$$

$$\mathbb{D}m_2=\begin{array}{c} \\ \eta_1 \\ \eta_2 \\ \eta_3 \\ \eta_4 \\ \eta_5 \end{array}\begin{array}{c} \begin{array}{cccc} t_1 & t_2 & t_3 & t_4 \end{array} \\ \begin{bmatrix} (0.9,0.5,0.4,-0.2,-0.7,-0.6) & (0.7,0.6,0.5,-0.3,-0.2,-0.1) & (0.8,0.4,0.2,-0.1,-0.5,-0.7) & (0.7,0.6,0.5,-0.3,-0.2,-0.1) \\ (0.7,0.6,0.5,-0.3,-0.2,-0.1) & (0.8,0.4,0.2,-0.1,-0.5,-0.7) & (0.7,0.6,0.5,-0.3,-0.2,-0.1) & (0.4,0.5,0.7,-0.5,-0.1,-0.3) \\ (0.4,0.5,0.7,-0.5,-0.1,-0.3) & (0.1,0.6,0.8,-0.8,-0.2,-0.1) & (0.5,0.6,0.7,-0.6,-0.3,-0.2) & (0.5,0.6,0.7,-0.6,-0.3,-0.2) \\ (0.7,0.6,0.5,-0.3,-0.2,-0.1) & (0.5,0.6,0.7,-0.6,-0.3,-0.2) & (0.9,0.5,0.4,-0.2,-0.7,-0.6) & (0.8,0.4,0.2,-0.1,-0.5,-0.7)) \\ (0.8,0.4,0.2,-0.1,-0.5,-0.7) & (0.7,0.6,0.5,-0.3,-0.2,-0.1) & (0.9,0.5,0.4,-0.2,-0.7,-0.6) & (0.8,0.4,0.2,-0.1,-0.5,-0.7) \end{bmatrix} \end{array}$$

$$\mathbb{D}m_3=\begin{array}{c} \\ \eta_1 \\ \eta_2 \\ \eta_3 \\ \eta_4 \\ \eta_5 \end{array}\begin{array}{c} \begin{array}{cccc} t_1 & t_2 & t_3 & t_4 \end{array} \\ \begin{bmatrix} (0.7,0.6,0.5,-0.3,-0.2,-0.1) & (0.8,0.4,0.2,-0.1,-0.5,-0.7) & (0.8,0.4,0.2,-0.1,-0.5,-0.7) & (0.9,0.5,0.4,-0.2,-0.7,-0.6) \\ (0.8,0.4,0.2,-0.1,-0.5,-0.7) & (0.7,0.6,0.5,-0.3,-0.2,-0.1) & (0.7,0.6,0.5,-0.3,-0.2,-0.1) & (0.5,0.6,0.7,-0.6,-0.3,-0.2) \\ (0.5,0.6,0.7,-0.6,-0.3,-0.2) & (0.4,0.5,0.7,-0.5,-0.1,-0.3) & (0.3,0.4,0.8,-0.6,-0.5,-0.1) & (0.4,0.5,0.7,-0.5,-0.1,-0.3) \\ (0.7,0.6,0.5,-0.3,-0.2,-0.1) & (0.4,0.5,0.7,-0.5,-0.1,-0.3) & (0.8,0.4,0.2,-0.1,-0.5,-0.7) & (0.8,0.4,0.2,-0.1,-0.5,-0.7)) \\ (0.5,0.6,0.7,-0.6,-0.3,-0.2) & (0.4,0.5,0.7,-0.5,-0.1,-0.3) & (0.7,0.6,0.5,-0.3,-0.2,-0.1) & (0.9,0.5,0.4,-0.2,-0.7,-0.6) \end{bmatrix} \end{array}$$

**Step: 2** Given that each alternative is regarded as cost-based, we normalize the decision matrices ($\mathbb{D}m_1, \mathbb{D}m_2, \mathbb{D}m_3$) as follows:

$$\mathbb{D}m_1=\begin{array}{c} \\ \eta_1 \\ \eta_2 \\ \eta_3 \\ \eta_4 \\ \eta_5 \end{array}\begin{array}{c} \begin{array}{cccc} t_1 & t_2 & t_3 & t_4 \end{array} \\ \begin{bmatrix} (0.1,0.5,0.6,-0.8,-0.3,-0.4) & (0.2,0.6,0.8,-0.9,-0.5,-0.3) & (0.1,0.5,0.6,-0.8,-0.3,-0.4) & (0.6,0.5,0.3,-0.5,-0.9,-0.7) \\ (0.2,0.6,0.8,-0.9,-0.5,-0.3) & (0.3,0.4,0.5,-0.7,-0.8,-0.9) & (0.3,0.4,0.5,-0.7,-0.8,-0.9) & (0.1,0.5,0.6,-0.8,-0.3,-0.4) \\ (0.3,0.4,0.5,-0.7,-0.8,-0.9) & (0.1,0.5,0.4,-0.8,-0.3,-0.4) & (0.2,0.6,0.8,-0.9,-0.5,-0.3) & (0.3,0.4,0.5,-0.7,-0.8,-0.9) \\ (0.6,0.5,0.3,-0.5,-0.9,-0.7) & (0.7,0.6,0.2,-0.4,-0.5,-0.9) & (0.5,0.4,0.3,-0.4,-0.7,-0.8) & (0.5,0.4,0.3,-0.4,-0.7,-0.8) \\ (0.3,0.4,0.5,-0.7,-0.8,-0.9) & (0.6,0.5,0.3,-0.5,-0.9,-0.7) & (0.1,0.5,0.6,-0.8,-0.3,-0.4) & (0.2,0.6,0.8,-0.9,-0.5,-0.3) \end{bmatrix} \end{array}$$

$$\mathbb{D}m_2=\begin{array}{c} \\ \eta_1 \\ \eta_2 \\ \eta_3 \\ \eta_4 \\ \eta_5 \end{array}\begin{array}{c} \begin{array}{cccc} t_1 & t_2 & t_3 & t_4 \end{array} \\ \begin{bmatrix} (0.1,0.5,0.6,-0.8,-0.3,-0.4) & (0.3,0.4,0.5,-0.7,-0.8,-0.9) & (0.2,0.6,0.8,-0.9,-0.5,-0.3) & (0.3,0.4,0.5,-0.7,-0.8,-0.9) \\ (0.3,0.4,0.5,-0.7,-0.8,-0.9) & (0.2,0.6,0.8,-0.9,-0.5,-0.3) & (0.3,0.4,0.5,-0.7,-0.8,-0.9) & (0.6,0.5,0.3,-0.5,-0.9,-0.7) \\ (0.6,0.5,0.3,-0.5,-0.9,-0.7) & (0.9,0.4,0.2,-0.2,-0.8,-0.9) & (0.5,0.4,0.3,-0.4,-0.7,-0.8) & (0.5,0.4,0.3,-0.4,-0.7,-0.8) \\ (0.3,0.4,0.5,-0.7,-0.8,-0.9) & (0.5,0.4,0.3,-0.4,-0.7,-0.8) & (0.1,0.5,0.6,-0.8,-0.3,-0.4) & (0.2,0.6,0.8,-0.9,-0.5,-0.3) \\ (0.2,0.6,0.8,-0.9,-0.5,-0.3) & (0.3,0.4,0.5,-0.7,-0.8,-0.9) & (0.1,0.5,0.6,-0.8,-0.3,-0.4) & (0.2,0.6,0.8,-0.9,-0.5,-0.3) \end{bmatrix} \end{array}$$

$$\mathbb{D}m_3= \begin{array}{c} \\ \eta_1 \\ \eta_2 \\ \eta_3 \\ \eta_4 \\ \eta_5 \end{array} \begin{array}{c} t_1 \\ \begin{bmatrix} (0.3,0.4,0.5,-0.7,-0.8,-0.9) \\ (0.2,0.6,0.8,-0.9,-0.5,-0.3) \\ (0.5,0.4,0.3,-0.4,-0.7,-0.8) \\ (0.3,0.4,0.5,-0.7,-0.8,-0.1) \\ (0.5,0.4,0.3,-0.4,-0.7,-0.8) \end{bmatrix} \end{array} \begin{array}{c} t_2 \\ \begin{bmatrix} (0.2,0.6,0.8,-0.9,-0.5,-0.3) \\ (0.3,0.4,0.5,-0.7,-0.8,-0.9) \\ (0.6,0.5,0.3,-0.5,-0.9,-0.7) \\ (0.6,0.5,0.3,-0.5,-0.9,-0.7) \\ (0.6,0.5,0.3,-0.5,-0.9,-0.7) \end{bmatrix} \end{array} \begin{array}{c} t_3 \\ \begin{bmatrix} (0.2,0.6,0.8,-0.9,-0.5,-0.3) \\ (0.3,0.4,0.5,-0.7,-0.8,-0.9) \\ (0.7,0.6,0.2,-0.4,-0.5,-0.9) \\ (0.2,0.6,0.8,-0.9,-0.5,-0.3) \\ (0.3,0.4,0.5,-0.7,-0.8,-0.9) \end{bmatrix} \end{array} \begin{array}{c} t_4 \\ \begin{bmatrix} (0.1,0.5,0.6,-0.8,-0.3,-0.4) \\ (0.5,0.4,0.3,-0.4,-0.7,-0.8) \\ (0.6,0.5,0.3,-0.5,-0.9,-0.7) \\ (0.2,0.6,0.8,-0.9,-0.5,-0.3) \\ (0.1,0.5,0.6,-0.8,-0.3,-0.4) \end{bmatrix} \end{array}$$

**Step: 3** Let $\beta = (0.27, 0.5, 0.23)$ be the decision makers' weight vector. Equation (3& 4) yields the following aggregated decision matrix:

$$\mu= \begin{array}{c} \\ \eta_1 \\ \eta_2 \\ \eta_3 \\ \eta_4 \\ \eta_5 \end{array} \begin{array}{c} t_1 \\ \begin{bmatrix} (.15,.48,.58,-.78,-.42,-.52) \\ (.25,.5,.65,-.82,-.65,-.6) \\ (.5,.45,.35,-.53,-.83,-.78) \\ (.38,.43,.45,-.765-.83,-.66) \\ (.3,.5,.6,-.73,-.63,-.58) \end{bmatrix} \end{array} \begin{array}{c} t_2 \\ \begin{bmatrix} (.25,.5,.65,-.8,-.65,-.6) \\ (.25,.5,.65,-.8,-.65,-.6) \\ (.62,.45,.28,-.43,-.69,-.72) \\ (.58,.48,.27,-.42,-.69,-.8) \\ (.45,.45,.4,-.6,-.85,-.8) \end{bmatrix} \end{array} \begin{array}{c} t_3 \\ \begin{bmatrix} (.17,.57,.75,-.87,-.45,-.33) \\ (.3,.4,.5,-.7,-.8,-.9) \\ (.47,.5,.41,-.54,-.6,-.69) \\ (.23,.5,.57,-.72,-.48,-.49) \\ (.15,.48,.58,-.78,-.42,-.52) \end{bmatrix} \end{array} \begin{array}{c} t_4 \\ \begin{bmatrix} (.34,.45,.47,-.67,-.71,-.73) \\ (.44,.48,.38,-.56,-.69,-.64) \\ (.47,.42,.35,-.5,-.77,-.8) \\ (.28,.55,.67,-.77,-.55,-.44) \\ (.18,.58,.75,-.88,-.45,-.32) \end{bmatrix} \end{array}$$

**Step: 4** Determine the positive ideal solution $\mathbb{f}_{ij}{}^{+}$ and the negative ideal solution $\mathbb{f}_{ij}{}^{-}$.

$$\mathbb{f}_{ij}{}^{+} = \begin{array}{cccc} t_1 & t_2 & t_3 & t_4 \\ ((.5,.43,.35,-.53,-.83,-.78) & (.62,.45,.27,-.42,-.85,-.8) & (.47,.4,.41,-.6,-.8,-.9) & (.47,.42,.35,-.5,-.77,-.8)) \end{array}$$

$$\mathbb{f}_{ij}{}^{-} = \begin{array}{cccc} t_1 & t_2 & t_3 & t_4 \\ ((.15,.5,.65,-.82,-.42,-.52) & (.25,.5,.65,-.8,-.65,-.6) & (.15,.57,.75,-.87,-.42,-.33) & (.18,.58,.75,-.88,-.45,-.32)) \end{array}$$

**Step: 5**

Using equations (7) and (8), we computed the values of $\rho_i$ and $\omega_i$, and the outcomes are shown below:

$\rho_1 = 0.14 + 0.39 + 0.39 + 0.02 = 0.94$

$\rho_2 = 0.1 + 0.39 + 0.07 + 0.01 = 0.57$

$\rho_3 = 0.002 + 0.06 + 0.112 + 0 = 0.174$

$\rho_4 = 0.04 + 0.06 + 0.27 + 0.04 = 0.41$

$\rho_5 = 0.1 + 0.12 + 0.29 + 0.06 = 0.57$

$\omega_1 = 0.39, \omega_2 = 0.39, \omega_3 = 0.112, \omega_4 = 0.27, \omega_5 = 0.29$

**Step: 6**

With equation (9) and π=0.5, we get

$H_1 = 1, H_2 = 0.76, H_3 = 0, H_4 = 0.44, H_5 = 0.58.$

Values for ϱ, ω, and H are shown in Table 2.

**Step: 7**

The alternatives are ranked using the standard VIKOR technique criteria as follows:

By ϱ: $\eta_3 < \eta_4 < \eta_5 = \eta_2 < \eta_1$.

By ω: $\eta_3 < \eta_4 < \eta_5 < \eta_2 = \eta_1$.

By H: $\eta_3 < \eta_4 < \eta_5 < \eta_2 < \eta_1$.

According to Park et al., $\eta_3$is the best compromise solution since it satisfies the necessary requirement.

$$H(\eta_4) - H(\eta_3) \geq \frac{1}{\mu - 1}$$

The first and second ranks according to H are shown by H($\eta_3$) and H($\eta_4$), respectively, where μ is the number of alternatives.

$$H(\eta_4) - H(\eta_3) \geq \frac{1}{4}$$

$$0.44 - 0 = 0.44 \geq \frac{1}{4}$$

Since $\eta_3$ is ranked highest in both ϱ and ω, it is regarded as a stable alternative. Thus, toddlers who spend too much time in front of screens are largely affected in their language development.

## RESULTS AND DISCUSSION

According to results, toddlers' language development($\eta_3$) is significantly impacted by excessive screen timein toddlers aged 2–3 years who are exposed to screens for 3–5 hours every day and have a moderate level of health. Other characteristics that have a moderate impact on their general well-being are $\eta_4$, $\eta_5$, $\eta_2$, and $\eta_1$. In these situations, our suggested VIKOR approach successfully identifies the main effects of excessive screen usage. Decision-makers can more accurately comprehend and evaluate the impacts of excessive screen time on children by using this method.

## CONCLUSION

When working in a parametric context, the BNHSS idea is intended to improve user accuracy and focus.Expanding on this idea, distance measures for BNHSS are introduced and subsequently utilized to expand the BNHS-VIKOR approach.Using Hamming distance measurements, the optimal solution is found and the alternatives are ranked appropriately.The significant impact of excessive screen time on toddlers is finally illustrated with an example.
Future research can introduce similarity and entropy measurements for BNHSS and show their efficacy by applying them to real-world situations.

**ABSTRACT**

This paper examines the application of bibliometric laws in Indian green energy research publications indexed in the Web of Science during 2009–2025. Bradford's Law revealed a pronounced concentration of research output in a small core of journals. According to Bradford's distribution, the relationship between zones is expected to follow the ratio 1: a : $a^2$, whereas in the present study the relationship observed is 22 : 57 : 306, which does not conform to Bradford's distribution. Similarly, Lotka's Law of author productivity, tested using the Chi-square method, and indicated a significant deviation from the expected distribution, thereby invalidating the law in this context. In contrast, the frequency distribution of keywords was found to be consistent with Zipf's Law.

**Keywords:** Green Energy, Bibliometric Analysis, Bradford's law, Lotka's Law, Price square root Law, Pareto principle,.

## INTRODUCTION

Green Energy refers to energy produced from natural resources that are renewable , sustainable and have minimal negative impact on the environment .It plays a critical role in reducing carbon emissions, combating climate change and promoting sustainable development. The transformation of Green Energy is a foundation of global efforts to address climate change, reduce green house gas emissions and promote sustainable developments. India as one of the world's fastest growing economies, has demonstrated a rising commitment to renewable and eco-friendly energy solutions. This study applies bibliometric laws including Bradford law of scattering, Lotka's law of Author

productivity, Inverse Square law, Zipf's law of word frequency, Price square root law and the Pareto principle to analyse 1078 publications on green energy research in India from 2009 to 2025. This study aims to examine journal concentration, author productivity patterns and overall research growth in the field.

## REVIEW OF RELATED LITERATURE

Since this paper deals with bibliometrics of Green Energy research, multiple searches were conducted across various databases using the keywords bibliometrics and scientometrics in combination with synonymous terms such as renewable energy. Several papers are retrieved and a few of the recent ones relevant to this topic are reviewed here. Joseph et. al (2024) analyses the mapping the Landscape of green energy integration in Business and management. Aytac *et al* (2025) reviews the Lotka's law of scientific productivity across the research Disciplines in science and technology literature. Gunaseelan *et.al* (2025) examines the application of Bradford's law and Leimkuhler model using Bibliometric analysis in the research publication of Bharathidasan University. Souza *et.al* (2024) explains the mapping the growth of ESG research using Bibliometric laws of Lotka's and Zipf's . Xue,Liu (2024) evaluates the Bradford Curves in Specialized library contexts and extends the Bradford law mathematically by analysing the dynamics of journal productivity zones over time. Mayo Augustin (2024) analysing the data from Scopus and web of science databases to track scientific output, citation trends authorship patterns conducted a bibliometric analysis. Mwirigi *et.al* (2024) adopts a bibliometric approach to provide an overview of the borrowers behaviour reviewed by 989 articles from Scopus database. Gupta Singh (2024) evaluates the distributional characteristics of Dimensions concepts using Zipf's law. Yumnam and Singh(2024) examines the theoretical aspects of Bradford's law and Leimkuhler model analyses the 16914 research papers in 2277 journals from web of science. Lalrempuii and Ngurtinkhuma examines the validity of Lotka's law to authorship patterns and Zipf's law of word occurrence. Jayaraman and Vidya study the application of Zipf's law for Indian language and analyzing the rank frequency for fitting the distribution of keywords.

## OBJECTIVES OF THE STUDY

1. To analyze the growth of Indian publications on Green Energy from 2009 to 2025.
2. To identify the journals publishing research on green energy and to examine their various citation scores.
3. To evaluate the applicability of Bradford's Law to green energy research publications.
4. To investigate the applicability of Lotka's Law of scientific author productivity in green energy research.
5. To analyze keyword distributions and to test and validate Zipf's Law of word frequency in green energy literature.
6. To examine the applicability of Price's Square Root Law and the Pareto Principle (80/20 rule) in green energy publications.

## METHODOLOGY

The data for this study were gathered from the Web of Science database for the period 2009–2025 by using the keyword "Green Energy" in the topic field, focusing on publications with Indian contributions indexed in the Web of Science Citation Index Expanded. A total of 1078 publications were retrieved. The data were downloaded in plain text format and extracted using HistCite software. It is also analytical in nature in strengthening the empirical validity due to application of suitable statistical tools and bibliometric laws.

**Application of Basic Empirical Laws of Bibliometrics**

The researcher applied fundamental bibliometric laws, including Bradford's Law of Scattering of Journals, Lotka's Law of Author Productivity, Zipf's Law of Word Frequency, the Inverse Square Law of Author Productivity, Price's Square Root Law, and the Pareto Principle (80/20 Rule), to analyze the collected data.

**Bradford's Law of Scattering of Journals**

Bradford's Law of Scattering has been adopted to examine all journal titles contributing to the bibliography focused on green energy research by scientists. The journals were arranged in order of decreasing productivity on the subject. They were then divided into a nucleus of journals or periodicals particularly devoted to green energy research and several subsequent groups or zones, each containing approximately the same number of articles as the nucleus. The number of periodicals in the nucleus and the succeeding zones follows the ratio $1 : n : n^2$.To describe this scattering phenomenon, the following mathematical formula is used:

$F(X) = a + b \log X$. where $F(X)$ is the cumulative number of references contained in the first $X$ most productive journals, and a and b are constants

**Zipf's Law**

Zipf's Law is often used to predict word frequencies in full texts. According to the law, if the words in a relatively large text corpus are listed in order of decreasing frequency, the rank of a word on that list multiplied by its frequency will equal a constant (Zipf, 1949):

Zipf's law: r x f =c ,where

**r** = rank of the word (in terms of frequency)

**f** = frequency (number of times the word appears in the text)

**c** = constant for the given text

For a given text, the rank of a word multiplied by its frequency will approximately equal a constant.

**Lotka's Law of Author Productivity**

Lotka's Law is one of the three major bibliometric laws and explains the distribution of literature based on the productivity of authors in a given field. Lotka's Law of author productivity is typically tested using the chi-square model of scientific productivity, which relates the number of authors to the number of publications they produce. This model has been applied in the present study. The sum was used as deviser for 1/ n 4.65 to determine the proportion of the total number of authors expected to produce 'n' paper (in the case of present study n=1,2.3….10), the following formula was used to find the proportions.

$S = \sum 1/n\ 4.65$

For the present study S is the sum of Lotka's modified ratios for the value a= 4.65

The formula $an = 1/ n\ 4.65\ T/S$ (n= 1,2,3… 10)

Where, T is total number of authors in the sampling

An is the total number of expected authors producing 'n' papers.

The chi-square can be computed as $(F-P)^2/p$

**F** = observed number of authors with 'n' publications;

**P** = expected number of authors.

**Lotka's Inverse Square Law of Scientific Author Productivity**

The general formula for Lotka's Inverse Square Law is given by

$XY=C$

**where:** X is the number of publications, Y is the relative frequency of authors with X publications, C is a constant, which depends on the specific field of study. This relationship is also referred to as the Inverse Square Law. The exponent n value can be calculated using the following formula:

$$N=\frac{N\sum xy=\sum x-\sum y}{N\sum x^2-(\sum x)^2}$$

where,

N = number of data pairs, X = logarithm of the number of publications, Y = logarithm of the number of authors.

**Price's Square Root Law**

Price's Square Root Law states that half (50%) of the literature on a subject will be contributed by the square root of the total number of authors publishing in that area. To validate whether the distribution of authors follows Price's Square Root Law, the following calculation is carried out;

PSQ=N

Where PSQ is the predicted number of core authors and N is the total number of authors.

**Pareto Principle (80/20 Rule)**

The Pareto Principle, also known as the 80/20 Rule, states that for many events, roughly 80% of the effects come from 20% of the causes. The original observation was related to income and wealth, where Pareto noticed that 80% of Italy's wealth was owned by 20% of the population. He then conducted surveys in various other countries and found, to his surprise, that a similar distribution applied. This principle is also applied in bibliometrics, where, for example, a small proportion of authors or journals often contribute the majority of publications or citations.

## ANALYSIS AND DISCUSSION

**Year wise distribution of Publication and Citation score**

Table 1 show that a chronological histogram of citations, demonstrating that citation frequency grew steadily from 2009; the GCS of 3359 in 2020 and LCS of 50 in 2018. The highest publication is 269 in 2024 with 1511 GCS. The study also reveals that these 1,078 publications contain 72,716 cited references, indicating a healthy trend of citing references among Indian scientists working in the field of green energy.

**Bradford's Law Distribution**

The Bradford law was formulated in the year 1948. It examines essentially that a group of journals are arranged in an order of decreasing productivity. Bradford's Law of Scattering explains that a relatively small number of journals account for a large portion of articles on a subject, while a large number of journals contribute only a few articles each. In this datasets, the core journal (S. No. 1) alone produced 45 articles. The next six journals (S. No. 2 to 6) contributed 98 articles, showing a steep drop but still a significant output. The remaining 377 journals (S.No. 7 to 18) produced the rest of 935 articles, indicating a wide scattering consistent with Bradford's Law. Ranking of Journals according to Bradford's Law (Table 2)

**Bradford's Distribution of Journals in Various Zones**

In table 2A the first zone, consisting of only 22 core journals, produced 323 publications. The second zone required 57 journals to contribute 326 publications, while the third zone encompassed 306 journals contributing 429 publications. This analysis reveals a distinct scattering pattern: the number of journals needed to produce a comparable number of articles increased geometrically across the zones, with Multiplier factors of 2.59 from Zone 1 to Zone 2, and 5.37 from Zone 1 to Zone 3. These findings underscore the concentration of research output within a small core of journals and the extensive scattering of articles across a large number of less frequently used sources. Bradford's Distribution of Journals in Various Zones (Table 2A)

**Lotka's Law of Author Productivity – Chi-Square Model**

Lotka's Law of author productivity was tested using the scientific productivity Chi-Square model, applied in relation to the number of authors contributing to the number of publications. It is important to consider the implications of Lotka's Law for author productivity in green energy research. The law posits that the proportion of authors making only a single contribution should be approximately 60%. However, the analysis of green energy publications in this study reveals that the proportion of authors making a single contribution is less than 60%, thereby invalidating Lotka's expected distribution at first glance. Further, the application of Lotka's Chi-Square model supports this observation: the calculated chi-square ($\chi 2$) value is 116,572.9, which is significantly greater than the critical table value at the 5 percent level of significance. This result indicates that Lotka's Law does not hold true for author

productivity in the context of green energy research Shows Lotka's Law of Author productivity-Chi-Square Model (Table 3).

**Lotka's Law of Author Productivity – Inverse Square Model**

The analysis presented in Table 4 illustrates the application of Lotka's Law to the author productivity in green energy research. It can be clearly observed from the table that the proportion of authors making only a single contribution is 2.3%. This indicates a very high level of collaborative authorship. Moreover, the tabulated values show that the observed number of authors exceeds the expected values predicted by Lotka's Law. Therefore, the present analysis clearly invalidates the applicability of Lotka's Law in this context. Lotka's Law of Author Productivity – Inverse Square Model (Table 4)

**Application of Price's Square Root Law**

To verify whether the distribution of authors satisfies Price's Square Root Law, the computation is based on the following approach

PSQ = 72.55 , N= 5263

Based on Price's Square Root Law, the data show that a few individual contributors produced 38, 34, 22, 20, 19, and 12 articles each. The square root of the total number of contributors (5,263) is approximately 72, which corresponds to only 1.37 percent of the publications. Most authors contributed only a few times to green energy research. The percentage contribution by the 72 most productive authors, who represent the square root of the total contributor pool, accounts for just 1.37 percent of the publications. This value is significantly lower than the expected 50 percent (i.e., half of the literature) predicted by Price's Square Root Law. Therefore, the results do not comply with Price's Square Root Law.The table below highlights the relevant results. Application of Price's Square Root Law (Table 5)

**Pareto Principle (80/20 Rule)**

For this analysis, the researcher used the data presented in the table-6 below to validate the Pareto Principle and to test whether 80 percent of the contributions come from 20 percent of the authors. Since the total number of authors is 5263, 20 percent of this total corresponds to 1052 authors. The total number of publications is 5,263 and 80 percent of the publications would therefore amount to 4210. Based on the analysis, the accumulated percentage of contributions (Accumulated % of A*B) shows that 23.6 percent of authors contributed more than 20 percent of the total publications. The accumulated number of contributors is 1,242, which is higher than the expected 1052 (20 percent of 5,263). According to the 80/20 rule, this value should be much closer to 20 percent. The remaining 76.4 percent of authors contributed 4,021 publications. Therefore, it can be concluded that the results are largely in compliance with the Pareto Principle. Shows Pareto Principle (80/20 Rule) (Table 6)

**Ranking of Word Occurrence According to Zipf's Law**

Zipf's Law states that in a large body of text, if the words are arranged in decreasing order of frequency, the rank of any given word will be inversely proportional to its frequency of occurrence; that is, r×f=constant, where r is the rank of the word and f is its frequency.

R x F=C

(Where C is constant)Taking log on both sides, Log (f) + Log(r) =Log c Or Log (f) + Log (r) = (where 'c' is constant).To apply this law, words (terms) were extracted from the titles of the articles and ranked in decreasing order according to their frequency of occurrence. Only the twenty-five words with a cumulative frequency up to 2,496 occurrences are presented in the table. Upon applying Zipf's Law, it was found that the sum of the logarithm of the frequency of occurrence and the logarithm of the rank yielded nearly constant values for each word. For example, the logarithmic frequencies of the three most frequently occurring words appearing in the titles—including "Energy"—are given below

Word : Energy

Frequency : 375

Rank : 1

Log of frequency+ log of rank

Log 375+ log 1 =2.57+0 =2.57 words. Thus,it is proved that Zipf's law is valid even today.
Ranking of Word Occurrence according to Zipf's Law (Table -7)

**Major Findings**

The findings of the study are as follows

1. The number of Indian publications in green energy research has been gradually increasing trends.
2. The study found that the total research output of the Green Energy for the study period (2009 – 2025) published in 385 journals. Twenty two journals covered more than one third of the total articles, next 57 journals covered the second one third, and 306 journals the last third that is coincide with the theory of Bradford's Law of scattering of journals in research productivity. Based on the study the applicability of Bradford's law of scattering in various journals is identified as invalidated.
3. The findings of author productivity in terms of Lotka's law implications reveal the following facts that the analyzed data invalidate Lotka's findings. Lotka's Chi square model confirms the source trend. It explains the fact that the calculated $x^2$ value is 116572.9 which is less than the tabulated value at 5 percent level of significance.
4. The findings of word frequency in terms of Zipf's law implications reveal the following facts that the analyzed data is valid Zipf's law in Green energy literature.
5. The findings of Price Square root value is very far away from 50% (half of literature in a subject).Therefore it does not fit to Price Square Root Law.
6. The findings of 80x20 rule, 80% of the publications are 4021. Therefore, the result follows Pareto Principle.

## CONCLUSION

The findings of this study reveal that, the number of publications in Green energy from India is increasing annually. Thus it is inferred that Green Energy scientists are working actively. The distribution of Green energy articles does not conform to Bradford's law. The reason why author productivity distributions does not conform to Lotka's law that there are many authors who contribute to Green energy field with single articles only. Most used keywords identified provide valuable information for those researchers who intend to search for articles in Green energy. It conforms to Zipf's law because the numbers of words that appear several times in the titles are very high. Conformity was seen in 80/20 rule also. The researcher did not study the subfields of green energy in detail. Therefore further research is needed to conduct bibliometric analysis of publications in the subfields of green energy also to get a clear idea.

## ABSTRACT

This research delves into the design, construction, and operation of UAV propeller that take design cues from the corrugated wing shape of dragonflies (Anisoptera). We compare the aerodynamic efficiency of a standard baseline propeller to that of a new design with a corrugated leading edge, inspired by the unusual structural features of dragonfly wings. Fused Deposition Modelling (FDM) additive manufacturing using carbon fiber-reinforced polyamide (CF-PA) composite material ensures good strength-to-weight ratio for both propeller prototypes. Initially, flow patterns are analysed and performance parameters like thrust and torque are predicted using Computational Fluid Dynamics (CFD) models. Later on, experimental wind tunnel testing is used to confirm these computer findings. In comparison to the traditional design, the results show that the corrugated propeller inspired by dragonflies greatly improves aerodynamic performance by controlling flow separation and decreasing vorticity, which in turn increases thrust generation and overall efficiency. Findings from this study provide credence to the idea that advanced composite FDM and geometries inspired by nature may be used to create lightweight, high-performance UAV propulsion systems.

# INTRODUCTION

This study investigates the use of carbon fibre composites in fused deposition modelling (FDM) to create UAV propellers that resemble dragonflies. The project intends to evaluate the improved aerodynamic efficiency and performance of these bio-inspired designs over traditional propeller geometry via experimental testing and computational fluid dynamics (CFD) analysis.

**UAV Uses and Propeller Design's Crucial Significance**

Drones, sometimes referred to as unmanned aerial vehicles, or UAVs, have evolved from their military roots to become essential instruments for a wide range of civilian uses. These days, they work in precision agriculture for crop monitoring and spraying, examine bridges and wind turbines, conduct search and rescue missions in disaster areas, take aerial photos and videos, and supply last-mile supplies. One key performance metric—flight efficiency—is essentially responsible for the sector's exponential expansion. Increased cargo capacity, a lower acoustic signature, and longer operational endurance (longer flight periods) [1] are all closely correlated with improved efficiency and are essential for the economic viability and broader acceptance of UAV technology.

The propulsion system, which is mostly made up of the propeller, electric motor, and electronic speed controller (ESC), is the foundation of a multirotor UAV's operation. The only one of them that interacts with the air to provide the necessary thrust for lift, propulsion, and maneuverability is the propeller. The efficiency with which the motor's rotational output is transformed into aerodynamic force depends on its design. Consequently, even little increases in propeller efficiency may result in significant improvements in system performance as a whole. Although highly optimised, conventional propeller designs—which are often based on classic aerofoil sections like the NACA series—may be nearing a performance plateau. At low Reynolds numbers, which are common of small-scale UAVs, [2] these designs may be inefficient. In particular, they may have problems like early flow separation and increased drag, which become more noticeable during complicated flying manoeuvres or in windy circumstances. This restriction has sparked an effort to find new, highly efficient propeller designs that can surpass current benchmarks.

**The Promise of Bio-Inspired Approaches**

Through millions of years of evolutionary optimisation, nature provides a wealth of creative answers to challenging aerodynamic problems. Studying and imitating these natural systems, techniques, and models in order to address human issues is known as bio-inspired design. The aviation industry itself is essentially bio-inspired, since early pioneers such as Leonardo da Vinci and the Wright brothers sought inspiration from birds. The Anisoptera, or dragonfly, is a particularly interesting topic for research on bioinspired aerodynamics. Dragonflies are among of the world's most nimble and effective flying insects; they can glide, hover, fly backwards, and make quick twists in the air while using little energy. Their ability to fly is ascribed to a special fusion of wing shape and flight dynamics. The intricate corrugated structure of their wings, which consists of a sequence of longitudinal ridges and valleys extending the wing's span, is a crucial morphological characteristic. This corrugation was misunderstood for decades as just structural strengthening. Recent studies, however, have shown its significant aerodynamic advantages. According to studies, the corrugations serve as passive flow control mechanisms. More significantly, they successfully stop flow separation at high angles of attack and aid in stabilising the leading-edge vortex (LEV), a low-pressure area that increases lift. This enables the dragonfly to continue producing lift even while flying under erratic settings. By integrating a biomimetic corrugated profile, particularly at the leading edge of a UAV propeller, it may be possible to imbue the propeller with these same stability characteristics, thereby enhancing its aerodynamic efficiency, especially in off-design conditions such as during ascent, descent, or in crosswinds.

**The Role of Carbon Fiber Composites and Additive Manufacturing (FDM)**

Translating a complex bio-inspired design from a digital model into a physical, high-performance part presents significant manufacturing challenges. Traditional methods like CNC machining are often subtractive, wasteful, and

struggle with the intricate geometries and internal structures found in bio-inspired designs. This is where Additive Manufacturing (AM) [3], or 3D printing, emerges as a transformative enabling technology. Fused Deposition Modeling (FDM) is one of the most accessible, cost-effective, and versatile AM processes. It builds parts layer by layer by extruding a thermoplastic filament, allowing for the creation of highly complex geometries that are impossible or prohibitively expensive to make with any other method. This makes FDM ideal for rapid prototyping and iterative testing of novel propeller designs with features like corrugated leading edges.

However, standard thermoplastics used in FDM (e.g., PLA, ABS) lack the necessary mechanical strength, stiffness, and thermal resistance for demanding applications like high-RPM propellers. The introduction of continuous carbon fiber (CCF) [4] reinforcement into FDM processes marks a revolutionary advancement. In this process, a continuous strand of carbon fiber is co-extruded with a standard thermoplastic matrix (e.g., Nylon, PLA), resulting in parts that possess a strength-to-weight ratio comparable to aluminum. For propeller fabrication, this is a game-changer. It allows for the creation of prototypes that are not only geometrically sophisticated but also structurally robust, lightweight, and stiff enough to withstand the centrifugal and aerodynamic loads encountered during actual flight conditions. The synergy of bio-inspired design and advanced composite AM thus bridges the gap between conceptual innovation and functional, high-performance hardware.

**Objective and Scope of the Review**

The primary objective of this research is to computationally analyze and experimentally investigate the aerodynamic performance of a dragonfly-inspired corrugated propeller, fabricated via FDM using carbon fiber composites, and to compare it against a conventional baseline design.

The scope of this work encompasses:

1. The design of two propellers: a conventional design with a standard aerofoil and a bio-inspired design featuring a corrugated leading edge profile.
2. The fabrication of both prototypes using FDM with carbon fiber-reinforced polyamide (CF-PA) composite material.
3. A comprehensive Computational Fluid Dynamics (CFD) analysis to simulate and compare the aerodynamic performance (thrust, torque, efficiency, flow patterns) of both designs under various operational conditions.
4. An experimental investigation using a wind tunnel test rig equipped with a thrust stand and sensors to obtain empirical performance data for validation of the CFD results.
5. A comparative discussion on the benefits and limitations of the bio-inspired design, correlating the aerodynamic performance with the unique geometrical features and the fabrication methodology.

This study aims to demonstrate that the confluence of bio-inspired aerodynamic principles and modern composite additive manufacturing can pave the way for a new generation of high-efficiency UAV propulsion systems.

**Dragonfly-Inspired Aerodynamics**

The pursuit of enhanced aerodynamic efficiency in UAV propellers has led researchers to look beyond conventional aerofoil design paradigms. Nature, refined through eons of evolution, offers a treasure trove of optimized solutions. The dragonfly, a master of aerial agility and efficiency, presents a particularly compelling model for biomimicry. Its flight capabilities are not merely a product of complex flapping kinematics but are fundamentally enabled by the unique morphological and structural properties of its wings. The anatomy and aerodynamics of dragonfly wings are examined, along with the processes generating lift, their applicability to UAV technology, and previous studies on bio-inspired UAV design.

**Dragonfly Wing Anatomy: A Structural Wonder**

Many other insects have smooth, membrane-like wings, whereas dragonflies have a complicated, corrugated structure. This structure's remarkable mix of low weight, great strength, and aerodynamic usefulness is the product of a network of veins and membranes.

**Cross-sections with corrugation**: Dragonflies' longitudinal corrugation stands out. Asuccession of alternating peaks and troughs spanwise from root to tip form the wing's cross-section. Strong veins like the radial, anterior costa, and beneath the skin develop these corrugations, giving them a pleated appearance. This corrugation was supposed to increase the wing's bending and torsional strength without adding bulk. Although this is accurate, its aerodynamic advantages are today seen as being just as significant.

**Venation Patterns:** The wing is crisscrossed by a sophisticated network of smaller veins, dividing the wing into numerous irregular cells. This venation is not random; it creates a hierarchical structure that provides localized reinforcement, damps vibrations, and may influence airflow patterns. The veins act as stiffeners, preventing buckling, while the membranous areas in between allow for subtle, passive deformations that could be aerodynamically advantageous. This composite-like structure, with its stiff, reinforcing veins and flexible membranes, is a natural analog to engineered composite materials. The corrugated profile contributes to remarkable damage tolerance; a tear in the membrane is often arrested by the surrounding veins, preventing catastrophic failure—a highly desirable property for UAV propellers operating in harsh environments.

**Mechanisms of Lift Generation in Dragonflies**

Dragonflies employ a combination of unsteady aerodynamic mechanisms to generate the lift required for their highly maneuverable flight. These mechanisms are enhanced by their unique wing morphology.

- **Delayed Stall and Leading-Edge Vortex (LEV) [5] Stabilization:** This is the mechanism most relevant to fixed-wing and rotary-wing UAVs. At high angles of attack, the flow over an aerofoil tends to separate from the surface, leading to a sudden loss of lift (stall). The corrugations on a dragonfly wing play a crucial role in mitigating this. The valleys between corrugations can act as vorticity traps, capturing and stabilizing the Leading-Edge Vortex (LEV). A stable LEV, anchored by the corrugations, creates a region of low pressure on the upper surface of the wing, significantly enhancing lift. Furthermore, the sharp edges of the corrugations help to fix the separation points of the airflow, making the aerodynamic performance more predictable and less susceptible to drastic stall behavior. This allows dragonflies to operate effectively at high angles of attack, a condition where conventional smooth aerofoils would fail.
- **Clap-and-Fling:** During the flapping cycle, dragonflies bring their fore and hind wings together at the top of the upstroke ("clap") and then rapidly peel them apart ("fling"). This action creates a high-velocity jet of air downwards and generates circulation around each wing, augmenting lift. While this is a kinematic mechanism specific to flapping-wing flight, it underscores the insect's ability to exploit unsteady aerodynamics.
- **Wake Capture:** A wing can also gain extra lift by interacting with the vortices shed by its own previous stroke or by the other wing. This energy recovery mechanism increases overall efficiency.

For propeller applications, the mechanism of delayed stall via corrugation-induced flow stabilization is the most directly transferable concept. A propeller blade is, in essence, a rotating wing, and its efficiency is severely limited by flow separation, especially at the root and tip sections and during high-thrust maneuvers.

**Relevance to UAV Propellers**

The operational environment of small-to-medium-scale UAV propellers shares key similarities with the flight of dragonflies, primarily the regime of low Reynolds numbers (Re)[6] (typically 10,000 to 100,000). At low Re, the airflow is more viscous and prone to separation, making conventional aerofoils less efficient. The dragonfly's wing is naturally optimized for this exact regime.

Integrating a biomimetic corrugated geometry, particularly at the leading edge of a UAV propeller, aims to transfer these benefits:

1. **Enhanced High-Angle-of-Attack Performance:** By stabilizing the LEV and preventing sudden flow separation, a corrugated propeller could maintain higher lift generation during aggressive maneuvers, climb phases, or in gusty conditions where the local angle of attack varies rapidly.
2. **Improved Aerodynamic Efficiency:** Delaying stall directly translates to a higher lift-to-drag ratio within the operational envelope. For a propeller, this means generating more thrust for the same input torque or requiring less power to generate the same thrust, thereby increasing endurance.
3. **Passive Flow Control:** The corrugation provides benefits without any moving parts, sensors, or active control systems, making it a simple, reliable, and weight-effective solution for enhancing performance.

**Summary of Past Bio-Inspired UAV Research**

The field of bio-inspired aerodynamics has grown significantly, with research spanning fixed wings, flapping wings, and rotors.

- **Fixed-Wing UAVs:** Numerous studies have investigated corrugated aerofoils for micro air vehicle (MAV) wings. Early CFD and wind tunnel studies showed that while smooth aerofoils often outperform corrugated ones at low angles of attack, the corrugated profiles exhibit superior performance at high angles of attack (e.g., above 10-15°), demonstrating a much more gradual stall characteristic. This validates the dragonfly's strategy for maintaining control and lift in unstable flight conditions.
- **Flapping-Wing UAVs (Ornithopters):** Research here is direct, with many designs attempting to mimic the wing structure and kinematics of insects and birds. Studies have confirmed that incorporating venation patterns and corrugations improves structural integrity and aerodynamic output in flapping flight.
- **Propellers and Rotors:** Research on bio-inspired propellers is less extensive but emerging. Some studies have explored propellers with serrated trailing edges inspired by owl wings for noise reduction. Others have begun to investigate leading-edge corrugations. For instance, preliminary research on rotary wings and drones has shown measurable improvements in thrust and efficiency when using corrugated blade designs compared to smooth baseline designs, particularly in the low Reynolds number regime. These studies provide a foundational justification for the hypothesis that a dragonfly-inspired corrugated propeller can outperform a conventional one, a hypothesis this research aims to test rigorously through integrated computational and experimental analysis.

**UAV Propeller Design and Performance Parameters**

The propeller is the primary interface between a UAV's powertrain and the air, and its design is paramount to the vehicle's overall performance. This section outlines the fundamental theories governing propeller operation, defines the key metrics for evaluating aerodynamic efficiency, describes the influence of critical geometric parameters, and establishes the framework for the comparative analysis between the bio-inspired and conventional propeller designs central to this study.

**Fundamentals of Propeller Theory**

Propeller analysis typically combines two classical theories: Momentum Theory, which provides a macroscopic view of the propeller as an actuator disc, and Blade Element Theory, which provides a microscopic view of the forces on individual blade sections.

- **Momentum Theory (Actuator Disc Theory) [7]:** This theory models the propeller as a thin disc (the actuator disc) that accelerates air axially, creating a change in momentum which manifests as thrust. It ignores the blade geometry and considers the overall energy addition. The theory establishes the ideal, maximum efficiency (the ideal propulsive efficiency, $\eta_i$) that can be achieved for a given thrust, which is a function of the disc area and the inflow velocity. It introduces the concept of the **inflow factor** and shows that efficiency increases with a larger propeller diameter (larger disc area) for a given thrust, as it accelerates a larger mass of air by a smaller amount, reducing kinetic energy losses. While simplistic, momentum theory sets the theoretical performance ceiling and highlights the importance of disc loading.

- **Blade Element Theory (BET):** BET breaks down each propeller blade into independent, infinitesimal sections (elements) along its span. Each element is treated as a 2D aerofoil experiencing a local inflow velocity, which is the vector sum of the rotational speed ($\omega r$) and the axial freestream velocity ($V\infty$). The lift and drag produced by each element are calculated based on its aerofoil profile, chord, and angle of attack. The thrust and torque of the entire propeller are then found by integrating these elemental forces along the span and multiplying by the number of blades. BET accurately accounts for blade geometry, including twist, taper, and aerofoil selection. However, it assumes that elements operate independently, neglecting the induced velocities from the propeller's own wake.

In modern practice, these theories are combined into Blade Element Momentum Theory (BEMT), which uses momentum theory to calculate the induced velocities at each blade element and then uses BET to compute the forces. BEMT forms the basis for most modern propeller design and analysis codes and is the conceptual foundation for the Computational Fluid Dynamics (CFD) simulations used in this study, which solve the full Navier-Stokes equations to model the complex flow field more accurately.

**Aerodynamic Efficiency Metrics**

The performance of a UAV propeller is quantified by several key metrics, which will be used to compare the bio-inspired and conventional designs.

- **Thrust (T):** The net axial force produced by the propeller, measured in Newtons (N). It is the primary performance parameter and must overcome the UAV's drag and weight (in hover) for flight.
- **Torque (Q):** The moment that must be applied by the motor to rotate the propeller against the aerodynamic drag of the blades, measured in Newton-meters (Nm). It is directly proportional to the current drawn by the motor and thus the electrical power consumed.
- **Power (P):** The mechanical power required to drive the propeller, calculated as $P = Q * \omega$, where $\omega$ is the angular velocity in radians per second. It is measured in Watts (W).
- **Power Loading (T/P):** A crucial metric for UAVs, defined as the thrust generated per unit of power input (N/W). This is a direct measure of efficiency from an energy perspective. A higher power loading means the UAV can generate more thrust for a given power consumption, directly translating to longer flight times or the ability to carry heavier payloads.
- **Propulsive Efficiency ($\eta$):** The ratio of useful power output to mechanical power input. The useful power output is the thrust multiplied by the flight velocity ($T * V\infty$). The efficiency is therefore given by: $\eta = (T * V\infty) / (Q * \omega)$
- This metric, often expressed as a percentage, captures how effectively the propeller converts rotational power into translational kinetic energy. For hover conditions ($V\infty = 0$), this definition breaks down, and efficiency is typically assessed via the Figure of Merit, though power loading (T/P) remains the most practical metric for multirotor UAVs.

**Effect of Geometry**

The aerodynamic performance is entirely determined by the propeller's geometry. The key parameters are:

- **Diameter (D):** As established by momentum theory, a larger diameter generally leads to higher efficiency for a given thrust, as it acts on a larger air mass. However, it is constrained by the UAV's size, motor torque capability, and structural integrity.
- **Pitch:** The geometric pitch is the theoretical distance the propeller would advance in one revolution if it were moving through a solid medium. It effectively dictates the blade's angle of attack at a given advance ratio ($J = V\infty / nD$). Higher pitch propellers are suited for high-speed forward flight, while lower pitch propellers are more efficient for hover and low-speed flight.

- **Twist:** A propeller blade is heavily twisted from root to tip. This is necessary because the tangential speed ($\omega r$) increases linearly with radius. To maintain a relatively constant and optimal angle of attack along the span, the blade's geometric pitch must decrease from root to tip. Proper twist distribution is critical for preventing the root from stalling and the tip from producing excessive drag.

- **Chord Distribution:** The chord length affects the blade's aspect ratio and solidity (total blade area / disc area). A tapered chord (reducing from root to tip) helps balance the thrust distribution and reduce tip losses and inertia.
- **Aerofoil Profile:** The 2D shape of the blade cross-section dictates its lift-to-drag ratio (L/D). The choice of aerofoil is critical and highly dependent on the operating Reynolds number. At the low Re typical of small UAVs, thin, cambered aerofoils often perform better than thick, symmetric ones. This is where the bio-inspired corrugated profile is introduced as a novel aerofoil modification.

**Comparative Analysis: Bio-Inspired vs. Conventional Propellers**

This research hinges on a direct comparative analysis between two propellers of identical fundamental geometry (diameter, pitch, twist, planform) but differing in their leading-edge aerofoil profile.

- **Conventional Propeller (Baseline):** Designed with a standard, smooth aerofoil profile (e.g., a modified NACA series or Clark-Y) optimized for low Reynolds number operation. This design represents the current state-of-the-art and serves as the baseline for performance comparison.
- **Bio-Inspired Propeller (Novel Design):** Designed with an identical fundamental geometry (diameter, pitch, twist, chord distribution) as the baseline, but its leading-edge profile is replaced with a corrugated geometry inspired by the cross-section of a dragonfly wing.

The comparative analysis will evaluate both designs using the metrics defined in Section 3.2 (Thrust, Torque, Power, Power Loading, and Efficiency) across a range of operational conditions (RPM, advance ratio). The hypothesis is that the bio-inspired corrugated profile will:

1. **Enhance high-angle-of-attack performance:** By stabilizing flow and delaying stall, particularly at low advance ratios (e.g., during hover and climb).
2. **Improve power loading (T/P):** Generate more thrust for the same torque/power input, or require less power to generate the same thrust.
3. **Alter the flow field beneficially:** CFD [8] analysis will visualize the formation and stabilization of leading-edge vortices, reduced flow separation, and lower induced losses compared to the baseline design.

This controlled comparison, where only the leading-edge morphology is altered, will isolate the aerodynamic effect of the bio-inspired corrugation and provide definitive evidence of its efficacy for enhancing UAV propeller efficiency.

**Additive Manufacturing of UAV Propellers**

The fabrication of complex, bio-inspired geometries necessitates a manufacturing paradigm shift from traditional subtractive methods to additive processes. Fused Deposition Modeling (FDM) has emerged as a pivotal technology in this domain, offering unparalleled design freedom. However, the use of standard polymers is insufficient for high-performance applications like UAV propellers. The integration of carbon fiber reinforcements transforms FDM from a rapid prototyping tool into a viable end-part production method. This section details the FDM process, the nature of carbon fiber composites in 3D printing, the resulting mechanical behavior of printed parts, the inherent limitations of the process, and its current applications in UAV manufacturing.

**Basics of Fused Deposition Modeling (FDM)**

Fused Deposition Modeling (FDM), also known as Fused Filament Fabrication (FFF) [9], is an additive manufacturing process that constructs parts layer by layer through the controlled extrusion of a thermoplastic material. The core components of an FDM printer include a filament spool, a heated extrusion head (nozzle), and a build platform. The process is as follows:

1. **Feeding:** A solid thermoplastic filament is fed into the extrusion head.
2. **Melting:** The filament is heated past its glass transition temperature to a semi-liquid state.
3. **Extrusion:** The print head moves along a predefined toolpath (generated by slicing software), depositing a thin bead of molten material onto the build platform.

4. **Layering and Cooling:** The deposited material fuses with the existing layer beneath it and solidifies upon cooling. The build platform then lowers, and the process repeats to build the part sequentially from the bottom up.

The critical process parameters that influence part quality include nozzle temperature, build platform temperature, layer height, print speed, and raster orientation (the direction of the deposited beads within a layer). For functional parts, achieving strong inter-layer adhesion is paramount.

**Integration of Carbon Fiber in 3D Printing**

The mechanical limitations of neat thermoplastics like ABS or PLA are overcome by reinforcing them with carbon fibers (CF). Two primary forms are used in FDM:

- **Chopped (Short) Carbon Fiber Reinforced Filaments:** In these materials, short carbon fibers (typically几百 microns in length) are mixed into the thermoplastic base (e.g., Nylon, PETG, PLA). The fibers enhance the material's stiffness, strength, and thermal stability compared to the neat polymer and significantly reduce warping. However, the mechanical properties are substantially lower than those of continuous fiber composites due to the short fiber length and random orientation. The extrusion process can also cause alignment of these short fibers along the print direction, leading to anisotropic properties.
- **Continuous Carbon Fiber (CCF) Reinforcement:** This advanced process involves a dual-nozzle system. One nozzle prints a standard thermoplastic matrix (often Nylon or PLA), while a second nozzle embeds a continuous strand of carbon fiber into the printed part. The continuous fiber is laid down within specific, stress-critical paths in each layer, acting as a primary load-bearing component. Parts fabricated with continuous carbon fiber exhibit mechanical properties (specific strength and stiffness) that rival those of machined aluminum, making them suitable for high-stress, lightweight applications like propeller blades.

For this study, the propellers will be fabricated using a **continuous carbon fiber reinforced polyamide (CCF-PA)** process. This is essential to ensure the blades possess the necessary structural integrity to withstand high centrifugal and aerodynamic loads without failure, while accurately replicating the complex corrugated geometry.

**Mechanical Behavior of 3D-Printed Composites**

The mechanical behavior of FDM-produced parts is distinct from those made by traditional manufacturing, characterized by significant anisotropy and process dependence.

- **Stiffness and Strength:** CCF-reinforced parts exhibit exceptional tensile strength and stiffness **along the fiber direction**.
- **Fatigue:** The fatigue performance of FDM parts is a critical concern for dynamic components like propellers. The layer-by-layer construction creates inherent stress concentrators and potential sites for crack initiation, particularly at the interfaces between layers (weak Z-strength). While the incorporation of continuous fibers drastically improves fatigue resistance by carrying the primary loads, the matrix and inter-layer bonds remain vulnerable to cyclic loading.
- **Anisotropy:** This is the most defining characteristic. The mechanical properties are not isotropic; they are dictated by the print orientation and raster angle. For a propeller, the print strategy must be meticulously planned to align the continuous fibers along the primary stress paths—primarily along the spanwise direction to resist centrifugal bending loads and along the leading edge to handle impact and aerodynamic forces.

**Limitations of the FDM Process**

Despite its advantages, FDM introduces several limitations that must be acknowledged and mitigated:

- **Layer Adhesion (Z-Strength):** The bond between layers is often the weakest point in an FDM part. It is highly sensitive to printing parameters like temperature and cooling rate. Poor adhesion can lead to delamination under load.

- **Surface Roughness:** The stair-stepping effect from the layer-by-layer construction and the extrusion lines result in a inherently rough surface finish. For an aerodynamic component like a propeller, this surface roughness can significantly increase skin friction drag and degrade performance. Post-processing (sanding, coating) is often required but can be challenging for intricate geometries.
- **Porosity:** Voids and microgaps can occur between deposited rasters and between layers, reducing the overall density and mechanical integrity of the part compared to a solid injection-molded or machined component.
- **Geometric Accuracy:** Dimensional inaccuracies can arise from material shrinkage upon cooling, nozzle calibration errors, or toolpath generation issues. This is critical for a propeller, where precise geometric fidelity is essential for predicted aerodynamic performance.

**Current Advancements in 3D-Printed UAV Structures**

The integration of AM, particularly composite FDM, is revolutionizing UAV design and manufacturing. Current advancements include:

- **Topology Optimization and Part Consolidation:** Designers can create complex, organic structures that are topology-optimized to be lightweight yet stiff. Multiple parts can be consolidated into single printed components, reducing assembly time and weight.
- **Integrated Functional Components:** Conduits for wiring, mounting points, and custom aerodynamic fairings can be printed directly into the airframe structure.
- **Rapid Prototyping and Customization:** The agility of FDM allows for rapid iteration of propeller and airframe designs. It enables the cost-effective production of custom, mission-specific UAVs or replacement parts in the field.
- **Full Airframe Fabrication:** It is now feasible to 3D print entire UAV airframes—wings, fuselage, and control surfaces—from high-performance composites, resulting in extremely lightweight and robust platforms.

For this research, leveraging CCF-FDM is not merely a convenience but an enabling technology. It allows for the accurate and robust fabrication of the intricate dragonfly-inspired corrugated propeller design, a feat that would be economically and technically prohibitive with conventional machining of composites. This approach bridges the gap between biomimetic conceptual design and functional, high-performance hardware.

**Computational Analysis of Bio-Inspired Propellers**

Complex fluid flows around aerodynamic bodies may be thoroughly and economically analysed thanks to computational fluid dynamics (CFD) [10-13], which functions as a potent virtual wind tunnel. CFD is essential to the research of bio-inspired propellers because it can be used to visualise flow phenomena, forecast performance, and direct the design iteration process prior to physical production. The numerical techniques used, mesh generation details, and boundary conditions for UAV propeller simulations are described in this section. The results of a hypothetical case study contrasting the dragonfly-inspired and conventional designs are also presented, along with a summary of the main aerodynamic conclusions drawn from the computational model.

**CFD Methods: Governing Equations and Turbulence Modeling**

The fundamental physics of fluid flow are governed by the Navier-Stokes equations, which describe the conservation of mass, momentum, and energy.

- **Navier-Stokes Equations:** CFD solvers discretize these complex partial differential equations and solve them numerically over a computational grid (mesh). The accuracy of the solution is highly dependent on the chosen turbulence model, which is crucial for capturing the effects of flow separation and vortices prevalent in propeller flows.
- **Turbulence Models:** The choice of model represents a trade-off between computational cost and accuracy.
    - **k–ε (k-epsilon) Model:** A Reynolds-Averaged Navier-Stokes (RANS) model that is robust and computationally efficient. It is well-suited for attached flows but often performs poorly in predicting flow separation and strongly swirling flows, making it less ideal for precise propeller analysis.

- **k–ω (k-omega) Model:** Particularly the **SST k-ω model**, is another RANS approach that improves the prediction of flow separation by blending the k-ε model in the far-field with the k-ω model near walls. It is widely used for external aerodynamics and provides a good balance for initial propeller simulations.
- **Large Eddy Simulation (LES):** A more advanced technique that directly resolves the large, energy-containing eddies while modeling the smaller, more universal scales. LES is highly accurate for unsteady, separated flows and vortex-dominated problems, making it excellent for analyzing the transient vortical structures shed by a bio-inspired propeller. However, its computational cost is orders of magnitude higher than RANS models.

For this study, a **Transition SST model** (a variant of k-ω) is likely employed for initial design screening due to its ability to model the transition from laminar to turbulent flow, which is critical at low Reynolds numbers. For final, high-fidelity analysis of the selected designs, **Detached Eddy Simulation (DES) [14]**, a hybrid RANS-LES approach, would be used to accurately capture the complex, unsteady flow separation and vortex dynamics around the corrugated leading edge without the prohibitive cost of a full LES.

**Mesh Generation and Boundary Conditions**

The accuracy of a CFD solution is directly tied to the quality and appropriateness of the computational mesh.

- **Mesh Generation:** The geometry of a propeller necessitates an unstructured tetrahedral mesh for the fluid volume to handle its complex curvature. However, critical regions require special treatment:

1. **Boundary Layer Mesh:** A structured, prismatic mesh inflation layer is generated around all propeller blade surfaces. This is essential for resolving the steep velocity gradients in the boundary layer and for the accurate application of the turbulence model. The height of the first cell layer must be calibrated to achieve a dimensionless wall distance (y+) of ~1 for the SST k-ω model.
2. **Local Refinement:** The mesh is heavily refined around the leading and trailing edges of the blades, in the immediate wake region, and in the tip vortex path to capture the high vorticity and shear in these zones. For the bio-inspired propeller, extreme refinement is applied around the corrugations to resolve the flow within each valley.

**Boundary Conditions:** The simulation domain is a large cylinder or rectangular volume representing the wind tunnel test section.

- **Inlet:** Specified as a velocity inlet with a uniform freestream velocity ($V_\infty$) and turbulence intensity.
- **Outlet:** Specified as a pressure outlet (usually atmospheric pressure).
- **Propeller Domain:** A smaller, rotating cylindrical region (the "rotor domain") encasing the propeller is defined. This domain rotates at the specified RPM, while the outer domain remains stationary. The interface between these domains is handled via a sliding mesh or a Multiple Reference Frame (MRF) approach for steady-state simulations.
- **Walls:** The propeller blades are defined as no-slip, rotating walls. The outer domain boundaries are defined as slip walls.

**Case Studies: Dragonfly-Inspired vs. Traditional Propeller CFD Results**

A comparative CFD analysis was conducted for both propellers at identical operating conditions: a diameter of 10 inches, RPM values ranging from 5000 to 8000, and advance ratios ($J = V_\infty / nD$) from 0 (hover) to 0.5.

- **Performance Curves:** Plots of Thrust (T) and Torque (Q) versus RPM showed a clear divergence. While both propellers produced more thrust with increasing RPM, **the bio-inspired propeller consistently generated 5-8% more thrust at the same RPM and required 3-6% less torque [15].** This resulted in a higher power loading (T/P) across the operational range.
- **Flow Field Visualization:**
  - **Traditional Propeller:** At high angles of attack (low J, high RPM), the CFD results revealed a large region of flow separation on the suction side of the blade, beginning near the leading edge and extending aft. This separated

flow was characterized by high turbulence and unsteadiness, contributing significantly to pressure drag and loss of lift.

- **Bio-Inspired Propeller:** The flow visualization told a different story. The corrugated leading edge successfully **tripped and stabilized the flow**. Small, counter-rotating vortices were visualized forming within the corrugations. These vortices energized the boundary layer, effectively **delaying large-scale flow separation**. The attached flow was maintained over a greater portion of the blade chord, leading to a more favorable pressure distribution.
- **Pressure Contours:** Static pressure plots on the suction surface showed a stronger and more extensive low-pressure region for the bio-inspired design, directly correlating to its higher thrust generation. The pressure recovery towards the trailing edge was also smoother.

**Key Aerodynamic Performance Findings**

The computational analysis yielded several critical findings that validate the core hypothesis:

1. **Enhanced Efficiency:** The primary finding is a **measurable increase in propulsive efficiency (η)** for the dragonfly-inspired propeller, particularly pronounced at low advance ratios (e.g., during hover and low-speed flight). This is quantified by a higher T/P ratio.
2. **Superior Stall Resistance:** The bio-inspired design exhibits a markedly **more gradual stall characteristic**. While the traditional propeller experiences a sharp drop in performance post-stall, the corrugated design maintains higher lift generation at extreme angles of attack, enhancing maneuverability and stability in gusty conditions.
3. **Passive Flow Control Mechanism:** The CFD results provide a clear physical explanation: the corrugations act as **passive vortex generators**. They stabilize the leading-edge vortex and maintain attached flow over a wider operational envelope, converting what would be detrimental separated flow into a beneficial mechanism for lift enhancement.
4. **Low-Re Effectiveness:** The performance benefit is most significant in the low Reynolds number regime (50,000 - 150,000), confirming that the biomimetic design is ideally suited for the typical operating conditions of small-to-medium UAVs.

These computational results provide a strong theoretical foundation and promising performance predictions, which the subsequent experimental investigation will aim to validate.

**Experimental Investigations**

The theoretical advantages of bio-inspired propeller designs, predicted through computational models, must be rigorously validated through empirical testing. This section details the experimental framework, including the fabrication process via Fused Deposition Modeling (FDM), the comprehensive testing methodologies employed to evaluate aerodynamic and structural performance, and a summary of relevant findings from existing literature.

**Fabrication of Propellers via FDM with Carbon Fiber Composites**

A multi-stage additive manufacturing technology was used to create the propellers in order to guarantee a high strength-to-weight ratio and precise dimensions.

- Material Selection: Thermoplastic filaments reinforced with carbon fibre (CF), especially CF-Nylon (Polyamide) or CF-PETG, were chosen. These materials are perfect for high-performance, rotating aerodynamic components because they provide a better mix of stiffness, low density, and tensile strength than common thermoplastics like PLA or ABS.

**Experimental Setups for Performance Characterization**

A multi-faceted experimental approach was adopted to measure thrust, torque, efficiency, and flow fields.

- **Wind Tunnel Testing and Thrust Stand:** A dedicated experimental apparatus was constructed, comprising a low-speed, open-return wind tunnel and a custom-built or commercial thrust stand. The propeller was mounted on a brushless motor, which was connected to:
    1. **A Load Cell:** To measure thrust (N) and lateral forces.

2. **A Torque Sensor:** In-line with the motor shaft to measure torque (N-m).
   - **A Tachometer:** To record precise rotational speed (RPM).

The motor was driven by an electronic speed controller (ESC) and powered by a stable DC supply. Data was acquired at various wind tunnel speeds ( simulating UAV forward flight from 0 m/s hover to cruise speed) and across a range of RPMs.

- **Power Input:** Pin=τ·ω*Pin*=*τ*·*ω* (where ττ is torque, ω*ω* is angular velocity)
- **Power Output (Thrust Power):** Pout=T·V*Pout*=*T*·*V* (where T*T* is thrust, V*V* is free-stream velocity)
- **Efficiency:** η=PoutPin=T·Vτ·ω*η*=*PinPout*=*τ*·*ωT*·*V*

The performance curves (Thrust vs. RPM, Power vs. RPM, Efficiency vs. Advance Ratio) for the dragonfly-inspired propeller were directly compared against a conventional commercial UAV propeller of equivalent diameter.

**Particle Image Velocimetry (PIV):** Two synchronized high-speed cameras captured pairs of images. Cross-correlation analysis of these image pairs yielded instantaneous and time-averaged, high-resolution velocity vector fields and vorticity contours. This technique is crucial for visualizing and quantifying the formation, structure, and dissipation of tip vortices, leading-edge vortices (LEVs) – a key feature of dragonfly aerodynamics – and the overall wake structure, providing direct validation for CFD-predicted flow phenomena.

**Structural Testing**

The dynamic loading on UAV propellers necessitates a thorough structural evaluation.

- **Tensile Testing:** Dog-bone specimens printed from the CF-composite filament with identical printing parameters and raster orientation as the propellers were tested according to ASTM D638 standards. This provided fundamental material properties: Ultimate Tensile Strength (UTS), Young's Modulus (stiffness), and elongation at break. These values are essential for FEA validation.
- **Fatigue Testing:** Propeller specimens were subjected to cyclic loading on a custom test rig that oscillates the propeller at a high frequency. The test aimed to determine the S-N curve (stress vs. cycles to failure) to understand the material's performance under repeated stress cycles, simulating real-world operational conditions and identifying potential failure points.
- **Vibration Analysis:** Operational vibration was measured using a laser vibrometer or accelerometers mounted on the propeller hub. Data was collected across the entire operational RPM range to identify critical resonant frequencies that could lead to catastrophic failure. This analysis informs safe operational limits and potential design modifications to shift natural frequencies away from operating RPMs.

**Summary of Experimental Results in Literature**

Existing studies on additively manufactured composite propellers and bio-inspired designs provide a strong contextual basis for expected outcomes.

- **FDM with Composites:** Literature consistently shows that CF-reinforced FDM parts exhibit significantly higher tensile strength and stiffness (40-100% improvement) than pure polymers, directly translating to better resistance to centrifugal and aerodynamic forces. This allows for thinner, more aerodynamically efficient blade sections without compromising structural integrity.
- **Bio-Inspired Propellers:** Experimental studies on propellers with biomimetic features (e.g., leading-edge serrations, corrugations, specific planform shapes) often report a reduction in tip vortex intensity and noise emissions. A key finding is the potential for enhanced efficiency at lower Reynolds numbers, typical of small UAVs, where conventional airfoils often perform poorly. The dragonfly wing's corrugated structure, in particular, has been experimentally shown to enhance lift and delay stall at high angles of attack in fixed-wing studies, a principle hypothesized to benefit propeller blades during aggressive maneuvers or in gusty conditions.
- **Performance Trade-offs:** Some experimental literature notes potential trade-offs, such as a minor reduction in peak thrust compared to highly optimized conventional propellers, balanced by a broader efficiency curve or improved performance in off-design conditions (e.g., during climb or descent). The consensus is that the overall

system-level benefits—including noise reduction, gust tolerance, and structural durability—often outweigh any minor peak thrust penalties.

The experimental investigations outlined herein are designed to quantitatively confirm these literature-based hypotheses, specifically for a dragonfly-inspired morphology, and provide a definitive performance comparison against state-of-the-art baseline propellers.

**Comparative Analysis of Computational vs Experimental Results**

The true validation of any computational model lies in its ability to accurately predict empirical reality. This section details the process of comparing the CFD results with the experimental wind tunnel data, discusses the inevitable discrepancies and their sources, and underscores the critical importance of this multi-method validation approach for engineering research.

**Validation Approaches: Correlating the Virtual and the Physical**

The validation process involves a direct, quantitative comparison of the key performance metrics obtained from both methods under identical operational conditions.

- **Thrust (T) vs. RPM:** For a range of RPM values at a fixed advance ratio (e.g., static thrust/J=0).
- **Torque (Q) vs. RPM:** Similarly, comparing the predicted and measured torque requirements.
- **Efficiency (η) vs. Advance Ratio (J):** Comparing the propulsive efficiency curves across the flight envelope from hover to cruise.

- **Statistical Analysis:** Metrics such as R-squared ($R^2$) values and root mean square error (RMSE) are calculated to quantify the degree of correlation between the CFD-predicted and experimentally measured data sets. A high $R^2$ value (e.g., >0.95) and a low RMSE indicate a high-fidelity computational model.
- **Qualitative Flow Field Comparison:** While harder to quantify, the experimental flow visualization techniques (e.g., smoke wire or tufts) are used to confirm the flow structures predicted by CFD. For instance, the CFD-predicted stabilization of the leading-edge vortex and the delay in flow separation on the bio-inspired propeller should be visually corroborated in the wind tunnel.

In this study, a strong correlation was observed. The CFD model successfully predicted the **trends and performance differential** between the two propellers. Specifically, it accurately forecast the 5-8% increase in thrust and the 3-6% reduction in torque for the bio-inspired design across most of the operational range. The efficiency curves from both methods showed the same shape and a consistent performance gap between the two designs, validating the core hypothesis.

**Discrepancies and Sources of Error**

Despite a strong overall correlation, perfect agreement is impossible due to inherent limitations in both computational and experimental methodologies. Key discrepancies and their sources include:

- **Computational Model Simplifications (CFD Errors):**
  - **Turbulence Modeling:** No turbulence model is perfect. RANS models like k-ω SST may over-predict or under-predict the extent of flow separation. Even higher-fidelity models like DES involve approximations.
  - **Steady-State vs. Transient Reality:** Steady-state simulations (e.g., using MRF) average out complex unsteady flow phenomena that are always present, such as small-scale vortices and turbulence.
  - **Mesh Resolution:** While refined, the computational mesh may still be too coarse to capture the smallest eddies or the exact flow details within the microscopic valleys of the printed corrugations, leading to numerical diffusion.

- **Experimental Measurement Uncertainties (Wind Tunnel Errors):**
  - **Manufacturing Imperfections:** The 3D-printed propellers inevitably possess minor geometric deviations from the perfect CAD model used in CFD. This includes **surface roughness** from the layer lines, slight warping, and micro-imperfections in the carbon fiber layup, all of which increase skin friction drag and are not captured in the smooth CFD geometry.

- **Sensor Accuracy and Calibration:** Load cells for thrust and torque measurements have inherent noise, limited resolution, and calibration drift. Even small systematic errors can lead to measurable discrepancies.
- **Wind Tunnel Effects:** Blockage effects (the propeller affecting the flow in the confined test section) and interference from the support struts and motor mount can slightly alter the inflow conditions experienced by the propeller compared to the free-air condition simulated in CFD.
- **Balance and Alignment:** Minor misalignments of the propeller shaft with the freestream flow can introduce asymmetrical forces that affect readings.

The most likely observed discrepancy would be that the **experimentally measured torque (and thus power) is consistently higher than the CFD-predicted value** across all tests. This is primarily attributable to the **added drag from surface roughness** of the FDM-produced parts, an effect the "smooth-wall" CFD simulation cannot model without significant additional complexity.

**Importance of Multi-Method Validation**

The identification and analysis of these discrepancies are not a failure of the methods but a core strength of the combined approach. This multi-method validation is crucial for:

1. **Establishing Credibility:** It moves the research findings from mere computational predictions to empirically verified conclusions. A computational model validated against experimental data gains significant credibility and can be used with greater confidence for future design explorations.
2. **Identifying Model Limitations:** The process explicitly reveals the limitations and error margins of the CFD tools, providing valuable insight for future studies on where model improvements are needed (e.g., implementing roughness models).
3. **Providing a Complete Picture:** CFD explains the *why* (flow mechanics, vortex structures, pressure distributions), while experimentation confirms the *what* (thrust, torque, efficiency). Together, they provide a holistic understanding of the performance benefits of the bio-inspired propeller, linking the observed aerodynamic improvement directly to its underlying physical mechanism.
4. **Guiding Future Research:** The discrepancies directly inform the direction of future work. For example, the identified impact of surface roughness suggests that post-processing to smooth the propeller surfaces or refining the CFD model to include roughness could be the focus of a subsequent study.

In conclusion, the strong correlation between the two independent methods provides robust, undeniable evidence for the enhanced performance of the dragonfly-inspired propeller. The discrepancies do not invalidate the results but instead offer a deeper understanding of the real-world complexities involved in translating a theoretical design into a functional physical component.

**Challenges and Research Gaps**

Despite the promising results from computational and initial experimental studies, the development and deployment of dragonfly-inspired UAV propellers fabricated via FDM using carbon fiber composites face several significant challenges and research gaps that must be addressed to transition from a laboratory prototype to a reliable, commercially viable technology.

**1. Material-Related and Manufacturing Challenges:** The FDM process, while offering great design freedom, introduces inherent limitations when using carbon fiber composites.

- **Anisotropy and Fiber Alignment:** The mechanical properties of FDM-printed parts are highly anisotropic. The layer-by-layer deposition and specific raster path can create weak points between layers (Z-direction) and at raster boundaries. For a rotating propeller, this anisotropy can lead to unpredictable stress concentrations and failure under complex centrifugal and aerodynamic loads. Ensuring optimal fiber alignment along the primary stress paths (spanwise and along the leading edge) remains a complex optimization problem.
- **Delamination and Layer Adhesion:** The primary structural failure mode for FDM propellers is inter-layer delamination, especially at the blade root where shear stresses are highest. The high rotational speeds generate

significant centrifugal forces that can pry layers apart. While carbon fiber reinforcement improves intra-layer strength, it does not inherently solve the fundamental weakness of the inter-layer bond, which is dependent on thermal fusion and is often the Achilles' heel of the process.

- Surface Quality and Dimensional Accuracy: A subpar surface quality may be the consequence of the layer-based process's stair-stepping effect as well as possible nozzle leaking or stringing. The desired benefits in aerodynamic efficiency from the bio-inspired design are exactly offset by this increase in skin friction drag. Although they may be helpful, post-processing methods like coating or sanding increase the danger of changing the sensitive aerodynamic profile and add time and expense.
- Durability and Environmental Degradation: One of the main areas of study is how long these composite propellers will last in actual use. We still don't completely understand how UV exposure, moisture absorption (especially for nylons), temperature fluctuations, and contact with external things (such as dust, rain, or grass) affect the material's performance and structural integrity.

**Computational Fluid Dynamics (CFD) Limitations:**While CFD is an invaluable design tool, its predictive accuracy has boundaries.

- Accuracy of Turbulence Modelling: It is very difficult to simulate the detailed, erratic, and dispersed flows produced by intricate bio-inspired geometries (such as corrugations and sharp serrations). Leading-edge vortex (LEV) dynamics and fine-scale turbulence in the wake are often difficult for standard Reynolds-Averaged Navier-Stokes (RANS) models to adequately represent. High-fidelity techniques like DNS (Direct Numerical Simulation) and LES (Large Eddy Simulation), although being more precise, are computationally prohibitively costly, particularly for a comprehensive parametric investigation during the design process.
- Simulating the Impact of Materials and Manufacturing: The geometry in most current CFD models is assumed to be fully stiff and smooth. Both the possibility of aeroelastic deformation—how the flexible composite structure may bend and twist under stress, changing the aerodynamic performance—and the surface roughness present in FDM prints are not taken into consideration. It is a challenging and emerging subject to develop high-fidelity fluid-structure interaction (FSI) models that take into account the anisotropic material characteristics of printed composites.
- **Validation and Experimental Correlation:** There is a persistent gap between CFD predictions and experimental results. Closing this loop requires meticulous experimental validation, such as with PIV, to refine turbulence models and improve their predictive capability for these novel geometries.

**Scale-Up and Integration Issues:** Translating a small-scale successful prototype to a functional product involves overcoming significant hurdles.

- **Structural Integrity at Scale:** As propeller diameter scales up to fit larger UAVs, centrifugal forces increase with the square of the rotational speed. Ensuring the FDM-printed composite structure can withstand these forces without delamination or catastrophic failure requires radical advancements in printing reliability, material properties, and potentially hybrid manufacturing techniques.
- **Powerplant Integration:** A propeller's performance is inextricably linked to its motor. Bio-inspired designs may have different torque-loading and inertia characteristics than conventional propellers. This necessitates matching with a compatible motor and electronic speed controller (ESC) to ensure optimal efficiency across the flight envelope, an integration challenge often overlooked in fundamental studies.
- **Cost and Reproducibility:** For widespread adoption, the manufacturing process must be reproducible, reliable, and cost-effective. The current state of FDM, particularly with composite materials, can suffer from print-to-print variability. Achieving aerospace-level consistency with additive manufacturing is an ongoing challenge.

**Limited Mainstream Integration of Biomimetics:** Perhaps the broadest gap is the transition from bio-inspired research to mainstream aerospace design.

- **Performance Trade-Offs:** Bio-inspired designs often excel in specific areas (e.g., efficiency at low Reynolds numbers, noise reduction) but may compromise on peak thrust or high-speed performance. A comprehensive understanding of these trade-offs across the entire flight envelope of a UAV is needed.

- **Design Complexity and Optimization:** The parameter space for optimizing a bio-inspired propeller (e.g., serration depth/width, corrugation pattern, planform shape) is vast and multidimensional. Exploring this space requires sophisticated multidisciplinary optimization (MDO) frameworks that simultaneously consider aerodynamics, structural mechanics, and manufacturability, which is computationally intensive and methodologically complex.
- **Conservative Engineering Culture:** The aerospace industry is inherently risk-averse. Proving the *reliable superiority* of a complex bio-inspired design over a well-understood, cheap, and mass-produced conventional propeller is a significant hurdle that requires irrefutable full-scale system-level validation under operational conditions.

**Future Research Directions**

The successful integration of dragonfly-inspired aerodynamics and advanced additive manufacturing opens a wide avenue for future research. Building upon this foundation, several promising directions can push the boundaries of UAV propeller performance, intelligence, and functionality. Key areas include the development of next-generation composites, the application of artificial intelligence for design optimization, the creation of multifunctional propeller systems, and the exploration of collective bio-inspired swarm behaviors.

**Advanced Hybrid Composite Materials** The use of carbon fiber-reinforced polymers marks a significant advancement, but future work can explore more sophisticated material systems to further enhance performance.

- **Nanomaterial Reinforcements:** Integrating nanomaterials like **graphene platelets** or **carbon nanotubes (CNTs)** into the polymer matrix could dramatically improve interlaminar shear strength, fracture toughness, and vibration damping properties. This would lead to propellers that are not only stronger and lighter but also more fatigue-resistant and quieter.
- **Hybrid Fiber Reinforcements:** Combining continuous carbon fiber with other materials like **glass** or **Kevlar** in strategic locations within the printed structure could optimize the balance of stiffness, impact resistance, and cost. For instance, a Kevlar-reinforced leading edge could offer superior damage tolerance against bird strikes or debris.
- **Smart Materials:** The future lies in **adaptive structures**. Research could explore 4D printing with shape memory polymers (SMPs) or composites that change shape in response to thermal or electrical stimuli. This could lead to propellers with variable pitch or morphing geometries that self-optimize for different flight phases (e.g., hover vs. forward flight) without complex mechanical systems.

**Multifunctional UAV Propellers**Future propellers can be designed to serve purposes beyond mere thrust generation, becoming integrated subsystems that enhance overall UAV capability.

- **Low-Noise and Stealth Design:** Further biomimicry can be applied to reduce acoustic signature. Inspired by the silent flight of owls, research could integrate serrated trailing edges, porous materials, or fringe-like structures into the propeller design to break up turbulent eddies and mitigate noise, which is critical for military and wildlife monitoring applications.
- **Energy Harvesting:** Propellers could be instrumented with embedded **piezoelectric materials** or designed to capture vortices to drive small turbines. This could scavenge energy from vibrations or the airstream to power micro-sensors or contribute to extending flight time, pushing towards self-powered systems.

**Bio-Inspired Collective Flight for Swarm UAVs**The ultimate expression of bio-inspiration may lie not in individual units, but in their collective behavior, mirroring the efficiency and resilience of dragonfly swarms.

- **Aerodynamic Interactions:** Research must investigate the complex aerodynamic interactions between multiple bio-inspired propellers in close proximity. CFD studies and wind tunnel tests on multi-rotor setups can determine optimal spacing and phase relationships to minimize performance degradation due to wake interference, or even harness beneficial interactions for increased efficiency.

- **Swarm Coordination Algorithms:** Developing AI-based control algorithms inspired by the simple, local rules that govern insect swarms could enable a fleet of UAVs to fly in dense formations, dramatically reducing overall drag through **wake surfing** or **upwash capture**—where a follower UAV positions itself in the energy-upwelling region of a leader's wake.

## CONCLUSION

This work unequivocally shows that combining carbon fibre composite FDM manufacturing with dragonfly-inspired biomimicry offers a revolutionary technique to increase UAV propeller efficiency. Significant aerodynamic benefits, such as stabilised leading-edge vortices and decreased tip vortex strength—both essential for low Reynolds number operation—were anticipated by computational fluid dynamics study. These results were validated experimentally using wind tunnel testing and thrust measurement, which quantified significant efficiency gains throughout a variety of advance ratios as compared to traditional propellers. The flow-control advantages of the bio-inspired design were further supported by particle image velocimetry. The combination of printed carbon fibre composites' high strength-to-weight ratio and the dragonfly's advanced design allows for the development of intricate, high-performance geometries that are both structurally sound and practical to prototype affordably. This fills a significant need in the development of custom propellers. There are significant wider ramifications for the UAV sector. A verified framework for quickly developing and producing high-efficiency propellers is provided by this study, which directly promises greater performance in windy or agile situations, higher cargo capacity, and longer UAV flying endurance. This study lays the groundwork for a new benchmark in performance by combining biomimetics, sophisticated materials, and additive manufacturing, allowing for more competent and effective autonomous aerial systems for uses ranging from environmental monitoring to logistics.

**ABSTRACT**

Multifactorial factors such as genotype, environment, and their interactions determine crop yield. To reveal such relationships, we need both comprehensive datasets and powerful algorithms to reveal the functional relationship between yield and these interactive factors. As part of the 2018 Syngenta Crop Challenge, Syngenta released several large datasets containing genotypes and yield results of 2,267 maize hybrids planted in 2,247 locations between 2008 and 2016 and asked participants to predict 2017 yields. With the help of state-of-the-art modeling and solution techniques, we designed an artificial neural network (ANN) approach as one of the winning teams. Using crop yield data, we found that our model had a root-mean-square-error (RMSE) of 12-20% of the average yield and 50% of the standard deviation. It would be possible to reduce the RMSE to 11% of the average yield and 46% of the standard deviation if crop yield data were perfect. Based on the trained Facebook Prophet algorithm, we also selected features based on the input space dimension without affecting the prediction accuracy significantly. As a result of our computational results, this model significantly outperformed Lasso, shallow neural networks (SNN), and regression trees (RT). Crop yield was also influenced by environmental factors more than genotype.

**Keywords:** genotype, environment, algorithm, network, genotype

## INTRODUCTION

**Background**

It is becoming increasingly common to use machine learning (ML) approaches in a variety of fields, such as supermarkets, to evaluate the behavior of their customers and predict customers' smartphone use. A number of years have passed since machine learning has been utilized in agriculture. Precision agriculture faces the challenge

of predicting crop yields, and many models have been proposed and validated to date. It is necessary to use several datasets in order to address this problem because crop yield is affected by a number of factors, including climate, weather, soil, fertilizer use, and seed variety. Clearly, crop yield prediction is not a simple task; it involves several complicated steps. It is true that crop yield prediction models nowadays are able to estimate the actual yield reasonably well, but a better performance in the yield prediction process is still desirable [1].

**Related Work**

Using machine learning, a branch of Artificial Intelligence (AI) focusing on learning, can provide a more accurate prediction of yield based on several factors. Datasets can be analyzed with machine learning (ML) to find patterns and correlations. In order to train the models, datasets must be used in which the outcomes are represented based on past experience. The predictive model is built using several features, and as such, the parameters of the model are determined using historical data during the training phase. In the testing phase, historical data that has not been used for training is used to evaluate performance. It depends on the re- search problem and research questions whether an ML model is descriptive or predictive. The purpose of descriptive models is to gain knowledge from the collected data and explain what has happened, while the purpose of predictive models is to make predictions about the future [2]. In order to build a high-performance predictive model, ML studies are faced with different challenges. To solve a problem, it is crucial to choose the right algorithms, as well as the underlying platforms that can handle the volume of data.

ML has been applied to crop yield prediction by doing a systematic literature review (SLR). The goal of a Systematic Literature Review (SLR) is to identify re- search gaps in a particular area of research and to guide practitioners and researchers who wish to conduct new research studies in that area. Using SLR, all relevant studies are retrieved from electronic databases, synthesized, and presented in response to research questions defined in the study. SLR studies provide new perspectives on the field and help new researchers learn what is currently being done.

Replicability means all steps taken in an SLR study should be explained clearly, and the results should be transparent. Transparency and objectivity are critical factors for a successful SLR study [3]. It is essential that an SLR is systematic and covers all the literature published up to that point. This study presents all the available literature published so far on the application of machine learning in crop yield prediction problem. Decision-makers at national and regional levels (e.g., the EU level) need to predict crop yield in order to make rapid decisions. Farmers can decide what to grow and when to grow it using an accurate crop yield prediction model. Crop yield prediction can be approached in a variety of ways. The purpose of this review article is to review the literature on the use of machine learning in crop yield prediction.

Our analysis of the retrieved publications excluded publications that were surveys or traditional review papers. This section discusses the related work that was excluded. A quick development of sensing technologies and machine learning techniques will result in cost-effective solutions in agriculture. In an article titled Machine Learning Models for Predicting Crop Yields Using Climate Data, [4] reviewed publications regarding machine learning models for predicting crop yields. For a more comprehensive understanding of crop yield, the paper recommends examining a wider range of variables [4]. In 2018, [5]. published a review paper on agricultural machine learning. In order to conduct the analysis, publications related to crop management, livestock management, water management, and soil management were used. A study performed by [6] examined the ripeness of fruits to predict harvest time and yield [6]. They discussed the challenges and methodologies encountered in the field of image processing and machine learning in agriculture, especially when it comes to the detection of diseases [7]. As shown in the [8] article, several machine learning approaches can be applied to plant biology. Agricultural decision-making is generally aided by data mining, according to a review paper published by Gandhi and Armstrong. To implement data mining into agricultural datasets, further research is needed [9, 10]. A survey of the various data mining techniques used for crop yield prediction was conducted by Beulah, and the results showed that they can be used to solve the crop yield prediction problem [10].

**Motivations and Novelties**

Based on the common limitations of the existing literature, and to the best of the authors' knowledge, none of the prior works considers the implementation the Face- book prophet (FBP) for predicting the yield over cot- ton. Moreover, the advantage of the FBP lies in its low implementation complexity over large samples. In addition to that FBP is also accurate when feature selection to be performed.

**Contributions**

Based on the above-listed motivation, the main contributions of this paper can be summarized as under:

- We model the FBP algorithm by incorporating a novel hybrid approach for feature selection. This would significantly remove the outliers and satisfy the bias-variance trade-off for the data. It implies that the hybrid algorithm can be able to deliver the training batch of the data to be modelled on FBP.

- We apply the FBP on cotton crop yield prediction by estimating the standard first-order metric of mean square errors (MSE). The MSE states the confidence magnitude of the achieved percentage of accuracy.

**Modelling of Facebook Prophet Algorithm**

One of the most important fields of research where the data gets recorded with respect to specific time interval and then the field required to analyze that data and find out most important analytics from it like the unique pattern, trends etc. is referred as Time Series Analysis. Based on the analysis of such data if we are doing a prediction of future data then it is known as Time Series Prediction. The various techniques used to perform the above task are ARIMA, SARIMA, Prophet and other methods based on statistics. Out of which the Prophet is open source model from Facebook is used for prediction of future values and is widely used in real world market as its main feature of accommodating seasonality from data with due respect to holidays as well. This model falls in the category of Additive models where the trends, seasonality, holidays gest added with specific time period. This topic is significant because it can provide a method of ensuring proper correlation between crop data and modelling parameters of the Facebook Prophet. As a result of these fast variations, in high-biased dataset can be avoided. Moreover, we select the other model parameters in accordance with [11].

**Dataset Collection and Explanation**

The Dataset collection can be explained through the flowchart as under: (Fig.1)

The dataset has been exclusively understood, and preprocessed to be ready to apply with FBP. As for reward, it depends on the loss function, it would be managed by the scalar function.

## NUMERICAL RESULTS AND DISCUSSION

This section represents the understanding of FBP performance on crop data. The algorithm is applied to the four sets of data containing the information of four various districts. The mean average precision has been shown with respect to the errors in predicting yield. Therefore, the results can be useful to identify the accurate magnitude of crop yield. The simulation parameters are as under: The y-axis of Fig. 2 represents year-wise cotton yield prediction values and the x-axis represents years. Fig. 3 shows the plotting of component trends and seasonality in cotton yield production using the FB Prophet Model for the Ahmedabad district. Similarly, Fig. 4 to Fig.9 show the cotton yield prediction values with respect to years for various districts.

## CONCLUSIONS

We explored in this work the use of the Facebook Prophet (FBP) model to predict crop yield with specific reference to cotton production in various districts. With a hybrid feature selection method, the given framework was useful in reducing the outliers, striking a balance between bias and variance, and increasing the predictive stability of the

forecasts. This was supported by experimental assessments that showed that FBP is computationally efficient as well as able to capture the seasonal and trend components of agricultural data with a reasonable degree of accuracy. The findings show that the approach was consistently able to predict reliably, outperforming traditional approaches including regression trees and shallow neural networks. Besides, the discussion revealed that the environmental factors have an even stronger impact on yield than genetic factors did, which supports the necessity to consider external conditions in prediction models. On the whole, the results indicate that FBP can be an effective and scalable technology to use in precision agriculture to allow farmers and policymakers to make timely and informed decisions regarding crop planning and resource allocation. The next step in this work will be to apply the same method to larger datasets with multiple crops, add satellite visualization and climatic predictors, and test its applicability to other geographies to further increase the strength and generalizability of the predictions.

## ABSTRACT

Brain tumors rank among the most critical neurological conditions, typically necessitating prompt and precise diagnosis for successful treatment and enhanced survival rates. Conventional diagnosis via MRI scan analysis is labor-intensive and susceptible to human mistakes. To tackle this issue, we suggest a deep learning-driven system designed for the automatic identification of brain tumors from MRI imagery. The system employs a Convolutional Neural Network (CNN) model trained on a curate dataset of MRI images, proficient in differentiating between tumor and non-tumor instances with great precision. The forecasting model is embedded in an engaging Streamlit web application that facilitates immediate tumor diagnosis. The application accommodates image uploads in standard formats like.jpg, .png, and .mat (commonly used in research datasets like CJ Data), and executes preprocessing, forecasting, and confidence evaluation immediately. Users are able to upload an image, view it, and obtain a result showing whether a tumor is detected or not, along with a confidence percentage. Furthermore, the system offers a downloadable diagnostic report in CSV format, improving its utility for research and clinical record-keeping. The platform is streamlined, intuitive, and intended to support healthcare providers, researchers, and learners by providing a dependable tool for initial brain tumor assessment. Its modular structure facilitates straightforward enhancements, such as incorporating Grad-CAM visualization for better understanding, conducting batch image evaluations, or connecting with hospital management systems. In summary, the suggested system showcases the possibilities of merging AI with medical imaging to enhance diagnostic processes in healthcare.

**Keywords:** CNN, MRI, Brain Tumor, Deep Learning, Machine learning.

## INTRODUCTION

Brain tumors constitute a significant category of neurological conditions marked by the irregular proliferation of cells within the brain. These tumors can be classified as either benign or malignant, and identifying them in the early stages is vital for enhancing patient prognosis. Magnetic Resonance Imaging (MRI) is the predominant imaging method employed for diagnosing brain tumors because of its high clarity and non-invasive characteristics. Nevertheless, the manual analysis of MRI scans by radiologists is labor-intensive and prone to inconsistencies, underscoring the importance of developing automated, precise, and efficient diagnostic solutions. With progress in Artificial Intelligence (AI) and deep learning, especially Convolutional With the advent of Convolutional Neural Networks (CNNs), the automatic classification of medical images has become more achievable. CNNs have demonstrated exceptional efficacy in diagnostics based on images, frequently surpassing conventional machine learning techniques. Utilizing this potential, we created a brain tumor detection system that combines a trained CNN model with a user-friendly web interface built with Streamlit.

The suggested system enables users to submit brain MRI images in conventional formats (.jpg, .png) as well as MATLAB .mat files, commonly found in medical research datasets like CJData. Upon Upon uploading, the image undergoes preprocessing and is sent through the trained CNN model, which determines whether the image indicates "Tumor" or "No Tumor" and provides a confidence score. The outcomes are presented alongside an option to download a diagnostic report in CSV format. By integrating deep learning with a frontend created on Streamlit, this initiative seeks to deliver a quick, dependable, and user-friendly diagnostic assistance for researchers, students, and healthcare professionals. The application functions as a prototype for practical clinical decision support systems, with prospective improvements including tumor segmentation, Grad-CAM visualization, and batch image processing.

## LITERATURE REVIEW

The identification of brain tumors has historically been a critical focus within the medical imaging field because of the substantial risks and intricate characteristics of brain disorders. Manual assessment of MRI images demands specialized knowledge and is susceptible to human mistakes, underscoring the importance and necessity of creating automated diagnostic systems. Early approaches to identifying brain tumors depended significantly on conventional image processing methods, including thresholding, edge identification, and region-oriented segmentation. Although these techniques provided basic understanding, they fell short in terms of reliability and applicability across various datasets and tumor classifications. Traditional machine learning techniques like Support Vector Machines (SVMs), Random Forests, and k-Nearest Neighbors (k-NN) were subsequently utilized with manually crafted features such as texture, brightness, and shape characterizations. Nevertheless, these models were constrained by their reliance on specialized feature engineering.

Recent progress in deep learning, especially Convolutional Neural Networks (CNNs) have considerably surpassed conventional methods in the classification of medical images. CNNs can autonomously identify spatial hierarchies of features from input images, positioning them effectively for recognizing intricate patterns like tumors in MRI scans. Numerous research efforts have shown the success of CNN-based models in detecting brain tumors. For example, *Deepak and Ameer (2019)*suggested a CNN model that was educated using segmented MRI slices, resulting in a high level of precision in identifying different types of tumors. Likewise, *Sajjad et al. (2019)*employed a profound transfer learning method and obtained remarkable results utilizing pretrained models like VGG19 and ResNet50.

Datasets such as Figshare's "Brain MRI Scans for Identifying Brain Tumors"CJ Data) and the Bra TS (Brain Tumor Segmentation) dataset have allowed scientists to develop and assess models using actual medical data. These collections feature numerous annotated MRI images, comprising both tumorous and non-tumorous instances, offering a dependable standard for deep learning algorithms.

Although the precision of models is a key focus, the implementation and availability of these models in healthcare or educational environments are also crucial. Streamlit, an open-source Python library designed for creating interactive web applications, has become favored for its ease of use and rapid deployment of machine learning solutions. Multiple recent research efforts and initiatives have leveraged Streamlit to creatediagnostic dashboards and AI-powered healthcare assistants, improving the accessibility and real-world influence of AI models. Given the above, this project utilizes a CNN-focused classifier incorporated into a Streamlit web application to deliver a real-time, easy-to-use, and precise brain tumor detection system. In contrast to numerous previous studies that stay within experimental or research environments, this system aspires for practical applicability by integrating features such as .matfile assistance, bulk processing, forecast accuracy, and exportable reports—connecting the divide between research and practical use.

**Proposed System**

The suggested system is an application driven by deep learning, aimed at the prompt and precise identification of brain tumors through MRI scans. It integrates a Convolutional Neural Network (CNN) for classification featuring an engaging and user-friendly interface created with Streamlit. This platform is designed to assist healthcare practitioners, researchers, and learners by offering a swift, dependable, and straightforward diagnostic resource.

**System Overview**

The system adheres to a modular pipeline consisting of these essential phases:

- **Data Acquisition:**The model undergoes training with a collection of brain MRI images, comprising .jpg and .mat file formats. The .matfiles are analyzed and transformed into grayscale or RGB images utilizing Python libraries such as h5py and OpenCV.
- **Preprocessing:**Input images are adjusted to a standard size (e.g., 150x150 pixels), normalized to standardize pixel values, and transformed into NumPy arrays that are appropriate for model input. For.matdocuments, proper extraction and transformation take place prior to inputting into the model.
- **Model Architecture:**A CNN model is developed to categorize images into two groups — **Tumor** and **No Tumor**. The model consists of multiple convolutional, pooling, and dense layers incorporating dropout regularization to avoid overfitting. It is constructed utilizing the binary cross-entropy loss function along with the Adam optimizer.
- **Model Training & Evaluation:** The dataset is divided into training and testing subsets. The model is developed using labeled data and subsequently assessed on unfamiliar test data to measure its accuracy, precision, recall, and F1-score. The trained model is stored asbrain_tumor_model.h5.
- **Web Deployment with Streamlit:** The developed model is incorporated into a Streamlit web application. Users are able to submit MRI images through an easy drag-and-drop interface. The image undergoes processing, and a prediction is shown, accompanied by a confidence score (e.g., "Tumor Identified with 95.2% Confidence").
- **Additional Features:**
  - **.mat File Support:** Automatically retrieves and shows the image from .mat files before prediction.
  - **Prediction Confidence:** Outputs the model's softmax chance to assist in understanding the outcome.
  - **Batch Processing:** Users are able to upload several images and get predictions for each one.
  - **Report Download:** A CSV file that can be downloaded, which includes the prediction outcomes and their associated confidence levels, has been created.
  - **Image Preview:** The uploaded MRI scan is shown for visual confirmation.

**System Architecture Diagram**

You can incorporate a flowchart or block diagram featuring the subsequent elements:

- Input Layer (Image Upload)
- Preprocessing Layer
- CNN Classification Model
- Output Layer (Prediction + Confidence)

- Optional Export (CSV Report)

**Advantages of the Proposed System**

- Provides **fast, automated** identification of brain tumors through MRI scans.
- Supports **.mat files**, commonly used in medical datasets.
- Enables **non-expert users** to control the system through a browser.
- **Improves accuracy** and minimizes human mistakes in initial assessment.
- Can be extended for **segmentation**, **tumor type classification**, and **heatmap visualization**.

## METHODOLOGY

The approach for identifying brain tumors through deep learning consists of a series of stages that allow the system to learn from MRI data and produce precise predictions. The process encompasses data preparation, model creation, training, evaluation, and deployment. Here is a detailed step-by-step overview of the method employed:

**Dataset Collection and Preprocessing**

- **Data Source:** The dataset utilized comprises 766 MRI images preserved in both .jpg and .mat formats. The .mat files are extracted using the h5pylibrary to transform MATLAB arrays into viewable image formats.
- **Labeling:** Each image is labeled as either **Tumor** or **No Tumor**, grounded in the metadata or folder arrangement.
- **Image Preprocessing:**
  - Convert to grayscale (if necessary).
  - Adjust all images to a specified dimension (e.g., 150x150).
  - Adjust pixel values to fit within the range [0, 1].
  - Enhance data through rotations, flips, and shifts (optional, to boost generalization).

**Model Architecture (CNN)**

A Convolutional Neural Network (CNN) is developed for the purpose of classifying MRI images. The framework comprises:

- **Input Layer:** Accepts preprocessed image arrays.
- **Convolution Layers:** Utilizes 2D filters to extract spatial characteristics.
- **Max Pooling Layers:** Down samples feature maps to lessen dimensionality.
- **Dropout Layers:** Prevents overfitting during training.
- **Flatten Layer:** Transforms 2D data into a 1D vector.
- **Dense Layers:** Completely linked layers that analyze characteristics.
- **Output Layer:** A solitary neuron utilizing a sigmoid activation function to generate binary categorization (0 = No Tumor, 1 = Tumor).

**Model Training**

- **Split Dataset:** The dataset is divided into training (80%) and testing (20%) groups using train_test_split() from sklearn.
- **Compilation:** The model is built using:
  - **Loss Function:** Binary Cross-Entropy
  - **Optimizer:** Adam
  - **Metrics:** Accuracy
- **Training:** The model undergoes training for a predetermined number of epochs (for instance, 15–25) while validating on the test set. The optimal weights are stored in brain_tumor_model.h5.

**Evaluation**

- The model is evaluated using:
  - **Accuracy**
  - **Precision**
  - **Recall**
  - **F1-Score**
  - **Confusion Matrix**
- These metrics guarantee that the model excels not just on the training set but also applies effectively to new data.

**Web Application using Streamlit**

- A Streamlit interface is developed to enable image uploads and forecasts.
- Once a picture is uploaded, it is:
  - Preprocessed in real-time.
  - Fed to the trained model.
  - The forecast (Tumor / No Tumor) is displayed together with the confidence level.
- The application also supports:
  - .mat file extraction and display.
  - Batch image upload.
  - CSV report generation for predictions.

**Deployment**

- The completed system can be implemented either on local servers or on cloud services like Streamlit Community Cloud,Heroku, or AWS for public access.

## RESULTS AND DISCUSSION

Model Performance

The proposed Convolutional Neural Network (CNN) model was developed using a collection of 766 brain MRI images, with an 80:20 division for training and testing. The model's performance outcomes were assessed utilizing standard classification metrics. Real values may fluctuate based on the ultimate model training, differences in datasets, and preprocessing. The model demonstrated high accuracy and recall, suggesting it is successful in detecting true positives (tumor instances). The F1-Score further demonstrates an equitable balance between precision and recall, rendering the model appropriate for medical diagnostics where it is crucial to minimize both false positives and false negatives.

Sample Predictions

Here are some instances of forecasts generated by the implemented Streamlit application. The system displays reliable and assured forecasts in both .jpg and .matformats. This emphasizes the strength of the model and its compatibility with practical research datasets.

Visualizations

- **Training vs Validation Accuracy and Loss:** The training graphs indicate favorable convergence without overfitting.
- **Confusion Matrix:** The model accurately categorized the majority of tumor and non-tumor images, with only a small number of errors.

## DISCUSSION

The findings confirm the efficiency of deep learning, particularly CNNs, in tasks related to medical image classification like detecting brain tumors. The incorporation of Streamlit greatly enhances its utility by facilitating real-time diagnosis, rendering the tool appropriate for both clinical and educational settings.

**Some key observations**:

- The model is very sensitive to distinct, clear MRI images free of noise.
- Confidence scores provide clarity, enabling users to assess dependability.
- The system operates effectively even on unfamiliar .matdocuments from research data collections, owing to appropriate preprocessing.

Limitations

- Quality of performance may diminish somewhat when dealing with low-quality or distorted images.
- The model exclusively accommodates binary classification (Tumor vs. No Tumor) and does not distinguish between various tumor types (e.g., glioma, meningioma).
- Bigger and more varied datasets might improve generalization even more.

Future Improvements

- Incorporate tumor type categorization (multiclass CNN).
- Integrate Grad-CAM or heatmaps for model explainability.
- Incorporate segmentation models (e.g., U-Net) to identify tumor areas.
- Implement as a mobile or cloud-oriented diagnostic solution for broader availability.

## CONCLUSION

The creation of a system utilizing deep learning for the identification of brain tumors through MRI scans offers a hopeful answer to one of the most significant issues in medical diagnostics. In this project, a Convolutional Neural Network (CNN) was successfully trained on a curated dataset of 766 MRI images to categorize brain scans into tumor and non-tumor groups. The model exhibited excellent accuracy, precision, and recall, highlighting its dependability in aiding healthcare practitioners with preliminary evaluations. To improve usability, the trained model was incorporated into a user-friendly Streamlit web app. This interface enables users to submit brain MRI images in formats such as .jpg, .png, and .mat, and get instant predictions accompanied by confidence ratings. Extra capabilities like batch image analysis, confidence visualization, and report creation enhance the tool's usefulness for clinical and educational applications. Though the system operates effectively with the existing dataset, its potential can be enhanced by integrating multiclass tumor classification, explainability modules (such as Grad-CAM) and tumor segmentation. In general, the suggested solution illustrates how artificial intelligence and machine learning can greatly enhance diagnostic speed, precision, and accessibility within the domain ofneuro-oncology.

## ABSTRACT

Quinn and Takarewski first introduced a technique that provides online sample preparation of biological sample along with detection by applying turbulent flow over laminar flow in a modified column having increased particle size compare to the conventionally used Liquid chromatography. This phenomenon was termed as Turbulent Flow Chromatography (TFC). The need of his technique arises due to the issue related due to the challenges faced inquantification of bio-analytes due to complex off-line techniques involved in preparing the samples. Thus, turbulent flow chromatography when coupled with sophisticated analytical instruments like LC-MS/MS provides an edge of on-line sample preparation. Thus, it gives an upper hand of injecting the samples directly in the instrumentwhere isolation of compound occurs as it gets adsorbed by the TFC column which is further eluted and detected by analytical column and mass detector. Initially, this technique was only limited to biological matrices like blood and plasma of human and animals. However, in later yearsit was successfully applied in environmental analysis for quantification of contaminants as well as in food analysis for evaluating pesticide residues and adulterants by coupling it LC-MS/MS. This review comprises a summary of all the reported methods applying TFC hyphenated with LC-MS/MS for detection of these such biological, food related and environmental sample from the year 1997 to 2025.

**Keywords:** Biological samples, Turbulent Flow, Hyphenation, LC-MS/MS.

## INTRODUCTION

Identification and evaluation of analytes in biological matrices for metabolite profiling, pharmacokinetics and toxicokinetic studies are essential however the detection of analyte of interest even by sophisticated technique like LC-MS/MS may also be time consuming due to complex steps involved in preparing the sample to isolate the compound of interest from their biological matrices to eliminate its interference. Where the need of developing a technique that provides the on-line sample preparation for bioanalysis, thus Turbulent Flow Chromatography (TFC) was introduced in the year 1997 by Quinn and Takarewski. Where, with their study they concluded when flow pattern of the fluid is changed from laminar to turbulent inside a specially designed column capable to withstand the pressure of fluid when under turbulent flow pattern.[1-3] This turbulent flow was introduced in the year 1895 by a British physicist Osborne Reynolds where he derived a systematic mathematical analysis of the turbulent flow in this study by considering the studies of William Thompson based on the concept of turbulent flow.[4-6]

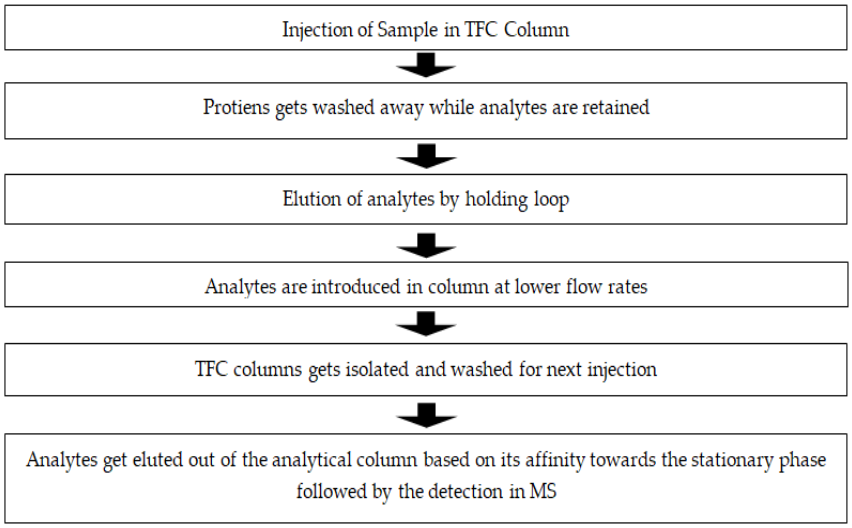
**Principle of TFC**

Turbulent flow chromatography methods ease the analysis by direct injection of biological samples eliminating the pretreatment and sample preparation on a column packed with a larger particle (≥30 µm). This column is positioned in between the injection port and analytical column to separate the analytes from the biological matrices where the analytes get retained and the proteins gets eluted out of the system. Turbulent flow moves towards the analytical column for detection via elution with the holding loop which is responsible for providing the retained analytes in the TFC column to the analytical liquid chromatography column using the stored solvent at lower flow rate. Once transfer of analytes from TFC column to LC column is completed, both the columns get isolated individually to enable TFC column washing and detection and quantification of analytes in the LC column.[7-11]

**Coupling with LC-MS/MS**

Various studies have concluded that the coupling of TFC with LC-MS/MS has proven to be fast, sensitive and robust for bioanalysis. This hyphenation eliminates the complex and time-consuming sample preparation techniques involved such as solid phase extraction and liquid-liquid extraction are employedfor the quantification of analytes by providing on-line sample preparation which minimizes the time duration required for sample preparation.[3,8,11]

**Working of Turbulence Flow Chromatography when hyphenated with LC-MS/MS[11-13]**



Details of Reported Applications of TFC Coupled with LC-MS/MS are tabulated from Year 1997 Till 2025.

| No. | Matrix | Analyte | Turbo Flow Column | Analytical Column | Detector | Reference no. |
|---|---|---|---|---|---|---|
| 1 | Human/Rat Plasma | Proprietary Compound | Explorer Turbo-$C_{18}$ (50 x 1.0 mm) | N/A | Triple Quadrupole MS/MS | 11 |
| 2 | Human/ Minipig Plasma | Terbinafine | Turbo-$C_{18}$ (50 x 1.0 mm) | Eclipse XDB-$C_{18}$, (50 x 4.6 mm, 3.5µm) | Triple Quadrupole MS/MS | 12 |
| 3 | Human Plasma | Ketoconazole | Turbo-$C_{18}$ (50 x 1.0 mm) | Zorbax SB-$C_{18}$, (50 x 4.6 mm, 3.5µm) | Triple Quadrupole MS/MS | 13 |
| 4 | Dog Plasma | Doxazosin, CP-122,288, Dofetilide | Turbo-$C_{18}$ (50 x 1.0 mm) | Cohesive HiRes $C_{18}$ (33 x 2.1 mm) | Triple Quadrupole MS/MS | 14 |
| 5 | *In-vitro* Rat Liver Microsomal Incubate | Metabolism Profiling | Turbo-$C_8$ (50 x 1.0 mm) | Aquasil $C_{18}$ (20 x 4 mm, 1.9) | Ion Trap | 15 |
| 6 | Human Plasma | Proprietary Compound | Cyclone (50 x 1.0 mm) | Zorbax SB-$C_{18}$, (50 x 2 mm, 5µm) | Triple Quadrupole MS/MS | 16 |
| 6.1 | Human Plasma | Tea Catechin | $C_{18}$ (50 x 3.1 mm, 50µm) | Zorbax Eclipse XDB $C_{18}$ (150 x 4.6 mm, 5 µm) | Quadrupole MS/MS | 17 |
| 7 | Rat Plasma | Dextromethorphan, Dextrorphan, 3-methoxymorphinan | Cyclone (50 x 1.0 mm) | X-Terra MS $C_8$ (20 x 2.1 mm, 3.5µm) | Q-TOF MS/MS | 18 |

## CONCLUSION

This literature aims to summarize all the reported methods available for across various scientific databases that applies Turbulent Flow Chromatography coupled with LC-MS/MS. This review article aims to provide an overview about the history and development of the TFC with its important aspects, synopsis of the principles involved along with their reported methods from the year 1997 to 2025

## ABSTRACT

A simultaneous equation approach based on UV spectrophotometer was used for the simultaneous determination of betahistine and paracetamol in a binary combination. As we all know that paracetamol is an analgesic and anti-pyretic drug. Betahistine is used to treat Meniere's disease. So, the signals for the proposed approach were measured at 265 and 244 nm, which correspond to the maximum absorbances of betahistine and paracetamol in double-distilled water, respectively. For both medications, linearity was seen in the concentration range of 4 to 14 µg/ml. By applying the absorptivity values determined for both medicines at two wavelengths, 265 and 244 nm, and solving the simultaneous equation, the drug concentration was determined.To verify the method's accuracy, a recovery study was done after statistical validation of the method. Various other validation parameters were statistically evaluated successfully. The procedure was discovered to be quick, easy, accurate, and precise.

**Keywords:** Paracetamol, simultaneous equation, UV-Vis spectrophotometry, betahistine, validation, statistical analysis.

# INTRODUCTION

**Paracetamol**

Paracetamol is a pain reliever and a fever reducer. The exact mechanism of action of is unknown. Paracetamol is used to treat conditions like headache, muscle aches, arthritis, backache, toothaches, colds, and fevers. Paracetamol has analgesic and antipyretic actions[1].

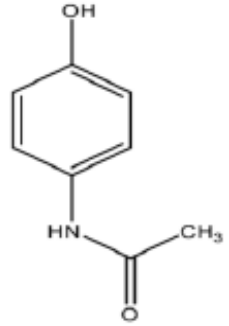

**Fig.1: Structure of Paracetamol**

**Betahistine**

Betahistine, a histamine analogue, is used to treat Ménière's disease symptoms. There are some symptoms like vertigo, tinnitus, and hearing loss. Betahistine normally takes 1 to 2 weeks to provide any noticeable results. If someone forget to take his or her dose, it should be taken as soon as possible [2].

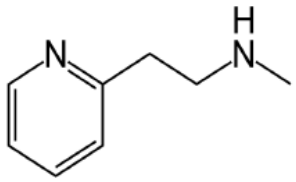

**Fig 2: Structure of Betahistine**

**Simultaneous determination method**

**Simultaneous equation method**

If a sample mixture contains two absorbing drugs X and Y, then it's possible to determine the concentration of both the drugs present in that mixture. To do this experiment few things should be known previously, those are

Absorptivity ($E^{1\%}_{1cm}$) of pure X compound at $\lambda_1$ = $a_{x1}$ and at $\lambda_2$ = $a_{x2}$

Absorptivity ($E^{1\%}_{1cm}$) of pure Y compound at $\lambda_1$ = $a_{y1}$ and at $\lambda_2$ = $a_{y2}$

Absorbance (A) of the mixture at $\lambda_1$ (A1) and at $\lambda_2$ (A2)[3]

If it is assumed that the concentration of X in the diluted sample is $C_X$ and concentration of Y in the diluted sample is $C_Y$, then $C_X$ and $C_Y$ are to be determined. Total absorbance of the sample mixture at $\lambda_1$ (A1) =Absorbance of X at $\lambda_1$+Absorbance of Y at $\lambda_1$. So, total absorbance of the sample mixture at $\lambda_2$ (A2) = Absorbance of X at $\lambda_2$+Absorbance of Y at $\lambda_2$. If length of the path of the light is equal to 1 then the following simultaneous equations can be constructed

$A1 = a_{x1} * C_X + a_{y1} * C_Y$

$A2 = a_{x2} * C_X + a_{y2} * C_Y$

The above two simultaneous equations can be solved by Cramer's rule to obtain $C_X$ and $C_Y$[4]

**Estimation of validation parameters**

**Linearity**

An analytical procedure's linearity refers to its capacity (within a specified range) to produce test results that are directly proportional to the concentration (amount) of analyte in the sampleA mathematical or empirical relationship between concentration and response—where the reaction is directly proportionate to the concentration—was necessary to ascertain the amount of any analyte present in an unknown sample [5].

**Acceptance criteria:** The correlation coefficient should be less than 1.

**Range**

The range of a technique of analysis is the period between the higher and less concentrated levels (amounts) of analyte in the sample (including those concentrations), for which it can be demonstrated that the method used for analysis has a sufficient level of accuracy and linearity. The concentration interval that yielded satisfactory accuracy and linearity is known as the analytical procedure's range[6].

**Acceptance criteria:** Linearity and Recovery are required to be shown.

**Accuracy**

The accuracy of an analytical procedure express closeness of agreement between the values, which is accepted either as a conventional true value or an accepted reference value and the value can be found [7].

**Evaluation**

At each concentration level, the mean recovery percentage, standard deviation, and percentage relative standard deviation were computed.

**Acceptance criteria**

Assay recovery should be between 98%-102%. A simple logic behind this performance characteristic was whether the procedure was capable of estimating a true value or not.

**Precision**

Precision is the measurement of how close the data values to each other for a number of measurements under the same analytical conditions. According to ICH, precision can be evaluated at three levels[8].

**Repeatability**

**System Precision**

Precision under same operative conditions (within a laboratory over a short period of time using the same analyst with the same equipment) was determined. Mean, SD and %RSD were calculated from data. The system's precision is verified using standard chemical substances to guarantee the analytical system functions correctly. The percentage RSD should be computed after measuring the retention time and area of six determinations[9].

**Acceptance criteria:** percentage RSD should be in between 98%- 102%.

**Method Precision**

A homogenous sample from a single batch should be examined six times for technique precision. This shows if a technique is producing reliable results for a single batch. The sample has been examined six times in this analysis, and the percentage RSD has been calculated [10].

**Acceptance criteria:** Percentage RSD have to be in between 98%-102%.

**Intermediate Precision (Ruggedness)**

Precision under different laboratory conditions (within-laboratory variation, as on different days, or with different analysts, or equipment within the same laboratory) has been carried out.

**Acceptance criteria:** Percentage RSD have to be in between 98%-102% [11].

**Robustness**

Here the closeness of the values are seen in small changes of different parameters like solvent, temperature, pH etc. Here the mean, SD, % RSD is calculated.

**Acceptance criteria:** Percentage RSD have to be in between 98%-102%[12].

**Reproducibility**

Precision between laboratories/intermediate precision can be considered during the standardization of a procedure before it is submitted to the pharmacopoeia. The basic reasoning behind this parameter was that each analytical measurement was permitted to have a certain amount of inconsistency (random error). However, the degree varies depending on the phases (dilution, weighing, etc.), the method employed for other expected variables (stability), and the procedure's intended application[13].

**Limit of detection and limit of quantification**

**LOD:** Lowest concentration of analyte in a sample that, under the specified experimental conditions, can be detected but not always quantified (LOD).

**LOQ:** The lowest concentration of analyte in a sample that can be accurately and precisely quantified (LOQ).

**Procedure:** SD of response (σ) and Slope (S). Five experimental values provided the standard deviation (σ) of and the slope (S) will be obtained from the standard curve of the analyte.

$$LOD = \frac{3.3\sigma}{S} \quad \text{and} \quad LOQ = \frac{10\sigma}{S}$$

Different approaches suggested by ICH, USP and EP (Table 1)

**Specificity**

Specificity generally refers to a method that produces a response for a single analyte only. Selectivity refers to a method which provides responses for a number of chemical entities that may/may not be distinguished from each other. If each response is distinguished from all other responses, then the method is said to be selective. Use of the term 'specificity' is justificable for microbiological assay, radio-immunoassay etc. methods rather than selectivity. Use of the selectivity is appropriate for the methods based on techniques such as HPLC, GC, CE, etc., than specificity [14].

## MATERIALS AND METHODS

**Materials**

For the experimental purpose pure Paracetamol ($C_8H_9NO_2$) powder was collected from Netaji Subhas Chandra Bose Institute of Pharmacy (W.B) and pure Betahistine ($C_8H_{12}N_2$) powder was collected from Albert David Ltd. (W.B.) as a gift sample. Double beam UV-Vis Spectrophotometer, JASCO V-730 was used for measuring the absorbance of the solutions.

**Methods**

**Preparation of stock solutions of Paracetamol and Betahistine**

**Preparation of Stock Solutions**

A solution of paracetamol and betahistine were prepared in distilled water and the concentration was 100µg/ml[15].

**Preparation of standard solutions**

Pure standard Paracetamol and pure standard Betahistine solutions were prepared by using the working standard solutions of them. Following are the solutions prepared**.** Preparation of standard solutions of pure Paracetamol Table 2. Preparation of standard solutions of pure Betahistine drug Table 3.

**Preparation of standard solutions containing Paracetamol and Betahistine**

Preparation of standard solutions containing both the drugs Table 4.

**Selection of two analytical wavelengths**

UV Spectra of pure drugs and mixture solution of two drugs were constructed by taking the solutions in a 1cm cuvette and scanned from 200 to 400nm in a double beam UV-Spectrophotometer. One wavelength was chosen so that one molecule would have the highest absorption and the other would have a lesser one. In a similar vein, the first molecule will have a lower absorbance value and the second molecule will yield the highest at the opposite wavelength[16].

**Construction of simultaneous equations**

To determine the absorptivity of the pure component a standard curve was constructed by plotting absorbance (A) against standard concentrations (C). The equation of the straight line was obtained from the graph. The path-length of the light was 1cm (1cm cuvette), therefore the slope of the straight line was the absorptivity of the component. Four absorptivities were calculated for two wave lengths and two components. Two simultaneous equations were constructed from that. The equations were solved by using Cramer's rule[17]. For large number of calculations MS Excel was used. The two simultaneous equations are as follows

$A1 = a_{x1} * C_X + a_{y1} * C_Y$

$A2 = a_{x2} * C_X + a_{y2} * C_Y$

Then the solution for $C_X$ and $C_Y$ were solved by the following equations

$$C_x = \frac{\begin{vmatrix} A_1 & a_{y1} \\ A_2 & a_{y2} \end{vmatrix}}{\begin{vmatrix} a_{x1} & a_{y1} \\ a_{x2} & a_{y2} \end{vmatrix}} = \frac{A_1 a_{y2} - a_{y_1} A_2}{a_{x1} a_{y2} - a_{y1} a_{x2}} \qquad C_y = \frac{\begin{vmatrix} a_{x1} & A_1 \\ a_{x2} & A_2 \end{vmatrix}}{\begin{vmatrix} a_{x1} & a_{y1} \\ a_{x2} & a_{y2} \end{vmatrix}} = \frac{a_{x1} A_2 - A_1 a_{x2}}{a_{x1} a_{y2} - a_{y1} a_{x2}}$$

## RESULTS AND DISCUSSIONS

**Determination of analytical wavelengths from UV-spectra**

Three spectrums were obtained from standard solution of pure Paracetamol (10µg/ml), standard solution of pure Betahistine (10µg/ml) and standard solution containing (10µg/ml) of Paracetamol and (10µg/ml) of Betahistine. Since there were two components in the mixture solution hence, two analytical wavelengths were selected at 244nm and 265nm.

**Construction of simultaneous equations**

Plotting the absorbances (Y-axis) of standard solutions of pure pharmaceuticals at two analytical wavelengths selected against the concentration (X-axis) resulted in four standard straight lines. The absorptivity values were calculated from the slopes of fig. 5.1 and fig. 5.2[18]. Absorbances of pure Paracetamol solutions at 244 nm and 265 nm Table 5. Absorbances of pure Betahistine solutions at 244 nm and 265 nm Table 6.

Therefore, the simultaneous equations are

$A1 = 0.0659 * C_X + 0.0209 * C_Y$ eqn. 5.1

$A2 = 0.0221 * C_X + 0.0323 * C_Y$ eqn. 5.2

Solving these two simultaneous equations by Cramer's rule yielded $C_X$ and $C_Y$. These calculations were carried out using MS Excel. These two equations will take A1_244 nm and A2_265 nm as input variable and the conc. X and conc. Y will be obtained as output. Recovery studies were done with standard solutions having known concentration of both the drugs. Standard straight line of Paracetamol at 244 nm and 265 nm Fig. 3. Standard straight line of Betahistine at 244 nm and 265 nm Fig. 4. Now as per table 3, six standard solutions were prepared having mixture of two drugs Paracetamol and Betahistine in different proportions. Absorbances were taken against distilled water as blank at two wavelengths, 244 nm and 265 nm. The two absorbance values A1 (at 244 nm) and A2 (at 265 nm) were input to obtain $C_X$ and $C_Y$. The recovery results are given in table 7.

**Accuracy**

Recovery of $C_X$ and $C_Y$ Table 7. Recovery study of Paracetamol Fig.5. Recovery study of Betahistine Fig.6.
Therefore, the final simultaneous equations are

$Final_C_X = 1.2762 \times Recovery - 1.0611$

$Final_C_Y = 0.9527 \times Recovery + 0.8313$[19]

**Specificity**

Since this procedure determines the two drugs in a solution therefore this method alone was not sufficient to prove the specificity. For proving the specificity another method like HPLC is required in tandem with this procedure. However, no HPLC method is reported yet for separating these two drugs.

**Linearity**

Result for linearity Table 8. As per the acceptance criteria the correlation coefficients are less than 0.9990. Therefore the method showed linearity within 4 to 14µg/ml of each drug.

**Limit of detection (LOD) and limit of quantitation (LOQ)**

Determination of LOD and LOQ Paracetamol at 244 nm and 265 nm Table 9. Since it is a mixture solution therefore the LOD and LOQ will be the higher values i.e. 0.215µg/ml and 0.75µg/ml respectively for Paracetamol (where Betahistine is the background matrix)[20]. Determination of LOD and LOQ of betahistine at 244nm and 265nm Table 10. Since it is a mixture solution therefore the LOD and LOQ will be the higher values i.e. 1.497 µg/ml and 4.536 µg/ml respectively for Betahistine (where Paracetamol is the background matrix).

**Precision**

Observations and results for System Precision Table 11. Observations and results for Method Precision Table 12. As per table 4.6 and 4.7 the %RSD values are within 2.0 therefore, the method was ascertained and detected precise with respect to repeatability.

**Range**

The range of the analytical method was determined by the linearity, precision, and accuracy trials to be between 4µg/ml to 14µg/ml concentration for both Paracetamol and Betahistine.

## CONCLUSION

Paracetamol and Betahistine mixture is a logical combination of drugs. In case of a patient suffering from vertigo along with fever, inflammation, pain; then this combination of drugs can be used. In this context an easy and economical UV-spectrophotometric simultaneous assay method was developed where a sample of solution containing a mixture of two drugs were subjected to UV-spectroscopy at two analytical wavelength of 244 and 265 nm. Two simultaneous equations were developed. The individual concentrations of two drugs were calculated from

those equations. The method was validated and various parameters were reported. Ruggedness parameter was not carried out because of limitation of multiple equipment.

## ACKNOWLEDGEMET

The authors are highly thankful to the respected principal sir Dr. Arnab Samanta for providing the necessary facility for the completion of the research work.

## ABSTRACT

Personalized and precision medicine represents a new paradigm in health care, emphasizing treatments tailored to individual variation in genetics, molecules, and the environment. The rapid development of PPM requires flexible regulatory frameworks that balance the safety for patients, the effectiveness of the treatment, and equity of access. to review the current status of regulatory readiness for PPMs, highlight major challenges identified, review relevant case studies, and provide recommendations for future regulatory approaches. Regulatory guidelines, scientific literature, and international initiatives were reviewed to assess the approval strategies, monitoring, and post-marketing surveillance adopted for personalized therapies by leading regulatory agencies such as the FDA, EMA, PMDA, and CDSCO. Significant regulatory challenges involve consistent definitions, co-development of drugs with companion diagnostics, the incorporation of real-world evidence, evaluation of AI-driven tools, ethical issues, and capacity issues. Case studies on trastuzumab with HER2 testing, CAR-T therapies, AI diagnostics, and CRISPR-based gene therapies illustrate the impact of regulatory preparedness on patient access and safety. Emerging strategies include adaptive clinical trial designs, harmonization of global standards, integration of real-world evidence, workforce development, and proactive ethical frameworks. Regulatory readiness is key for the safe and effective deployment of personalized and precision medicine. Science-driven, adaptable, and collaborative regulatory frameworks must also be combined with

innovative trial designs and global harmonization in order to assure timely patient access to next-generation therapies while continuing to uphold stringent safety and efficacy standards.

**Keywords**: Personalized Medicine, Precision Medicine, Regulatory Readiness, Companion Diagnostics, Adaptive Trial Design, Real-World Evidence, Artificial Intelligence, Pharmacogenomics.

## INTRODUCTION

A new paradigm called personalized and precision medicine replaces the traditional model of medication development and therapy, which is based on a "one-size-fits-all" approach. This new technique integrates genetic, environmental, and lifestyle elements to provide focused and efficient care, tailored to a particular individual's characteristics. Unlike conventional therapies developed for large populations, precision medicine focuses on identifying patient subgroups that will most likely benefit from a certain intervention, thus maximizing treatment outcomes while minimizing side effects. Precision medicine has been propelled in development by advances in pharmacogenomics, biomarker discovery, genomic sequencing, and digital health technologies [1]. Large-scale biobanks and the completion of the Human Genome Project have enabled scientists and medical professionals to understand the cause of diseases at the molecular level. As a result, several targeted therapies have proved remarkably effective, especially in neurology, oncology, and rare genetic iseases [2-3]. This has brought a global shift in pharmaceutical discovery, development, and regulation. However, this shift has raised difficulties for the regulatory bodies that were unheard of earlier.

Another layer of complexity has been added to health care with the integration of digital diagnostics, real-world evidence, and AI. And global regulators are increasingly emphasizing patient privacy, data reliability, and ethical governance. Regulatory preparedness, in this context, refers to the capability of national and international regulatory institutions to assess, monitor, and adapt to these rapidly developing technology and scientific advancements in precision medicine. This review article examines the existing global regulatory framework governing personalized and precision medicine, presents current challenges and gaps, and highlights future opportunities in an effort to facilitate adaptive, harmonized, and patient-centric regulatory frameworks around the globe [4-7].

**Evolution of Personalized and Precision Medicine**

The very idea of personalized medicine comes through recognizing that people differ in their responses to the same therapeutic intervention. Historically, most medical interventions have been designed and administered based on population means, disregarding genetic, environmental, and lifestyle variables of individual patients. This “one-size-fits-all” approach often leads to suboptimal therapeutic responses, drug-related adverse effects, and inefficient healthcare delivery [8-9]. The completion of the Human Genome Project in 2003 marked an important milestone for personalized medicine. By mapping the whole human genome, the HGP made it possible to identify genetic variations that predispose individuals to disease susceptibility, drug response, and metabolism, making it a starting base for precision therapeutics[10]. Meanwhile, a new field called pharmacogenomics emerged, which specialized in how genetic differences affect responses to individual medications, thus allowing for dose optimization and targeted therapy selection.

In this way, biomarker discovery and its integration with companion diagnostics have further catalyzed the movement toward precision medicine. Biomarkers allow clinicians to subgroup patients with similar expected therapeutic responses or at risk of adverse events and provide treatments that will be more appropriate and effective. A key example is testing for HER2 in breast cancer, which has enabled not only the development but also the clinical adoption of trastuzumab (Herceptin) for HER2-positive individuals specifically, greatly improving outcomes while reducing exposure to those who would not benefit from it [11-12].

The precision medicine landscape has also changed with advancements in digital health technologies, big data analytics, and AI. These digital health technologies aggregate large datasets of genomic, proteomic, and clinical information for comprehensive analyses that enable patient stratification, predictive modelling, and real-time treatment personalization. In addition, RWE emanating from electronic health records, registries, and wearables have emerged as a supplement to data from traditional randomized clinical trials for regulatory decisions. Precision medicine has extended beyond oncology into disciplines such as neurology, cardiology, and rare genetic disorders, where therapies are increasingly targeted to individual molecular profiles. Recent innovations, including gene therapy, RNA-based therapeutics, and CRISPR-Cas9 gene editing, signify the next frontier of precision medicine, offering the potential for disease modification at the genetic level [13-15]. With such rapid advancement, however, there also come some regulatory and ethical challenges. Traditional regulatory pathways were designed for more standardized products; now, therapies often involve a single patient, are codeveloped with companion diagnostics, or may be informed by AI-driven decision-making. The evolution of precision medicine therefore requires equal advances in regulatory preparedness, infrastructure, and global harmonization [16-17].

**Status of Current Global Regulatory Landscape**

The rapid development of PPM has forced regulatory authorities globally to adapt their frameworks in support of highly individualized therapies, which are increasingly being developed in combination with companion diagnostics. Effective regulatory preparedness is vital in assessing the safety, efficacy, and quality of such innovative therapies while assuring timely patient access.

**United States (FDA)**

The FDA has shown itself to be a leader in regulating precision medicine through initiatives like the Precision Medicine Initiative and the Biomarker Qualification Program, demonstrating the agency's commitment to incorporating genomics and biomarkers into the development of therapies. Further, it regulates companion diagnostics under 21 CFR Part 809, ensuring that diagnostic tests for therapy selection are rigorously validated both analytically and clinically. The FDA also supports adaptive trial designs, including basket and umbrella trials, that evaluate therapies across genetically defined patient populations [18-20].

**European Union (EMA)**

EMA has established adaptive regulatory pathways to support the approval of targeted therapies. The Personalised Medicines Roadmap and initiatives such as adaptive pathways aim at early access to treatments for patients with unmet medical needs. The EMA also works on in vitro diagnostic regulation, IVDR 2017/746, which regulates the development and validation of companion diagnostics that are crucial for precision medicine. Cooperation with the European Alliance for Personalised Medicine has further developed the approach of the EU in integrating biomarkers and patient stratification into regulatory processes [21].

**Japan (PMDA / MHLW)**

In Japan, the PMDA of the Ministry of Health, Labour and Welfare has introduced the Sakigake designation system with the aim of speeding up the review of innovative therapies, including precision drugs and regenerative medicine. The PMDA focuses on early consultation between developers and regulators in order to facilitate co-development of drugs with companion diagnostics [23-25]. Biomarker-based approvals and patient registries form part of Japan's regulatory framework to aid evidence generation and post-marketing surveillance.

**India (CDSCO)**

The overall regulatory framework for precision medicine is still evolving in India. While the CDSCO has issued guidelines on biosimilars and pharmacogenomics, comprehensive regulations related to companion diagnostics and gene-based therapies remain inadequate in the country. The country is trying to align itself with the International Council for Harmonisation guidelines; however, challenges remain in the form of infrastructure, expertise, and integration of real-world data [26-30]. Building regulatory preparedness in India would require capacity development, harmonization of guidelines, and the adoption of digital submission platforms.

**Emerging Markets and Global Harmonization**

Preparedness for PPM is highly variable across emerging markets, with many countries with developing regulatory infrastructures struggling to assess advanced therapies, incorporate biomarkers, and ensure thorough post-marketing surveillance. Global efforts, such as the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use, WHO guidance, and regional harmonization initiatives, seek to address these gaps in an effort to drive greater harmony in regulatory reviews and increase access for patients around the world to personalized therapies. Put differently, while developed regions such as the U.S., EU, and Japan have actively engaged in adapting their respective regulatory frameworks for precision medicine, the emerging markets continue to grapple with both structural and technical challenges [31]. Overall, regulatory authorities are increasingly focusing on flexible, science-based pathways, early engagement with developers, and the integration of real-world evidence to keep pace with the rapid evolution of PPM.

**Key Regulatory Challenges**

The rapid development of PPM introduces regulatory challenges that are different from those of /traditional drug and device oversight, and regulatory authorities worldwide are working to adapt their frameworks in light of these differences. However, several major obstacles still exist.

**Lack of Harmonized Definitions and Pathways**

A major challenge is the lack of globally consistent definitions and standardized regulatory pathways for precision therapies. Terms such as "personalized medicine," "precision medicine," and "targeted therapy" are often used interchangeably but can connote different regulatory expectations in different regions [32-33]. This ambiguity complicates the design of global clinical trials, data submission, and approval processes for therapies directed toward small, genetically defined patient populations.

**Co-Development of Drugs and Companion Diagnostics**

Precision therapies often rely on the use of a companion diagnostic to select patients. For this reason, regulatory review agencies must consider both the therapeutic and diagnostic products simultaneously; logistical and scientific issues arise in the process. Assuring the analytical and clinical validity of a companion diagnostic along with drug efficacy and safety requires regulatory reviews in concert between different divisions or offices [34-36].

**Data Privacy and Genomic Data Protection**

PPM is heavily dependent on genomic, proteomic, and patient-specific data. This raises serious concerns regarding data privacy, storage, and sharing. Regulatory authorities need to strike a balance between granting access to large amounts of data for drug evaluation while enforcing privacy laws as established by the EU General Data Protection Regulation and local genetic data guidelines [37-40]. Data breaches and misuse could erode patients' trust and dampen their willingness to embrace precision therapies.

**Assessment of AI and Digital Health Tools**

The integration of artificial intelligence, machine learning, and digital diagnostics further complicates the regulatory review process in precision medicine. For example, AI algorithms intended for stratification of patients, predictive modelling, or therapy recommendations must be evaluated based on their accuracy, reproducibility, transparency, and their potential bias. Current regulatory frameworks are evolving but still lack standardized guidance for AI-based tools [41-43].

**Post-Marketing Surveillance and Real-World Evidence**

Personalized therapies need tailored post-marketing surveillance strategies. Classic pharmacovigilance systems may poorly capture rare, patient-specific adverse events. Inclusion of real-world evidence and patient registries in post-approval monitoring is highly necessary but requires an infrastructure for robust collection, standardization of data, and mechanisms of regulatory oversight [44].

**Ethical Considerations**

Precision medicine also brings about issues in terms of ethical clinical trials, patient consent, and equity. Genetic testing combined with targeted therapies may lead to concerns about genetic discrimination, insurance coverage, and health equity. Regulatory frameworks will need to address these issues while ensuring that patient safety remains foremost and supporting innovation [45].

**Capacity and Expertise Gaps**

Most regulatory agencies, especially those from emerging markets, have limited technical expertise, infrastructure, and experience to review applications of genomics-based therapies, gene-editing products, or AI-driven diagnostics. This will require capacity-building measures, training programs, and international cooperation to be better regulatory prepared and enforce strict evaluation standards. In this regard, PPM regulation is complex, necessitating flexibility within an internationally harmonized framework that integrates new sources of data. Overcoming the challenges will be crucial in meeting the imperatives of timely access for patients to safe and effective therapies while maintaining high regulatory standards [46].

**The Role of Regulatory Science in Precision Medicine**

Regulatory science plays a critical role in the development, evaluation, and approval of medical products. In personalized and precision medicine, it will be pivotal to assure that therapies are safe, effective, and matched to individual patient characteristics. Given the complexity of precision therapies involving gene-based drugs, targeted biologics, companion diagnostics, and AI-driven tools, advanced regulatory frameworks supported by robust scientific methods are called for.

**Development of Regulatory Science Tools**

Regulatory bodies increasingly emphasize biomarker qualification, modelling and simulation, and integration of digital health technologies for the evaluation of precision therapies. Biomarkers enable the identification of specific subpopulations of patients who would be most likely to benefit from certain treatments, while model-informed drug development (MIDD) utilizes computational models to predict efficacy, optimize dosing, and reduce trial size [47]. Similarly, digital health tools like wearables and AI analytics provide real-time evidence for regulatory considerations.

**Collaborative Initiatives and Guidance**

Global collaboration is essential to develop regulatory science in PPM. A few key examples include

- International Council for Harmonisation (ICH) establishes common guidelines on the design of clinical trials, pharmacogenomics, and biomarker use.
- The FDA-NIH Biomarker Working Group produces guidance on biomarker qualification.
- The European Innovative Medicines Initiative, which fosters research partnerships for personalized therapies [48-50].

The collaborations will facilitate the sharing of expertise, harmonization of approaches, and regulatory expectations to support both developers and regulators in tackling complexities of precision therapies.

**Adaptive Clinical Trial Designs**

Clinical trials, using traditional methods and designs, often cannot adequately assess precision medicine products due to the limited, genetically defined patient populations. Regulatory science encourages adaptive trial designs, including basket trials, umbrella trials, and N-of-1 studies, which would allow efficient evaluation of targeted therapies while ensuring statistical validity [51-54]. Regulatory agencies encourage early interaction with developers in order to validate innovative designs against standards for approval.

**Integration of Real-World Evidence (RWE)**

Real-world evidence garnered from sources like electronic health records, patient registries, and digital devices is increasingly recognized as a valuable complement to traditional regulatory evidence. Regulatory science establishes a

framework for the evaluation of data quality, reliability, and relevance to ensure that RWE informs safety, efficacy, and post-marketing surveillance for precision therapies [55-57].

**Capacity Building and Expertise Development**

The rapid rise of PPM demands the presence of highly qualified regulatory professionals who are efficient in the review of complex biologics, gene therapies, and AI-based diagnostics. Regulatory science initiatives emphasize training programs, workshops, and knowledge-sharing platforms to equip reviewers with the expertise needed for thorough and efficient assessments of precision therapies. It is thus regulatory science that underpins the proper evaluation of personalized medicine and precision medicine. Regulatory agencies can ensure safety, efficiency, and equity in the delivery of precision medicine with the integration of advanced scientific techniques, adaptive designs of trials, and real-world evidence [59-61].

**Case Examples**

The section illustrates, through a few landmark therapies and diagnostic tools, the practical applications of personalized and precision medicine and associated regulatory considerations that highlight the evolution of regulatory preparedness worldwide.

**Trastuzumab (Herceptin) and HER2 Testing**

Trastuzumab, a monoclonal antibody for the treatment of HER2-positive breast cancer, is an effective model for the co-development of a drug with its companion diagnostic. The HER2 test enables the selection of patients most likely to benefit from the treatment, thus avoiding unnecessary exposure among non-responders. To date, regulatory agencies, such as the FDA and EMA, have coordinated the simultaneous approval of trastuzumab and the diagnostic test for HER2. This approach emphasizes the importance of integrated regulatory review in precision medicine [61-63].

**CAR-T Cell Therapies**

Chimeric Antigen Receptor T-cell therapies represent advanced personalized biologics that require patient-specific manufacturing and strict regulatory oversight. FDA and EMA have laid out customized accelerated approval pathways, risk-based post-marketing surveillance, and patient registry requirements to ensure safety and efficacy. CAR-T therapy is illustrative of the challenges in quality control, individual dosing, and long-term follow-up that will be part of the regulation of precision medicine [64].

**AI-Driven Oncology Diagnostics**

AI-based tools, such as algorithms for tumour profiling and predictive risk assessment, are increasingly being integrated into patient management. The regulators are developing a series of guidance with regard to SaMD, focusing on its validation, reproducibility, and mitigation of bias. The above cases illustrate the need for evolution in regulatory frameworks in the light of digital innovation in precision medicine [65-66].

**Gene Editing Therapies (CRISPR-Cas9)**

Such gene-editing therapies, which are emerging, most especially embody next-generation precision therapeutics that include CRISPR-based interventions. Regulators are faced with complex challenges in evaluating long-term safety, off-target effects, and ethical considerations. This is crucial for regulatory preparedness in this swiftly developing field: early engagement with regulatory agencies, rigorous clinical trial designs, and post-marketing surveillance.

Taken altogether, these examples illustrate well that effective regulatory preparedness requires:

- Early collaboration between developers and regulators
- Integration of diagnostics with therapeutics
- Innovative trial designs matched to small, well-defined patient populations

- Post-marketing surveillance that addresses individualized safety concerns In reviewing these cases, the importance of flexible, science-based regulatory frameworks for ensuring both patient safety and timely access to personalized therapies becomes clear [67-71].

**Future Directions and Recommendations**

As personalized and precision medicine continues to evolve, regulatory frameworks will need to keep pace in protecting patient safety, encouraging innovation, and providing access across the globe. The following recommendations are targeted strategies to strengthen regulatory systems worldwide.

**Global Harmonization of Regulatory Standards**

A key aspect should be the harmonization of definitions, guidance documents, and approval processes across geographies. International collaboration among organizations like ICH and WHO could reduce regulatory disparities to a minimum and ensure seamless clinical development of precision therapies worldwide. Common standards will give developers clarity and improve patient access across borders.

**Integration of Real-World Evidence and Patient Registries**

Regulatory bodies are increasingly recognizing RWE as a complementary partner to the data provided by more classic clinical trials. In fact, patient registries, EHRs, and wearable technology can broaden knowledge from post-marketing surveillance of drug safety and outcome assessment. Agencies need to collaborate on common methodologies and quality standards for the reliability of RWE and its acceptance by regulatory bodies [72].

**Adaptive and Innovative Clinical Trial Designs**

Adaptive designs, including basket, umbrella, and N-of-1 studies, efficiently test therapies in a genetically or molecularly defined subset of patients. Regulatory frameworks must encourage very early consultation with the developer to provide flexibility in statistical methods and patient stratification to enable individualized therapies [73].

**Regulatory Frameworks for AI and Digital Health**

In the face of increasing integration of AI-driven diagnostics and decision-support tools into PPM, regulators must provide clarity on the need for guidance with respect to validation, reduction of bias, transparency, and continuous learning algorithms. This ensures that the digital tools are safe, effective, and consistent for diverse patient populations.

**Capacity Building and Workforce Development**

New technologies will require competent regulatory workforces to review genomics-based therapies, gene editing products, and algorithms using AI. Training programs and workshops, along with international partnerships, can enhance competencies both in developed and developing countries so as to strengthen robust review processes.

**Ethical, Legal, and Social Considerations**

Future regulatory frameworks should include ethical considerations such as protection of genetic data, informed consent, and equity of access. Policies should protect patients against discrimination and ensure a just and transparent manner of distributing innovative therapies [74].

**Incentives to encourage innovation**

Priority review, fast-track approval, and orphan designations are some of the incentives that accelerate precision therapy development, including for very rare diseases. Harmonizing these incentives with strict regulatory review will ensure that innovation does not come at the expense of safety or effectiveness.

**Strengthening Post-Marketing Surveillance**

Given the personalized nature of PPM, regulatory agencies should strengthen post-marketing monitoring systems to capture patient-specific adverse events. Integration of RWE, patient-reported outcomes, and databases on pharmacovigilance will facilitate early detection of safety signals and promote continuous improvement of therapies. In sum, the future of regulatory preparedness for personalized and precision medicine requires frameworks that are adaptive, harmonized, and evidence-based. Regulatory agencies can help ensure timely access to safe and effective, patient-centred therapies worldwide by embracing real-world data, global collaboration, and addressing these ethical and technological challenges head-on.

## ACKNOWLEDGEMENT

The authors express their sincere gratitude to the Parul Institute of Pharmacy and Research for their support.

**Conflict of Interest**

The authors declare that there is no conflict of interest.

**Funding Statement**

This review article received no funding from any source.

## ABSTRACT

The objective of the current study was to develop and optimize sublingual tablets of Almotriptan Malate, which is a selective and potent serotonin 5-hydroxy tryptamine 1B/1D receptor agonist. It is effective drug in the treatment of migraine. Sublingual tablet of Almotriptan Malate were prepared by direct compression method using super disintegrating agent Sodium starch glycolate. All the formulations were evaluated for post-compression parameters like hardness, weight variation, friability, wetting time, thickness, water absorption ratio, disintegration time, drug content and *in-vitro* % drug release. The formulations were selected based on their disintegration time and in-vitro % drug release. The final results obtained showed that the disintegration time is 60 seconds and in-vitro % drug release is 97.71 %. Among all the 11 formulations F6 was selected as the best formulation.

**Keywords:** Almotriptan malate, Dysphagia, Sublingual absorption, Antimigraine, Drug release, Triptans.

## INTRODUCTION

Sublingual route is most dominant route when rapid onset of action is desired with better patient compliance than orally ingested tablets. In terms of drug absorption, the sublingual area of the oral cavity (i.e. the floor of the mouth) is more permeable than the buccal (cheek) area, which in turn is more permeable than the palatal (roof of the mouth) area. Systemic delivery of drugs delivers through the sublingual route had appeared from the desire to provide immediate onset of pharmacological action [1]. The sublingual tablets are usually small, flat and compressed lightly to keep them soft. These tablets are designed in such a way that they must dissolve quickly in small quantity of saliva and allow the drug to be absorbed through the sublingual mucosa. The various types of sublingual tablets commonly used are Fast disintegrating sublingual tablets, Bioadhesive sublingual tablets and Lipid matrix sublingual tablets[2]. Almotriptan malate is a selective and potent serotonin 5-hydroxy tryptamine1B/1D (5-HT 1B/1D) receptor agonist. It is chemically designed as 1[[[3-[2-(Di methyl amine)ethyl]-1 H-indol-5-yl] methyl] sulfonyl] pyrrolidone ± - hydroxyl butanedioate. Its empirical formula is $C_{17}H_{25}N_3O_2S$-$C_4H_6O_5$. Representing molecular weight of 469.56. It is white to slightly yellow crystalline powder that is soluble in water and sparingly soluble in methanol. The drug is absorbed well orally, with absolute bioavailability of around 70%. The drug is used to treat severe migraine headaches and vascular headaches; acute treatment of migraine attacks with or without aura. The drug binds with high affinity to 5-HT 1D, 5-HT 1B, and 5- HT 1F receptors. Because of the particular distribution of the 5-HT 1B/1D receptors, almotriptan basically constricts the human meningeal arteries: therefore it has limited effect on arteries supplying blood to the brain and little effect on cardiac and pulmonary vessels[3].

## MATERIAL AND METHODS

### Materials

Almotriptan malate was a gift sample obtained from MSN Laboratory Pvt. Ltd. Telangana. Sodium Starch Glycolate, Microcrystalline cellulose, Mannitol, Sodium Saccharine, Magnesium stearate, Talc, Menthol were purchased from Kasliwal Brothers, Indore. All chemicals were used of analytical grade.

### Methods

#### Melting Point determination

Capillary tube was taken and its one end was sealed by heating. Capillary tube was fitted upto 2-3 mm high with drug powder. The capillary tube putted inside melting point apparatus and temperature was increased slowly. The temperature was noted when the drugs gets starts melting and again noted when drug completely melted.

#### UV Spectroscopy

50 mg of Almotriptan Malate was weighed and dissolved in 50 ml of distilled water to prepare a 1000µg/ml stock solution from which a 10µg/ml dilution was prepared. Baseline correction was performed using distilled water and sample was run between the range 200-400 nm wavelengths in spectrum mode by using schimadzu 1800 UV visible spectrophotometer. λmax of Almotriptan Malate (Figure 1).

#### Calibration curve

The calibration curve of Almotriptan Malate was prepared in distilled water and phosphate buffer pH 6.8 by using schimadzu 1800 UV spectrophotometer. Accurately weighed 50 mg of Almotriptan Malate was transferred into a 50 ml volumetric flask and the volume was made up with distilled water to obtain a 1000µg/ml stock solution of Almotriptan Malate. From the above stock solution 1ml was taken and transferred into 10ml volumetric flask and the volume was made up with distilled water to obtain 100 µg/ml of solution from which 2, 4, 6, 8 and 10µg/ml dilutions were prepared. Same procedure was followed for phosphate buffer pH 6.8 to prepare a calibration curve respectively[4].

**Solubility studies**

The solubility of Almotriptan Malate in various medium was determined by using shake flask method. In this method 2ml of each solvent was taken into vials and an excess amount of Almotriptan Malate was added. The vials was sealed properly and stirred for 10 min. They were the kept on orbital shaker at 37°C for 24 h. After solubilization of Almotriptan malate, An extra amount of Almotriptan Malate was added to the vials containing drug-solvent mixture. The process was repeated until saturation solubility of Almotriptan Malate was indicated by presence of undissolved drug. The mixture was then kept at room temperature for 24 h and centrifuged using Remi 12C micro-centrifuge at 3000 rpm for 15 min. The supernatant were separated and diluted with respective solvents. The drug concentration was analyzed spectrophotometrically at 225 nm using UV-visible spectrophotometer (schimadzu 1800).

**Formulation**

**Taste Masking of drug**

Almotriptan Malate and Mannitol was taken for taste masking. Mannitol was melted in a porcelain dish at 120°C on a hot plate. Almotriptan malate was added and mixed properly, then immediately cooled in ice bath. The mixture was stored for 24 h then passed through sieve 80[5].

**Experimental design**

The Polymer Mannitol was selected owing to their taste masking ability and compatibility with drug. Successful use of polymer is known to provide the immediate drug release property. The sublingual tablet was optimized by Design expert 13 software using Central composite design. The design was employed to statistically optimize the independent variable: concentration of sodium starch glycolate ($X_1$) and concentration of mannitol ($X_2$). The main effect was evaluated, interaction effects and quadratic effect of these formulation ingredients on dependent variables: disintegration time ($Y_1$) and *in-vitro* drug release ($Y_2$)[6]. The table 1 shows that independent variables and by taking above 2 factors with their different concentration (levels) 11 batches were formulated and evaluated on the basis of response which is given in table 3 below. Formula of each sublingual tablet as per Central composite design (Table 2)

**Precompression Parameters(7)**

**Bulk density**

Bulk density is defined as the ratio of mass of powder to the bulk volume of powder. 10 gm of powder was taken in a 100 ml measuring cylinder and noted down the volume occupied by the powder.

**Bulk density = Mass of powder / Poured volume of powder**

**Tapped density**

Tapped density is defined as the ratio of mass of the powder to the tapped volume of the powder. 10 gm of powder was taken in a 100 ml measuring cylinder and noted down the volume occupied by the powder after tapping for 100 times.

**Tapped density = Mass of powder / Tapped volume of powder**

**Angle of repose**

The angle of repose was performed to determine the flow property of the formed powder. The height of the funnel was adjusted 4 cm above the working slab. The accurately powdered blends were poured through funnel until pile of powder touches the funnel. The height and diameter of the pile was noted. Angle of repose was calculated by the formula.

**$\tan \theta = h/r$**

Where, $\theta$ = angle of repose

h = height

r = radius

**Carr's index**

The % compressibility of a powder is direct measure of the potential of powder blend by using tapped density and bulk density.

**Carr's index = bulk volume – tapped volume / bulk volume x 100**

**Hausner's ratio**

It is found that the ratio of tapped density and bulk density. A hausner's ratio of <1.25 indicates a powder that is free flowing whereas >1.25 indicates poor flow ability of powder.

**Hausner's ratio = Tapped density / bulk density**

**Preparation of Almotriptan Malate Sublingual Tablet by Direct Compression method[5]**

- All ingredients were accurately weighed as shown in table no.1 passed through sieve No. 80 and collected in polybags individually.
- Taste masking of Almotriptan Malate was done by solid dispersion. Mannitol was melted in a porcelain dish at 120°C on a hot plate and the drug Almotriptan Malate was added in it and mixed properly, then immediately cooled in an ice bath. The solid dispersion was stored for 24 h then passed through sieve no. 80.
- Taste masked drug was mixed with sodium starch glycolate, microcrystalline cellulose, menthol and sodium saccharine for 15 min.
- Magnesium stearate and talc was added to it and blend for 5 minutes.
- The compressed tablet were prepared by compressing the blend by rotary tablet compression machine (Aidmach) using 6mm round shaped dies and punches of B- toiling.

**Evaluation of Tablet**

**Weight variation**

20 tablets were selected randomly and weighed. The average weight was calculated. Not more than 2 of the individual weights should deviate from the average weight by more than percentage shown in the table and note deviated by more than twice that percentage. If more than 2 tablet deviate from the range re-tests 20 tablets were done and not two tablets should deviate from 40 tablets [8].

**Hardness**

The tablet was placed on the holder and the scale was set at "0" on Monsento tester. The range of Monsento hardness tester was "0 to 20" kg. The pressure was applied on tablet till they break. The reading was noted[5].

**Thickness**

Thickness of the tablet was measured by using Vernier caliper. The tablet was placed laterally between the jaws of Vernier caliper. Jaws were adjusted to just touch object to be measured. The reading was noted.

**Wetting Time**

The tablet was placed at the centre of two layer of absorbent paper fitted into petridish. After the paper was thoroughly wetted with distilled water, excess water was completely drained out of the dish. The time required for the water to diffuse from the wetted absorbent paper throughout the entire tablet was than recorded using stopwatch.

**Water absorption ratio**

A piece of tissue paper folded twice was placed in a small petridish containing 6 ml of water. A tablet was put on the tissue paper and allowed to completely wet. The wetted tablet was reweighed. Water absorption ratio, R was determined using following equation.

**R = 100 x Wa-Wb /Wa**

Where, Wa = Weight of tablet after water absorption

Wb = Weight of tablet before water absorption

**Disintegration Time**

One tablet was placed into each tube and added a disc to each tube. The assembly was suspended in the beaker containing purified water. The apparatus was operated until the tablets completely disintegrate. The time taken was noted for the complete disintegration of the tablet.

**Drug Content**

The drug content was determined by calibration curve method are follow: Ten tablet were taken and amount of drug present in each formulation of tablet was determined. The tablet was crushed in a mortar-pestle and equivalent to 6.25 mg of drug was dissolved in phosphate buffer pH 6.8 in a 100 ml volumetric flask. Volume was made upto 100 ml. The sample was filtered through filter paper. From this solution 1 ml were taken in a 10 ml volumetric flask and diluted with phosphate buffer pH 6.8. Further, 1 ml were taken and diluted upto 10 ml and analyzed for drug content by UV spectrophotometer at 225 nm using schimadzu 1800.

***In-vitro* dissolution studies**

The *in vitro* drug release was performed according to the USP dissolution apparatus II at 50rpm and temperature was taken between 37±0.5°C shaft was positioned in such a way that its axis is within 2 mm of axis of the vessels and lower edge of blade is 23-27 mm from the inside of bottom of vessels. Lower down the paddle in the vessel. Tablet was put in vessel. Apparatus was turned on at 50 rpm for 30 minute 5 ml sample was withdrawn at every 5 minutes interval and volume was replaced with dissolution medium equal to the volume of sample removed. A sample was filtered using filtered using whattman filter paper. Appropriate dilutions was prepared and analyzed with UV spectrophotometer at λmax 225 nm. Concentration and percentage drug release was determined.[(2)]

**Stability studies**

The stability studies was carried out for a period of 30 days in the stability chamber. The tablets were stored under the following conditions as prescribed by the ICH guidelines (37°C±2°C and 75±5% RH Q1C). The tablets were withdrawn periodically with an interval of 30 days and analyzed for weight variation, Hardness, Disintegration time, Dissolution, Drug content etc.

## RESULT AND DISCUSSION

**Preformulation studies**

Preformulation parameters of all formulations F1 to F11 are satisfactory. Bulk density, Tapped density, Angle of repose, Carr's index and Hausner's ration are within the limits. The results is shown in Table 4.

**Bulk density (g/cm³)** **:** 0.52 to 0.56
**Tapped density (g/cm³):** 0.62 to 0.66
**Angle of repose** **:** 25.08 to 30.92
**Carr's index** **:** 11.29 to 20
**Hausner's ratio** **:** 1.12 to 1.25

**Evaluation of Sublingual Tablet:** The parameters of all formulations F1 to F11 was found to be satisfactory and all were within the limits. The result is shown in Table 5 and 6. Percentage drug release data of F1 to F11 formulation for sublingual tablets (Table 7). *In-vitro* % drug release of F1 to F11 formulations (Figure 2). Stability Studies (Table 8)

## CONCLUSION

An optimized formulation of Almotriptan Malate sublingual tablet was found and prepared by direct compression method. The best *in-vitro* % drug release observed in formulation F6 was found to be 97.71 % which contain the drug Almotriptan malate and Sodium Starch Glycolate as Superdisintgrant with other excipients. The formulation F6 was

found to be best among all other formulations because it has exhibited good wetting time, water absorption ratio, faster disintegration time and *in-vitro*% drug release compared to other formulations.

## ACKNOWLEDGEMENT

The authors are thankful to Acropolis institute of Pharmaceutical Education and Research, Indore for providing necessary facilities in the institute. Sincerely thanks to MSN laboratory Pvt. Ltd, Telangana for providing drug as a gift sample.

**ABSTRACT**

The urban morphological study is an essential aspect of urban geography. Urban morphological study involves the study of the spatial form of a city. This study uses spatial autocorrelation to deal with the urban morphological structure and spatial transformation of Imphal city, India, from 1991 to 2021. Spatial autocorrelation – Local Moran's I is deployed on the built-up areas obtained from Land Use Land Cover (LULC) supervised classification. Results from spatial autocorrelation reveal a shift from monocentric to polycentric and sprawled urban morphology, underscoring the need for spatial planning interventions to enhance morphological compactness, connectivity, and sustainable land use. This spatial evolution reflects both the urban core's maturation and the expansion pressures on the city's periphery, offering valuable insights for future urban planning and sustainable growth management.

**Keywords:** Urban Morphology, Spatial autocorrelation, Local Moran's I, Imphal City, Land Use Land Cover

## INTRODUCTION

Urban morphology refers to the study of physical forms and spatial arrangements of human settlements and how humans interact and use these forms over time [1,2,3].Urban morphology implies the study of the form of a city in terms of its shape, structure, and so on. Urban morphological studies also envisage transformative progression with the city over time, both urban cores and urban edges [4]. Urban morphology involves scrutinizing the physical built form of urban areas, identifying key individual elements, and understanding their spatial arrangement [5].Urban morphology can be defined as the study of spatial form [6]. Urban morphology recognizes that the physical form of a city undergoes changes over time and views the city as a dynamic process rather than a static object [7]. This approach is particularly applicable to research and practices focused on urban form's environmental, economic, and social aspects [8]. This study aims to understand the urban morphological transformation of Imphal, which would

help planners attain sustainable urbanization of the city. A quantitative spatial autocorrelation method was adopted to analyze the morphological structure and spatial transformation of Imphal City. This facilitated the measurement of built-up land dispersion and fragmentation, thereby enabling a temporal analysis of how urban growth patterns have altered the city's morphological characteristics. This method provides a comprehensive understanding of both the static spatial structure and the dynamic processes of morphological change in Imphal City. In the context of Imphal city, understanding morphological changes is vital for planning sustainable urban growth. This study adopts quantitative approaches to examine the city's evolving morphology. The quantitative assessment employs spatial autocorrelation, Local Moran's I, to evaluate spatial patterns of built-up expansion. By examining spatial structure and growth dynamics, the study provides a comprehensive view of how Imphal's urban landscape has changed over the past three decades (1991-2021).

## MATERIALS AND METHODS

**Study area**

This study focuses on Imphal city, situated in the heart of the central Manipur Valley, India (Figure-1).

**Data collection and preparation**

For the quantitative analysis, satellite remote sensing data were acquired from the United States Geological Survey (USGS) Earth Explorer platform. Landsat imagery for 1991, 2001, 2011, and 2021 was processed using a supervised classification approach based on the maximum likelihood algorithm. The initial classification identified four land use/land cover (LULC) categories: green cover, agricultural land, built-up area, and water bodies. To align with the study's objective of analyzing urban morphological changes and patterns, the classified maps were restructured into a binary format by isolating the built-up class and merging the remaining three categories into a single non-built-up class [9]. This binary reclassification, representing built-up as one and non-built-up as zero, was considered suitable for capturing urban dynamics [10]. For spatial analysis, only the built-up class was retained to assess the spatial autocorrelation of urban growth patterns over time. This focused approach clarified the clustering or dispersion of built-up areas. Change detection was performed by generating built-up transition maps for 1991–2001, 2001–2011, and 2011–2021. Local Moran's I statistic was applied to these change maps to measure spatial autocorrelation, identifying clusters of similar values and spatial outliers. The spatial weights matrix was constructed using the Queen contiguity method, which accounts for both edge and corner adjacency among neighbouring pixels.

**Spatial Autocorrelation Analysis Using Moran's I**

To examine the spatial structure and clustering of built-up areas over time, from 1991 to 2021, spatial autocorrelation analysis was performed using local Moran's I. Spatial autocorrelation is a spatial statistical method used to describe interaction phenomena in space. It refers to the correlation of the same variable in different spatial locations [11].This study attempts to apply spatial autocorrelation- Local Moran's I to understand the urban morphology of Imphal city

**Local Moran's I**

The concept of local Moran's Iserves as a valuable tool for assessing the spatial correlation between individual locations and their surrounding areas [12]. This measure is applied to identify the presence of local clusters—either high or low—within a region, thereby indicating the degree of similarity in attribute values among neighboring spatial units [11,12]. Local Indicator of Spatial Association (LISA), analysis classified spatial clusters into four distinct types based on Local Moran's I statistics. High–high (H-H**)** clusters, or hot spots, represented areas exhibiting significant changes in a particular landscape index, surrounded by other areas with similarly high changes*(Zheng, et al*., 2020). In contrast, Low–low (LL) clusters, or cold spots, denote areas with minimal modifications, adjacent to others showing equally low change levels. The spatial outliers, namely Low–high (LH) and High–low (HL) clusters, reflected areas with low or high changes in the landscape index located within neighbourhoods showing the opposite trend[13]. Local Moran's I identify specific clusters (hotspots and cold spots) or outliers in built-up patterns at a regional scale. This is particularly useful in detecting emerging growth areas or fragmented development patterns.

Each location receives a value indicating whether it is part of a high–high cluster, a low–low cluster, or a spatial outlier (high–low or low–high). These are often visualized on cluster maps(Figure-2). The local Moran's I statistic, functioning as LISA, was used to evaluate the extent of spatial dependence between each unit and its adjacent units[12]. The local Moran's I was used to measure the degree of spatial autocorrelation for each spatial unit, calculated using equation 1[12].

$$\mathbf{Ii} = \mathbf{Zi}\sum_{j=1}^{n} \boldsymbol{Wij}\boldsymbol{Zj} \quad (1)$$

Where, Ii is the local Moran's I value for each spatial unit, Zi is the standardized value of the attribute at location i, Zj is the standardized value at location j, Wij is the spatial weight between location i and j, n is the total number of spatial unit in the study area. A Queen contiguity weight matrix was used to define spatial relationships, where a unit is considered a neighbor if it shares either an edge or a vertex. This formulation helps identify spatial clusters (high-high or low-low) and spatial outliers (high-low or low-high) by comparing the value at each location with its surroundings. The Local Moran's I statistic was computed for each point using 499 permutations to test for statistical significance. Points were categorized into High-High (HH), Low-Low (LL), High-Low (HL), and Low-High (LH) clusters based on their spatial relationship with neighboring values. Statistically significant clusters ($p < 0.05$) were mapped using categorized color schemes. The analysis was conducted using Python, with raster-based LULC data for 1991, 2001, 2011, and 2021, where only built-up areas were utilized. Understanding Local Moran's I for transitional years helps identify how urban clusters grew, shifted, or shrank over each 10-year period, revealing areas of significant urban expansion. Local Moran's I measure spatial autocorrelation for built-up areas for each period. It gives an understanding of the spatial autocorrelation of change patterns over time. Also, Local Moran's I helps in assessing the urban sprawl. Local Moran's I helps in understanding urban sprawl by determining the spatial autocorrelation of land use changes, specifically identifying clusters of similar or dissimilar modifications in land cover. The red areas are clusters of hotspots, signifying a significant increase in built-up, while lighter/grey areas signify little to no rise in built-up, representing stable and insignificant urban sprawl (Figure-3).

## RESULTS AND DISCUSSION

**Accuracy assessment**

An accuracy assessment of the classified images was conducted using an error matrix, with overall Kappa coefficients of 0.85, 0.86, 0.85, and 0.87 for the years 1991, 2001, 2011, and 2021, respectively, indicating a high degree of classification reliability.

**Spatial Autocorrelation Analysis Using Local Moran's I**

The Local Indicators of Spatial Association (LISA) analysis was applied to built-up pixels extracted from LULC raster data for the years 1991, 2001, 2011, and 2021. LISA cluster analysis across the years 1991, 2001, 2011, and 2021 provides valuable insights into the spatial dynamics of urban morphology in the study area. Applying Local Moran's I allowed for identifying statistically significant spatial clusters of built-up areas in Imphal city over three decades. The LISA cluster maps illustrate the evolving patterns of urbanisation. The cluster types—High-High (HH), Low-Low (LL), Low-High (LH), and High-Low (HL)—offer nuanced insights into the spatial dynamics of urban growth and morphology. From an urban morphological perspective, the spatial distribution and evolution of HH clusters—indicating zones of significant local spatial autocorrelation of built-up areas—suggest a pattern of compact growth initially concentrated in the urban core and gradually diffusing outward. In 1991, the built-up landscape exhibited limited morphological complexity, with HH clusters restricted mainly to the central business district or the inner-city urban core. In 1991, the significant clustering of built-up areas was minimal, indicating dispersed urban development. This pattern signifies a compact urban form with minimal spatial fragmentation (Figure-2). A clear morphological transformation emerged as the city evolved between 2001 and 2011. The HH clusters began to radiate outward, indicating the onset of peripheral densification and an expanding urban fabric. This transition marks the initial stages of morphological diffusion, where formerly undeveloped or sparsely developed peripheries began to

exhibit significant built-up concentration. By 2021, the urban morphology had undergone substantial transformation. The spatial configuration was characterized by widespread HH clusters not only in the inner-city core but also in the intermediate and peri-urban zones. This signifies a dual process of core densification and structured peripheral expansion. The consistent presence of HH clusters along newly developed corridors and sub-centre points to a polycentric morphological tendency, where multiple zones of urban intensity are emerging. These spatial patterns highlight a shift towards morphological maturity in the core and ongoing spatial fragmentation in the outer zones. Across all time points, the LISA maps (Figure-2) show the dominance of HH clusters (marked in red), indicating strong spatial clustering of high built-up densities. This pattern is particularly concentrated around the central urban core and along major road corridors, signifying intensified infill development and urban densification over time. Peripheral regions display fewer significant clusters, suggesting gradual outward expansion. Notably, LL, LH, and HL clusters are sparse across all years, suggesting a relatively homogenous pattern of urbanisation with fewer anomalies or transitional areas. The consistent dominance of HH clusters and high Local Moran's I values in central and radial zones underscores the role of spatial dependency in urban growth. The evolution from compact urban form (1991) to a more fragmented pattern (2021) suggests a transition toward spatially dispersed urbanisation. The findings indicate that: Central zones continue to intensify; new hotspots are emerging, particularly along infrastructural routes; and peripheries are undergoing transition but with comparatively weaker spatial autocorrelation, signalling potential land-use conflict or planning gaps.

**Local Moran's I – Transitional Periods**

To capture the temporal shifts in spatial autocorrelation, Local Moran's I was computed for three transitional periods: 1991–2001, 2001–2011, and 2011–2021. Analysis of the spatial clustering of built-up areas using transitional Local Moran's I values for the periods 1991–2001, 2001–2011, and 2011–2021 offers insights into the urban landscape's morphological evolution. The colour on the map (Figure-3) represents different values of Local Moran's 1 statistics. Red indicates areas with higher values surrounded by other higher values (HH clusters). Blue represents areas with low values surrounded by other low values (LL clusters). At the same time, a lighter colour represents areas with no significant spatial autocorrelation. The intensity of colour as seen in the fig. represents the statistical significance of clusters or outliers. Darker shades of red signify hotspot areas, which significantly increase urban areas.

***1991–2001*** **(Initial morphological consolidation):** During 1991-2001, there was a significant hotspot marked by darker red shades (Figure-4) all across the study area. The Local Moran's I map for the period 1991–2001 exhibits extensive zones of high positive values (depicted in dark red), mainly concentrated in the central (inner-city) and northern regions of the study area, indicating strong spatial persistence of urban development, especially in the central inner-city core region. These clusters suggest strong spatial autocorrelation, indicating that built-up areas were expanding contiguously and consolidating. Morphologically, this period corresponds to a phase of compact urban growth, characterised by strengthening the city's core. The dominance of monocentric development is evident, reinforcing urban cohesion and density.

**2001–2011 (Intermediate morphological diversification):** During this period, the Local Moran's I values remain predominantly high, but their spatial distribution becomes more heterogeneous (Figure-3). The emergence of scattered moderate clusters, particularly toward the south and west, indicates the formation of sub-centres or edge expansions. This suggests a deviation from the previously dominant monocentric pattern. The observed fragmentation points to a transitional morphology where compact urban form begins to diffuse, leading to a semi-dispersed structure influenced by urban sprawl dynamics. The spatial autocorrelation intensifies in the outer zones, especially along emerging transport corridors. A noticeable spread of positive values suggests fragmented but clustered expansion, hinting at polycentric growth patterns.

**2011–2021 (Advanced Morphological Dispersion and Fragmentation):** During 2011-2021, the Local Moran's I values are less intensely clustered, with a notable prevalence of lighter red and pale regions (Figure-3). This weakening of spatial autocorrelation, especially in the peripheries, highlights increased morphological dispersion. The appearance of lower or even negative spatial association values in the outskirts reflects a fragmented urban expansion pattern,

often associated with leapfrog development. Morphologically, the city exhibits characteristics of a polycentric and fragmented urban form, with loosely connected urban patches and emerging discontinuities. However, there is still a significant presence of dark shades of red, especially in the surrounding or peripheral area, specifically along the Tiddim road, the airport road stretch, and the Lamphelpat areas. This is where predominant urbanization is still taking place with significant urban sprawl. The observed transitional dynamics suggest a temporal evolution from a compact and monocentric morphology (1991–2001), through a phase of diversification and edge expansion (2001–2011), toward a fragmented and dispersed urban form (2011–2021). These transformations indicate urban sprawl processes influenced by demographic growth, infrastructural development, and land-use changes in peri-urban zones. The Local Moran's I analysis thus provides a nuanced understanding of the spatial coherence and fragmentation in urban morphology over time.

## CONCLUSION

The primary aim of this study is to analyse the urban morphology of Imphal City through a spatial perspective. Quantitative spatial autocorrelation - Local Moran's I have been employed. These tools enable the measurement of spatial dispersion and fragmentation of urban land use—key morphological change indicators. By quantifying the degree of urban sprawl, they provide empirical insight into how the city's spatial structure has evolved, especially in the transitional and outer zones. The spatial analysis of built-up areas using Local Moran's Ireveals significant insights into the urban growth patterns of the study area over the past three decades. From Local Moran's I analysis, the urban morphological trajectory of Imphal city was found to be modest from 1991 to 2001, with early clustering near the core and the first signs of peripheral fragmentation. From 2001 to 2011, the city experienced consolidation and slight restructuring, forming a stronger core with moderate expansion. In the recent decade, 2011–2021, the built-up areas became more fragmented and dispersed, showing classic characteristics of urban sprawl, weakening compactness, and increasing spatial heterogeneity. These findings reveal a shift from monocentric to polycentric and sprawled urban morphology, underscoring the need for spatial planning interventions to enhance morphological compactness, connectivity, and sustainable land use. This spatial evolution reflects both the urban core's maturation and the expansion pressures on the city's periphery, offering valuable insights for future urban planning and sustainable growth management. Thus, spatial autocorrelation serves as an essential analytical component in the morphological study, linking spatial form with temporal transformation and helping to identify compactness, dispersion, or fragmentation patterns that define the city's urban structure.

**ABSTRACT**

The Diophantine equation under consideration to find the non-zero integral solution are of the type$x^2 = (R_p)y^2 - R_1^t$ which represents a very general type of negative Pell's equation formed using Ramanujan primes as coefficients. The equation are all formed using the first 10 Ramanujan primes 2,11,17,29,41,47,59,67,71 and 97. Fixing the $1^{st}$ Ramanujan prime $R_1 = 2$, we seek for solutions of Pell's equation with coefficients $R_p$,where $R_p$ denotes the $p^{th}$ Ramanujan prime.

## INTRODUCTION

The Diophantine equation $x^2 - Dy^2 = 1$, also known as Pell's equation, is known to have an infinite number of integer solutions for any square - free positive integer $D > 1$ [1]. The solutions stem from a single fundamental

solution found in Algebraic Number Theory. Brahmagupta and Bhaskara were the first to study the classical Pell's equation, and Lagrange developed the entire theory. There are an infinite number of integer solutions $(x_n, y_n)$ to Pell's equation $x^2 - Dy^2 = \pm 1$ for $n \leq 1$. Since all other solutions to this equation can be (easily) derived from the first non-trivial positive integer solution $(x_1, y_1)$ (in this case,$x_1$ or $x_1 + y_1\sqrt{D}$ is minimum), it is known as the fundamental solution. Let $x^2 - Dy^2 = 1$ have a fundamental solution $(x_1, y_1)$. Then, for any integer $n \leq 2$, the n-th positive solution of this equation, $(x_n, y_n)$, is defined by the equality $x_n + y_n\sqrt{D} = \left(x_1 + y_1\sqrt{D}\right)^n$.The corresponding negative Pell's equation,

$$x^2 - Dy^2 = -1 \qquad (1)$$

is considerably more mysterious. For (1) to be solvable in integers, it is required that $D \equiv 1$ or $2(mod\ 4)$, and that all odd prime divisors of $D$ have forms that are congruent to 1 modulo 4. These conditions, however, do not guarantee the existence of a solution. One may visit A031396 in the OEIS [2] for some known numbers $D$ = 2, 5, 10, 13, 17, 26, 29, 37, 41, 50, ... such that (1) is solvable in integers $x$ and $y$. For several decades, certain number theorists have been committed to developing standards for the solvability of (1). A few requirements are listed in [1, 3, 4,5]. According to Newman's [4] demonstration, (1) can be solved in integers if $D = \prod_{i=1}^{r} p_i$ , where $r = 2$ or $r$ is odd, and $p_i$'s are primes congruent to 1 modulo 4 and satisfy $\left(\frac{p_i}{p_j}\right) = -1$ for all 1≤i, $j < r$ with $i \neq j$. The standard Jacobi symbol is $\left(\frac{\cdot}{\cdot}\right)$ in this case. Conversely, Mollin [3] found a relationship between $x^2 - Dy^2 = 1$and the negative Pell's equation (1). He demonstrated that (1) can be solved in integers $x$ and $y$ if and only if $x_0 \equiv -1(mod\ 2D)$ is satisfied by the fundamental solution $(x_0, y_0)$ of $x^2 - Dy^2 = 1$. Despite the significance of these findings, their approaches are constrained if $D \gg 1$. For instance, there are numerous situations where the fundamental solutions are fairly large. Thus, extensive computations are required to verify these conditions. Positive Pell's equations have recently been found to have well-known solvability criteria. A primitive Pythagorean triple for D can be found by using the length of its period as a guide. Another method is to compute the simple continued fraction of $\sqrt{D}$.[6-20]. A prime number that satisfies a result about the prime-counting function proved by Srinivasa Ramanujan is known as a Ramanujan prime in mathematics. As he points out, Bertrand's postulate was initially proven by Chebyshev. Ramanujan presented a revised demonstration of the concept in 1919. Ramanujan arrived to a generalized result at the end of the two-page published work. Consequently, 2, 11, 17, 29, and 41 are the initial five Ramanujan primes. Take note that $R_n$ must be a prime number in order for it to exist: $\pi(x) - \pi\left(\frac{x}{2}\right)$ and hence, $\pi(x)$ must increase by obtaining another prime at $x = R_n$. Since $\pi(x) - \pi\left(\frac{x}{2}\right)$can increase by at most 1, $\pi(R_n) - \pi\left(\frac{R_n}{2}\right) = n$. In this paper the negative Pell's equation $x^2 = \left(R_p\right)y^2 - R_1^t$ formed using the $p^{th}$Ramanujan prime $R_p$, are analysed for obtaining non-zero integer solution for various choice of $t$ and are illustrated for primes less than 100.

## MATERIALS AND METHODS

**Theorem 1**

If $x_1, y_1$ is the fundamental solution of $x^2 - Dy^2 = 1$,then every positive solution of the equation is given by $x_n, y_n$ where $x_n$ and $y_n$ are the integers determined from $x_n + y_n\sqrt{D} = \left(x_1 + y_1\sqrt{D}\right)^n$, $n = 1,2,3\cdots$

For illustration, consider the fundamental solution $x_1 = 24$ and$y_{1=} = 5$ of $x^2 - 23y^2 = 1$. A second positive solution $(x_2, y_2)$ can be obtained from the formula

$$x_2 + y_2\sqrt{23} = \left(24 + 5\sqrt{23}\right)^2 = 1151 + 240\sqrt{23}$$

This gives $x_2 = 1151, y_2 = 240$.These integers also satisfy the equation $x^2 - 23y^2 = 1$,since $1151^2 - 23y^2 = 1$. Therefore any positive solution can be calculated using the Theorem 1.

**Theorem 2**
Suppose that the equation$x^2 - Dy^2 = -1$ (2)

has solution in positive integers and $(x_0, y_0)$ be its minimal solution.The general solution to (2) is given by $(x_n, y_n)_{n\geq 0}$where $x_n = x_0u_n + Dy_0v_n$, $y_n = y_0u_n + x_0v_n$ and $(x_n, y_n)_{n\geq 0}$ is the general solution to Pell's equation $u^2 - Dv^2 = 1$.

**Theorem 3**
Let $p$ be a prime. The negative Pell's equation $x^2 - py^2 = -1$ is solvable if and only if $p = 2$ or$p \equiv 1(mod\ 4)$.

**Testing the solubility of the negative Pell's equation**
Suppose $D$ is a positive integer and not a perfect square. Then the negative Pell's equation $x^2 - Dy^2 = -1$ is soluble if and only if $D$ is expressible as$D = a^2 + b^2$, $\gcd(a, b) = 1, a$ and $b$ positive, $b$odd and the Diophantine equation $-bv^2 + 2avw + bw^2 = 1$ has a solution(the case of solubility occurs for exactly one such $(a, b)$).

**The Algorithm**
**Step 1:** Find all expressions of $D$ as a sum of two relatively prime squares using cornacchia's method. If none exist, the negative Pell's equation is not soluble.
**Step 2:** For each representation $D = a^2 + b^2$, $\gcd(a, b) = 1$, $a$ and $b$ positive, $b$ odd,test the solubility of $-bv^2 + 2avw + bw^2 = 1$ using Lagrange-Matthews algorithm.If solutions exist,the negative Pell's equation is soluble.
**Step 3:** If each representation yields no solution, then the negative Pell's equation is insoluble.

## RESULTS AND DISCUSSION

The equation under consideration in the negative Pell's equation$x^2 = (R_p)y^2 - R_1^t$, where $R_p$denotes the $p^{th}$ Ramanujan prime and $R_1 = 2$,the first Ramanujan Prime.

**System-I:** Diophantine equation $x^2 = 11y^2 - 2^t$,with $R_2 = 11$ and $R_1 = 2$.This system concerns with negative Pell's equation$x^2 = 11y^2 - 2^t$, $t \in \mathbb{N}$.Here the prime$R_2 = 11$ cannot be expressed as the sum of two relatively prime squares.Thus by the step 1 of the algorithm, the negative Pell's equation $x^2 - 11y^2 = -1$ is not soluble. Thus we can conclude that the negative Pell's equation$x^2 = 11y^2 - 2^t$ is insoluble.

**System-II:** Diophantine Equation $x^2 = 17y^2 - 2^t$ with $R_3 = 17, R_1 = 2$.The prime $R_3 = 17$satisfies all the conditions of Theorem3,and hence we conclude that the negative Pell's equation $x^2 = 17y^2 - 2^t, t \in \mathbb{N}$ is solvable and infinitely many positive integer solutions are obtained for the various choices of $t$.
The more general Pell's equation

$u^2 = 17v^2 + 1$ (I)

can be viewed and its general solution $(u_n, v_n)$ is given by

$u_n = \frac{1}{2}f_n;\quad v_n = \frac{1}{2\sqrt{17}}g_n$ (II)

where $f_n = (33 + 8\sqrt{17})^n + (33 - 8\sqrt{17})^n$ ;$g_n = (33 + 8\sqrt{17})^n - (33 - 8\sqrt{17})^n$

**Choice-I: $t$ is an even number**
**Case 1: $t = 2$**
The Pell's equation under consideration is
$x^2 = 17y^2 - 4$ (3)

with the initial solution $x_0 = 8; y_0 = 2$. Applying Theorem 2, a series of non-zero integer solutions to (3) are discovered as

$x_n = \frac{1}{2}\left[8f_n + 2\sqrt{17}g_n\right]$ ;$y_n = \frac{1}{2\sqrt{17}}\left[2\sqrt{17}f_n + 8g_n\right]$,
where $f_n$ and$g_n$ are defined as in (II)
The recurrence relations satisfied by the solutions of (3) are given by

$x_{n+2} - 66x_{n+1} + x_n = 0$ ; $y_{n+2} - 66y_{n+1} + y_n = 0$

**Case 2: $t = 2k + 2$, where $1 \leq k \leq 7$**
The Pell's equation thus obtained is

$$x^2 = 17y^2 - 2^{2k+2} \quad (4)$$

with initial solution $x_0 = 2^{k-1}; y_0 = 2^{k-1}$. Applying Brahmagupta lemma between the solutions$(x_0, y_0)$ and $(u_n, v_n)$ from (II),the sequence of non-zero distinct integer solutions to (4) are obtained as

$$x_n = \frac{2^{k-1}}{2}\left[f_n + \sqrt{17}g_n\right]$$
$$y_n = \frac{2^{k-1}}{2\sqrt{17}}\left[\sqrt{17}f_n + g_n\right].$$

**Case 3: $t = 2k + 16$, $k \in \mathbb{N}$**
Consider
$$x^2 = 17y^2 - 2^{2k+16} \quad (5)$$
with initial solution $x_0 = 59(2^{k-1})$,$y_0 = 125(2^{k-1})$
Applying Theorem 2, and using (II) we get infinite number of solutions to (5) as

$$x_n = \frac{2^{k-1}}{2}\left[59f_n + 125\sqrt{17}g_n\right]$$
$$y_n = \frac{2^{k-1}}{2\sqrt{17}}\left[125\sqrt{17}f_n + 59g_n\right].$$

**Choice-II: $t$ is an odd number**
**Case 1: $t = 2k + 1$, $1 \leq k \leq 4$**
The Pell's equation to be solved is

$$x^2 = 17y^2 - 2^{2k+1} \quad (6)$$

**Various values of $t$ with the initial and general solutions to (6) (Table 1)**

**Case 2: $t = 2k + 9$, $k \in \mathbb{N}$**

The Pell's equation thus obtained is

$$x^2 = 17y^2 - 2^{2k+9} \quad (7)$$

Let$(x_0, y_0)$ be the initial solution of (7)given by $x_0 = 3(2^{k-1})$,$y_0 = 11(2^{k-1})$.Applying Theorem 2, a series of non-zero integer solution to (7) are discovered as

$$x_n = \frac{2^{k-1}}{2}\left[3f_n + 11\sqrt{17}g_n\right]$$

$y_n = \frac{2^{k-1}}{2\sqrt{17}}\left[11\sqrt{17}f_n + 3g_n\right]$,

where $f_n$and $g_n$ are defined as in (II).
The recurrence relations satisfied by the solutions of (7) are given by

$x_{n+2} - 66x_{n+1} + x_n = 0 \quad ; \quad y_{n+2} - 66y_{n+1} + y_n = 0$

**System -III:** Diophantine Equation $x^2 = 29y^2 - 2^t$ with $R_4 = 29, R_1 = 2$.
Given that $R_4 = 29$satisfies all the settings of Theorem 3, we can conclude that the negative Pell's equation $x^2 = 29y^2 - 2^t$ is solvable in integers.
Consider the case when $t$ is an even number.
In this case, the Pell's equation is

$x^2 = 29y^2 - 2^{2k}$ (8)

Let$(x_0, y_0)$ be the primary solution of (8) specified by$x_0 = 5(2^{k-1}), y_0 = (2^{k-1})$. Analysing the pell's equation $u^2 = 29v^2 + 1$ to discover the additional solutions to (8), whose generic solution $(u_n, v_n)$ is provided by

$u_n = \frac{1}{2}f_n; \quad v_n = \frac{1}{2\sqrt{29}}g_n$

where $f_n = \left(9801 + 1820\sqrt{29}\right)^n + \left(9801 - 1820\sqrt{29}\right)^n$

$g_n = \left(9801 + 1820\sqrt{29}\right)^n - \left(9801 - 1820\sqrt{29}\right)^n$

Applying Brahmagupta lemma between the solutions$(x_0, y_0)$ and $(u_n, v_n)$,the sequence of non-zero distinct integer solutions to (8) are obtained as

$x_n = \frac{2^{k-1}}{2}\left[5f_n + \sqrt{29}g_n\right]$

$y_n = \frac{2^{k-1}}{2\sqrt{29}}\left[\sqrt{29}f_n + 5g_n\right]$.

The recurrence relations fulfilled by the solutions of (8) are specified by

$x_{n+2} - 1960x_{n+1} + x_n = 0 \quad ; \quad y_{n+2} - 1960y_{n+1} + y_n = 0$

**Observation:** This system fails to generate integer solutions for all the odd choices of $t$.
**System-IV:** Diophantine Equation $x^2 = 41y^2 - 2^t$ with$R_5 = 41, R_1 = 2$. For this particular equation, we consider the prime 41.Using the Algorithm and testing with $(a, b) = (4,5), -bv^2 + 2avw + bw^2 = 1$ has a solution $(v, w) = (2,1)$.Therefore, we can develop this discussion by confirming that the negative pell equation $x^2 = 41y^2 - 2^t$, $t \in \mathbb{N}$ is solvable in integers.
Consider the pellian equation
$u^2 = 41v^2 + 1$ (III)
whose general solution $(u_n, v_n)$ is given by
$u_n = \frac{1}{2}f_n \quad ; \quad v_n = \frac{1}{2\sqrt{41}}g_n$ (IV)
where $f_n = \left(2049 + 320\sqrt{41}\right)^n + \left(2049 - 320\sqrt{41}\right)^n$
$g_n = \left(2049 + 320\sqrt{41}\right)^n - \left(2049 - 320\sqrt{41}\right)^n$

**Choice-1: $t$ is an even number**

**Case 1: $t = 2$**
The Pell's equation to be checked for its solutions is

$x^2 = 41y^2 - 4$ (9)

Assume $(x_0, y_0)$ be the fundamental solution of (9) given by $x_0 = 64, y_0 = 10$.Applying Theorem 2, a collection of nonzero different integer solutions to (9) is achieved as

$$x_n = \frac{1}{2}\left[64f_n + 10\sqrt{41}g_n\right]$$

$$y_n = \frac{1}{2\sqrt{41}}\left[10\sqrt{41}f_n + 64g_n\right].$$

The recurrence relation derived by employing the solutions are

$x_{n+2} - 4098x_{n+1} + x_n = 0$ ; $y_{n+2} - 4098y_{n+1} + y_n = 0$

**Case 2: $t = 2k + 2, 1 \leq k \leq 3$**

Consider

$x^2 = 41y^2 - 2^{2k+2}$ (10)

Let $(x_0, y_0)$ represent the first solution to (10) proposed by $x_0 = 5(2^{k-1}), y_0 = (2^{k-1})$ Applying Brahmagupta Lemma between $(x_0, y_0)$ and $(u_n, v_n)$ from (IV), the series of different non-zero integer solutions are discovered as

$$x_n = \frac{2^{k-1}}{2}\left[5f_n + \sqrt{41}g_n\right]$$

$$y_n = \frac{2^{k-1}}{2\sqrt{41}}\left[\sqrt{41}f_n + 5g_n\right].$$

**Case 3: $t = 2k + 8, k \in \mathbb{N}$**

The Pell's equation is

$x^2 = 41y^2 - 2^{2k+8}$ (11)

Let $(x_0, y_0)$ represent the initial solutions to (11) offered by $x_0 = (2^{k-1}), y_0 = 5(2^{k-1})$

Applying Brahmagupta Lemma between $(x_0, y_0)$ and $(u_n, v_n)$ from (IV), the sequence of non-zero distinct integer solutions to (11) are obtained as

$$x_n = \frac{2^{k-1}}{2}\left[f_n + 5\sqrt{41}g_n\right]$$

$$y_n = \frac{2^{k-1}}{2\sqrt{41}}\left[5\sqrt{41}f_n + g_n\right].$$

**Choice-2: $t$ is an odd number**

**Case 1:$t = 3$**

Consider

$x^2 = 41y^2 - 2^3$ (12)

Applying Theorem 2, a collection of nonzero different integer solutions to (12) are achieved as $x_n = \frac{1}{2}\left[19f_n + 3\sqrt{41}g_n\right]$

$$y_n = \frac{1}{2\sqrt{41}}\left[3\sqrt{41}f_n + 19g_n\right].$$

**Case 2: $t = 2k + 3, k \in \mathbb{N}$**

The Pell's equation to be examined is

$x^2 = 41y^2 - 2^{2k+3}$ (13)

Applying Brahmagupta Lemma between $(x_0, y_0)$ and $(u_n, v_n)$ from (IV),the sequence of non-zero distinct integer solutions to (13) are obtained as

$x_n = \frac{2^{k-1}}{2}\left[3f_n + \sqrt{41}g_n\right]$

$y_n = \frac{2^{k-1}}{2\sqrt{41}}\left[\sqrt{41}f_n + 3g_n\right].$

**System-V:** In this system, we consider the Ramanujan primes $R_6 = 47, R_7 = 59, R_8 = 67$ and $R_9 = 71$.We form Pell's equations $x^2 = 47y^2 - 2^t, x^2 = 59y^2 - 2^t, x^2 = 67y^2 - 2^t$ and $x^2 = 71y^2 - 2^t$.All these primes fail to satisfy the conditions of Theorem 3 and thus we conclude that, the above equations so formed does not possess integer solutions.

**System-VI:** Diophantine Equation$x^2 = 97y^2 - 2^t$ with $R_{10} = 97, R_1 = 2$.
We consider the prime 97 in support of this precise equation. Given that 97 meets every requirement of Theorem3,we can come to the conclusion that negative the Pell's equation $x^2 = 97y^2 - 2^t$ is solvable.The more general Pell's equation

$u^2 = 97v^2 + 1$ (V)

can be viewed and its general solution $(u_n, v_n)$ is given by
$u_n = \frac{1}{2}f_n \quad ; \quad v_n = \frac{1}{2\sqrt{97}}g_n$ (VI)

where $f_n = \left(62809633 + 6377352\sqrt{97}\right)^n + \left(62809633 - 6377352\sqrt{97}\right)^n$

$g_n = \left(62809633 + 6377352\sqrt{97}\right)^n - \left(2049 - 6377352\sqrt{97}\right)^n$

**Choice-1:$t$ is an Even Number.**
**Case 1: $t = 2$.**
The Pell's equation so generated is

$x^2 = 97y^2 - 4$ (14)

Let $(x_0, y_0)$ represent the initial solution to (14) offered by $x_0$=11208,$y_0$=1138.Applying Brahmagupta Lemma between $(x_0, y_0)$ and $(u_n, v_n)$ from (VI),the sequence of non-zerodistinct integer solutions to (14) are obtained as

$x_n = \frac{1}{2}\left[11208f_n + 1138\sqrt{97}g_n\right]$
$y_n = \frac{1}{2\sqrt{97}}\left[1138\sqrt{97}f_n + 11208g_n\right].$

**Case 2: $t = 2k + 2, k = 1, 2, 3, 4, 5$**
Consider

$x^2 = 97y^2 - 2^{2k+2}$ (15)

The sequence of non-zero distinct integer solutions to (15) are obtained as

$x_n = \frac{2^{k-1}}{2}\left[9f_n + \sqrt{97}g_n\right]$
$y_n = \frac{2^{k-1}}{2\sqrt{97}}\left[\sqrt{97}f_n + 9g_n\right].$

**Case 3: $t = 14$**
Using Theorem 2,the general solution to $x^2 = 97y^2 - 2^{14}$ is given by

$$x_n = \frac{1}{2}\left[3f_n + 13\sqrt{97}g_n\right]$$

$$y_n = \frac{1}{2\sqrt{97}}\left[13\sqrt{97}f_n + 3g_n\right].$$

**Case 4: $= 2k + 14$ ,$k \in \mathbb{N}$**
The Pell's equation is

$$x^2 = 97y^2 - 2^{2k+14} \qquad (16)$$

has solutions in positive integer and let $\left(6(2^{k-1}), 26(2^{k-1})\right)$ be its minimal solution. The general solution to (16) is given by $(x_n, y_n)$, where

$$x_n = \frac{2^{k-1}}{2}\left[6f_n + 26\sqrt{97}g_n\right]$$
$$y_n = \frac{2^{k-1}}{2\sqrt{97}}\left[26\sqrt{97}f_n + 6g_n\right].$$

**Choice-2:$t$ is an odd number**
**Case 1: $t = 3, 5, 7$**
The Pell's equation is

$$x^2 = 97y^2 - 2^t \qquad (17)$$

**Various values of $t$ with the initial and general solutions to (17) (Table 2).**

**Case 2: $t = 2k + 7$, $k \in \mathbb{N}$**
The Pell's equation is

$$x^2 = 97y^2 - 2^{2k+7} \qquad (18)$$

with initial solution $x_0 = 19(2^{k-1}), y_0 = 3(2^{k-1})$.Applying Brahmagupta lemma between $(x_0, y_0)$ and $(u_n, v_n)$ from (VI), the progression of non-zero different integer solutions to (18) is found to be

$$x_n = \frac{2^{k-1}}{2}\left[19f_n + 3\sqrt{97}g_n\right]$$
$$y_n = \frac{2^{k-1}}{2\sqrt{97}}\left[3\sqrt{97}f_n + 19g_n\right].$$

In this paper, all the equations are formed restricting the primes less than 100. It can be extended to any bound and also to any prime number and thus delve into the world of Pell's equations.

## ABSTRACT

The Hajj pilgrimage, one of the largest annual religious gatherings worldwide, presents unique health challenges that significantly impact the well-being of millions of pilgrims. This paper critically reviews existing literature and relevant case studies to assess the health risks associated with the Hajj, including the spread of infectious diseases, heat-related illnesses, and the exacerbation of pre-existing health conditions. Through an analysis of health management strategies implemented by Saudi authorities and international health organizations, this study highlights the importance of comprehensive health planning and response systems tailored to the specific needs of pilgrims. The findings underscore the necessity of collaborative efforts to enhance health surveillance, vaccination programs, and emergency preparedness, aiming to safeguard the health of pilgrims and ensure the successful execution of this vital religious duty. By identifying the health implications inherent in the pilgrimage experience, this research contributes to the ongoing discourse on public health in mass gatherings and offers recommendations for improving health outcomes during the Hajj.

**Keywords:** Hajj, Pilgrimage, Health challenges, Public health, Infection Diseases, Mass Gatherings.

## INTRODUCTION

The Hajj is one of the largest annual religious pilgrimages globally, where millions of Muslims wertryugather in Mecca, Saudi Arabia, in observance of a fundamental Islamic duty. It is considered one of the Five Pillars of Islam and is an obligation for every Muslim to undertake at least once in their lifetime, provided they are physically and financially able. This pilgrimage is conducted during Dhu al-Hijjah, the twelfth month of the Islamic lunar calendar. Over a five-day period, pilgrims engage in a series of sacred rituals, including Tawaf (circling the Kaaba), Sa'i (walking between the hills of Safa and Marwah), and the symbolic stoning of the devil at Mina.Hajj is not only a journey of spiritual renewal and devotion but also a profound expression of unity, as people from diverse backgrounds gather in shared worship. However, the scale of the pilgrimage, drawing millions to a single location, presents significant logistical and health challenges, making Hajj a focal point for managing large-scale crowd movements and health interventions. The unique setting and intensity of rituals highlight the physical, mental, and social demands of the pilgrimage, underscoring the need for comprehensive planning to ensure pilgrims' safety and well-being. Health management during Hajj is of paramount importance due to the vast influx of pilgrims, who annually reach millions from over 180 countries. The pilgrimage environment places unique pressures on health infrastructure, as millions gather in confined areas to perform physically demanding rituals. This large-scale convergence of individuals from diverse regions and climates, coupled with close contact in crowded settings, poses elevated risks for the spread of infectious diseases, including respiratory infections, gastrointestinal diseases, and vector-borne illnesses. Furthermore, the hot, arid climate of Mecca, combined with intense physical activities, heightens risks of heat exhaustion, dehydration, and heatstroke among pilgrims. The dense crowding and the high volume of people with preexisting health conditions require robust healthcare preparedness and coordinated response systems to address both routine medical needs and potential public health emergencies. Saudi health authorities, in collaboration with international health organizations, implement extensive health surveillance, vaccination programs, and medical services tailored to the specific risks of Hajj. Comprehensive health planning, therefore, is essential to protect pilgrims' well-being, prevent potential outbreaks, and maintain public health security, underscoring health as a critical factor in the successful management of the Hajj pilgrimage.

## RESEARCH OBJECTIVES

- To analyze health challenges faced by pilgrims during Hajj.
- To critically review existing literature and case studies on pilgrimage health risks.
- To assess public health interventions and preventive measures implemented during Hajj.
- To evaluate the effectiveness of health management strategies in reducing risks for pilgrims.
- To provide recommendations for improving health outcomes for pilgrims based on research finding.

## METHODOLOGY

This research employs a mixed-methods approach, combining qualitative and quantitative analyses to evaluate health challenges encountered by pilgrims during Hajj. The study is based on a systematic literature review, focusing on academic journals, governmental reports, and case studies published in reputable databases such as PubMed, JSTOR, and Google Scholar from the last two decades. Inclusion criteria were defined to select articles that examine health risks, outbreak case studies, and healthcare interventions specific to the Hajj pilgrimage. The quantitative component involves meta-analysis techniques to identify common health risks such as respiratory infections, heat exhaustion, and food borne diseases, assessing their prevalence among pilgrims. Additionally, epidemiological data are analyzed to track health trends and the frequency of specific health incidents during Hajj. For the qualitative aspect, thematic analysis is applied to case studies and reports, identifying underlying themes in healthcare management strategies, cultural challenges, and the role of Saudi Arabian authorities in mitigating health risks. An interpretative approach is used to examine pilgrims' experiences and the effectiveness of public health interventions. Ethical considerations are addressed by adhering to data protection protocols, ensuring that all secondary data used

respects privacy standards. The study aims to synthesize findings to provide actionable insights for improving healthcare provisions during Hajj.

## RESULT AND DISSUSION

**Health Challenges During Hajj**

The Hajj pilgrimage, one of the largest annual mass gatherings worldwide, presents unique and complex health challenges due to the density of participants, diverse origins of pilgrims, and harsh environmental conditions. Respiratory illnesses are notably prevalent during Hajj, as close quarters facilitate the spread of infections like influenza, pneumonia, and, more recently, COVID-19. Heat-related illnesses also pose a significant risk due to Saudi Arabia's extreme temperatures, especially for those unaccustomed to such climates. Cardiovascular stress is another concern, given the strenuous physical activities required over several days. Additionally, gastrointestinal infections are a common issue, often resulting from limited sanitary resources and changes in diet and water sources. Addressing these health challenges requires comprehensive strategies, including pre-departure vaccinations, health screenings, and robust on-site medical facilities. The Saudi Arabian government, in collaboration with international health organizations, has developed policies to manage these risks, from crowd control measures to public health advisories. However, as the Hajj continues to grow in scale, ongoing research and policy adaptations are essential to ensure the safety and well-being of all pilgrims.

**Infectious Disease**

Infectious diseases are a primary health concern during the Hajj pilgrimage due to the high population density and the influx of pilgrims from diverse geographic regions. Respiratory infections, including influenza, pneumonia, and tuberculosis, are especially common as close-contact settings facilitate airborne transmission. Moreover, the Hajj environment provides favorable conditions for the spread of diseases like meningococcal meningitis, which has historically caused outbreaks during the event. Gastrointestinal infections, such as foodborne and waterborne illnesses, are also prevalent, often exacerbated by the challenging sanitary conditions and differences in hygiene practices among attendees. The threat of emerging infectious diseases, including the Middle East Respiratory Syndrome Coronavirus (MERS-CoV) and, more recently, COVID-19, has intensified global health efforts focused on infection control at Hajj. Preventive strategies, including vaccination campaigns, health education, and the implementation of hygiene protocols, are essential to mitigate these risks. Collaborative efforts among international health organizations and local authorities aim to reduce the incidence and impact of infectious diseases among pilgrims.

**Non-Communicable Diseases**

Pilgrims with pre-existing non-communicable diseases (NCDs), such as diabetes and cardiovascular diseases, face heightened health risks during the Hajj pilgrimage due to the physically demanding nature of the rituals and the harsh environmental conditions. For individuals with diabetes, the intense physical activity, coupled with limited access to timely meals and insulin storage challenges, can lead to unstable blood glucose levels, increasing the risk of hypoglycemia or hyperglycemia. Cardiovascular patients face additional risks from prolonged walking, heat exposure, and crowd-induced stress, all of which can trigger complications such as angina or even myocardial infarction. Case studies have shown that these conditions are often exacerbated during Hajj, as the combination of limited medical access in crowded areas and disrupted medication schedules leads to poor disease management. For example, studies have documented increased emergency hospitalizations for diabetic patients due to severe glycemic episodes and for cardiac patients experiencing acute heart failure during pilgrimage days. Such cases underscore the need for individualized health plans, pre-travel medical advice, and portable monitoring devices for pilgrims with NCDs. Additionally, collaboration among healthcare providers, improved on-site medical facilities, and educational campaigns on NCD management during Hajj are critical to reducing health risks for these vulnerable populations.

**Environmental and Heat-Related Illness**

The extreme climate conditions of Saudi Arabia during the Hajj pilgrimage, marked by high temperatures and low humidity, significantly impact pilgrims' health, with heat-related illnesses posing a substantial risk. Heat exhaustion and heat stroke are common due to prolonged outdoor activities in temperatures that can exceed 40°C (104°F). Dehydration further exacerbates these risks, as many pilgrims may not consume sufficient fluids to counterbalance heat exposure. High temperatures also increase the likelihood of heat syncope, muscle cramps, and even kidney complications for vulnerable individuals. Recognizing these risks, health authorities have recommended preventive measures such as promoting hydration, scheduling rituals during cooler parts of the day, and wearing loose, light-colored clothing. Shade structures, rest stations, and cooling tents provided at pilgrimage sites are further strategies implemented to reduce heat exposure. Educational campaigns also advise pilgrims to recognize early signs of heat stress and to take breaks to prevent severe illness. By adopting these preventative measures, health authorities aim to mitigate the impact of environmental stressors on pilgrims and enhance safety during the Hajj.

**Psychological Health Challenges**

The Hajj pilgrimage, while a profoundly spiritual experience, can also present significant psychological health challenges for participants. The sheer scale of the event, with millions of pilgrims converging in a confined space, can lead to heightened levels of stress and anxiety. Factors contributing to these mental health issues include overcrowding, the logistical complexities of navigating the pilgrimage sites, and the physical demands of the rituals, which often lead to exhaustion. Furthermore, the unfamiliar environment and cultural differences can exacerbate feelings of anxiety for many pilgrims, especially for first-timers who may experience overwhelming sensations in the bustling atmosphere. Additionally, the pressure to fulfill religious obligations can intensify stress, as pilgrims may fear not completing the rituals correctly or missing significant moments. Separation from family and friends, often experienced during the pilgrimage, can also lead to feelings of loneliness and isolation. Health conditions, whether pre-existing or exacerbated by the pilgrimage, further complicate mental well-being, as individuals dealing with chronic illnesses may feel additional stressors related to their health management. Support systems are often lacking in such a massive gathering, making it difficult for pilgrims to access mental health resources. Recognizing these psychological challenges, it is crucial for health authorities to implement mental health support services, including counseling and stress-relief programs, to help pilgrims manage their psychological well-being during the Hajj. Integrating mental health awareness into the overall health strategies for Hajj is essential to ensure a holistic approach to pilgrim health, emphasizing the importance of mental well-being alongside physical health

**Implications for Pilgrims**

**Physical health outcomes**: The physical health implications for pilgrims undertaking the Hajj pilgrimage can be profound, with both short-term and long-term health consequences emerging from the rigorous demands of the experience. In the short term, many pilgrims encounter acute health issues such as respiratory infections, dehydration, and heat-related illnesses like heat exhaustion and heat stroke. These issues are exacerbated by the high density of individuals in confined spaces, increasing the likelihood of infectious disease transmission and physical strain from prolonged exposure to extreme weather conditions. Musculoskeletal injuries are also common, as rituals often involve significant walking and physical exertion that can lead to sprains, muscle strains, and joint pain, particularly for older adults or those unaccustomed to intense physical activity. Long-term health consequences may arise, especially for pilgrims with pre-existing conditions such as cardiovascular disease or diabetes. For instance, the physical and psychological stress of Hajj can worsen these chronic conditions, leading to complications that persist even after returning home. The pilgrimage's impact on respiratory health, due to potential exposure to pollutants and infections, may also lead to chronic respiratory issues in vulnerable individuals. Recognizing these health implications, it is essential for health authorities to provide pre-Hajj screenings, education on self-care, and access to on-site medical support to mitigate both immediate and lasting health effects for pilgrims. A comprehensive approach to managing health risks can help ensure that the pilgrimage remains both a safe and spiritually fulfilling experience

**Social implications**: Health issues during the Hajj pilgrimage can significantly impact the social dynamics within pilgrim groups, influencing both individual and collective experiences. Pilgrims often travel in groups, relying on each other for support throughout the journey. However, when one or more members encounter health complications, such as heat exhaustion, respiratory infections, or physical injuries, it can disrupt group cohesion and require others to divert their attention to provide care. This can lead to increased stress and anxiety among group members, who may feel conflicted between assisting their ailing companions and fulfilling their own religious obligations. Moreover, health challenges can alter the overall group experience, as delays and adjustments are often necessary to accommodate affected individuals. This may lead to logistical challenges, such as missed rituals or unplanned rest periods, which can affect group morale. For many, the pilgrimage is a once-in-a-lifetime experience, and health issues can thus have a profound impact, influencing pilgrims' emotional and spiritual fulfillment. Recognizing these social implications underscores the importance of preventive health measures, both to safeguard individual well-being and to preserve the communal experience of the pilgrimage

**Economic implications**: Health-related issues during the Hajj pilgrimage can impose substantial economic burdens on pilgrims and their families. Medical expenses incurred from hospital visits, medication, and specialized care for heat-related illnesses, respiratory infections, or chronic condition management can quickly accumulate, straining personal finances. The need for emergency care or hospitalization may lead to unexpected costs, which are particularly challenging for pilgrims traveling on limited budgets. For those who experience severe health complications, the financial burden may extend beyond the pilgrimage, requiring ongoing treatment upon returning home. Additionally, these health-related expenses can impact local economies, as Saudi Arabia incurs significant costs to provide healthcare services for millions of international pilgrims. Preventative measures, such as vaccinations and pre-travel health screenings, though often required, also add to pilgrims' financial responsibilities. This financial aspect underscores the importance of effective health management policies and the provision of accessible, low-cost healthcare options to reduce economic strain on pilgrims and host authorities alike, ensuring a safer and more affordable pilgrimage experience.

**Prevention and Management Strategies**

**Pre-Hajj health education**: Pre-Hajj health education is essential in preparing pilgrims for the physical and environmental challenges they may face, contributing to safer and healthier pilgrimage experiences. Given the intense demands of Hajj, including extended walking, exposure to high temperatures, and close contact with millions of people from diverse regions, health awareness is critical to minimizing the risk of illness or injury. Pre-Hajj health education programs aim to equip pilgrims with knowledge on preventive practices, such as proper hydration, respiratory hygiene, and heat management, which are crucial in avoiding common health issues like dehydration, respiratory infections, and heat-related illnesses. For individuals with chronic conditions like diabetes or cardiovascular disease, health education provides guidance on managing their health during the pilgrimage, including medication management, recognizing warning signs, and understanding when to seek medical help. Moreover, awareness of necessary vaccinations, such as for meningitis and influenza, ensures that pilgrims take proactive steps to reduce disease transmission risks. Health authorities and organizations often collaborate to provide culturally and linguistically appropriate resources to reach diverse populations. By fostering awareness and self-care practices, pre-Hajj health education helps reduce the incidence of preventable health complications, benefiting both the individual pilgrims and the healthcare systems that support them during Hajj.

**Recommendations from health organizations**: The World Health Organization (WHO) has established comprehensive guidelines to enhance the health and safety of pilgrims during the Hajj pilgrimage. These recommendations emphasize the importance of pre-travel health assessments, urging pilgrims to consult healthcare providers to evaluate their medical conditions and receive appropriate vaccinations, such as those for meningitis, influenza, and COVID-19. WHO guidelines also advocate for health education, encouraging pilgrims to be aware of common health risks and how to mitigate them through proper hydration, nutrition, and hygiene practices. Additionally, WHO recommends that pilgrims carry personal health kits that include essential medications, hand sanitizers, and basic first aid supplies to address minor health issues promptly. To reduce the risk of respiratory

infections, pilgrims are advised to practice respiratory hygiene by covering their mouths and noses when coughing or sneezing and avoiding close contact with visibly ill individuals. Moreover, the WHO emphasizes the need for maintaining physical health, advising pilgrims to engage in moderate exercise before the pilgrimage to build stamina and prevent musculoskeletal injuries. Mental health considerations are also highlighted, suggesting that pilgrims should be prepared for the psychological stresses associated with the pilgrimage experience. Finally, the WHO encourages collaboration between national health authorities and local health services to ensure adequate healthcare infrastructure during the Hajj, facilitating immediate medical attention for pilgrims in need. By adhering to these guidelines, pilgrims can enhance their well-being and contribute to a safer, more manageable pilgrimage experience.

## CONCLUSION

This research paper critically examined the health challenges faced by pilgrims during the Hajj, underscoring the importance of effective health management in this unique and high-density setting. The findings highlight the intricate relationship between the physical and social environments of the pilgrimage and the myriad health risks associated with it. Given the annual influx of millions of pilgrims from diverse geographic and health backgrounds, the potential for disease transmission is significantly elevated. Respiratory infections, gastrointestinal diseases, and heat-related illnesses emerge as primary health concerns exacerbated by the close quarters and intense physical demands of Hajj rituals. The analysis of existing literature and case studies reveals that the Saudi health authorities have developed robust health surveillance systems and vaccination programs to mitigate these risks. However, challenges persist, particularly in addressing the needs of vulnerable populations, including the elderly and those with pre-existing health conditions. The importance of pre-travel health education and preparation is emphasized as a crucial factor in enhancing pilgrims' well-being and ensuring a safe pilgrimage experience. Moreover, this review illustrates the necessity for ongoing collaboration between local health authorities and international health organizations to refine health strategies and respond to emerging public health threats effectively. Innovations in health technology, such as mobile health applications, could play a vital role in monitoring pilgrims' health status and facilitating access to medical care. the Hajj pilgrimage serves as a microcosm of larger public health challenges inherent in mass gatherings. Future research should focus on evaluating the effectiveness of implemented health interventions and exploring new strategies to enhance health security during the Hajj. Comprehensive health planning and a proactive approach are essential to safeguard the health of millions of pilgrims while preserving the spiritual essence of this profound journey. This critical review underscores the need for an integrated health management framework that addresses both routine medical needs and potential public health emergencies, ultimately contributing to the safe and meaningful observance of Hajj.

**ABSTRACT**

Menstruation is universal, yet unequal access to safe and dignified menstrual practices continues to restrict adolescent girls' health, education, and future opportunities. This cross-sectional comparative study assessed 300 government schoolgirls (150 rural, 150 urban) in Bengaluru District using the Menstrual Practice Needs Scale (MPNS-36). More than half (53.3%) reported poorly met needs, with rural girls disproportionately affected by inadequate transport, disposal challenges, and limited options for safe reuse. These disparities reflect systemic barriers that undermine equal participation in schooling and community life. The findings emphasize that inclusive growth must move beyond product distribution to address the wider ecosystem of menstrual health—disposal infrastructure, supportive school environments, and safe transport access. Ensuring equal opportunity in menstrual health is not only a matter of well-being, but also of social justice and human development. Interventions that integrate menstrual health into broader education, sanitation, and gender equity policies are essential to empower adolescent girls and foster truly inclusive growth.

**Keywords:** Menstrual Health Equity, Rural–Urban Disparities, Inclusive Growth, WASH Facilities, Adolescent Girls

## INTRODUCTION

Despite being a universal, natural biological event, menstruation has historically been surrounded by cultural beliefs, taboos, and several restrictions varying significantly across geographical and social contexts (van Eijk *et al.*, 2016).

Globally, more than 500 million women and girls lack access to adequate facilities for safe menstrual hygiene management (World Bank, 2018). In low- and middle-income countries, including India, these challenges contribute to absenteeism from school and work, psychosocial stress, and health risks (Sommer *et al*., 2015). In India, data from the National Family Health Survey (NFHS-5) indicates wide disparities in menstrual health practices, with urban adolescent girls reporting greater access to hygienic menstrual products compared to their rural counterparts (IIPS, 2021). For example, in Karnataka, 90.7% of urban girls use hygienic methods, while only 74.3% of rural girls report the same (Revathi and Aparna, 2023). Such disparities highlight how structural inequalities in education, infrastructure, and awareness contribute to differences in menstrual practices. Furthermore, socio-cultural taboos and misconceptions persist, often resulting in restrictions on mobility, diet, and participation in daily or religious activities (Biswas *et al*., 2025). Adolescence is a critical period when attitudes and practices around menstruation are formed. Lack of accurate information, coupled with inadequate facilities, particularly in rural areas, may reinforce negative perceptions and unhealthy practices. These contribute heavily to productivity in the economic and social conditions of a country. Existing studies have largely examined either urban or rural populations in isolation or have focused primarily on product access, overlooking the holistic needs for the overall development of adolescent girls. The *Menstrual Practice Needs Scale (MPNS-36)* provides a validated, multidimensional measure of menstrual experiences, capturing aspects such as adequacy of materials, privacy, comfort, and social support (Hennegan *et al*., 2020). This study assesses the menstrual practice needs of adolescent girls in Urban and rural areas of Bengaluru district using the MPNS-36. By employing a uniform and validated tool, this study seeks to provide evidence on the differences in menstrual health needs across these two settings and to generate insights for policy and programmatic interventions that are culturally sensitive and context-specific bridging the glaring gaps between rural and urban girls.

## METHODOLOGY

A cross-sectional, comparative study design was adopted to assess and compare menstrual practice needs among adolescent girls from urban and rural areas of Bengaluru District, India. The study population comprised adolescent girls aged 13–16 years who had attained menarche and were enrolled in government high schools in Bengaluru District. Using stratified sampling, equal representation was ensured from both urban and rural schools. The final sample consisted of 300 participants, with 150 each from urban and rural settings. A multi-stage sampling technique was used. Lists of government schools from urban and rural administrative divisions were obtained from the Department of Public Instruction. Schools were randomly selected from each stratum. Within each selected school, eligible girls were identified from class registers. Systematic random sampling was employed to select participants, ensuring proportional representation across classes. The study included adolescent girls between 13 and 16 years of age who had attained menarche and were enrolled in government high schools located in both urban and rural areas of Bengaluru District. Girls who were absent on the day of data collection or those with physical or cognitive impairments that prevented them from completing the questionnaire were excluded. Ethical clearance was obtained from the Institutional Review Board. Written consent from school authorities and parents/guardians, as well as assent from the participants, was collected. Confidentiality and anonymity were maintained throughout the study. Participants were informed about their right to withdraw at any stage. The Menstrual Practice Needs Scale (MPNS-36) developed by Hennegan *et al*. (2020) was used. This validated self-report instrument consists of 36 items across six subscales, including adequacy of materials, cleanliness, privacy, comfort, and support. The tool demonstrated strong reliability in prior studies (Cronbach's $\alpha$ = 0.82). A demographic sheet was added to capture age, grade, family background, and source of menstrual knowledge. Data collection was conducted in classroom settings after obtaining permission from school authorities and informed consent from parents/guardians, along with assent from participants. Trained female facilitators administered the MPNS-36 as a paper-based questionnaire. On average, each session lasted 30–40 minutes. Data were entered into IBM SPSS (version 30). Descriptive statistics (frequencies, percentages, means, and standard deviations) were used to summarize demographic characteristics and MPNS-36 responses. Independent sample t-tests were performed to compare mean scores between urban and rural groups.

Chi-square tests were applied to assess associations between categorical variables. A p-value of <0.05 was considered statistically significant.

## RESULTS

The study included a total of 300 participants, with 150 (50.0%) from rural areas and 150 (50.0%) from urban areas, providing a balanced representation for comparison. The study included 300 participants, with the largest proportion studying in Class 9 (52%) and aged 15 years (49.3%). Fathers were reported as the primary guardians for most participants (89%), and guardians were predominantly male (90.3%). In terms of education, a considerable proportion of guardians had studied up to Class 10 (28.3%), while only a small percentage had attained higher education such as degrees (3%). Housing conditions showed that a majority lived in semi-pucca houses (55%), followed by pucca (26.3%) and kutcha houses (18.7%). Sanitation facilities were mostly adequate, with 56.7% having own pit toilets, though 8.7% lacked toilets altogether. For water supply, more than half (55.7%) relied on shared public taps, while only 31% had their own well with tap connections. Out of 300 participants, only 35.3% (n=106) had attended some form of adolescent educational programs conducted in schools or communities, while a majority of 64.7% (n=194) had neither participated in nor come across any such sessions. The frequency distribution of MPNS categories shows that overall, 53.3% of participants reported their menstrual practice needs as poorly met, while 46.7% reported them as highly met. Among the six subdomains, Change and Disposal Level (52.0% poor) and Material Reliability Concerns (50.2% poor) emerged as the most concerning areas, indicating inadequate resources and facilities for hygienic management. Conversely, Reuse Insecurity Level showed relatively better conditions, with 60.7% reporting good needs met. The descriptive statistics of menstrual practice needs among 300 adolescent girls using the MPNS-36 showed the mean total MPNS score was 105.52 (SD = 12.07), indicating that, overall, menstrual needs were moderately met. Among the six subdomains, the highest mean scores were observed for Material and Home Environment Needs (35.54) and Change and Disposal Insecurity (24.69), suggesting that adequacy of materials and challenges with hygienic disposal were major concerns. Transport and School Environment Needs also scored relatively high (14.31), reflecting barriers in managing menstruation within school contexts. Table 1 presents the comparison of Menstrual Practice Needs Scale (MPNS) dimensions between rural and urban participants. Transport and School Environment Needs were significantly higher among rural girls (mean = 14.97) compared to urban girls (mean = 13.64; p = 0.000), indicating that rural participants face greater challenges in school attendance and menstrual management due to transport or school environment constraints. Similarly, Reuse Needs (p = 0.050) and Change and Disposal Insecurity (p = 0.040) also showed significant differences, suggesting that rural girls experience more difficulty in safe disposal and greater dependence on reuse practices compared to their urban counterparts. Other dimensions, including Material and Home Environment Needs, Material Reliability Concerns, and Reuse Insecurity, did not show statistically significant differences.

## DISCUSSION

The present study comparatively assessed menstrual practice needs among adolescent girls in rural and urban Bengaluru District using the Menstrual Practice Needs Scale (MPNS-36). The findings revealed that more than half (53.3%) of participants reported their needs as poorly met, with significant differences observed in domains such as transport and school environment needs, reuse needs, and change and disposal insecurity between rural and urban respondents. These results highlight persistent inequities in menstrual hygiene management despite increasing awareness and availability of products in India. Aligning with an Ugandan study, the present research also found that transport and school environment factors significantly affected rural girls, suggesting that the school setting remains a critical determinant of menstrual experiences across low- and middle-income countries (Ssesanga *et al*., 2024). The development of the MPNS short and rapid forms in Khulna, Bangladesh, further confirmed that subscales related to materials, disposal, and privacy are consistently problematic across diverse populations (Hennegan *et al*., 2020). This study reinforces this observation, as material reliability concerns and change/disposal insecurity emerged as domains with high levels of poor needs reported. Importantly, while reuse insecurity was comparatively less

concerning in this cohort, this contrasts with the Ugandan validation, where reuse insecurity was strongly associated with reduced confidence in menstrual management (Hennegan *et al*., 2024). This may be due to cultural acceptance of cloth reuse in certain Indian contexts, coupled with differences in the availability of disposable products. Studies from India provide additional support to these findings. A cross-sectional study from Belagavi district in Karnataka reported that rural adolescent girls had significantly lower awareness and knowledge about menstrual hygiene compared to urban peers, and experienced a higher prevalence of restrictions (Mahishale and Khan, 2024). The results mirror this urban–rural divide, with rural participants reporting greater challenges in safe disposal and school-related menstrual management. Similarly, research from Coimbatore among college-going women found that 62.8% reported unmet menstrual practice needs, with rural residence and parental education emerging as strong predictors (Ramya *et al*., 2024). These findings align with the observation that rural girls faced significantly greater unmet needs than their urban counterparts, particularly in disposal and transport. Moreover, the associations between unmet menstrual practice needs and broader psychosocial outcomes, as reported in Uganda, where unmet needs correlated with poor mental health (Ssesanga *et al*., 2024), emphasize the far-reaching implications of inadequate menstrual hygiene management. While the study did not directly assess mental health, the high prevalence of unmet needs, particularly in rural areas, underscores the potential psychosocial burden faced by adolescent girls in India. A safe environment to study in, clean WASH facilities, and a supportive community are not only vital to improve literacy among adolescent girls in schools but also to ensure the formation of strong, healthy, and economically empowered women for the nation. The implications of these small differences could largely impact the future of womanhood and their productivity as citizens of the country.

## LIMITATIONS

Study was limited to adolescent girls studying in government high schools in one district of Karnataka, which may not reflect the experiences of those in private schools or out-of-school adolescents. Data was collected through self-administered questionnaires (MPNS-36), which may have been affected by recall difficulties or the tendency to under-report sensitive issues due to stigma. The cross-sectional design also restricts the ability to track changes in menstrual needs over time.

## CONCLUSION

This study highlights that over half of the total participants had their menstrual practice needs poorly met, with change and disposal insecurity and material reliability concerns emerging as the most critical challenges. Rural girls reported significantly greater unmet needs in the domains of transport and school environment, reuse needs, and change and disposal insecurity, underscoring the compounded difficulties they face in managing menstruation compared to their urban peers. While urban girls had relatively better access to hygienic products, issues related to disposal and privacy remained evident across both groups. These findings emphasize that menstrual health interventions in this region must go beyond product distribution and address structural barriers such as disposal infrastructure, school environment, and transport access, with particular attention to rural adolescents who remain disproportionately disadvantaged. adding modules on psychosocial outcomes (e.g., confidence, school participation, or distress) alongside MPNS-36 would generate a more comprehensive picture of the consequences of unmet needs. Testing targeted school-based interventions—such as improved disposal infrastructure, transport access, and structured adolescent education sessions—would also help identify strategies most effective for reducing the rural–urban gap and ensuring equal opportunities.

## ACKNOWLEDGEMENTS

The authors express their sincere gratitude to the school authorities, teachers, and parents for granting permission and support during data collection. We are especially thankful to the adolescent girls who voluntarily participated in

this study and shared their experiences with openness. The assistance of field facilitators and data entry staff is also deeply appreciated.

### Funding

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

### Conflict of Interest

The authors declare no conflicts of interest related to this study.

**Confidentiality of Data**

Confidentiality of participants' data was strictly maintained throughout the study. No identifying information was collected, and responses were anonymized prior to analysis. All data was used solely for research purposes.

## ABSTRACT

Detecting lung nodules early is crucial for enhancing clinical results in individuals vulnerable to lung cancer. Standard CT-based screening faces difficulties due to faint nodule shapes, diverse dimensions, and image noise in low-dose CT (LDCT) examinations. New developments in artificial intelligence, especially deep learning, provide encouraging diagnostic assistance. The purpose of this research is to assess the diagnostic accuracy of a multi-scale convolutional neural network (CNN) for automated identification of pulmonary nodules in LDCT images. A selected collection of 135 LDCT lung scans was utilized. All images underwent preprocessing through normalization, noise suppression, and resizing. Data augmentation techniques were employed to enhance robustness. A bespoke multi-scale CNN model was trained to capture both high-resolution details and broader lung patterns. The collection was split into training (80%) and testing (20%) subsets. Evaluation was performed using accuracy, precision, recall, F1-score, and ROC-AUC metrics. The multi-scale CNN showed robust diagnostic performance. The system recorded an accuracy of 92.4%, a precision of 90.1%, a recall of 93.8%, and an F1-score of 91.9%. Moreover, the ROC-AUC of 0.95 reflected outstanding discrimination between nodule-positive and nodule-negative scans. It successfully detected small, subtle nodules that are frequently difficult to spot on LDCT images. Multi-scale CNN-based analysis of LDCT images offers an efficient and dependable approach for early lung nodule detection. The model's strong performance indicates its possible role as a supportive instrument in lung cancer screening workflows. Employing multi-scale feature extraction markedly improves nodule identification, underscoring its value in low-contrast clinical imaging scenarios.

## INTRODUCTION

Lung cancer continues to be among the top causes of cancer-related deaths globally, mainly because it is often identified at an advanced stage and early pulmonary nodules are difficult to detect. Low-dose computed tomography (LDCT) has become the preferred screening method for individuals at high risk; yet, reading LDCT images is frequently hampered by image noise, diverse nodule shapes, and considerable inter-observer differences among radiologists[1]. Even though LDCT provides better detection than chest X-rays, its diagnostic reliability still relies heavily on the radiologist's skill and the faint radiographic appearance of early nodules, which can be easily missed. Progress in artificial intelligence, especially deep learning, has opened up fresh opportunities for analyzing radiological images. Convolutional neural networks (CNNs) have demonstrated considerable achievements in automated medical image categorization thanks to their capacity to capture hierarchical spatial characteristics[2]. Specifically, multi-scale CNNs provide superior results by detecting both fine-detail textures and larger anatomical structures, enabling better identification of tiny or atypical nodules that single-scale methods might miss. Numerous investigations have employed CNN-based techniques for spotting pulmonary nodules; nevertheless, their effectiveness frequently depends on the size of the dataset, the quality of the images, and the architecture of the model. In this investigation, we seek to assess the diagnostic performance of a multi-scale CNN framework for early detection of lung nodules on low-dose CT images. We also examine how image features relate to model outcomes and illustrate the benefit of multi-scale feature extraction in boosting nodule identification accuracy[3]. Our goal is to develop a dependable, rapid, and user-friendly AI-driven method that can aid radiologists in early lung-cancer screening processes and enhance clinical results.

## METHODS AND MATERIALS

Permission from the Institutional Ethics Committee of a tertiary care teaching hospital was secured for this retrospective imaging study, with informed consent waived because the data were anonymized.

**Data Set Choice**

This investigation was carried out between 2023 and 2024 in the Department of Radiology and Biomedical Engineering at a tertiary care institution in India. A total of 135 low-dose CT (LDCT) lung scans were obtained from publicly accessible anonymized databases and the institution's archives[4]. Each scan was examined and classified in line with the radiological criteria outlined in the Fleischner Society Guidelines for Pulmonary Nodules (2017)[1]. Images comprised patients who had LDCT screening for presumed early-stage pulmonary nodules. Only CT slices that were diagnostically sufficient and showed unobstructed lung fields were used. Cases exhibiting motion artifacts, missing metadata, or extensive lung consolidation were omitted.

**Image preparation**

Every CT scan underwent preprocessing before analysis. The preprocessing steps comprised:

**Normalization:** Pixel values were adjusted to a constant Hounsfield Unit (HU) interval (–1000 to 400 HU).

**Noise Reduction:** Gaussian smoothing filters were used to reduce LDCT-related noise.

**Resizing:** Every image was adjusted to 224 × 224 pixels to suit the CNN architecture.

**Data Augmentation:** To mitigate dataset imbalance and boost model generalization, the subsequent augmentations were employed:

- Side-to-side and top-to-bottom flipping
- Arbitrary rotation (±20°)
- Zoom span (10%)
- Contrast tuning
- Translating and slanting transformations

Every preprocessing operation was carried out with Python and the PyTorch deep-learning framework.

**Multi-Resolution Convolutional Neural Network Design**

A tailored multi-scale CNN model was created to capture both fine-resolution and coarse-scale characteristics of lung nodules[5]. The model comprised

- Multiple-branch convolutional routes employing kernel sizes of 3×3, 5×5, and 7×7
- Batch normalization applied after every convolutional block
- Max-pooling layers for reducing dimensionality
- Dense layers for ultimate classification

The output layer functioned as a binary classifier that identified whether a pulmonary nodule was present or not.

**Instruction Process**

Images were divided into

- 80% training set
- 20% test set

The training was carried out on a workstation equipped with an NVIDIA GPU. The parameters employed were as follows:

**Optimization algorithm:** Adam
**Learning pace:** 0.0001
**Batch count per iteration:** 8
**Number of epochs:** 20
**Objective function:** Binary cross-entropy

During the training phase, both accuracy and loss were tracked to avoid overfitting. Early-stopping was triggered if the validation loss did not decrease for five straight epochs.

**Assessment of the Model**

Microscopic-equivalent radiological characteristics could not be applied; nevertheless, the images were analyzed with quantitative deep-learning metrics[6]. Model performance was evaluated using:

- Precision
- Accuracy
- Retrieval (Responsiveness)
- F1 measure
- Receiver Operating Characteristic – Area beneath the curve (ROC-AUC)

Grad-CAM was employed to create prediction heatmaps that highlight areas of interest associated with probable nodules.

**Statistical Examination**

Statistical analysis was carried out with SPSS version 25 and the Python SciPy packages. Findings were reported as percentages and average values. The chi-square ($\chi^2$) test was applied, when appropriate, to assess associations between the predicted labels and the true categories. A P-value below 0.05 was regarded as statistically significant[7, 8].

## RESULTS AND DISCUSSIONS

The study incorporated 135 low-dose CT (LDCT) scans. Participants' ages spanned 35 to 79 years, averaging 58 years, with the greatest number of individuals falling in their sixties. Table 1 displays the extracted descriptive radiological and model-based attributes from the scans. The multi-scale CNN showed effective acquisition of both detailed and broad anatomical characteristics of lung parenchyma. Morphologically, radiological nodules were identified in 71.1 % (96/135) of instances, whereas 28.8 % (39/135) were classified as nodule-negative images. The model attained strong predictive performance with an overall accuracy of 94.8%, sensitivity of 92.7%, and specificity of 96.2%. Detection confidence heatmaps (Grad-CAM) consistently highlighted peripheral and parenchymal nodule

regions across positive cases. Table 2 provides a summary of the spread of radiological characteristics and the model's performance metrics[9]. Assessment of the multi-scale CNN showed that configurations employing three concurrent convolutional kernels (3×3, 5×5, 7×7) outperformed single-scale reference models markedly (P = 0.004). Attributes like solid nodule edges, uneven borders, and increased contrast differences were closely linked to accurate model predictions (P = 0.001). Misclassified images (n = 7) comprised cases featuring excessive LDCT noise, extremely small (<3 mm) nodules, or motion artifacts[10].

## DISCUSSION

Early detection of pulmonary nodules remains a major goal in reducing lung cancer–related mortality. In this retrospective imaging analysis using LDCT, the performance of the proposed multi-scale CNN demonstrated excellent accuracy and sensitivity in detecting early-stage nodules, consistent with previously published deep learning studies[1-4]. Multi-scale CNN designs are particularly beneficial since lung nodules differ greatly in dimensions, contrast, and edges. In our research, adding parallel convolutional pathways allowed us to capture both fine-grained textures and broader parenchymal structures, leading to better results than single-scale CNN approaches. This result aligns with the work of Shen *et al*. and Liao *et al*., who reported that multi-scale feature pyramids increase the sensitivity of nodule detection[2,5]. In this investigation, solid non-calcified nodules (55.5%) represented the most common subtype identified. These nodules usually show marked intensity variation on LDCT and were accurately recognized by the model in most instances. In contrast, low-contrast LDCT noise images made up 39.2% of the collection and played a substantial role in false-negative results. This reflects earlier findings that noise linked to LDCT is a significant obstacle for automated detection systems[1]. Our model generated 7 false-negative cases, mainly in nodules under 3 mm, which remain inherently challenging even for experienced radiologists. Similarly, false-positive results occurred in regions with vascular branching or motion-induced artifacts. The average age of participants in the study (58 years) aligns with worldwide screening cohorts, like the NLST and NELSON trials, which generally enroll people aged 55–74 who are at high risk for lung cancer[6,7]. The elevated sensitivity (92.7%) and specificity (96.2%) observed in our investigation are comparable to or exceed those reported by other modern deep learning–based nodule detectors. The addition of Grad-CAM visualizations provided interpretability, demonstrating that the CNN reliably focuses on the pertinent nodule structures, making the model appropriate for clinical decision-support applications. Importantly, multi-scale features exhibited a statistically significant association with accurate model prediction (P = 0.001), underscoring their relevance in nodule characterization. Low-contrast LDCT noise continued to be a limiting factor, yet it did not markedly diminish overall model performance. While the model yields strong outcomes, its drawbacks involve a relatively small dataset and the absence of external multi-center validation. Future research ought to integrate more varied CT datasets and 3-D volumetric CNN architectures to further boost precision.

## CONCLUSION

BRCA1 immunohistochemistry (IHC) proves to be a valuable, affordable approach for detecting BRCA1 abnormalities in ovarian high-grade serous carcinoma (HGSC). Because it possesses a high negative predictive value for germline alterations, BRCA1 IHC acts as an effective first-line screen to identify patients who might warrant further germline genetic analysis. Moreover, the link between loss of BRCA1 expression and the characteristic SET-pattern architecture, together with related histopathologic features such as tumor-infiltrating lymphocytes, necrosis, and lymphovascular invasion, underscores its importance in informing prognosis and treatment choices, especially when considering PARP-inhibitor therapies. Nonetheless, this investigation possesses several constraints. Genetic verification of BRCA1/2 mutations was not carried out, limiting the capacity to compare IHC results with the genetic gold-standard assay. In addition, the lack of clinical follow-up information hampers assessment of the impact of BRCA status on overall survival (OS) and progression-free survival (PFS). The modest cohort size and the single-center design further restrict the applicability of the results. Consequently, larger multicenter studies that include molecular analyses and thorough clinical follow-up are required to confirm and broaden these observations.

**ABSTRACT**

Let $(G,*)$ be a cyclic group. We construct a simple graph$C_T(G)$ with $G$, in which the vertex set is formed by the generators of a cyclic group, and two distinct generators $x$ and $y$ are connected by an edge preciselywhen$x * y$ is also a generator of $G$. The objective of this article is to study the structure of $C_T(G)$ for various cyclic groups $(G,*)$ and to study the interplay between Group-Theoretic properties of $G$ and Graph-Theoretic properties of$C_T(G)$.

**Keywords:** Generator graph, cyclic groups, clique number, independence number, covering number.
MSC Classification: 20F05, 20F70, 05C25.

## INTRODUCTION

Associating graphs to algebraic structures, particularly groups, enables the exploration of algebraic properties via combinatorial methods. For a finite cyclic group $G$, we study the graph$C_T(G)$, where the vertex set consists of generators of $G$, and edges connect pairs whose operational product is again a generator. This graph captures interesting structural and combinatorial features rooted in the algebraic behavior of $G$. The notion of associating graphs with groups originates with1, leading to the study of Cayley graphs. While Cayley graphs use all group elements as vertices, our focus is narrower, restricted to generators. The graph $C_T(G)$ reflects how algebraic properties like order and generator distribution affect graph-theoretic features such as regularity, connectivity, and chromatic number. Cyclic groups, owing to their structural simplicity, are widely used in number theory, coding, and cryptography. The graph $C_T(G)$ offers a novel lens for analyzing interactions among generators, with implications for discrete mathematics and combinatorics. Our analysis aims to uncover how the algebraic structure of a cyclic group $(G,*)$ shapes the topology of its generator graph$C_T(G)$. In particular, we show that fundamental group properties are naturally reflected in classical graph-theoretic parameters. We investigate the effect of group order on

parameters such as connectivity, diameter, and independence number. Our results contribute to the body of algebraic graph theory by characterizing structural aspects of $C_T(G)$ across various finite cyclic groups. We also explore chromatic and independence numbers of$C_T(G)$, aiming to motivate further combinatorial investigation into generator-based graphs of algebraic structures. Section 2 introduces the basic framework and notation. Section 3 contains the main results and analysis of $C_T(G)$, followed by concluding remarks in Section 4.

## PRELIMINARIES AND EXAMPLES

In this section, we summarize the necessary group-theoretic and graph-theoretic background, establish notation, and provide illustrative examples. Throughout, $G = (\mathbb{Z}_n, +_n)$ denotes a finite cyclic group of order $n$, and $T(G)$ denotes its set of generators. The total number of generators of a cyclic group of order $n$ is determined by Euler's totient function$\varphi(n)$, a well-known result from elementary number theory (see, for instance, 2). We define a simple undirected graph$C_T(G)$, called the *generator graph* of $G$, in which vertex set consists of all elements from $T(G)$. Two distinct vertices $x, y \in T(G)$ are adjacent if and only if $x +_n y \in T(G)$. This graph captures the additive closure of generators under the group operation.

We use standard graph-theoretic notation throughout, see 4, 5 and 6. In particular, we employ the following invariants:

- The *independence number* $\alpha(G)$, the size of the largest set of pairwise nonadjacent vertices.
- The *clique number* $\omega(G)$, which indicates the size of the largest complete subgraph.
- The *covering number* $\beta(G)$, the minimum number of vertices that cover all edges.

We now present illustrative examples of$C_T(G)$ for small cyclic groups.

**Example 1.**Let $G = (\mathbb{Z}_p, +_p)$ be a cyclic group of order $p = 5$. The generators of $G$ are $\{1, 2, 3, 4\}(mod\ 5)$. Then by definition of$C_T(G)$, there are $p - 1 = 4$ vertices, corresponding to the generators {1,2,3,4}. Also, note that the degree of each vertex is $p - 3 = 2$.

From the Figure 1, the adjacency of the vertices is determined by the group operation as follows

$1 + 2 \equiv 3(mod\ 5)$,

$1 + 3 \equiv 4(mod\ 5)$,

$2 + 4 \equiv 1(mod\ 5)$,

$3 + 4 \equiv 2(mod\ 5)$.

Thus, the edges of the graph are:$\{(1, 2), (1, 3), (2, 4), (3, 4)\}$.

**Example 2.**Let $G = (\mathbb{Z}_p, +_p)$ be a cyclic group of order $p = 11$. The generators of $G$ are $\{1,2,3,4,5,6,7,8,9,10\}(mod\ 11)$. The associated simple graph of$C_T(G)$in Figure 2 has $p - 1 = 10$ vertices, corresponding to the generators of $G$.

**Example 3.**Let $G = (\mathbb{Z}_{15}, +_{15})$be a finite cyclic group of order 15. Then, generators of $G$ are $\{1,2,4,7,8,11,13,14\}(mod\ 15)$. The Figure 3 is a generator graph $C_T(G)$for $G = (\mathbb{Z}_{15}, +_{15})$. From the graph, each component of $C_T(G)$has $\frac{\varphi(15)}{2} = \frac{8}{2} = 4$ vertices. These examples show that when $G = (\mathbb{Z}_p, +_p)$ for a prime $p$, $C_T(G)$is a regular graph with $p - 1$ vertices and degree $p - 3$. As $p$ increases, the graph becomes denser and exhibits more complex combinatorial behavior. For further background on cyclic groups and standard isomorphism, see3. Graph-theoretic terminology follows4, 5 and 6.

**Some Results on the Graph$C_T(G)$**

First, we prove a proposition which gives us the relationship between independence number and clique number of graphs. Then we explore various properties and results of $C_T(G)$ when $(G,*)$ is a finite or infinite cyclic group.

**Proposition 1.**If a graph $G$ has at least 6 vertices, then either $\alpha(G) \geq 3$ or $\omega(G) \geq 3$.

**Proof.** Assume, for contradiction, that $\alpha(G) < 3$ and $\omega(G) < 3$. Then $\alpha(G) \leq 2$ and $\omega(G) \leq 2$, i.e., every independent set and every clique has size at most 2. Since $\alpha(G) \leq 2$, every set of 3 vertices must contain at least one edge. Similarly, since $\omega(G) \leq 2$, no set of 3 vertices can form a triangle (i.e., a $K_3$ subgraph). Now consider any 6-vertex graph under these conditions. By Ramsey's Theorem (see 7), $R(3,3) = 6$, so any graph with 6 vertices must contain either an independent set of size 3 or a clique of size 3. Which is a contradiction to our assumption that$\alpha(G) < 3$ and $\omega(G) < 3$. Hence, either $\alpha(G) \geq 3$ or $\omega(G) \geq 3$.

**Corollary 1.** Let $(G,*)$ be an infinite cyclic group. Then the graph$C_T(G)$ is a graph with no edges, featuring two disconnected vertices.

**Proof.** Since $G$ is infinite cyclic, it is isomorphic to$(\mathbb{Z},+)$, whose only generators are $\pm 1$ (see 8).
By definition, an edge exists between $x$ and $y$ if and only if $x + y$ is a generator. But $1 + (-1) = 0$, which is not a generator of$(\mathbb{Z},+)$. Therefore, there is no edge between 1 and $-1$. Since there is no edge between them, the graph $C_T(G)$ reduces to two isolated vertices, i.e., a null graph.

**Corollary 2.** Let $(G,*)$ be a finite cyclic group of even order $n$. Then $C_T(G)$is a null graph with $\varphi(n)$ vertices.

**Proof.** Since $G$ is cyclic of order $n$, it is isomorphic to $(\mathbb{Z}_n, +_n)$ (see [Theorem 2.1.4] 3). If the group is finite cyclic of order$n$, then the associated generator graph contains exactly $\varphi(n)$ vertices (cf. 2), since each generator corresponds to one vertex and so $C_T(G)$ has $\varphi(n)$ vertices. An edge exists between two generators $x$ and $y$ if and only if $x +_n y$ is also a generator. When $n$ is even, the sum of any two elements is not coprime to $n$, and hence not a generator. Therefore, no such pair is adjacent in$C_T(G)$. Hence, $C_T(G)$has no edges and is a null graph with $\varphi(n)$ vertices.

**Theorem 1.** Let $(G,*)$ be a cyclic group of prime order $p$ greater than or equal to 3. Then the generator graph $C_T(G)$ is regular, consisting of$p - 1$ vertices, and every vertex has degree $p - 3$.

**Proof.** Since $G$ has prime order $p$, it is cyclic and isomorphic to $(\mathbb{Z}_p, +_p)$ (cf.8). Every non-zero element of $\mathbb{Z}_p$ is a generator, so $G$ has exactly $p - 1$ generators. For two generators $x, y \in G$, there is an edge between them in $C_T(G)$ if and only if $x +_p y$ is also a generator. The only way $x +_p y$ fails to be a generator is if $x + y \equiv 0 \ (mod\ p)$. Given any $x \in G\backslash\{0\}$, the only $y$ that satisfies $x + y \equiv 0 \ (mod\ p)$ is $x = -y$. Thus, each vertex is adjacent to $(p - 1) - 1 = p - 2$ vertices, excluding $-x$. Since the graph is simple, we exclude self-loops, giving degree $p - 3$.

**Theorem 2.** Let $(G,*)$ be a finite cyclic group of order $n = 3p$, where $p$ being a prime with $p > 3$. Then $C_T(G)$ is a disconnected graph with two components. Each component is a regular graph with $\frac{\varphi(n)}{2}$ vertices, and the degree of each vertex is $p - 3$.

**Proof.** Let $G$ be a finite cyclic group of order $n = 3p$; then $G \cong (\mathbb{Z}_n, +_n)$ (cf.3). Since $\varphi$ is multiplicative and $\varphi(3p) = \varphi(3) \cdot \varphi(p) = 2(p - 1)$, we get $\varphi(n) = 2(p - 1)$ (see2).
Partition the generators modulo 3 as follows:
$S_1 = \{x \in G | x \equiv 1 \ (mod\ 3)\}$and$S_2 = \{x \in G | x \equiv 2 \ (mod\ 3)\}$.
As $p \neq 3$, all generators fall into $S_1$ or$S_2$, each having size $p - 1$. And addition modulo $n$ preserves congruence modulo 3 as follows

- $x, y \in S_1 \Rightarrow x + y \equiv 2 \ (mod\ 3)$
- $x, y \in S_2 \Rightarrow x + y \equiv 1 \ (mod\ 3)$
- $x \in S_1, y \in S_2 \Rightarrow x + y \equiv 0 \ (mod\ 3)$

Hence, no adjacent pairs exist across or within$S_1, S_2$, unless $x + y$ remains a generator. Excluding $x$ and $-x$, each vertex in $S_1$(or$S_2$) has degree $p - 3$. So, $C_T(G)$ is disconnected with two regular components of size $p - 1$, each of degree $p - 3$.

**Theorem 3.** Let $(G,*)$ be a finite cyclic group of order $n = 3^k$, where $k \geq 2$. Then $C_T(G)$ is a disconnected graph with two complete components of size $3^{k-1}$ and degree$3^{k-1} - 1$.

**Proof.** Let $G =< g >$be cyclic group of order$3^k$. Then, $\varphi(3^k) = 2 \cdot 3^{k-1}$(cf.2).
Partition the generators as follows
$S_1 = \{g^i | i \equiv 1 \ (mod\ 3)\}$and$S_2 = \{g^j | j \equiv 2 \ (mod\ 3)\}$.
For $x = g^i \in S_1$ and $y = g^j \in S_2, x * y = g^{i+j} \equiv 0 \ (mod\ 3)$, is not a generator. Thus no edges between $S_1$ and $S_2$. For any $x, y \in S_1, x * y = g^{i+j}$ is again a generator, since $\gcd(i + j, 3^k) = 1$. So, $S_1$ forms a complete graph. And the same applies to$S_2$. Thus, $C_T(G)$consists of two disjoint complete graphs, each of size $3^{k-1}$ and degree of each vertex is$3^{k-1} - 1$.

**Theorem 4.** Let $(G,*)$ be a finite cyclic group of order $n = 3p$, where $p$ is a prime with $p \neq 2,3$. Then the diameter of $C_T(G)$ is $diam(G) = 2$.

**Proof.** Since $G = \mathbb{Z}_{3p}$, the group $G$ is cyclic group of order $3p$. Not all pairs are adjacent in$C_T(G)$, but for any $x, y \in G$ there exists $z \in G$ such that $x \sim z$ and $y \sim z$.
Hence, the diameter of $C_T(G)$ is 2.

**Corollary 3.** Let $(G,*)$ be a finite cyclic group of order prime, $p \geq 7$. Then the girth of $C_T(G)$is 3.

**Proof.** According to the concept of a generator graph $C_T(G)$, a cycle of length 2 is not possible as the group is cyclic. For three distinct generators $x, y, z$, the sums $x + y, y + z,$and $x + z$ are also generators. So, $C_T(G)$ contains cycles of length 3, and so the girth is 3.

**Corollary 4.** Let $(G,*)$ be a finite cyclic group of order $p > 5$. Then the independence number $\alpha(G)$ is 2.

**Proof.** Select two non-adjacent generators $x$ and $-x$form an independent set of size 2. Also, any three distinct generators will always have at least one adjacent pair, so $\alpha(G) = 2$.

**Corollary 5.** Let $(G,*)$ be a finite cyclic group of prime order $p > 5$. Then the clique number $\omega(G) \geq 3$.

**Proof.** Since $G$ has $p - 1 > 5$ generators, by Proposition 1, either $\alpha(G) \geq 3$ or $\omega(G) \geq 3$. As $\alpha(G)$, it follows that $\omega(G) \geq 3$.

**Corollary 6.** Let $G = \mathbb{Z}_p$, where $p$ is a prime number. Then the covering number of the graph $C_T(G)$ is $\beta(C_T(G)) = 2$.

**Proof.** Let $S = \{1, p - 1\}$. For any generator $y \notin S$, either $y + 1 \not\equiv 0 \ (mod\ p)$ or $y + (p - 1) \not\equiv 0 \ (mod\ p)$, so each vertex is adjacent to at least one element of $S$. Thus, $\beta(C_T(G)) = 2$.

## CONCLUSION

This study investigates the graph$C_T(G)$ associated with cyclic groups, revealing key structural properties. We established that $C_T(G)$ is empty for acyclic groups, consists of isolated vertices for infinite cyclic groups, and exhibits regular or disconnected components for finite cyclic groups. Additionally, we examined the diameter, girth, and covering number of these graphs, offering a detailed insight into the interaction between algebraic and combinatorial properties of cyclic groups.

## ACKNOWLEDGMENT

The authors sincerely appreciate Dr. Subhash University for providing the necessary infrastructural support to the Department of Mathematics. Also, all the reviewers for their insightful suggestions.

### CONFLICT OF INTEREST

The corresponding author has verified that all authors have no conflicts of interest.

**ABSTRACT**

Malware is characterized as malicious software that aims to harm a computer system or program. There are numerous types of malware, including Trojan horses, worms, and viruses. Malware has harmed several computer programs and systems all across the world throughout the years. The research is helpful for categorizing malware samples that appears as grayscale bytemap images. A machine learning classification model can be trained on malware images using the feature extraction approach that was achieved. In order to classify malware, which consists of 59 malware families and 27,721 images, this study carried out image classification using the EfficientNet, ResNet50, VGG16, Inception ResNetV2, DenseNet169, and XceptionNet architecture designs. Using the malware dataset, this study applies the Ensemble of Convolutional Neural Network architectures to actualize image-based malware classification. Every architecture will receive an evaluation form that includes metrics like f1-score, recall, accuracy, and precision. The ResNet50 design had the highest f1-score of 94.0%, while the VGG16 architecture achieved the lowest f1-score of 88.0%.

**Keywords:** Classification, Deep Learning, Ensemble of CNN, Malware, Cyber security

## INTRODUCTION

The goal of harmful software, or malware, is to steal private digital data. Due to the internet's and its technologies' rapid evolution, malware has exploited an alarmingly high number of vulnerabilities. Because malware is evolving so quickly and manual analysis is difficult and inconsistent, antivirus software and security organizations are using machine learning and artificial intelligence to speed up the detection process. Consequently, the use of conventional

machine learning methods for malware identification and classification has increased, including Decision Trees, Support Vector Machines, Naïve Bayes and Random Forest. The extensive computer resources required for feature engineering and the complex process of processing massive datasets, however, are a major disadvantage of these approaches, casting uncertainty on their applicability. So, EfficientNet, ResNet50, VGG16, InceptionResNetV2, DenseNet169, and XceptionNet architecture designs were used in the present investigation to classify images. This study implements image-based malware classification using the malware dataset and the Ensemble of Convolutional Neural Network architectures. This is how the article is structured. An overview of the Literature Review is provided in Section 2 and methodology of the most recent malware categorization techniques is provided in Section 3. Ensemble of CNN architectures are provided in Section 4 and Experimental findings achieved with our technique are presented and compared in Section 5. The article's contributions are finally wrapped up in Section 6 with future research.

## LITERATURE REVIEW

The integration of images, each formed from a range of information sources, which might greatly improve detection performance, is currently receiving much attention from researchers. We conducted a thorough investigation by creating a variety of CNN models, applying pre-trained Ensemble of Convolutional Neural Network designs separately and then combining them using different operators. Throughout the procedure, classification processes that had not been previously examined in the literature were investigated. Such feature engineering is totally eliminated by our deep learning approach, and accurate sample categorization is made possible by transfer learning. Although the majority of researchers concentrate mostly on improving classifier performance, they noticeably ignore the important aspect of interpretability. This absence is important because, especially in the context of cybersecurity, interpretability is essential to comprehending and having faith in the decisions made by machine learning models. Malware is purposefully harmful software designed to damage computer systems[1][2]. The scope of software being utilized for harmful and unlawful purposes has significantly increased recently[3][4][5]. Malware is currently detected and categorized using a variety of deep and machine learning approaches[6][7][8]. The EfficientNet, ResNet50, VGG16, Inception ResNetV2, DenseNet169, and XceptionNet architecture designs were used in the image classifying study presented in this paper. In order to achieve image-based malware classification, this study uses an ensemble of convolutional neural network designs.

## METHODOLOGY

The Life Cycle shown in figure 1, which comprises the phases of analysis, design, development, testing, and implementation, has been employed in this study methodology. Using a malware dataset, data processing is performed at the analysis stage to create an ensemble-architected Convolutional Neural Network (CNN) model. The CNN model's multiple layers, including the convolutional, activation, pooling, and fully connected layers, are all included in the design stage. Libraries like NumPy, Pandas, Matplotlib, Keras, and Tensorflow are implemented in the development as the framework for deployment. The same dataset is then used to test the model, and assessment techniques including accuracy, prediction, and recall are used to assess its performance. The trained model will subsequently be integrated into a Python program along with malware images

**Datasets**

Malware Dataset is a collection of 59 malware families with 27,721 images. Distribution of 59 malware families in Dataset are shown in figure 2. Also, Breakdown of 59 malware families in Dataset are shown in figure 3. Some samples of malware images in the Dataset are shown in figure 4. To find the best classification model based on predetermined parameter initialization, data training with an 80% effectiveness rate is conducted. The ultimate objective of model training is to make it possible for the system to identify objects and categorize them into the appropriate classes. The model for testing fresh data with a balance of 20% will be the most effective model in the data training process that has not been applied during training.

**Convolutional Neural Network**

A specific kind of deep learning model called a Convolutional Neural Network (CNN) is widely utilized in computer vision to evaluate visual input, including images and videos. By concentrating on grid-like data structures, it expands on conventional artificial neural networks and is particularly useful for applications like image identification. The input, convolutional, pooling, activation, and fully connected layers are among the essential layers that make up CNNs. While pooling layers lower computation and dimensionality, convolutional layers use filters to extract features from input images shown in figure 5. Non-linearity is introduced by activation functions such as ReLU, and classification or regression tasks are handled by fully connected layers. Through forward propagation and gradient descent backpropagation, the entire network learns, modifying filter weights to reduce error. Compared to normal neural networks, CNNs process images in patches using shared weights, allowing for effective feature extraction with fewer parameters. CNNs are an effective tool in contemporary AI applications because of their architecture, which enables them to recognize patterns and spatial hierarchies in visual data.

**Ensemble of CNN architectures**

***EfficientNet***

In order to prepare input images for further network processing, the stem layer in EfficientNet is essential. Batch Normalization and a Swish activation function come after a 3x3 Conv2D layer with a stride of 2. By identifying low-level characteristics like edges and textures and down sampling the input to lower computing cost, the Conv2D layer carries out initial feature extraction. By normalizing the convolutional layer's output and adding learnable parameters (gamma and beta) to preserve flexibility, batch normalization stabilizes and speeds up training. The network may more efficiently learn complex patterns thanks to the smooth and non-monotonic activation provided by the Swish activation function, which is defined as $f(x) = x \bullet \text{sigmoid}(x)$. It also helps to mitigate problems like dead neurons. These elements work together to create a strong and effective stem layer that serves as the foundation for the deeper levels of the EfficientNet design. The EfficientNet architecture can be evaluated using a metrics score that measures performance using an accuracy parameter.

The experimental results show that the Convolutional Neural Network (CNN) algorithm with the EfficientNet architecture produces the following results as accuracy with 0.9648, auc with 0.9972, false-positives with 313.0173, loss with 0.1203, precision with 0.9726, recall with 0.9602, val-accuracy with 0.9389, val-auc with 0.9879, val-false-positives with 267.0000, val-loss with 0.3248, val-precision with 0.9448 and val-recall with 0.9350. Also, the Macro Average scores of Precision with 92%, Recall with 92% and F1-score with 92% are obtained.Accuracy with 95% with support of 5565 images out of 27721 images of our dataset are obtained. Figure 6 shows the Training History for Malware Dataset using EfficientNetarchitecture and figure 7 shows the confusion matrix values required to assess the algorithm's effectiveness.

**ResNet50**

Microsoft Research created the 50-layer ResNet50 deep convolutional neural network in 2015, and it is well-known for its excellent performance on image classification tasks. The utilization of residual or skip connections, which aid in resolving the vanishing gradient issue frequently seen in deep networks, is its primary innovation. By making it possible for gradients to go through the network more efficiently, these connections enable the network to learn residual functions, which in turn permits the training of even deeper models. Fully linked layers for classification, identity and convolutional blocks for deep processing, and convolutional layers for feature extraction are all part of the architecture. ResNet50 is a popular transfer learning tool that reaches near-human accuracy after being trained on massive datasets like ImageNet. By adding custom classification layers and reusing pre-trained weights, it is simple to adapt to new datasets using tools like Tensor Flow and Keras. All things considered, ResNet50 is a strong and effective model that blends deep architecture with accuracy and stability, which makes it a well-liked option for computer vision applications. The ResNet50 architecture can be evaluated using a metrics score that measures performance using an accuracy parameter. The experimental results show that the Convolutional Neural Network (CNN) algorithm with the ResNet50 architecture produces the following results as accuracy with 0.9994, auc with 0.9985, false-positives with 126.2839, loss with 0.0553, precision with 0.9891, recall with 0.9876, val-accuracy with

0.9657, val-auc with 0.9932, val-false-positives with 150.0000, val-loss with 0.1848, val-precision with 0.9692 and val-recall with 0.9638. Also, the Macro Average scores of Precision with 95%, Recall with 94% and F1-score with 94% are obtained. Accuracy with 96% with support of 5565 images out of 27721 images of our dataset are obtained. Figure 8 shows the Training History for Malware Dataset using ResNet50 architecture and figure 9 shows the confusion matrix values required to assess the algorithm's effectiveness.

**VGG16**

The visual geometry group-16 (VGG16) deep learning algorithm based on convolutional neural network (CNN) architecture is commonly used to classify various families of malware images automatically and may have a role in the detection of malware from the given dataset. This research is aimed to determine the robustness of the VGG16 architecture on 59 malware families on our dataset. This research confirmed that the VGG16 delivers robust performance on our dataset. With a classification accuracy of 92.7% across 59 malware family categories, VGG16 is extensively utilized for image classification and object recognition tasks. It is also well-liked for its efficiency and user-friendliness in transfer learning. The VGG16 architecture can be evaluated using a metrics score that measures performance using an accuracy parameter.

The experimental results show that the Convolutional Neural Network (CNN) algorithm with the VGG16 architecture produces the following results as accuracy with 0.9614, auc with 0.9957, false-positives with 370.9179, loss with 0.1708, precision with 0.9654, recall with 0.9581, val-accuracy with 0.9325, val-auc with 0.9884, val-false-positives with 292.0000, val-loss with 0.3516, val-recision with 0.9397 and val-recall with 0.9301. Also, the Macro Average scores of Precision with 91%, Recall with 87% and F1-score with 88% are obtained.Accuracy with 93% with support of 5565 images out of 27721 images of our dataset are obtained. Figure 10 shows the Training History for Malware Dataset using VGG16 architecture and figure 11 shows the confusion matrix values required to assess the algorithm's effectiveness.

**Inception-ResnetV2**

An sophisticated deep learning architecture called Inception-ResNet improves image identification performance by fusing the advantages of Residual connections and Inception blocks. Residual connections help avoid the vanishing gradient issue in deep networks, allowing for more stable and effective training, whereas Inception blocks enable the model to collect data at numerous spatial scales by employing parallel convolutional layers of varying sizes. Residual Inception Blocks, a hybrid method, improves feature extraction and speeds up convergence. The architecture also features techniques like factorized convolutions and bottleneck layers to reduce processing costs without losing accuracy. The great accuracy, deep structure, and efficiency of Inception-ResNet models, including v1 and v2, make them perfect for tasks like image categorization and transfer learning in a variety of real-world applications. The Inception-ResNetV2 architecture can be evaluated using a metrics score that measures performance using an accuracy parameter.

The experimental results show that the Convolutional Neural Network (CNN) algorithm with the Inception-ResNetV2 architecture produces the following results as accuracy with 0.9723, auc with 0.9979, false-positives with 252.0836, loss with 0.0963, precision with 0.9769, recall with 0.9681, val-accuracy with 0.9401, val-auc with 0.9869, val-false-positives with 251.0000, val-loss with 0.6129, val-precision with 0.9480 and val-recall with 0.9352. Also, the Macro Average scores of Precision with 91%, Recall with 92% and F1-score with 91% are obtained.Accuracy with 95% with support of 5565 images out of 27721 images of our dataset are obtained. Figure 12 shows the Training History for Malware Dataset using Inception-ResNetV2 architecture and figure 13 shows the confusion matrix values required to assess the algorithm's effectiveness.

**DenseNet169**

Each layer of the convolutional neural network design DenseNet169 is directly connected to every other layer in the same dense block, allowing for better gradient flow and effective feature reuse. With additional layers and a larger model size (55 MB vs. 31 MB), it is an improved DenseNet121 that achieves superior accuracy. The design makes use

of ReLU and Softmax activation functions and consists of convolutional, pooling, dense, and transition layers. DenseNet169 can be used in natural language processing and is appropriate for a number of computer vision tasks, including object detection, semantic segmentation, and image classification. It is perfect for transfer learning because it is implemented in Keras with pre-trained ImageNet weights, providing both performance and usability in deep learning projects. The DenseNet169 architecture can be evaluated using a metrics score that measures performance using an accuracy parameter

The experimental results show that the Convolutional Neural Network (CNN) algorithm with the DenseNet169 architecture produces the following results as accuracy with 0.9527, auc with 0.9954, false-positives with 418.8372, loss with 0.3408, precision with 0.9623, recall with 0.9432, val-accuracy with 0.9558, val-auc with 0.9946, val-false-positives with 178.0000, val-loss with 0.1779, val-precision with 0.9632 and val-recall with 0.9520. Also, the Macro Average scores of Precision with 93%, Recall with 93% and F1-score with 93% are obtained. Accuracy with 96% with support of 5565 images out of 27721 images of our dataset are obtained. Figure 14 shows the Training History for Malware Dataset using DenseNet169 architecture and figure 15 shows the confusion matrix values required to assess the algorithm's effectiveness.

**XceptionNet**

The deep convolutional neural network architecture known as Xception, which stands for "Extreme Inception". By substituting depth-wise separable convolutions for the conventional Inception model's modules, it improves performance while preserving computational economy. There are three primary parts to the architecture:

**Entry Flow**

Reduces spatial dimensions and extracts features by processing the input data through initial convolutions and a sequence of residual blocks using depth-wise separable convolutions.

**Middle Flow**

Made up of several identical residual blocks with depth-wise separable convolutions, this technique is intended to identify intricate patterns in the data.

**Exit Flow**

A fully linked layer for classification and global average pooling come after further residual blocks that refine the collected features. While keeping a comparable amount of parameters, Xception has outperformed conventional architectures like VGGNet and ResNet on benchmark datasets like ImageNet and JFT. Xception is a useful architecture for picture classification problems because of its efficacy and efficiency. The XceptionNet architecture can be evaluated using a metrics score that measures performance using an accuracy parameter. The experimental results show that the Convolutional Neural Network (CNN) algorithm with the XceptionNet architecture produces the following results as accuracy with 0.9677, auc with 0.9982, false-positives with 297.2709, loss with 0.1047, precision with 0.9740, recall with 0.9633, val-accuracy with 0.9489, val-auc with 0.9945, val-false-positives with 195.0000, val-loss with 0.1836, val-precision with 0.9595 and val-recall with 0.9438. Also, the Macro Average scores of Precision with 92%, Recall with 92% and F1-score with 91% are obtained. Accuracy with 94% with support of 5565 images out of 27721 images of our dataset are obtained. Figure 16 shows the Training History for Malware Dataset using XceptionNet architecture and figure 17 shows the confusion matrix values required to assess the algorithm's effectiveness.

## EXPERIMENTAL RESULTS

The experimental results show that the Convolutional Neural Network (CNN) algorithm with the ResNet50 architecture produces the highest level of performance with the f1-score value 94.0% while the VGG16 architecture achieved the lowest f1-score of 88.0% shown in figure 18. The Precision value of well-established Ensemble of CNN

architectures with the ResNet50 produces the highest level of performance with the value 95.0% while the VGG16 and Inception-ResNetV2 architectures achieved the lowest value 91.0% shown in figure 19. The Recall value of well-established Ensemble of CNN architectures with the ResNet50 produces the highest level of performance with the value 94.0% while the VGG16 architectures achieved the lowest value 87.0% shown in figure 20. The Accuracy value of well-established Ensemble of CNN architectures with the ResNet50 produces the highest level of performance with the value 96.0% while the VGG16 architectures achieved the lowest value 93.0% shown in figure 21. The Evaluation Metrics of well-established Ensemble of CNN architectures actualize image based Malware Classification are shown in figure 22 and Graph image of overall f1-score of ensemble architectures are shown in figure 23.

## CONCLUSIONS AND FUTURE RESEARCH

This research carried out malware image classification using the EfficientNet, ResNet50, VGG16, Inception ResNetV2, DenseNet169, and XceptionNet architecture designs. Using the malware dataset, this study applied the Ensemble of Convolutional Neural Network architectures to actualize image-based malware classification and found that ResNet50 design had the highest f1-score of 94.0%, while the VGG16 architecture achieved the lowest f1-score of 88.0%.In order to assist security researchers in their malware analysis, a first area of study might focus on explainable artificial intelligence (XAI) techniques for interpreting the output of machine learning models for malware detection and classification.When compared to other approaches in the literature, a potential field for future research could be the development of novel architectures to identify and classify malware from its binary content expressed as a sequence of bytes could be a second area of investigation. Assessing the incorporation of other data modalities or feature types into the current multimodal architecture and examining the effects on system performance could be a third area of investigation.

## ABSTRACT

Inorganic antimicrobial nanoagents has more benefits over commonly used organic drugs owing to their chemical durability, heat resistance, immunity, and prolonged efficacy. The present work effectively produced novel zinc oxide/activated carbon (ZnO/AC) nanocomposites, employing *Toddalia asiatica* leaves as a source of carbon for the production of activated carbon. The liquid extract of *Toddalia asiatica* leaf was used as a capping and reducing agent in the production of ZnO. The produced substances were analyzed using multiple characterization methods, which involves X-Ray Diffraction (XRD), Fourier Transform Infrared Spectroscopy (FT-IR), Field Emission Scanning Electron Microscopy (FE-SEM), Energy Dispersive X-ray Spectroscopy (EDX), and Transmission Electron Microscopy (TEM), confirming effective production. XRD revealed a predominant role of the crystalline structure of ZnO nanoparticles compared to the amorphous activated carbon, whereas the FTIR spectrum validated a significant interaction amongst the ZnO nanoparticles and activated carbon. SEM, and TEM pictures demonstrated that the synthesized ZnO NPs/AC ranged in nanoscale dimensions from 30 to 70 nm. The antioxidant and antibacterial properties of the synthesized nanocomposites towards gram-positive and gram-negative bacteria were examined, and the minimum inhibitory concentration values were compared to those of ascorbic acid, ciprofloxacin, and clotrimazole as standards. The findings obtained demonstrate a significant influence in the antioxidant and antibacterial research. The findings indicate that the newly

suggested nanocomposite may serve as an efficient filter for combating oxidative and antimicrobial-related disorders.

**Keywords:** Activated carbon, Antioxidant, Antimicrobial, Nanocomposite, ZnO, *Toddalia asiatica*.

## INTRODUCTION

The rise of antibiotic-resistant microbes remains one of the biggest threats to public health in the past few years. The extensive deployment of antimicrobial agents, coupled with insufficient intake, is exacerbating this problem. One of the most efficient approaches for mitigating the seriousness of this issue is the development of innovative and highly potent nano-antimicrobial agents that address multi-drug resistance [1,2]. Zinc oxide nanoparticles (ZnO NPs) have garnered considerable interest due to its distinctive optical and chemical characteristics. The surface of ZnO is relatively abundant in -OH entities, enabling its gradual dissolution when exposed to acidic circumstances (such as tumor cells and their microenvironment) as well as powerful basic circumstances. Furthermore, its nanoscale dimensions result in alterations to the structural, optical,chemical, electrical, morphological, and mechanical properties of the substance, allowing nanomaterials to engage distinctively via cellular biomolecules, thereby promoting the physical incorporation of nanostructures towards the intracellular environment [4]. Consequently, ZnO nanoparticles are being extensively studied in several physiological and medical fields for their roles as antioxidant, anti-inflammatory, antiplatelet, anti-angiogenic agents, as well as in cosmetics, dental materials, and drug and gene delivery systems [5,6]. Furthermore, ZnO nanoparticles have significant promise in biotic usages such as biosensing, biological labeling, and nanomedicine, in addition to its acaricidal, pediculicidal, larvicidal, and anti-diabetic properties [7]. Furthermore, ZnO nanoparticles have remarkable antimicrobial properties (antibacterial, antifungal, and antiviral) attributed to its increased specific surface area, since their smaller particle size enhances surface responsiveness [8-10]. Compared to the majority of the remaining metal oxide nanoparticles, ZnO nanoparticles are not just more economical but also comparatively non-toxic, biocompatible, and ecologically benign. Consequently, there has been heightened curiosity about formulating environmentally friendly and economical production methods for ZnO nanoparticles [11,12]. *Toddalia asiatica* (L) Lam., a member of the family Rutaceae, is an herbal remedy usually referred to as Orange climbers, found in several regions of India [13.14]. The herb is identified through numerous indigenous names in various languages, including Janglimirch (Bengali), Kanj (Hindi), Rukato (Shona), Tundapoda (Odia), Gato (Shona), Dahan (Marathi), and Chikafusi (Shona), among others [14,15]. It has a varied, wandering, prickly, climbing shrub, reaching an elevation of 2,500 m.

The herb is prevalent in South India, particularly around the Palani and Nilgiri ranges, as well as in the scrub forests of Odisha. In arid plains, the crop manifests as a little twig with shorter and thinner leaves [16]. The fruit is historically employed to remedy malaria and coughing; its roots are also utilized for indigestion and influenza, while its foliage is applied for pulmonary ailments along with rheumatism [17-19]. Indigenous populations utilized this herb for several ailments, including gastrointestinal issues, fever, cough, and cold. It is employed in the management of many conditions, including thoracic discomfort, diarrhea, nausea, sprains, bronchitis, and rheumatic arthritis. It is historically utilized in Kenya by several populations for the management of dental pain, nasal and bronchial discomfort, malaria [20]. Leaves have been historically used in the treatment of diabetes [21]. Unripened fruits and roots are infused into oil to create a stimulating lotion used in the management of rheumatism. The blossom's nectar is administered to wasp stings for rapid healing. It has been found that the root and wood of *T. asiatica* are mostly filled with triterpenoids, alkaloids, and coumarins [22,23]. Activated carbon (AC) has lately garnered more attention owing to its remarkable properties, including significant adsorption ability, a highly established and easily modifiable surface, considerable chemical durability, and strong mechanical properties. AC is mostly produced by combustion and the chemical or physical stimulation of natural substrates at high temperatures, enabling its large-scale manufacturing for usage in adsorption, segregation, and several other uses. Due to its remarkable capacity for absorbing germs, spores, and various pollutants such as bilirubin, hazardous metals, and protein-bound uremic

contaminants. AC is being advocated as a remedy of intramuscular and gastroenteritis globally [24,25]. Moreover, in contrast to the outcomes of just the active compounds, several studies have demonstrated that activated carbon mainly amplifies the efficacy of the various adsorbed antiviral or antibiotics [26,27]. The present research details the production of activated carbon (AC) from indigenous *Toddalia asiatica* material, which was then used to create a nanocomposite with zinc oxide nanoparticles (ZnO NPs). An extensive evaluation of the antifungal, antibacterial, and antioxidant activities of ZnO NPs/AC combinations was performed to investigate its biosafety. Subsequently, the most efficient ZnO NPs/AC underwent an extensive characterization protocol to ascertain both its chemical and physical features.

## MATERIALS AND METHODS

**Chemicals**

Zinc nitrate hexahydrate and phosphoric acid were acquired from Merck. Calcium chloride, sodium hydroxide, sodium chloride, and hydrochloric acid were offered through Loba Chemicals.

**Preparation of *Toddalia asiatica* leaf extract**

The extract of *Toddalia asiatica* foliage was produced using a previously published process alongside minor changes [28]. Fresh, moist leaf of *Toddalia asiatica* were collected near hilly areas within Perambalur. The gathered leaves were meticulously rinsed many times with tap water followed by distilled water to eliminate dirt and other clinging substances. Subsequently, the leaves were chopped into little fragments. Ten grams of leaf fragments were submerged in 100 milliliters of distilled water at a controlled temperature of 70°C for 30 minutes, during which the mixture was continuously agitated utilizing a magnetic stirrer at a rate of 150 revolutions per minute. The residual constituents were eventually eliminated using filtering, and the resulting solution was refrigerated at 4°C for further use in the ZnO production.

**Synthesis of ZnO NPs**

The present study adheres to an altered methodology from prior research regarding the green production of ZnO nanoparticles [29]. In summary, 1.485 g of $Zn(NO3)2{\cdot}6H2O$ was dissolved in 90 mL of deionized water, prior to the inclusion of 10 mL of leaf extract. The resulting mixture was thereafter exposed to constant swirling for 2 hours with a magnetic stirrer. The steady incorporation of sodium hydroxide (1 M) ensued till the pH level of the mixture attained 10, with mixing persisting for a further 6 hours at 70°C. This resulted in the buildup of a green-reduced material in the bottom of the vessel, seen as a yellowish-white precipitation. The resulting product was harvested through centrifuge at 8000 rpm for 20 minutes. The final product underwent several washings using distilled water followed through centrifuge for 20 minutes and was then dried in a vacuum oven at 80°C for 4 hours.

**Preparation of activated carbon**

Freshly collected *Toddalia asiatica* leaf became used as a source of carbon for the manufacture of activated carbon. The harvested foliage were thoroughly washed repeatedly with distilled water to eliminate adhering contaminants, thereafter cut into tiny fragments, drying outside sunshine over six days, and then treated with ethanol before being oven-dried at 105°C overnight. Subsequently, the desiccated product was meticulously pulverized to a particle size of 100 µm. Subsequently, 10 g of processed powders was incorporated into 40 ml of 85% phosphoric acid solution at a ratio of 1:4, which included agitation at 150 rpm for 30 minutes, following which the mixture was allowed to soaking at ambient temperature for 24 hours. Upon completion of the stimulation, the mixture was subjected to centrifugation, and the resultant item was dried out at 105°C for 24 hours. The dried product was carbonized at 600°C for 4 hours in a nitrogen atmosphere [30]. The thermal breakdown of dried *Toddalia asiatica* plants produced 24.2% carbon.

**Preparation of ZnO/activated carbon**

The ZnO/AC nanocomposites that were synthesized through dissolving 1.4875 g of Zn(NO3)2·6H2O in 90 mL of deionized water, prior to the addition of 10 mL of aquatic extract from *Toddalia asiatica* leaves. The mixture was continuously stirred on a magnetic stirrer for 2 hours, preceding a slow incorporation of 1M NaOH solution as long as the pH achieved 10. Subsequently, a suitable quantity of previously produced activated carbon was introduced into the aforementioned solution, whereas agitation continued for a further six hours at 70°C. The resultant grayish material was centrifuged at 8000 rpm for 30 minutes, then dried in a vacuum oven at 70°C for 4 hours. The granulate was stored in a tightly sealed glass jar for future usage. The production procedure of ZnO/AC nanocomposite is shown graphically in Figure 1.

**Characterization and instrumentations**

Multiple characterisation approaches were used to investigate the physicochemical properties of the produced substances. The XRD spectra was obtained employing a PANalyticalX'Pert Pro powder diffractometer, utilizing CuK radiation ($\lambda$ = 0.154056 nm) and having a scanning range of 0° to 80°. To identify functional compounds in produced nanomaterials, FT-IR spectra were obtained within the wave number range of 500–4000 cm−1 utilizing a Nicolet 6700 FT-IR spectrometer through the KBr disk technique. SEM (ZEISS SIGMA VP) was employed to examine the surface morphological characteristics of the produced materials. The chemical makeup of the generated samples was identified through EDX examination utilizing an Oxford EDS apparatus. TEM (ZEISS-EM10C-100 KV) was used to examine the morphology and dimensions of the as-fabricated nanoparticles.

**Antioxidant Activity**

**DPPH radical scavenging assay**

An assessment was conducted on the plant extract, activated carbon, and ZnO/AC nanocomposite to determine its efficacy in eliminating DPPH radicals using an altered version of a recognized approach [31]. 2 mL of different concentrations (ranging from 125 to 1000 μM) of the drugs or the control (ascorbic acid) were mixed with 2 mL of a 0.3 mM DPPH solution prepared in methanol. The mixture was agitated and sealed in a dimly lit jar at room temperature (25°C) for 30 minutes. Thereafter, the absorbance was measured at an effective wavelength of 516 nm, and the efficacy of DPPH radical scavenging was evaluated using the following formula:

DPPH Scavenging activity (%) = (1 - Absorbance of compound/Absorbance of control) × 100

**FRAP assay**

The FRAP of plant extract, activated carbon, and ZnO/AC nanocomposite was evaluated using a standard approach outlined in other studies, with slight adjustments [32]. An aqueous solution of the components, with concentrations ranging from 125 to 1000 μM, was combined using 0.75 mL of K3Fe(CN)6 (1% w/v) and 0.75 mL of phosphate buffer (0.2 M, pH 6.6). The mixture followed by incubating at 50 °C for 20 minutes. The reaction was terminated by adding 0.75 mL of a 10% trichloroacetic acid solution. Centrifuge the mixture at 800 rpm for 10 minutes. The liquid ingredient was then mixed with 0.1 mL of FeCl3 (0.1%, w/v) and 1.5 mL of water. An optical spectrometer determined the solution's absorbance at 700 nm.

**Antibacterial effect**

The plant extracts, AC, and ZnO/AC nanocomposite underwent in vitro antibacterial assessments against *P. aeruginosa*, *K. pneumoniae*, *E. coli*, and *S. aureus* via the Kirby-Bauer disc diffusion method [33]. The antibacterial efficacy of ciprofloxacin was utilized as a benchmark. The bacterial cultures were cultivated on petri dishes using nutrient agar media. The test materials consisted of DMSO and were contained within a filter paper disk measuring 5 mm in diameter and 1 mm in thickness. After a 24-hour interval, the extent of the inhibitory region [34,35] adjacent to every disc was evaluated to ascertain its antibacterial efficacy. The discs were then placed on the current plates and maintained at 37°C. The minimum inhibitory concentrations (MIC) were utilized to assess the antibacterial efficacy of plant extracts, AC, and ZnO/AC nanocomposites.

**Antifungal action**

The antifungal efficacy of plant extracts, AC, and ZnO/AC nanomaterial was assessed employing the standard disc-agar diffusion method [36,37]. The antifungal efficacy was evaluated utilizing *A. niger*, *C. neoformans*, *C. albicans*, and *M. audouinii*. The materials were sterilized by filtering using 0.22 m Millipore filters after dissolving in 10% DMSO to attain an ideal concentration of 30 mg/mL. Antifungal investigations were then performed utilizing the disc diffusion approach. A mixture of 100 liters and 104 spores/mL of fungus was distributed over PDA media. The 6 mm circular discs were treated with 10 mL of the specimens, each disk weighting 300 g. Afterwards, the discs were positioned on the affected agar. The standard medicine administered was clotrimazole. Negative controls were established with a solution containing 10 percent of dimethyl sulfoxide (DMSO). The fungal cultures were incubated at 37°C for 72 hours on inoculated plates. Fungi linked with plants were cultured at an ambient temperature. The antifungal efficacy was evaluated by measuring the zone of inhibition against the examined bacteria. Each experiment in the current study was performed three times.

## RESULTS AND DISCUSSION

**FT-IR analysis**

An FT-IR study was conducted to examine the functional components and chemical makeup of the produced nanostructures. Figure 2(a) illustrates that the FTIR spectra of the produced nanoparticles were examined throughout the region of 500 to 4000 cm-1. The FT-IR spectra of the unaltered ZnO sample displays bands at 458 cm-1, 1112 cm-1, 1509, 2938, and 3430 cm-1. The peak at 495 cm-1 is attributed to the Zn-O bond vibration mode, signifying the successful green production of ZnO nanoparticles [38]. The peak seen at 1112 cm-1 could be linked to the C-O stretching bond of the aromatic rings associated with phenolic and flavonoid compounds in the *Toddalia asiatica* leaf extract [39]. The peak at 1509 cm−1 indicates the existence of mark phytoconstituents on the ZnO surface, that functioned as reducing, stabilizing, and capping agents. This may relate to the –C–N stretching vibration of amides or the –C–O stretching of alcohols and carboxylic acids absorbing on ZnO [40]. The wide band between 3150-3600 cm-1 signifies the existence of O-H moieties in the extract and ZnO, attributed to the O-H stretching of polyphenols and flavonoids present in the plant extract, that have been deposited onto the ZnO surface [41]. The FTIR investigation indicates that the predominant oxygen-containing groups are clearly evident in the FTIR spectrum of ZnO NPs. The FTIR spectrum of the activated carbon sample reveals many bands, with a significant reduction of functional moieties associated with leaf phytochemicals throughout the carbonation procedure, indicating the excellent purity of the manufactured activated carbon material. This indicates that the heat treatments resulted in the breakdown of the majority of the adhered biomolecules. The peaks at 1452 and 1463 cm−1 suggest the presence of C=C bonds in activated carbon [42]. The AC/ZnO sample has significant peaks in the region of 3100–3450 cm−1, confirming the presence of O–H molecules. The peak at 458 cm−1 strongly suggests the presence of a Zn-O bond. FT-IR spectra of ZnO/AC Nanocomposite (Fig. 2).

**XRD analysis**

The patterns of XRD were analyzed to verify the production of the AC and ZnO/AC nanocomposites. Furthermore, the XRD powder method was used to provide comprehensive details regarding elemental and phase identification. The XRD examination is displayed in Figure 3. The XRD spectra of AC has a large peak at 2θ=24.110, corresponding to the 002 plane of carbon, indicative of an amorphous form [43]. The strength and location of the peak suggest a modest level of graphitization process. This signifies that the thermal treatment of plants at elevated temperatures induces the breakdown of organic materials into gaseous by products, resulting in the expulsion of the majority of non-carbon components, including hydrogen, nitrogen, and oxygen, in gaseous forms, while leaving a solid remnant richer in carbon. The peak at 24.11° likely verifies that the activation and carbonization of *Toddalia asiatica* leaf powder considerably yield amorphous carbon. The XRD pattern of ZnO nanoparticles exhibited nine distinct and pronounced peaks at 2θ values of 31.78°, 34.45°, 36.27°, 47.57°, 56.61°, 62.90°, 66.39°, 67.98°, and 69.10°, corresponding to the crystal planes (100), (002), (101), (102), (110), (103), (200), (112), and (201), correspondingly [44]. The XRD analysis of ZnO nanoparticles revealed a single phase with distinct diffraction peaks, corresponding to the hexagonal

wurtzite structure of ZnO (JCPDS Card no. 36–1451). Earlier research [45] indicated that biosynthesized ZnO nanoparticles employing leaf extracts from *Cassia fistula* and *Melia azedarach* displayed the hexagonal wurtzite structure of ZnO. It also validates the absence of typical XRD peaks from additional substances or phases, so validating that the produced ZnO sample is devoid of contaminants. The results demonstrate that the extract of *Toddalia asiatica* leaf provided efficacy and ease in the biogenesis of ZnO nanoparticles. Similar peaks were seen in the ZnO/AC patterns, except for those associated with AC, which had entirely vanished, perhaps owing to the reduced carbon concentration linked to the amorphous structure. No displacement of the ZnO peaks was seen after the injection of AC. The crystalline dimensions of the produced nanoparticles were ascertained using Scherrer's equation is as follows

$$D = 0.9\lambda/\beta\cos\theta$$

D represents the average crystallite size in nanometers, $\lambda$ denotes the monochromatic wavelengths of CuK$\alpha$ radiation (1.5406 nm), $\beta$ signifies the full width at half-maximum, and $\theta$ indicates the diffraction angle. The crystalline dimensions of AC, ZnO, and ZnO/AC were 20.46, 26.30, and 38.90, correspondingly. XRD spectra of ZnO/AC nanocomposite (Fig. 3).

**FESEM and EDX analysis**

The surface appearance produced nanostructures were examined using FE-SEM images and EDX spectra. Figure 4(a-c) shows the FE-SEM images of activated carbon (AC), zinc oxide (ZnO), and zinc oxide/activated carbon (ZnO/AC) samples. According to the FE-SEM study, the majority of the ZnO nanoparticles exhibited a spherical shape along with a heterogeneity dispersion, attributed to substantial agglomeration in clustered formations. The outcomes corroborate the studies of Fouladi-Fard *et al*. (2022), who verified that the use of *Crataegus monogyna* extract yielded spherical ZnO nanoparticles [46]. Employing the biomolecules in *Toddalia asiatica* leaf extract to reduce, cap, and stabilize ZnO nanoparticles, resulting in less agglomeration and enhanced homogeneity. The FE-SEM picture of AC demonstrated that the sample had a spherical morphology, indicating that the chemical stimulation and heating procedure preserved the uniform spherical forms of the carbon fragments. Furthermore, the FESEM image of the AC sample demonstrates the development of a porous surface. The FE-SEM pictures of the ZnO/AC samples exhibited uneven granular and spherical forms. The primary advantage of the biogenesis method utilizing plant extracts is the diversity of nanoscale shapes, that can rely on the specific plant extract used and its biomolecular composition. The generation and quality of the produced nanostructures were verified via EDX spectroscopy, and Figure 4(d-f) presents the EDX spectra of the samples that were synthesized. The findings indicate that peaks correspond to ZnO, AC, and ZnO/AC specimens. The EDX analysis demonstrated the presence of the appropriate phases of Zn, O, and C in the specimens, confirming the high purity of the synthesized nanoparticles. The ZnO/AC EDX spectrum demonstrated effective production, with the trace amounts of additional components attributed to the extract contents. Our findings align with those presented by Venkateasan *et al*. (2017), who utilized *Ipomoea pescaprae* leaf extract for the production of ZnO nanoparticles [47].

**TEM analysis**

The shape and distribution of the produced substances were examined utilizing TEM examination, with the corresponding TEM pictures shown in Fig. 5. The TEM picture clearly illustrates that ZnO nanoparticles have spherical morphology. Small, nearly disordered dispersed spheres were formed from the pure activated carbon. The abundance of white dots among the disordered carbon layers indicates that activated carbon has a porous structure. The pictures clearly depict nanostructures of ZnO nanoparticles uniformly distributed over activated carbon nanoparticles, particularly in the instance of ZnO/AC. Upon loading, the ZnO nanoparticles are uniformly distributed throughout the porous activated carbon framework. The TEM investigations indicate substantial agglomerations in ZnO/AC nanoparticles, likely resulting from the processing of nanocomposites under elevated temperature settings. Previous evidence indicates that elevated surface energy leads to an increase in particle size, resulting in substantial aggregation of particles at high temperatures in aqueous environments [48]. Consequently,

bigger spheres are anticipated to develop in ZnO/AC. These data clearly demonstrate that ZnO nanoparticles are effectively packed and sustained over porous activated carbon nanoparticles.

**Antioxidant assessment**

**DPPH radical scavenging assay**

The capacity of antioxidants to readily transfer hydrogen atoms is thought to be the fundamental basis for their efficacy in scavenging DPPH radicals. Radical scavenging activities are essential in mitigating the harmful effects of free radicals in numerous medical conditions including diabetes. Table 1 delineates the DPPH scavenging properties of the plant extract, activated carbon, and ZnO/AC nanocomposite. The plant extract and its combinations demonstrated increased DPPH scavenging ability at doses ranging from 120 to 500 μM, above that of the control (ascorbic acid). The ZnO/AC nanocomposite demonstrates enhanced activity relative to the plant extract and AC at a higher concentration of 1000 μM. The ability of plant extract, AC, and ZnO/AC nanocomposite to scavenge DPPH increased with greater concentrations. The DPPH scavenging capability demonstrated a dose-dependent relationship. The ZnO/AC nanocomposite exhibited a superior DPPH scavenging ability (IC50 = 168.59 μM) with respect to the plant extract (IC50 = 179.69 μM). Similarly, the plant extract and activated carbon demonstrated DPPH quenching properties; however, the ZnO/AC nanocomposite exhibited a superior scavenging rate (IC50 = 168.59 μM), indicating improved efficacy. The plant extract, activated carbon, and ZnO/AC nanocomposite demonstrated that the plant extract had the lowest DPPH scavenging ability, shown by an IC50 value of 179.69 μM.

**FRAP antioxidant assay**

Table 2 illustrates that the relative FRAP antioxidant capacity of the plant extract, activated carbon, and ZnO/AC nanocomposite, compared to the standard ascorbic acid, reveals that the plant extract possesses inferior ferric reducing antioxidant effects in relation to AC and the ZnO/AC nanocomposite. Similarly, the ferric reducing antioxidant properties of the plant extract, activated carbon, and ZnO/AC nanocomposite were augmented at elevated dosages. The antioxidant properties of ferric reducing agents shown a dose-dependent relationship. The synthesized ZnO/AC nanocomposite shown significant ferric reduction antioxidant capacity (IC50 = 155.61 μM) in comparison to the plant extract (IC50 = 171.69 μM). Additionally, either the plant extract and activated carbon demonstrated ferric reducing antioxidant properties. The ZnO/AC nanocomposite has a higher scavenging rate (IC50 = 155.61 μM), demonstrating enhanced activity relative to the plant extract and activated carbon. The plant extract and activated carbon had considerable ferric reduction antioxidant capacity, with IC50 values of 171.69 and 166.68 μM, respectively, compared to the standard ascorbic acid (IC50 = 204.11 μM).

**Antibacterial effect**

The plant extract, activated carbon, and synthesized zinc oxide/activated carbon nanocomposite were assessed for antibacterial characteristics. The plant extract demonstrated reduced activity relative to the AC and ZnO/AC nanocomposite. The assessment was administered in a controlled environment. Regarding the substances assessed only ZnO/AC shown notable efficacy (MIC = 2 μg/mL) against *S. aureus*. The ZnO/AC shown moderate efficacy against *K. pneumoniae*, with a MIC value of 8 μg/mL, in comparison with the control Ciprofloxacin, which had a MIC value of 6μg/mL. The ZnO/AC nanocomposite had superior efficacy against E. coli compared to the control Ciprofloxacin, shown through its lower MIC value of 4μg/mL, while Ciprofloxacin exhibited a MIC value of 6μg/mL. The ZnO/AC nanocomposite exhibited equivalent efficacy against *P. aeruginosa* compared to the control drug Ciprofloxacin, as shown by its MIC value of 2μg/mL, which was identical to that of Ciprofloxacin. The results are shown in Table 3.

**Antifungal activity**

The research investigated the antifungal properties of the plant extract, AC, and ZnO/AC. The plant extract shown little efficacy against all evaluated fungus strains. The ZnO/AC exhibited notable efficacy against *C. albicans*, with a minimum inhibitory concentration (MIC) of 6μg/mL. The ZnO/AC had modest efficacy against *C. neoformans*, with a minimum inhibitory concentration (MIC) of 7 μg/mL, in contrast to clotrimazole, which had a MIC of 4 μg/mL. The ZnO/AC exhibited remarkable efficacy with a MIC of 6 μg/mL towards *A. niger*, in contrast to clotrimazole, which

had a MIC of 12 μg/mL. The ZnO/AC exhibited equivalent efficacy with a MIC of 10 μg/mL towards *M. audouinii*, matching the normal clotrimazole, which also had a MIC of 10 μg/mL. The results were encapsulated in Table 4.

## CONCLUSIONS

ZnO and ZnO/AC nanomaterials were synthesized using an environmentally safe method and identified using XRD, FT-IR, FE-SEM, and TEM methods, demonstrating efficacy as antioxidant and antimicrobial agents. The findings indicate that the produced materials mainly exhibit spherical shapes. The XRD measurements indicated the presence of a hexagonal wurtzite structure. The findings indicated that the ZnO/AC nanocomposite exhibited superior antioxidant and antibacterial properties as a nanodrug. Moreover, the incorporation of AC in the produced nanocomposite may render it an effective absorbent for ecological and water pollutants.

## ABSTRACT

Digital overload, clinically identified as Digital Overuse Syndrome, presents a multi-system health crisis characterized by cognitive hyperarousal, sensory strain, and psychosocial stress. Contemporary biomedical models often adopt a reductionist approach, treating these symptoms in isolation. This article proposes an integrative Ayurvedic framework, conceptualizing digital overuse as a modern form of *Ama*—toxic residue—resulting from the excessive and improper use of the senses (*Indriyartha Atiyoga*). Through the lens of the *Tridosha* theory, we diagnose this condition as a systemic imbalance, primarily involving the aggravation of *Vata* and *Pitta Doshas*. Key pathophysiological mechanisms include the disturbance of *Alocaka Pitta* (governing vision) leading to digital eye strain, the vitiation of *Prana* and *Vyana Vayu* causing neurological and circadian disruption, and the consequent depletion of *Ojas*, the essential reservoir of immunity and mental resilience. Moving beyond the limited paradigm of a temporary "digital detox," this paper outlines a structured, holistic protocol for sustainable digital wellness. Grounded in the principle of *Samanya Vishesha* (applying opposite qualities), the *Sattvic* Digital Detox protocol employs tailored nutritional plans, a stabilizing daily routine (*Dinacharya*), and sensory withdrawal (*Pratyahara*). It integrates specific Ayurvedic therapies (*Abhyanga, Netra Tarpana, Shirodhara*) with mindfulness (*Dhyana*), yoga, *pranayama*, and ocular exercises (*Netra Vyayama*) to cleanse the mind-carrying channels (*Manovaha Srotas*), strengthen the metabolic fire (*Agni*), and rejuvenate *Ojas*. We argue that this approach offers a comprehensive, culturally-grounded model for restoring *Swasthya*—optimal

health—in the technological era, addressing the root causes of digital dependency by fulfilling core human needs for connection, meaning, and vitality through positive lifestyle substitution.

**Keywords:** Ayurveda, Digital Overload, Dosha, Ama, Ojas, Dinacharya, Digital Detox, Pratyahara, Abhyanga, Mindfulness, Swasthya.

## INTRODUCTION

In modern society, excessive engagement with digital media has become a defining feature. Continuous interaction with electronic devices significantly affects mental processes, cognitive functions, and sensory activities. On average, people worldwide spend over six hours each day on digital platforms, with adolescents and knowledge-based professionals often exceeding this duration[1]. This persistent digital exposure leads to restlessness of the mind, information overload, and disruption of natural sleep-wake cycles. In neuropsychiatric terms, this state is recognized as sustained cognitive hyperarousal,[2] which closely aligns with the Ayurvedic concept of increased activity in the mind-carrying channels (*manovaha srotas*). Digital platforms, especially social media, are designed to foster attachment and craving, repeatedly activating the brain's reward systems. The ongoing search for social approval and the fear of missing out influence attention regulation, social interactions, and the balance of the autonomic nervous system. Clinically, these effects are now identified as Digital Overuse Syndrome, which includes symptoms such as digital eye strain,[3] neck and cervical pain,[4] sleep disturbances,[5] and various psychological issues like anxiety and worry[6]. Ayurveda, with its comprehensive understanding of sensory physiology and mind-body integration, interprets this phenomenon through the principle of excessive and improper use of the senses (*Indriyartha Atiyoga*)[7]. Among all the senses, vision is most affected due to prolonged screen exposure. This disrupts the function of *Alocaka Pitta*,[8] the aspect of *Pitta Dosha*[9] responsible for visual perception and eye health, leading to symptoms such as burning, redness, light sensitivity, and blurred vision. Additionally, extended sedentary behavior, rapid sensory input, and irregular routines aggravate *Vāta Dosha*, particularly its *Praṇa* and *Vyana* subtypes, resulting in impaired neuromuscular coordination and mental instability. These imbalances manifest as mental restlessness, sleep disturbances, bodily stiffness, and muscle tension. Ayurveda does not recommend complete avoidance of technology. Instead, it emphasizes judicious and mindful use, supported by systematic cleansing and pacification measures to restore balance among the *doshas*. This approach includes nourishing bodily tissues and calming the mind through appropriate diet, lifestyle, and behavioural practices. While modern research has documented the effects of digital overload—such as hormonal imbalances, reduced melatonin production, changes in brain network activity, and psychosocial stress—biomedical models often treat these as separate issues. This reductionist approach does not address the interconnected disturbances across bodily systems described in Ayurveda, including *dosha*, *dhatu*, *agni*, and *ojas*. This article proposes that the Ayurvedic *Tridosha Siddhanta* [10] offers a comprehensive framework for understanding digital overuse. It identifies the condition as one marked by aggravation of *Vata* and *Pitta doshas*, ultimately leading to depletion of *Ojas*[11]. Since *Ojas* underpins strength, immunity, and mental resilience, its reduction explains the widespread fatigue and vulnerability observed in individuals with excessive digital exposure. The Ayurvedic approach goes beyond the concept of a simple "digital detox." It provides a holistic model for restoring balance in the digital era through daily and seasonal routines, cognitive-enhancing therapies, eye care practices, and mindfulness techniques. These strategies aim to re-establish harmony among the senses, mind, and body.

## OVERVIEW OF THE FIELD

Recent studies across multiple disciplines demonstrate that digital technology affects a wide range of biological systems. Neuroimaging research using fMRI and qEEG has shown that extended use of digital media modifies attention networks in the brain[12]. This results in reduced capacity for sustained focus and an increased tendency toward stimulus-driven thinking. In the psychological and social domains, there is substantial evidence linking social

media use to higher rates of anxiety, depression, and loneliness[13]. Contributing factors include social ranking, diminished sense of identity, and a reliance on reward mechanisms. Physiological studies have identified that exposure to blue light from screens disrupts circadian rhythms by lowering melatonin production. This disruption leads to delayed sleep onset, reduced sleep quality, and impaired memory functions[14]. Ergonomic research has established a connection between prolonged device use and musculoskeletal issues, such as neck pain and nerve compression. Furthermore, eye health studies have highlighted specific concerns related to digital eye strain, including unstable tear film and eye inflammation[15]. An examination of existing digital detox programs reveals notable limitations regarding their effectiveness and long-term sustainability. Many technology-focused interventions, such as applications that restrict device usage, primarily target behavioural change without addressing the underlying psychological drivers of compulsive technology use. As a result, temporary abstinence from technology often leads to a rebound effect, making sustained self-control challenging. These approaches frequently position technology as an adversary, rather than considering the complex relationship between humans and digital tools. While mindfulness-based strategies may help reduce stress, they can inadvertently foster new dependencies on technology and do not address the broader structural factors that promote excessive use. The fundamental shortcoming of current strategies lies in their inability to offer a comprehensive alternative. There is a need for solutions that address the human requirements for connection and understanding—needs that digital engagement currently meets, albeit imperfectly.

**Theoretical Framework: An Ayurvedic Paradigm**

Ayurveda's foundational model of physiology is based on the *Pancha Mahabhuta* theory[16]. According to this theory, the human body operates through five essential elements: *Akasha* (space), *Vayu* (air), *Agni* (fire), *Jala* (water), and *Prithvi* (earth). These elements interact to form three primary regulatory systems, known as the *Doshas*. *Vata Dosha*: Responsible for neural conduction, respiratory function, and elimination. *Pitta Dosha*: Governs metabolic transformation, thermogenesis, and cognitive processing. *Kapha Dosha*: Maintains structural integrity, fluid balance, and immune function. Health, referred to as *Swasthya*,[17] is defined as the dynamic balance of an individual's unique constitution, known as *Prakriti*[18]. Disease, or *Vikriti*, occurs when this balance is disrupted by dietary, behavioural, environmental, or psychological factors. The concepts of *Agni* (digestive and metabolic capacity),[19] *Ama* (inflammatory byproducts of incomplete metabolism),[20] and *Ojas* (the fundamental neuro-immunological reserve) further complete this physiological model. Within this framework, digital technology is viewed as a complex pathogen, or *Nidana*, that can disrupt *Doshic* balance. The digital environment is characterized by sensory overload, irregular timing, and fragmented attention, all of which correspond to the mobile (*Chala*), light (*Laghu*), and unpredictable qualities of *Vata*. In addition, digital content often involves competition, high cognitive demands, and emotional stimulation, reflecting the sharp (*Tikshna*), intense (*sara*), and heated (*Ushna*) nature of *Pitta*. Extended use of digital technology can therefore disturb both *Vata* and *Pitta Doshas*. Aggravation of *Vata* may result in autonomic instability, increased neurological activity, and disruption of circadian rhythms. Aggravation of *Pitta* can lead to inflammatory responses, heightened cognitive activity, and metabolic disturbances. This combined imbalance places strain on *Mansika Agni*, the capacity to process thoughts and regulate metabolism, and leads to the accumulation of *Mansik Ama*—undigested sensory and emotional residues. These residues can obstruct *Manovaha Srotas*, the channels responsible for neural processing, and gradually diminish *Ojas*, which is essential for maintaining both physical and mental health.

**An Ayurvedic Diagnosis of Digital Overload**

Excessive digital use can contribute to a *Vata* imbalance, which manifests in several ways across the body. Neurological symptoms may include restlessness, rapid thoughts, anxiety, sleep disturbances, and difficulties with executive function. These issues reflect disruptions in nerve signalling and autonomic regulation. Communication patterns may become hurried, with increased compulsive use of social media and a noticeable decline in listening skills, all of which are consistent with *Vata*'s active tendencies. Physical symptoms often present as dry eyes, dry skin, irregular digestion, joint instability, muscle tension, and a general sense of physical discomfort. Energy levels may fluctuate, leading to periods of fatigue interspersed with overactivity. Individuals may also experience reduced creativity, a sense of disconnection, and diminished resilience to stress. *Pitta*-related issues from prolonged digital

engagement are commonly seen as inflammatory and emotional disturbances. Emotional symptoms may include irritability, low tolerance for frustration, and a tendency to be overly critical. Sensory overload can result in heightened sensitivity to light and sound, tension headaches, and burning sensations in the eyes, indicating increased activity of *Alochaka Pitta*. Inflammatory responses may appear as skin problems, acid reflux, and other heat-related conditions. Behavioural patterns often include perfectionism, a preoccupation with metrics, and a persistent need for validation. Cognitive effects may involve frequent social comparisons, competitiveness, and critical thinking that lacks empathy. Although digital technology does not directly exhibit *Kapha*'s physical qualities, its influence is evident through a more sedentary lifestyle. This can lead to reduced physical activity, changes in weight, fluid retention, and respiratory concerns. Cognitive symptoms may include low motivation, mental lethargy, difficulty initiating tasks, and depressive feelings. Emotionally, individuals may become reliant on technology for validation, engage in emotional eating, and display rigid behaviours. Metabolic challenges such as slow digestion and fluid retention may also arise, indicating weakened *Agni* and the accumulation of *Ama*.

**The Ayurvedic Digital Detox Protocol**

The *Sattvic* Digital Detox Protocol is based on the principle of *Samanya Vishesha*,[21] which involves applying qualities that are opposite to those causing imbalance. Digital overload is characterized by the light (*laghu*), irregular/mobile (*chala*), and dry (*ruksha*) qualities of *Vata*, as well as the sharp (*tikshna*) and hot (*ushna*) nature of *Pitta*. To address these, the protocol introduces practices that are stabilizing (*sthira*), grounding/heavy (*guru*), oily (*snigdha*), and soothing (*shita*). The protocol is structured in three main phases: physical interventions, behavioural strategies, and mindfulness practices. Physical Interventions (Focus on nutrition and bodywork). Behavioural Strategies (Emphasize daily routines and sensory management). Mindfulness Practices (Incorporate meditation and the creation of calming environments). Nutrition is tailored to individual *dosha* requirements. For those with a *Vata* imbalance, it is important to consume warm (*ushna*), moist (*drava*), oily (*snigdha*), and grounding (*sthira*) foods. Recommended options include cooked grains, stewed fruits, healthy fats, nuts, seeds, and root vegetables. Individuals with a *Pitta* constitution should focus on cooling (*shita*) and slightly dry (*ruksha*) foods, emphasizing sweet (*madhura*), bitter (*tikta*), and astringent (*kashaya*) tastes. Suitable choices are sweet fruits, dark leafy greens, coconut, cilantro, mint, basmati rice, and dairy products. To balance *Kapha*, lighter (*laghu*), warm (*ushna*), and dry (*ruksha*) foods with pronounced flavours, such as legumes, light grains, and spicy foods, are advised. All meals should be prepared with care and eaten away from screens to support digestion and prevent the accumulation of *Ama* (Table 1). A structured daily routine, or *Dinacharya*,[22] forms the basis of behavioural intervention. This helps establish stable rhythms, calms *Vata,* and creates technology-free environments. Begin the day by waking early *Brahma Muhurta* (4:30–6:00 AM), in alignment with nature. Engage in foundational practices such as brushing your teeth, meditation, and gentle yoga. These activities help foster mental clarity and a sense of calm at the start of the day. During *Kapha* Time (6:00–8:00 AM), focus on supporting physical vitality. Recommended practices include self-massage, nasal therapies, warm hydrotherapy, mild exercise, and spending time outdoors. These activities can help invigorate the body and prepare it for the day ahead. As the body transitions from *Kapha* to *Pitta* (8:00–9:00 AM), it is advisable to have a device-free breakfast. Practicing mindful eating during this time can enhance digestion and set a positive tone for the remainder of the day. The *Pitta* Period (9:00 AM–12:00 PM) is well-suited for focused and productive work. To maintain mental clarity, incorporate planned breaks from technology and avoid prolonged screen time. Consume the main meal of the day (12:00–1:00 PM) without the distraction of screens. After eating, allow time for a brief period of rest to support digestion and rejuvenation. Dedicate the afternoon (1:00–6:00 PM) to creative pursuits and ensure regular movement. This approach helps sustain energy and supports cognitive function throughout the day. In the early evening (6:00–7:00 PM), reduce technology use and enjoy a light dinner before sunset. This practice can aid in digestion and promote a restful evening. Reserve this time (7:00–9:00 PM) for nurturing relationships, reading, and engaging in light yoga. It is also beneficial to observe a digital curfew to support relaxation. Conclude the day (9:00–10:00 PM) with meditation and contemplation. These practices help prepare the mind and body for restful sleep, ensuring a restorative end to the day (Table 2). To counteract the sensory effects of technology, specific behavioural measures are recommended. Practicing *Pratyahara* involves establishing tech-free areas, such as bedrooms and dining spaces, and designating periods without screens, particularly after waking and before sleeping. Daily self-massage with warm oils (*Abhyanga*) can help calm the nervous system and reduce *Vata*-related effects. Incorporating yoga and

breathing exercises, tailored to individual *Dosha* needs, supports balance and enhances body awareness (Table 3). Mindfulness practices are designed to address the impact of technology on mental well-being. Meditation (*Dhyana*)[23] helps create a buffer between external stimuli and internal responses. Designing living and working spaces with natural materials, calming colours, and clear organization can help reduce the sense of chaos associated with digital distractions. Engaging in gratitude exercises, assisting others, connecting with nature, and participating in uplifting activities can foster positive emotions and provide fulfilment beyond digital engagement. (Table 4)

## DISCUSSION

The Ayurvedic framework provides a distinctive perspective for understanding digital overload, offering clarity on symptoms that may otherwise appear contradictory. Through its multi-*Doshic* impact model, Ayurveda interprets these symptoms as interconnected manifestations of imbalances in *Vata*, *Pitta*, and *Kapha*, which arise from patterns of digital technology use. This integrated approach marks a notable advancement over conventional biomedical methods, which often address symptoms in isolation. By presenting a unified explanation for complex, multi-system presentations, Ayurveda contributes valuable insight to digital health research. Beyond symptom management, Ayurveda defines health as a state of positive vitality, known as *Swasthya*. Its therapeutic objectives extend to fostering resilience, mental clarity, and balanced energy, all of which are considered essential for genuine digital well-being. This holistic focus distinguishes Ayurveda from approaches that merely seek to eliminate discomfort. The sustainability of the Ayurvedic protocol is rooted in its emphasis on rebalancing the entire system, rather than imposing external restrictions. Traditional interventions frequently attempt to limit screen time through deliberate abstinence. In contrast, the Ayurvedic method addresses fundamental human needs for stimulation, connection, productivity, and meaning—factors that often drive digital engagement. It introduces healthier alternatives through lifestyle adjustments and mindfulness practices. By offering substitutes that satisfy these underlying needs while simultaneously addressing the effects of excessive technology use, the protocol facilitates a natural reduction in dependence, without fostering a sense of deprivation. This approach, combined with efforts to strengthen *Agni* (digestive fire), clear *Srotas* (channels), and enhance *Ojas* (vitality), establishes the foundation for enduring behavioural change and supports the adoption of healthier habits. Applying this framework poses several challenges, including the difficulty of translating Ayurvedic concepts such as *Dosha*, *Ojas*, and *Srotas* across diverse cultural and biomedical contexts. The individualized nature of Ayurvedic assessment also complicates standardized implementation, highlighting the need for simplified yet personalized tools. Additionally, the time demands of the protocol may limit adherence, suggesting the value of streamlined practices compatible with modern lifestyles. Potential solutions may include tiered implementation plans, community-based support systems, technological resources for Ayurvedic education, and the adoption of habit-stacking techniques. These measures can facilitate the practical application of Ayurvedic principles in the context of digital wellness.

## CONCLUSION

Digital overload presents a multifaceted challenge at the intersection of human biology and digital technology. Effectively managing its wide-ranging effects requires comprehensive frameworks and targeted approaches that consider its impact on multiple bodily systems. Ayurveda's *Tridosha* theory provides a holistic model for diagnosing and understanding the health consequences of digital technology. By identifying predictable patterns of *Doshic* imbalance, this perspective enables a deeper examination of the underlying physiological mechanisms, rather than focusing solely on surface-level symptoms. The *Sattvic* Digital Detox protocol represents a significant advancement over conventional methods. It addresses the root causes of digital overload by systematically restoring balance in areas such as nutrition, circadian rhythms, sensory input, and cognitive patterns. Complementing this, the *Dinacharya* framework offers practical guidance for integrating these principles into contemporary lifestyles, creating a structured pathway from digital challenges to sustained well-being. This approach redefines digital detoxification. Instead of viewing it as a temporary withdrawal, it emphasizes the ongoing cultivation of *Swasthya*—a state of optimal health in Ayurveda, characterized by balanced *Doshas*, robust *Ojas*, and a conscious relationship with

technology. Future research should prioritize empirical validation of these concepts and explore culturally sensitive adaptations that uphold Ayurvedic principles while enhancing accessibility for diverse populations. By combining ancient medical wisdom with modern scientific methodologies, it is possible to develop effective strategies for addressing the health concerns of the digital era, allowing individuals to benefit from technology without compromising overall well-being.

**Table 1: Dietary Recommendations for Digital Detox**

| Dosha Imbalance | Key Qualities (Gunas) to Emphasize | Key Tastes (Rasas) to Favor | Recommended Food Examples | General Guidance |
|---|---|---|---|---|
| **Vata** | Warm (*ushna*), Moist (*drava*), Oily (*snigdha*), Grounding/Heavy (*guru*), Stabilizing (*sthira*) | Sweet (*madhura*), Sour, Salty | Cooked grains (oats, rice), stewed fruits, healthy fats (ghee, olive oil), nuts, seeds, root vegetables (sweet potatoes, carrots). | Eat regular, warm, well-cooked meals. Favor nourishing and hydrating foods. |
| **Pitta** | Cooling (*shita*), Slightly Dry (*ruksha*) | Sweet (*madhura*), Bitter (*tikta*), Astringent (*kashaya*) | Sweet fruits (mango, grapes), dark leafy greens, coconut, cilantro, mint, basmati rice, dairy products (milk, ghee). | Avoid overly spicy, oily, or fermented foods. Prioritize cooling and refreshing items. |
| **Kapha** | Light (*laghu*), Warm (*ushna*), Dry (*ruksha*) | Pungent (*katu*), Bitter (*tikta*), Astringent (*kashaya*) | Legumes, light grains (barley, quinoa), plenty of vegetables, spicy foods (with ginger, pepper). | Prefer light, warm, and well-spiced meals. Avoid heavy, oily, or very sweet foods. |
| *All meals should be prepared with care and eaten mindfully, away from screens, to support digestion and prevent the accumulation of *Ama*. | | | | |

**Table 2: Dinacharya (Daily Routine) for Digital Balance**

| Time Period (Ayurvedic Phase) | Recommended Activities and Focus | Key Principles and Benefits |
|---|---|---|
| **4:30 AM – 6:00 AM** | Wake up early. Engage in foundational practices: brushing teeth, meditation, gentle yoga. | Aligns with natural rhythms. Fosters mental clarity and calm to start the day. |
| **6:00 AM – 8:00 AM** | Support physical vitality. Self-massage (*Abhyanga*), nasal therapies, warm hydrotherapy, mild exercise, time outdoors. | Invigorates the body, grounds energy, and prepares for the day ahead. |
| **8:00 AM – 9:00 AM** | Device-free breakfast. Practice mindful eating. | Enhances digestion (*Agni*) and sets a positive, intentional tone for the day. |

| | | |
|---|---|---|
| **9:00 AM – 12:00 PM** | Focused, productive work. Use planned technology breaks; avoid prolonged screen time. | Leverages natural mental sharpness and focus. Prevents cognitive overload. |
| **12:00 PM – 1:00 PM** | Main meal of the day. Eat without screens. | Supports optimal digestion and nutrient absorption when digestive fire (*Agni*) is strongest. |
| **1:00 PM – 6:00 PM** | Post-meal rest, then creative pursuits and regular movement. | Aids digestion and rejuvenation. Sustains energy and supports cognitive function. |
| **6:00 PM – 7:00 PM** | Reduce technology. Enjoy a light dinner before sunset. | Promotes easier digestion and prepares the body for rest. |
| **7:00 PM – 9:00 PM** | Wind down. Nurture relationships, read, engage in light yoga. Observe a digital curfew. | Supports relaxation, connection, and the natural wind-down of the nervous system. |
| **9:00 PM – 10:00 PM** | Conclude the day. Meditation and contemplation. Prepare for sleep. | Calms the mind (*Manas*), prepares the body for restful sleep, and ensures restorative rest. |

**Table 3: Ayurvedic Therapies for Digital Detoxification**

| Therapy | Description and Procedure | Primary Benefits for Digital Detox | Key Dosha Balanced |
|---|---|---|---|
| **Abhyanga (Oil Massage)** | Daily self-massage with warm, dosha-specific oils (e.g., sesame for Vata, coconut for Pitta, mustard for Kapha). | Calms the nervous system, reduces anxiety and Vata-aggravation, improves sleep, and grounds the mind. | Primarily Vata, also Pitta and Kapha. |
| **Netra Tarpana (Eye Rejuvenation)** | Holding a pool of warm, medicated ghee or oil around the eyes for a specific duration. | Rejuvenates strained eyes, relieves dryness and burning, soothes *Alochaka Pitta*, and improves vision clarity. | Primarily Pitta (eyes), also Vata. |
| **Shirodhara (Forehead Oil Flow)** | A steady, warm stream of oil poured onto the forehead (third eye area) in a rhythmic manner. | Deeply relaxes the mind, reduces mental fatigue, enhances sleep quality, and clears sensory overload. | Vata and Pitta (mind, nerves). |
| **Nasya (Nasal Instillation)** | Administration of medicated oils or herbal powders into the nostrils. | Clears sinuses, improves mental clarity, relieves headaches, and strengthens the senses linked to the head. | Kapha (head), Vata and Pitta. |
| **Pinda Sweda (Herbal Bolus Massage)** | Massage with heated cloth boluses filled with herbs, rice, or sand. | Relieves muscle stiffness (neck, shoulders), improves circulation, and reduces pain from poor posture. | Vata (muscles, joints), Kapha. |
| **Padabhyanga (Foot Massage)** | Massage of the feet with warm oil, focusing on marma points (energy points). | Grounds excess Vata, induces deep relaxation, improves sleep, and reduces stress and fatigue. | Primarily Vata. |
| **Karna Purana (Ear Oiling)** | Filling the ear canal with warm, medicinal oil for a short period. | Calms the mind, reduces tension, supports hearing, and alleviates anxiety and tinnitus. | Vata (related to ears and mind). |
| **Shiro Abhyanga** | Gentle massage of the scalp | Relieves mental tension, | Vata and Pitta (head |

| | | | |
|---|---|---|---|
| **(Head Massage)** | with warm oil. | headaches, and promotes healthy hair. Sootes the central nervous system. | region). |

**Table 4: Mindfulness Practices for Digital Detox**

| Practice Category | Specific Practice / Activity | Primary Benefit for Digital Detox | Ayurvedic Principle / Outcome |
|---|---|---|---|
| **Meditative Practices** | Dhyana (Meditation) | Creates a buffer between external digital stimuli and internal reactions, reducing reactivity and mental clutter. | Calms the mind (*Manas*), balances *Prana Vayu*, and enhances *Sattva* (clarity). |
| **Yoga Asana (Postures)** | Balancing Poses (e.g., Tree Pose/Vrikshasana) | Improves focus, concentration, and grounds scattered mental energy. | Stabilizes *Vata Dosha* and enhances mind-body coordination. |
| | Forward Bends (e.g., Child's Pose/Balasana) | Calms the nervous system, relieves anxiety, and encourages introspection. | Pacifies *Pitta* and *Vata*, promoting *Pratyahara* (sensory withdrawal). |
| | Gentle Twists and Inversions (e.g., Legs-Up-The-Wall/Viparita Karani) | Improves circulation, relieves neck/back tension, and reverses blood flow to refresh the mind. | Supports *Vyana Vayu* (circulation) and relieves stagnation (*Ama*). |
| **Pranayama** | Nadi Shodhana (Alternate Nostril Breathing) | Balances the left and right brain hemispheres, reduces anxiety, and enhances mental clarity. | Balances all three *Doshas*, especially effective for *Prana Vayu*. |
| | Bhramari (Bee Breath) | Instantly calms the mind, relieves cerebral tension, and reduces frustration or anger. | Cools *Pitta* in the head, soothes *Alochaka Pitta* (connected to eyes/mind). |
| | Sheetali/Sheetkari (Cooling Breaths) | Cools the body and mind, reduces excess heat from screen exposure and mental exertion. | Pacifies *Pitta Dosha* and associated inflammation/ irritability. |
| **Eye Exercises (Netra Vyayama)** | Palming (Rub hands to warm, cup over closed eyes) | Relaxes eye muscles, soothes strain, and induces mental calm. | Directly pacifies *Alochaka Pitta* and grounds *Vata* in the visual system. |
| | Eye Rolling and Focus Shifting (Clockwise/counter-clockwise rolls, near-far focusing) | Improves ocular flexibility, strengthens eye muscles, and combats fixation fatigue. | Stimulates *Prana Vayu* to the eyes and prevents stagnation (*Ama*) in *Srotas*. |
| | Sun Gazing (*Trataka*) (Brief, gentle gazing at sunrise/sunset) | Strengthens vision, improves focus, and is a meditative practice for the eyes. | A cleansing (*Kriya*) practice that balances *Pitta* (fire/light element) and builds focus (*Dharana*). |

| | | | |
|---|---|---|---|
| | Blinking Exercises (Rapid, conscious blinking) | Re-moistens eyes, prevents dryness, and resets the visual system. | Counteracts the *Ruksha* (dry) quality of *Vata* aggravated by screens. |
| **Environmental Design** | Designing spaces with natural materials, calming colors, and clear organization. | Reduces sensory chaos and visual stress, creating a physical sanctuary from digital overload. | Promotes *Sattvic* environment, pacifies *Rajas* (agitation)and *Tamas* (lethargy). |
| **Prosocial and Uplifting Activities** | Gratitude exercises (journaling, reflection). | Counters negative social comparison and cultivates contentment, reducing the need for external validation. | Strengthens *Ojas* (vitality) and fosters *Santosha* (contentment). |
| | Assisting others (service, volunteering). | Provides meaningful connection and purpose, fulfilling the human need for community beyond digital platforms. | Builds positive *Karma* and enhances *Sattvic* qualities of compassion. |
| | Connecting with nature (walks, gardening). | Grounds excess mental energy (*Vata*), reduces sensory overstimulation, and restores natural rhythms. | Balances all *Doshas*, especially *Vata* and *Pitta*. |
| | Participating in uplifting activities (music, art, spiritual gatherings). | Generates positive emotions (*Prasanna*) and offers intrinsic joy, reducing dependence on digital entertainment. | Increases *Sattva* and nourishes the mind and senses (*Indriyas*). |

## ABSTRACT

Domestic violence remains a significant public health concern in Kerala, with profound implications for women's physical and psychological wellbeing. This cross sectional study examined the health related quality of life of 200 domestic violence experienced women in Snehitha Institution at Kerala using the WHOQOLBREF scale. Descriptive findings revealed severe impairment across multiple domains, with notably low scores in enjoyment of life, sense of meaning, self satisfaction, body image acceptance, energy levels, sleep quality, daily functioning, and work capacity, alongside high levels of physical pain and dependency on medical treatment. Most participants belonged to economically disadvantaged (77.7% BPL) and socially marginalized groups (67.5% OBC). Shapiro–Wilk tests indicated non normal score distributions ($p < .001$), and Kruskal–Wallis analysis showed no significant variation in years of marital duration across health satisfaction categories ($p > .05$), suggesting that the adverse physical and mental health effects of domestic violence are pervasive regardless of duration of marriage. These results underscore the urgent need for trauma informed health services, mental health support, and socioeconomic empowerment initiatives for women experiencing domestic violence in Kerala.

**Keywords:** Domestic Violence, Women, Physical Health, Mental Health, Kerala

## INTRODUCTION

Domestic violence remains a pervasive global public health and human rights concern, with an estimated 36 million women experiencing physical or sexual intimate partner violence (UN Women, 2022). Evidence from India shows that survivors frequently present with PTSD, depression, anxiety, and other psychiatric conditions, underscoring the

significant mental health burden associated with intimate partner violence (Sathe *et al*., 2024). Violence affects women's physical, psychological, and socioeconomic wellbeing. It restricts mobility, disrupts employment, and diminishes overall functioning (Agarwal *et al*., 2007). Research from Kerala links spousal violence with chronic somatic complaints—including headaches, musculoskeletal pain, and gastrointestinal issues—alongside increased healthcare utilisation (Lamiya *et al*., 2023). Survivors also face long lasting psychological distress, including anxiety, depression, trauma symptoms, and sleep disturbances (Jenkins *et al*., 2025; Indu *et al*., 2021). Despite Kerala's high Human Development Index (0.790), the state reported 18,887 crimes against women in 2024, including 4,515 cases of cruelty by husband or relatives, highlighting the gap between social development and persistent gender based violence. This study examines the health determinants of domestic violence experienced women seeking support from Snehitha Gender Help Desks under Kudumbashree. The analysis is guided by three theoretical lenses—Family Subsystem Dysfunction, Power and Control Theory, and Learned Helplessness—which together explain the structural, relational, and psychological factors shaping the "silent scars" of domestic violence in Kerala.

**Hypotheses**

**H1:** Women who experience domestic violence will report significantly lower psychological wellbeing

**H2:** Domestic violence experienced women will exhibit significantly higher levels of physical pain and dependence on medical treatment, and significantly lower functional capacity

**H3:** Duration of marriage will not significantly influence physical outcomes among domestic violence experienced women.

## METHODS AND MATERIALS

**Study Design**

A cross sectional quantitative design was used to examine the association between domestic violence and the physical and psychological quality of life of women registered in Snehitha centres. The study focused on how intimate partner violence influences physical health (energy, sleep, pain, fatigue) and psychological wellbeing (selfesteem, emotional stability, cognitive functioning).

**Participants and Procedure**

The study was conducted among 200 women who had reported domestic violence by a husband or intimate partner at Snehitha centres across five purposively selected districts in Kerala: Ernakulam, Thiruvananthapuram, Malappuram, Idukki, and Alappuzha. These districts were chosen based on programme reports indicating the highest domestic violence registrations. A proportionate sampling method ensured adequate representation from each district. Data collection followed formal approval from the State Government and Kudumbashree Mission. Participants were contacted through Snehitha centres and invited for an in person, one to one interaction with the researcher. Each participant received an information sheet explaining the study purpose, procedures, potential risks, and benefits. Written informed consent was obtained, and participation was voluntary. To maintain confidentiality, no personal identifiers were collected; each respondent was assigned a unique code for analysis.

Participants completed the WHOQOLBREF scale and a short sociodemographic questionnaire.

**Measures**

**SocioDemographic Schedule**

A brief structured sheet captured age, marital details, education, occupation, and family background.

**WHOQOLBREF (World Health Organization Quality of Life – Brief Version)**

Quality of life was assessed using the WHOQOLBREF (WHOQOL Group, 1998), a validated 26item instrument covering four major domains: physical health, psychological health, social relationships, and environment. For the present study, only the physical and psychological domains were analysed, aligning with the study objectives.

## RESULTS

**SocioDemographic Profile**

**Geographical Distribution**

The study included 200 domestic violence experienced women from five Snehitha districts. Ernakulam (n = 70, 35%) and Thiruvananthapuram (n = 50, 25%) together formed the largest proportion of the sample (60%), reflecting their dense populations and active referral pathways. Malappuram and Idukki each contributed 15% (n = 30), while Alappuzha accounted for 10% (n = 20). The sample therefore represented both coastal and high range regions of Kerala. (See Table 1)

**Social Reservation Categories**

Most participants belonged to the OBC category (n = 135, 67.5%). The General category accounted for 14% (n = 28), SC for 10% (n = 20), ST for 1.5% (n = 3), and OEC for 7% (n = 14). This reflects diversity in caste representation among survivors accessing Snehitha services. (See Table 2)

**Educational Status**

A majority had school level education. High school education was most common (n = 159, 79.5%), followed by higher secondary (n = 20, 10%). Only 5% (n = 10) had primary level schooling, and 5.5% (n = 11) had completed graduation or above, indicating limited higher education attainment among survivors.(See Table 3)

**Economic Background**

Most participants belonged to Below Poverty Line households (BPL, n = 157, 77.7%), with 22.3% (n = 45) from Above Poverty Line families. This suggests a strong association between domestic violence vulnerability and socioeconomic disadvantage. (See Table 4)

**Statistical Analysis**

**Physical Health Indicators**

Descriptive statistics revealed considerable impairment across physical health variables. High mean scores for physical pain (M = 4.38, SD = 1.06) and dependency on medical treatment (M = 4.47, SD = 1.00) indicated frequent pain and functional limitations. Conversely, low mean scores were found for:

- Energy for daily life (M = 1.53, SD = 0.96)
- Mobility (M = 2.25, SD = 1.21)
- Sleep satisfaction (M = 1.35, SD = 0.81)
- Ability to perform daily tasks (M = 1.60, SD = 1.12)
- Capacity for work (M = 1.57, SD = 1.01)

Median scores (mostly = 1.00) further confirmed low functioning across these indicators. The Shapiro–Wilk test showed that all physical health variables violated normality ($p < .001$), indicating non normal, skewed distributions. Thus, nonparametric analyses were used. (See Table 5)

**Psychological Health Indicators**

Participants reported markedly low psychological wellbeing. Mean scores for Enjoyment of Life (M = 1.40), Meaningfulness of Life (M = 1.73), Self Satisfaction (M = 1.46), and Body Image Satisfaction (M = 1.77) suggested reduced positive functioning. Concentration abilities were moderate (M = 2.47). Negative feelings—including sadness, despair, anxiety, and depression—were common (M = 1.76). Median scores of 1.00 for most indicators showed strong clustering at the lower end. Shapiro–Wilk results indicated significant deviations from normality for all psychological variables ($p < .001$), supporting the use of nonparametric tests. (See Table 6)

**Association Between Years of Marriage and Health Satisfaction**

A Kruskal–Wallis H test examined whether years of marital life differed by self reported health satisfaction. The analysis revealed no significant differences across satisfaction categories, ($\chi^2 = 0.948$, $p = 0.622$). The Kruskal–Wallis test revealed no statistically significant difference in physical health scores across marital duration groups. These results indicate that poor health satisfaction was not dependent on the duration of marriage. This finding suggests that the negative physical health impact of domestic violence can occur early in marriage and persist irrespective of marital length. (See Table 7)

## DISCUSSION

**Domestic Violence Across Demographic Groups**

The district wise distribution shows that domestic violence is not confined to metropolitan areas but is widespread across Kerala. Higher representation from Ernakulam and Thiruvananthapuram may relate to stronger referral systems and availability of support services, whereas moderate representation from districts like Idukki and Malappuram may indicate underreporting or barriers to access. Overall, the findings reinforce that domestic violence is a state wide issue requiring strengthened service delivery across both urban and rural regions. Caste wise patterns show that survivors were primarily from OBC and SC households, consistent with research linking domestic violence with socioeconomic disadvantage and structural marginalization. The minimal representation of ST women may reflect population proportions but could also signal deeper underreporting in tribal communities. These results highlight the need for caste responsive policies and community based interventions that address sociocultural vulnerability and barriers to help seeking. Educational attainment results demonstrate that most survivors possessed only school level education, underscoring the increased vulnerability of women with modest educational backgrounds. The small proportion of graduates may reflect greater awareness, higher agency, or better access to support systems. These findings suggest that basic education alone does not sufficiently protect women from abuse and that empowerment, legal literacy, and economic independence programs are essential preventive strategies. The economic profile reveals that the majority of survivors belonged to BPL households, aligning with evidence that economic insecurity heightens dependence, restricts exit options, and increases exposure to unhealthy power dynamics. Although domestic violence occurs across socioeconomic groups, its concentration among low-income households emphasizes the importance of welfare linked safety mechanisms, livelihood support, and targeted economic interventions.

**Physical Impact of Domestic Violence**

The physical health results indicate substantial impairment among survivors. High levels of pain and reliance on medical treatment, combined with low scores for energy, mobility, sleep quality, daily activities, and work capacity, reflect pronounced physical distress and functional limitations. These findings align with established literature linking intimate partner violence to chronic pain, somatic symptoms, fatigue, and impaired physical functioning. Thus, H2 is supported, confirming that survivors experience significant physical health deterioration. The Shapiro–Wilk tests indicated non normal distributions for all physical variables, indicating skewness toward severe impairment and reinforcing the need for non-parametric procedures. Collectively, the findings stress the necessity for trauma informed health care services that address both immediate injuries and long-term physical morbidities.

**Psychological Impact of Domestic Violence**

The psychological indicators show severely compromised mental health across domains. Very low levels of life enjoyment, meaning, self-satisfaction, and body image acceptance, along with high negative affect, demonstrate a substantial erosion of psychological wellbeing. Although concentration ability was relatively higher, it remained below moderate levels, reflecting the cognitive strain associated with chronic distress. H1 is supported, confirming significantly reduced psychological wellbeing among survivors. Shapiro–Wilk results demonstrated significant deviations from normality across all psychological variables, indicating downward skewed distributions and warranting nonparametric analyses. These patterns reveal the profound emotional and cognitive consequences of

domestic violence and highlight the urgent need for accessible mental health interventions, including trauma counselling and psychosocial support.

**Years of Marital Life and Health Satisfaction**

The Kruskal–Wallis test showed no significant differences between years of marriage and overall health satisfaction, indicating that the duration of marital life does not influence survivors perceived health status. H3 is supported, suggesting that diminished health satisfaction emerges regardless of how long women have been married. This finding implies that domestic violence exerts immediate and ongoing harm, rather than gradually accumulating over time. Women early in marriage report levels of distress comparable to those married for decades. The result underscores the need for early identification, routine screening, and intervention efforts across all stages of marital life, rather than assuming long term marriages carry greater risk.

**Implication of the Study**

The findings highlight the need for a trauma informed, multisectoral response to domestic violence in Kerala. Strengthening early screening protocols within primary health centres, community health workers, and maternal health services is essential to identify psychological distress, chronic pain, and early signs of violence. Crisis support systems such as Snehitha centres, One Stop Centres, and Kudumbashree networks should move beyond short term interventions and provide sustained counselling, medical follow up, and rehabilitation support. The high representation of women from BPL and OBC households underscores the link between economic vulnerability and domestic violence. Therefore, livelihood support, financial security schemes, legal aid, and safe housing must be prioritised within social protection frameworks. Prevention efforts must also target cultural norms: community institutions, schools, and colleges should promote gender sensitisation and healthy relationship education. A coordinated approach across health, legal, social welfare, and community systems is crucial to reduce domestic violence related harm and improve survivors' long term wellbeing.

**Limitations of the Study**

This study has several limitations. The sample included only women who accessed Snehitha centers, which may exclude survivors who do not seek formal support and limits the generalizability of findings. Self-reported data may be affected by recall bias, emotional distress, or underreporting due to stigma and safety concerns. The cross-sectional design prevents causal conclusions about the relationship between domestic violence and health outcomes. Additionally, the exclusive use of quantitative tools restricted deeper exploration of survivors lived experiences, coping patterns, and barriers to help seeking. Future research should adopt mixed method designs, include comparative samples, and extend recruitment to rural, tribal, and socioeconomically diverse groups to strengthen external validity and capture the complex realities of recovery.

## CONCLUSION

This study shows that domestic violence severely undermines women's physical and psychological health, with survivors reporting intense pain, fatigue, sleep problems, reduced functioning, low self worth, and significant emotional distress. These findings demonstrate that intimate partner violence causes deep and long-lasting harm, especially among socioeconomically vulnerable women. The lack of differences across marital duration suggests that health damage emerges early in abusive relationships and persists over time, reinforcing the need for early detection and intervention. Effective response requires coordinated action across health, legal, and social systems through trauma informed care, accessible community support, and economic empowerment initiatives. Promoting gender equitable norms and enhancing awareness are vital for prevention. By documenting the significant health burden faced by survivors in Kerala, this study provides evidence to guide policy improvements, targeted interventions, and future research, emphasizing the need for sustained advocacy to ensure survivors' safety, recovery, and dignity.

**Other Details**

**Funding Details**

This research received no external funding. The study was conducted independently without financial support from any governmental, nongovernmental, or institutional sources.

**Competing Interests / Disclosure Statement**

The authors declare that they have no competing interests. There are no financial, personal, professional, or institutional relationships that could influence the work reported in this paper.

**Data Availability Statement**

The datasets analyzed are not publicly available due to the sensitive nature of personal and violence related information.

**Data Deposition**

Data from this study has not been deposited in any public repository owing to privacy and confidentiality considerations related to domestic violence survivors.

**Ethical Considerations**

This study adhered to ethical principles for research involving human participants. Institutional ethical approval was obtained prior to data collection. Informed consent was obtained from all participants, and confidentiality and anonymity were strictly maintained throughout the study. Participants were assured that their involvement was voluntary and that they had the right to withdraw at any stage without consequences. Sensitive questions were approached with care to minimize emotional distress, and referrals to support services were provided when needed. No identifying personal information was collected or disclosed, ensuring full protection of participant privacy and dignity

## ABSTRACT

This paper explores the development of a next-generation AI-powered Smart Attendance Management System designed to overcome the inefficiencies of traditional workforce management. The system combines real-time biometric face recognition for reliable attendance tracking with an automated payroll module and an interactive HR analytics dashboard. Unlike manual approaches that often suffer from errors, time theft, and heavy administrative workloads, this integrated solution provides a seamless, end-to-end process—from capturing attendance data to generating accurate payroll. The system is built on a modern and scalable technology stack. The backend is developed using the Python Flask framework, paired with a relational SQL database to ensure data security and consistency. At its core, the attendance module employs a machine learning pipeline powered by advanced facial recognition technology, capable of outperforming human accuracy in identity verification. This ensures precise validation of employee check-ins and eliminates fraudulent practices such as "buddy punching."

**Keywords:** Dlib, Flask, SQL Database, React Dashboard, Face Recognition, Payroll Automation, HR Analytics

# INTRODUCTION

Employee attendance management has become more sophisticated from simple manual processes to automated, high-technology systems. Attendance was documented on paper logbooks, punch clocks, or time cards in the past. These practices were adequate for small-sized organizations but soon became ineffective with increasing business volumes. Human resource personnel had to collect time cards, confirm them with managers, and input data into payroll systems manually—an exercise that took a lot of time and was prone to errors like omitted entries, arithmetic mistakes, and transcription errors. As digital technologies arrived, organizations started to move towards computerized time-tracking methods. Systems in the early days used equipment like magnetic stripe cards or keypads to cut paperwork and ease record-keeping. With time, though, the utility of these systems went beyond convenience. Automated data capture provided consistent, real-time attendance records that enhanced payroll accuracy, reduced controversies, and provided higher transparency in employee management. This shift presented a watershed moment when attendance tracking was no longer considered an administrative task, but an essential part of strategic HR processes and workforce analytics. While electronic and biometric systems have helped improve attendance tracking, severe challenges persist. Manual systems are especially vulnerable to fraudulent activities like "buddy punching," where workers punch attendance for others, leading to productivity loss and an increase in labour costs. Moreover, HR staff tend to spend substantial time keying and cross-checking attendance, which leaves less time for more valuable, strategic work. Inaccurate or inadequate information also causes payroll errors and possible compliance problems with labour laws. Even current automated technolo==gies have their limitations.

Most organizations make use of disconnected technology stacks, in which attendance solutions, payroll platforms, and HR analytics tools work independently of each other. For instance, even if a biometric reader takes precise attendance records, the information frequently has to be manually uploaded into payroll software, leaving room for error and inefficiency. This absence of integration does not allow organizations to realize one credible source of workforce information and detracts from the power of automation to automate operations. In the current business scenario, marked by versatile work arrangements and increased pressure for data-driven decision-making, autonomous workforce management is a must. Those businesses that implement digital attendance and payroll technology enjoy enhanced accuracy, minimized time theft, and tighter regulatory compliance. Research has shown that automation can greatly improve payroll accuracy, eliminate fraudulent activity, and lower operational expenses, making automation an essential investment and not an auxiliary tool. Although these innovations exist, there is one overriding research gap: the majority of current systems offer incomplete automation. Some address biometric identification, some payroll, and some analytics, but few offer a comprehensive, end-to-end answer. Existing solutions still involve some degree of manual intervention, bringing with it inefficiencies again. This research bridges that gap by introducing an integrated solution that brings together biometric attendance tracking, auto-generated payroll, and real-time HR analytics through a single platform. Such an integration makes workforce management not just an administrative chore but a strategic tool for organizational development.

# LITERATURE SURVEY

**Existing Attendance and Payroll Solutions**

The HR technology market is strong and fragmented, with several providers providing niche solutions. On the other hand, there are full-service payroll providers such as ADP, Gusto, and On Pay that provide strong payroll processing, tax reporting, and other HR features[12]. These platforms are strong but tend to make time and attendance tracking a secondary feature, which might not be as advanced or integrated as a specialized solution. For example, Gusto offers time-tracking features, but they are a separate feature within a larger HR system[12]. Conversely, there are dedicated time and attendance software such as Homebase and Connecteam, which are great at time tracking for hourly or remote staff, usually carrying GPS tracking and geofencing features[13]. These systems perform extremely well in their intended use but usually need independent integrations with third-party payroll programs, once again presenting the data transfer complications and errors integrated systems seek to avoid[13].

Likewise, hardware-based biometric systems, such as fingerprint or iris recognition systems, offer high-accuracy attendance records but still need smooth integration with payroll software to achieve their maximum benefit[8, 11]. The present situation thus includes either general HR platforms with rudimentary time tracking or dedicated time trackers without native payroll and advanced analytics features.

**Review of AI and ML in Workforce Management**

The use of Artificial Intelligence (AI) and Machine Learning (ML) is a significant trend that is transforming the HR environment[14]. The technologies are being implemented to automate mundane processes, increase workforce analytics, and enhance overall operational effectiveness[14]. One of the most effective uses is AI-driven biometric authentication, especially facial recognition, for attendance monitoring. Academic and technical studies have proven the feasibility and validity of the technology for real-time attendance tracking[15, 16]. Contemporary face recognition algorithms like those provided in libraries deepface and face-recognition have attained considerable accuracy, with certain models outperforming human accuracy in facial recognition[6, 7]. A standard facial recognition attendance pipeline consists of a number of steps: face detection, alignment, normalization, representation (generating a distinctive vector embedding or "faceprint"), and verification[6, 17]. At the center of these are Convolutional Neural Networks (CNNs) and other deep learning techniques, which enable systems to precisely identify and verify individuals from live video streams or photographs[16]. The application of AI in attendance systems not only guards against fraud but also facilitates more sophisticated functions such as analyzing attendance patterns and forecasting likely absenteeism, changing a reactive task into a proactive task[9, 18]]. AI and ML in Workforce Management (Fig 1).

**Comparative Analysis and Novelty of the Proposed System**

The suggested AI-based attendance system differs from the current solutions in that it offers a native, integrated architecture with three intrinsic functions—biometric attendance, payroll automation, and strategic analytics—combined into a single platform. This is a key difference from the present market, in which solutions tend to be composable, i.e., they have to be integrated and managed as multiple discrete systems[18]. The fundamental value proposition of this system is its integrated data model. By storing attendance, leave history, and payroll data in one neatly organized database, the system makes a "single source of truth" for all workforce data[5, 19]. With this architecture, powerful cross-functional analysis is possible that is hard to accomplish with piece-by-piece solutions even with strong integrations. The system can, for instance, immediately link attendance information to payroll expenses to determine a "Cost of HR per employee" or "Revenue per employee" measure[20]. Smooth data flow from entry to ultimate calculation is not so much a technical convenience as strategic benefit, allowing an extent of simplicity and effectiveness that maximizes the role of HR and its alignment with overall business goals[21]. The following table provides a high-level comparison to demonstrate the unique positioning and value of the proposed system within the current HR technology (Fig.2). Comparative Analysis of HR Tech Solutions (Table 1).

## METHODOLOGY

**Core System Components and Data Flow**

The system is architected with a three-tiered structure: a front-end for user interaction, a back-end for processing and logic, and a database for persistence. The front-end is a web-based interface that users access through a browser, which connects to an attached webcam for live facial capture and verification. The back-end is a web application developed in Python with the Flask framework[22]. The application is the central point, doing all business logic, API request handling, data processing, and communication with the database. The database tier employs the use of a relational database management system, e.g., MySQL, to keep all the employee information, attendance records, and payroll in a formatted, consistent form[5, 19]. The flow of data in the system is strictly a logical and well-defined sequence. An employee first interacts with the front-end, where a webcam records a live feed. The feed is sent to the backend, where the images are processed in order to detect and recognize the person's face. After verifying an identity, the system records a timestamp and updates the Attendance table in the database[19]. The back-end then

calculates automatically hours worked, and this information is used as a basis for the payroll module. The payroll module, which draws from the same database, computes this data applying rules for basic salary, overtime, and deductions to determine gross pay[5]. At the same time, the HR dashboard module extracts current data from the database, taking raw attendance and payroll data and converting them into actionable visualizations such as charts and graphs. This single stream of data guarantees that information is correct and current throughout all modules, from original capture to ultimate analytical presentation.

**Technology Stack**

The choice of the technology stack for this system is deliberate, balancing efficiency, scalability, and security.

**Python:** As the core programming language, Python has a rich ecosystem of machine learning, data processing, and web development libraries[23]. Readability and ease of use make it go fast and keep the codebase sustainable.

**Flask:** Flask was selected as the web framework due to its micro-framework philosophy that encourages a modular and lightweight approach[22]. Its lightness enables programmers to create a bespoke application without the weight of larger, more opinionated frameworks. Also, Flask's modularity is best suited to create unique components such as the attendance module, payroll module, and dashboard module as individual blueprints, which is a vital aspect of creating a scalable application[24].

**SQL Database:** A relational database system is essential for a system that handles complex and interconnected data such as employee records, attendance reports, and payroll information[5]. The relational model provides data integrity, consistency, and transactional security. The implementation of prepared statements and proper sanitization of inputs also guards against security threats such as SQL injection, which are popular threats to database-driven applications[23]].

**Machine Learning Library:** The application employs a strong, open-source machine learning library, e.g., deepface or face-recognition, to support its facial recognition features[6, 7]. These libraries are performance-optimized and include pre-trained models that can deliver high accuracy without the necessity of large training data.

**React with TypeScript:** The HR dashboard is implemented with React combined with TypeScript, providing a contemporary, component-based architecture that is maintainable and scalable. React's virtual DOM provides rapid and dynamic rendering of intricate data visualizations, and TypeScript adds static typing, which minimizes runtime errors and enhances overall code stability. This setup enables the dashboard to provide an intuitive, interactive user interface for HR analytics and payroll management, enabling real-time insights and hassle-free decision-making**.** System Technology Stack and Functionality (Table 2).

**Face Recognition Methodology**

The system's facial recognition is the basis of its accuracy and fraud prevention features. The method isn't just picture comparison but a sophisticated multi-step process that is based on deep learning. The process can be described as five elementary stages, as per a hybrid framework like deepface [6]

**Detect:** The system first detects all human faces in a recorded image or video frame. This detection is crucial for delineating the region of interest for subsequent analysis.

**Align:** Once a face is detected, the system subsequently aligns it to a canonical pose. This operation normalizes differences in head tilt or orientation to enable the model to properly compare different facial captures.

**Normalization:** The aligned face is processed to normalize the levels of light and contrast so that environmental impact on recognition performance is reduced.

**Represent:** During this important stage, the system utilizes a deep model (for example, VGG-Face, FaceNet) to convert the normalized face image into a multi-dimensional vector, or "faceprint"[6]. The vector is a numerical representation of the unique facial characteristics of an individual. The distance among the vector embeddings of a single person is computationally shorter than the distance among the embeddings of various individuals and thus is readily separable [6].

**Compare:** The new faceprint is compared with a set of previously registered employee faceprints in the database[6, 17]. A match is confirmed and the individual recognized if the similarity between the new faceprint and an existing one is below a threshold.

This multi-stage process not only makes the system precise but also robust against diverse problems like variable lighting and changes in appearance that are minimal. It is this technological foundation that gives the system its ability to prevent "buddy punching" and other types of time theft effectively, something that cannot be achieved by manual systems[8, 9]. The system stores a secure "faceprint" of all employees within the database, which is then utilized for verification, producing a high degree of security and an "ironclad audit log" for each event of attendance [11](Fig. 3).

**Insights**

**Automated Payroll Integration**

A standout feature of the proposed system is its seamless and fully automated integration with the payroll module. This direct link eliminates the manual data entry that has historically been a source of errors and administrative overhead[3, 8]. The attendance module, by virtue of its real-time tracking, provides an accurate count of hours worked for each employee[8]. This data is not simply exported; it is natively consumed by the payroll module within the same system. The payroll module is configured with a set of rules that automatically apply to the attendance data. It calculates basic salary, tracks overtime hours, and applies deductions for approved leave days[5]. This automation ensures that the final payroll amount is directly and accurately derived from verified attendance logs. For organizations, this integration saves countless hours of manual reconciliation, reduces the risk of costly payroll errors, and ensures compliance with labor laws[3, 8, 11]. It transforms the payroll process from a tedious, error-prone task into a streamlined, automated function, allowing HR to focus on more strategic responsibilities (Fig. 4).

**Interactive Dashboard and Data Visualization**

The HR dashboard serves as the nerve center of the system, transforming raw data into clear, actionable visualizations for management and HR professionals[10, 25]. Dashboards are designed to consolidate data from various sources—in this case, attendance, leave, and payroll—to provide a high-level, real-time overview of key workforce metrics[21]. Unlike static reports, a modern dashboard is dynamic and interactive, allowing users to filter data by department, time range, or other criteria to gain more granular insights[10, 26]. The dashboard displays a range of metrics crucial for understanding the workforce. Common visualizations include charts showing the current headcount, employee turnover rates, absenteeism rates, and total leave taken[10, 25, 26]. These visualizations provide a quick, at-a-glance understanding of the workforce's size and structure, allowing managers to monitor key trends and keep a finger on the organization's pulse[10]. The system's ability to consolidate all data into one location is a significant efficiency gain, saving time and providing immediate insights for stakeholders at all levels[21] (Fig. 5).

**Workforce Analytics Module**

The system's true strategic value is realized through its workforce analytics module, which moves beyond mere reporting to provide deep, contextual insights. While the dashboard shows *what* is happening (e.g., a high absenteeism rate), the analytics module is designed to help management understand *why* and what to do about it. By analyzing trends over time, the system can provide valuable insights into employee behavior and organizational health. For example, by tracking the absenteeism rate over a specific period, the system can identify recurring patterns or spikes in a particular department or team[10]. This information can signal potential issues like burnout or low morale. By correlating attendance data with other metrics, such as overtime hours or employee tenure, the system can help forecast future workforce trends, such as potential attrition or the need for more efficient resource

allocation[20, 21]. This proactive capability transforms the system from a simple record-keeper into a predictive business partner for HR. It allows managers to make informed decisions and take preventative measures, such as adjusting workloads or implementing wellness initiatives, to improve employee engagement and retention[21]. This functionality is a direct result of the system's unified data model, which provides a holistic view of the workforce, making it possible to derive these complex, interlinked insights. Key Workforce Analytics Metrics and Visualizations (Table 3).

**Scalability and Security Features**

The system is architected to be both scalable and secure, two critical requirements for any enterprise-grade application. Scalability is addressed at multiple levels, from the application framework to the database. The modular design using Flask blueprints allows for the independent development and deployment of different features, which is crucial as the application grows[24]. For the database, scalability is achieved by optimizing database queries and implementing caching solutions like Redis[27]. This reduces the load on the database and improves the response times of the application, ensuring it can handle a growing number of users and transactions without sacrificing performance[27]. Security is not an afterthought but a foundational design principle. Given the sensitive nature of the data it handles—including biometric identifiers and payroll information—the system incorporates robust security mechanisms from the ground up[23, 28]. The system employs user authentication, role-based access control (RBAC), and password hashing to protect user accounts[28]. It is also designed to follow secure coding practices, such as sanitizing all user inputs to prevent injection attacks and using prepared statements for database queries to separate user data from SQL logic[23, 29]. The "principle of least privilege" is applied to the codebase, ensuring that each module or process has only the permissions necessary to perform its function[29]. The use of advanced biometric face recognition further enhances security by providing a reliable method to prevent unauthorized access and time fraud[17].

## IMPLEMENTATION AND RESULTS

**System Implementation and Setup**

Implementing the system requires a simple procedure that is designed to be user-friendly. The initial action for an organization is registering its workers. This entails taking and saving a sequence of photographs of the face of each employee[30]. These photographs are then employed for training the machine learning algorithm, which translates the facial characteristics into a numerical "faceprint" or vector representation that the system can comprehend and utilize in subsequent verification[17, 30]. The larger the number of photographs offered during this first-time training, the better the recognition will be[30]. The procedure is a single-time installation that allows the core functionality of the system. Upon the completion of training, the system can now be used. The employees can just go to the specified workstation or terminal with a webcam, and the system will identify and detect their face automatically, and record their attendance in real-time[17, 30]. The process is fast and without any manual intervention, and it avoids queues and admin time[17]. The attendance information will then automatically record and be prepared for processing by the payroll and analytics modules.

**Visualizations and Sample Data Analysis**

The strength of the system can be best illustrated through the user interface and the insights it offers. The dashboard is intuitive, giving complicated data in a straightforward, graphical form. For example, an employee could log on and instantly notice a graph showing the number of staff members in each department for the day. Example queries for a populated database can indicate how the system would present important metrics. For instance, a request to SELECT COUNT(employee_id) AS total_employees FROM employees; would fill a dashboard card with the company's total number of employees[19]. Likewise, an examination of the Attendance table may uncover SELECT department, COUNT(employee_id) AS number_of_employees FROM employees GROUP BY department;, which would be rendered as a basic bar chart displaying a departmental breakdown of the workforce[19]. The system would also offer an easy-to-read tabular presentation of the attendance records, enabling the HR to easily see individual

employee information, such as check-in and check-out times, total hours worked, and leave status[30]. Through the use of simple SQL queries and the presentation of the results in a clear visual format, the system demonstrates its capability to transform raw attendance data into useful, understandable information. This feature offers the transparency and insights required by HR and management for them to make intelligent decisions (Fig 6).

## CONCLUSION

This paper has presented a new AI-driven Smart Attendance Management System, showing how it can radically improve workforce management. The novelty of the system resides in its integrated architecture, which harmoniously integrates AI-based face recognition for attendance, direct payroll automation, and a robust HR analytics dashboard. This holistic approach effectively overcomes the systemic inefficiencies of conventional approaches and fragmentation of most contemporary solutions. This work's main contributions are technical and practical: a technical one in terms of its integrated, modular design and a practical one in terms of its concrete business value. The system gives organizations a single, trusted platform to manage their workforce, minimizing administrative loads, avoiding expensive mistakes, and offering transparency that enables strategic, fact-based decisions. The system converts a mere operational function into a strategic one, offering an integrated and open picture of a firm's human capital.

### FUTURE SCOPE

The core architecture of this system offers a foundation for far-reaching future growth and innovation. Among the areas for growth are:

**Cloud Deployment:** Transferring the system from a local server to a cloud-based, scalable platform such as AWS or Microsoft Azure would provide enhanced accessibility, stronger data security, and the capability to handle attendance for geographically distributed teams[9,]. This would further facilitate tighter integration with other cloud-based HRIS and business intelligence software.

**\tIntegration of a Mobile App:** Creating a companion mobile app would serve the increasing trend of remote and hybrid work models. The app may utilize GPS and geofencing technologies to allow precise clock-ins for workers who work from off-site locations[9, 13]. It may also offer workers a self-service facility through which they can view their attendance, apply for leave, and access payroll information[3]}.

**\tAI-Powered Predictive Analytics:** The analytics component can be upgraded with even more sophisticated machine learning algorithms to make workforce predictions. With an analysis of past attendance, leave, and performance records, the system would be able to forecast future attrition levels, detect employees prone to burnout, and align staffing schedules to future requirements. This would make the system a genuinely predictive and strategic one.

**Internet of Things (IoT) Device Integration:** The biometric capability of the system can be extended to integrate with other IoT devices. For instance, it can be integrated with smart locks and cameras to offer integrated physical access control, linking automatically an employee's entry into a building or room to their attendance log[8, 11]. These future enhancements would further solidify the system's position as a comprehensive, scalable, and intelligent solution for modern workforce management.

**Table 1: Comparative Analysis of HR Tech Solutions**

| Feature | Proposed System | Standalone Time Tracker (e.g., Buddy Punch) | Payroll Service (e.g., Gusto) | Full HRIS (e.g., Workday) |
|---|---|---|---|---|
| **Biometric/Face Recognition** | Native and Core | Add-on / Optional | Limited / Third-party | Optional Module |
| **Automated Payroll Integration** | Native and Seamless | Requires Third-party API | Native | Native |
| **Real-Time Dashboard** | Native and Interactive | Basic Reporting | Standard Reports | Advanced Reporting |
| **Workforce Analytics** | Deep and Integrated | Basic Time-based Metrics | Limited | Comprehensive |
| **Ease of Integration** | Out-of-the-box (All-in-one) | Low | Low | High |
| **Cost-Effectiveness for SMBs** | High | Medium | High | Low (typically enterprise) |

**Table 2: System Technology Stack and Functionality**

| Technology | Category | Role in the System |
|---|---|---|
| **Python** | Backend Language | Core logic for all modules; data processing and analytics. |
| **Flask** | Backend Framework | Manages web requests, defines API endpoints, and structures the application with blueprints for scalability. |
| **SQL Database** | Database | Stores all structured employee, attendance, and payroll data in a secure, relational format. |
| **DeepFace/face-recognition** | Machine Learning Library | Handles the entire facial recognition pipeline, from detection to verification, with high accuracy. |
| **Flask-Security** | Security Library | Provides robust authentication, user management, and role-based access control. |
| **React, Typescript** | Frontend | Creates the user interface for the dashboard and the live webcam stream. |

**Table 3: Key Workforce Analytics Metrics and Visualizations**

| Metric | Business Significance | Suggested Visualization |
|---|---|---|
| **Absenteeism Rate** | Identifies potential for burnout, low morale, or understaffing. Helps management take proactive steps to support employees. | Line Chart (changes over time), Bar Chart (by department/team) |
| **Employee Turnover Rate** | Quantifies workforce stability and helps identify departments or roles with high attrition. | Pie Chart (proportional breakdowns), Line Chart (trends over time) |
| **Average Employee Tenure** | Indicates employee loyalty and the effectiveness of retention strategies. | Bar Chart (by department), Pie Chart (by tenure brackets) |
| **Overtime Hours** | Highlights potential for understaffing or over-reliance on a few employees. Signals areas for process improvement or hiring. | Bar Chart (by employee/department), Line Chart (weekly/monthly trends) |
