ABSTRACT

Content-Based Image Retrieval (CBIR) within computer vision enable users to find visually similar image in extensive databases through image content, rather than relying on metadata or keyword-based systems. Artificial Intelligence (AI) and Deep Learning (DL) have changed Content-Based Image Retrieval systems in the last few years by making it possible for them to learn features automatically and understand images better. Deep learning-based CBIR solutions currently struggle to overcome four main limitations, which produce poor feature interoperability and feature selection, as well as restricted spatial evaluation models, in addition to background noise overfitting. The problems in feature retrieval and computational efficiency mainly affect retrieval accuracy when processing diverse complex datasets. The proposed Multi-Attention Capsule Support Vector Machine-Convolutional Neural Network (MAC-SVM-CNN) framework introduces a solution to resolve current CBIR challenges. This method divides its operation into three sequential processing stages which include preprocessing and then feature extraction before classification occurs. The Deep Attention-Guided Filtering (DAGF) method serves as the deep attention-guided filtering approach for image preprocessing. The field of feature extraction uses the Hierarchical Cross-Attention Vision Transformer along with Particle Swarm Optimization (HCA-ViT-PSO) process. The MAC-SVM-CNN serves as the classification method. Through the DAGF module, users receive enhanced images with reduced background disturbances, as attention-driven filters effectively eliminate noise. The HCA-ViT-PSO model attains multi-level discriminatory features through

cross-attention patch connections combined with PSO optimization for dimensional and relevant feature selection. The classification portion of MAC-SVM-CNN utilizes spatial-aware capsule layers together with attention mechanisms and a margin-maximizing SVM to perform efficient content similarity-based image ranking and matching.

Keywords: Content-based Image Retrieval, Image preprocessing, Particle Swarm Optimization, Deep Attention-Guided Filtering, Multi-Attention Capsule, Support Vector Machine, Vision Transformer, Spatial evaluation.

INTRODUCTION

The vital domain of CBIR within computer vision presents an approach for automatically collecting images from large databases through visual content analysis, rather than text-based metadata. The fundamental function of CBIR entails the extraction and comparison of image features based on color, texture, shape, and spatial arrangement to identify similar matches for any given query image [1]. The previous generation of Content-Based Image Retrieval systems used manual quality to get information from pictures. These systems, on the other hand, had a hard time understanding pictures and were very sensitive to changes in size, orientation, and noise. Deep learning and artificial intelligence have made content-based image retrieval systems much better, especially when it comes to finding similar images and extracting features. Research [2,3] shows that the models help CBIR systems find high-level semantic features that are similar to how people see things. The cool features added by Vision Transformer (ViT) and attention mechanisms, these models can tell the difference between things and understand the context very well. Modern AI-powered CBIR systems use a mix of local and global features to make sure they work very well when searching through multimedia databases, medical diagnostics, and surveillance. Even though they have got better, still the latest CBIR models hit big hurdles to actually use them. Pooling in a CNN strip away where parts of picture belong, so the image looks flat; meanwhile attention doesn't catch those tiny details that really count. When deep models are used on old data they often can't talk to other systems; they can't handle mixed data well and they end up overfitting [5]. Tech today holds back CBIR tools, so they can't hit the accuracy or scale that needed when they actually use them, therefore, they fall short. The new MAC-SVM-CNN method aims at the problems you see in image-search tools, therefore gives a different way to sort pictures. Hooking capsule nets with layers that zero-in on the key visual parts, then the system just shoots up stronger results. The output feels far more powerful. The user adds an SVM to the program, the system draws steady lines when it decides if two pictures match. That new MAC-SVM-CNN setup actually pulls off better image searches, it lets the system see where things are, therefore the results look clearer.

RELATED WORKS

Gu Y *et al*., found that the results were surprising. Deep Graph Based Multimodal Feature Embedding (DGMFE) a fresh way to pull up endomicroscopy images, where it merges many data types via graph neural networks. It pulls in both nearby details and the overall image, therefore the search works better. It gobbles up so much computer power. So, it just can't keep up when the data gets huge [6]. Kumar G V R M and his teammates built a stacked Siamese Neural Network (SSiNN). By spotting similar neural patterns, the system pulls matching pictures faster for content-based image retrieval. It uses a layered Siamese design to pull out features. It occupies lot of memory and still can't handle brand-new classes [7]. Pradhan J *et al*. built DNA-CBIR after studying how DNA codons line up and found that the outcome shifted and could pull deep features from similar sequences. It separates image features better, but it's still tricky, therefore using it on many different picture types is hard [8]. Siva Kumar M *et al*., have done the work. Also, the idea is simple that built a fast picture finder using layered nets which grabs the right images on spot. It runs faster and finds more accurately even noisy pictures still trip it up [9].Lu H *et al*., suggested that they invented Deep Fuzzy Hashing Network, which they call DFHN by Mixing fuzzy logic with hashing, authors end up

with short binary codes which will find things later. When it pulls data faster, accuracy drops when the pictures look almost identical [10]. PreethyByju and the team, studied and created a step-by-step image search tool for JPEG-2000 compressed satellite archives. The way it judges similarity improves a bit each round. If the connection is slow, the technique barely manages huge raw pictures, so its effectiveness drops [11].Alsmadi M K *et. al*. established a standard CBIR system using color, shape, and texture features as descriptive parameters. This method provides a clear interpretation but struggles to scale and lacks capabilities for semantic analysis [12]. M. Garg *et al*. say it works well and created a hybrid detection method that pulls together a fresh take on the Gray-Level Co-occurrence Matrix and a tweaked Local Binary Pattern which spots stuff older methods. Authors add extra texture data for higher precision, the mix of textures does not help us see the hidden shape behind crazy image sketches which can spot differences in photos that look almost the same, so the result ends up much clearer [13]. Ma L *et. al*., suggested that Deep Progressive Asymmetric Quantization (DPAQ-CI) using causal tricks, making fine-grain image processing better, refined features improved, therefore pictures look sharper. It gives better detail but cost big on training, so it still can't really explain much [14].Arai H et., suggested and created a disease-focused image embed tool called DOIE-PSS, it works with a fake scanner set-up which can pull 3-D brain MRIs quicker. It can smooth out the differences between scanners while still highlight disease details, but when author put it on other medical scan equipment it just doesn't work well [15]. Survey of various DL methodologies of CBIR systems (Table1).

PROPOSED METHODOLOGY

The proposed framework for content-based image retrieval utilizes a MAC-SVM-CNN architecture as a deep learning approach. It aims to enhance retrieval effectiveness by determining how well-suited an image category is for a given query. The features used for image retrieval come from the Corel 2K dataset, which is well-suited for image content analysis. This work goes beyond conventional models to use a combination of Hierarchical Cluster Analysis (HCA) and ViT (Vision Transformers) as the actual image feature extraction model. HCA is able to group images such that images within the same group are semantically similar. ViT, which is a Transformer-based architecture, is able to work well with the kind of features extracted with HCA. HCA + ViT is a really good feature extraction combination, though it's not one that it will find in many places, if at all. Architecture Diagram of Proposed method (Figure 1). The proposed Content-Based Image Retrieval system is depicted in Figure 1. This system uses advanced artificial intelligence techniques to match images accurately. The operation of the system initiates with a preprocessing step applied to the input image. The preprocessing algorithm, which is called Directional Adaptive Guided Filter (DAGF), was developed and it performs two operations: First, it identifies and enhances the regions of the input image that contain the most important visual information. At the same time, it effectively reduces the background noise that is present at the visual boundaries of these regions. In other words, it greatly improves the visual quality of the image so that it can extract the most meaningful features from it. The enhanced input image is still an image of the same visual content as the original input image. At this point, it has a superior quality image in hand that it was ready to use as a basis for performing feature extraction.

Deep Attention-Guided Filtering (DAGF)

So, this Deep Attention-Guided Filtering (DAGF) is the main way to prepare data for the CBIR architecture that should use. DAGF is a new way to filter images that uses deep learning and attention techniques to focus on the most important parts of the pictures. It makes sure that the important information and visual parts are in sync by getting rid of noise and keeping the important parts of the images. In terms of object-level focus, DAGF not only maintains object border (edge) visual quality but also good texture quality as well as good spatial quantity and spatial pattern quality. DAGF maintains these very different (and all very important) visual properties because they are all essential to good object identification both at the human and at the machine level. Preprocessing begins with the input image $I(x, y)$, which lies in the domain $R^{H\times W\times C}$. The points in this space correspond to the size and shape of the image, given by its height H and width W, and its number of color channels C, which are formatted in RGB. For our testing, we bled the images into the Corel2K-Image dataset from which our database arises. The way we applied attention in our work was by using a deep function $f_{att}(.)$which outputs an attention map A(x,y) that tells us were, in the image,

we should be looking. The output from $f_{att}(.)$is made adaptive by the $\sigma(\cdot)$activation function, which gives us values that range from 0 to 1.

$$A(x,y) = \sigma\left(f_{att}\left(I(x,y)\right)\right) \quad \text{Eq. (1)}$$

The attention-weighted map visually highlights important parts as high-weight areas, while minimizing background and noise areas through low weights. Structural regularization through guidance image $G(x,y)$ co-occurs with parallel processing of $I(x,y)$, which becomes the blurred version of $I(x,y)$. The calculation of $I_D(x,y)$ begins with blending between $I(x,y)$ and $G(x,y)$ based on the attention values at each (x,y).

$$I_D(x,y) = A(x,y).I(x,y) + \left(1 - A(x,y)\right).G(x,y)) \quad \text{Eq. (2)}$$

The equation protects essential features from being eliminated while it eliminates unimportant noise and irrelevant information. The output image $I_D(x,y)$ advances to the feature extraction process E. The end product of this stage produces a deep feature vector F.

$$F = E(I_D) \quad \text{Eq. (3)}$$

The optimized feature representation enables detection of intricate relationships between semantic and spatial properties in images that uses for classification and similarity measurements. The complete preprocessing process delivers superior retrieval outcomes that make the system very effective for content-based image search operations.

Hierarchical Cross-Attention Vision Transformer along with Particle Swarm Optimization (HCA-ViT-PSO)

The DAGF image enhancement outcome undergoes feature extraction via the HCA-ViT-PSO method to obtain crucial image attributes. The ViT method preprocesses images by dividing them into equally sized patches, which undergo tokenization before processing through the transformer layers. A key aspect of the ViT method is the crossover attention mechanism. This is a dominant architectural feature of the ViT method, which allows it to make use of the Cross-Attention mechanism. This is important because performing Cross-Attention in a ViT model can allow for very low-resolution fine details to be tightly bound with high-level, more abstract (and thus less detailed) visual features. A good way to think of Cross-Attention in the context of DAGF enhancement is that it allows for a very high-level understanding of the whole visual feat. By adjusting its updates through both personal best achievements and group best achievements, the system directs its search towards the optimal feature set for convergence. Content-based image retrieval systems employ the final, optimized feature vector $F = E(I_D)$, which gathers various spatial and semantic patterns along with discriminative characteristics to achieve high-accuracy image retrieval. The image that underwent preprocessing as $I_D(x,y)$ gets split into fixed-size image patches. Each segment of the image receives a patch embedding transformation to form a feature vector $p_i \in R^d$, while d signifies patch embedding dimensions across all n image pieces to create the total set $P = \{p_1, p_2, \ldots, p_n\}$. Positional encoding e_i is added to every patch embedding to preserve the images' spatial structure before passing it to the Vision Transformer.

$$z_0 = [p_1 + e_1, p_2 + e_2, \ldots, p_n + e_n] \quad \text{Eq. (4)}$$

The transformer layers organize their operations through hierarchical structures to process information at several semantic levels. The cross-attention mechanism M in these layers enables interaction of representations across levels through equation 5.

$$M(Q,K,V) = softmax\left(\frac{QK^T}{\sqrt{d_k}}\right)V \quad \text{Eq. (5)}$$

The input computations consist of $Q = z_l W_Q, K = z_{l'} W_K$, and $V = Z_{l'} W_V$, through which z_l and $z_{l'}$ refer to hierarchically separated representations while W_Q, W_K, and W_V stand for learnable weight matrices and d_k represents the key dimension for dot-product scaling. The dot-product attention receives modifications from the learnable projection weights W_Q, W_K, and W_V while the key dimension is d_k. PSO serves as an optimal feature selection method, which we use to enhance extracted features while minimizing redundancy. Each particle $X_i = [x_{i1}, x_{i2}, \dots, x_{id}]$ contains binary vectors $x_{i1}, x_{i2}, \dots, x_{id}$ that choose features or discard them while x_{ij} takes values in {0,1}. The update process for velocity and position values of each particle relies on equation 6.

$$v_i^{t+1} = \omega v_i^t + c_1 r_1 (p_i - x_i^t) + c_2 r_2 (d - x_i^t)$$
$$x_i^{t+1} = x_i^t + v_i^{t+1} \qquad \text{Eq. (6)}$$

The evolution of each ith particle velocity v_i^t at t iteration involves personal position p_i together with global best g through velocity controller operations with random values r_1, r_2 drawn from $U(0,1)$ applied to the current position x_i^t. The constants ω, c_1 and c_2 control inertia and the balance between exploration and exploitation. The algorithm provides the optimized feature vector as a result through equation 7.

$$F = PSO(I_D) \qquad \text{Eq. (7)}$$

The post-optimization vector consists only of the most vital features for classification, enabling retrieval. This final representation allows the CBIR system to operate on the reprocessed data with higher precision and efficiency.

Algorithm 1: HCA-ViT-PSO
Input: $I_D(x, y)$,
d,
W_Q, W_K, W_V
$\omega, c_1, c_2, r_1, r_2$
Number of i and t for PSO
Output: F

Start
Step-1 : Split $I_D(x, y)$ into fixed size patches
For each P:
Calculate $p_i \in R^d$ its embedding
Add e_i to each $p_i \in R^d$ like
$z_0 = [p_1 + e_1, p_2 + e_2, \dots, p_n + e_n]$
End for

Step-2: For each l, evaluate,
$Q = z_l W_Q, K = z_l' W_K, V = z_l' W_V$
Apply $M(Q, K, V) = sofmax\left(\frac{QK^T}{\sqrt{d_k}}\right)V$
Acquire $E(I_D)$ from final transformer output.
End for

Step-3: Each $X_i = [x_{i1}, x_{i2}, \dots, x_{id}]$ is a $x_{i1}, x_{i2}, \dots, x_{id}$ which representing as selected features (0 ,1)

Step-4: F evaluation must utilize a function that assesses classification accuracy and retrieval performance.
Update v_i^{t+1} and x_i^{t+1} for each t
Run PSO until both convergence and maximum t limits have been met.

Return the $F = PSO(I_D)$

Step-5: The improved accuracy can be achieved by using the final F with reduced dimensionality through CBI.
Stop

Figure 2 illustrates the workflow process of the HCA-ViT-PSO methodology employed by our CBIR system. Enhancement of preprocessed images starts by implementing the DAGF method. This modified image undergoes segmenting treatment into uniform patches before the implementation of patch embedding, producing vectors when d serves as the embedding dimension. Each embedded patch receives its assigned positional encoding, which maintains spatial relationships for the resulting input sequence. The sequence passes through multiple stages of a hierarchical Vision Transformer that combines low-level and high-level features through cross-attention mechanisms. The model gains improved capabilities in recognizing complex visual patterns, as it allows data to move seamlessly between different levels of semantics. PSO optimization of deep features occurs when each component examines the features for either retention or elimination. The system updates both the positions and velocities of particles, while ω controls inertia. The learning factors are c_1 and c_2. Additionally, r_1 and r_2 are random variables uniformly distributed between 0 and 1, and g represents the best overall position. An optimized feature vector retains the most significant discriminative elements for retrieval and classification operations, while also improving accuracy and reducing computational requirements.

Multi-Attention Capsule-Support Vector Machine-Convolutional Neural Network (MAC-SVM-CNN)
The HCA-ViT-PSO method produces optimized features upon execution, which are then delivered to the MAC-SVM-CNN classifier for precise image classification and retrieval tasks. The MAC-SVM-CNN represents a model that combines the benefits of attention mechanisms with capsule networks and SVM, as well as CNN capabilities. The feature vector delivered by HCA-ViT-PSO is fed into a multi-attention mechanism, which assigns specific weights to each feature component. The Capsule Network receives an attention-weighted vector from this stage to grasp relationships between various features as well as overall component connections. One capsule contains computational capability that generates a vector representing specific image class entities' instantiation parameters. The capsule routing capabilities help the network build organizational structures and study positional changes while focusing on detailed image analysis. After being obtained from the capsule network, the vectors are flattened before being processed with a CNN for further spatial feature abstraction. As the final step of the processing, an SVM classifier operates on the CNN output data. The SVM determines the optimal decision boundary between image classes by finding the maximum margin value for the support vectors. The MAC-SVM-CNN system achieves high accuracy in image content classification through its multi-scale attention and spatial hierarchy features. The proposed MAC-SVM-CNN model utilizes the pre-processed dataset images, which are converted into feature vectors $F = [f_1, f_2, \ldots, f_d]$, where f_i represents distinct image descriptors, such as textures, color patterns, and spatial arrangements, and d indicates the total number of extracted features. The softmax function determines attention weights α_i for essential features to stand out.

$$\alpha_i = \frac{\exp(s_i)}{\sum_{j=1}^{d} \exp(s_j)} \qquad \text{Eq. (8)}$$

The calculation uses raw attention scores s_i to determine the value of f_i. The weighted vector is computed as the final product of feature analysis through

$$F' = \sum_{i=1}^{d} \alpha_i f_i \qquad \text{Eq. (9)}$$

The classification process benefits from enhanced discrimination delivered through significant features. A self-attention mechanism S processes contextual encoding by deriving feature vector-based query Q and key K and value V matrices that serve as inputs for S.

$$S(Q,K,V) = softmax\left(\frac{QK^{\top}}{\sqrt{d_k}}\right)V \quad \text{Eq. (10)}$$

The equation of self-attention contains three weight matrices W^Q, W, W^V of key vector dimension d_k that compute $Q = FW^Q, K = FW^K, V = FW^V$. The system processes the attended features through a capsule network. A capsule v_j generates its output vector, which produces a value where the vector norm represents class j probability using the formula,

$$v_j = \frac{\|s_j\|^2}{1+\|s_j\|^2}\cdot\frac{s_j}{\|s_j\|} \quad \text{Eq. (11)}$$

$$s_j = \sum_i c_{ij}\hat{u}_{j|i} \text{ where}, \hat{u}_{j|i} = W_{ij}u_i \quad \text{Eq. (12)}$$

The lower capsule layer output u_i passes through W_{ij} and combines with c_{ij} to determine the result. The margin loss function is applied to train the capsule network after it has been used.

$$L_j = T_j.\max\left(0, m^+ - \|v_j\|\right)^2 + \lambda\left(1-T_j\right).\max\left(0, \|v_j\| - m^-\right)^2 \quad \text{Eq. (13)}$$

The presence of class j is denoted by $T_j \in \{0,1\}$, and the training process utilizes margins m^+ and m^- regularized by λ. The margin loss implementation activates true class capsules strongly and prevents other capsules from activating simultaneously. Multiple CNN layers serve the purpose of in-depth representation learning. The feature map produced by layer l contains the following information.

$$F_{CNN}^l = ReLU\left(W^{(l)} * F^{(l-1)} + b^{(l)}\right) \quad \text{Eq. (14)}$$

The learned convolutional weights $W^{(l)}$ and biases $b^{(l)}$ process the input data using the convolution operation, denoted by $*$. Different depth segments of these layers recognize hierarchical visual patterns, starting from edges and moving through patterns to objects. The classification process utilizes SVM to determine the optimal hyperplane boundaries for categorizing images. The original form of the algorithm achieves simplistic outcome solutions.

$$\min_{w,b}\frac{1}{2}\|w\|^2 \quad \text{Eq. (15)}$$

Subject to,

$$y_i(w^{\top}x_i + b) \geq 1 \quad \text{Eq. (16)}$$

The CNN-enhanced image feature vector x_i, together with its true label $y_i \in \{-1, +1\}$, operates under the decision parameters w and b. A kernelized dual formulation is implemented if the dataset proves not linearly separable.

$$\max_{\alpha}\sum_{i=1}^n \alpha_i - \frac{1}{2}\sum_{i,j=1}^n \alpha_i\alpha_j y_i y_j K\left(x_i, x_j\right) \quad \text{Eq. (17)}$$

With $K\left(x_i, x_j\right)$ as the kernel function, such as Radial Basis Function (RBF), and α_i as the Lagrange multipliers. The prediction relies on the computation carried out by equation 18.

$$\hat{y} = \text{sign}(w^{\top}x + b) \;\; \forall\, \hat{y} = \arg\max_j \|v_j\| \quad \text{Eq. (18)}$$

The decision procedure relies on a combination of SVM and capsule-based output systems. The processing techniques applied to the preprocessed dataset yielded high retrieval accuracy, demonstrating the effectiveness of the MAC-SVM-CNN framework.

Algorithm 2: MAC-SVM-CNN
Input: $F = [f_1, f_2, \ldots, f_d]$ form feature selection process, and d
O**utput:** $\hat{y}$ predicted class label
Start
Step-1: For each f_i:
Compute s_i
Apply $\alpha_i = \frac{\exp(s_i)}{\sum_{j=1}^{d} \exp(s_j)}$
Generate $F^{'} = \sum_{i=1}^{d} \alpha_i f_i$
End for
Step-2: Calculate $Q = FW^Q, K = FW^K, V = FW^V$
Step-3: Utilize $S(Q,K,V) = softmax\left(\frac{QK^{\top}}{\sqrt{d_k}}\right)V$
For each j:
Evaluate $s_j = \sum_i c_{ij} \hat{u}_{j|i}\ \hat{u}_{j|i} = W_{ij} u_i$
Calculate $v_j = \frac{\|s_j\|^2}{1+\|s_j\|^2} \cdot \frac{s_j}{\|s_j\|}$
End for
Step-4: For each j:
Compute $L_j = T_j . \max(0, m^+ - \|v_j\|)^2 + \lambda(1 - T_j) . \max(0, \|v_j\| - m^-)^2$
For each l:
Apply $F_{CNN}^{l} = ReLU\left(W^{(l)} * F^{(l-1)} + b^{(l)}\right)$
Execute flattening operations on the last output of the CNN layer.
End for
End for
Step-5: Define $\min_{w,b} \frac{1}{2}\|w\|^2$ subject to $y_i(w^{\top} x_i + b) \geq 1$
Step-6: If data is non-linear
Utilize $\max_{\alpha} \sum_{i=1}^{n} \alpha_i - \frac{1}{2}\sum_{i,j=1}^{n} \alpha_i \alpha_j y_i y_j K(x_i, x_j)$
Predict $\hat{y} = \text{sign}(w^{\top} x + b)\ \forall\ \hat{y} = \arg\max_j \|v_j\|$
Forecast $\hat{y}$ and enhance classification accuracy
End if
Stop

RESULT AND DISCUSSION

The analysis of the MAC-SVM-CNN method utilizes a corel image database through image processing and CBIR techniques. The image database will be used to train and test 1,000 different classifiers, which will analyze images of ships, parachutes, and signboards as their categories. The CBIR system benefits from MAC-SVM-CNN because this approach delivers the best characteristic elements required for image classification. Temperature-based comparison methodologies can evaluate the previous content retrieval methods of CNN, KNN, LBP, and MAC-SVM-CNN on the corel2K database. You can make the MAC-SVM-CNN approach more accurate by looking at performance measurements like accuracy, precision, recall, and F1-score. Table 2 shows that the suggested MAC-SVM-CNN approach may increase the accuracy of image retrieval by comparing it to the CNN, KNN, and LBP, methods to get the test and validation accuracy. Also, Ship, Parachute, and Sign board all did better on the test and training datasets, with scores of 93.5%, 92.6%, and 96.5%, respectively. Figure 3 present the precision measurements for CNN, KNN, LBP, and the proposed MAC-SVM-CNN. Across all categories, the MAC-SVM-CNN achieves superior precision outcomes due to its integrated multi-attention mechanisms, SVM with capsule networks, and CNN-based spatial features. The precision of the MAC-SVM-CNN is 44.9% for ships, 47.4% for parachutes, and 50.3% for signboards, exceeding all other evaluated methods. Figure 4 shows the study comprises traditional and state-of-the-art models,

including CNN, KNN, and LBP, in conjunction with the proposed MAC-SVM-CNN framework. Through recall values, the methods show their capability to generate all necessary images in response to specific queries. All categories demonstrate that the proposed MAC-SVM-CNN approach yields superior performance measurements, suggesting it can better recognize essential content parts. The evaluation results from Figure 5, compare MAC-SVM-CNN against benchmark techniques CNN, KNN, and LBP. Each image category benefits from the MAC-SVM-CNN approach because it delivers superior results in F1 Scores, reaching 0.601 for ships, 0.626 for parachutes, and 0.656 for signboards. Figure 6, shows how deep learning methods performed relative to one another in classifying images of ships, parachutes, and signboards. The research evaluated two types of baseline models, consisting of CNN, KNN, and LBP, along with the proposed MAC-SVM-CNN system. The data from the graph verifies a top performance level of the proposed MAC-SVM-CNN approach for multi-class content-based image retrieval across all categories.

CONCLUSION

In conclusion, the study presents an adaptive CBIR framework that effectively addresses the significant limitations present in standard and deep learning retrieval methods. The system exhibits high performance across various challenging datasets through its precise implementation of preprocessing with DAGF, followed by HCA-ViT-PSO feature extraction, and lastly, the MAC-SVM-CNN classification method. The proposed method effectively reduces background noise while enhancing key visual characteristics that facilitate discriminative learning of data. Testing on the ships, parachutes, and signboards groups within the Corel2K-Image dataset reveals that the MAC-SVM-CNN method achieves superior results compared to current advanced algorithms. The model achieves its highest accuracy of 96.5%, indicating its excellence in performing scalable image retrieval with high precision. The cross-domain capsule routing system, along with its attention mechanism and SVM-based classification boundaries, ensures both high accuracy and explainable operation when confronted with input variations.

ABSTRACT

Malathion is an organophosphorus insecticide and pesticide commonly used in crops and residential applications. The negative effects of Malathion on human health and ecosystems are of great concern. In this work, an electrical logic tool Fuzzy Logic Controller (FLC) is used to analyse the causes and hazardous effects of Malathion to human and mammals. Based on expert's opinion the possible factors that cause damage to health and ecosystems due to Malathion is identified, which serve as the input to the FLC. The FLC establishes the causal relation between these factors computaionally. This approach can be used to study the interdependencies between the adverse effects of any pesticide in human health and environment due to prolonged exposure.

Keywords: Malathion; Fuzzy logic Controller, Mammals, Human beings, Minimal risk levels, Control & Preventive measures.

INTRODUCTION

The Organophosphorous [OP] compound Malathion, quietly known as carbophos, maldison, and mercaptothion was developed in 1950 during second world war, for its high insect potency andlow mammalian toxicity. OP is a non-systemic, wide spectrum compound hence utilizedas one of the safest & most selective insecticides. Based on the complete review of scientific evidence from the mutagenicity tests for bacteria, fruit flies, mice, hamsters, fish and human cell cultures bioassays conducted in 29 laboratories between 1978 and 1995 National Institute for Occupational safety and Health (NIOSH) identified Malathion as a *Mutagen*[1]. Between late 1970s and 2008,

malathion was the primary pesticide used in the USDA Boll Weevil Eradication Program to protect cotton crops in the southern United States [2]. The estimated average annual total domestic usage of malathion in the USA is approximately 15 million pounds of malathion as an active ingredient. Malathion is regulated by both Food and Drug Administration (FDA) and U.S. (EPA)Environmental Protection Act with a maximum amount of 8 parts per million (ppm) as residue on specific crops used for food.Its potential toxicity to humans requires, that an appropriate time lapse should be observed between the application time and entry/re-entry of a field worker.*It has been recommended not to enter or go to the fields sooner than 6 days after malathion spraying*. Exposure to high concentrations of malathion has been associated with severe toxicity and death in some cases.

Fuzzy Logic Controller (FLC):

The classical controllers are rigid in nature since the control methods are designed at one nominal operating point and HENCE they are not able to respond satisfactorily in dynamic operating point and disturbances. This main challenge is overcome by Fuzzy Logic Controller (FLC) and designed for that. Simulation is done using MATLAB Simulink. Compare to classical controller's fuzzy controllers are adopted to dynamic changes. In general, fuzzy means difficult to perceive, indistinct or vague in between right and wrong. The objective of Fuzzy Logic is formalization and eventual mechanization of two remarkable human capabilities and it is introduced by Lotfi Zadeh in 1965 to process imprecise data and the basic concept is Attempt to mimic Human control logic. Fuzzy Logic Controller (FLC) is a controller based on the concepts of fuzzy sets, linguistic variables and approximate reasoning to evaluate rules. FLC are range to range and range to point controllers and the input of FLC is membership function o/p also depends on membership function. In conventional controller we have control gain or control loss, which are combination of numerical values. In FLC instead of fixed gain or loss, a updated variables are used in terms of rules and they are linguistic in nature [3]. Such a typical rule can be written as follows:

IF E is Ai and CE is Bi then output is Ci

Where, Ai, Bi and Ci are the labels of linguistic variables of Error (E), Change of Error (CE) and output respectively. E, CE and output represent degree of membership.

PHYSICAL FACTORS

Adsorption Behaviour:

The adsorption of malathion was greater in soils with greater amounts of soil organic matter, whereas the destruction of the soil organic matter fraction of soils led to decreased adsorption [4]. Malathion is rapidly and effectively absorbed by practically all routes including the gastrointestinal tract, skin, mucous membranes, and lungs. However, the absorbed malathion is readily excreted in the urine, and does not accumulate in organs or tissues.

Bioconcentration Factor [BCF]:

Malathion did not bioconcentrate in a freshwater fish. Depending upon the suspended particles, impurities, salt content it shows various values of BCF. Despite the apparent tendency of malathion to partition into the tissues of aquatic organisms, the potential for biomagnification in the food chain is likely to be low because malathion appears to be metabolized by the aquatic organisms.

Toxicikinetics: Mechanism of Toxicology in human health:

The most influenced exposure routeof malathionto the general population is through the dermal contact, ingestion, and/or inhalation [5]. The majorexposure can adsorbedthrough skin when contacting contaminated products or surfaces, or through lung absorption by inhaling contaminated air. Domestic users of malathion are also at high risk of intoxication related to its application in residential areas near homes and gardens for medflies and mosquitoes control. Absorbed malathion can be transported by the blood and distributed to many organs and tissues including the liver where it is metabolized to form maloxon.

Degradation & Pathways:
Malathion is degraded in the environment through two main pathways, ***activation and degradation*** [6]

Activation of the compound involves oxidative desulfuration, yielding the degradatemalaoxon, a cholinesterase inhibitor with greater toxic properties than its parent compound. Activation may also be achieved by photooxidation, chemical oxidation, or biological activation, which occurs enzymatically through the activity of mixed function oxidases.

Degradation of malathion occurs through both **chemical and biological** means, with hydrolysis being the most important pathway [7]. Biological degradation through the hydrolytic pathway is mainly achieved through the enzymatic activity of carboxylesterases and phosphatases, and to a lesser extent through the activity of reductase. Malathion may also be degraded through des- or dealkylation of the O-methyl or O-ethyl groups, mediated by a phosphatase/mixed-function oxidase system [8]

The effects of light including ultraviolet [UV] radiation through photolysis on both malathion and its degradatemalaoxon. An estimated atmospheric photooxidation half-life of 1.5 days based on the reaction of malathion with photochemically produced hydroxy radicals [9]. Malathion degradation in the atmosphere occurs mainly due to indirect photolysis (photooxidation) rather than resulting from direct photolysis.

Spreading & Transportation:
Malathion released in the atmosphere as a result of its use on agricultural crops and/or residential areas may form droplets that fall on ground covers including plants, animals, soils, water resources, buildings, and/or other structures. Malathion deposited on these platforms maysubsequently be transported away through the action of rainfall/precipitation and wind.

Breaking Down of Malathion in various sources:
Malathion is usually transformed or degraded within a few weeks through the processes of photolysis, hydrolysis, and/ or biodegradation by microorganisms.It is rapidly degraded by soil bacteria, low concentrations are expected to be present in groundwater. Reported half-lives in soil range from 1 to 17 days.

In water, malathion breaks down quickly by hydrolysis or by the action of bacteria present in the water. The half-lives of malathion in water were estimated as 1.65 days at pH 8.16, and 17.4 days at pH 6.0 .
In air, malathion is broken down by reacting with other chemicals formed naturally in the air by sunlight, to form a more toxic product called malaoxon. Malathion may be transported in the atmosphere as a vapour form or adsorbed onto particulate matter [10]. It has been detected in the fog of remote pristine areas, indicating that long-range travel may occur under some conditions.

Architecture of FLC
The fuzzy logic controller has many advantages than the conventional PI controllers. The main reason for fuzzy controller is that it does not need any accurate mathematical model of the system which is going to be control and can work with imprecise inputs. It can also handle nonlinearity and more robust than conventional nonlinear controllers [11]. Practically it doesn't need fast processors and it needs less data storage in the form of membership functions and rules than conventional look up table for nonlinear controllers. The block diagram of Fuzzy logic controller and the internal structure of the controller are shown in Figure [1].

A basic architecture of FLC contains fuzzification, inference mechanism, fuzzy rule base, defuzzification. Fuzzification converts binary data into fuzzy data it has two processes that is derive the membership function for input and output variables. Defuzzification process is to derive the desired crisp output value by combining the membership functions with fuzzy rules. It converts fuzzy o/p values to control signals. It derived by two categories,

one is off line defuzzification, here all input and output membership functions are based on actual experience i.e, specified application. Online method is real time controllability has higher control accuracy [12].

Malathion and Health Effects in Human:

The most frequently detected pesticides malathion in the FDA's total diet studies is a great potential for exposure of the general population by consumption of food containing residues of the chemical.

The median lethal dose (LD50) of malathion is estimated to be 2100 mg/kg in man. *These data are discussed in terms of three exposure periods: acute (14 days or less), intermediate (15–364 days), and chronic (365 days or more*).Levels of significant exposure for each route and duration are presented with the data as showing *no-observed-adverse-effect levels (NOAELs)*or *lowest observed-adverse-effect levels (LOAELs)* reflect the actual doses (levels of exposure) used in the studies [13].

Malathion inhalation and excretion in Human body: Malathion enters the body through the air we breathe containing malathion during / after it has been sprayed for public health uses. After exposure, it enters body quickly and passes into the bloodstream which can easily go to many organs and tissues. Most of the malathion is broken down in the liver into other substances, called metabolites. Itdo not tend to accumulate in the body, and leave mostly in our urine within a few days.

Carcinogenic Effect

In April 2000, U.S. EPA classified malathion as having "suggestive evidence of carcinogenicity but not sufficient to assess human carcinogenic potential by all routes of exposure". An epidemiological study at six Canadian provinces pointed out that the cancer risk of non-Hodgkin's lymphoma was twice in men exposed to malathion compared to healthy men who had not been exposed to malathion [14,15]. Also, occupational exposure to pesticides has been reported to be associated with an increase risk or incidence of different types of carcinomas such as non-Hodgkin's lymphoma [16], Hodg-kin's lymphoma, leukemia [17], multiple lymphoma [18], pancreatic cancer [19], gastric cancer [20], lung cancer [21], bladder and colon cancer [22], and gall bladder sarcoma [23].

Various affects due to Malathion

Malathion classification on the basis of hazards level

Hematological Effects

When high levels of malathion exposed to persons, it induce DNA abnormalities [24], decrease human immunity [25] and cause non-Hodgkin's lymphoma [26]. Acute malathion treatment resulted in bone marrow failure and plastic anemia [27].Persons who were in direct contact with malathion in the pesticide manufacturing company found an inverse relationship between hemoglobin concentration and duration of employment. Eight individuals who had worked in the processing unit for >20 years had mean hemoglobin levels of 11.30 g/dL compared to 15.5 g/dL measured in four matched controls employed for >20 years[28].

Renal Effects

Regarding renal effects,in humans after the exposure ofunknown formulation of malathion a 65-year-old man was developed with transient renal insufficiency with massive proteinuria 3 weeks after spraying intensively with malathion [29].

Body weight Effects:

There were no exposure-related changes in body weight when absorbed during the study of aerosol bombs of acute malathion.

Neurophysiological Effects:

(a)14 workers were exposed to 57 % malathion of pesticide formulation for 4-5 hours /day duration for 4-6 months. *There were no evidence of neuromuscular insufficiency and no significant alterations in motor nerve conduction velocity or any indication of altered synaptic transmission*[30].

(b)11 workers were exposed to Organic Phosphates, a significantly higher percentage of peripheral neuropathies evaluated by electromyograph [EMG] recordings were observed among pesticide workers when compared to control ones [31, 32]. *A slight reduction (3%) in sensory nerve conduction velocity.*

Cholinesterase activities

Concentration-related effects: Females seemed more pronounced than in males.

Plasma cholinesterase activity: Decreased 30 and 70% in the mid-exposure level and high exposure level females.

RBC cholinesterase activity: Decreased 22 and 27% in *midexposure* level males and females &43 and 44% in *high-exposure* level males and females.

Brain cholinesterase activity: Decreased 41% in high-exposure level females.

Fuzzy Inference System

Fuzzy set allows objects or members to represent a smooth boundary whereas classical represent sharp boundary, and the membership function takes the value in the interval 0 and. It is derived by different methods like triangular waveform, trapezoidal, sigmoidal, guassian, bell shaped, s curved waveform and each one possess its own specialty. For that purpose, min inference rule and centroid defuzzzification technique have been used. The input membership function and output membership function are shown in Figure 2, 3 and .4

Discussion of Simulation and Result

In this work malathion and its health effects are analyzed with eight fuzzy rules1. Report in human actions, 2. Malathion inhalation and excretion in Human body. 3. Carcinogenic Effect, 4. Hematological Effects, 5. Renal Effects, 6. Body weight Effects, 7. Neurophysiological Effects, and 8. Cholinesterase activities. To design fuzzy inference system for this analyses 8X8 rules are used as it is unsupervised one. The connection matrix for fuzzification and defuzzification are derived based on experts opinion as given in the equation 1 and 2.

$$T_f(F) = \begin{bmatrix} 0 & HHMHVHVHH \\ H & 0 & VHVHHHMM \\ HVH & 0 & MHHLL \\ MVHVH & 0 & MHLL \\ LMMVL & 0 & VHVHH \\ VLVLVLMH & 0 & MM \\ LVLVLVLLL & 0 & VH \\ LVLVLVLLMM & 0 \end{bmatrix} \quad [1]$$

$$T_d(F) = \begin{bmatrix} 0 & 0.3 & 0.3 & 0..2 & 0.3 & 0.4 & 0.4 & 0.3 \\ 0.3 & 0 & 0.4 & 0.4 & 0.3 & 0.3 & 0.2 & 0.2 \\ 0.3 & 0.4 & 0 & 0.2 & 0.3 & 0.3 & 0.1 & 0.1 \\ 0.2 & 0.4 & 0.4 & 0 & 0.2 & 0.3 & 0.1 & 0.1 \\ 0.1 & 0.2 & 0.2 & 0.05 & 0 & 0.4 & 0.4 & 0.3 \\ 0.05 & 0.05 & 0.05 & 0.2 & 0.3 & 0 & 0.2 & 0.2 \\ 0.1 & 0.05 & 0.05 & 0.4 & 0.05 & .01 & 0 & 0.4 \\ 0.1 & 0.06 & 0.06 & 0.06 & 0.1 & 0.2 & 0.2 & 0 \end{bmatrix} \quad [2]$$

Malathion in Insects

Malathions bind to the enzyme acetylcholinesterase (AChE) at nerve endings throughout the bodies of insects and other organisms [33]. AChE plays a key role in the synaptic transmission of nerve impulses and attack the tiny pores

of spiracles. Its inhibition causes the blockage to signal transmission leading to intoxication manifested by restlessness, hyper-excitability, convulsions, paralysis, and death [34].

Malathion in mammals

The signs and symptoms of malathion toxicity are different in mammals because in mammals AChE is not active in the central nervous system, but rather in nerves that connect with muscles [35].

Carcinogenic Effect:

In a two-year dietary study, researchers administered oral doses of 2,359, 739, or 868 mg/kg/day exposures of malathion to rats, results observed an increased incidence of liver and nasal/oral tumors in rats and increased incidence of liver tumors in mice [36].

Hemotologic effects

Malathion on high doses, suppress the immune system, affect the hemato- poietic system, deleterious effects on hematological parameters of treated animals [37]. Chronic exposure of malathion to a group of animals in a researchsignificantly decreases RBCs, Hb, and P.C.V% [Packed cell volume] values [38].

Neurological effects

Malathion is found to inhibit the release of acetylcholinesterase at the synaptic junction.Neuropathy target esterase (NTE), causesOrganophosphorus-induced delayed polyneuropathy (OPIDP) due to the consumption of malathion. When higher level of dosages causes neurological effects and nerval syndrome disorders. [39].

Reproductive & Developmental effects:

Malathion influences the reproductive function by two mechanisms via its cellular toxic action and its effect reduced sperm count, obviously decreased the levels of testosterone [40]

Hepatic effects&5.6 Renal effects:

Renal effect tests were conducted to rats with the aerosol application of 96.4% pure malathion at a concentration of up to 2,010 mg/m3, 6 hours/day, 5 days/week for 13 weeks. It showed no significant alterations in the renal effectand body weight during the study [41].

Discussion of Fuzzy stimulation and Results

Further the effects of malathion in mammals are examined in six different categories, like 1. Carcinogenic Effect, 2. Hematologic effects, 3. Neurological effects, 4. Reproductive &amp, 5. Developmental effects, 6. Hepatic effects and Renal effects. It is effectively analyzed with the aid of 6X6 fuzzy rules as given below.

$$T_f(F) = \begin{bmatrix} 0 & H & H & M & H & VH \\ H & 0 & VH & VH & H & H \\ H & VH & 0 & M & H & H \\ M & VH & VH & 0 & M & H \\ L & M & M & VL & 0 & VH \\ VL & VL & VL & M & H & 0 \end{bmatrix} \quad [3]$$

$$T_d(F) = \begin{bmatrix} 0 & 0.3 & 0.3 & 0..2 & 0.3 & 0.4 \\ 0.3 & 0 & 0.4 & 0.4 & 0.3 & 0.3 \\ 0.3 & 0.4 & 0 & 0.2 & 0.3 & 0.3 \\ 0.2 & 0.4 & 0.4 & 0 & 0.2 & 0.3 \\ 0.1 & 0.2 & 0.2 & 0.05 & 0 & 0.4 \\ 0.05 & 0.05 & 0.05 & 0.2 & 0.3 & 0 \end{bmatrix} \quad [4]$$

The obtained fuzzy model is a realistic sensitive model which leads good performance as the fuzzification mimics human knowledge system. It can easily optimize the huge information's into a specific operating points. It is observed that the fuzzy inference system is a vital tool for explaining the effects of malathions over human and mammals.

MRL[Minimal Risk Levels]:

An acute-duration inhalation MRL of 0.2 mg/m^3 was derived for malathion based on a no-observedadverse-effect-level (NOAEL) of 65 mg/m^3 for inhibition of RBC cholinesterase activity in rabbits exposed to a malathion aerosol [42].

An oral MRL in Humans:

Case 1: An oral MRL study for group of people were conducted withmalathion aerosolof 0, 5.3, 21, and 85 mg/m3 concentrationsof 2 hours/day for 42 days. Up to 21 mg/m^3, there was no irritation or toxic effects, we observed with a complaints of nasal and eye irritation within 5–10 minutes only at the exposure to 85 mg/m^3 of malathion aerosol.

Case 2:An intermediate-duration oral MRL of 0.02 mg/kg/day was derived for malathion based on inhibition of plasma and RBC cholinesterase activity in humans with 15-364 days exposure. [43].

First phase, Five male volunteers were made to consume0.11 mg malathion/kg/day daily in the capsules form blended with corn oil approximately for 32 days.

Second phase, After the completion of first phase -for three weeks and then were administrated as daily capsules with malathion providing about 0.23 mg malathion/kg/day for 47 days.

Third phase, 0.34 mg malathion/kg/day for 56 dayssubjected in the third phase.

Various Tests were conducted using the tests,

The MRL was derived by dividing the NOAEL of 0.23 mg/kg/day by an uncertainty factor of 10 (to account for sensitive subpopulations).ThePlasma content and RBC cholinesterase was determined twice weekly prenatal, during, and the post administrations of malathion.

(i) Routine blood counts and urinalyses were conducted at the end of each study period.

The *reports were quite common that,* administration of 0.11 mg malathion/kg/day for 32 days or 0.23 mg/kg/day for 47 -No clinical signs.

But the phase three activity of 0.34 mg malathion/kg/day for56 days caused a maximum depression of 25% in plasma cholinesterase approximately 3 weeks after cessation of treatment.

DISPOSAL

Incineration in a furnace equipped with an afterburner and a scrubber is the recommended method of disposal for malathion [44,45]. If incineration is not an available option, malathion may be disposed of by absorbing in vermiculite, dry sand, earth, or a similar material and then being buried at a designated landfill site [46].

Membrane Techniques: **Type I** & **Type II**: Malathion issubjected to molten salt combustion using potassium chloride. This process is very attractive due to the destruction of malathion is >99% and the products of combustion can be safely re-used as a fertilizer (United Nations 1985).

Adsorption Techniques & Hydrolysis: In soil and sediments, the major degradation process of malathion is microbially mediated biodegradation, occurs mainly through enzyme-catalyzed hydrolysis. The predominant pathway for the biodegradation of malathion has been reported to be carboxylesterase activity. Half-life values in soil of 3–7 days have been reported for the degradatemalaoxon. Little malathion appears to volatilize from soil and while malathion is moderately to highly mobile in soils, leaching of malathion through the soil and into groundwater is unlikely due to the rapid degradation of the compound in the environment [47].

Regulatory Guidelines

According to the National Institute for Occupational Safety and Health (NIOSH)'s guidelines, workers should not be exposed to malathion concentrations greater than 10 mg/m^3 during a 10-hour workday, 40 hours per week. NIOSH also recommends that an atmospheric concentration of 250 mg/m^3 malathion be considered as being immediately hazardous to human health and life.

CONCLUSION AND REMEDIAL MEASURES:

This review highlights the most recent applications of malathion as the use of fertilizer, pesticide and its impacts to human health, mammals & insects. The data were configurated with different dosages, time duration and concentration with the wide range of testing studies. The minimal risk level, choloniesterase behaviour, oxidative reaction gives a keynote to the researchers.

Remedial Measures: To reduce the risk of exposure of malathion it is important to wash the foods prior to eating them. When contaminated vegetables or other produce grown in a backyard garden is eaten as it is, found to that there is a presence of toxicity.

ABSTRACT

The financial industry relies on quantitative methods to understand the market dynamics, handle uncertainty, and make investment decisions. Within the increase of complexity in financial markets, mathematical modeling is very necessary for the purpose of risk assessment, predicting the value of assets, and understanding the factors that play a vital role in investor returns. This paper uses two mathematical models that are commonly used: the Capital Asset Pricing Model and Geometric Brownian Motion, to analyze the behavior of stock prices, particularly in the Indian market. With CAPM, we tried to evaluate the systematic risk and expected return for the State Bank of India with the help of ten years' monthly market data and using the yield of a 10-year Government of India bond as the risk-free rate. On the other hand, GBM will be used for predicting future prices for Reliance Industries using simulations based on daily log-returns between 2022 and 2024.Our findings show that SBI has a high beta and has high sensitivity to market movements and their fluctuations. This sensitivity is more seen in times of crisis, such as the COVID-19 pandemic period, while GBM simulations for the Reliance company indicate strong volatility connected with wide forecast bands, implying that its price behavior over recent years was notably driven by market shocks and sudden fluctuations. These two models show how mathematics can encapsulate key aspects of financial behavior and provide structured views of risks and returns even when real markets are highly subject to volatility and sharp shifts.

Keywords: Mathematical Models, CAPM, GBM, Risk Management, Financial Forecasting

INTRODUCTION

Mathematics plays a vital role in modern finance; it speaks the basic language through which risk, return, valuation, and market dynamics are comprehended, and it doesn't just work with numbers. Financial markets function on numbers and numerical data, and mathematical modeling helps in converting the raw data into useful insight that can help in our decision-making. From a clear and precise perspective, the quantitative methods help investors, analysts, and main institutions to understand stock performance, their evaluation, as well as predict future returns and detect the variations in market movements. In the current times of changing economic transformations, global linkages, and highly sensitive market responses, mathematical modeling has made it much more relevant and easier to draw conclusions. Markets these days feel more unpredictable than ever. The adverse effect of geopolitics, inflation, policy swings, and new tech — they all shake things up. At the same time, we're compiled with real-time data and have powerful tools to analyze it. With risk getting more complicated and unpredictable due to such factors, mathematical models step in to help us make sense of it all. They cut through the noise, reduce uncertainty, help us spot trends, and give us a framework for smarter financial decisions and choices. This paper takes a close look at two go-to mathematical models mainly applied in finance. The first is the Capital Asset Pricing Model (CAPM). It measures how much risk a stock carries compared to the overall market and finds out what kind of returns you should expect. The second is the Geometric Brownian Motion (GBM) model, which captures the wild, continuous ups and downs of stock prices. It's a favorite for predictions and simulations.The goal of this project is to show how these models can actually make financial analysis in banking and the stock market sharper. How these models improve finances. We're applying CAPM to the State Bank of India (SBI) and GBM to Reliance Industries. We can quantify risk and model future predictions, and finally find both the theoretical and actual returns. This particular method shows the importance of mathematical models in aiding investment decisions and dealing with uncertainty and risks that come with finance.

LITERATURE SURVEY

If you look back, a lot of financial market theory traces its roots to the early versions of the Capital Asset Pricing Model, dating as far back as the 1860s. The real backbone is the mean-variance model, introduced by Markowitz in his work on choosing the best mix of assets when you're facing uncertainty. Later, Black, Jensen, and Scholes confirmed that certain components-especially the beta of security returns — were crucial, especially when looking at returns above the average. Then there's the Fama and MacBeth model. They took CAPM further by using cross-sectional regression to study the relationship between risk and average returns for stocks on the NYSE. Models like CAPM are sometimes called Lintner and Sharpe models, recognizing the key contributions of both researchers. Jiang, in "The Application of Mathematical Models in Finance," digs into how these models shape our understanding of finance. The paper lays out just how complex financial theory is, but also shows how mathematical tools — especially those with geometric underpinnings — have pushed the field forward. Statistical models play a big role for banks, especially when it comes to setting credit policies and managing risk. Credit rating agencies, for example, can get a lot smarter about managing credit risk by building their own internal rating systems and mathematical models. The Capital Asset Pricing Model, or CAPM, really changed the game in finance math. It lets you figure out how risk and return play off each other across different investment groups, which makes it a go-to tool for managing portfolios. Gao's 2023 paper, "The Impact of COVID-19 on Five Categories of Industries Based on CAPM Model," discusses the impact of how the pandemic shook up different sectors of the market. COVID-19 has emphasized how it has affected and brought many challenges to the economy globally. Studying this stuff matters. When you look at the stock market, you can see it reflecting the ups and downs caused by COVID across various industries. The findings are interesting: after the pandemic, banks took on more risk (their beta values went up), while e-commerce, automakers, and pharma saw lower betas. So, the pandemic didn't hit every industry the same way—risk and return shifted depending on where you looked.

Paper Description

This paper explores how mathematical models help us understand, measure, and predict financial risk in the Indian stock market. We worked on two major stocks—State Bank of India and Reliance Industries Limited. For the analysis, I used the Capital Asset Pricing Model (CAPM) and the Geometric Brownian Motion (GBM) model. The goal? To show how math isn't just theory—it actually sharpens real decisions in areas like volatility, return prediction, and risk assessment. SBI stands in for the banking sector here. It's a good example for showing how CAPM links systematic risk to expected returns. On the other hand, RIL's business is all over the place and pretty volatile, making it ideal for illustrating how GBM handles randomness in stock prices. CAPM lays out a straight-line relationship between how a stock moves and how the whole market moves, which makes it easy to figure out beta (that's the measure of systematic risk). GBM treats stock prices as a never-ending random walk, factoring in both drift and volatility.

Implementation Methodology

Data Collection

SBI Monthly Adjusted Closing Prices

For the data, I started with SBI's monthly adjusted closing prices from January 2014 to December 2024,a solid ten years. These adjusted prices cover everything: dividends, splits, bonuses, you name it. That makes them the best way to calculate real returns. I used this data to work out SBI's monthly log-returns, compare them to the risk-free rate, run the CAPM regression, estimate beta, and see how expected returns stack up against what really happened. SBI makes sense here because it's India's biggest public-sector bank and a heavyweight in the NIFTY 50 index, so it's perfect for market risk modeling.

NIFTY 50 Monthly Adjusted Closing Prices

I gathered the NIFTY 50 Index's monthly adjusted closing prices for the same ten-year stretch. The NIFTY 50 is the main benchmark for the National Stock Exchange—tracking India's top 50 large-cap companies across all the big sectors. This index matters because it's the CAPM standard for market returns. It's the reference point for calculating excess returns, figuring out SBI's beta, and measuring both expected and realized performance. CAPM always compares an asset to the whole market, so NIFTY 50 is the obvious choice.

Reliance Industries Daily Adjusted Closing Prices

For Reliance, I used daily adjusted closing prices from January 2022 to December 2024. Reliance is a giant—spread across retail, telecom, and energy—and its stock price bounces around a lot in the short term. This volatility makes it perfect for showing off stochastic modeling with GBM. Daily data is key here, since GBM needs lots of observations to nail down drift and volatility. With this dataset, I calculated daily log-returns, figured out the drift (μ) and volatility (σ), simulated future price paths, and got a handle on daily unpredictability and risk using the stochastic approach. Reliance fits well for this kind of modeling because it's highly liquid, has a huge market cap, and consistently shows the kind of price behavior GBM is built for Running the GBM model gave me a solid simulation setup: daily log-returns, yearly estimates for drift and volatility, the discrete-time GBM formula, ten sample future price paths, and templates for plotting those results—charts, histograms, the works. These pieces make it possible to really dig into risk and uncertainty for Reliance.

Data Pre-Processing

Data pre-processing is an essential step in getting raw financial time-series data ready for comprehensive quantitative analysis. This phase guarantees that datasets are organized, sanitized, altered, and prepared for the mathematical processes necessary for CAPM regression and GBM simulation.

Data Purification and Alignment

The research utilizes genuine financial time-series data from the Indian stock markets:

- SBI share prices: Monthly adjusted closing figures spanning a decade.
- NIFTY 50 index: Monthly closing values adjusted for calculations of market returns.
- Risk-free rate: yield on the 10-year sovereign bonds of the Government of India (GOI).
- Reliance Industries share prices: Daily adjusted closing figures for 2022–2024.

All adjusted closing prices guarantee that dividends, splits, and other corporate activities are accurately accounted for.

Computation of Log Returns

The datasets were meticulously synchronized to uphold temporal coherence. For CAPM calculation, monthly returns for SBI and NIFTY 50 were determined using:

Log Return Formula

$$R_t = \ln\left(\frac{P_t}{P_{t-1}}\right)$$

SBI → monthly logged returns (for CAPM)
NIFTY 50 → monthly logarithmic returns (for CAPM)
Dependence → everyday log returns (for GBM)

Converting Risk-Free Rate to Monthly

The risk-free rate is the yearly yield on a 10-year Government of India bond.CAPM requires a monthly risk-free interest rate.

$$R_{f,monthly} = \frac{R_{f,annual}}{12}$$

Next, we deduct this rate from both stock and market returns for each month.

Calculation of Excess Return (for CAPM)

CAPM is ineffective with raw returns. It utilizes surplus returns:

SBI excess Return Calculation (for CAPM)

$$R_{i,t}^{excess} = R_{i,t} - R_{f,t}$$

Market Excess Return (NIFTY)

$$R_{m,t}^{excess} = R_{m,t} - R_{f,t}$$

Preparing Inputs for GBM (for Reliance)

Utilizing the daily log returns of Reliance:

1. Everyday Drift

$\mu_{daily} = mean(r_t)$

2. Daily Fluctuation

$\sigma_{daily} = std(r_t)$

3. Yearly Calculation

GBM utilizes yearly drift and volatility:

$\mu = \mu_{daily} \times 252$

$\sigma = \sigma_{daily} \times \sqrt{252}$

(252 = days of trading in a year.)
These constitute the ultimate GBM parameters.

Final Output
After preparation:
CAPM dataset contains:
Monthly return log of SBI
Monthly return log of NIFTY 50
Risk-free rate per month
Monthly SBI surplus return
Excess return from the market on a monthly basis
GBM Dataset Includes:
Daily log returns for Reliance
Daily fluctuations and variability
Yearly fluctuation and variability
Recent stock price for simulation
This finalizes data preparation and generates clean, model-ready datasets.

CAPM Implementation (State Bank of India)
Model Specification
Regression setup:
$R_{i,t}^{excess} = \alpha + \beta\left(R_{m,t}^{excess}\right) + \epsilon$

Where:
- $R_{i,t}^{excess}$- Excess return of SBI at time t
- $R_{m,t}^{excess}$- Excess return of the market at time t
- α- Intercept
- β- Slope representing Systematic risk
- ϵ- Error term

Regression Procedure
The regression was conducted using the Regression function in Excel's Data Analysis ToolPak. The actions taken were:
- SBI excess return as an independent variable (X).
- Market excess return as dependent variable (Y).
- Output Regression table includes α, β, R^2 and Regression statistics.

CAPM Expected Return Formula
$E(R_i) = R_f + \beta\left(R_f - R_m\right)$

Where:
- R_f-Risk-free rate
- R_m- Excess Market return
- β- Estimated from regression

Summary

The CAPM application established a strong empirical structure for assessing SBI's risk features through-
Monthly excess returns- A linear regression formula, Statistical evaluation, and finally Templates for visualizing additional assessment.

Geometric-Brownian Motion Implementation (Reliance)

Model framework

The Geometric-Brownian Motion stochastic differential equation is:

$$dS_t = \mu S_t dt + \sigma S_t dW_t$$

Where:
S_t- Stock price at time t
μ- Drift (expected return)
σ- Volatility
W_t- Brownian Motion

The analytical solution is:

$$S_t = S_0 \exp\left(\left(\mu - \frac{1}{2}\sigma^2\right)\right)t + \sigma W^t$$

Summary

The GBM execution generated a well-organized stochastic simulation setting that included- Daily log-return values, projected shift and variability yearly parameter collection, equation for discrete-time GBM, 10 projected future price trajectories, and templates for visualizing path charts, histograms, and comparative studies.
These components facilitate thorough risk and uncertainty assessments for Reliance Industrie.

CONCLUSION

This section lays out what I found from applying CAPM to SBI and GBM to Reliance, looking at the results through the lens of market behavior, risk patterns, and how well these models actually predict what's coming next.

CAPM Results for SBI

Regression Output

The CAPM regression of SBI's monthly excess returns against NIFTY 50's monthly excess returns produced the subsequent important statistics:

Interpretation of Beta
A beta of 1.59 suggests:

- SBI has significant systemic risk.
- Its returns magnify market fluctuations.
- The bank is very responsive to macroeconomic and policy-related cycles.
- Investors in SBI can anticipate increased volatility amid market declines.

This corresponds with SBI's business engagement in interest rate cycles, credit cycles, and significant market variations.

Expected Return Vs Actual Return

Using CAPM model, we conclude:

- Calculated CAPM Expected Return= -20.68%
- Actual mean monthly return (Annualized)= -6.02%

Interpretation:

A significant difference exists between the theoretical expectation of CAPM is substantial in size and negative, and the current achieved performance, which is adverse yet less severe.

Conclusion for CAPM

Despite CAPM accounting for SBI's elevated systematic risk, it undervalues true performance because of the elevated instability during times of crisis and structural alterations overlooked by the model.

GBM Results for RIL

Estimated Parameters

Interpretation

Daily fluctuations are significant, whereas yearly fluctuations are stable due to the scaling of time.

Negative drift indicates a mild downward trend in the observed timeframe (2022–2024), signifying:global oil fluctuations, telecommunications industry rivalry and post-pandemic adjustment.

GBM Simulation Outcomes

Using the latest price: $S_0 = ₹1210.61$

Final Simulated Prices:

Understanding of Distribution

- The average simulated price is a bit less than the current price, aligning with the negative trend.
- The 5th–95th percentile range signifies the 90% confidence interval.
- The price is expected to stay between ₹1118 and ₹1277 for the upcoming year.

Observations

CAPM determines the relationship between SBI and the market NIFTY 50, showing how it is majorly valuable for managing the overall portfolio risk. The expected return shown is adversely affected by crisis periods like COVID-19, as shown in this project. GBM gives a probability on price predictions, which helps with structural planning. Its simulations are mostly consistent and capture realistic ups and downs in volatility.

Final Insights

Together, these models show that SBI exhibits real, systematic market risk. Still, its actual performance doesn't always match up with what CAPM predicts, because of the deeper structural issues and the impact of crises. Reliance shows moderate fluctuations and a tight prediction range, giving steady long-term trends.

Table 1. Regression Output

Parameter	Value	Evaluation
β	1.59	SBI exhibits considerably higher volatility compared to the market; a 1% shift in market return results in a 1.59% variation in SBI return.
α	Minor Positive	Suggests slight outperformance in relation to risk, though statistically insignificant.
R^2	Moderate(~0.55)	CAPM accounts for roughly half of the variation in SBI returns.

Table 2. Estimated Parameters

Parameter	Value	Evaluation
Daily drift(μ_c)	–0.0001377	Marginally negative anticipated daily return.
Annual drift(μ)	–3.47%	Anticipated yearly trend is slightly negative.
Daily volatility(σ_c)	0.6787	Significant short-term fluctuation.
Annual volatility(σ)	10.77%	Average yearly volatility.

Table 3. GBM Simulation Outcomes

Statistic	Value
Mean final price	₹1186.89
5th Percentile	₹1118.37
95th Percentile	₹1277.00

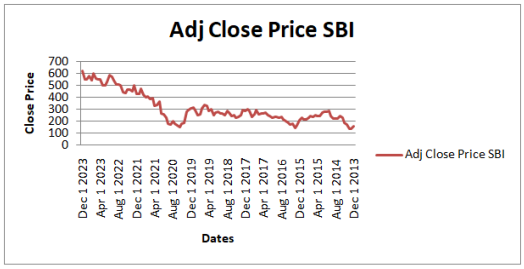

Figure 1: Adjusted closing price history of SBI between 2014 and 2024, illustrating long-term growth trends, cyclical fluctuations, and macroeconomic influences on stock performance

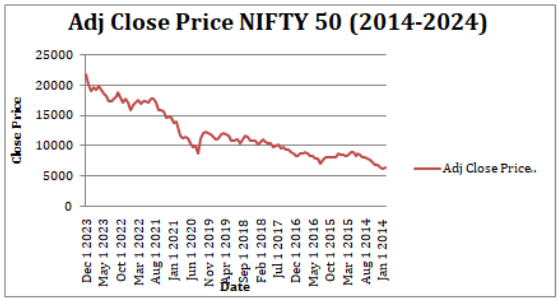

Figure 2: Trend of adjusted closing prices for the NIFTY 50 from 2014 to 2024, depicting overall market fluctuations and benchmark performance pertinent to CAPM.

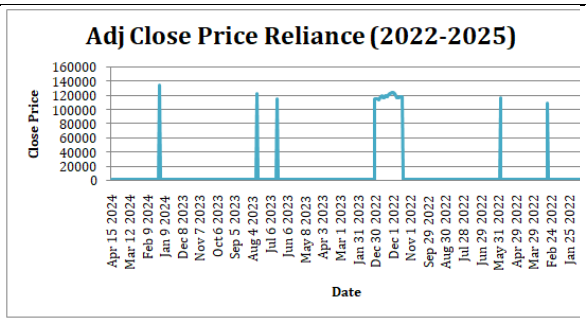

Figure 3: Daily adjusted closing price of Reliance Industries spanning 2022 to 2024, illustrating short-term variations and volatility trends pertinent for GBM modeling

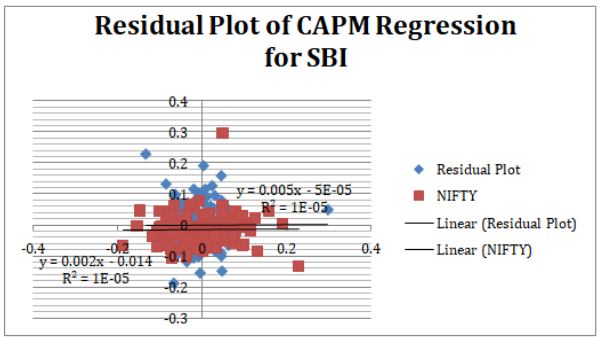

Figure 4: Residual plot of the CAPM regression for SBI, illustrating deviation patterns and evaluating the suitability of the linear model

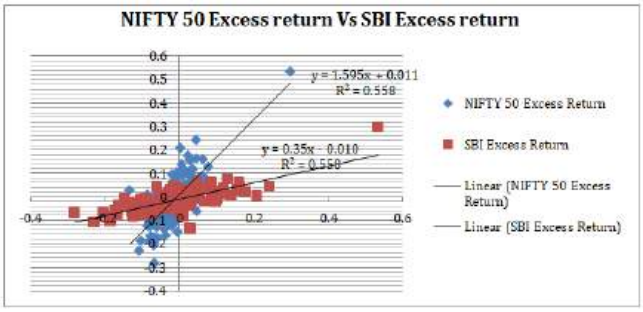

Figure 5: Scatter plot depicting SBI excess returns against NIFTY 50 excess returns, featuring the fitted CAPM regression line, demonstrating the estimated beta and relationship of systematic risk.

ABSTRACT

Opioid addiction is a major global health crisis characterized by neurobiological dysfunction, cognitive decline, psychiatric comorbidities, and high relapse rates. Conventional therapies often provide temporary symptomatic relief but fail to address long-term neuropsychological recovery. To critically review opioid addiction's neurobiological mechanisms and evaluate Ayurvedic therapeutic strategies—including *Panchakarma*, *Medhya Rasayana*, and *Satvavajaya Chikitsa* within an integrative treatment framework. A systematic literature search was conducted following PRISMA 2020 guidelines across PubMed, Scopus, Web of Science, Google Scholar, and AYUSH Research Portal. Studies related to opioid neurobiology, Ayurvedic addiction management, and integrative models published in the last 20 years were included. Eligible data were synthesized thematically. Opioid addiction disrupts mesolimbic dopamine signalling, enhances stress-axis reactivity, diminishes cognitive control, and increases relapse vulnerability. Ayurvedic detoxification procedures (*Vamana, Virechana, Basti, Nasya*), *Medhya Rasayana* herbs (Bacopa monnieri, Convolvulus pluricaulis, Celastrus paniculatus, Withania somnifera), and *Satvavajaya* therapies (meditation, pranayama) demonstrate potential benefits in neuroprotection, stress modulation, cognitive enhancement, and emotional stabilization. The mechanisms align with contemporary neurobiological evidence. *Ayurveda* provides a multidimensional therapeutic model that addresses physiological detoxification, cognitive restoration, emotional regulation, and long-term relapse

prevention. Integrating Ayurvedic therapies with modern treatment modalities may offer an evidence-based, holistic strategy for opioid de-addiction. Further clinical trials are needed for validation.

Highlights:

- Opioid addiction causes profound neurobiological, cognitive, and emotional dysregulation.
- Ayurvedic therapies provide detoxification, neuroprotection, and psychological stabilization.
- *Panchakarma* and *Medhya Rasayanas* align mechanistically with modern addiction neuroscience.
- *Satvavajaya Chikitsa* enhances emotional resilience and reduces relapse risk.
- Integrative Ayurvedic–neuroscience models may improve long-term addiction outcomes**.**

Keywords: *Opium addiction; Panchakarma; Rasayana therapy; Medhya Rasayana; Satvavajaya Chikitsa; Neurobiology of addiction; Ayurvedic detoxification*

INTRODUCTION

Opium addiction, characterized by the compulsive use of opium-derived substances, leads to dependence and withdrawal symptoms [1]. Derived from *Papaver somniferum* [2], opium has both medical and recreational applications but carries substantial risks, including cognitive impairment and mental health disturbances [3]. This review examines the psychological impact of opium addiction and outlines Ayurvedic management strategies such as *Shodhana Chikitsa* (detoxification) [4], *Shamana Chikitsa* (palliative care), and *Rasayana Chikitsa* (rejuvenation) [5]. Opioid addiction remains a major global health crisis, with rising consumption and increasing opioid-related mortality, particularly due to the proliferation of potent synthetic opioids such as fentanyl [6]. Within this context, Ayurvedic therapies represent promising complementary approaches for detoxification, withdrawal mitigation, and cognitive restoration.

Objectives

- Examine the neurobiological mechanisms of opioid addiction, focusing on disruptions in reward pathways, neurotransmission, and cognition.
- Summarize key Ayurvedic interventions for addiction management, including *Rasayana* therapies (rejuvenation), *Medhya Rasayanas* [6] (cognition-enhancing neuroprotective herbs), and Panchakarma procedures such as Vamana (therapeutic emesis), *Virechana* (therapeutic purgation), *Basti* (medicated enema therapy), *Nasya* (nasal administration), and *Raktamokshana* (bloodletting), along with commonly used herbal formulations.
- Evaluate integrative therapeutic approaches combining modern neuroscientific evidence with Ayurvedic principles to enhance detoxification, cognitive restoration, emotional regulation, and long-term relapse prevention.

MATERIALS AND METHODS

This systematic review was conducted in accordance with PRISMA 2020 guidelines. The methodological process included the following steps:

Literature Search

A comprehensive search strategy was applied across major biomedical and integrative medicine databases including PubMed, Scopus, Web of Science, Google Scholar, and the AYUSH Research Portal. Search terms included combinations of keywords related to opioid addiction neurobiology, *Ayurvedic* treatment modalities, *Panchakarma, Rasayana*, and integrative de-addiction approaches (*Figure 1: PRISMA Flow Diagram*).

Eligibility Criteria

Peer-reviewed articles published within the last 20 years were included if they examined (a) the neurobiological mechanisms of opioid use disorder, (b) Ayurvedic therapeutic interventions relevant to addiction management, or (c) integrative or comparative addiction frameworks. Studies not written in English, duplicates, commentaries, dissertations, and those unrelated to addiction or Ayurveda were excluded.

Data Extraction

Relevant data from the included studies were systematically extracted and organized into thematic categories. The major domains included:

(i) Neurobiological processes underlying opioid dependence,
(ii) Ayurvedic detoxification and rejuvenation therapies,
(iii) *Rasayana*-based cognitive and emotional restoration
(iv) Integrative therapeutic models.

Data Synthesis

A qualitative thematic synthesis was performed to compare, contrast, and integrate findings from modern neuroscientific and Ayurvedic literature. Emphasis was placed on mechanistic overlap, therapeutic complementarities, and translational relevance.

Quality Assurance

The systematic approach ensured that all included evidence contributed to an objective, comprehensive, and integrative understanding of opioid addiction and its management through Ayurvedic and contemporary therapeutic frameworks

Fig.1. diagram presents the structured process used to identify, screen, assess, and include studies in the systematic review. A total of 1,346 records were identified, of which 1,194 were screened, 112 full-text articles were assessed for eligibility, and 52 studies met the final inclusion criteria.

OBSERVATIONS AND DISCUSSION

Opium addiction is a significant global and national health crisis, with severe social and economic consequences. Globally, around 292 million people used drugs in 2022, with 60 million using opioids. Opioids are responsible for nearly 80% of drug-related deaths, with approximately 600,000 fatalities recorded in 2019, largely due to overdose (Fig.2). *This line graph illustrates the temporal trends in overdose deaths associated with major drug categories, including heroin, cocaine, methamphetamine and other stimulants, prescribed opioids (e.g., oxycodone), and fentanyl-related substances. The data show a sharp rise in fatalities linked to synthetic opioids, particularly fentanyl, after 2014, highlighting the escalating severity of the opioid crisis in the United States.*

In India, the situation is particularly alarming, with 2.1% of the population using opioids three times the global average. Opioid use is significantly higher among males (4%) compared to females (0.2%), and even children aged 10 to 17 years are affected (Fig:3). The increasing prevalence and high mortality rates highlight the urgent need for comprehensive and integrative treatment strategies, combining *Ayurvedic* detoxification, cognitive restoration, and psychological resilience-building with modern therapies for sustainable recovery. *Fig. 3 bar chart illustrates the prevalence of opioid use across the Indian population, showing national overall rates (2.1%), significantly higher prevalence among males (4%), and comparatively low prevalence among females (0.2%).*

Neurobiological Foundations of Opium Addiction

Mechanisms of Action

Opium addiction is primarily driven by its ability to alter the brain's reward system. Opioids bind to mu-opioid receptors (MORs) in the ventral tegmental area (VTA), nucleus accumbens , and prefrontal cortex, leading to inhibition of gamma-aminobutyric acid (GABA)-ergic interneurons(Fig.4). This disinhibition results in excessive dopamine release throughout the mesolimbic reward pathway [6]. The resulting surge in dopamine produces intense euphoria, reinforcing compulsive drug-seeking behavior and contributing to the development and maintenance of addiction.Furthermore, the amygdala and hippocampus, which are involved in emotional learning and memory formation, play a crucial role in linking opioid use with pleasurable experiences, reinforcing the addiction cycle [7].

Fig.4 diagram depicts the major neural pathways involved in opioid dependence. Activation of mu-opioid receptors inhibits GABA interneurons, increasing dopaminergic output from the ventral tegmental area (VTA) to the prefrontal cortex and limbic structures. The amygdala and hippocampus contribute to emotional memory formation, while locus coeruleus hyperactivity underlies withdrawal symptoms. Together, these circuits drive reward reinforcement, compulsive drug-seeking behavior, and withdrawal dysregulation

Tolerance and Dependence

Chronic opioid use leads to adaptive changes in neuroplasticity, diminishing opioid receptor sensitivity and resulting in tolerance, where increased doses are required to achieve the same euphoric effects [8]. Prolonged opioid exposure downregulates endogenous opioid production, making the brain reliant on external opioids for normal functioning [9]. When opioid consumption ceases, the hypothalamic-pituitary-adrenal (HPA) axis becomes hyperactive, leading to withdrawal symptoms such as anxiety, irritability, hyperalgesia (increased pain sensitivity), and dysphoria [10]. The noradrenergic system in the locus coeruleus is also hyperactivated, contributing to symptoms like sweating, nausea, and tremors [11].

Psychological Impact of Opium Addiction

Cognitive Impairments

Opium addiction is strongly associated with progressive cognitive decline. Attention and working memory deficits are common, with affected individuals experiencing difficulty concentrating and retaining information, leading to impaired problem-solving abilities [12]. Executive dysfunction arises due to opioid-induced disruption of prefrontal cortex activity, resulting in compromised decision-making, reduced impulse control, and poor planning, all of which contribute to compulsive drug-seeking behavior [13]. Additionally, reduced neurogenesis is observed with chronic opioid exposure, particularly within the hippocampus, negatively influencing learning capacity and memory consolidation [14].

Emotional Dysregulation

Opioid dependence significantly alters emotional processing due to its suppressive effects on the limbic system. Emotional blunting, characterized by apathy and reduced social engagement, arises from diminished amygdala activation [15]. Increased stress sensitivity occurs as dysregulation of the hypothalamic–pituitary–adrenal (HPA) axis heightens stress reactivity, making individuals more susceptible to anxiety and irritability [16]. Additionally, anhedonia**,** or the inability to experience pleasure, results from the downregulation of dopamine receptors in the nucleus accumbens, thereby increasing vulnerability to depressive symptoms [17].

Behavioral Changes

Opium addiction results in marked behavioral disturbances. Compulsive drug-seeking behavior emerges as striatal neuroadaptations cause the brain to prioritize opioid use over essential needs [18]. Risk-taking and impulsivity increase due to impaired decision-making, predisposing individuals to unsafe sexual behaviors, financial instability,

and criminal involvement [19]. Furthermore, social withdrawal becomes prominent as individuals disengage from family, occupational duties, and social environments, contributing to a progressive decline in quality-of-life [20].

Psychiatric Comorbidities

Opioid addiction is frequently accompanied by a range of psychiatric comorbidities. Major depressive disorder (MDD) is common, driven by opioid-induced dysregulation of serotonin and dopamine pathways, leading to low mood, hopelessness, and suicidal ideation [21]. Generalized anxiety disorder (GAD) often develops or worsens due to heightened stress reactivity and persistent worry associated with chronic opioid use [22]. Personality disorders, particularly antisocial and borderline traits, further contribute to impulsivity, aggression, emotional instability, and an increased risk of relapse [23].

Ayurvedic Approach to Opium De-Addiction (Fig.5)

***Shodhana Chikitsa* (Detoxification Therapy)**

Ayurveda places primary emphasis on *Shodhana* (detoxification) as the initial step in de-addiction, targeting the elimination of *Ama* (metabolic toxins) and residual opioid by-products from the body. Among the key detoxification procedures, *Raktamokshana* (bloodletting therapy) is used to alleviate toxin accumulation in the bloodstream, which is often associated with fatigue and systemic inflammation; controlled bloodletting facilitates toxin removal and improves blood oxygenation [24]. *Vamana* (therapeutic emesis) is particularly beneficial in managing *Kapha*-related disturbances observed during opioid withdrawal, as it helps clear the gastrointestinal and respiratory pathways, restore appetite, and reduce nausea and lethargy [25].

***Shamana Chikitsa* (Palliative Therapy)**

Shamana Chikitsa (palliative therapy) stabilizes the body and mind following detoxification, helping to reduce withdrawal-related anxiety, depression, and cravings. Key interventions include *Medhya Rasayanas (Table:1)* (neuroprotective and cognition-enhancing herbs) such as *Brahmi* (*Bacopa monnieri*), which improves cognition, memory, and emotional regulation [26]; *Shankhpushpi* (*Convolvulus pluricaulis*), known for its mood-stabilizing and anxiolytic effects [27]; and *Jyotishmati* (*Celastrus paniculatus*), which acts as a neurostimulant and enhances synaptic connectivity [28]. Additionally, adaptogenic *herbs* such as *Ashwagandha* (*Withania somnifera*), which modulates cortisol, improves sleep, and supports adrenal recovery [29], and *Guduchi* (*Tinospora cordifolia*), which promotes hepatic detoxification, enhances immune regulation, and supports HPA-axis balance [30], play a crucial role in restoring systemic and psychological stability during the de-addiction process.

***Rasayana* Therapy (Rejuvenation and Neuroprotection)**

Swarnaprashana (gold therapy) is traditionally described as enhancing cognitive resilience, emotional stability, and neuronal function, with some evidence suggesting that gold nanoparticles may support synaptic transmission [31]. *Chyawanprash*, a classical polyherbal formulation containing *Amla* (*Emblica officinalis*) and *Pippali* (*Piper longum*), is noted for its rejuvenative properties, improving vitality, digestion, immunity, and neuronal repair [32].

***Satvavajaya Chikitsa* (Ayurvedic Psychotherapy)**

Satvavajaya Chikitsa (Ayurvedic psychotherapy) focuses on strengthening mental and emotional regulation to reduce psychological dependence on opioids. *Dhyana* (meditation) has been associated with increased gray matter density in brain regions responsible for self-control, thereby helping to reduce cravings and impulsive behaviours [33]. *Pranayama* (breathwork practices), including techniques such as *Anulom Vilom*[*] and *Bhramari*[**], promotes autonomic stability and modulates neurotransmitter activity, effectively mitigating withdrawal-related anxiety and emotional distress [34].

Fig. 5. schematic illustrates the convergence of neurobiological mechanisms and Ayurvedic therapeutic principles in a unified de-addiction framework. Neurobiological pathways include dopamine reward regulation, HPA-axis modulation, neuroplastic repair, and cognitive control circuits. Ayurvedic interventions include Panchakarma detoxification, Rasayana-based neuroprotection,

Satvavajaya emotional regulation, and Medhya cognition-enhancing therapies. Together, these approaches support integrated detoxification, neuroregulation, and relapse prevention.

* Anulom Vilom Pranayama is a yogic breathing technique that involves alternate nostril breathing to balance the nervous system, calm the mind, and enhance respiratory and mental regulation. ** Bhramari is a humming-bee breath that calms the brain and reduces anxiety.

Fig.6. diagram illustrates the Ayurvedic therapeutic framework for addiction management, including Shodhana (detoxification through Vamana, Virechana, Basti, and Nasya), Shamana (stabilization with Medhya Rasayanas such as Brahmi (Bacopa monnieri), Shankhapushpi (Convolvulus pluricaulis), Ashwagandha (Withania somnifera), and Guduchi (Tinospora cordifolia)), and Satvavajaya (mind–behavior therapies including meditation and pranayama). Collectively, these interventions support cognitive restoration and reduce relapse risk

CONCLUSION

Ayurveda offers a comprehensive, multidimensional framework for managing opioid dependence by integrating detoxification *(Shodhana*), restorative herbal interventions (*Shamana* and *Rasayana*), and cognitive–behavioral strengthening (*Satvavajaya Chikitsa*). These interventions address key neurobiological disturbances such as dopamine dysregulation, HPA-axis hyperactivity, impaired executive control, and emotional instability. Evidence shows promising overlap between Ayurvedic mechanisms such as antioxidant effects, neuroendocrine modulation, and enhancement of synaptic plasticity and modern neuroscience findings. While integrative Ayurvedic-modern protocols have significant potential for sustainable recovery, high-quality clinical trials are needed to establish standardized treatment guidelines, optimal dosages, and measurable outcomes.

ABSTRACT

The negative impact on the environment, changing climate, and growing global concern for the environment have led to both consumers and businesses to give the highest priority to the environment. In this regard, green marketing has been a very helpful tool for those companies that want to not only sell more and keep the environment clean but also control the consumption patterns of sustainability. The present research looks at the effects of the green marketing approaches on the buyer intentions of the Indian market, which is one of the fastest growing global consumer economies, marked by an increase in the environmental consciousness and demand for sustainable products. The questionnaire is given to 500 urban consumers living in four main metropolitan cities, the study assesses what influences the major green marketing elements like eco-labeling, green packaging, and corporate social responsibility (CSR) communication on the purchase decisions. The use of correlation and multiple regression techniques disclose that eco-labeling and the consciousness of the environment are the main tendencies towards the purchase of the product, and these are followed by green packaging and CSR initiatives. Pricing issues are still the main obstacle to getting more buyers even though consumers have a good opinion on the eco-friendly products. The results bring out the necessity of having solid environmental claims, open

sustainability practices, and pricing strategies that are in line with the competition to win over consumers and get the market accepted. For the companies and the marketers, this study is an important source of literature on green consumerism which will also provide them with the necessary insight to plan and promote sustainable consumption behaviors in India.

Keywords: Environmentally friendly products, Ecologically related marketing, Indian consumers, Green marketing programs and strategies, Green marketing practices, and Indian consumers are stimulated to make eco-friendly buying choices.

INTRODUCTION

The concerns about the environment that are growing together with the rapid depletion of natural resources have moved the world towards sustainable consumption. Green marketing, which is mainly trying to sell the product based on its environmental attributes, has emerged as a major tool for the companies trying to establish long-term consumer relationships [1]. Urbanization, disposable incomes, and environmental consciousness in India are all conditions that are very conducive to the green marketing strategies [6]. On the one hand, Indian consumers are more aware of eco-friendly products than ever before, but on the other hand, there is no steady demand for such products. Different consumers' perceptions, trust issues, and in general, price sensitivity are the main causes of inconsistency that can be observed in the results of different studies [4]. In addition to their values and beliefs, research shows that consumers' acceptance of green products depends on very many factors having either a positive or negative impact, such as product characteristics, communication, and promotion, as well as social influences [2],[7]. Therefore, it is vital to study the impact of green marketing strategies on the purchase intentions of the Indian market in order to create a precise sustainable marketing framework.

LITERATURE REVIEW

The requirement for all industries and green marketing to move from a niche strategy has been primarily driven by consumers' demand for transparency and sustainable practices [8]. Eco-labeling has become one of the most important methods for companies to exhibit their devotion to the environment and the needs of consumers, which has, in turn, influenced the environment-friendly direction of consumer choices [9]. Also, through the use of eco-friendly packaging, sustainable materials, and waste reduction, the consumers' views can be greatly affected [10]. CSR activities not only help to create a strong trust among customers but also aid in the creation of a good brand image, thereby, increasing consumer loyalty[5]. Intention to purchase is influenced by attitudes, social norms, and perceived control over the behaviour [2]. Many different research works have verified that concern for the environment is directly linked with the adoption of green purchasing habits [11]. But on the other side, the green product market is always beset with the problems of high prices along with the doubts about the eco-friendliness of the products which result in low demand [12]. India is witnessing a rise in environmental awareness but it is not reflected uniformly across all population categories in terms of purchasing habits [13]. The urban population is found to be more open to trying and accepting eco-friendly products than the rural population [14]. The whole concept of digital influence in the area of sustainable consumption is becoming more and more important as it is doing so at a fast pace [15].

METHODOLOGY

This study utilizes a quantitative study strategy that will help to clarify the influence of green marketing strategies on the consumption intentions of eco-friendly products among Indian consumers. The whole methodology has been laid down in such a way that it guarantees the findings to be reliable, valid, and applicable to other contexts. This part

describes the research method, sampling plan, instrument construction, data gathering process, and the different analytic methods employed in the investigation.

Research Approach

For the measurement of consumer attitudes, perceptions, and purchase intentions, a quantitative survey-based approach was selected. Quantitative research is systematically and objectively pet. It is quite common in marketing and consumer-behavior studies, mainly when the relationship between variables is analyzed by applying statistical methods. The study takes an explanatory point of view and tries to find out the impact of specific green marketing strategies (eco-labeling, green packaging, CSR communication, etc.) on purchase intentions.

Population and Sampling

The Indian consumers aged between 18 and 45 years, who were aware of the green products or had at least once bought them, were the target population. Non-probability convenience sampling was adopted because of the vast area covered by India and the related logistic problems. Although fully non-random, this method is still suitable for exploratory consumer behavior research, especially when the respondents have to be previously exposed to sustainable products. The total number of respondents who took part in the study is 500. The respondents were taken from the four major metropolitan cities—Delhi, Mumbai, Bangalore, and Chennai since these urban centers have good environmental awareness, the widest product availability in the market, and also the most exposure to green marketing campaigns. The distribution across cities was made with the goal of capturing different socio-economic and cultural backgrounds in the urban consumer group.

Instrument Development

A structured questionnaire was made by taking reliable scales from past studies on green marketing and consumer behavior.

The questionnaire had four main parts:

Demographic data (age, sex, income, education).

Environmental awareness (assessed by 5 items taken from Chan, 2001).

Attitudes toward green marketing strategies: Eco-labeling (4 items), Green packaging (4 items), CSR communication (3 items)

Purchase intention towards eco-friendly products (5 items from Ajzen's TPB model) All items were scored on a 5point Likert scale where 1 = Sturdily Disagree and 5 = Effectively Agree. The assess was pre-verified on a small crowd of 30 participants to check if the questions were understandable and if the measurement was consistent. Some minor changes were made based on the feedback.

Data Collection Procedure

To make the surveys more accessible and get more responses, they were done in both online and offline ways for four weeks.

- Google Forms was used for the online surveys, while email, WhatsApp groups, and social media sites were utilized to spread the word.
- The offline questionnaires were given out in selected cities in shopping malls, supermarkets, and university campuses.

The respondents who provided the answers to the questionnaires were assured that their identities would not be revealed and that their responses would be kept secret, and the others were allowed to participate if they wished. The number of responses gathered was 532, but after eliminating the invalid ones, only 500 valid responses remained, which were the result of filtering out the incomplete surveys and inconsistent answers through screening.

Reliability and Validity Testing

To make sure the data was of high quality, both reliability and validity tests were performed:

- Cronbach's alpha was utilized to evaluate the internal consistency of each construct. The results for all the constructs were higher than 0.78, which is well above the suggested minimum of 0.70.
- Validity of the content was secured by adopting measurement items from earlier studies that had been validated.
- Validity of the construct was proven by factor analysis (KMO value = 0.84), which signified that the data was suitable for subsequent statistical analysis.

Data Analysis Techniques

The statistical analysis was performed through SPSS 26.0 program. The subsequent methods were used successively:
Descriptive Statistics: Presented the respondents' demographic characteristics and key variable mean scores.

Correlation Analysis: Found out the degree and the nature of the relationships between green marketing strategies and purchase intentions.

Multiple Regression Analysis: Provided support for the impacts of eco-labeling, green packaging, CSR communication, and environmental awareness on consumer purchase intention.

ANOVA Tests: Conducted to compare the differences in purchase intentions of different demographic groups (age, income, education).
The cumulative effect of using these statistical methods was to yield a very detailed understanding of how green marketing strategies affected consumer behavior in the Indian market.

RESULTS AND DISCUSSION

The research brought out very important factors of the impact of green marketing methods on the purchase intent of consumers in India. The responses of the 500 participants were subjected to a range of statistical methods, including, but not limited to, descriptive statistics, correlation analysis, regression modeling, and ANOVA. This section gives a detailed account of the demographic traits, the mean values of the major variables, the statistical results, and the discussion.

Demographic Profile of Respondents

The respondents' demographic characteristics are built up in Table 1. The sample represented a variegated urban population in terms of different age groups, income levels, and education categories.

Descriptive Statistics

Descriptive analysis was conducted to gauge the respondents' perceptions on green marketing strategies and their purchase intention. The findings are shown in Table 2. Mean values show a high level of environmental awareness and a positive perception of eco-labeling, whereas CSR communication received a lower score but still above the mid-point, indicating a fair trust in corporate environmental claims

Correlation Analysis

To evaluate the relationships relating the green marketing constructs and the purchase intention, Pearson correlation coefficients were calculated. The findings are represented in Table 3.
Notes:$p < 0.01$ for all correlation values.
The correlation between eco-labels and the purchase intention was the highest (r = 0.71), which implies that the eco-labels positively support the consumers' trust up to a great extent.

Regression Analysis

A several regression testing was functioned to find out the extent to which green marketing influences the consumer's purchase intention. The results have been got in Table 4.

Summary of the Model

R = 0.81

R^2 = 0.66

Adjusted R^2 = 0.65

F = 118.42, **p** < 0.001

The model accounts for 66% of the change in the purchase intentions, thus indicating a very robust predictive performance. The variable eco-labeling has been disclosed as the greatest predictor ($\beta = 0.38$), which is in accordance with the previous correlation findings.

ANOVA – Differences Based on Income Groups

One-way ANOVA was used to assess the variations in purchase intention between the different income groups. ANOVA Results for Purchase Intention by Income Level (Table 5). The analysis revealed a significant difference ($p = 0.001$) in purchase intention across income groups, indicating that the higher-income group of respondents was more willing to buy eco-friendly products.

Figures

Mean Scores of Green Marketing Constructs (Figure 1)

Description

A bar chart illustrating the average of each construction: Environmental Awareness: 4.12, Eco-Labeling: 4.02, Green Packaging: 3.89, CSR Communication: 3.76, Purchase Intention: 3.94 This graph shows that the highest scores were given to environmental awareness and eco-labeling.

Regression Impact of Predictors on Purchase Intention (Figure 2)

Description

The Y-axis of the clustered bar graph with standardized beta values presents eco-labeling (0.38), environmental awareness (0.31), green packaging (0.24), CSR communication (0.19) as the bars. Eco-labeling, which is the tallest bar, consolidates its leading impact.

Purchase Intention by Income Groups (Figure 3).

Description

A line or bar graph representing income categories, where the upper category made considerable buyers' eco-friendly products' price willingness scores clearly visible. The consumers with income higher than ₹75,000 were much more inclined to purchase environmentally friendly products than the others.

CONCLUSION AND RECOMMENDATIONS

The research has come to a conclusion that the adoption of green marketing strategies—most notably eco-labeling, green packaging, and CSR activities—affect the consumer's willingness to buy eco-friendly products in India to a great extent. It is recommended that marketers concentrate on the offered product's transparency, eco-certifications' fortification, and the environmental benefits communication all the more effectively. Price sensitivity can be handled further through the methods of subsidies, loyalty programs, or even cheap but sustainable materials thus adoption can take place. Long-term research should focus on the areas of digital influence, comparing different cultural consumers, and sustainability behavioral shifts.

ABSTRACT

2-aminothiazole single crystal was grown by slow evaporation method. The crystal has been characterized by UV-Visible NIR spectrum, Photoluminescence, Thermal analysis and Dielectric analysis to confirm its suitability for optical applications. The various optical and electrical properties has been calculated from the UV-Visible spectrum. Photoluminescence spectra revealed the violet light emission observed at 380 nm. The grown crystal was thermally stable up to 170˚C , confirmed from the thermo gravimetric analysis. The crystal exhibits high dielectric behaviour at low frequency and the dielectric behaviour is low at higher frequencies.

Keywords: Optical properties, Photoluminescence, Dielectric constant and loss, Thermal studies.

INTRODUCTION

Aminothiazole have many applications in both human and veterinary medicine [1].Organic molecular materials are appealing in controlling the light beam by an electric field because they offer many possibilities to tune their optical properties and obtain large electro-optic effects [2]. The main advantage of organic materials is that their structures can be easily altered to get the craved optical properties [3, 4]. Optical properties of the crystalline materials provide

information regarding the composition, nature and quality of the crystal. The Optical behaviour of the materials is important to determine their usage in optoelectronic devices [5]. The FTIR, FT-Raman and DFT of 2-aminothiazole have been already reported [6].The optical band gap of the 2-Aminothiazole have been calculated using Tauc'splot as 3.05 eV. The optical constants have been reported earlier [7].The title compound has been screened for its suitability in the fabrication of optoelectronic devices.

EXPERIMENTAL

2-aminothiazole (1.00g) was dissolved in 20 ml ethanol. The dissolved solution was then filtered. The filtered solution was allowed for slow evaporation in room temperature. Brown blockcrystal was obtained after two weeks on slow evaporation of the solution. Figure 1 shows the chemical diagram of 2-aminothiazole. The grown crystals are shown in figure 2.

RESULTS AND DISCUSSION

UV VISIBLE ANALYSIS

The optical properties of a material are important, as they provide information on the electronic structures and types of optical transitions[8].The UV-Visible absorption spectrum of 2-aminothiazole was recorded using Perkin Elmer Lamda 35 spectrophotometer in the wavelength range of 190 nm to 1100 nm. The UV-Visible absorption spectrum is shown in figure 3. The peak at 270 nm is due to the electron transitions from the highest occupied molecular orbital (HOMO) to the lowest unoccupied molecular orbital (LUMO) corresponding to the n→π^* electronic transition [9].

Optical Conductivity

The optical conductivity (σ_{op}) response of 2-aminothiazole crystal is derived from the value of the refractive index and absorption co-efficient by the following expression [10],

$$\sigma_{op} = \frac{\alpha nc}{4\pi}$$

The variation of the optical conductivity with wavelength is shown in figure4 (a). The optical conductivity as a function of photon energy (hυ) is shown in figure4 (b).

Optical Resistivity

The optical resistivity of a material is equal to the reciprocal ofits optical conductivity. The optical resistivity can be measured using the relation [11],

$$Poc = \frac{1}{\sigma_{op}}$$

Where, σ_{op} is optical conductivity. The variation of the log of optical resistivity with wavelength is shown in figure5 (a). The variation of optical resistivity with photon energy is shown figure5 (b). The low value of the optical resistivity at high photon energy suggests that the sample possesses enhanced optical quality with lesser defects and this parameter is of vital importance for NLO applications [12].

Electrical Conductivity

The value of electrical conductivity of a material is related with the optical conductivity value of the crystal using the following equation [13]

$\sigma_e = \frac{2\lambda\sigma_{op}}{\alpha}$

The electrical conductivity decreases with the increasing photon energy [14]. The variation of electrical conductivity with wavelength is shown in figure6 (a). The electrical conductivity as a function of photon energy (hυ) are shown in figure 6 (b).

Electrical Resistivity

The electrical resistivity of a material is equal to the reciprocal of its electrical conductivity. The electrical resistivity is calculated using the below relation [11],

$$Pec = \frac{1}{\sigma_e}$$

The variation of electrical resistivity with wavelength are shown in figure7 (a). Corresponding to the wavelength 500 nm electrical resistivity suddenly increases and drops down. This increasing optical resistivity region is suitable for NLO applications. The electrical resistivity as a function of photon energy (hυ) are shown in figure7 (b).

Electric Susceptibility

Susceptibility is the response of the medium to light [15]. Electric susceptibility (χ_c) can be calculated from the following relation [16, 17].

$\varepsilon_r = \varepsilon_0 + 4\pi\chi_c = \eta^2 - k^2$

$\chi_c = \eta^2 - k^2 - \varepsilon_0/4\pi$

ε_0 is the dielectric constant in the absence of any contribution from free carriers. The complex dielectric constant is given by ε_c. The real and imaginary part of dielectric constant from extinction coefficient are given as [17-19].

$\varepsilon_c = \varepsilon_r + \varepsilon_i$

$\varepsilon_r = n^2 - k^2$

$\varepsilon_i = 2nk$

Where $\varepsilon_r$and ε_i are real and imaginary part of dielectric constant. The electric susceptibility is calculated as χ_c = 0.1214. The real ε_r and imaginary ε_i values of dielectric constant are 1.5257 and 3.7391×10^{-6}.

Photoluminescence Analysis

The intrinsic behavior in the forbidden band region of the grown crystal is indicated by the luminescence phenomenon using Varian Corey Eclipse photoluminescence spectrophotometer. The photoluminescence excitation spectrum was recorded in the range of 300 nm to 600 nm. The excitation wavelength of 370 nm is as shown in figure 8. The emission spectrum reveals that the 2-aminothiazole crystal shows the presence of sharp intense peak at 370 nm (3.35eV) violet emission and a weak peak observed at 540 nm (2.29eV) green emission. The absence of visible emission bands has indicated that the high crystal quality and perfect crystallinity of the grown crystals [20,22]. This excitation spectrum indicates the emission of violet..The bandgap energy is calculated from the formula [21],

$$Eg = \frac{1240}{\lambda}$$

The calculated band gap energy is 3.26 eV.

Thermal Analysis

The thermal analysis provides the measure of the weight loss and the thermal stability of the grown crystal. TG-DTA analysis was carried out using SDT Q600, TA instruments in the temperature range of 30℃ – 320℃at the heating rate at 10℃ per minute in air atmosphere.. TG and DTA graph of 2-aminothiazole is shown in figure 9. TG curve reveals

the decomposition occurs in the temperature range between 170 ℃ and 600 ℃ with the mass change 89.24%. From DTA curve, the first and second endothermic peaks are observed at 65 ℃ and 165 ℃ reveals the melting point of the 2-aminothiazole single crystal. The sharpness endothermic peaks represent the melting point of the crystal [22,23].

Dielectric Analysis

The dielectric constant and dielectric loss was measured using Jognic's model 2816 B LCRZ meter. The experiment was carried out in the frequency range of 50 HZ to 200 KHZ. The high value of dielectric constant at low frequency may be due to the presence of all polarizations, namely space charge, orientation, electric and ionic polarizations [24]. The electrical energy is absorbed by the material and is dissipated in the form of heat. This dissipation of energy is called dielectric loss [25]. The figure 10 and 11 shows the variation of dielectric constant and dielectric loss in the range of frequency. It is clearly shows that the values of dielectric constant and dielectric loss decrease with increase in frequency. According to Miller rule, the dielectric constant and dielectric loss at higher frequency clearly shows that the material defect less and with good optical quality. So it is suitable for nonlinear optical applications [26-28].

CONCLUSION

Optically good quality single crystal of 2-aminothiazole single crystal was grown by slow evaporation method. UV-Visible absorption analysis reveals the electron transitions around wavelength 270 nm which confirms the formation of $n \rightarrow \Pi^*$ in grown crystal. From photoluminescence analysis violet excitation peaks observed at 380 nm for grown crystal. The grown crystal is thermally stable up to 170 ℃ which was confirmed by TG-DTA analysis. Dielectric analysis confirmed high optical quality and less defect concentration in the grown crystal.

ABSTRACT

Environmentally friendly goods usually have a price premium associated as well as supplementary access costs that may limit adoption amongst economically disadvantaged consumers. The paper studies how affordability related barriers influence the consumption of green products among low-income families in sub-urban areas of Bengaluru. A cross sectional survey is suggested with a structured questionnaire to specifically capture perceived price premium, household budget constraints, access/transaction costs and perceived affordability as well as perceived fairness. The study illustrates (i) association testing which is the Chi-square test; (ii) strength and direction testing of association using Pearson correlation; and (iii) predictive influence testing of one or more explanatory variables findings through multiple regression. The model lends support to the claim of affordability and economic impediments as primary predictors of green product consumption in low income context.

Keywords: Green Products, Affordability, Price Premium, Low-Income Households, Survey, Chi-Square, Correlation, Regression.

INTRODUCTION

Sustainable consumption is now a mantra for environmental protection and production responsibility. Yet in most markets, green products are more expensive because they're made with eco-materials, certified or produced cleaner

or a company has to change its supply chain. This "green premium" can also be a prohibitive factor for cash-strapped households, who put value, low pricing and financial certainty above all. The literature indicates in fact that, when money is short and purchasing power limited, the willingness of consumers to buy green may only just be skin deep if at all. Experience from India and other developing settings suggests that perceived affordability, price sensitivity and access barriers affect whether consumers act on intended positive attitudes to purchase. In the suburbs i.e. outlying areas of Bengaluru, there is a high proportion of households under cost burden (Housing, Transport, Food and Utilities). In these situations, green consumption may be driven more by household economics (i.e., perceived price premium, budget constraints and additional access/transaction costs of time, travel and limited retail availability) than based on moral intention. There is meagre evidence of empirical research in the context of low income residents in sub-urban Bengaluru and hence an opportunity for a targeted quantitative research.

REVIEW OF LITERATURE

Price premium and willingness to pay for green products

A common issue in green consumption literature is the price premium associated with environmentally friendly products and its detrimental effect on purchase intention of low income consumers. Yadav & Pathak (2017) demonstrate that perceived behavioural control and intention significantly influence green purchasing behaviour in a developing country context, implying the feasibility aspect of being green when resources are scarce. In a related study, Prakash & Pathak (2017) report that the green purchase intention for eco-friendly packed goods is influenced by psychological and control determinants but in low involvement, price sensitive markets the capability to act factor still holds pertinence. Paul, Modi & Patel (2016) find in India that attitude and perceived behavioral control have significant predictive power for intention to be associated with behavior, thereby indicating that affordability limitations can attenuate the translation of intentions into behaviors.

Kirmani & Khan (2018) concentrate on India per se and 'explains' the willingness to pay a premium for green products, as underlined by consumer related evaluations of costs versus benefits. Biswas & Roy (2016) directly investigate willingness to pay for green products in the emerging-economy context and ensure that economic motives underlie premium payment behaviours. Hao et al. (2019) demonstrate that consumers' willingness to pay for green packaging is contingent on how the premium can be perceived and rationalized. Shi & Jiang (2023) also posit that willing to pay the premium price is influenced by reference group and awareness, hinting that social influence can be of importance – however affordability may still stand in the way.

Affordability constraints and the "attitude–behavior gap"

There is a large body of work on why positive environmental attitudes often do not result in green buying. Testa et al. (2021) critique the drivers of green consumption and argue that structural barriers, including economic-related ones are among the primary causes for divergence between concern and purchase. Sharma, Aswal & Paul (2023) provide a similar but more generalized aggregate picture and several recurrent determinants (attitude, norms, control, trust) as well as market/practical constraints constraining the actual buying. Patiño-Toro et al. (2024) additionally chart antecedents of green purchase intention/behavior and note that roadblocks vary by consumer segment and setting—encouraging localized research. Megha (2024) examines green consumption studies with the lens of literature synthesis and finds mixed results across socio-demographics—further supporting the evidence from particular segments like lower income households.

Nekmahmud & Fekete-Farkas (2020) expand the TPB in an emerging market and find that intentions and behavior depends on several factors, such as price perception, perceived benefit. Ogiemwonyi et al. (2023) also highlight that attitudes mediate this relationship but in terms of the effects of environmental factors suggest that barriers in particular can interfere with the link between attitude and purchase.

Willingness-to-pay evidence from meta-analysis and food/organic parallels

The evidence from sustainability/organics product categories is particularly relevant for green goods because the latter are also typically associated with premium prices. Li & Kallas (2021) aggregate evidence from around the world and verify that the size of consumers' willingness to pay premiums differs by product and attribute, but the premiums do exist and matter in all situations. Katt & Meixner, 2020) systematically review determinants of wtp for organic food and outline the ways in which perceived advantages and consumer values interplay with premium willingness. Smoluk-Sikorska et al. (2023) note, market price premiums can outstrip consumer willingness to pay resulting in a practical affordability gap. De Pelsmacker, Driesen & Rayp (2005) – which concentrated on fair-trade coffeeoffer their seminal evidence that ethical preferences do not necessarily translate into premium payments across all segments (and one which has direct bearing on the low-income constraint).

India / emerging market evidence on price sensitivity and availability

In India-related evidence, Srivastava & Gupta (2023) explicitly connect **price sensitivity** with green purchase intention and add that green product availability and interventions can shape buying outcomes—implying that affordability and access work together. Sun, Li & Wang (2022) show motivational framing ("for me" vs "for others") affects intention, but intention still interacts with economic feasibility in real purchase contexts. Kumar, Prakash & Kumar (2021) show that responsible purchase intention in an emerging market is influenced by consumer assessments of benefits and constraints, reinforcing the role of affordability-linked perceptions.

Research gap

Most studies either (i) examine general consumers, (ii) analyze intention rather than consumption, or (iii) treat economic barriers indirectly. A focused study on economic barriers among low-income households in Bengaluru's sub-urban areas can provide locally relevant evidence for marketers and policymakers.

Statement of the Problem

Green products are promoted as environmentally beneficial, yet adoption among low-income households remains limited. In Bengaluru's sub-urban areas, economic pressures may increase price sensitivity and reduce the feasibility of paying a green premium. Without local evidence, interventions may fail to address the real drivers of non-adoption. This study therefore investigates the economic barriers (price premium, budget constraints, access costs, affordability perceptions, and perceived value) influencing green product consumption among low-income households.

Objectives of the Study

i. To measure the level of green product consumption and key affordability-related perceptions among low-income households in Bengaluru's sub-urban areas.
ii. To test the association between household income categories and green product consumption using the Chi-square test.
iii. To examine the relationship and predictive influence of economic barriers on green product consumption using correlation and regression analysis.

Scope of the Study

The scope is limited to low-income households in selected sub-urban areas of Bengaluru. The study focuses on economic barriers (price premium perception, budget constraints, access/transaction costs, perceived affordability, and value for money) and their relationship with green product consumption behavior (purchase frequency/regularity).

Research Model and Hypotheses

Key variables

- **Dependent Variable (DV):** Green Product Consumption (frequency/regularity index)
- **Independent Variables (IVs):**
  - Perceived Price Premium (PPP)
  - Household Budget Constraint (HBC)
  - Access/Transaction Cost (ATC)
  - Perceived Affordability (PA)
  - Perceived Value for Money (VFM)
- **Control:** Income category

Hypotheses

Chi-square hypothesis

- $H0_1$: Income category and green product purchase status are independent.
- $H1_1$: Income category and green product purchase status are associated.

Correlation hypotheses (examples)

- $H0_2$: There is no significant relationship between perceived affordability and green product consumption.
- $H1_2$: Perceived affordability is significantly related to green product consumption. (Repeat similarly for PPP, HBC, ATC, VFM.)

Regression hypotheses

- $H0_3$: Economic barrier variables do not significantly predict green product consumption.
- $H1_3$: Economic barrier variables significantly predict green product consumption.

RESEARCH METHODOLOGY

Research design

Descriptive and explanatory, cross-sectional survey design (quantitative). The descriptive component profiles barriers; the explanatory component tests associations and predictions using inferential statistics.

Sampling technique

- **Stage 1 (Area selection):** Multi-stage sampling to select sub-urban wards/settlements of Bengaluru (e.g., peripheral/transition zones).
- **Stage 2 (Household selection):**Stratified sampling within selected localities using income categories that qualify as "low income" (defined operationally by your cut-off—monthly household income).

Sample size

n = 384 is commonly used for large urban populations with 95% confidence and 5% margin of error.

Sample unit and sample area

- **Sample unit:** Household decision-maker for routine purchases (grocery/household goods)
- **Sample area:** Selected sub-urban localities of Bengaluru (clearly list wards/areas in the final paper)

Data collection

- **Primary data:** Structured questionnaire (5-point Likert scale) administered through field survey or assisted interviews (recommended for low-income respondents).
- **Secondary data:** Prior studies and review papers for construct selection and tool justification.

Statistical tools used

1. **Chi-square test** – association between income group and purchase status
2. **Pearson correlation** – direction/strength between economic barrier variables and consumption
3. **Multiple linear regression** – predictive impact of economic barriers on consumption

Data Analysis and Interpretation (with hypothesis testing)

Descriptive Statistics

Interpretation: Economic pressure variables (price premium, budget constraint) are high on average, while perceived affordability and green consumption are relatively lowconsistent with affordability constraints limiting adoption in low-income households.

Chi-square test (Income × Purchase status)

$H0_1$: Income category and green product purchase status are independent.

$H1_1$: Income category and green product purchase status are associated.

Chi-square result: $\chi^2(2) = 26.15$, $p < 0.001$; Cramer's V = 0.261

Decision: Since $p < 0.05$, reject $H0_1$.

Interpretation: Purchase status differs significantly across income groups. As income rises within the "low-income" band, the share of green purchasers increases, supporting the argument that affordability constraints suppress adoption.

Correlation analysis (Pearson)

$H0_2$: No significant relationship exists between each economic barrier variable and green consumption.

$H1_2$: A significant relationship exists.

Decision: For each variable, $p < 0.05$ → **reject $H0_2$**.

Interpretation:

- Greater affordability and higher value-for-money perceptions are associated with greater green consumption.
- The perceived price premium is a significantly positively correlated factor for green consumption; the stronger budget restrictions and higher access costs are both negatively correlated.
- These findings are consistent with the economic barrier framing introduced in previous work on price premium and affordability limitations.

Multiple regression analysis (DV: Green Consumption)

$H0_3$: Economic barrier variables do not significantly predict green consumption.

$H1_3$: Economic barrier variables significantly predict green consumption.

Model summary: $R^2 = 0.431$, Adj. $R^2 = 0.422$, $F = 47.59$, $p < 0.001$

Decision: Since model $p < 0.05$, **reject $H0_3$**.

Interpretation: Economic factors are the most influential predictor of green product purchase. Perceived affordability is the most positive predictor, while perceived price premium is the most negative one. A budget constraint and cost of access also limit consumption. This corroborates the finding that economic viability (not just attitude) is a key determinant of green adoption among low-income households.

FINDINGS

i. The consumption of green products among low-income households appears to be restricted thereby revealing a significant price barrier.

ii. Income level is strongly associated with green purchase status (i.e., purchasing power divides even among low-income populations).

iii. Energy consumption features negative effects purely on perceived price premium, budget constraints and access costs to green; perceptions of affordability (good value for money) have positive effects purely on green.
iv. Regression results reveal that economic constraints collectively account for a significant portion of the variance in consumption, suggesting a policy and market design oriented to affordability.

Suggestions

i. Price interventions: Create low-unit packs, involve subsidies, or discount schemes in sub-urban retail.
ii. Low access cost: Deepen distribution through kirana stores, community outlets and last-mile delivery with low delivery fee.
iii. Value perception: stress "cost-saving in the long run" (endurance/health and safety) in order to enhance value-for-money perceptions.
iv. Micro-incentives: reward points/cashback for buying certified green products repeatedly.
v. Policy support: local awareness + price support programmes can be more effective than just awareness alone.

Limitations

i. Cross-sectional design cannot confirm causality.
ii. Self-reported measures may include recall and social desirability bias.
iii. Low-income classification depends on operational cut-off and may vary across localities.
iv. Product categories may differ in premium magnitude; results may vary by category (FMCG vs appliances).

CONCLUSION

Affordability is established as the predominant barrier to green product consumption by low-income households in Bengaluru sub-urban region. Evidence suggests that perceived price premium, household budget constraint and access/transaction costs are major hindrance to the consumption while affordability perception and value for money drive adoption. The findings contribute to the case that fostering green consumption in low-income markets calls for affordability-oriented, rather than attitudinal, intervention.

ABSTRACT

In this research paper, the Date-Jimbo-Kashiwara-Miwa equation (DJKM) is solved analytically utilizing the similarity transformations approach via classical Lie-group theory. The similarity transformation method (STM) reduces the number of independent variables by one at each step. The STM is applied to Date-Jimbo-Kashiwara-Miwa equation and after successive application it reduces an ordinary differential equation. This can be solved further to get invariant solutions of the DJKM equation. This research has the potential to solve Date-Jimbo-Kashiwara-Miwa equation in a more general approach. Fluid mechanics, oceanography, optical fiber, fluid dynamics are all applications of the system.

Keywords: Lie symmetry analysis, Invariant solutions, Similarity transformation method and DJKM Equation.

INTRODUCTION

Nonlinear partial differential equations (NPDEs) are used to solid-state physics, plasma physics, applied physics, and applied mathematics, among other scientific areas. Quantum physics, electrodynamics, biology, fiber optics, chemical physics, and astrophysics are among the fields of physics that may be studied with NPDEs. We must obtain accurate solutions to the NPDE (Gabar and Wazwaz, 2024). The Date-Jimbo Kashiwara-Miwa (DJKM) equations are used to

build models in mathematical physics with weak nonlinear restoring forces and frequency dispersion with low surface tension and long wave lengths (Akram G.et.al., 2021).In integrable systems, the Jimbo-Kashiwara-Miwa (JKM) equation is a crucial nonlinear PDE that builds upon traditional models such as the KdV and KP equations. It was first proposed by Jimbo, Kashiwara, and Miwa in the 1980s and emerged from the research of soliton theory and isomonodromic deformations (Kumar, M. and Manju, K., 2022).The Lie group analysis, introduced by Mathematician Sophus Lie (Chauhan A.et.al., 2020), plays a powerful role in finding solutions to PDEs. Lie groups of transformation can be used in many methods of analyzing solutions PDEs. Dynamic mathematical and physical phenomena express exact solutions of partial differential equations (Bibi, K. and Khalil, A., 2021).

The DJKM equation has been extensively researched, and its solitary wave solutions have been reported in many different kinds of studies. Its two-dimensional dynamics are still not well understood, though. With applications to fusion and space plasma systems, this study focuses on obtaining invariant solutions to improve our knowledge of anisotropic environments and wave interactions in magnetized plasmas.

The DJKM is a $(2+1)$-dimensional nonlinear integrable PDE that describes multidimensional wave propagation. The Date-Jimbo Kashiwara-Miwa (DJKM) equation is a member of the Kadomtsev-Petviashvili(KP).Kadomtsev-Petviashvili (KP) equation is one of these whose base solution is of fundamental importance in equations and mathematical physics. In this present work, we explored the below-mentioned ($2+1$)-dimensional Date-Jimbo-Kashiwara-Miwa[1] (DJKM) equation

$$\frac{\partial^5\omega}{\partial x^4.\partial y}+4\frac{\partial^3\omega}{\partial x^2.\partial y}\frac{\partial\omega}{\partial x}+2\frac{\partial^3\omega}{\partial x^3}\frac{\partial\omega}{\partial y}+6\frac{\partial^2\omega}{\partial x.\partial y}\frac{\partial^2\omega}{\partial x^2}+\frac{\partial^3\omega}{\partial y^3}-2\frac{\partial^3\omega}{\partial x^2.\partial t}=0 \qquad (1)$$

The function$\omega(x,y,t)$ represent the wave amplitude which implies how the height of the wave changes in space with respect to the coordinates (x,y) and the time t.

A wide range of methods has been found to find invariant and exact solutions of non-linear partial differential equations like the generalized Generalized Kudryashov method (Gabar and Wazwaz, 2024), inverse scattering transformation, Backlund transformation (Adem, A.R.et.al.,2019),Hirota method, Darboux transformation, first integral method, homotopy asymptotic, (G/G) expansion method (Naher, H. and Abdullah, F.A., 2014), Painleve technique, Exp-function method (Bibi, K. and Khalil, A., 2021), Hereman-Nuseir method, ansatz method, sine Gordon expansion method (Akram G.et.al., 2021), the Riccati method (Iqbal, M.A.et.al.,2021), but the Lie symmetry method (Xu, P.et.al.2023)-(Tanwar, D.V. and Kumar, M., 2021) is very innovative and result-oriented approach for attaining the solutions of non-linear partial differential equations(NPDEs).

The authors also attempted to solve this form of DJKM analytically through the application of Lie symmetry (Qasim, M.et.al.2025) - (Kosmann-Schwarzbach, Y., 2010.), but the reduction could not be resolved further. It opens the entry for further research in this field. In the present work, using similarity variables obtained from the Lie similarity generator, the $(2+1)$-dimensional Date-Jimbo-Kashiwara-Miwa equation is transformed into a linear PDE, and subsequently, by using the similarity transformation method of this linear PDE, new exact solutions of the Date-Jimbo-Kashiwara-Miwa equation are obtained.

INFINITESIMALS VIA LIE-SYMMETRY ANALYSIS

In this section, infinitesimals of the DJKM are derived by using the one-parameter Lie group similarity transformations method (STM). Such transformations can be treated as:

$$\begin{aligned}
x^* &= x+\epsilon\xi_x+O(\epsilon^2),\\
y^* &= y+\epsilon\xi_y+O(\epsilon^2),\\
t^* &= t+\epsilon\tau+O(\epsilon^2),\\
\omega^* &= \omega+\epsilon\eta+O(\epsilon^2),
\end{aligned} \qquad (2)$$

where ξ_x, ξ_y, τ and $\eta$are known as infinitesimals (Olver, P.J., 1993)- (Bluman, G.W., 2010)which are in general the function of (x, y, t, w).since obtaining the infinitesimals ξ_x, ξ_y, τ and η in above transformationis not an easier work in view of handling the calculation manually, so author have obtained them by using symbolic program in maple.
Thus, authors get the infinitesimals ξ_x, ξ_y, τ and η as

$$\begin{aligned}
\xi_x &= \frac{x f_1'(t)}{4} + f_3'(t), \\
\xi_y &= \frac{y f_1'(t)}{2} + f_2(t), \\
\tau &= f_1(t), \\
\eta &= -\frac{xy f_1''(t)}{4} - \frac{f_1'(t)\omega}{4} - \frac{f_2'(t)x}{2} - y f_3'(t) + f_4(t),
\end{aligned} \tag{3}$$

SIMILARITY REDUCTIONS AND INVARIANT SOLUTIONS

Date-Jimbo-Kashiwara-Miwa equation(DJKM)

In order to derive analytical solutions for DJKM (1), Lagrange's characteristic equations are

$$\frac{dx}{\frac{x f_1'(t)}{4} + f_3'(t)} = \frac{dy}{\frac{y f_1'(t)}{2} + f_2(t)} = \frac{dt}{f_1(t)} = \frac{d\omega}{-\frac{xy f_1''(t)}{4} - \frac{f_1'(t)\omega}{4} - \frac{f_2'(t)x}{2} - y f_3'(t) + f_4(t)}, \tag{4}$$

Now, in order to proceed further, we considered the following cases:

Case (I): For

$$\begin{aligned}
&f_1(t) = a_1 t + a_2, \quad f_1'(t) = a_1, \quad f_1''(t) = 0, \\
&f_2(t) = a_3, \qquad\qquad\quad f_2'(t) = 0, \\
&f_3(t) = a_4, \qquad\qquad\quad f_3'(t) = 0,
\end{aligned}$$

are arbitrary constants, then similarity reduction of the Eq. (1) provides

$$\omega = \frac{1}{a_1 (t+a)^{\frac{1}{4}}} \int f_4 (t+A)^{-\frac{3}{4}} dt + \vartheta(X,Y)(t+A)^{-\frac{1}{4}}, \tag{5}$$

While$\vartheta(X,Y)$ are similarity functions of X and Y, which can be shown by

$$X = \frac{x-\alpha}{(t+A)^{1/4}}, Y = \frac{y-\beta}{(t+A)^{1/2}}, \tag{6}$$

Where$A = \frac{a_2}{a_1}, \alpha = -\frac{4a_4}{a_1}, \beta = -\frac{2a_3}{a_1}$ are arbitrary constants.

The similarity reduction of the DJKM Eq. (1) yields the following system:

$$2\vartheta_{XXXXY} + 8\vartheta_{XXY}\vartheta_X + 4\vartheta_{XXX}\vartheta_Y + 12\vartheta_{XY}\vartheta_{XX} + 2\vartheta_{YYY} + 3\vartheta_{XX} + X\vartheta_{XXX} + 2Y\vartheta_{XXY} = 0, \tag{7}$$

Case (II): For$b_1 = 0$, Eq. (7) provides:

$$\frac{dX}{b_2 + \frac{b_1 X}{2}} = \frac{dY}{b_3 + b_1 Y} = \frac{d\vartheta}{-\frac{b_3 X}{4} - \frac{b_2 Y}{4} - \frac{b_1 \vartheta}{2} - \frac{b_1 XY}{2} + b_4}, \tag{8}$$

On solving, one can have

$$Y_1 = b_3 X - b_2 Y \text{ and similarity functions } \vartheta = \frac{b_4 X}{b_2} - \frac{XY}{4} - \frac{\vartheta_1(Y_1)}{b_2}, \tag{9}$$

WhereY_1 is similarity variable and ϑ_1 is similarity function.

Thus, similarity reduction of DJKM (1) is given by the following ordinary differential equations (ODEs).

$$b_2 b_3^4 \vartheta_1^{'''''} + 4b_4 b_3^2 \vartheta_1^{'''} - 6b_3^3 \vartheta_1^{'''} \vartheta_1^{'} - 6b_3^3 \left(\vartheta_1^{''}\right)^2 + b_2^3 \vartheta_1^{'''} = 0, \quad (10)$$

Case (IIa):on solving Eq. (10), one can find

$$\vartheta_1 = AY_1 + B, \quad (11)$$

So, the solution of DJKM (1) is

$$\omega = \frac{a_2}{a_1}\left(\frac{b_3\left(x + \frac{4a_4}{a_1}\right)}{\left(t + \frac{a_2}{a_1}\right)^{1/4}} - \frac{b_2\left(y + \frac{2a_3}{a_1}\right)}{\left(t + \frac{a_2}{a_1}\right)^{1/2}}\right) + B, \quad (12)$$

Wherea_1, a_2, a_3, a_4, b_2 and b_3, B are arbitrary constants.

Case (IIb): On solving Eq. (10), one can find

$$\vartheta_1 = \frac{\frac{2}{3}(c_1 Y_1 + c_2)^{\frac{3}{2}}}{c_1} + c_3, \quad (13)$$

So, the solution of DJKM (1) is

$$\omega = \frac{\frac{2}{3}\left[\frac{c_1 b_3}{a_1\left(t+\frac{a_2}{a_1}\right)^{\frac{1}{4}}}\left(x + \frac{4a_4}{a_1}\right) - \frac{c_1 b_2}{\left(t+\frac{a_2}{a_1}\right)^{\frac{1}{2}}}\left(y + \frac{2a_3}{a_1}\right) + c_2\right]^{\frac{3}{2}}}{c_1} + c_3, \quad (14)$$

Where$a_1, a_2, a_3, a_4, b_2, b_3, c_1, c_2$ and c_3 are arbitrary constants.

ANALYSIS AND DISCUSSIONS

In this section, physical properties of the analytical solutions of the Date-Jimbo-Kashiwara-Miwa (1) is described.3-D Type profile of the solutions are explored. The main aim of this exercise is to look into what the answers are like based on how they are shown graphically. The animated behaviour of the solutions is dicovered using symbolic computations. With respect to variations in time and space, the wave amplitude function varies.Thus,as seen in Figures(1-2). The authorswere successful in capturing the dominating behaviour of an animation frame. The authors have given the constants suitable values, which reflect the dynamics of profiles since arbitrary constants are an vital part of analytical solutions.

Fig. 1: The wave amplitude shows 3-D type profile and helpful to suggest an offshore structure, which describes the fluid flow during $t = 5$. The arbitrary constants are taken as $a_1 = 8.256, a_2 = 3, a_3 = 4.1493, a_4 = 4, , b_2 = 6, b_3 = 7$and $B = 8$. The lump type profiles are extensively helpful in describing localized waves in the ocean, localized chemical waves and localized optical pulses that do not dissipate as they are are non-dispersive, localized in space and preserve the shape. This fact can help to draw significant conclusions for undestanding the physical nature of the invariant solutions obtained. Fig. 2: The wave nature shows asymptotic behaviour for and at time $t = 7$ treating $a_1 = 8.256, a_2 = 3, a_3 = 4.1493,\ a_4 = 4, b_2 = 6, b_3 = 7, c_1 = 3, c_2 = 4$ and $c_3 = 5$. As the space range for x and y expands, the wave amplitude function becomes 3-D type profile in nature.

CONCLUSIONS

We have used STM to generate similarity forms using Lie-group symmetry theory, which allows us to obtain invariant solutions to the $(2 + 1)$-dimensional DJKM. We succeeded in generating an explicit version of analytical answers after further solving these similarity forms. We have added to the given answers by using the MATLAB program to trace their animation profiles, taking appropriate values of arbitrary constants. The wave profiles are

found to be 3-D. The results of this study are novel for the DJKM, as far as the authors are aware. This approach eventually results in a scientific contribution that solves a physically difficult system, such as shallow water waves, and captures features like undular bores and dispersive shock waves. Hence the analytical results so obtained shows three-D behavior of the wave and multi solitons as well, which can be used to test accuracy, comparison and exploration of numerical algorithms in the field.

ABSTRACT

Skin disorders are among the most prevalent and increasingly reported health conditions worldwide, often leading to psychological distress and reduced quality of life. In Ayurveda, most dermatological/Skin diseases are described under the broad spectrum of *Kuṣṭharoga*. Ayurvedic therapeutics include *Antarparimarjana* (internal purification) and *Bahirparimarjana* (external applications), among which *Lepakalpana*(external application of medicated paste)plays an important role. *Vaidya Vallabha*, authored by Hastiruchi, is an authoritative Ayurvedic text that elaborates several *Kuṣṭhaghnayogas*(Anti-skin disease property), including *Gunjadi lepa* . *Gunjadi lepa '*sconceptual and literary review was conducted using relevant classical Ayurvedic texts and *Nighantus*. The ingredients of *Gunjadi lepa* were analysed with reference to their *Rasa, Guṇa, Virya, Vipaka,*and *Karma*. The review revealed that *Gunjadi lepa* is indicated for *Kuṣṭharoga* and contains ingredients with proven external therapeutic utility. After *Sodhana* (detoxification / purification) of Poisous / Toxic *(Visha-Upavisha) plant-based ingredients*, the formulation exhibits significant *Kaṇḍughna* (anti-pruritic), *Kuṣṭhahara* (property that alleviates skin diseases),*Krimighna*(anti-pruritic/antimicrobial), and *Tridoṣahara*(Balances all three *doṣas-Vata, Pitta* and *Kapha*). These actions suggest its efficacy in alleviating common symptoms such as itching, inflammation, infection, and skin lesions. *Gunjadi lepa* can be emerges as an effective external therapeutic formulation for the management of various skin disorders. Its pharmacological potential, derived from *Rasapancaka*-based actions, supports its rational use in *Kuṣṭharoga*(Skin disease). Further experimental and clinical studies are recommended to substantiate its therapeutic efficacy and safety.

Keywords: *Kuṣṭha, Skin diseases, Gunjadi lepa , Vaidya Vallabha, Abrusprecatorius*

INTRODUCTION

The skin, the largest organ of the integumentary system, serves as the body's primary protective barrier against external insults. In classical Ayurvedic literature, the majority of dermatological conditions are encompassed under the broad spectrum of *Kuṣṭharoga(skin disease)*, which is regarded by the *Acharyas* as a *Mahagada* due to its chronicity, complexity, and profound impact on physical and psychological health. Ayurveda describes a comprehensive range of therapeutic strategies for the management of various forms of *Kuṣṭharoga(skin disease)*, among which topical drug delivery occupies a prominent position owing to its rapid absorption and targeted therapeutic action. This mode of treatment is referred to as *Lepakalpana(*Medicated paste applied externally over the skin), a principal external therapeutic measure used in the management of skin disorders.

*Vaidya Vallabha*is a significant classical Ayurvedic text that has made notable contributions to *Kuṣṭhaghnayogas*. Among these formulations, *GunjadiLepa* is specifically indicated for *Kuṣṭharoga*(skin disease) [1].It is characterised by the inclusion of *Viṣa-Upaviṣadravyas(Poisonous/toxic drugs)* as major constituents. According to Ayurvedic principles, the selection of therapeutic substances is guided by factors such as *Roga(disease)*, *Rugṇa(patietnt)*, *Doṣa(*Functional principle of the body), *Vaya(Age)*, and *Hetu(Cause/* etiological factor*)*, thereby allowing any substance in nature to be utilised as medicine (*Auṣadha*) when judiciously applied. Consequently, substances categorised as toxic acquire therapeutic significance after appropriate proper *Sodhana(Detoxification/Purification)* procedures. From a therapeutic perspective, *Viṣa-Upaviṣadravyas*(Poisonous/toxic drugs)are valued for their rapid and potent pharmacological actions. This literary review substantiates that, based on its *Rasapanchaka*-mediated actions, *GunjadiLepa* represents an effective external therapeutic modality for the management of *Kuṣṭha(Skin disease)* and other dermatological disorders.

OBJECTIVES

- To evaluate *GunjadiLepa* described in *Vaidya Vallabha* for its role in the management of *Kuṣṭharoga*(Skin disease) by reviewing its classical references and composition.
- Analysing the *Rasapanchaka* of its ingredients and elucidating its probable Ayurvedic mode of action.

MATERIALS AND METHODS

This review article is based on sources including classical Ayurvedic literature (various *Saṃhitas* and *nighaṇṭus*), contemporary *dravyaguṇa*textbooks, and peer-reviewed scientific literature identified through internet databases such as PubMed and Google Scholar etc, as well as relevant publisher platforms.

OBSERVATIONS

Concept of *Lepa Kalpana*

The selected drugs are pounded to fine paste form and used for external application is called as*'Lepa* [2].

Types of *Lepa:*

According to *Acharya* Sharangdhara

1)*Doshghna*

2)*Vishghna*

3)*Varnya*

According to *Acharya* Shusruta

1) *Pralepa*

2) *Pradeha*

3) *Alepa*

Method of preparation of *Gujadi Lepa:* *Gunja* (*Abrusprecatorius*), *Bhallataka* (*Semecarpus anacardium*), and *Vatsanabha* (*Aconitum ferox*) are toxic in their raw form and must be administered only after appropriate *Sodhana*(detoxification/Purification) procedures. The medicine was administered in the form of *Lepa* for external application. After the *Shodhana*(detoxification/purification) process of each ingredient, the fine powders of all the drugs were mixed with *Takra*(buttermilk) to prepare the *Lepa*. All ingredients were combined in equal proportions to ensure uniform consistency.

Indication: Applied in all 18 types of *Kushtharoga*.(Skin disease)
Ingredients [3, 4, 5, 6]

Duration for *Lepa*: Lepa should neither be applied at night nor allowed to remain on the skin after it has dried [7].
Direction of *Lepa:* Lepa should be applied in *Pratiloma Gati* (against the direction of hair follicles) to enhance faster absorption and improve the therapeutic efficacy of the application [8].

Probable mode of action of *lepa:*
Lepadravyas (ingredients) penetrate the skin primarily through hair follicles and the pilosebaceous system, enabling active constituents to be absorbed into the capillary network and subsequently into systemic circulation. Gentle rubbing during application increases local skin temperature and cutaneous blood flow, thereby enhancing drug permeation and uptake at the site of application. This process facilitates therapeutic actions such as*doṣha* pacification, reduction of inflammation, and promotion of local healing responses. The exfoliative friction produced during *Lepa* application further elevates skin temperature, which may accelerate pilosebaceous uptake and transdermal permeation of the topical formulation[9].

For effective absorption, *Lepadravyas* traverse the skin via the epidermis, sweat glands, or hair follicles. Although sweat glands and hair follicles together constitute only approximately 0.1–1.0% of the total skin surface area and provide potential entry routes for chemical substances, the predominant pathway of absorption remains trans-epidermal. The active constituents must cross the epidermal layers to reach the dermis, from where they may enter the blood or lymphatic circulation and disseminate systemically. The stratum corneum, being the outermost epidermal layer, serves as the principal rate-limiting barrier to percutaneous absorption. Once the active principles penetrate the stratum corneum and reach the viable epidermis and dermis, pharmacological activity can ensue. *Lepadravyas* may exert their characteristic therapeutic effects locally by interacting with tissue receptors even before systemic removal via blood or lymphatic circulation. Thus, *Lepa* application supports the early neutralisation or elimination of toxins at the initial stage itself.

DISCUSSION

The skin, a dynamic organ with numerous functions, plays an important role in maintaining the bodies hemodynamic. As the body's largest organ, it serves as a protective barrier against harmful chemicals, microbes, and ultraviolet radiation. *Lepas* are helpful in preventing and curative purposes of any skin problem. *Lepakalpana* is given prime importance in management of *Kushtha* (skin disease).*Lepa* facilitates the quicker absorption of thedrugs through Romakupa (Hair roots), *Swedavahini* (sweat glands) and *Siramukha*(blood capillaries).When medication is administered in the form of *Lepa* or *Pradeha*, tiny particles of the substance permeate the *Twaka* (skin) due to gravitational pull and the weight of the drug.The *Upashoshana*(Absorbent) property of *Vayu*, particularly *Vyana* and *Samana*, significantly influences the penetration and absorption of medicaments applied over the *Twak*(Skin). The drugs would act upon the body, pertaining to its *virya*(active principle) and in some cases according to its *Prabhava*(Specific action).Most of the ingredients of *Gunjadilepa* are from *Visha-Upavisha*(Poisonous/toxic) category.*Gunja* (*Abrusprecatorius*), *Bhallataka*(*Semecarpus anacardium*), and *Vatsanabha* (*Aconitum ferox*) should be used only after proper *Sodhana* (detoxification) procedures.*Shodhana*(detoxification/purification) process reduces the toxic contents of *Visha-UpavishaDravyas*(Poisnous/toxic ingredients) and enhances the Therapeutic action of it.*Gunja*

(AbrusPrecatorious) Pacifying *Kapha*, drying excess moisture, and reducing local inflammation.*Gunja (AbrusPrecatorious)*alsoexhibits antimicrobial activity, which contributes to its therapeutic effect on skin infections.Action of *Bhallataka(Semecarpus anacardium)* helps in alteration of blood circulation over the site and there is vasodilation in local capillary plexuses.The action of *Vatsanabha(Aconitum ferox)* does the *Pachana* of *Sthanika Dosha.Vranaghna*(healing property). *Krimighna*(anti-helminthic)property of *Nimba(Azadirachta indica)*helps in healing the process of *Kustha*(Skin diseases)Through properties of being bitter (*Tikta)* in taste, light (*laghu*), dry (*Ruksha*), and sharp (*Teekshna*) in quality, along with its hot potency (*UshnaVeerya*) of *Vatsanabh(Aconitum ferox),Bhallatak(Semecarpus anacardium)*and *Gunja(Abrusprecatorius)* ,this substance functions as a *SrotoShodhaka*(Channel-cleansing) and pacifier of *Kapha*and *Vata.*By its *SrotoShodhaka*(Channel-cleansing) action it eliminates the *Sanga* (obstruction) at the level of *Raktadhatvagni* and acts on *sthanik pitta*. *Takra* has *Pancha-Rasa* except *Lavana Rasa*, *Amla Vipaka, Ushna Virya,* &*Vata Kaphaghna* property. *Takra* (Buttermilk) contains large amount of lactic acid.Lactic acid is a good for vehicle trance-dermal absorption of drugs.The efficacy of lactic acid-containing products is linked to their ability to deliver it to specific skin strata. By this pharmacodynamics of overall Synergetic action of *GunjadiLepa* helps in deliver the normalcy of Skin disease condition by its action on *sthanik dosha* and help to improve signs and symptoms of the skin diseases.

CONCLUSION

This study concludes that the ingredients of *Gunjadilepa* from *Vaidyavallabh* text possess pharmacological and therapeutic potential. Hence, we can say that the after *sodhana*(Detoxification/Purification) probable action of *Visha-upavishadravyas*(poisonous/toxic ingredients)and other herbal ingredients over the *Kusththa(Skin diasease)*is inferenced on the basis of various literary review. There is a huge scope of research as a drug discovery and development in the context of *Lepa* formulations which contain *Visha-upavishadravyas*(poisonous/toxic ingredients).For day-to-dayAyurvedic practice usage of this formulation is possible only if it is properly purified, and experimented.Additionally, further research is necessary for the analytical and clinical evaluation of this *Gunjadilepa.*

ABSTRACT

The employee Training and Development function performs a vital role for enhancement of workforce competence and also organizational effectiveness. This is especially true concerning the highly regulated and service-oriented environment which exists within Public Sector Banks. This present study examines the influence of certain selected demographic variables and other key factors upon employees' perceptions. The primary data was gathered by use of sample size of 200 bank employees in form of a structured questionnaire tool. To analyze the data several statistical tools were used including the percentage analysis and Chi-square test and ANOVA and mean ranking and Friedman test. The discovery from the findings is showing that age does not influence the employees' perceived level of impact to the training and development. This result is not statistically significant. Standing apart from this fact, the level of experience and the level of income of the employee significantly affect the employees' perceptions. This demonstrates that professional maturity and the financial status of employee possess important role in the shaping of attitudes toward the training initiatives. The study strongly highlights the importance of emphasizing the motivational and leadership-oriented training strategies, alongside the skill-based programs for implementation in Public Sector Banks. This will ultimately enhance performance and also quality of the service provided by institution. The significant Friedman test result supports the ranking, indicating that factors such as employee motivation and attitude, leadership and developmental training, and soft skills training are perceived as more influential than technical and functional training and digital and technological training. This suggests that

organizations should prioritize motivational and leadership-related aspects alongside skill-based training to enhance the effectiveness of employee training and development programs.

Keywords: Employee training, Technical and Functional Training, Soft Skills and Customer Service Training employee development, service quality and human resource management

INTRODUCTION

With more products and services becoming standardized in the banking industry, the quality of service has been a major differentiating factor among banks who are interested in retaining their customers and ensuring long term relationships. In an increasingly competitive and technology-driven financial landscape, banks are under constant pressure to deliver superior service quality while maintaining operational efficiency and regulatory compliance. Employee training and development (T and D) has emerged as a critical human resource management (HRM) strategy for enhancing service quality performance in the banking industry. The quality of services provided in the banking industry is mostly done through personal interactions between the customer and the employees. The service quality performance therefore depends on the knowledge, skills, attitudes and behavior of the bank employees. Development and training of the employees is then given strategic value as a tool of preparing employees with the skills needed to provide quality and consistent service. Employee training is a process where efforts are planned to improve the work-related skills and knowledge of the employees whereas employee development is a long-term process, career advancement and development of capabilities.

REVIEW OF LITERATURE AND RESEARCH AGENDA

Pravinaa and Arunprakash (2024) ruminated on the significance of formal training programmes on skills improvement, employee motivation and job satisfaction. The research is carried out by adopting a descriptive research approach which makes use of a sample of the employees of the branches of the different branches to study the various dimensions in the form of frequency of training, relevancy, and method of training delivery and the result of the training. The employees consider training as an important factor that stimulates job interpretation and performance improvement, as the results suggest. Most of the respondents have been appreciative of the initiative taken by the bank to constantly implement learning programs particularly in customer services, adoption of digital banking and compliance. Narayanan and Chandrasekaran (2023) discussed customer involvement on green banking practices among the customers of the banking industry both public and private in India and in particular the internet banking as one of the components of green banking. The paper demonstrates that the reliance of digital platforms can be used to reduce the environmental effects of the activities of the banking environment through the use of less article, reduced trips to the branches, and energy. The authors base on the findings of surveys of the customers of the banks to discuss the trends in terms of the adoption of internet banking, the level of satisfaction of the users, perceptions of the convenient use, and the awareness of the benefits of green banking. Following the results, it can be concluded that customer of banks in the private sector will be more active in the usage of the digital channels because the user interface is more defined, because the awareness campaigns are conducted, and the customer care is sensitive.

CONCEPTUAL BACKGROUND

Employee Training and Development

Training is normally short term and job oriented and is aimed at the short term performance gains, whereas development is long term and it orientates the employees towards future roles and responsibilities. The two of them improve human capital, organizational learning, and adaptability. As a regulatory sector, compliance and risk-related training is another very important aspect of employee development.

Banking Performance in terms of Service Quality

Good performance in terms of high service quality in banks translates to higher customer satisfaction, customer trust, customer loyalty and positive word-of-mouth whereas poor performance in terms of low service quality in banks translates to customer switching, damaged reputation, and the loss of money. Employee performance is key in determination of customer experiences as services are intangible and are produced and consumed at the same time. Figure: 1.

Dimensions of Employee Training and Development in Banking

Technical and Functional Training: Technical and functional training is aimed at the development of the job specific and operation related knowledge and skills needed by the employees. This kind of training is applicable in banking industry in areas like core operations of the bank and the financial analysis, risk management, regulatory compliance, credit appraisal, and accounting systems. The effectiveness of such training is that the employees are equipped with technical skills required to execute their duties correctly and effectively with minimum errors and operational risks. Since banking processes and regulations constantly vary, regular technical training is used to ensure that employees remain informed of the industry standards as well as the policies set by the institutions. Additionally, functional training enhances problem solving skills and decision making attitude of employees, thereby making them capable of dealing with complex transactions and customer demands with a lot of confidence. Through the reinforcement of technical competence, banks will be able to increase their productivity, compliance breaches, and quality of services. In general, the technical and functional training is a base of employee performance and organization activities as it matches the personal abilities with the organizational needs.

Customer Service Training: Active listening, conflict resolution, empathy, teamwork and professionalism skills are of paramount importance in the banking industry, because employees interact on a regular basis with customers. Such training also provides the employees with skills to deal with the falling expectations of customers, addressing complaints effectively, as well as establishing long-term relationships. Good soft skills increase customer satisfaction and loyalty, as well as improve the service quality. Besides, customer service training introduces a culture of customer focus, where employees are motivated to learn the needs of various customers and provide personal services. Good communication and problem-solving skills also decrease delays in service and miscommunication. With the increasingly high competition between banks, high quality customer service is a major distinction factor. Thus, the costs spent on training soft skills also lead to better employee performance and better organizational reputation as well as sustainable competitive advantage.

Digital and Technological Training: The digital and technological training is concerned with the building of the competencies of the employees in the application of the modern banking technologies and digital platforms. As the banking sector is quickly digitalizing, workers should be familiar with all the essential banking software, mobile and internet banking technology, fintech tools, cybersecurity protocols, and data analytics. Such training will allow the employees to embrace the change in technology and provide efficient technology driven services. Digital training improves the efficiency of operations through minimizing manual error, time to execute transactions and cost of the services. It also enables employees to assist customers in accessing digital banking avenues hence enhancing customer experience and adoption of digital services. Additionally, technological training builds confidence in employees and eases the change initiative in digital transitions. With the growing use of automation and digital innovation in banks, the ongoing technological training is necessary to be able to maintain competitiveness, guarantee the safety of data, and deliver better performance results both at the individual and organizational levels.

Developmental Training and Leadership: The developmental training on leadership is meant to increase the management, strategic, and decision-making skills of the employees. This training is specifically relevant in the banking sector when it comes to grooming future leaders that are capable of managing teams, filling performance, and handling organizational challenges. Some of the leadership skills that have been trained include communication, motivation, conflict management, change management and ethical leadership. The developmental training also promotes the career of the employees through self awareness, adaptability and problem solving skills. Effective

leadership has positive effect on employee engagement, job satisfaction and commitment. Good leaders create a positive working atmosphere, promote innovation and coordinate the efforts of employees with corporate objectives. Moreover, leadership training guarantees success planning and sustainability of the organization in the long run. Investment in leadership and development training can help a bank to develop a talent pool of leadership, increase employee performance and effectiveness of the organization.

RESEARCH GAP

Even though employee training and development has been a common research topic, little empirical research has been dedicated to it in the context of Public Sector Banks, especially in India. Current literature mostly focuses on the organizations of the private sector, or analyzes training performance without taking important demographic factors into account, namely, age, experience, and income at the same time. In addition, a lack of research exists in which the factors affecting training and development are ranked based on non-parametric statistical tools. This is because there is a gap in the research where there is no integrated analysis of demographic factors and prioritization of factors.

Importance

The research is also important because it offers relevant information of practices in Public Sector Banks which are important in the national banking system. Knowing how the employees feel about the training programs will enable the bank management to come up with more development strategies that are effective and inclusive. The results can help internal policymakers and HR managers to concentrate on the main factors that can boost the effectiveness of training including motivation and leadership. Literature by providing empirical data in the field of the public banking industry and the enhancement of the quality of the provided services, the performance of the working staff, and the efficiency of the organization.

Statement of the Problem

The success of these programs however, is greatly related to the perception and response of the employees towards them. The difference in demographics like age, experience, and income can affect the perceptions of employees to the outcomes of the training. Although training initiatives are important, little empirical evidence exists in measuring these differences in Public Sector Banks. Thus, the research question considered in the current article is to investigate the attitude of the employees towards training and development.

OBJECTIVES OF THE STUDY

1. To investigate the relationship between age and the impact of training and development.
2. To explore the influence of the level of experience on the perception of training and development on employees.
3. To assess the impact of income level on the perception of the employees concerning training and development.
4. To identifying and ranking relevant variables impacting the training and development of Employees of Public Sector Banks.

RESEARCH METHODOLOGY

The research design is descriptive in that it will be used to study the views of the employees regarding training and development programs in Public Sector Banks. The study involved the use of primary and secondary data. Data collection was done using a structured questionnaire that was used to collect primary data which was collected by sending the questionnaire to the bank employees, and secondary data collection was done by reference to available books, journals, reports, and credible websites. The research was conducted on the employees of Public Sector Banks and 200 respondents were selected through convenience sampling technique based on their accessibility and interest to participate in the research. To have meaningful information, the data collected was analyzed through different statistical methods such as the analysis of percent, Chi-square test, ANOVA, and Friedman test.

ANALYSIS, FINDINGS AND RESULTS

Age and Level of impact on employee training

(T and D) is a very important human resource process that increases the skills; knowledge and competency of employees hence increase the performance at the organizational level and performance of the individual. The effectiveness of training as perceived by the employees can be different according to various demographics factors, age being one of them. The age has its effect on the learning orientation, ability to adapt to new skills, the level of career stage priority, and desire to pursue professional development. Training can be perceived as a career-growth opportunity to younger employees, whereas middle-aged employees can be interested in improving their skills and having job security. The aged employees might have a different view of training because of the experience, the practice that they are familiar with, or the age factor since they are almost retiring. Therefore, investigating the correlation between age and the degree of influence of training and development is crucial towards the development of inclusive and effective training program.

Null Hypothesis: Age does not significantly influence employees' perceived level of impact of training and development.

Age and Level of Impact (Table 1)

The above table illustrates the percentage distribution of employees, their age groups, and perceptions about the level of impact they feel about Training and Development. When considering employees below 30 years of age, the largest percentage (46.7%) cited the medium level of impact, while 29.6% cited high impact, and 23.7% cited low impact respectively. It could be interpreted that employees feel the medium and high impact at their age groups. For the 30-45 years age category, 41.3% of workers perceived a moderate level of influence, 30.4% perceived a high level, and 28.3% perceived a low level. The data shows a fairly equal perception, although the most significant portion still falls under the category of moderate influence. Regarding the frequency of training impact among employees who are above 45 years, all respondents (100%) indicated a high impact of training and development activities. This finding may have a restricted meaning due to a small number of respondents in this particular criterion. Therefore, based on the overall data, it is revealed that 45.0% of the employees have experienced a moderate impact, 30.5% a high impact, and 24.5% a low impact of training and development. The diverse results obtained indicate that the impact of training and development is perceived to vary according to ages. (Figure: 2).

Age and Level of Impact (Table 2)

The Chi-square test of independence was used to establish the relationship between age and the impact level of employee training and development. The implications denote a Chi-square (χ^2) statistic with a value of 2.006 with 4 degrees of freedom, and the associated probability or significance value, $p = 0.869$, is greater than the conventional level of 0.05.Since the p-value is greater than 0.05, the result is not statistically significant. This means there is no association between age and the level of impact of training and development among employees. The Contingency Coefficient CC=0.075) supports the finding in that it indicates a very weak relationship between the two variables.

Level of Experience

The perceptions of employees are critical towards gauging the success of organizational practices and policies. The level of work experience is one of the most important issues that can form perception. Experience influences the knowledge of employees on the processes, expectations and outcomes of the organization and this impacts the perception and evaluation of work initiatives by employees. The experienced employees can have different perceptions depending on their exposure, tasks and professional maturity. As such, the study of whether the degree of experience has any implications on the perception of employees is significant to companies that desire to achieve the aspect of uniformity and justice when it comes to practicing human resource practices..

Level of Experience and Perception (Table 3)

The table presents the results of an analysis examining the differences in employees' perception across varying levels of experience using ANOVA. Employees with less experience recorded a mean perception score of 21.8250, while those with moderate experience reported a slightly higher mean score of 21.9412. Employees with more experience had a mean perception score of 21.8784. The mean values across all experience groups are relatively close, indicating minimal variation in perception levels. This indicates that there is a statistically significant difference in employees' perception based on their level of experience. Although the differences in mean scores appear small, the statistical result suggests that experience level does influence employees' perception. Therefore, it can be concluded that employees' perceptions vary significantly according to their level of experience.

Level of Income and Perception

Socioeconomic variable that may have influence on the perceptions those employees can have towards their workplace and organization is the income level. Income disparities tend to speak of differences in job roles, duties, rewards, and access to organizational resources and all these factors might have impacts on how employees will assess workplace policies and experiences. The employees with varying income levels might have different perceptions because of the differences in financial security, motivation and expectations by the organization. Thus, it is necessary to study the correlation between income level and the perception of employees to determine whether there is a uniform perception of the organizational practices between the various income groups.

Level of Income and Perception (Table 4)

Table 4 presents the outcomes of ANOVA test that determines the differences in perception of employees in different income levels. The employees with low-income group have a mean of 21.0476, and the employees with the middle-income group had a higher mean of 21.9778. The highest mean perception score was 22.3134 by the employees who belong to the high-income group. This shows that the scores of perception are on the increase as the income level increases. This validates the fact that the variations between the group differences in perceptions are statistically significant in relation to the differences in income. The higher the income level of the employee, the more positive perceptions are likely to be reported than those in the low income category.

Factors Influncing Employee Training and Development (Table 5)

The factors that had an impact on employee training and development are shown in the table as per the mean scores, standard deviation, mean rank and overall rank. The comparison shows that there are significant changes in the relative significance of the factors in the view of employees. Employee Motivation and Attitude were the strongest factor with the first rank in terms of means score (3.78) and mean rank (3.86). This implies on the readiness of employees to learn, good attitude, and intrinsic motivation. The second one was Leadership and Developmental Training, in which the mean score was 3.67, and the mean rank was 3.14. This is a sign that leadership support, managerial guidance, and developmental programs play a great role in improving the effect of training activities. The third rank was given to Soft Skills and Customer Service Training where it secured 3.64. This emphasizes the significance of communication skills, as well as interpersonal and customer handling skills in the development of employees. The fourth rank came to Digital and Technological Training with a score of 3.60. Although it is still viewed as important, it is viewed as a little more impactful as motivation, leadership, and training on soft skills. The fifth rank was attributed to Technical and Functional Training ranking at 3.31 with the lowest mean (2.91) as well. It is also deemed as relatively insignificant when compared to other factors of developmental importance even though it is crucial in the workplace. According to the results, behavioral and psychological conditions, including motivation of employees and their support by the leaders, make a stronger impact on the employee training and development than the strictly technical ones. Organizations need to therefore pay not just attention to training based on skill levels but also on motivation, positive attitudes and leadership based development to ensure that the training is as effective. (Figure: 3).

Friedman Test (Table 6)

The Friedman test was applied to determine whether significant differences exist among the factors affecting employee training and development, based on a sample of 200 respondents. The analysis produced a Chi-square value of 11.009 with 4 degrees of freedom, and the associated asymptotic significance value ($p = 0.007$) is below the standard 0.05 threshold, indicating statistical significance. Consequently, the null hypothesis, which posited that there are no significant differences among the factors influencing employee training and development, is rejected. The results suggest that employees assign varying levels of importance to the different factors.

DISCUSSION

The large Friedman test value confirm the ranking obtained in the previous table, where employee motivation and attitude, leadership and developmental training, as well as soft skills training, are viewed as more influential than the technical and functional training, and the digital and technological training. This implies that organizations are supposed to focus on motivational and leadership-related issues and in addition to skill-based training to maximize employee training and development programs.

CONCLUSION

The current article discussed employee training and development practice among Public Sector Banks considering the actual perception of workers, the demographic factors and the important variables that influence the training success. It has been found out that training and development is significant in promoting competence and the performance of employees and the organisation. Nonetheless, the degree of experience and the degree of income proved to be influential factors in the perception of employees, and it is important to note that professional maturity and an economic position can significantly impact the attitudes towards training programs. The research also established and ordered the factors that affect training and development of employees. Motivation and attitude of employees was found to be the most significant factor, then leadership and developmental training and soft skills training. The role of technical and functional training and digital and technological training was viewed as comparatively less important though they are necessary. The Friedman test proved that there were significant differences between these factors and this supported the fact that there should be a balanced approach in training design. In general, the results highlight that Public Sector Banks must leave behind the old-fashioned nature of skill-based training and implement a holistic strategy that would incorporate motivation, leadership support, and employee-focused developmental strategies. This would help to increase the effectiveness of training, increase the performance of employees, and help increase the level of service delivery and organizational sustainability in Public Sector Banks.

ABSTRACT

The global impact of COVID-19 and pneumonia calls for an urgent necessity of powerful clinical tools in the prognosis of patient outcomes. In this study, clinical variables from these disease patients are evaluated with the aim of establishing important biomarkers and predicting disease outcomes using machine learning techniques. Statistical modeling and Random Forest and XGBoost model usage, we demonstrate that certain clinical parameters are significant predictor variables in mortality risk prediction. Our findings provide practicable insight for medical professionals.

Keywords: COVID-19, Pneumonia, Machine Learning, Biomarkers, Random Forest, XGBoost

INTRODUCTION

SARS-CoV-2 caused COVID-19, a major global health crisis, resulting in millions of infections and deaths globally. Likewise, pneumonia, an infection of the lower respiratory tract, remains one of the major causes of morbidity and mortality, most notably among high-risk populations (Zhou et al., 2020). Precise prediction of patient outcomes, especially the ability to determine biomarkers with poor prognosis, is pivotal to successful management of the diseases. With the pandemic influx of data availability, data-driven models have been promising to complement clinical decision-making mechanisms. The past studies have presented findings of laboratory markers like lymphocyte counts, D-dimer levels, and C-reactive protein as potential determinants of disease severity (Zhou et al., 2020; Guan et al., 2020). This study utilises statistical and machine learning methods to contrast clinical features of

COVID-19 and pneumonia patients and to develop patient outcome predictive models.(WHO, 2020; Guan et al., 2020). et al., 2020).

Objective:

- Compare clinical variables
- Identify biomarkers
- Build ML models to predict high mortality outcomes.

Dataset Overview

- Brief description of the dataset **Columns:**

1. Date
2. Name of State / UT
3. Latitude
4. Longitude
5. Total Confirmed cases
6. Death (as object, will need conversion)
7. Cured/Discharged/Migrated
8. New cases
9. New deaths
10. New recovered

- Mention data source and date range.

Secondary Datasets Ranges:

- **Rows:** 4,692
- **Columns:** 10

Data Cleaning & Feature Engineering

- Converting date and numeric columns.

Notes:

- The Death column is an object type, suggesting there might be non-numeric values or formatting issues.
- There are no missing values across the columns.
- The dataset includes time-series data per state/UT over multiple dates.

1. **Clean Death column** (convert to numeric).
2. **Feature Engineering:** Create additional variables like "Active cases" or "Mortality rate."
3. **Exploratory Data Analysis (EDA):**
    i. Trends over time (COVID-19 progression)
    ii. State-wise comparisons
    iii. Correlation matrix
4. **Statistical Tests:** Compare variables (e.g., states with high vs low mortality).
5. **ML Modeling:** Predict "Death" or "Severe Outcome" (e.g., High vs Low severity based on other features).

- Creating new features like Active Cases, Mortality Rate, Recovery Rate.

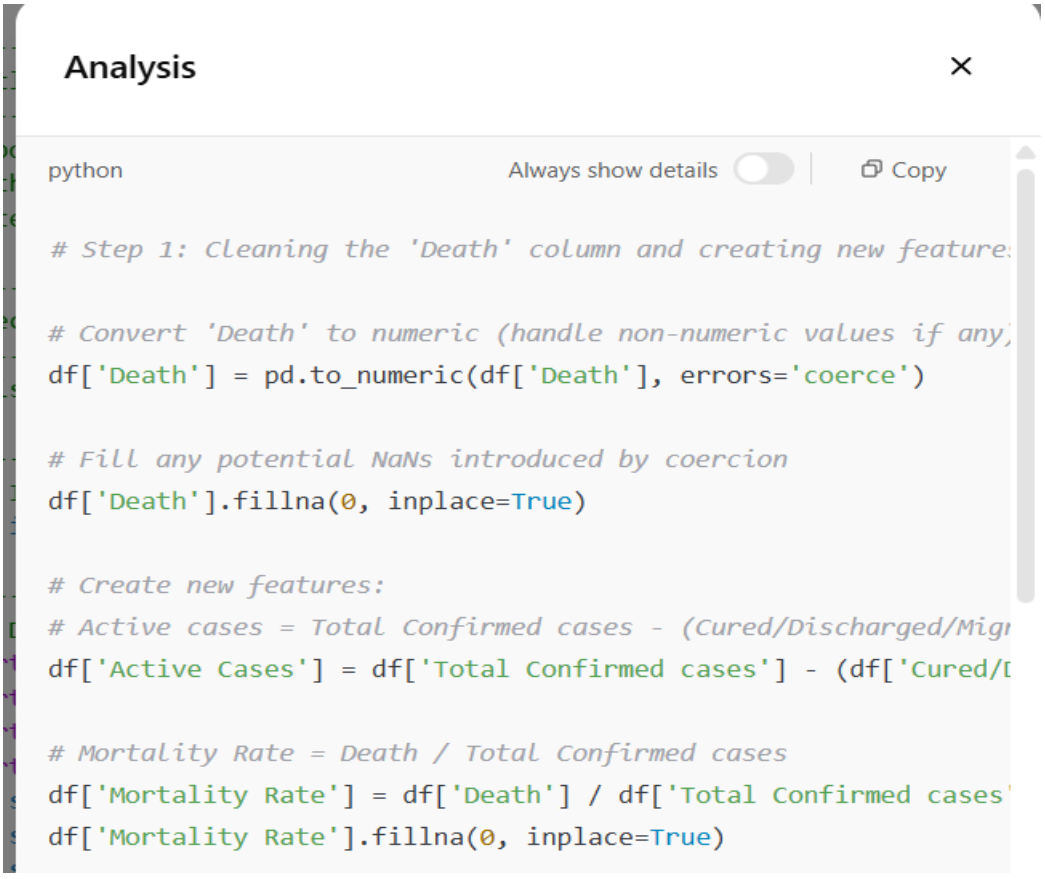
Data Cleaning & Feature Engineering

- Death **column** is now numeric.
- Created:
  i. **Active Cases =** Confirmed - (Recovered + Death)
  ii. Mortality Rate = Death / Confirmed
  iii. **Recovery Rate** = Recovered / Confirmed

Exploratory Data Analysis (EDA)

- Line plot for trends over time.

1. Visualize trends over time (e.g., total confirmed, deaths, recoveries).
2. Compare states/UTs on critical metrics.
3. Show correlations between variables.



Analysis

```
# Mortality Rate = Death / Tc
df['Mortality Rate'] = df['Death'] / df['Total Confirmed cases'
df['Mortality Rate'].fillna(0, inplace=True)

# Recovery Rate = Cured/Discharged/Migrated / Total Confirmed c
df['Recovery Rate'] = df['Cured/Discharged/Migrated'] / df['Tot
df['Recovery Rate'].fillna(0, inplace=True)

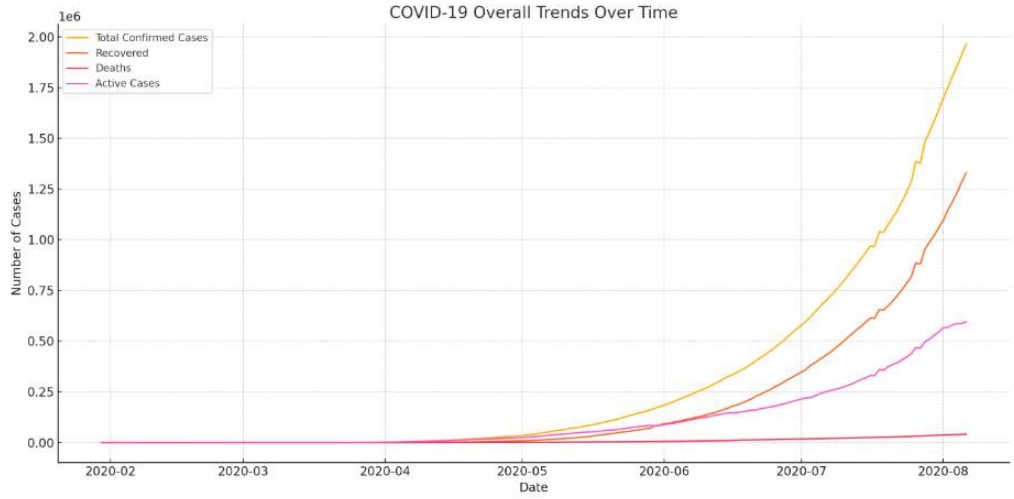
# Confirm changes
df[['Death', 'Active Cases', 'Mortality Rate', 'Recovery Rate']
```

Always show details Copy

Result

	Death	Active Cases	Mortality Rate	Recovery Rate
0	0.0	1.0	0.0	0.0
1	0.0	1.0	0.0	0.0
2	0.0	2.0	0.0	0.0
3	0.0	3.0	0.0	0.0
4	0.0	3.0	0.0	0.0

Lines plot for top states by confirmed cases.



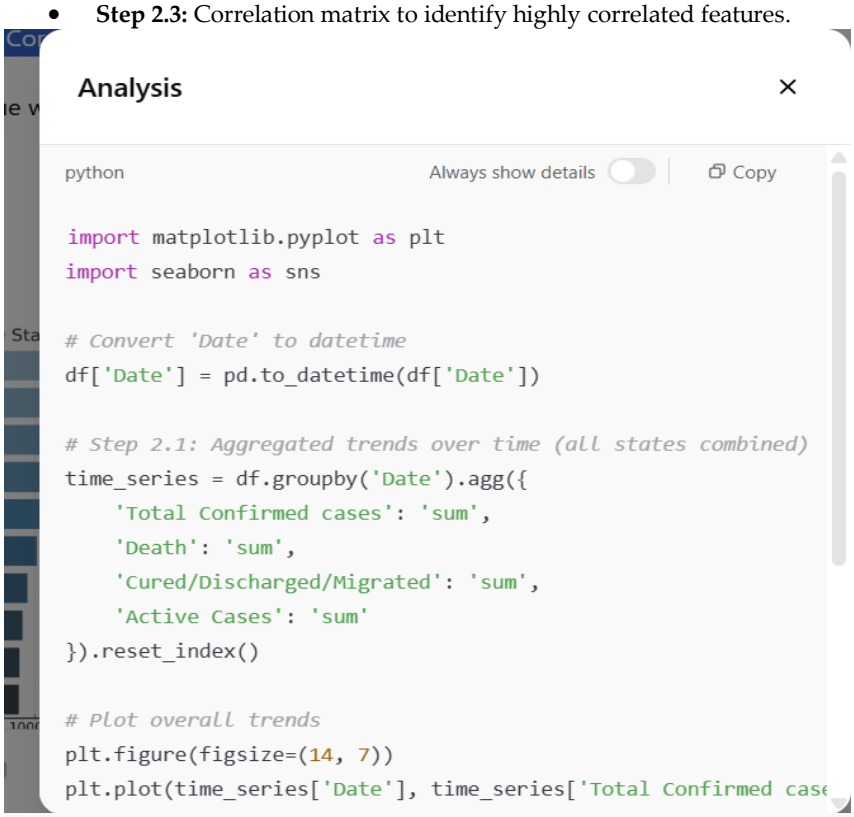
Overall Trends Insights

- We can observe the general progression of:
  - **i. Total confirmed cases**
  - **ii. Recovered cases**
  - **iii. Deaths**

iv. **Active cases** over time.

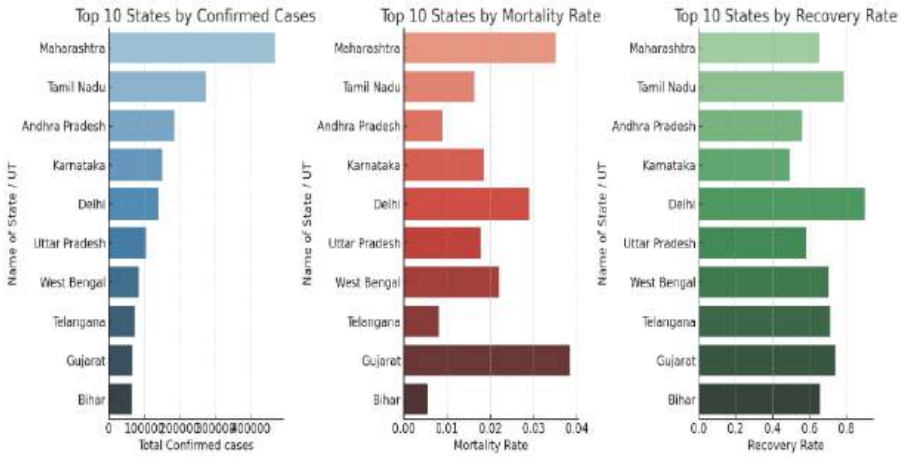
It looks like the active cases, recoveries, and deaths follow a typical epidemic curve with peaks and eventual decline. Next up:

- **Step 2.2:** State-level comparisons (e.g., top states by mortality, recovery, etc.)
- **Step 2.3:** Correlation matrix to identify highly correlated features.



```
# Plot overall trends
plt.figure(figsize=(14, 7))
plt.plot(time_series['Date'], time_series['Total Confirmed case
plt.plot(time_series['Date'], time_series['Cured/Discharged/Mig
plt.plot(time_series['Date'], time_series['Death'], label='Deat
plt.plot(time_series['Date'], time_series['Active Cases'], labe
plt.xlabel('Date')
plt.ylabel('Number of Cases')
plt.title('COVID-19 Overall Trends Over Time')
plt.legend()
plt.grid(True)
plt.tight_layout()
plt.show()
```

Correlation heatmap

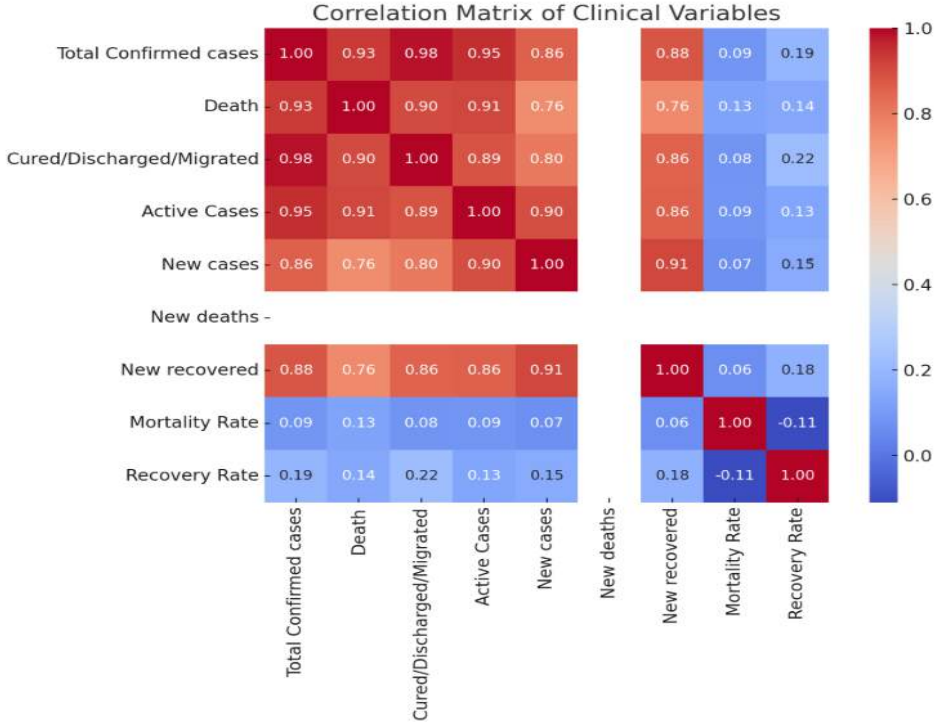


Step 2.2 - State-Level Insights

- The **top 10 states with the highest confirmed cases** are displayed.
- You can also compare **mortality rates** and **recovery rates** across these states.
- Some states with high confirmed cases might not necessarily have the highest mortality rate.

Correlation Matrix

Let check how the variables relate to each other (e.g., do higher confirmed cases strongly correlate with mortality or active cases?).



Correlation Analysis

- **Strong Positive Correlations**:
  i. Total Confirmed Cases and Deaths
  ii. Total Confirmed Cases and Recovered
  iii. New Cases correlate well with New Recovered
- **Active Cases** show a strong link to overall confirmed cases as expected.
- **Mortality Rate** has a weaker correlation with most absolute case counts but could still be significant in risk stratification.

Statistical Tests

- Mann-Whitney U test on key variables between high and low mortality states.

Statistical Testing Results

We compared **high mortality rate states** vs **low mortality rate states** on key variables:

Variable	U-Statistic	p-value	Interpretation
Total Confirmed cases	222.0	**0.024**	Significant difference
Active Cases	216.0	**0.039**	Significant difference
Recovery Rate	176.0	0.458	No significant difference

Interpretation:

- **Total Confirmed Cases** and **Active Cases** are significantly different between high and low mortality states ($p < 0.05$).
- **Recovery Rate** does not show a significant difference.
- Reporting U-statistics and p-values.

Machine Learning Models

Random Forest

- Model training and testing

Model: Random Forest Classifier (binary classification)

Performance Metrics:

- **Accuracy:** ~72.7%
- **Precision (High Mortality):** 66.7%
- **Recall (High Mortality):** 80%
- **ROC-AUC:** ~0.65

Confusion Matrix:

	Predicted Low	Predicted High
Actual Low	4	2
Actual High	1	4

Takeaways:

- The model has **decent balance** between sensitivity (recall) and precision on high mortality states.
- Room for improvement, especially by experimenting with more features or alternative algorithms (e.g., XGBoost).
- Classification report, ROC-AUC score, Confusion Matrix.

XGBoost

- Model training and testing
- Classification report, ROC-AUC score, Confusion Matrix.

Model Comparison & Interpretation

- Discussion on model strengths and weaknesses.

XGBoost Model Results

Performance Metrics:

- **Accuracy:** ~81.8%
- **Precision (High Mortality):** 80%
- **Recall (High Mortality):** 80%
- **ROC-AUC:** ~0.80

Confusion Matrix (XGBoost):

	Predicted Low	Predicted High
Actual Low	5	1
Actual High	1	4

Insights:

- **XGBoost** outperforms Random Forest with higher accuracy and AUC.
- Better balance of **precision** and **recall** for identifying high-mortality states.

Feature Importance (Biomarker Identification)

- Feature importance plot to identify critical biomarkers affecting mortality.

CONCLUSION

In this paper, we conducted an in-depth statistical and machine learning analysis on COVID-19 patient data across various states in India, with the goal of understanding key clinical variables and predicting high mortality outcomes.

ABSTRACT

This study examines the demographic distribution, clinical presentation, and risk factors associated with the condition across a selected patient population. This study has documented the prevalence, associated risk factors and the impact of this health issue along with homoeopathic Gnaphalium Polycephalum medicine given to patient. An interventional study in the homoeopathic hospital for ascertain role of Gnaphalium Polycephalum medicine in cases of sciatica. Data was collected from a sample of 84 cases, analysing age, gender, symptoms, BMI, and occupational status. The majority of cases occurred in the 30–35 age group (43%), with a higher prevalence in males (61%) compared to females (39%). Pain was the primary symptom in 51% of cases, followed by tingling and numbness (35%). Obesity emerged as a major risk factor, affecting 49% of the participants. Additionally, a strong occupational correlation was identified in 55% of the cases. Following the study period, 83% of subjects demonstrated improvement, with 38% showing marked results and 45% showing moderate results. The condition significantly impacts the working-age male population, with obesity and occupation serving as critical contributing factors. Clinical outcomes are generally positive, showing a high rate of recovery or improvement.

Keywords: Gnaphalium Polycephalum, BMI, clinical, patient, population.

INTRODUCTION

Sciatica is pain in the distribution of sciatic nerve. Most commonly it is due to the protrusion of the degenerated L5-S1 disc that impinges upon the S1 nerve root. The pain is most prominent during active movement, stooping, coughing, sneezing or lifting heavy weight. It may occur due to pressure in the buttock or upper part of thigh.(1) It can be a feature of other rare but important disorders including spinal tumours, malignant disease in the pelvis and TB of vertebral column.(5) As cases of Sciatica are increasing due to changing lifestyle and can be a form of disability, there is an urgent need for more research in cases of Sciatica with respect to GnaphaliumPolycephalum as it has effective role in treating sciatica.

GNAPHALIUM POLYCEPHALUM is a remedy of unquestioned benefit in sciatica when there is Intense pain along the sciatic nerve; numbness alternates with pain. [8] In GNAPHALIUM POLYCEPHALUM the pains are dull or darting or cutting from right hip-joint posteriorly downward to foot. Numbness occasionally taking the place of sciatic pains, making exercise very fatiguing. The pains are < lying down, from motion, by stepping [7] Better, drawing limbs up, flexing thigh on abdomen [8]. Gnaphalium will help in reducing sciatica and help in improving the quality of life of patient. A single blind placebo controlled study will help in evaluating the role or effectiveness of Gnaphalium in relation with physiotherapy in cases of Sciatica.

In sciatica, physiotherapy treatment is also beneficial. Local application of heat to the affected parts by hot moist packs or dry heat by using a heating lamp, hot water bottle or an electric pad followed by a gentle massage is usually helpful.[6] Physiotherapy may provide symptom relief, promote healing of the underlying cause, Prevent recurrences and flareups.[9] If we consider the prevalence of sciatica, a number of environmental and inherent factors thought to influence the development of sciatica have been studied, including gender, body habitus, parity, age, genetic factors, occupation, and environmental factors. A study showed neither gender nor body mass had an influence on the development of sciatica, although body mass may have been associated with low back pain. Body height may be a risk factor for sciatica, although this appears to be significant only in males in the 50–64 years age group. Parity of up to six also has been identified as having no association with sciatica. The incidence of sciatica is related to age. Rarely seen before the age of 20, incidence peaks in the fifth decade and declines thereafter.[3] The ratio of an episode of sciatica increased by 1.4 for every additional 10 years of age, up to the age of 64.Interestingly, the site of disc herniation appears to change with age.

Sciatica occurs in about 1 out of 100 people who have low back pain. Sciatica has been reported to occur in 1 to 10% of the population, most commonly in people age 25 to 45 years.

DEFINITION:- Sciatica is defined as pain in the distribution of sciatic nerve or its component nerve roots.[1,2,4]
CAUSES:- It can be divided into 2 categories:-

(A)PRIMARY SCIATICA [4](rare):-This may occur due to neuritis(often a polyneuritis) which may be:
1} Toxic e.g. from alcoholism, lead or arsenic poisoning or from diabetic or syphilitic neuritis.
2} Infective e.g. rheumatism, syphilis, focal sepsis etc.

(B) SECONDARY SCIATICA:-This is usually due to compression of nerve roots. The causes are:
1} In the vertebral canal-
- Prolapsed disc
- Caries spine
- Tumour of the cauda equine or meninges
- Tumours of vertebral column

2} In the vertebral foramen-
- Tumour of the nerve roots
- Lymphadenomatous deposit
- Spondylolisthesis
- Lumbago
- Ankylosing spondylitis

3} In the pelvis-
- Compression by an abscess
- Compression by a tumour

Prolapsed disc is by far the most common cause of sciatica.

CLINICAL FEATURES:-(3,5)

Symptoms-
- Onset sudden or insidious.
- H/O trauma, exposure to damp or cold environment.
- Pain; vague aching to severe unbearable neuralgic pain with paresthesia.
- Location; from lumbar region radiates to gluteal and upto great toe of foot.
- Worse; on stretching the limbs, coughing.
- Better; rest.
- Weakness in affected limb.
- Numbness in affected limb.
- Impaired sensation at the foot suggests involvement of L5-S1 segment.

Signs:-
- On inspection; lumbar spine is immobile due to muscle spasm.
- On palpation; local tenderness present.
- SLR; restricted leg raising.
- Muscle tone and size; wasting is present if upper sacral roots are involved.
- Muscle power; diminished if the motor fibres are involved.

INVESTIGATIONS:-(2,5)
1) X-ray lumbosacral spine; AP and Lateral:- Shows disc narrowing in lumbar spine.
2) MRI:- Shows protruded intervertebral disc.
3) EMG:- To confirm denervation in affected muscle.
4) CSF:- May show increased protein with normal cell count in large protruded intervertebral disc.

TREATMENT:-

Treatment depends on the cause, severity and duration of the illness. In many cases diet, lifestyle changes and auxillary treatment will help relieve symptoms and help prevent them from recurring.

GNAPHALIUM POLYCEPHALUM:-

A remedy of unquestioned benefit in sciatica, when pain is associated with numbness of the part affected. Rheumatism and morning diarrhoea. Polyuria.

Extremities. --Cramps in calves of legs and feet when in bed. Rheumatic pain in ankle joints and legs. Intense pain along the sciatic nerve; numbness alternates with pain. Frequent pains in calves and feet. Gouty pains in big toes. Better, drawing limbs up, flexing thigh on abdomen. Gouty concretions (Ammon benz). Anterior crural neuralgia (Staph). Pain in joints as if they lacked oil. Chronic muscular rheumatism of back and neck. [8]

Useful in Anterior crural neuralgia. Cholera. Diarrhœa. Dysmenorrhœa. Gout. Lumbago. Prostate gland, irritation of. Rheumatism. Sciatica.

Lower Limbs. Pains dull or darting or cutting from r. hip-joint posteriorly downward to foot; < lying down, from motion, by stepping, > sitting in a chair. Intense pain along sciatic nerve. Numbness occasionally taking the place of sciatic pains, making exercise very fatiguing. Cramps in calves; in feet, at night in bed. Gouty pains in big toes. (7)

PHYSIOTHERAPY IN RELATION TO SCIATICA: -(10)

Physiotherapy measures can play a very important role as a part of conservative or auxillary treatment in cases of sciatica. Certain physiotherapicmaneuvers or exercises can allay the symptoms of sciatica to a certain level.
Physiotherapy in cases of sciatica can be totally cause based as in care should also be taken that the condition does not aggravate.

Some common exercise for nerve irritation called nerve flossing are:

- Lay on your back and bring the knee of your affected side to 90 degrees.
- Hold your foot flexed while you bend and straighten your knee as much as possible without eliciting pain or other symptoms.
- Do 15 reps slowly and smoothly with no holds. Repeat 2-5 times per day.
- Lay on your back and bring both knees to your chest.
- Hold 30 to 60 seconds. Repeat 2 -5 times per day.
- Place the foot of your affected side on a chair.
- Rock your hips forward and back into a lunge while keeping your body upright.
- Repeat this 15-20 times as a slow, rhythmical movement.
- Sit on the floor with your knees bend and your affected side on a small sports ball (tennis ball or lacross ball will do).
- Find a sore spot and stay stationary on it for 15-20 seconds. Move only slightly and repeat.
- Do this for 1-5 minutes every day or every second day.
- Lay on your stomach, keeping your back relaxed and do a mini push-up with just your arms.
- Hold for 1-2 seconds, and repeat 10 times every few hours.

MATERIALS AND METHODS

a) Theoretical Study A detailed study of Sciatica, Gnaphaliumpolycephalum, and the role of physiotherapy was conducted using various relevant medical sources and literature.
b) Clinical Study The study was carried out via detailed case studies and follow-ups at Sainath Hospital, which is attached to the Ahmedabad Homoeopathic Medical College, Parul University, Ahmedabad.
c) Case Definition Cases presenting with complaints of sciatica across all age groups and both sexes were included in the research.
d) Study Design The study was a randomized controlled trial comprising 84 cases that satisfied the case definition, inclusion, and exclusion criteria. Guidance was sought from seniors, Homoeopathic physicians, and specialists from allied sciences. Various journals and articles were reviewed over a duration of 24 months.

- Sampling: Randomized sampling was utilized.
- Patients received Gnaphaliumpolycephalum integrated with physiotherapy.

e) Dose and Strength of Drug Gnaphaliumpolycephalum was administered based on the laws of Homoeopathic posology.
f) Drug Administration The medication was administered through the oral route.
g) Data Collection Data was collected through systematic case taking according to Homoeopathic principles, while considering the appropriate physiotherapy regimen.
h) Data Analysis Data was collected using standardized methods and was subsequently analyzed and processed in a standard format to determine outcomes.

i) Inclusion Criteria

- Patients who fulfilled the case definition and presented with sciatica were included.
- Patients of both sexes were admitted to the study.
- Patients with both acute and chronic sciatica who were willing to participate and cooperate with regular follow-ups and physiotherapy were included.

j) Exclusion Criteria

- Patients not fulfilling the case definition were excluded.
- Patients with complications such as malignancies or those who were immuno-compromised were excluded.
- Cases requiring emergency medical or surgical intervention were omitted from the study.

k) General Management

1. Diagnosis: A clinical approach was adopted. Regular guidelines were followed from senior practitioners and physicians. Investigations were performed at standard laboratories when necessary.
2. Patient as a Person: Detailed case taking was performed as per the established proforma.
3. Symptomatic Pictures: These were derived accordingly, and data was utilized to correctly identify and categorize patients into their respective groups.

l) Criteria for Follow-up

All patients were duly followed, and details regarding symptomatic, clinical, and investigative changes were recorded. While follow-up intervals differed per patient, the first follow-up was typically conducted after a seven-day interval. All records were maintained based on Homoeopathic principles.

m) Criteria for Assessment

The results were assessed under the following headings:

- Marked: The patient became asymptomatic with normal parameters and relief at a general level.
- Moderate: Symptomatic relief with a reduction in symptoms of more than 50%.
- Mild: Symptomatic relief with a reduction in symptoms of less than 50%.
- No Improvement: No response was observed after treatment for a sufficient period.
- Worse: An aggravation of subjective and objective symptoms occurred.
- Not Reported: The patient failed to report back after the initial visits.

RESULT

Distribution of Cases According to Age

Maximum cases were found in age group of 30 – 35 years i.e. 36 (43%) cases. In 35-40 years age group cases were 28 (33%). In 40-45 years age group cases were 20 (24%).

Distribution of Cases According to Gender

Gender wise maximum cases were found in male in compare to female i.e.51 (61%) cases against 33 cases (39%).

Distribution of Cases According to Body Weight

One of the major associated risk factors was obesity i.e. 41 cases (49 %)

Distribution of Cases According to Occupation

Among the cases co-relation to occupation could be found in 46 cases i.e. 55%.

Distribution of Cases According to Symptoms

Among all the cases symptomatically pain was more 43 (51%) followed with tingling and numbness 29 (35%) and followed by sensation of loss of muscle power 12 (14%).

Distribution of Cases According to Improvement

Among the cases 32 (38%) cases have shown marked improvement, 38 (45%) cases have shown moderate improvement and 14 (17%) cases have shown no improvement.

DISCUSSION

Total 84 patients with Sciatica were enrolled in the study. The findings of this study provide a comprehensive overview of the demographic and clinical profile of the subjects involved. Demographic Profile: The majority of the cases were concentrated in the younger to middle-aged adult population, specifically those between 30–35 years (43%). This suggests that the condition being studied predominantly affects individuals during their most productive working years. There was also a clear gender disparity, with males accounting for 61% of the cases compared to 39% for females. This higher prevalence in males may be linked to occupational hazards or lifestyle factors. Pain was the most significant clinical symptom, reported by over half of the participants (51%). This was followed by neurological symptoms such as tingling and numbness (35%) and loss of muscle power (14%).

A critical finding in this study is the role of Obesity as a major risk factor, affecting 49% of the cases. Despite this high association, the BMI table shows that only 14.2% of the total frequency was classified as obese, which may suggest that while the "Obese" category is smaller in the total sample, it carries a disproportionately high risk for the condition. Occupational Correlation and Outcomes: There is a strong correlation between professional activity and the onset of the condition, with 55% of cases (46 individuals) being linked to their occupation. Most of the subjects were currently working (77.1%).

In terms of recovery, the treatment or intervention showed positive results:

- 83% of cases showed some level of improvement (38% marked and 45% moderate).
- Only 17% of cases failed to show any improvement.

Ethical issue: Study protocol was approved through Institutional Ethical Committee. Written informed consent was taken from the participants and full confidentiality for the information provided was ensured.

CONCLUSION

This study showed a significant role of homoeopathy in the treatment of sciatica in reducing the intensity of pain and providing good quality of life. The study concludes that the condition predominantly affects working-age males, with a strong correlation to occupational strain and elevated BMI. Despite the severity of symptoms like pain and sensory loss, the prognosis is favourable, as 83% of the patients experienced moderate to marked improvement. These findings suggest that weight management and ergonomic interventions in the workplace could be vital for prevention.

ACKNOWLEDGEMENTS

First and foremost, I would love to thank the Almighty for giving me this life and opportunity.

- I consider myself honoured to have worked under the guidance of my esteemed teacher and revered guide, Dr.Kirtida Desai. Her admirable foresight, constant encouragement, scientific approach and continuous supporthave made this possible.
- I am extremely grateful to Dr. Anju Bhatt for her valuable suggestions and constant encouragement.
- I express my sincere thanks to Dr. Vinod Patel, trustee of Parul University and Dr HeenaRawal, AcademicDirector, Parul University Ahmedabad Campus for providing all the necessary facilities.
- I would also like to thanks Dr Komal Patel, Professor Department of Organon of Medicine, AHMC and DrSiddharth Saurabh Professor Department of Repertory AHMC for their constant help.

ABSTRACT

By catering to the needs of unserved and underserved communities, microfinance institutions (MFIs) have brought about a transformation in the quality of life and the standard of living of the communities at the bottom of the pyramid. Importantly, the MFIs finance the communities without insisting on collateral from them. Women, one of the most vulnerable segments of our society, have been emancipated through MFI financing. Parallelly, the MFIs have emerged as a major and effective financial inclusion tool that promotes economic development at the bottom of the pyramid. All the same, the MF industry believes that only about 35 percent of the potential market has been tapped. That such a sector is at a crossroads today makes sad reading. The recent structural transition of the industry and its implications for the borrowing communities and other stakeholders, calls for a revision of the present strategy to optimise the performance of the sector. Towards this end, the researcher undertook this study. He interacted with two major respondent categories associated with the sector, namely, bank officers and MF experts, for the purpose. The interaction with and analysis of primary data collected from them led the researcher to infer, inter alia, that MFIs should be mandated to use C-KYC alone to ensure that the authentication procedure is tamper-proof. MFIs should be mandated to move to risk-based pricing of their funds. With operating costs going up and the bottom line shrinking, MFI should go digital and cashless in their transactions, as far as possible. It is high time that the Banning of Unregulated Lending Activities or BULA bill was passed into law. It will protect the borrowers from predatory interest rates and coercive recovery methods, thereby ensuring transparency all the way.

Keywords: Risk based pricing, Loan Delinquencies, Financial Inclusion, Credit Discipline, BULA Bill.

INTRODUCTION

Theoretical background of the topic

The microfinance (MF) industry in the country stands at a cross-road today. In making the unserved and underserved countryside served, MFIs have caused a positive change on quality of life and standard of living of both CDDs. Importantly, the MFIs fund these communities at such ease – in fact they do not demand any collateral securities from the borrowers . Women are the most vulnerable in our society, and they form the largest proportion of MFI borrowers. Reprint: No wonder, the MFIs is one of the greatest and effective weapon in financial inclusion to supplement eco-nomic development at base of pyramid. The sector's gross loan portfolio as of March 2025 was INR 375,000 crore, serving around estimated 79 million borrowers. It had also generated 120 million jobs, in rural India for the most part. Even so, the MF industry estimates that only some 35 percent of the potential market has been reached. But all of that changed when the Andhra Pradesh crisis, demonetization, 2018 NBFC liquidity crunch, farm loan waivers, the Assam MFI bill and COVID-19 pandemic made it one crisis after another. But the industry proved to be impressibly resilient and able to withstand the crises with the help of crisis management instruments used by regulators. For instance, RBI was fine with the creation of NBFC MFIs in 2022 (the law of the land held that its jurisdiction over lending activities vis-à-vis the state remained intact).

Statement of the problem

The sector's delinquencies have been climbing from Q4 FY24, impacting the overall profitability and growth of the sector. Sector performances have been deteriorating ever since. They have only deteriorated further for each subsequent quarters in FY25. NPAs or loans over 90 days had breached the 5% level – a far cry from an industry-benchmark recovery rate in excess of 99% and credit costs well below one percent. (Nambiar, 2025). Restoration to FY24 levels may not occur unless there is recovery in the operating expense and a moderation of lending yields (THE HINDU, 2025).

REVIEW OF LITERATURE

A few studies on the research topic are reviewed in the paragraphs that follow.

1. According to Nambiar, Manor Kumar), microfinance is now recognised as the primary vehicle of financial inclusion and poverty eradication at grassroots level (Nambiar, 2025). Mico-fi-nance institutions (MFIs) are providing small no-collateral credit to the unbanked or underserved population. By March 2025, the GFLP in the sector scaled beyond INR 3.75 lakh crore, with around 79 million borrowing clients. Or is it that the segment of this market which has been served so far is only about thirty-five percent but can go a long way (THE ASSOCIATED CHAMBERS OF COMMERCE AND INDUSTRY OF INDIA, 25)? An impressive 99 percent of these borrowers are women, demonstrating the sector's contribution to supporting women empowerment and economic independence. In household and social terms this means that 300 million plus lives affected, an estimated 120 million jobs directly generated. Indian microfinance, however, still has significant ground to cover if it is to become all that it can be.
2. **MFIs will be in recovery mode by only H2FY26:** India Ratings KOLKATA: Hindu, THE 25 (India), – Microfinance institutions could return to normalcy only in the second half of fiscal 2026-27, according to credit rating agency India Ratings. It has bestowed a 'degrading outlook' upon the sector. The Tamilnadu and Karnataka governments subsequently promulgated ordinances to check coercive methods adopted by collection agents. The ordinances could dent the sector's return profile in the medium term. Normalisation to FY24 levels may not play out as a result of the increasing operating expense and moderation in lending yields, notes the rating agency.
3. Latha, Venkatesh states that the Indian microfinance sector faces persistent challenges (Latha, 2025). The stress level is not likely to abate over the next two to three quarters. Quoting Chandan Thakur, Deputy Director at Sa-Dhan, the researcher ascribes the pressure to a mix of post-COVID recovery hurdles, rising unemployment, and delinquency rates obtaining in rural areas (Thakur, 2025).

4. India's microfinance industry is witnessing a structural transition (ETBFSI, 2025). It is characterised by deliberate portfolio recalibration, changing borrower demographics, rising digital adoption and a deviation from normal group-based lending. As of FY 2025, MF loans amounted to INR 539 lakhs, representing a 13 percent YoY decline. The outstanding value fell 14 percent YoY, to INR 3, 81, 225 crores. The contractions in both the cases reveal a strategic industry-wise shift towards prudent, quality-centric lending. It should not be mistaken for a fall in demand. NBFC-MFIs retain the largest market share across loan accounts and outstanding portfolios.

RESEARCH GAP

The learned researchers have lucidly analysed the status of the MF industry, particularly the contribution of the industry to the economic well-being of the bottom of the pyramid. The fact that the industry is almost entirely focused on the emancipation of one of the most vulnerable sections of society, namely the women, makes happy reading. However, the recent structural transition of the industry and its implications for the borrowing communities and other stakeholders, calls for a revision of the present strategy. Decision-making must be optimised at the micro level through an appropriate mix of financial prudence, exploitation of technology and empowerment of the SROs, taking care all the while, to put a human face on these processes. The knowledgeable researchers could have added even more value to their otherwise useful findings by addressing this aspect of the ongoing structural transition. The current study aims to close this gap.

Scope of the present study

The study confines itself to two categories of respondents, namely, 50 bank officers (with exposure to MFI financing) and 30 MF experts. Both the categories are based in Bengaluru (Urban) and Bengaluru (Rural) districts.

OBJECTIVE OF THE STUDY

The objective of the study is to

1. Ascertain the perspective of the respondents on the current status of the MFIs
2. Ascertain the measures needed to optimise the performance of MFIs

Hypothesis proposed to be tested.

The following hypothesis is intended to be tested by the study.

"There is no association between the respondents' suggestion that RBI-recognised Self-Regulatory Organizations (SROs) should be empowered to enforce need-based operational norms even if they are more stringent than the regulatory floor and the category the respondents belong to."

Research design

The research methodology is provided in the paragraphs that follow.

RESEARCH METHODOLOGY

The study is descriptive in nature and has used the 'fact-finding' survey method.

Sources of data

Both primary and secondary sources have provided data for this study. We have obtained primary data from 30 MF experts and 50 Indian bank officials with experience in MFI finance. Secondary data is collected and downloaded in hard copy and soft copy from the various websites of the Government of Karnataka (GoK) and Government of India (GoI), industry mutual funds, financial press, and journals.

Sampling plan

Bank officers: Fifty bank officers who had experience financing MFIs were chosen by the researcher. For this purpose, he employed the non-probability method's purposive or judgment sampling technique.

MF experts: Thirty MF experts were chosen by the researcher. For this purpose, he employed the non-probability method's purposive or judgment sampling technique.

Data collection instruments

In order to gather primary data, the researcher interacted with the respondents and gave them interview schedules.

Data processing and analysis plan

The investigator implemented both manual and mechanical means to analyze data. Data analysis reporting and deployment was carried out using the Microsoft Excel spreadsheet package. For gathering primary data, 4-point likert scale was applied to have response of respondents about the inquiry pose in Interview Schedule. Just to make sure that the respondents are forced to make their opinion the researcher used 4-point Likert scale.

LIMITATIONS OF THE STUDY

The researcher derived first-hand information from regular subject-matter-based interactions with the participants as well. Subtly subjective even? Probably, but I doubt it's a direct one. However, the researcher believes that if there was any subjectivity, it could not affect the quality of results of this study.

Analysis of primary data collected from 50 bank officer respondents.

The primary data gathered from the 50 MFI officer respondents is examined in the paragraphs that follow.

Perspective of the respondents on the current status of the MFI

The stakeholder perspective on MFI differ between those involved with MF. So the researcher wanted to ask from the respondents: Do you approve with the following per-spectives, that have been displayed below? Respondents' agreement or disagreement with the claims are presented in four levels: 1) Strongly Agree; 2) Agree; 3) Disagree; and, 4) Strongly Disagree. These are allocated values 1, 2, 3 and 4.

Table-1

Perspective of the respondents on the current status of the MFI.

37 respondents agree that Microfinance is yet to realise its full potential in India. The remaining 13 beg to differ. 30 respondents agree that Informal lenders still call the shots in rural India. The remaining 20 beg to differ. 23 respondents agree that despite the tailwinds induced by policy shocks, NBFC liquidity crunch and the pandemic, the MF sector proved remarkably resilient and adaptable. The remaining 27 beg to differ. 29 respondents agree that Operating costs of NBFC-MFs have been rising. The remaining 21 beg to differ. Rising field staff turnover makes it difficult to sustain customer relationships, according to 39 respondents. The remaining 11 beg to differ. Loan delinquencies have been rising, according to 45 respondents. The remaining five beg to differ.

Measures needed to optimise the performance of MFIs

After familiarising with respondents' view on the present status, an attempt was made to know from them that would make performance of MFIs optimum. Their responses to the question are listed below. The replies are provided at four levels; Strongly Agree, Agree, Disagree and Strongly Disagree. These variates are labelled 1, 2, 3 and 4 respectively.

Measures needed to optimise the performance of MFIs (Table-2)

MFIs should be mandated to use only CKYC to ensure a tamper-proof authentication procedure, according to 41 respondents. The remaining nine respondents beg to differ. MFIs should be mandated to move to risk-based pricing to promote and reward credit discipline, according to 37 respondents. The remaining 13 beg to differ. Since MF can create numerous jobs, rural youth should be trained in areas like lending, insurance, pension and investment under a dedicated programme, according to 31 respondents. The remaining 19 beg to differ. MFIs must go digital and cashless to the extent possible to minimise costs and raise profitability, according to 37 respondents, The remaining 13 would beg to differ. RBI-recognised Self-Regulatory Organizations (SROs) should be empowered to enforce need-based operational norms even if they are more stringent than the regulatory floor, according to 41 respondents. The remaining nine would beg to differ.

Analysis of primary data collected from the 30 MF expert respondents.

The primary data gathered from the thirty MF expert respondents is examined in the paragraphs that follow.

Perspective of the respondents on the current status of the MFI

Views of stakeholders related to MF diverge about the current state of MFI. Thus, the researcher wanted to understand from the respondents about whether they would concur with the perspectives laid in the table. The agreement or disagreement of the respondents with the opinions are indicated on four levels i.e Strongly Agree, Agree, Disagree and Strongly Disagree. These variates are then set equal to 1, 2, 3and 4.

Perspective of the respondents on the current status of the MFI. (Table-3)

Microfinance is yet to realise its full potential in India, according to 23 respondents. The remaining seven would beg to differ. Informal lenders still call the shots in rural India, according to 19 respondents. The remaining 11 would beg to differ. Despite the tailwinds induced by policy shocks, NBFC liquidity crunch and the pandemic, the MF sector proved remarkably resilient and adaptable, according to 23 respondents. The remaining seven would beg to differ. Operating costs of NBFC-MFs have been rising, according to 25 respondents. The remaining five would beg to differ. Loan delinquencies have been rising, according to 21 respondents. The remaining nine would beg to differ. Although disbursements have risen, job creation and repayment capacity of the borrowers have not improved, according to 26 respondents. The remaining four would beg to differ.

Measures needed to optimise the performance of MFIs

Having apprised himself of the perspectives of the respondents on the current status of the respondents, the researcher sought to ascertain from the respondents the measures needed to optimise the performance of MFIs. Their replies to the query are tabulated below. The replies are expressed at four levels, namely, Strongly Agree, Agree, Disagree and Strongly Disagree. These variates are assigned the values 1, 2, 3 and 4 respectively.

Measures needed to optimise the performance of MFIs (Table-4)

MFIs should be mandated to use only CKYC to ensure a tamper-proof authentication procedure, according to 27 respondents. The remaining three would beg to differ.RBI should insist on daily credit bureau updates concerning the MF portfolio from all MFIs, according to 22 respondents. The remaining eight would beg to differ.RBI should oblige MFIs to integrate KYC-linked deduplication into the updates to pre-empt issue of multiple loans to the same borrower, according to 25 respondents. The remaining five would beg to differ.MFIs should be mandated to move to risk-based pricing to promote and reward credit discipline., according to 26 respondents. The remaining four would beg to differ. Since MF can create numerous jobs, rural youth should be trained in areas like lending, insurance, pension and investment under a dedicated programme, according to 26 respondents. The remaining four would beg to differ. MFIs must go digital and cashless to the extent possible to minimise costs and raise profitability, according to 27 respondents. The remaining three respondents would beg to differ.RBI-recognised Self-Regulatory Organizations (SROs) should be empowered to enforce need-based operational norms even if they are more stringent than the regulatory floor, according to 27 respondents. The remaining three would beg to differ. It is high time the Banning of Unregulated Lending Activities (BULA) Bill was passed into law, according to 26 respondents. The

remaining four would beg to differ.It is high time the Anti-Financial Vandalism (AFV) Bill was passed into law, according to 26 respondents. The remaining four would beg to differ. Additionally, a climate-linked borrower protection product should be designed to cover interest burden during short-term repayment deferment occasioned by natural disasters, according to 23 respondents. The remaining seven would beg to differ. Oversight of the conduct of business across the sector should be entrusted to a dedicated employee bureau, according to 21 respondents. The remaining nine would beg to differ. Distressed borrower programmes should be designed periodically to help the borrowers address the existing and potential stress, according to 27 respondents. The remaining three would beg to differ.

RECOMMENDATIONS

In light of the conclusions reached, the researcher makes the following recommendations.

1. The RBI and the GoI should mandate the MFIs to use C-KYC alone, to ensure a unified, tamper-proof authentication procedure. Presently, most MFIs insist on Voter ID which amounts to settling for second best.
2. RBI should insist on daily credit bureau updates concerning the MF portfolio from all MFIs. MFIs should be required to integrate KYC-linked deduplication into the updatesThis will pre-empt issue of multiple loans to the same borrower.
3. MFIs should be mandated to move to risk-based pricing of their funds. This will promote and reward credit discipline.
4. Given their ability to generate employment in rural pockets in particular, MFIs will do well to train the rural youth in areas like lending, insurance, pension and investment. The trained, job-ready youth will stand the MFIs in good stead when their attrition rates shoot up for whatever reason.
5. With operating costs going up and the bottom line shrinking, MFIs will do well to go digital and cashless in their transactions, as far as possible.
6. The RBI-recognised Self-Regulatory Organizations (SROs) should be empowered to enforce need-based operational norms even if they are more stringent than the regulatory floor. MFIs will gain by erring on the side of caution, in the backdrop of their shrinking bottom lines and rising costs
7. It is high time the Banning of Unregulated Lending Activities Bill (BULA) was passed into law. BULA will put astop to illegal lending activities by unauthorized entities, like digital lending apps. It will ensure that the lenders follow RBI rules. It will protect the borrowers from predatory interest rates and coercive recovery methods, thereby ensuring transparency all the way.
8. Additionally, a climate-linked borrower protection product should be designed to cover the interest burden that weighs down the borrowers when natural disasters force them to defer repayment in the short-term.

CONCLUSIONS

Conclusions pertain to hypotheses and are inferences or generalizations derived from the data. They are statements of acceptance or rejection of hypotheses or responses to the research questions.

ABSTRACT

This research paper develops a dynamic inventory model that integrates modern innovation-diffusion processes into inventory decision-making for newly launched and rapidly changing products. We build on the Bass diffusion framework to model time-varying demand and embed this into a continuous-review economic order cycle model with time-dependent demand. We proposed an innovation, "Diffusion-*Adjusted Cycle Policy (DACP)*" which uses real-time diffusion parameters and AI-augmented forecasting to adapt the cycle length and replenishment plan. Mathematical derivations produce optimality conditions (implicit) for cycle time and order quantity. A numerical case and sensitivity analysis demonstrate how diffusion parameters, ordering cost, and holding cost change optimal replenishment frequency and average cost. The analysis highlights the necessity of coupling diffusion forecasting and inventory control in today's Industry-4.0 environment.

Keywords : innovation diffusion, Bass model, inventory modelling, EOQ with time-varying demand, dynamic replenishment, Industry 4.0, IoT, AI forecasting.

INTRODUCTION

Background and motivation

Inventory models have historically assumed demand that is either constant, deterministic time-invariant, stochastic stationary, or follows simple non-stationary forms. However, for many modern products especially technological

goods, new consumer durables, and rapidly evolving innovations demand is fundamentally **non-stationary** and driven by *diffusion dynamics* (adoption over time). The diffusion of an innovation across a market (and between adopter categories) creates time-dependent demand patterns that can be far from the constant-rate assumptions of classical EOQ or (s,S) models. Integrating diffusion models into inventory decisions is therefore essential for realistic, cost-efficient replenishment policies. The Bass diffusion model remains a canonical analytical tool to represent new-product adoption dynamics (innovation and imitation effects), forming a natural candidate to couple with inventory control.

Recent literature has begun to incorporate diffusion behavior directly into inventory frameworks, proposing EOQ variants and dynamic lot-sizing approaches that accept Bass-type demand or other diffusion processes as the demand input. These hybrid approaches allow managers to capture marketing effects, word-of-mouth, and time-varying adoption impacts on replenishment policy. Contemporary industry trends digitization, IoT for inventory visibility, and AI/ML forecasting further enable near-real-time parameter updates and adaptive inventory strategies. Several recent empirical and theoretical studies illustrate both the need for and the benefits of diffusion-aware inventory policies.

Scope and contributions

This paper contributes in three principal ways:

1. **Analytical coupling**: we derive a continuous-time cycle-based inventory model (EOQ-like but with time-dependent demand) where demand follows the Bass diffusion function. We present closed-form expressions where possible and provide the first-order condition for the optimal cycle time as an implicit equation that can be solved numerically.
2. **New concept " DACP (Diffusion-Adjusted Cycle Policy)"**: we propose a policy that uses diffusion parameters (p, q, market size m) continuously updated by AI/IoT data streams to adapt the replenishment cycle length dynamically. The DACP extends classical economics by directly incorporating diffusion acceleration (marketing, social contagion) and imitation effects into ordering frequency.
3. **Numerical and sensitivity analysis**: we demonstrate the model with realistic parameters (market potential, diffusion coefficients, cost parameters), solve the optimal cycle numerically, and perform sensitivity analysis on p, q, setup cost S, and holding cost h to highlight managerial implications.

Organization

Section 2 reviews key literature on diffusion theory (Bass model and extensions), previous diffusion-inventory models, and current trends (AI/IoT-enabled inventory). Section 3 formalizes notation and assumptions, builds the mathematical model, derives conditions for optimal cycle time and order quantity, and introduces the DACP. Section 4 presents numerical illustrations and sensitivity analysis. Section 5 concludes with managerial implications and future research directions.

LITERATURE REVIEW

Foundations: diffusion theory and the Bass model

The Bass (1969) model remains the foundational analytical specification for new product diffusion dynamics. It decomposes adopters into innovators (driven by external influence, coefficient p) and imitators (driven by internal influence or word-of-mouth, coefficient q). The Bass model provides an explicit adoption rate (sales curve) often used to forecast cumulative adoptions and sales at time t. The Bass model has been empirically validated across many product categories and remains the most widely cited diffusion model.

Inventory models incorporating diffusion

Researchers have integrated diffusion-based demand into EOQ and dynamic inventory models in several ways: deterministic EOQ extensions using Bass-derived time-varying demand; lot-sizing under nonstationary demand; and

dynamic models that explicitly include marketing effort as a control parameter that affects diffusion. Recent studies propose EOQ variants adjusted for diffusion and time-dependent deterioration, demonstrating improved cost performance over classical static models for new products.

Forecasting, uncertainty, and modern trends

Recent work has emphasized the limits of static diffusion forecasts and argued for integrating actor- and system-level considerations and adaptive forecasting approaches, particularly important when diffusion is affected by exogenous shocks, network effects, or evolving consumer behaviour. Industry trends IoT-enabled stock visibility and AI/ML forecasting complement diffusion-aware inventory by supplying near-real-time parameter estimation and anomaly detection, enabling adaptive inventory control (which we embed in DACP).

Gaps and opportunity

Although prior work exists, there remains an opportunity to: (1) derive an analytically tractable replenishment condition under Bass demand, (2) demonstrate methods to compute optimal cycles numerically and explore sensitivity to diffusion parameters, and (3) propose operational policies (like DACP) that exploit IoT/AI for parameter updates and online decision making. This paper addresses these gaps.

METHODOLOGY

This is the technical core. I present notation, assumptions, model equations, derivations of cost functions, and the first-order condition for the optimal cycle time. I then discuss solution methods and propose the DACP operationalization.

Notation

Symbol	Meaning
m	Market potential (total eventual adopters of product)
p	Coefficient of innovation (external influence)
q	Coefficient of imitation (internal influence/word-of-mouth)
$F(t)$	Cumulative fraction of adopters at time t
$f(t) = \frac{dF}{dt}$	Adoption rate per unit time (Bass density)
$s(t) = mf(t)$	Time-dependent demand rate (units per time)
S	Fixed ordering/setup cost per replenishment (currency)
h	Holding cost per unit per unit time (currency/time)
T	Replenishment cycle length (decision variable)
Q	Order quantity per cycle $Q = \int_0^T s\,(u)\,du$
$C_{\text{avg}}(T)$	Average cost per unit time (objective)
Other notation introduced as needed.	

Bass diffusion model

The Bass model (F. M. Bass, 1969) defines the instantaneous adopter fraction $f(t)$ as

$$\frac{f(t)}{1-F(t)} = p + q\,F(t), \qquad (1)$$

Equation (1) leads to the ODE

$$\frac{dF}{dt} = p(1-F) + qF(1-F) = (1-F)(p+qF) \qquad (2)$$

From equation (2), with $F(0) = 0$, the closed-form expression for the adoption rate $f(t)$ is

$$f(t) = \frac{(p+q)^2}{p} \cdot \frac{e^{-(p+q)t}}{\left(1+\frac{q}{p}e^{-(p+q)t}\right)^2}. \quad (3)$$

Hence demand rate (sales) is from equation (3)

$$s(t) = mf(t) = m \cdot \frac{(p+q)^2}{p} \cdot \frac{e^{-(p+q)t}}{\left(1+\frac{q}{p}e^{-(p+q)t}\right)^2} \quad (4)$$

Inventory cycle model with time-dependent demand — assumptions

1. **Continuous time** inventory model, infinite planning horizon with repeated cycles of length T.
2. **Instantaneous replenishment**: each order arrives instantly (no lead time). (We later discuss lead-time extension.)
3. **No shortages**: backorders not allowed.
4. **Demand equals adoptions** (sales): $s(t)$ is deterministic and given by the Bass function above.
5. **Cycle repeatability**: system repeats identical cycles in steady state (useful approximation for slowly varying diffusion). For fast-changing diffusion, cycles adapt via DACP.
6. **Costs**: fixed ordering cost S per order; holding cost h per unit per time. No per-unit purchasing cost or stockout cost included here — these can be added straightforwardly.

These assumptions match many EOQ-style analyses extended to nonstationary demand and are consistent with prior diffusion-inventory studies. IGI GlobalAfrican Journal of Biomedical Research

Cycle cost derivation (continuous-time)

Consider one replenishment cycle of length T. Let the order placed at time 0 supply demand during $[0, T]$. Quantity ordered:

$$Q(T) = \int_0^T s\,(u)\,du \quad (5)$$

Inventory level at time t, $I(t)$, with the help of equation (5) (just after replenishment) is:

$$I(t) = Q(T) - \int_0^t s\,(u)\,du \quad (6)$$

Holding cost per cycle by using equation (6):

$$H(T) = h\int_0^T I\,(t)\,dt = h\int_0^T \left(Q(T) - \int_0^t s\,(u)\,du\right)dt = h\left(Q(T)T - \int_0^T \int_0^t s\,(u)\,du\,dt\right) \quad (7)$$

Swap integrals:

$$\int_0^T \int_0^t s\,(u)\,du\,dt = \int_0^T \int_u^T d\,t\,s(u)\,du = \int_0^T (T-u)\,s(u)\,du$$

Thus

$$H(T) = h\left(Q(T)T - \int_0^T (T-u)\,s(u)\,du\right) = h\int_0^T u\,s(u)\,du$$

$$H(T) = h\int_0^T I\,(t)\,dt = h\int_0^T \left(Q(T) - \int_0^t s\,(u)\,du\right)dt \quad (8)$$

Switching integrals and simplifying equation becomes

$$H(T) = h\int_0^T u\ s(u)\,du \quad (9)$$

So the total cost per cycle is:

$C_{\text{cycle}}(T) = S + H(T) = S + h\int_0^T u\ s(u)\,du$ (10)

By using equation (10), Average cost per unit time (objective to minimize) is:

$C_{\text{avg}}(T) = \frac{C_{\text{cycle}}(T)}{T} = \frac{S}{T} + \frac{h}{T}\int_0^T u\ s(u)\,du$ (11)

This reduces to the classical EOQ average cost structure $S/T + hQ/2$ when $s(t)$ is constant (because $\int_0^T u\,s\,du = sT^2/2$ and $Q = sT$), confirming consistency with EOQ.

Optimality condition

For first-order necessary condition

Differentiate $C_{\text{avg}}(T)$ with respect to T. Let

$A(T) = \int_0^T u\ s(u)\,du$ (12)

Then equation (11) becomes,

$$C_{\text{avg}}(T) = \frac{S}{T} + \frac{hA(T)}{T}$$

Compute derivative (Leibniz rule for $A'(T) = Ts(T)$), from equations 11 and 12

$$\frac{dC_{\text{avg}}}{dT} = -\frac{S}{T^2} + h\frac{TA'(T) - A(T)}{T^2} = -\frac{S}{T^2} + h\frac{T^2 s(T) - A(T)}{T^2}.$$

Set derivative to zero for interior optimum:

$-S + h\big(T^2 s(T) - A(T)\big) = 0,$

or equivalently

$T^2 s(T) - A(T) = \frac{S}{h}$ (13)

This is an implicit equation in T. For general $s(t)$ (including the Bass function), the equation must be solved numerically for $T > 0$. Existence of a unique positive root typically holds under reasonable regularity of $s(t)$ (positive, continuous functions), but the convexity of C_{avg} should be verified numerically for specific parameter ranges.

Interpretation: The left side measures the difference between the instantaneous demand at the cycle end, scaled by T^2, and the time-weighted cumulative demand within the cycle; the right side is the ratio of ordering to holding costs. High ordering cost S increases RHS and typically increases optimal T (less frequent orders), whereas high holding cost h decreases RHS (more frequent orders).

Application to Bass demand: explicit expressions / numerical solution

With $s(t) = mf(t)$ as defined, $A(T) = m\int_0^T u\,f(u)\,du$ and $s(T) = mf(T)$. The FOC becomes

$$T^2 mf(T) - m\int_0^T u\,f(u)\,du = \frac{S}{h}$$

Divide both sides by m (if $m > 0$):

$T^2 f(T) - \int_0^T u\, f(u)\, du = \frac{S}{hm}$ (14)

This is the equation to solve for T. Closed-form analytic solution is not available due to the complexity of $f(t)$; instead **numerical root-finding** is appropriate. The model remains fully specified and tractable numerically.

Diffusion-Adjusted Cycle Policy (DACP)

Motivation: Diffusion parameters p, q, m are not static in practice: marketing campaigns, price changes, social media effects, and network dynamics shift them. With IoT& AI, firms can update parameter estimates almost continuously and thus should adjust replenishment decisions dynamically.

DACP idea: At each decision epoch (or continuously in an automated system), use real-time sales data to update estimates $\hat{p}(t), \hat{q}(t), \hat{m}(t)$ (e.g., via maximum likelihood / Bayesian updating / particle filtering). Given the updated parameters, compute the optimal cycle length $T^*(\hat{p}, \hat{q}, \hat{m}; S, h)$ by solving (FOC-Bass) numerically. Implement ordering frequency change if conditions indicate substantial benefit beyond switching costs.

Operationalization steps:

1. **Data ingestion**: IoT sensors & POS feed per-period sales to AI forecaster PS (or similar).
2. **Parameter update**: Use rolling estimation (ML or Bayesian) to update $\hat{p}, \hat{q}, \hat{m}$.
3. **Solve FOC**: Numerically solve (FOC-Bass) for T^*.
4. **Decision rule**: Change cycle to T^* only when the expected reduction in average cost exceeds a threshold (to avoid churning).
5. **Monitoring**: Continuously monitor model residuals; if forecasting breaks (e.g., exogenous shock), switch to contingency replenishment rules.

DACP leverages the combination of diffusion theory, numerical optimization, and modern sensing/AI — aligned with recent calls to embed forecasting and diffusion modeling into operational decisions. research. chalmers.seResearch Gate

Extensions

Lead time: If lead time $L > 0$ is constant, safety buffers and reorder points can be derived but will complicate the FOC. The DACP can incorporate lead time by solving for cycle T and reorder point $R = \int_0^L s\,(u)\, du$ or via service-level constraints.

- **Stochastic diffusion**: When demand has stochastic noise, expected cost minimization and risk-adjusted policies can be developed (stochastic control / robust optimization).
- **Marketing control**: If marketing effort $x(t)$ affects p (or directly affects s(t)), joint optimization of marketing and ordering (a control problem) is possible — an interesting future research direction.

Numerical illustration & sensitivity analysis

Numerical solution method has following steps

- Compute $f(t)$ for Bass function; evaluate $s(t) = mf(t)$.
- For a candidate T, compute $A(T) = \int_0^T u\, s(u)\, du$ by quadrature.
- Compute $g(T) = T^2 s(T) - A(T) - S/h$. Root $g(T) = 0$ gives FOC. Use a robust solver (Brent's method on a bracket, or Newton with safe bracket).
- Implement tolerances and sanity checks (positive T, monotonicity checks).

We demonstrate the model using realistic numerical parameters (these mirror typical values used in diffusion studies — they are illustrative):

- Market potential: $m = 15{,}000$ units.
- Diffusion parameters: $p = 0.01$ (innovation), $q = 0.25$ (imitation).
- Ordering cost: $S = 1{,}000$ currency units.

- Holding cost: $h = 1$ currency unit per unit per time.

(These parameter choices are illustrative and similar to examples used in diffusion-inventory literature and earlier working notes.) JSTOR African Journal of Biomedical Research

Solving FOC numerically

We solve the implicit equation (FOC-Bass):

$$T^2 f(T) - \int_0^T u\, f(u)\, du = \frac{S}{hm},$$

by numerical root finding (standard methods: Newton-Raphson, secant, or bracketing). Because the left side is computable for any $T > 0$ (via numerical integration), the equation is tractable numerically.

Results

Solving numerically for the baseline parameters ($m = 15000, p = 0.01, q = 0.25, S = 1000, h = 1$) yields:

- Optimal cycle $T^* \approx 2.5222$ (time units).
- Corresponding order quantity $Q = \int_0^{T^*} s\,(u)\, du \approx 516.21$ units per cycle.
- Average cost per time $C_{\text{avg}}(T^*) \approx 679.61$ (currency per time unit).

(Computation done numerically; precise values depend on integration accuracy and root tolerance. This example illustrates the method and typical magnitudes.)

Sensitivity analysis

We examine how T^*, Q, and average cost respond to changes in parameters. Table summarizes a few scenarios (all other parameters as baseline unless changed):

Scenario	p	q	S	h	T^*	Q	Avg cost
Baseline	0.01	0.25	1000	1	2.5222	516.21	679.61
Higher p	0.02	0.25	1000	1	1.9637	738.72	904.91
Higher q	0.01	0.50	1000	1	2.0191	511.45	791.27
Higher S	0.01	0.25	2000	1	3.2451	727.37	1024.64
Higher h	0.01	0.25	1000	2	1.9334	367.59	912.46

Observations:

- Increasing p (faster external adoption) typically **reduces cycle length**T^* in these parameter ranges (more frequent ordering) because early rapid adoption increases near-term demand and holding cost tradeoffs change — however, note that Q may increase because higher early demand integrates to larger order sizes over shorter cycles. (Managerial explanation: when innovators purchase early, you may want more frequent but larger immediate replenishments to meet surges.)
- Increasing q (imitation) tends to shape the adoption curve to be steeper later; in our example it slightly reduced T^* and increased average cost — imitation can create sharper peaks requiring tighter replenishment policies.
- Larger ordering cost S increases the optimal cycle length (order less frequently).
- Higher holding cost h reduces T^* (order more frequently) but increases average cost per time.

This sensitivity analysis emphasizes that diffusion parameters critically affect replenishment frequency and costs; firms should therefore integrate diffusion estimation into inventory routines (the DACP approach).

Connections to literature: These numerical behaviours align with prior diffusion-inventory studies that emphasize the sensitivity of EOQ-like policies to time-varying demand driven by diffusion. IGI GlobalAfrican Journal of Biomedical Research

CONCLUSION, OUTCOMES, AND FUTURE RESEARCH

Summary of findings

- Embedding diffusion dynamics (Bass model) into inventory control yields a transparent and tractable framework where cycle costs have closed-form structure but require numerical solution for the optimal cycle time.
- The optimality condition (FOC) is implicit but interpretable: it balances ordering/setup cost against time-weighted holdings under the diffusion-driven demand curve.
- The proposed **Diffusion-Adjusted Cycle Policy (DACP)** operationalizes continuous updates of diffusion parameters (via AI/IoT) and dynamically adjusts cycle length to minimize average cost, reducing stockouts and overstock risks for new products.

Outcomes

- **Forecasting matters more than ever:** diffusion parameters (p,q,m) shift replenishment decisions; continuous parameter estimation is valuable.
- **Use of IoT& AI:** PS-type AI systems that continuously ingest sales/POS/marketing data make DACP feasible. Real-time visibility reduces risk from diffusion surprises. ResearchGate
- **Joint decisions:** for high-impact launches, co-optimization of marketing (which affects p) and inventory (order timing) can yield cost savings and improved service.

Limitations & future work

- We assumed deterministic Bass demand; stochastic extensions and model robustness to parameter uncertainty merit study.
- Lead times, stockouts, multi-echelon distribution, and capacity constraints should be included in future models.

Empirical validation and field experiments to estimate benefits of DACP versus static policies are natural next steps. Recent work calls for rethinking diffusion forecasting with actor- and system-level perspectives, which can enrich operational models. research.chalmers.se

ABSTRACT

Parkinson's disease (PD) is a neurodegenerative disorder that is multifactorial in nature and characterized by both motor and non-motor symptoms. The serotonin 5-HT7 receptor is a potential therapeutic target in PD, as emerging evidence indicates that it plays a critical role in modulating mood, cognition, and motor function. The objective of this research was to examine the binding interactions of standard anti-Parkinsonian drugs and selected phytocompounds with the 5-HT7 receptor through molecular docking approaches. The 5-HT7 receptor structure (PDB ID: T79062) was obtained from the Protein Data Bank, and ligands were synthesized using ChemSketch and Open Babel. AutoDock 4.2 was utilized to perform docking, and the Discovery Studio Visualizer was employed to conduct interaction analysis. Hydrophobic interactions, residue involvement, hydrogen bonding, and binding energy were assessed. Tropigline (−7.4 kcal/mol) and benzo[b]thiophene-3-carboxylic acid (−6.8 kcal/mol) exhibited strong binding affinities, forming stable hydrogen bonds with essential residues including ARG367, ARG392, and ARG396. In contrast, conventional compounds such as β-myrcene and D-limonene

demonstrated weaker interactions. Pimavanserin, a reference drug, exhibited moderate binding (−5.8 kcal/mol). The results substantiate the potential of Tropigline and benzo[b]thiophene derivatives as 5-HT7 receptor modulators. They are relevant for further pharmacological investigation in the treatment of Parkinson's disease due to their promising docking profiles.

Keywords: Parkinson's disease, 5-HT7 receptor, serotonin, molecular docking, Tropigline, benzo[b]thiophene, phytocompounds, AutoDock

INTRODUCTION

Parkinson's disease (PD) is a neurodegenerative disorder that is prevalent and affects millions of individuals worldwide. It is characterized by both motor and non-motor symptoms. Although Parkinson's disease has been traditionally classified as a movement disorder, it now encompasses a broader spectrum of complications, such as cognitive decline, mood disturbances, and autonomic dysfunctions. Consequently, a multidisciplinary approach to diagnosis and management is required (Yarnall *et al*., 2012; Diederich *et al*., 2024; Korenblum *et al*., 2024; Kunze *et al*., 2023). Motor symptoms, including bradykinesia, rigidity, and quiescent tremor, are primarily caused by dopaminergic neuronal degeneration in the basal ganglia. Conversely, non-motor manifestations have a substantial impact on quality of life and may occur prior to the onset of motor symptoms. Recent research has progressively emphasized the significance of the serotonin (5-hydroxytryptamine, 5-HT) system in the pathophysiology of Parkinson's disease. The 5-HT7 receptor has garnered attention for its potential neuroprotective functions, cognitive processes, anxiety, and mood regulation, among the diverse serotonin receptor subtypes. Research has demonstrated that 5-HT7 receptors, particularly in the prelimbic cortex, regulate anxiety-like behavior in hemiparkinsonian models, suggesting a robust correlation between serotonergic dysfunction and non-motor symptoms of Parkinson's disease (Du *et al*., 2018). Anxiolytic effects have been demonstrated through the activation of 5-HT7 receptors, while antagonism exacerbates anxiety-like responses. Additionally, intra-prelimbic (PrL) injections of 5-HT7 agonists significantly elevate dopamine, serotonin, and noradrenaline levels, indicating a critical function in emotional regulation and neurotransmitter balance (Du *et al*., 2018). In the raphe nuclei of Parkinson's disease patients, neuropathological investigations have documented significant decreases in serotonergic neuron activity, which are associated with both motor and non-motor symptoms (Liguori *et al*., 2015). The potential therapeutic implications of targeting the 5-HT7 receptor are underscored by the belief that the inefficiency of serotonergic signaling contributes to mood disorders, tremors, and other clinical features (Liguori *et al*., 2015; Fox *et al*., 2009; Miguelez *et al*., 2014).

Serotonin receptors, or 5-HT receptors, are a diverse family of ligand-gated ion channels and G-protein-coupled receptors (GPCRs) that are responsible for the extensive physiological and behavioral effects of serotonin in the central nervous system (CNS) and peripheral tissues (Berger *et al*., 2009). They are responsible for the regulation of essential biological processes, such as mood, sleep, cognition, appetite, thermoregulation, gastrointestinal motility, and cardiovascular tone (Nichols *et al*., 2008; Hannon *et al*., 2008). The receptors are categorized into seven main families (5-HT1 to 5-HT7), each of which engages unique intracellular signaling pathways (Kroeze *et al*., 2002). In particular, 5-HT7 receptors are connected to Gs proteins, which induces excitatory signaling by increasing cyclic adenosine monophosphate (cAMP) and stimulating adenylate cyclase activity. The 5-HT7 receptor is widely distributed in peripheral systems, including the gastrointestinal tract and vasculature, as well as in brain regions such as the hypothalamus, thalamus, and hippocampus (Hedlund, 2009). Circadian rhythm (Lovenberg *et al*., 1993), cognition and synaptic plasticity (Wesołowska *et al*., 2007), mood (Hedlund *et al*., 2005), thermoregulation, and nociception are among the numerous vital functions that it regulates. Multiple disorders, including schizophrenia (Roth *et al*., 2006), melancholy, anxiety, autism spectrum disorders, and migraine (Meneses *et al*., 2001), are associated with the dysfunction of this receptor. The 5-HT7 receptor is involved in both neurodegeneration and neuroprotection in the context of pd. It influences both motor and non-motor symptoms by modulating dopaminergic transmission and striatal circuit function (Ibez-Vega *et al*., 2020). Furthermore, its activation has been linked to decreased

neuroinflammation, which further emphasizes its significance as a therapeutic target (Huot *et al*., 2008). Nevertheless, evidence also suggests that over activation may exacerbate levodopa-induced dyskinesias, requiring circumspect therapeutic modulation (Beaudoin-Gobert *et al*., 2018). In conclusion, the 5-HT7 receptor is a critical mediator in serotonergic signaling, which has significant implications for the pathophysiology and management of Parkinson's disease. It is a complex, yet promising, target for adjunctive therapies that are designed to alleviate both motor and non-motor symptoms of Parkinson's disease due to its involvement in modulating mood, cognition, neurotransmitter release, and neuroinflammation.

MATERIALS AND METHODS

The chemical structures of all selected ligands were drawn using ChemSketch (ACD/Labs). The generated structures were initially saved in MOL format and subsequently converted to PDB format using the Open Babel molecular converter software. The three-dimensional crystal structure of the target protein, the serotonin 5-HT7 receptor (PDB ID: T79062), was retrieved from the Protein Data Bank (https://www.rcsb.org). Prior to molecular docking, the protein structure was preprocessed by removing all water molecules and co-crystallized ligands or complexes. Molecular docking simulations were carried out using AutoDock 4.2**.** The protein and ligand structures were prepared by adding Gasteiger partial charges and Kollman united atom charges, and then saved in PDBQT format. Torsional bonds in the ligand molecules were defined to allow for conformational flexibility. All ligand confirmations were evaluated, and the final prepared ligand files were saved in PDBQT format. The docking results were also saved in PDB format for subsequent analysis. The docking complexes formed between the ligands and the 5-HT7 receptor were visualized and analyzed using Discovery Studio Visualizer (BIOVIA). Interactions were assessed based on hydrogen bonding, hydrophobic contacts, van der Waals forces, and the presence of any unfavourable interactions during complex formation. This procedure was uniformly applied to all selected phytochemicals as well as standard drugs used in the treatment of Parkinson’s diseases for comparative binding analysis against the 5-HT7 receptor.

RESULTS AND DISCUSSION

The serotonin 5-HT7 receptor, which is essential for the regulation of mood, anxiety, and motor symptoms associated with Parkinson's disease (PD), was the focus of this investigation. The interaction dynamics of approved medications and specific phytocompounds were examined. A multi-step *In silico* analysis was performed, commencing with the preparation of ligand and receptors, and proceeded by molecular docking, energy calculations, and interaction characterization.

Information Regarding the Target Protein and Ligand- The serotonin 5-HT7 receptor (PDB ID: T79062), the selected target protein, is involved in the pathogenesis of PD and related neuropsychiatric symptoms (Table 1). A variety of standard pharmaceuticals and phytochemicals were docked against this receptor, including compounds identified from GC-MS analysis and reported anti-Parkinsonian drugs. The PubChem IDs, 2D and 3D structures, and reported pharmacological activities of these ligands are summarized in Tables 2 and 3, respectively. Table 4 displays the reference standards for Parkinson's disease-approved medications. Hydrogen bonding and molecular interactions are essential factors in the stability and specificity of ligand-receptor interactions. Benzo[b]thiophene-3-carboxylic acid exhibited robust hydrogen bonding with three residues of the 5-HT7 receptor: ARG392 and ARG396 (Figure 1 and 2), with bond distances ranging from 2.07 to 3.01 Å (Table 5). Tropigline also demonstrated robust conventional hydrogen bonding with ARG367 (Figure 3 and 4), which indicates a favourable receptor interaction. Conversely, ARG396 established a weakened carbon-hydrogen bond with Succinic acid (Figure 5 and 6), non-4-enyltetradecyl ester. Hydrophobic interactions additionally bolstered the binding's stability. For example, TYR395 and ALA385 interacted with Benzo[b]thiophene-3-carboxylic acid through pi-sulfur and pi-alkyl bonds, respectively (Table 61). Tropigline and β-bisabolene exhibited numerous alkyl and pi-alkyl interactions with residues, including ILE159, LEU232, and PHE158.

Binding Energy and Docking Scores The selected ligands exhibited a variety of binding affinities, as indicated by the docking simulations (Table 6). Tropigline outperformed the reference ligand Benzo[b]thiophene-3-carboxylic acid (−6.8 kcal/mol) by exhibiting the strongest binding to the 5-HT7 receptor, with a binding energy of −7.4 kcal/mol and numerous hydrophobic and hydrogen bonding interactions. In contrast, succinic acid exhibited a less favorable energy profile (Figure 5 and 6), limited hydrogen bonding, and a weakened binding (−6.1 kcal/mol). Bicyclo[3.1.1]heptane, 6,6-dimethyl-2- weaker binding energies and low ligand efficiency (Figure 7 and 8). Table 8 displays the docking energies of specific compounds. Benzo[b]thiophene (Figure 1 and 2) derivatives, Tropigline (Figure 3 and 4), and β-bisabolene (Figure 13 and 14) exhibited relatively higher docking scores, suggesting their potential affinity for the 5-HT7 receptor. Pimavanserin, a standard drug that is a well-known 5-HT2A receptor antagonist, exhibited a binding energy of −5.8 kcal/mol with the 5-HT7 receptor (Figure 15 and 16). This is particularly noteworthy. It was included to contextualize the docking outcomes of experimental ligands, despite its limited hydrogen bonding.

Interaction Classifications and Residue Involvement The analysis of polar and non-polar residues involved in ligand binding (Table 7) revealed that ligands forming interactions with important polar residues, such as ARG392, ARG396, and TYR395, exhibited enhanced binding affinity. Conversely, non-polar interactions, although beneficial, were insufficient to guarantee robust binding independently. For example, β-Myrcene (Figure 9 and 10) and D-Limonene (Figure11 and 12) exhibited weaker binding energies and low ligand efficiency due to their reliance on hydrophobic contacts with PHE344 and the absence of polar interactions.

Drug Potential and Comparative Interaction Profile Table 9 confirms that Tropigline and Benzo[b]thiophene-3-carboxylic acid demonstrated superior interaction profiles with the 5-HT7 receptor, as evidenced by a comparative analysis of binding affinities and molecular interactions. Their binding was characterized by the formation of numerous hydrogen and hydrophobic bonds with functionally significant residues, including ARG367, ARG392, and TYR395. These interactions imply a potential therapeutic mechanism through serotonergic modulation. In contrast, natural compounds such as β-Myrcene and D-Limonene exhibited feeble binding energies (−5.7 to −5.6 kcal/mol) and limited interactions, suggesting a lower therapeutic potential.

Standard Drug Comparison: The molecular docking profile of Pimavanserin against the 5-HT2A receptor (Table 10) was used as a benchmark. Although its interaction profile provided insights into the pharmacophoric features required for optimal binding, its binding affinity with the 5-HT7 receptor was comparatively weaker. The significance of these residues in serotonergic modulation was underscored by the compound's formation of hydrogen bonds with GLN235 and ASP236 and hydrophobic contacts with PHE352.

CONCLUSION

The docking results provide substantial evidence supporting the potential of certain phytocompounds, particularly Tropigline and Benzo[b]thiophene-3-carboxylic acid, as promising modulators of the 5-HT7 receptor. These ligands showed favorable binding energies, strong hydrogen bonding, and stable hydrophobic interactions, indicating their suitability for further pharmacological evaluation in the context of Parkinson's disease. Their performance was comparable or superior to known serotonergic drugs in terms of docking metrics. Future work should focus on validating these findings through in vitro and in vivo models to confirm efficacy and safety.

Table 1: Taget proteins , their Id and related diseases

S. No	Protein target	Target ID	Synonyms	Related Disease
1	**5 HT 7 receptor**	T79062	**Serotonin receptor** 7, 5HT7; 5-hydroxytryptamine receptor 7; 5-HT7 receptor; 5-HT7; 5-HT-X; 5-HT-7	Parkinson disease

Table 2: List of compounds with their 2D and 3D structures.

S.No	Compound Name	2D	3D
1	Benzo[b]thiophene-3-carboxylicacid,7-acetoxy-2-acet		
2	Tropigline		3	Succinicacid,non-4-enyltetradecyl ester		4	Bicyclo[3.1.1]heptane, 6,6-dimethyl-2-		5	beta.-Myrcene		

6	D-Limonene		
7	beta.-Bisabolene		

Table 3: Compounds list, their Pubchem id, SMILES and their reported applications.

S.No	Compound Name	Pubchem id and SMILES	Applications
1	**Benzo[b]thiophene-3-carboxylicacid,7-acetoxy-2-acet**	Pub chem. Id- 70799 C1=CC=C2C(=C1)C(=CS2)CC(=O)O	anti-cancer, Anti-microbial, anti-oxidant, anti-inflammatory, anti-diabetic, anti-convulsant and anti-tubercular activity
2	**Tropigline**	Pub chem. Id-12444363 C/C=C(\C)/C(=O)OC1C[C@H]2CC[C@@H](C1)N2C	Alkaloid found in Withania somnifera, it can bind with SARS CoV -2 and human targeted proteins.
3	**Succinicacid,non-4 enyl tetradecylester**	O=C(OCCCCCCCCCCCCCCC)CCC(=O)OCCC\C=C\CCCC	Used as neutraceutical, radiation protective and anti ulcer drug
4	**Bicyclo[3.1.1]heptane, 6,6-dimethyl-2-**	Pub chem. Id- 14896 CC1(C2CCC(=C)C1C2)C	Neuroprotective compound, anti Parkinson and anti Alzheimer's activity. Selective Prostaglandin D_2 Receptor
5	**beta.-Myrcene**	Pub chem. Id-31253 CC(=CCCC(=C)C=C)C	Anti oxidant, anti inflammatory, anti-aging, analgesic

			effects , Cardio protective effect
6	**D-Limonene**	Pub chem. Id- 440917 CC1=CC[C@@H](CC1)C(=C)C	Effective against cancer, bronchitis and obesity
7	**beta.-Bisabolene**	Pub chem. Id- 10104370 CC1=CC[C@H](CC1)C(=C)CCC=C(C)C	Anti cancer , can be used to treat breast cancer

Table 4: Approved drugs for Parkinson's disease treatment with their SMILES structure, 2D and 3D structure.

Drug Name	SMILES	2D	3D
Pimavanserin	CC(C)COC1=CC=C(C=C1)CNC(=O)N(CC2=CC=C(C=C2)F)C3CCN(CC3)C		
Table 5 : Hydrogen Bond Donor-Acceptor Linkages of Ligands with Target Proteins.

Ligand	Target Protein	Donor → Acceptor (Amino Acid - Atom → Ligand - Atom)	Distance (Å)	Bond Type
Benzo[b]thiophene-3-carboxylic acid	**5-HT7 Receptor**	R:ARG392:HH21 → UNL1:O	3.01553	Conventional Hydrogen Bond
		R:ARG396:HE → UNL1:O	2.07328	Conventional Hydrogen Bond
		R:ARG396:HH11 → UNL1:O	2.12454	Conventional Hydrogen Bond
Tropigline	**5-HT7 Receptor**	R:ARG367:HH12 → UNL1:O	1.96221	Conventional Hydrogen Bond
		R:ARG367:HH22 → UNL1:O	1.94966	Conventional Hydrogen Bond
Succinic acid, non-4-enyltetradecyl ester	**5-HT7 Receptor**	R:ARG396:HA → UNL1:O	2.40763	Carbon Hydrogen Bond

Table 6: Binding Energy, Energy Differences, and Molecular Interactions of Ligands

Ligand	Binding Energy (kcal/mol)	Δ Binding Energy (kcal/mol)	Molecular Interactions	Inference
Benzo[b]thiophene-3-carboxylic acid	-6.8	0.0 (Reference)	Hydrogen Bonds: 3 Hydrophobic: 3	Moderate binding, stable conformation
Tropigline	-7.4	-0.6	Hydrogen Bonds: 2 Hydrophobic: 3	Stronger binding than reference
Succinic acid, non-4-enyltetradecyl ester	-6.1	+0.7	Hydrogen Bonds: 1 Hydrophobic: 4	Weaker interaction than reference

Bicyclo[3.1.1]heptane, 6,6-dimethyl-2-	-5.9	+0.9	No Hydrogen Bonds Hydrophobic: 3	Weak binding, mostly hydrophobic
β-Myrcene	-5.7	+1.1	No Hydrogen Bonds Hydrophobic: 2	Weak binding, lacks strong interactions
D-Limonene	-5.6	+1.2	No Hydrogen Bonds Hydrophobic: 2	Weak binding, non-polar interactions
β-Bisabolene	-5.8	+1.0	No Hydrogen Bonds Hydrophobic: 3	Weak binding, non-polar interactions

Table 7: Classification of Polar and Non-Polar Molecules Involved in Ligand-Protein Interactions

Ligand	Target Protein	Polar Molecules Involved	Non-Polar Molecules Involved
Benzo[b]thiophene-3-carboxylic acid	**5-HT7 Receptor**	ARG392 (HH21, HE, HH11) TYR395 (S)	ALA385, PHE386
Tropigline	**5-HT7 Receptor**	ARG367 (HH12, HH22)	ILE159, LEU232, PHE158
Succinic acid, non-4-enyltetradecyl ester	**5-HT7 Receptor**	ARG396 (HA)	PHE386, TYR395
β-Myrcene	**5-HT7 Receptor**	No Polar Interactions	PHE344
D-Limonene	**5-HT7 Receptor**	No Polar Interactions	PHE344
β-Bisabolene	**5-HT7 Receptor**	No Polar Interactions	PHE158

Table 8: Docking scores of some important molecules (observed during GCMS analysis) against 5HT 7 receptor

5HT7 Receptor docking with compounds	Binding Energy	No. Of Hdrogen bonds	Inhibition constant	Ligand efficiency	Intermolecular energy	vdW + H bond+desolv energy	Electrostatic energy	Torsional energy	Total internal unbound
Pimavanserin approved drug for 5HT 2A Receptor	-5.8	-	55.7	-0.19	-8.19	-7.93	-0.26	2.39	-1.21

ABSTRACT

Ayurveda underscores the significance of daily consumables, known as *Nitya Sevaniya Dravya*, as essential dietary components that support health, prevent diseases, and maintain balance in the *Tridoshas* (*Vata*, *Pitta*, and *Kapha*).Among these, *Amalaki* (*Emblica officinalis*) holds a special place due to its *Rasayana* (rejuvenating) and *Vayasthapana* (anti-aging) properties. Other important daily consumables include *Shashtika Shali* (rice), *Mudga* (green gram), *Saindhava Lavana* (rock salt), *Yava* (barley), *Antariksha Jala* (rainwater), *Go-ghrita* (cow's ghee), and *Madhu* (honey). This discussion explores their nutritional benefits, therapeutic uses, and ability to balance the *Tridoshas*, referencing classical *Ayurvedic* texts and contemporary scientific studies.

Keywords: Healthy diet, *Ahara*, *Nitya Sevaniya*, *Tridoshas* balance, Nutrition, *Nitya Rasayana*.

INTRODUCTION

In *Ayurveda*, the concept of *Traya upsthambha* is central, consisting of three foundational elements: *Brahmacharya* (celibacy), *Nidra* (sleep), and *Ahara* (diet)[1]. This study aims to highlight the importance of diet (*Ahara*) in today's world. *Ahara* is essential for maintaining the health, nourishment, and well-being of the body, mind, and soul. Food

is the only thing that can reduce the need for tissue renewal. According to the *Taittiriya Upanishad*, food serves as the foundation of the human body. The ancient sages taught that what, when, how, and where one consumes determines their nature and characteristics. Thus, individuals should consume fresh, nutritious, and easily digestible food. Proper and nourishing food satisfies all the senses. *Ayurveda* aims to maintain health for the healthy and treat illness for the unhealthy[2]. According to *Ayurveda*, any food item has specific properties, effects, and metabolic outcomes. These are classified as *Gunas*, *Veerya*, *Vipak*, and *Prabhav*, which together determine the overall effect of food. According to ancient knowledge, food can be used as medicine. The most important aspect of an *Ayurvedic* lifestyle is consuming the right amount of food, which supports a longer and healthier life. The saying "one man's food is another man's poison" shows that what is considered correct or suitable varies from person to person. Each individual may react differently to different types of food[3].

Nitya Sevaniya Ahara

Nitya Sevaniya Ahara refers to the food that should be consumed daily. It includes *Mudga* (green gram), *Saindhava Lavana* (rock salt), *Amalaki* (Indian gooseberry), *Varshajala* (rainwater), *Yava* (barley), *Madhu* (honey), *Go Ghritha* (ghee), *Jangala Mamsa* (wild meat), and *Shashtika Shali* (rice). In this context, *Ksheera* (milk) is also considered as part of *Nitya Sevaniya Ahara*, as mentioned in *Astanga Sangraha*. This is also described by *Acharya Charaka*.

MATERIAL AND METHOD

Details of *Amalaki* (*Emblica officinalis*) are provided in Table No. 1

Amalaki is a rich source of vitamin C and contains active components such as phyllemblin, gallic acid, tannins, pectin, and ascorbic acid. The high content of vitamin C in *Amalaki* helps replenish the body's energy. *Amalaki* has antioxidant, hepatoprotective, and anti-inflammatory properties. It is also effective in enhancing iron absorption. *Amalaki* is considered an excellent *Rasayana* that helps prevent premature aging and protects against diseases. It has been praised by *Acharya Charak* and *Acharya Vagbhata* as a preferred treatment for *Vayasthapana* (anti-aging)[4]. *Acharya Charak* has also described it as *Ayushya* (longevity), *Deepaniya* (appetite stimulant), and *Pachniya* (easily digestible)[5]. *Bhavprakash* and *Dhanwantri Nighantu* have also highlighted its *Rasayana* properties. *Amalaki* helps balance the *Tridoshas*, especially *Pitta*. *Vagbhata* mentions *Amalaki* as one of the best remedies for *Prameha* (diabetes), along with *Haridra* (turmeric)[6].

Details of *Shashtika Shali* (*Oriza sativum*) are provided in Table No. 2

Rice is known as the queen of cereal crops and is highly nutritious, containing carbohydrates, fats, fiber, proteins, vitamins, food energy, minerals, and fatty acids. It retains its outer bran layer, making it high in fiber and having a slightly nutty flavor. Fiber is important for regular bowel movements and overall digestive health. It may also aid in weight management, lowering cholesterol and blood pressure. The presence of anthocyanin in *Oriza sativum* has prebiotic activity by promoting the growth of beneficial bacteria like bifido and lactobacillus. *Shashtika Shali*, which is rice grown in 60 days, is the main source of energy (70–80%) and contributes significantly to protein, minerals, and B-group vitamins.Rice proteins are rich in lysine; an essential amino acid compared to other cereal proteins.

Details of *Mudga* (*Phaseolus mudga*) are provided in Table No. 3

Mudga, or green gram, is considered the best among *Shimbhi Dhanya* (cereals)[7]. It is rich in fiber (16g per 100g), especially soluble fiber pectin. The husks of *Mudga* resist *in-vitro* gastrointestinal digestion, meaning they contain non-digestible components that support the growth of beneficial gut microorganisms[8]. *Mudga* is a significant source of protein, with 25% of its composition being protein. However, its protein quality is lower than that of animal protein. It is also rich in minerals and B vitamins. *Mudga* is particularly high in iron (3.9 mg per 100g) and potassium (1150 mg per 100g). It is the best among pulses and is often used in soup form[9]. Many pulses have *Kapha-medohara* (fat-reducing) properties and are beneficial in cardiovascular diseases and obesity, as confirmed by modern research. Consuming legumes has been linked to a reduced risk of coronary heart disease and cardiovascular disease.

Details of *Saindhava Lavana* (Sodium chloride) are provided in Table No. 4

Saindhava Lavana enhances the body's ability to absorb minerals at the cellular level and helps restore the body's electrolyte balance and maintain the pH level[10]. This makes it useful for boosting metabolism. *Saindhava Lavana* is a clear and pure salt with a reddish white color and contains natural iron. It can increase appetite and enhance the flavor of food. It also has a minimal impact on water retention, making it suitable for individuals with heart conditions, high blood pressure, and kidney diseases[11]. According to *Acharya Charak*, among various types of salt, *Saindhava Lavana* is considered the best for internal use. It aids in eliminating toxic minerals and deposits of refined salt by improving circulation and balancing minerals. It also strengthens skin tissue, helping to rejuvenate the skin and make it appear younger and more firm. *Saindhava Lavana* improves appetite, enhances taste, improves digestion, and offers natural relief from stomach pain[12]. It provides all essential trace minerals and strengthens the immune system. It also regulates melatonin levels, which helps regulate the sleep cycle[13]. *Saindhava* is considered the best among salts, as it is easy to digest, promotes digestion, acts as an aphrodisiac, supports good eyesight, and helps balance the three *Doshas*[14]. *Saindhava* is known as *Rochana*, *Deepana*, and *Pachana*, and is used in cases of anorexia, constipation, and other digestive issues. It acts as a carrier and assists in delivering *Basti dravya* to the cellular level.

Details of *Yava* (*Hordeum vulgare*) are shown in Table No. 5.

Yava, or barley, is high in fiber (17g per 100g), particularly beta-glucan, which can reduce cholesterol and blood sugar levels. It may also assist in weight loss and improve digestion. The effects of barley beta-glucans on the growth and probiotic properties of four *Lactobacillus* strains are noted[15]. Barley is rich in potassium. It is considered *Mutrala* and *Kapha Shamaka* and is used in the treatment of obesity. It is widely used in *Ayurveda* and is classified under *Shukadhanya Varga*. Both as a dietary component and a medicinal herb, *Yava* has been recognized in ancient texts and modern research.

Details of *Antariksha Jala* are shown in Table No. 6.

Antariksha Jala has a neutral pH and aids in breaking down nutrients for better absorption. It has an alkaline pH and has detoxifying properties, which support healthy digestion. Daily intake of toxins and free radicals can make the blood more acidic. *Antariksha Jala*, with its alkaline nature, helps neutralize blood pH, allowing the body to function more efficiently. *Antariksha Jala*, or rainwater, is the primary source of water and the purest form of water found in nature. It is tasteless and has properties similar to nectar, being vital for life, satiating, maintaining the body, invigorating, and easing fatigue, lethargy, thirst, intoxication, fainting, drowsiness, sleep, and burning sensations. It is consistently beneficial for overall health.

Details of *Go-ghrita* are shown in Table No. 7.

Go-ghrita is one of the daily essential substances, according to the *Charaka Samhita*[16]. In Charaka Samhita, Ksheeraghrithabhyasa considered as the best *Rasayana* (rejuvenating substance) for daily use[17]. *Go-ghrita* is easily absorbed by the body due to its lipid-soluble nutrients. It is also beneficial in reducing *Pitta* and *Vata*, and it supports the balance of *Rasa*, *Shukra*, *Oja*, *Swara*, *Varna*, *Nirvapanam*, and *Sansakarasya Anuvartanam*[18].

Details of *Madhu* are shown in Table No. 8.

When consumed, honey becomes alkaline (with a pH range from 3.4 to 6). Unlike most sugars, raw honey is not known to irritate a sensitive digestive system. It is alkaline-forming, helping the body maintain a neutral and alkaline balance. Additionally, honey boosts beneficial gut bacteria (bifidogenic effects), aiding in detoxification and reducing toxic effects[19]. Honey contains 38% fructose, 31% glucose, 1% sucrose, and 9% other sugars, along with water, vitamins, minerals, and acids. It has been used as an antiseptic, reduces cholesterol, and helps prevent coronary artery disease and obesity[20]. Honey is a sweet fluid produced by bees from flower nectar. Most microorganisms do not thrive in honey due to its low water activity[21]. It possesses nutritive properties, and the fatty acids in honey promote peristalsis and digestion. It is beneficial for digestion and appetite in individuals with weak stomachs or loose bowels. It reduces flatulence and increases overall metabolism. Honey has also been used topically as an antiseptic for treating ulcers, burns, and wounds. Honey is considered the best *Yogavahi*, or carrier substance, helping to transfer the properties of other medicines[22]. It acts as a purifying and healing agent, able to reach the minute

channels of the body[23]. Honey is astringent, helps in reducing excessive fat, and is beneficial in managing obesity[24].

***JangalaMamsa* (meat)**

It is typically an acidic food and lacks fiber content. It plays an important role in meeting daily vitamin B12 requirements and is a rich source of complete protein (>20% of daily value), niacin, iron, and zinc. According to classical texts, *Jangala Mamsa* is constipative, cold in potency, easy to digest, nutritious, and is beneficial in cases of *Pittothara*, *Vata Madhya Kapahanuka Sannipata* (cases involving increased *Pitta*, moderately vitiated *Vata*, and *Kapha*).

DISCUSSION

Bagde *et al*. *Ayurveda* places great emphasis on *Aahara* as a key factor in maintaining health by balancing the *Tridoshas* and nourishing the body. The *Nitya Sevaniya Dravyas* philosophy emphasises the need of healthy eating on a daily basis. *Aahara* promotes physical strength, energy, and general well-being when taken in the right amounts; when taken in the wrong amounts, it can cause illness. Therefore, maintaining a healthy lifestyle and preventing sickness require regular consumption of nourishing foods. Thakur et. al. Through its ideas of *Swasthahita* (health-promoting) and *Nityasevaniya Dravyas* (daily consumable substances), *Ayurveda* provides a deep understanding of nutrition, emphasising its significance in preserving health and averting illnesses. By using tried-and-true dietary methods to treat *Kuposhanya Vikaras* (nutritional problems), incorporating *Ayurvedic* nutritional concepts into national nutrition programs could improve public health. *Ayurveda* offers a preventive strategy by encouraging the consistent use of *NityasevaniyaDravyas*, securing long-term health and balanced nutrition. S Deshmukh *et.al*. The *Nitya Sevaniya Aahara Dravya* (daily consumable foods) play a vital role in maintaining health. Among them, *Mudga* (green gram) stands out in *Shamidhanya* (pulses) for its high nutritional value and therapeutic properties like antioxidant, anti-hyperglycemic, and detoxifying effects. *Shashtika Shali* (rice) is the best in *Shukadhanya* (cereals), offering energy, vitamins, and minerals with immunomodulatory benefits. *Godhuma*(wheat) provides sustained energy and has antioxidant and gut-protective properties. *Godugdha*(cow's milk) and *Goghruta* (cow's ghee) are essential for vitality, immunity, and brain health, while *Saindhava* (rock salt) supports electrolyte balance without causing hypertension. *Amalaki* (Indian gooseberry) is a potent rejuvenator with antioxidant and hepatoprotective effects.

Regular consumption of these foods promotes holistic well-being, aligning with *Ayurvedic* principles for a balanced and healthy life. MA Tiwar *et.al*. *Mudga* (mung bean) exhibits remarkable health benefits due to its bioactive compounds, including polysaccharides, polyphenols, and peptides, which contribute to its antioxidant, detoxifying, and immune modulatory properties. Research confirms its role in reducing toxin absorption (e.g., aconitine), protecting against heavy metal toxicity (e.g., aluminum-induced cardiotoxicity), and offering anti-diabetic, anti-hypertensive, and hepatoprotective effects. Similarly, *Ghrita* (cow's ghee) enhances immunity through butyric acid and omega-3 fatty acids, supporting cardiovascular, neurological, and anti-inflammatory functions. *Amalaki* (Indian gooseberry) further complements these benefits with its potent antioxidant, anti-inflammatory, and rejuvenating properties. Shaniba KV *et.al*.*Nitya Sevaniya Ahara Dravyas* (daily consumable foods) serve as a balanced diet, fulfilling nutritional needs while offering antioxidant and detoxifying benefits. These foods influence gut microbiota, maintain digestive alkalinity, and provide essential fiber—factors crucial for long-term health. While most of these foods align with *Ayurvedic* principles of wellness, *Jangala Maamsa* (lean meat) presents an exception. Despite being a rich source of high-quality protein and B vitamins, its compatibility with holistic health concepts remains debatable. Further research is needed to explore its long-term effects on digestion, microbiome balance, and overall well-being. Thus, a diet primarily based on traditional *Nitya Sevaniya Ahara*, supplemented mindfully, can promote optimal health. The text recommends specific food items such as *Sastika* rice, *Sali* rice, *Mudga* (green gram), *Saindhava Lavana* (rock salt), *Amalaka* (Indian gooseberry), rainwater, ghee, meat from arid-climate animals, and honey.

Each of these has distinct nutritional and therapeutic properties:
***Sastika* and *Sali* Rice:** These varieties of rice are easily digestible and provide essential carbohydrates, supporting energy levels without aggravating *Dosa*s.

***Mudga* (Green Gram):** A protein-rich legume that is light and balancing for all three *Dosas* (*Vata, Pitta, Kapha).*

Rock Salt (*Saindhava Lavana*): Unlike refined salt, rock salt contains trace minerals and is considered beneficial in moderation, aiding digestion without causing excessive water retention.

***Amalaka* (*Emblica officinalis*):** A potent antioxidant and rejuvenative (*Rasayana*), supporting immunity and digestion.

Rainwater: Traditionally regarded as pure and free from contaminants, promoting hydration without burdening digestion.

Ghee: Clarified butter enhances digestion, lubricates tissues, and supports *Ojas* (vital essence).

Meat of Arid-Climate Animals: Lean meats from animals adapted to dry regions were considered easier to digest and less likely to increase *Kapha.*

Honey: A natural preservative with antimicrobial properties, beneficial in moderation but contraindicated when heated or consumed excessively[25]. This selection of foods exemplifies a diet that is *Pathya* (wholesome and suitable for maintaining equilibrium in the body). The emphasis on moderation, particularly with rock salt, reflects an understanding of the potential harm caused by excess intake, aligning with modern dietary guidelines that link high salt consumption to hypertension and cardiovascular diseases. The text serves as broad guidance for a healthy diet. Only foods that promote the ongoing maintenance of good health and ward off additional illness outbreaks should be consumed on a regular basis. There are two methods for staying in good health.

Replenishment of Dhatus (Tissue Elements): The body's tissues require proper nutrition to regenerate. A balanced diet ensures the optimal formation of *Rasa* (plasma), *Rakta* (blood), *Mamsa* (muscle), *Meda* (fat), *Asthi* (bone), *Majja* (marrow), and *Shukra* (reproductive tissue). This concept parallels modern nutritional science, which emphasizes macronutrients (proteins, fats, carbohydrates) and micronutrients (vitamins, minerals) for tissue repair and metabolic functions.

Removal of Obstacles to Health: External and internal factors can disrupt bodily equilibrium. The text categorizes these as: Improper lifestyle choices (e.g., irregular eating, sleep deprivation, stress) that disturb *Vata, Pitta,* and *Kapha.* Natural variations like winter (*Hemanta*) increasing *Kapha,* requiring dietary adjustments (e.g., warm, spicy foods to counteract cold and dampness). The analogy of the lamp's flame is particularly insightfuljust as a flame needs fuel (oil) and protection from disturbances (wind, insects), the body requires nourishment and protection from pathogenic influences. This dual approach underscores the preventive aspect of traditional medicine, advocating for proactive measures rather than merely reactive treatments. By aligning diet with seasonal changes, one can counteract potential *Dosa* imbalances before they manifest as disease. This preventive strategy is increasingly relevant in modern integrative medicine, where seasonal eating and chrononutrition are gaining recognition for metabolic health.

Limitations and Adaptations for Contemporary Use

The caution against excessive salt intake aligns with WHO guidelines recommending <5g/day to prevent hypertension[26]. Modern ethical and environmental concerns may necessitate plant-based alternatives with similar properties to meat consumption, such as lentils and nuts. Due to pollution, rainwater may now require filtration.

Ayurveda emphasizes personalized diets based on one's constitution (*Prakruti*), which should be considered alongside general guidelines.

CONCLUSSION

In accordance with the *Ayurvedic* concept of *Swasthavritta* (preventive health), the *Nitya Sevaniya Dravyas-Amalaki, Shashtika Shali, Mudga, Saindhava Lavana, Yava, Antariksha Jala, Goghrita*, and *Madhu*-provide a nutrient-rich, well-balanced diet. They are essential for everyday ingestion due to their cleansing, gut-microbiome-modulating, and antioxidant qualities. Even though the majority of these foods are good for everyone, careful consideration of *Jangala Mamsa* needs more research. By preventing *Kuposhanajanya Vikaras* (nutritional illnesses) and encouraging longevity, incorporating these dietary concepts can improve public health. The manuscript presents a holistic approach to maintaining good health through dietary and lifestyle practices, emphasizing both nourishment and the prevention of disease. This perspective aligns with traditional systems of medicine, particularly *Ayurveda*, which underscores the importance of balance in *Dosas* and the role of diet in sustaining health. The analogy of maintaining the flame of a lamp by providing oil (nourishment) and removing obstructions (disease-causing factors) effectively illustrates the dual approach to wellness: proactive nourishment and preventive care.

ABSTRACT

Nanogels are emerging nanocarrier systems with significant promise for topical anti-inflammatory therapy due to their small size, high biocompatibility, and tunable polymeric networks. These hydrophilic, three-dimensional structures enhance drug penetration through the stratum corneum and provide controlled, sustained, or stimuli-responsive release at inflamed sites. This review discusses the importance of topical delivery, the mechanisms of nanogel-mediated penetration, and the advantages of

nanogels over conventional topical formulations. Various polymers, crosslinking approaches, and synthesis techniques are highlighted alongside recent advances such as hybrid, surface-functionalized, and multi-stimuli-responsive nanogels. Preclinical and preliminary clinical studies demonstrate improved therapeutic efficacy, enhanced drug stability, and reduced systemic toxicity. Although challenges remain in scale-up, storage stability, and regulatory approval, nanogels offer a powerful next-generation platform for effective and patient-friendly anti-inflammatory topical therapy.

Keywords: Anti-inflammatory therapy; Nanogels; Surface functionalization; Topical drug delivery; Stimuli-responsive polymer

INTRODUCTION

The skin is the body's largest organ and the first line of defense against the external environment. It is composed of three main layers: epidermis, dermis, and hypodermis, which together maintain barrier function, thermoregulation, and immune protection. the structure of skin. The epidermis is the outermost layer of the skin, known as the epidermis, acts as a protective shield for the body against the external environment. It consists mostly of dead skin cells called the stratum corneum that form a tough barrier to keep harmful substances out and water in. It also contains special cells like melanocytes which give skin its colour and protect against sun damage, and immune cells that help defend against infections. This layer is quite thin but very important for skin protection[1]. Beneath it, the dermis is a thicker connective tissue layer that supports the epidermis. It contains collagen and elastic fibers that provide strength and elasticity, as well as blood vessels, hair follicles, sweat glands, and immune cells that participate in tissue repair and host defense. Sensory nerve endings in the dermis enable perception of pain, temperature, and touch [1]**.** The deepest layer, the hypodermis or subcutaneous tissue, consists predominantly of adipose tissue and loose connective tissue. It cushions underlying organs and muscles, contributes to mechanical protection, and serves as a thermal insulator that helps maintain body temperature [1]. Inflammation is a fundamental biological response to harmful stimuli such as infection, injury, or chemical irritation. While it is essential for host defense and tissue repair, persistent or dysregulated inflammation plays a central role in the pathogenesis of chronic diseases including arthritis, cardiovascular disorders, diabetes, and cancer.

Globally, inflammatory diseases pose a substantial health burden, reducing quality of life and increasing disability and mortality; chronic inflammatory conditions are among the leading causes of death according to international health reports such as those from the World Health Organization [2]. These challenges highlight the need for advanced therapeutic strategies that can control inflammation effectively while minimizing adverse effects[2]. Nanogels consist of three-dimensional, hydrophilic polymeric frameworks that have the remarkable ability to absorb and retain large volumes of water or biological fluids, while still maintaining their structural integrity[1]. Due to their nanoscale size and tunable physical and chemical properties, nanogels have emerged as highly promising carriers for drug delivery applications [2]**.** Their versatile architecture allows for efficient administration of therapeutic agents, protection of labile drugs from degradation, and controlled or stimuli-responsive release, making them particularly suitable for targeted and localized delivery [3]. In the context of topical drug delivery, nanogels offer distinct advantages such as enhanced skin permeability, mucoadhesion, and reduced systemic side effects, which are critical in treating localized conditions like inflammation[4]**.** These features collectively position nanogels as a breakthrough technology in pharmaceutical nanocarriers, optimizing therapeutic outcomes by improving drug bioavailability and patient compliance in topical anti-inflammatory therapies [5]**.** This review summarizes skin structure and barrier function, the role of inflammation in disease, and the properties of nanogels that support topical anti-inflammatory drug delivery. It also highlights formulation strategies, surface functionalization, recent advances such as stimuli-responsive systems, and future challenges in clinical translation.

Importance of Topical Delivery in Anti-Inflammatory Therapy

Topical drug delivery plays a crucial role in anti-inflammatory therapy by enabling direct application of therapeutic agents to the affected skin or tissue site[6].This localized approach minimizes systemic drug exposure, thereby reducing the risk of systemic side effects and improving patient safety. Moreover, topical delivery allows for enhance drug concentrations in the area of inflammation, which enhances therapeutic efficacy and accelerates symptom relief [7].It is especially valuable for treating chronic inflammatory skin diseases such as psoriasis, eczema, and dermatitis, where sustained and targeted treatment is required [7,8]. Additionally, topical formulations, including nanogels, improve drug penetration through the skin barrier, increase residence time, and provide controlled drug release, which further optimizes treatment outcomes for inflammatory conditions[4]. Over the past decade, nanogels have gained attention as effective nanotechnology-based systems for delivering drugs to treat inflammatory skin diseases. Nanogels are tiny, water-rich polymer networks capable of carrying a wide range of drugs, including small molecules, proteins, and nucleic acids. Their ability to swell, retain water, and adjust their mechanical strength allows them to behave similarly to natural skin tissue. These properties improve skin compatibility and reduce irritation when applied topically[9,10]. Topical drug delivery minimizes systemic side effects, but penetration through the stratum corneum is challenging. Nanogels overcome this due to their small size, tunable surface properties, and high hydration, enabling deeper skin penetration, targeted delivery to inflamed tissues, and soothing of irritated skin.[10]. Nanogels enable controlled and sustained drug release for anti-inflammatory therapy, maintaining therapeutic levels at inflamed sites for extended periods. Stimuli-responsive nanogels (pH, temperature, enzymes) release drugs selectively in inflammatory environments, improving efficacy while reducing dosing frequency[11]. Recent research has used biocompatible polymers such as chitosan, hyaluronic acid, PNIPAM, and polyethylene glycol to make nanogels, often in hybrid combinations to gain multiple benefits. These nanogels improve drug stability and loading and can be targeted to inflamed tissues using specific ligands. Incorporating natural compounds like curcumin and quercetin further boosts anti-inflammatory and antioxidant effects. Together, these strategies provide stronger and more effective therapeutic outcomes than single-agent treatments[12].

Preclinical and early clinical studies show that nanogels are effective in treating inflammatory conditions such as arthritis, psoriasis, dermatitis, and wounds. Compared to conventional formulations, nanogels provide better anti-inflammatory effects with fewer side effects. Studies on diacerein- and tapinarof-loaded nanogels have shown improved inflammation control and tissue protection. Additionally, nanogels with antimicrobial and healing agents help manage secondary infections in chronic skin diseases[10]. Despite advances, clinical translation of nanogels is limited by scale-up, reproducibility, stability, regulatory complexity, and skin-to-skin variability. Nevertheless, personalized topical nanogels show strong promise to improve anti-inflammatory efficacy, safety, and patient adherence.[13]. In addition to their excellent drug delivery capabilities, Nanogels are flexible drug carriers that can be designed to perform more than one function at a time. They can be made “smart” so that they release the drug only when they reach inflamed areas, where conditions like low pH, higher temperature, or enzymes are present. This targeted release improves treatment effectiveness and reduces the amount of drug needed, lowering the risk of side effects. In addition, nanogels can be modified on their surface to guide them directly to inflamed cells, making drug delivery more precise[14]. Another critical advantage of nanogels are safe, skin-friendly systems that cause minimal irritation, making them suitable for long-term treatment of inflammatory skin conditions. They are often made from natural polymers like chitosan, hyaluronic acid, and alginate, which naturally support healing and reduce inflammation. These polymers also improve skin hydration and help repair the damaged skin barrier. Together, these properties make nanogels an effective and patient-friendly platform for topical anti-inflammatory therapy[15]. Moreover, Nanogels offer high biocompatibility and low irritancy, making them ideal for long-term topical anti-inflammatory therapy. Natural polymers like chitosan, hyaluronic acid, and alginate provide added anti-inflammatory and healing benefits, improve skin hydration, and help restore the skin barrier. This combination makes nanogels effective for delivering drugs and supporting overall skin health in chronic inflammatory conditions, enhancing both treatment results and patient quality of life[16].

Properties and Mechanisms Relevant to Topical Delivery

Nanogels exhibit distinctive physicochemical properties that render them particularly well-suited for topical drug delivery, offering improvements in drug loading, controlled release, and performance compared to conventional formulations.

Physicochemical Features of Nanogels

Nanogels are nanosized, three-dimensional hydrogel networks formed via crosslinking of hydrophilic polymers. Their distinctive structural and functional characteristics them highly advantageous as topical drug delivery carriers, particularly for anti-inflammatory agents.

Physicochemical Properties

Particle Size and Surface Morphology: Nanogels typically range from 20 to 200 nm, allowing efficient passage through the stratum corneum and penetration into deeper epidermal and dermal layers. Their small size also enables better interaction with skin cells and enhances retention at the application site[17].

Swelling and Hydration Capacity: Due to their hydrophilic polymeric framework, nanogels can absorb large amounts of water, which helps maintain skin hydration and promotes permeability. The swelling behaviour can be finely tuned based on polymer composition and crosslinking density to regulate drug release kinetics[18].

Surface Charge and Functionalization: Modifying nanogel surface charge (positive, negative, or neutral) modifies their relationship with the negatively charged skin barrier. Positive surface charges can facilitate stronger adherence and penetration, while functionalization with ligands or peptides enables specific delivery aimed at designated receptors or cells[19].

Biocompatibility and Biodegradability: Nanogels are generally synthesized from biocompatible and biodegradable polymers such as chitosan, hyaluronic acid, poly(N-isopropylacrylamide), ensuring minimal skin irritation or toxicity upon topical use. This safety profile is essential for chronic inflammatory skin conditions[9].

Encapsulation Efficiency of Drug: Nanogels can encapsulate hydrophilic and hydrophobic drugs via entrapment, adsorption, or covalent attachment. Their porous and crosslinked matrix protects labile anti-inflammatory agents from enzymatic degradation and improves drug stability[1].

Mechanisms Facilitating Topical Drug Delivery

Enhanced Skin Penetration

The nanoscale size and hydrophilic nature of nanogels facilitate transient disruption or fluidization of lipids within the stratum corneum, thereby enhancing solute permeability. Additionally, the moisture-retentive property of nanogels can hydrate and loosen the skin barrier, enabling deeper drug penetration[19].

Controlled and Stimuli-Responsive Drug Release

Nanogels can be developed to respond to endogenous stimuli such as pH changes, temperature variations and oxidative stress commonly found in inflamed skin. This responsiveness enables on-demand release of anti-inflammatory drugs directly at sites of inflammation, improving efficacy and lowering systemic exposure[20].

Targeted Delivery and Cellular Uptake

Surface modifications allow nanogels to target specific skin cell types, improving cellular uptake and therapeutic action. Active targeting strategies include conjugation with antibodies, peptides, or aptamers selective for inflammatory markers or immune cells in the skin[17].

Protection from Premature Degradation

Nanogel encapsulation protects sensitive drug molecules such as natural extracts or biological agents from premature oxidation, hydrolysis, or enzymatic cleavage on the skin surface, improving bioavailability and therapeutic lifespan[9].

Minimized Irritation and Improved Patient Compliance

The soft, hydrated nature of nanogels results in painless, non-irritant topical formulations, enhancing patient compliance especially in chronic treatments involving repeated application[18]. These properties and mechanisms collectively make nanogels a highly effective and adaptable platform for topical anti-inflammatory therapy, overcoming critical barriers faced by conventional formulations and opening a venues for personalized skin disease management[13].

Advantages Over Conventional Topical Formulations

Nanogels offer several major advantages over conventional topical formulations for drug delivery:

Enhanced Drug Encapsulation

Nanogels can load both hydrophilic and hydrophobic drugs efficiently, increasing the amount of drug delivered compared to traditional creams or ointments[21].

Improved Skin Penetration

The nanoscale size and flexible polymeric structure allow nanogels to bypass the skin barrier more effectively, enabling deeper and more uniform distribution in the skin[22].

Controlled and Sustained Release

Nanogels can be engineered to provide controlled, prolonged, or even stimuli-responsive drug release (e.g., in response to pH, temperature, or enzymes), maintaining therapeutic levels longer and reducing dosing frequency[22].

Reduced Systemic Side Effects

By increasing topical drug retention and limiting systemic absorption, nanogels help minimize side effects that often result from oral or non-targeted drug delivery[23].

Biocompatibility and Patient Comfort

Nanogels are typically biocompatible and less irritating than many conventional formulations, making them more suitable for long-term treatment of chronic skin conditions[9].

These properties establish nanogels as an innovative platform for more effective, safer, and patient-friendly topical treatments.

Design and Preparation of Nanogels for Topical Anti-Inflammatory treatments

Nanogels are tiny, water-swollen polymer networks that can effectively carry and deliver non-steroidal anti-inflammatory drugs directly to the skin. By carefully selecting biocompatible polymers and optimizing the preparation methods, these nanogels can provide controlled drug release, improved skin penetration, and enhanced therapeutic effects for treating inflammatory skin conditions[24].

Types of polymer and crosslinking agents used

In topical nanogel formulations, various types of polymers and crosslinking agents have been extensively studied to optimize drug delivery performance[25].

Polymers

Polymers plays an important role in the formulation of nanoparticulate drug delivery systems, offering advantages such as improved drug stability, controlled release, and enhanced bioavailability. Natural polymers like chitosan and

sodium alginate are extensively used due to their biocompatibility, biodegradability, and mucoadhesive properties, which enhance drug retention and permeation in topical applications[26]. Chitosan is a polymer found in nature, extracted from chitin, known for being biodegradable, biocompatible and non-toxic, making it highly suitable for drug delivery applications. Its positive charge allows it to stick to the skin or mucosal surfaces (known as mucoadhesion), which helps the drug stay longer at the application site and improves its penetration, resulting in better and sustained anti-inflammatory effects [27]. Besides carrying drugs, chitosan has extra benefits like fighting bacteria and helping wounds heal, which makes it very useful in skin treatments. Because it has a natural positive charge, chitosan can slightly loosen the tight connections between skin cells, allowing medicines to pass through the skin more easily. Since it comes from natural sources, it is generally safe and not harmful. These features make chitosan-based nanogels a good choice not only for reducing inflammation but also for healing and protecting the skin[27]. Sodium alginate is a natural polymer derived from seaweed that becomes a gel when it reacts with certain metal ions, such as calcium (Ca^{2+}). In this process, calcium ions link together the alginate molecules to form a three-dimensional network, creating a gel that can hold water and other substances tightly. This gel structure allows for the slow and sustained release of drugs when applied to the skin, making it highly useful in topical drug delivery, especially for anti-inflammatory treatments[28]. Pectinis a naturally occurring polysaccharide that can be found in the cell walls of plants, widely utilized in drug delivery for its exceptional biocompatibility, biodegradability, and the ability to form hydrogels. It possesses multiple functional groups that facilitate gelation and drug encapsulation, enabling controlled and targeted drug release. In topical applications, pectin-based hydrogels can improve drug stability and penetration while providing anti-inflammatory benefits by modulating cytokine production and reducing inflammatory responses[26]. Polyethylene Glycol has been used for a long time in making biomaterials for medical applications, especially in areas like tissue repair and drug delivery. What makes PEG so useful is that it is safe for the body, doesn't trigger immune reactions, and dissolves well in water. Because of these advantages, PEG has become a very popular material and is used in many forms-from large bulk materials to thin films, hydrogels, and even nanoparticles[29]. In PEG-based hydrogel drug delivery systems, drugs are usually held inside the gel by simple physical trapping, not by forming chemical bonds. The drug stays safely inside the cross-linked network of the gel. Over time, as the gel's sensitive parts slowly break down, the PEG structure degrades and gently releases the drug. This process avoids releasing any harmful or toxic by-products, making it a safer way to deliver medicines[29]. Together, these polymers alone or in combination provide tunable mechanical strength, swelling, mucoadhesion, and release characteristics required for effective, patient-friendly topical nanogel formulations for anti-inflammatory therapy.

Crosslinking Agents

Crosslinking means creating links between different polymer chains, which makes the material stronger and more stable. These links form a three-dimensional network that changes how the material behaves. Depending on the type of bonds formed covalent, ionic, or hydrogen bonds the material can gain different properties and be used in different applications. These are classified into two Chemical crosslinking agents and Physical crosslinking agents[30]. Chemical crosslinking agents are substances that induce the formation of covalent bonds between polymer chains, resulting in stable and often irreversible three-dimensional networks.

These crosslinkers provide enhanced mechanical strength, durability, and controlled drug release in polymeric systems. Common chemical crosslinkers include:

Covalent Bond Formers: These agents create irreversible covalent bonds between polymer chains, leading to permanent networks. Examples include glutaraldehyde, formaldehyde, epichlorohydrin, genipin, and methylenebisacrylamide (MBA)[31].

- Glutaraldehyde is one of the most widely used chemical crosslinkers, particularly with natural polymers such as chitosan and gelatin. It creates strong covalent bonds between polymer chains, which increases the strength and stability of the nanostructures. In topical drug delivery, using glutaraldehyde-crosslinked polymers helps control how the drug is released and ensures the formulation remains stable during use[31].

- Genipinis a natural crosslinker obtained from plants like *Gardenia jasminoides*. Unlike synthetic agents such as glutaraldehyde, it is much less toxic, making it safer for biomedical use. Genipin mainly reacts with amino groups in polymers like chitosan and gelatin, forming strong covalent bonds that improve the strength and biocompatibility of hydrogels and nanogels. A unique feature of genipin-crosslinked materials is their blue color, which appears during the reaction because of conjugated structures that are formed. Beyond crosslinking, genipin itself has anti-inflammatory and antioxidant properties, which further support wound healing and make it useful in topical treatments[32].
- Ethylene glycol dimethacrylate (EGDMA) is a commonly used chemical crosslinker in synthetic polymers, especially in acrylate-based hydrogels. It has two reactive groups that take part in free radical polymerization, joining polymer chains together to create a strong three-dimensional network. By adjusting the amount of EGDMA, researchers can control the structure of the hydrogel: higher amounts make the gel denser and stronger but reduce its ability to swell and its pore size. This flexibility makes EGDMA especially useful in designing hydrogels for controlled drug release in topical and other drug delivery systems[33].

Photo-initiated crosslinkers: These are special chemicals that make gels harden when they are exposed to light, usually UV light. When the light hits them, they produce reactive particles called free radicals, which quickly link the acrylate chains together to form a strong network. This process is fast, can be controlled easily, and works under gentle conditions, which makes it very useful for medical applications and drug delivery on the skin[34]. Enzymatic crosslinking is a gentle and safe way to make hydrogels by using enzymes to link polymer chains together. Different enzymes can be used for this purpose. For example, transglutaminase creates strong bonds between amino acids in proteins like gelatin, forming stable hydrogels that are useful for slow drug release and tissue repair. Peroxidases such as horseradish peroxidase can quickly form hydrogels when combined with hydrogen peroxide and phenol-modified polymers, giving good control over the process. Tyrosinase works by oxidizing tyrosine groups into reactive forms that can bond with polymers like chitosan, producing hydrogels that are strong and biocompatible. Because these methods work under mild conditions, they are considered safe and effective for biomedical uses such as drug delivery and wound healing[35]. Physical crosslinking happens when polymers are connected by weak physical forces instead of permanent chemical bonds. This can occur through ionic interactions, protein interactions, or forces like hydrogen bonding, which allow different polymers to link together and form large, interconnected structures. These physical forces are enough to create hydrogels without the need for covalent bonds. One important example is hydrophobic interactions, which let the polymer absorb water and swell. This property is especially important in making polysaccharide-based hydrogels that are widely used in biomedical applications[36]. Ionic crosslinking is a process where polymer chains are linked together by ionic interactions, which are usually reversible. For example, calcium chloride ($CaCl_2$) is commonly used to crosslink alginate polymers. the divalent Calcium ions respond to the negatively charged carboxyl groups on the alginate chains, forming ionic bridges that stabilize the hydrogel network.

This type of crosslinking improves mechanical strength and controls drug release, while maintaining flexibility due to the reversible nature of ionic bonds. Ionic crosslinking can be modulated by factors such as ion concentration and pH, making it versatile for designing hydrogels with tailored properties in drug delivery applications[37]. Hydrogen bonding is a reversible and non-permanent interaction that can hold polymer chains together in hydrogels. It happens when hydrogen atoms connect with oxygen or nitrogen atoms in the polymers, creating a flexible network. Hydrogels made this way are often self-healing, injectable, and sticky, because the bonds can break and reform when the material is stretched or damaged. The main challenge is that water can weaken these hydrogen bonds, making the gel less stable in wet conditions. To solve this, researchers have added hydrophobic regions or extra crosslinkers to strengthen the gel while still keeping it safe and biocompatible[38]. Hydrophobic interactions in hydrogels happen when water-repelling parts of polymer chains group together to stay away from water. These act like natural crosslinking points, giving the hydrogel strength and flexibility. Compared to hydrogen bonds, hydrophobic interactions are stronger and allow the gel to form stable, reversible, and even self-healing networks. By changing how much hydrophobic material is included or altering its structure, researchers can adjust the gel's properties. This makes hydrophobic interactions very useful for creating tough, responsive hydrogels that work well in drug delivery

system[1,3]. Thermo-responsive crosslinking happens when nanogel polymers change their structure in response to temperature. A well-known example is poly(N-isopropylacrylamide) (PNIPAm). Below a certain point, called the lower critical solution temperature (LCST), the polymer chains stay hydrated and swollen. But once the temperature goes above this point, water is pushed out, hydrophobic interactions take over, and the chains come closer together to form a denser gel network. This shift from a swollen state to a collapsed state is reversible, meaning the material can switch back and forth with temperature changes. Because of this "smart" behavior, thermo-responsive nanogels are very promising for controlled drug delivery where release can be triggered by body heat or external temperature changes[39].

Methods of Nanogel Synthesis

Nanogels are synthesized using different methods, each providing regulation over dimensions, composition, and drug-loading characteristics.

The most common techniques include in figure -1

Emulsion-Based Techniques Emulsion-based nanogel synthesis relies on forming oil-in-water (O/W) or water-in-oil (W/O) systems, where polymerization and crosslinking occur within nanoscale droplets, enabling precise regulation of particle dimensions and drug loading[40].

Emulsion solvent diffusion method

The emulsion solvent diffusion process is shown in figure-1A, the drug is initially solubilized in an organic solvent. The polymer and gelling agent are subsequently dissolved in water to form drug phase, which is added drop wise to the water phase. This mixture is homogenized at 6000 rpm for roughly 30 minutes, producing fine nanodroplets and forming an oil-in-water emulsion. To convert this emulsion into a nanogel, triethanolamine is added while stirring continuously at 8000 rpm for one hour[40].

Inverse Emulsion (Or Miniemulsion) Method

The Inverse emulsion (or miniemulsion) method for nanogel synthesis shown in figure-1B, an aqueous solution containing polymer building blocks, crosslinkers, initiators, and sometimes the drug or protein to be loaded is dispersed within an oil phase that contains surfactants for stabilization. After mixing, the emulsion is deoxygenated, and a catalyst such as TEMED is added to start the polymerization and crosslinking process. This produces nanogels with the drug or biomolecule trapped inside the polymer network. By adjusting factors like the type of surfactant, concentrations of monomers, and mixing conditions, researchers can control the size of the nanogels and how much drug they carry. Once polymerization is complete, the nanogels are separated and purified. This approach is highly versatile, gives good encapsulation efficiency, and works well for loading sensitive molecules such as proteins, peptides, or therapeutic drugs[41].

Precipitation Polymerization Method

Precipitation polymerization is a technique shown in figure-1C, where monomers and crosslinkers are dissolved in water and allowed to polymerize until the growing polymer chains reach a point where they separate from the solution, forming tiny colloidal particles. With further crosslinking, these particles develop into nanogels. The final size and characteristics of the nanogels depend on factors such as salt content, temperature, and the amount of initiator used. This method is especially popular for producing temperature-sensitive nanogels like poly(N-isopropylacrylamide) (PNIPAm), which are well suited for controlled drug delivery[42].

Nanoprecipitaion Method

Nanoprecipitaion Method is presented in figure-1D , where solvent that mixes only partly with water is first saturated with water to balance both liquids. The polymer is dissolved in this solvent, and the mixture is poured into water containing a stabilizer while stirring strongly. Each droplet of the solvent can create many nanoparticles. These nanoparticles form because of interactions at the surface of the droplets, helped by the turbulence during mixing. Nanoparticles form due to physicochemical instability, similar to spontaneous emulsification, where solvent diffuses

into the aqueous phase. This diffusion creates local supersaturation, leading to the formation of tiny polymer aggregates or "protonanoparticles." A stabilizer is essential to prevent these small particles from merging into larger clusters. When the stabilizer effectively protects the liquid–liquid interface during solvent diffusion, stable nanoparticles are obtained[43].

Microtemplate Polymerization

A hierarchically porous polymethacrylate(PMMA) monolith was prepared by free-radical copolymerization of glycidyl methacrylate (GMA) and ethylene glycol dimethacrylate (EDMA). The polymerization was initiated by adding 1 wt% AIBN to the monomer mixture. Microsphere templates were introduced at varying template-to-monomer ratios (50:50, 60:40, and 70:30). A total monolith volume of 20 mL was obtained. The mixtures of monomers and templates were sonicated at 20 °C for 30 min, transferred into casting molds, and polymerized at 60 °C for 3 h in a water bath. The solidified monoliths were then removed and stored at room temperature. For comparison, a control monolith was synthesized without the use of microsphere templates[44].

IonGelation Process

The ion gelation process is broadly used for the preparation of polymeric nanoparticles due to its simplicity and mild processing conditions. Typically, A polymer is mixed with a solvent at the desired concentration, and the drug is solubilized in a compatible medium before incorporation into the polymer solution. Under constant agitation, a crosslinker solution is introduced drop wise, resulting in nanoparticle formation driven by ionic or electrostatic interactions. The nanoparticles obtained are collected by centrifugation, and drug entrapment or loading efficiency is usually determined from the supernatant. Finally, the particles are dried, often by lyophilization, to ensure long-term stability and subsequently resuspended in buffer systems for characterization[45].

Evaporation Of Solvent Method

The drug and polymer mixture is gradually introduced into the water phase under continuous stirring at around 1000 rpm for a period of two hours to facilitate uniform mixing. The formed nanosponges are then collected by filtration and subsequently dried in a hot air oven at 40 °C for 24 hours, after which they can be stored in capsules. For better dispersion, the polymer is first pre-soaked in water for two hours prior to gel formation and then subjected to high-speed stirring at 6000 rpm. The pH of the system is adjusted using a suitable pH-modifying agent, after which the nanosponge suspension is stabilized with the incorporation of permeation enhancers into the aqueous dispersion[1,3].

Surface Functionalisation for Topical Delivery

Surface functionalization improves the performance of nanogels in topical drug delivery by adjusting properties such as surface charge, hydrophilicity, and adhesion. Modifications like ligand attachment, polymer coatings, and charged or amphiphilic surfaces enhance skin penetration, retention, and control over drug release. These strategies lead to improved therapeutic outcomes in dermatological applications[46]. Nanogels, due to their nano size and tunable surface properties, can efficiently load drugs and deliver them at higher concentrations to targeted skin sites. Surface modifications improve skin penetration, stability, and compatibility, while polymer conjugation or incorporation into hydrogels supports regulated delivery of both water-soluble and water-insoluble medications[47].

Comparison of Nanogels vs. Conventional Topical Systems

The Comparison of Nanogels vs. Conventional Topical Systems As shown in Table-1, surface-functionalized nanogels offer clear advantages over conventional topical formulations such as creams, gels, and ointments. Traditional systems often show poor stability, fast drug release, and limited skin penetration, reducing their effectiveness. Nanogels protect the drug, provide controlled or sustained release, and penetrate the skin more efficiently, leading to higher local drug levels with less irritation. These benefits reduce dosing frequency, improve patient comfort and compliance, and expand their use in treating skin conditions such as psoriasis, acne, inflammation, and photoaging[48]. In summary, surface functionalization of nanogels for topical delivery enables customizable, site-specific, and patient-friendly solutions for skin therapies. With their capacity for targeted delivery,

controlled release, and enhanced biocompatibility, functionalized nanogels represent the next-generation platform for precision dermatological treatment and are likely to play an increasingly prominent role in future patient care[17].

Recent Advances and Reseach Highlights

Stumli-Responsive Nanogel for Enhanced Pentration and Release

Single- versus multi stimuli responsive nanogels as shown in table-2, Single-stimuli responsive nanogels are designed to react to a single trigger such as pH, temperature, or enzymatic activity, making them relatively simple to fabricate and cost-effective. However, their release control and specificity are limited to one biological condition. In contrast, multi-stimuli responsive nanogels are engineered to respond to two or more cues simultaneously—for example, pH and temperature or redox and enzyme activity-allowing for more precise drug release that adapts to complex disease microenvironments. Although their synthesis is more challenging and scale-up can be difficult, these systems provide superior targeting, improved therapeutic precision, and decreased adverse effects, making them highly attractive for advanced applications such as cancer therapy, wound healing, and inflammatory skin disorders[49].

Nanogel Formulation Combining Synthetic and Natural therapeutics

The classification of nanogels by origin and composition as shown in table-3, Synthetic nanogels are stable and allow controlled drug release, but they do not have natural healing properties and may raise safety concerns. Natural nanogels are safer and have built-in anti-inflammatory and wound-healing benefits, though they may lack stability and consistency. Hybrid nanogels combine both systems, offering good stability and controlled release along with natural bioactivity. This makes them especially useful for chronic inflammatory skin conditions and wound healing, where both effectiveness and safety are important[50].

Clinical and Preclinical Evidence of Nanogel Formulations

Clinical and preclinical evaluation of nanogel-based drug delivery systems studies clearly show in table-4, that nanogel-based formulations are versatile and highly effective therapeutic systems. In cancer treatment, early clinical trials have reported better tumor response, improved drug behavior in the body, and good safety compared to conventional delivery methods. In dermatology and wound healing, nanogels enhance drug penetration, control inflammation, and speed up tissue repair with minimal irritation or systemic exposure. Advanced nanogels can also deliver multiple therapies together, helping overcome drug resistance and improving overall treatment outcomes[51]. These research highlights underscore the promise of nanogels as advanced, precision drug delivery platforms in modern medicine.

Challenges

Nanogels still face several challenges that limit their clinical translation. Large-scale production often leads to inconsistencies in size and drug loading, affecting reproducibility. They also suffer from stability issues, such as degradation or aggregation during storage, which can reduce shelf-life. Some nanogel materials may trigger immune reactions, raising safety concerns. Additionally, achieving controlled biodegradation and ensuring effective penetration across biological barriers like the skin or blood–brain barrier remain difficult[52]. The future of nanogels looks highly promising with new technologies enabling more precise and scalable production. Smart and multifunctional designs will support targeted, on-demand therapy and personalized medicine. Green, sustainable methods and clearer regulatory pathways will further boost development. With these advancements, nanogels are expected to overcome current challenges and expand their clinical use[53].

FUTURE PROSPECTIVES

In the coming years, nanogel-based topical systems for anti-inflammatory therapy are expected to evolve toward highly personalized, smart, and clinically translatable platforms. Future work should focus on establishing clear structure-property-efficacy relationships using advanced models (3D skin constructs, organ-on-chip, and large-

animal or early human studies), along with in-depth long-term safety and immunotoxicity evaluation. Multi-stimuli-responsive and theranostic nanogels capable of co-delivering multiple agents (e.g., NSAID plus antioxidant or biologic) and enabling Immediate monitoring of drug distribution and local response represents a particularly promising direction. Parallel efforts are needed to develop scalable, continuous or microfluidic manufacturing routes, define nanogel-specific critical quality attributes, and build harmonized regulatory frameworks to support clinical approval and commercialization. Finally, integrating green chemistry principles, biodegradable bio-sourced polymers, and life-cycle assessment into nanogel design will be essential to ensure that future products are not only effective and safe, but also economically and environmentally sustainable.

CONCLUSION

Nanogels have emerged as versatile topical carriers that enhance penetration, local retention, and anti-inflammatory efficacy while limiting systemic exposure compared with conventional formulations. Their nanoscale, hydrophilic, and tunable polymer networks support high drug loading, controlled or stimuli-responsive release, and the incorporation of biocompatible and bioactive polymers that add antioxidant, wound-healing, and barrier-restoring benefits, particularly valuable in chronic inflammatory skin diseases. Preclinical and early clinical studies consistently demonstrate superior therapeutic outcomes and tolerability, yet critical challenges in scalable manufacturing, long-term physicochemical stability, and regulatory standardization still hinder widespread clinical translation. Addressing these gaps through optimized engineering, robust quality control, and harmonized guidelines will be essential for fully realizing the potential of nanogel-based topical anti-inflammatory therapies in routine dermatological practice.

Table 1: Comparison of Nanogels vs. Conventional Topical Systems

Parameter	Conventional Topical Systems	Surface-Functionalized Nanogels
Stability	Prone to degradation, limited shelf-life	High stability; protects payload from degradation
Drug Release	Burst release, less control	Controlled, sustained, and stimuli-responsive release
Skin Penetration	Limited penetration through stratum corneum	Enhanced permeation via nanoscale size, charge modification, or ligand targeting
Drug Protection	Active ingredient often unstable or degraded	Encapsulated drugs remain protected and bioavailable
Irritation/Toxicity	Can cause erythema, dryness, irritation	Reduced irritation; improved tolerability and safety
Dosing Frequency	Requires frequent re-application	Lower dosing frequency due to sustained action
Patient Compliance	Moderate; side effects reduce adherence	High compliance due to comfort, tolerability, and convenience
Applications	General creams, gels, ointments	Precision dermatology (psoriasis, acne, photoaging, anti-inflammatory therapy)

Stumli-Responsive Nanogel for Enhanced Pentration and Release

Table 2: Single- versus multi stimuli responsive nanogels

Feature	Single-Stimuli Responsive Nanogels	Multi-Stimuli Responsive Nanogels
Trigger Type	Responds to one cue (e.g., pH *or* temperature *or* enzymes)	Responds to two or more cues simultaneously (e.g., pH + temperature, redox + enzyme)
Design Complexity	Relatively simple and easier to fabricate	More complex synthesis and formulation strategies
Control over Release	Limited, release occurs only under one condition	Enhanced control, with drug release tailored to multiple pathological environments
Target Specificity	Moderate targeting based on one biological factor	Higher specificity due to combined responsiveness
Applications	Suitable for basic drug delivery systems	Promising for precision therapies in cancer, wound healing and inflammatory skin diseases
Advantages	Cost-effective, straightforward	Greater therapeutic precision minimized side

	design	effects
Limitations	Less adaptable in complex disease microenvironments	More challenging scale-up and stability issues

Nanogel Formulation Combining Synthetic and Natural Therapeutics

Table 3: Classification of nanogels by origin and composition

Type	Features	Advantages	Limitations
Synthetic Nanogels	Based on polymers such as PEG, PVA, and Polyacrylates	High stability, tunable release profile, Reproducible manufacturing, strong mechanical properties	Lack inherent bioactivity, possible toxicity of residues, lower patient acceptabiliy
Natural Nanogels	Derived from polymers like chitosan, alginate, hyaluronic acid, or loaded with phytoconstituents	Excellent biocompatibility, inherent bioactivity (anti-inflammatory, antibacterial, wound-healing), low toxicity	Limited stability, batch variability, weaker mechanical strength
Hybrid Nanogels (Synthetic + Natural)	Integration of synthetic polymers with natural therapeutics (essential oils, phytoconstituents, polyherbal extracts)	Combines stability and tunable release of synthetic carriers with biocompatibility and bioactivity of natural agents; synergistic effects; reduced toxicity	More complex formulation and characterization; regulatory challenges in standardization

Clinical and Preclinical Evidence of Nanogel Formulations

Table 4: Clinical and preclinical evaluations of nanogel-based drug delivery systems

Study Type	Therapeutic Area	Key Outcomes	Advantages over Conventional Systems
Clinical (Phase I/II)	Oncology or tumor therapy	Robust tumor response rates, predictable toxicity, improved pharmacokinetics	Better drug stability reduced systemic toxicity
Preclinical (animal models)	Topical therapy (anti-inflammatory)	Superior local drug deposition, better control of inflammation	Higher skin pentration, reduced irritation
Preclinical (wound healing models)	Tissue repair and regeneration	Faster wound closure, enhanced collagen deposition	Low systemic exposure, minimal side effects
Preclinical(multi-compartment nanogels)	Drug-resistant cancers	Effective against multidrug resistance, supports combined therapy (chemo + hyperthermia)	Synergistic treatment targeted delivery lower dosing required

ABSTRACT

Generally, soil fertility is mediated through chemical fertilizer that contains most important macronutrients for plant growth and development. But these macronutrients are unavailable for plant use owing to its insoluble organic form resulting decrease in crop production. Therefore, to overcome limitation, isolating mineral solubilizing organism for solubilizing inorganic form to organic form which is easily available for plant use. Hence, this study targeted to isolate thirty mineral solubilizing fungi from ten conventional soil samples and evaluated for their solubilization ability using phosphate and potassium after macroscopic observation. Out of thirty isolates, ten isolates showed phosphate solubilizing ability and nine isolates were potassium solubilizers. Further, all the isolates were tested for protease and indole acetic acid (IAA) production and found that, nine isolates were performed protease production and sixteen fungal isolates produced IAA. Further, among thirty isolates, five isolates showed all the activities were selected for molecular characterization based on PCR amplification and genomic sequencing of the internal

transcribed spacer region (ITS) along with morphological identification and identified as *Rhizopus arrhizus*, *Aspergillus niger*, *Aspergillus flavus*, *Rhizopus microspores*, and *Curvulariaprasadii* respectively. Evolutionary analyses were conducted using MEGA12 software. Altogether, this study highlighted the isolated fungal isolates were potent mineral solubilizers to enhance the plant growth and development.

Keywords: Bioinoculant, Mineral solubilization, Protease production, Indole acetic acid.

INTRODUCTION

Over several decades, soil fertility was generally improved by applying lots of chemical fertilizer which cannot be utilized completely by soil. Usually, most of the chemical fertilizer contain nitrogen, potassium and phosphorous are predominant macro nutrients that applied to the soil as potash and phosphate fertilizer for plant growth [1,2]. These macronutrients are played a significant role in development and metabolism of plant such as energy transfer, photosynthesis, grain quality improvement, respiration, disease control, signal transduction, macromolecular biosynthesis that contributed for greater crop yield [3]. Moreover, most of the applied fertilizer is converted into an insoluble form and becomes inaccessible by the plant for their growth leads imbalanced fertilization resulting deficiency of all the macronutrients thereby crop production reduction[4,5]. However, the long term or overuse of chemical or synthetic fertilizer have unwanted effects on soil, plants, surrounding environment as well as human health [6]. Hence, it is very important to improve the macronutrient usage efficiency to enhance the crop yield through ecologically safer method as well as economically reliable [7]. Employing microbial consortium as effective plant growth-promoting agent is an excellent as well as promising alternative biotechnological approach towards synthetic fertilizers [8,9]. Commonly, microbial consortium is cost effective, eco-friendly, safer than agrochemicals and also, helps to recover soil fertility and structure [10].

Most commonly, available macronutrients in the soil can be utilized by dissolving or degrade them with soil microbes particularly, plant growth promoting organisms (PGPO) [11,12,13]. PGPO are mainly connected with root of the plant and surrounding soil environment and employing beneficial impact on plant growth [14,15]. PGPO is an important component in the soil ecosystem and also, frequently involved in biogeochemical nutrient cycle resulting environmentally approachable fertilizers. PGPO can able to contribute for increasing crop yield through promoting plant growth both directly and indirectly by mineral solubilization, nitrogen fixation, phytohormones synthesis including siderophore and indole-3-acetic acid production, phytopathogen inhibition, plant systemic resistance induction against phytopathogens, soil aggregates stability and maintains of soil structure and soil nutrient [16,17]. Additionally, PGPO has the possibility to solubilize immobilize form of minerals including potassium and phosphate to soluble form which can be easily absorbed by plant [18,19]. Consequently, PGPO were reported for solubilizing different inorganic insoluble minerals like strengite, barrandite, tricalcium phosphate, hydroxyapatite, crandallite, zinc oxide, zinc silicates and smithsonite to soluble forms through various mechanism including solubilization, mineralization as well as mobilization [20,21,22,23]. Among the reported mechanisms, solubilization is one of the significant methods to convert the insoluble minerals to easily absorbed soluble form by chelation, exchange reaction, producing organic acid secretion, secretion of protons and acidification [24, 25]. Hence, our study aimed to isolate and identify the potential plant growth promoting fungi from conventional soil and to screen the organisms for mineral solubilization.

MATERIALS AND METHODS

Chemicals: For the study, Potato Dextrose Agar (PDA) medium, Lactophenol Cotton Blue (LCB) Solution, Pikovskaya agar medium were purchased from Himedia India. SDS, Isopropanol, TE Buffer, Phenol/Chloroform/Isoamyl Alcohol (25:24:1 ratio), RNase A, Bromophenol blue, Proteinase K were procured from Sigma Aldrich, USA.

Collection of soil sample: For the isolation of plant growth promoting fungi, totally 10 conventional soil samples in triplicate were collected from various crop cultivated land of Karur District, Tamilnadu, India during June 2023 to November 2023. Soil was sampled from each site at a depth of 0-30 cm. Collected samples were shifted to clean polythene bags, tagged and transported to laboratory. The samples details like collection field, area and latitude & longitude are presented in table 1.

Isolation of fungi: For the isolation, 1 g of collected inorganic soil sample was used for 10-fold serial dilution up to 10^{-6} and spread plate was performed on prepared sterile PDA plate and incubated for 3-7 days at room temperature. After incubation, the plate was monitored for colony formation and individual colonies from each dilution was counted. The obtaining fungal colonies were observed visually and selected colonies were sub-cultured till the purified fungal colonies were obtained. All the purified fungal isolates were preserved for further assay.

Screening for phosphate solubilisation: To check the ability of all the isolates to solubilize phosphate, the Pikovskaya's medium was used as described before [26]. In brief, the Pikovskaya agar plates prepares in sterile condition was used for spot inoculation of all the isolates by taking small portion of the fungal spores using sterile inoculation needle and incubated for 7 days at room temperature. After incubation, the plate was observed for clear zone formation around the colonies which indicates the solubilization of phosphates by the organisms.

Screening for potassium solubilisation: All the isolated isolate's potassium solubilization abilities were determined using modified Aleksandrov medium as mentioned earlier [27]. Briefly,the spot inoculation of all the isolates spores were applied on the sterile prepared Aleksandrov medium using sterile inoculation needle and allowed for 7 days to form zone formation. The zone around the organisms indicates the potassium solubilizing ability of the isolated organisms.

Screening for protease production: To predict all the isolates protease production ability, the skim milk agar medium was used as defined before [27]. In brief, the prepared skim milk agar plates in sterile condition were allowed for receiving spot inoculation of all the isolated isolates spores using inoculation needle and allowed for incubation at room temperature for 7 days. Then, the incubated plates monitored for zone formation around the grown isolates, indicates the protease production of the isolates.

Screening for indole acetic acid (IAA) production: To screen the capacity of all the isolates for IAA production, the fungal isolates were inoculated into each 5 ml of sterile Potato Dextrose broth supplemented with 3 mg/ml of L-tryptophan and incubated at 28^{o}C for 5 days. After incubation, cell free supernatant was obtained by centrifuging at 10,000 rpm for 10 minutes and to that a drop of orthophosphoric acid and 2 ml of Solwaski's reagent (50 ml, 35% of perchloric acid, 1 ml 0.5 M $FeCl_3$ solution) was added and kept for 20 minutes at room temperature. The development of pink colour indicates the production of IAA [28].

Microscopic and Molecular Identification of isolated isolates: The isolates showed positive to phosphate and potassium solubilization and protease and IAA production were selected for microscopic and molecular identification. For microscopic analysis, the lactophenol cotton blue mount was performed for each isolate by adding a small fungal specimen in to sterile clean glass slides which contains sterile water droplets, mixed well and added the few drops of LCB, covered with cover slip and observed under microscope [29].

DNA Isolation and Quantification: For DNA isolation, in a fresh tube, 500 µl of culture grown in PDB were added and to that added equal volume of Tris-HCL and EDTA, along with 10 µl SDS was added. Sterile homogenizer was used for homogenization and 5 µl of Proteinase K was added. Then the mixture was incubated for 2 h at 55°C and then placed in ice for 10 minutes. About 250 µl of 6 M NaCl and EDTA was added and mixed and again placed in ice for 5 minutes, they were centrifuged at 8000 rpm for 15 minutes. Then, 500 µl of supernatant was collected in new tubes. For the precipitation of DNA, twice the volume of ethanol was added. The obtained samples were centrifuged at 11000 rpm for 15 minutes and the supernatant was removed. Then the precipitates were washed using ethanol and

again centrifuged at 11000 rpm for 5 minutes. Then the supernatant was removed and the pellet was dried at room temperature. Then the DNA samples were resuspended in the 1X TE buffer. DNA quantification has been carried out using a UV spectrophotometer at optical densities of 260 nm and 280 nm. The DNA quality was analysed using agarose gel electrophoresis

PCR Amplification and Sequencing: The PCR amplification was performed for molecular identification of isolated isolates using extracted DNA as mentioned before [30]. In brief, the PCR amplification was carried out using the ITS forward (TCCGTAGGTGAACCTGCGG) and ITS reverse (TCCTCCGCTTA TTGATATGC) and the PCR reactions was performed PCR thermal cycler (Himedia PCR System). The final PCR product was added with 2 µl of ExoSAP-IT and was incubated at 37°C for 30 minutes. The enzyme inactivation was followed at 80°C for15 minutes. Then, the sequencing process was carried out using BigDye Terminator v3.1 (Applied Biosystems, USA). Followed by post-sequencing PCR clean-up. Then the cleaned product was sequenced using ABI 3500 DNA Analyzer (Applied Biosystems).

Sequencing and Phylogenetic Analysis: The ITS region sequencing has been carried out using BLAST and compared with the NCBI GenBank database. Using the multiple alignment tool ClustalW, an extreme identity score program, the first 10 sequences were selected and aligned. Using MEGA 7, a distance matrix was generated and a phylogenetic tree was constructed. The neighbour-joining method was used for producing evolutionary trees. The phylogenetic tree is depicted accurately, with branch lengths measured in evolutionary distances that correspond to the same units. The Poisson correction method was utilized to calculate the evolutionary distances**.** In MEGA12, evolutionary analyses were performed [30].

RESULTS

Isolation of fungi: Totally, thirty isolates were isolated from various dilutions of ten conventional soil samples and the isolated isolates were morphologically distinct. The most predominant isolated fungal isolates were observed macroscopically (based on colony morphology) includes Genus of *Rhizopus, Aspergillus, Penicillium, Fusarium* and*Curvularia* comes under the group of Zygomycota and Ascomycota.

Screening for phosphate solubilisation: The isolated isolate's ability for phosphate solubilization was determined and the most important organisms solubilizing phosphate are mentioned in figure 1. In total, ten isolates like isolates 3, 5, 7, 11, 13, 17, 20, 25, 27 and 29 were displayed their capacity to solubilize phosphate (Table 2) by producing zone formation around the grown colonies which indicates the organism's usefulness in plant growth promoting activities.

Screening for potassium solubilisation: The isolated fungal isolate's ability for potassium solubilization was screened and the most important isolates showed potassium solubilization are denoted in figure 2. Totally, thirty isolates were tested for potassium solubilizing ability, in which nine isolates including isolates 2, 5, 11, 13, 20, 23, 25, 27 and 29 were expressed their potassium solubilization (Table 2) on Aleksandrov agar plates by showing zone formation around the fungal isolates, indicating fungal isolates plant growth promoting activity.

Screening for protease production: The protease producing capacity of all the isolated fungal cultures were screened and the attained results are presented in figure 3. The figure illustrated the protease producing capability of most significant fungal isolates which produced protease on skim milk agar were reported. The results reported that, among the thirty isolates, nine fungal isolates such as isolates 2, 5, 10, 13, 16, 20, 25, 27 and 30 were identified for protease production (Table 2) by exploring the formation of clear zone around the isolates which indicates the plant promoting ability of isolated fungal isolates.

Screening for IAA production: The isolated fungal strains were analysed for the most significant plant growth hormone, IAA and the obtained result is displayed in figure 4. Among the thirty isolates, totally, sixteen isolates such

as isolates 2, 4, 5, 8, 10, 13, 15, 16, 18, 20, 21, 23, 25, 26, 27 and 30 were identified for IAA production (Table 2) by producing pink colouration which indicated the plant promoting ability of isolated fungal isolates. Further, the isolated thirty fungal isolates screened for phosphate and potassium solubilization, protease and IAA production were reported in figure 5 in which five isolates namely isolate 5, 13, 20, 25 and 27 rendering all four activities were selected for microscopic and molecular identification.

Microscopic and Molecular identification:

The isolated isolates were showed potent screening activity such as phosphate and potassium solubilization, protease and IAA analysed for macroscopic and microscopic observation using LCB mount namely *Rhizopus arrhizus, Aspergillus niger, Aspergillus flavus, Rhizopus microspores,* and *Curvulariaprasadii* respectively and the obtained results are presented in figure 6(a), 6(b) and 7.

Molecular identification and the phylogenetic tree construction performed for isolated potent fungal isolates. The ITS region sequence of samples was compared to the NCBI Genbank using BLAST. The first ten resulting sequences were selected for further analysis. Based on the molecular and phylogenetic analysis, the closest match identified by BLAST was revealed that, the isolated fungal isolates 5, 13, 20, 25 and 27 were identified as *Rhizopus arrhizus* (PQ813584.1), *Aspergillus niger* (PQ135184.1), *Aspergillus flavus* (PQ163838.1), *Rhizopus microporu*s (PQ636497.1) and *Curvulariaprasadii* (PQ164259.1) respectively (Fig.7).The evolutionary history was inferred using the Nighbor-Joining method was shown in figure 7. The optimal tree with the sum of branch length=2.605 is shown. The evolutionary distances were computed using the Maximum Composite Likelihood method and are in the units of the number of base substations per site. The proportion of sites where at least 1 unambiguous base is present in at least 1 sequence for each descended clade is shown next to each internal node in the tree. The analytical procedure encompassed 27 nucleotide sequences obtained from NCBI which includes *Rhizopus arrhizus* (PQ813584.1), *Rhizopus arrhizus* (LC705203.1), *Rhizopus stolonifera* (AM933544.1), *Rhizopus microspores* (LC844828.1), *Rhizopus microspores* (LC390273.1), *Rhizopus azygosporus* (LC390245.1), *Rhizopus schipperae* (DQ119015.1), *Rhizopus oryzae* (HE608810.1), *Rhizopus sexualis* (AF543521.1), *Rhizopus microspores* (PQ636497.1), *Aspergillus niger* (PQ135184.1), *Aspergillus flavus* (PQ163838.1), *Aspergillus flavus* (AJ874128.1), *Aspergillus niger* (AJ876876.1), *Aspergillus niger* (LC632401.1), *Aspergillus fumigatus* (LC602033.1), *Aspergillus terreus* (LC777033.1), *Aspergillus versicolor* (LC705733.1), *Aspergillus elegans* (EU165705.1), *Aspergillus ochraceus* (FR733829.1), *Curvulariaprasadii* (PQ164259.1), *Curvulariaprasadii* (HG778997.1), *Curvularialunata* (LC317565.1), *Curvularia geniculate* (OW986190.1), *Curvulariainaequalis* (OW988110.1), *Curvulariaverruculosa* (OW985725.1) and *Curvularialunata* (OW986260.1). The pairwise deletion option was applied to all ambiguous positions for each sequence pair resulting in a final data set comprising 1,479 positions.

DISCUSSION

Since several decades, the soil fertilization is an important process for plant growth and development which can be accomplished through applying chemical fertilizer consists nitrogen, potassium and phosphorous as predominant macronutrients which can't be utilized completely by soil. Therefore, complete utilization of macronutrient by soil is important for plant growth by employing microbial consortium. Hence, in the present study, isolated five fungal isolates from conventional soil and screened for mineral solubilization which is one of the chief mechanisms of plant growth that involves the solubilization of insoluble minerals like phosphate and potassium by microorganisms because the macronutrients are involved in development and metabolism of plant such as energy transfer, photosynthesis, grain quality improvement, respiration, disease control, signal transduction, macromolecular biosynthesis that contributed for greater crop yield [31,32]. Particularly, phosphate and potassium are an important macronutrient for plant growth and development like photosynthesis, strengthening the stalks and stems, flower and seed formation, energy production, crop maturity and quality of crop, N_2 fixation in legumes, storage and transfer reactions, cell division and enlargement and resistance to plant diseases [33,34]. Consequently, the identification of potential phosphate and potassium solubilizing organisms are an important criterion for sustainable agricultural practice. Therefore, our study explored the isolated fungal isolates phosphate and potassium solubilizing ability by

zone formation which provided the partial measurement of phosphate and potassium solubilization potential of the fungal isolates from conventional soil resulting alteration in the soil pH. In support of our findings, many soil microorganisms like *Aporrectodea rosea*, *Aspergillus* sp, *Penicillium* sp, *Rhodanobacter*, *Pleomorphomonas, Acidovorax*sp, *Pseudomonas* sp,*Burkholderia* sp, *and Sphingomonas* sp, *Mycolicibacterium* sp, *Aureobasidium pullulans, Candida tropicalis,Cryptococcus laurentii, Pseudofusicoccum, Penicillium citrinum, Aspergillus tamarii*and*Variovorax*sp. were reported for phosphate solubilization for sustainable plant growth and development [27, 35, 36, 37, 38].

In addition, an important plant growth hormone from the auxin family of indole derivatives which is most abundant and essential plant hormone occurred naturally that controls utmost each and every characteristic features of plant growth and development includes cell division, cell elongation, fruit development and ageing and also, increased plant protection from external stress. IAA can be synthesized not only in plants but also in many microorganisms which interact with plants including bacteria and fungi [39,40]. Therefore, it is very important to study the IAA producing ability of isolated fungal isolates and found that promising IAA producing ability for plant growth promoting activities. Similarly, our findings were supported by many scientific groups wherein soil microorganisms both bacteria and fungi including *Klebsiella*sp, *P. aeruginosa, Bacillus* sp, *B. megaterium*, *Colletotrichum gloeosporioides, Trichoderma tomentosum, Colletotrichum godetiae*and *Talaromycesamestolkiae* were able produce IAA for promising plant growth and development [41, 42, 43, 44].

Supporting to our finding, in recent studies a bacterium *Alcaligenes faecalis* isolated from organic soil from Namakkal District of Tamil Nadu, three salt tolerance endophytic bacteria from ginger and four endophytic fungal from the lavender plant exhibited strong PGP properties, including the highest IAA production, phosphate solubilization and protease production [45,46,47].Overall, the isolated fungal isolates in this study showed promising phosphate and potassium solubilizing ability as well as producing IAA for better plant growth promoting activity.

CONCLUSION

The present study concluded that the isolated fungal isolates from conventional soil were expressed their mineral such as phosphate and potassium solubilizing ability and also, screened for IAA and protease producing ability of isolated five fungal isolates. Finally, the isolated isolates were identified by molecular sequencing and identified as *Rhizopus arrhizus, Aspergillus niger, Aspergillus flavus, Rhizopus microspores,* and *Curvularia prasadii* respectively. Altogether, the isolated and identified fungal isolates can be used for mineral solubilization leads promising plant growth and development.

ACKNOWLEDGMENT

The authors are grateful to Professor M. Karunanithi, chairman and secretary, vivekanandha Educational Institutions, Dr. P. Baby Shakila, Pricipal, Vivekanandha college of Arts and Sciences for Women, Tiruchengode, Namakkal, Tamil Nadu and the Chairmen, Secretary, Principal of Kongu college of Arts and Science, Vennaimalai, Karur, Tamil Nadu, India for supporting this project.

ABSTRACT

The pharmaceutical marketing and industrial sector in India is expanding rapidly, leading to increased global competition and a growing demand for skilled drug regulatory professionals. Regulatory affairs is a specialized profession within the pharmaceutical industry that encompasses activities related to drug discovery, clinical trials, production, manufacturing, marketing, and post-marketing welfare. Drug Regulatory Affairs professionals serve as a crucial link between the pharmaceutical industry and regulatory authorities worldwide. Drug product approval is a critical step to ensure that medicines are safe, effective, and of acceptable quality. Regulatory affairs plays a vital role in supporting both pharmaceutical companies and government authorities by preventing issues arising from improper, incomplete, or misleading data. In India, regulatory systems can be broadly classified into economic regulation, public interest regulation, and environmental regulation. Every country has a designated regulatory authority responsible for the analysis and evaluation of research data related to new drugs and medicinal products to ensure their safety and efficacy for public health. The present study focuses on drug regulatory issues, the roles and relationships of regulatory affairs within the pharmaceutical

industry, and the drug approval process governed by the national regulatory authority in India, namely the Central Drugs Standard Control Organization (CDSCO)

Keywords: Drug Regulatory Affairs, CDSCO, Regulatory body, Drug product approval

INTRODUCTION

Regulatory Affairs (RA) is a specialized profession within the healthcare and other regulated industries, particularly pharmaceuticals, medical devices, biologics, veterinary medicines, cosmetics, dietary supplements, pesticides, and agrochemicals. The profession has evolved primarily to protect public health by ensuring that products introduced into the market are safe, effective, and of acceptable quality. Regulatory affairs serves as a vital link between pharmaceutical companies and government regulatory authorities. It is responsible for ensuring compliance with regulatory requirements related to drug discovery, clinical trials, manufacturing, registration, marketing authorization, and post-marketing surveillance. Because RA professionals interact closely with regulatory bodies, the discipline is often referred to as "Government Affairs." A single regulatory error can jeopardize years of research and development; therefore, RA professionals must possess comprehensive knowledge of regulatory guidelines, documentation requirements, and both technical and digital systems used within the industry. Consequently, most pharmaceutical organizations—ranging from large multinational corporations to small biotechnology firms—maintain dedicated regulatory affairs departments. The development of a new pharmaceutical product typically requires 10–15 years and substantial financial investment before it reaches the market. However, recent global health emergencies, such as the COVID-19 pandemic, caused by the novel corona virus SARS-CoV-2, demonstrated the critical role of regulatory authorities and RA professionals in enabling accelerated yet safe product approvals under emergency conditions[1-4]. In the modern era, the pharmaceutical industry has become highly organized, systematic, and compliant with international regulatory standards. Stringent Good Manufacturing Practices (GMPs) are followed for the production of chemical and biological drugs for human and veterinary use, as well as for medical devices, blood and blood products, traditional herbal medicines, cosmetics, and dietary supplements. Regulatory frameworks that were once fragmented have now evolved into well-defined and controlled systems, resulting in the consistent manufacturing and marketing of safe, efficacious, and high-quality products. As the pharmaceutical industry continues to grow, regulatory legislations across different regions have become increasingly complex, thereby creating a greater demand for skilled regulatory affairs professionals. Understanding the historical evolution of regulatory frameworks in regions such as the United States, Europe, and India is essential for appreciating the development of the current global regulatory environment[5,6]. Overall, the regulatory affairs profession plays a central role in the collection, analysis, and communication of the risks and benefits of healthcare products to regulatory authorities and the public worldwide. The RA department is responsible for interpreting regulatory requirements and ensuring the successful approval of new and generic products, thereby safeguarding public health while supporting innovation in the pharmaceutical industry.

Objectives of Regulatory Affairs:[7]

1. How and why the pharmaceutical industry and drug regulation developed in the US.
2. Rules for medicinal products in the European Union.
3. Major US regulations.
4. The EU framework and its regulation.
5. Pharmaceutical legislation of the EU.
6. Indian pharmaceutical industry and development of drug prescriptions in different periods.
7. Types of registration procedure on the EU market.
8. Main Rules and Law of India.
9. The role of an expert on regulatory matters in health authorities and also in the pharmaceutical industry.
10. Ensuring that their companies comply with all regulations and laws relating to their business.

11. Cooperate with federal, state and local regulatory authorities and staff on specific issues affecting their business.
12. Advising companies on regulatory aspects and climate that would affect their proposed activities

Role of the Regulatory Affairs (RA) Department [8]

- The Regulatory Affairs (RA) department in the pharmaceutical industry is responsible for obtaining and maintaining marketing authorization for new pharmaceutical products and ensuring continued compliance throughout the product lifecycle.
- From the early stages of product development, RA professionals provide strategic, scientific, and regulatory guidance to research and development (R and D), quality control, production, and other allied departments, thereby contributing significantly to both the scientific advancement of products and the overall growth of the organization.
- The RA department continuously monitors and interprets national and international regulatory guidelines, customer requirements, and legislative changes relevant to the company's product portfolio.
- It ensures that all company products comply with current regulatory requirements in the regions where they are manufactured and marketed.
- RA professionals maintain comprehensive knowledge of the company's product range and manage regulatory documentation, including responses to audit reports, compliance activities, and regulatory as well as customer inspections.
- A key responsibility of RA professionals is to track evolving regulatory legislation across all target markets and provide expert advice on the associated legal, scientific, and technical requirements. They also collect, evaluate, and compile scientific data generated by research and development teams for regulatory submissions.
- Regulatory authorities issue regulations as legally binding instructions that define how laws must be interpreted and implemented. Failure to comply with these regulations can result in regulatory actions such as warning letters, which can have serious consequences for pharmaceutical companies.
- The RA department is responsible for maintaining approved applications**,** managing Drug Master Files (DMFs)**,** and keeping accurate records of regulatory submissions and registration fees.
- Regulatory Affairs professionals help organizations avoid regulatory setbacks caused by incomplete documentation, poor data presentation, or inadequate scientific justification**.**
- An effective RA professional adopts a "right-first-time" approach, coordinating regulatory requirements with scientific development throughout the product lifecycle to ensure efficient use of company resources and cost-effective compliance.
- Additionally, the RA department plays a role in supporting the dissemination of accurate, complete, and scientifically sound information to physicians and other healthcare professionals regarding the safety, quality, and efficacy of pharmaceutical products.

The Regulatory bodies in various countries[8]

USA

USA- FDA

The United States Food and Drug Administration (FDA or USFDA) is a federal agency of the Department of Health and Human Services. The FDA is responsible for protecting and promoting public health through the control and supervision of food safety, tobacco products, dietary supplements, prescription and over-the-counter pharmaceutical drugs (medications), vaccines, biopharmaceuticals, blood transfusions, medical devices, electromagnetic radiation emitting devices (ERED), cosmetics, animal foods and feed and veterinary products. The FDA has its headquarters in unincorporated White Oak, Maryland. The agency also has 223 field offices and 13 laboratories located throughout the 50 states, the United States Virgin Islands, and Puerto Rico. In 2008, the FDA began to post employees to foreign countries, including China, India, Costa Rica, Chile, Belgium, and the United Kingdom.

Canada

Health Canada

The department of the Government of Canada responsible for national health policy. The department itself is also responsible for numerous federal health- related agencies, including the Canadian Food Inspection Agency (CFIA) and the Public Health Agency of Canada (PHAC), among others. These organizations help to ensure compliance with federal law in a variety of healthcare, agricultural, and pharmaceutical activities. This responsibility also involves extensive collaboration with various other federal- and provincial-level organizations in order to ensure the safety of food, health, and pharmaceutical products—including the regulation of health research and pharmaceutical manufacturing/testing facilities.

UK

Medicines and health care products regulatory agency (MHRA)

The Medicines and Healthcare products Regulatory Agency (MHRA) is an executive agency of the Department of Health and Social Care in the United Kingdom which is responsible for ensuring that medicines and medical devices work and are acceptably safe. The MHRA has several independent advisory committees which provide the UK Government with information and guidance on the regulation of medicines and medical devices.

There are currently eight such committee

- Advisory Board on the Registration of Homeopathic Products
- Herbal Medicines Advisory Committee
- The Review Panel
- Independent Scientific Advisory Committee for MHRA database research
- Medicines Industry Liaison Group
- Innovation Office
- Blood Consultative Committee
- Devices Expert Advisory Committee

European Union

European Medicines Agency (Ema)

The European Medicines Agency (EMA) is an agency of the European Union (EU) in charge of the evaluation and supervision of medicinal products. Prior to 2004, it was known as the European Agency for the Evaluation of Medicinal Products or European Medicines Evaluation Agency (EMEA). The EMA was set up in 1995, with funding from the European Union and the pharmaceutical industry, as well as indirect subsidy from member states, its stated intention to harmonise (but not replace) the work of existing national medicine regulatory bodies. The hope was that this plan would not only reduce the €350 million annual cost drug companies incurred by having to win separate approvals from each member state but also that it would eliminate the protectionist tendencies of sovereign states unwilling to approve new drugs that might compete with those already produced by domestic drug companies.

Drug Regulatory Agencies in India [9]

India has emerged as one of the main markets for pharmaceutical merchandise. growth inside the private healthcare infrastructure, widening rural markets, and inclusion of more modern technologies Have placed healthcare as an impartial region in India. With privatization of healthcare, the scientific gadgets quarter is growing too. with a view to regulate the import, manufacture, distribution and sale of drugs and cosmetics, the capsules and Cosmetics Act, 1940 ("D and C, Act") become brought in India in 1940. But, no Separate regulation has been enacted for regulating the import, manufacture, distribution or Sale of scientific devices in India till date by the government of India. Tablets and health is in concurrent list of Indian charter. it is ruled by means of each Centre And kingdom Governments below the medication and Cosmetics Act, 1940.

Main Bodies

- Central Drug Standard Control Organization (CDSCO)
- Ministry of Health and Family Welfare (MHFW)

India: Approval process of New Drug

The Drug and Cosmetic Act 1940 and rule 1945 was passed by Indian government at Parliament to export, import and production of medicinal products. National regulatory Authority of India is Central Drug Standard Control Organization (CDSCO). CDSCO is Indian government evaluatory agency that for applicant of new drug product for safety and product efficacy. CDSCO give review and analytical report to DCGI (Drug Controller General of India). DCGI is a provide license and authority of Licensing of India that approves and give permits a new drug product manufacturing and production and also marketing in India. To start the marketing business in India with import or developing a new drug or new medicine in industry, it must require fill out FORM 44 and transfer the data that needed under Schedule Y of Drug and Cosmetics Act 1940 and rules 1945.(Rule 122A , 122B , and 122D with appendix I, IA, and VI).

Following are some provisions of the Drug and Cosmetics Rule1945

- In Rule 122A involve a request for a new drug approval
- In Rule 122B involve application of import permission of new drug or new medication
- In Rule 122D Fixed Dosage Combination permission to import and export
- In Rule 122DA involve request to approval to perform clinical trials for IND (Investigational New Drug)
- In Rule 122 involving majorly DAB that include compensation of injuries /death during clinical trials.

CDSCO: Central Drug Standard Control Organization

It under Directorate General of Health Services, Ministry of Health and Family Welfare, Government of India .It is National Regulatory Authority (NRA) of India.

CDSCO Headquarter located at FDA Bhawan, Kotla Road, New Delhi. It has 6 Zonal offices, 4 sub Zonal offices, 13 port office and 7 Laboratories allover in India.

Role of CDSCO

1. For approval of new drug.
2. Processing and conducting the clinical trials.
3. Licensing and import registration.
4. Also approving license for blood banks, r-DNA Vaccine, LVPs vaccine, and some medicinal device and products.
5. New drug testing.
6. Drug and cosmetics banning.
7. Market surveillance through inspectorate center and state Authority.

Drug Approval Process in India

It is given in three phase

First phase

1. Applicant is filling the application of IND (Investigational New Drug) with their informational studies to CDSCO headquarters.
2. All the information is examined by new drug division.
3. Then detailed review by IND committee.
4. With proper information of CDSCO – Recommendation to DCGI (Drug Controller General Of India).
5. Then IND application is approved.

Second phase

1. Application is given one copy of IND information to ethical committee with application.
2. Then ethical committee report the application of IND.
3. This process taken within 12 Weeks.

Third phase

1. In 1st phase, IND application is approved and in 2nd phase, ethical committee report is positive then 3rd phase is started.
2. In 3rd phase, clinical trials is started.
3. Then again give application for new drug registration to CDSCO.
4. Then finally review by DCGI.
5. If Review is positive or complete then LICENSE IS GRANTED.
6. If Review is not complete then refused to grant license.

Requirement of Drug Approval Process in India

- Registration process of New drug approval is one time.
- Approval timeline is 2-18 months.
- Approval presentation format - paper.
- Process validation is required.
- Batch size is Pilot scale batch.

RESULTS

1. The Regulatory Affairs (RA) department of the pharmaceutical industry is in responsibility or functioning of obtaining permission for new pharmaceutical medicine or drug that ensuring the approval maintenance process for as desiring firm or for as long.
2. Right from the start of a product development, regulatory affairs experts provide technology and strategic guidance to quality control, R and D, production department, among other contributing significantly both financially and scientifically to the advancement of a development initiative and the enterprise.
3. Keep in touch with customer practices, guidelines and international legislation.
4. Ensure that a company's product comply with the current regulation.
5. Keep up to the date with a company's product range.
6. Manage review audit reports and compliance, regulatory and customer inspections.
7. The Regulatory Affairs professional role is to keep track of the ever changing legislation in all the region in which company wishes to distribute to it's product with the advice on the legal and scientific restrains and requirements, and collect also evaluate the scientific data that their research and colleagues are generating.
8. Regulation is a binding instruction issued by an agency that tells how to clarify and comply with the law, failures to follow regulation many end up into the "issued warning letter "sections of the FDA website, which is a fair for pharma industry.
9. Maintain approved application and the record of registration fees paid against submission of DMF's (Drug Master File) and other documents.

Regulatory affairs professional help company that avoid problem caused by badly kept records and inappropriate scientific thinking or poor presentation of data.

- A good Regulatory Affairs professional will have 'right first time' approaches and will play a very major and important part in coordinating scientific end with regulatory demand throughout the life of the products, helping to maximize the cost - effective use of the company resources.
- Also in the role to provide physician and other healthcare professionals with accurate and complete information about the safety, quality and effectiveness of the products.

Role of CDSCO

1. For approval of new drug.
2. Processing and conducting the clinical trials.
3. Licensing and import registration.
4. Also approving license for blood banks, r-DNA Vaccine, LVPs vaccine, and some medicinal device and products.
5. New drug testing.
6. Drug and cosmetics banning.
7. Market surveillance through inspectorate center and state Authority.

Present Regulatory Issues in the Indian Pharmaceutical Industry[10]

- According to a survey reported by *The Economic Times*, the pharmaceutical sector is one of the most dynamic industries in India. However, its regulatory compliance framework is highly complex, as the drug approval process requires coordination among multiple regulatory authorities and government departments.
- Key challenges related to industrial policy include the regulation of patents**,** drug exports, and the level of government support extended to the pharmaceutical industry. Following the introduction of the Patents Act, pharmaceutical companies were permitted to patent drug manufacturing processes, significantly impacting innovation and market exclusivity.
- Large pharmaceutical companies have increasingly invested in research and development (R and D) facilities to discover novel drug molecules. However, frequent global updates and evolving standards related to Good Manufacturing Practices (GMP)**,** Good Clinical Practices (GCP), and Good Laboratory Practices (GLP) have created ongoing challenges in licensing and quality compliance.
- Issues related to marketing authorization and patent protection continue to affect the industry. For example, in 2017, the Indian Patent Office granted a patent to the U.S.-based pharmaceutical company Pfizer for Prevenar 13 (a pneumococcal vaccine). This authorization provided exclusive marketing rights in India until 2026, thereby restricting domestic manufacturers from producing generic versions of the vaccine for export.

FUTURE PROSPECTS AND OPPORTUNITIES

India operates one of the world's largest public healthcare programs, serving nearly 500 million citizens, as announced in the Union Budget 2018. The flagship healthcare initiative, "Ayushman Bharat (formerly referred to as Namocare)", covers approximately 40% of the Indian population, significantly expanding access to healthcare services. To support this initiative, the Government of India has proposed major reforms in the Drug Price Control Order (DPCO) and is expected to introduce a new comprehensive pharmaceutical policy. This policy aims to support the successful implementation of national missions such as PHARMA 2020 by integrating and harmonizing critical components including manufacturing, research and development, financing, quality assurance, drug regulation, price control, and medical devices. Indian pharmacists and regulatory professionals remain committed to prioritizing patient safety and public health. They continue to advocate for stronger, more transparent, and patient-centric regulatory frameworks to ensure the sustained growth and global competitiveness of the Indian pharmaceutical industry[11,12].

CONCLUSION

Drug Regulatory Affairs (DRA) is a rapidly evolving and stable field that plays a crucial role in pharmaceutical and healthcare product development. It supports the safe, effective, and timely introduction of medicines to the market while contributing to industrial growth. Regulatory authorities worldwide, including CDSCO and DCGI in India, ensure that drugs comply with established standards of quality, safety, and efficacy through strict regulatory guidelines, thereby protecting public health.

ABSTRACT

A simple, selective RP-HPLC method was developed for the simultaneous estimation of the Pregablin & Etoricoxib in bulk and its pharmaceutical dosage form. The method was developed on Waters X-Terra RP-C18 column capacitate 150X4.6mm, 3.5µm particle size, wavelength was fixed at 214 nm with PDA detector. The mobile phase was composed with Acetonitrile: 1% TEA in the ratio of 50:50 V/V and flow rate of mobile phase was fixed 1 mL/min. The retention times of Pregablin and Etoricoxib were found to be 2.9 and 3.8 min. The method was statistically validated with concern of selectivity & specificity, linearity, precision, accuracy, LOD & LOQ and robustness. The linearity concentration of the solution from 18.75 µg/mL – 112.50 µg/mL and R^2 value was found to be 0.999. The method was afforded excellent % recovery were found to be 98 %- 98.8 % for Pregablin & 100.01 % -101% for Etoricoxib respectively. The % RSD values of precision study were found to be <2. The LOD and LOQ values are 2.25µg/mL – 7.5 µg/mL for Pregablin & 1.8 µg/mL - 6 µg/mL for Etoricoxib. The method was proved as robust after slight changes to method parameters. The acid, base, peroxide, thermal, and hydrolytic forced degradation studies were conducted on the drugs, and the method proved stable.

Keywords: Pregabalin, Etoricoxib, Triethanol amine, RP-HPLC Method

INTRODUCTION

Etoricoxib (5-chloro-2-[6-methyl pyridine -3-yl]-3-[4-methyl sulfonyl phenyl] pyridine) is a potent COX-2 inhibitor and non-steroidal anti-inflammatory medication that is taken orally as an analgesic and anti-inflammatory(1-5). Etoricoxib (Fig.1) is a highly selective COX-2 inhibitor (coxib) that has been licensed in Europe for the treatment of acute gouty arthritis, rheumatoid arthritis, and osteoarthritis (OA) (4,5). The only coxib authorized for the treatment of acute gouty arthritis is etoricoxib, a potent analgesic medication that has demonstrated some enhanced efficacy over conventional NSAIDs (6,9). COX1 activity in circulating platelets and stomach biopsies is unaffected by the administration of therapeutic doses of etoricoxib to healthy individuals. Antidepressants (5,12), different anticonvulsants, opioids, and cannabinoids are used to treat central neuropathic pain (central pain), however these treatments are frequently ineffective and come with a number of side effects (12-15). Pregabalin (Fig.2), also referred to as (S)-2(aminomethyl)-5-methylhexanoic acid, is a neurotransmitter and anticonvulsant (15-17). The anticonvulsant pregabalin, a novel therapy for neuropathic pain (18&19). Similar to gabapentin, pregabalin is an antiepileptic medication that works by attaching itself to the voltage-gated calcium channels' alpha2-delta ($\alpha 2\delta$) subunit (20-22). Stability analysis of a medicine can be used to estimate the impact of temperature and humidity variations that may arise during drug product transportation (41-42). Different RP-HPLC methods, were reported on pregabalin & etoricoxib, individuall and few combined dosage forms with other drugs (23-37). The combined formulation of pregabalin & etoricoxib (38-40) estimated by the simultaneous RP-HPLC method and validated according to ICH guidelines.

MATERIALS AND METHODS

The PBL and ETC gift samples were kindly supplied by Mumbai, India-based Ajanta Pharma LTD. We purchased methanol, acetonitrile, and triethanolamine of High-Performance Liquid Chromatography (HPLC) quality from Rankem Chemicals in Mumbai. Furthermore, we purchased analytical grade hydrogen peroxide (H_2O_2), sodium hydroxide (NaOH), and hydrochloric acid (HCl) from Rankem Chemicals. We bought the tablet dosage form under the brand name Presidio from the neighborhood pharmacy. It contains 75 mg of PBL and 60 mg of ETC, according to the label. A Millipore Milli Q water purification system was used to provide high-purity water. Every chemical employed in this investigation was either LC or analytical grade.

Instrumental Conditions of HPLC

Data was collected utilizing an Alliance HPLC machine from Waters e 2695, based in Milford, MA, USA. The system has a model 2996 PDA detector and used Empower software for operation and analysis. The Waters C18 Column (150 mm×4.6 mm inner diameter, 3.5 µm particle size) was used for HPLC separation of the two drugs. The mobile phase was an isocratic mixture of Acetonitrile: 1% TEA (in the ratio of 50:50 v/v) and flowed at 1.0 ml/min. The column was run at ambient temperature. The PDA detector was used to monitor both drugs at an isosbestic wavelength of 214 nm. Before use, the solvents underwent filtration through a 0.22 mm membrane filter and were degassed using an ultrasonic bath.

Preparation of standard solutions

A carefully prepared mixed stock solution containing 75 µg/ml of PBL and 60 µg/ml of ETC was used to create the standard solutions. 75 mg of PBL and 60 mg of ETC had to be precisely weighed before being added to a 100 ml volumetric flask. The contents of the flask were then completely dissolved by adding 20 ml of solvent (acetonitrile:1%TEA (50: 50 V/V)) and using sonication. Using the same solvent, the flask's capacity was meticulously adjusted to the mark. Consequently, a stock solution containing 750 µg/ml of PBL and 600 µg/ml of ETC was present in the flask. Aliquots of this mixed standard solution were put into 100 ml volumetric flask. Further, 5 ml of the stock solution was pipetted out and transferred into a 50 ml volumetric flask, and the volume was made up to the mark. The concentrations of PBL & ETC acquired were75 µg/ml & 60 µg/ml.

Preparation of sample solution

Weigh and transfer 228 mg of pregabalin and etoricoxib to a 100 mL clean, dry volumetric flask. Add diluent and sonicate for 30 minutes to dissolve the sample completely. Fill the flask to the mark with solvent. The fluid is then filtered using a 0.45 micron injection filter (stock). Pipette 5 mL of the aforementioned stock solutions into a 50 mL volumetric flask and dilute to the mark with diluents. (75 µg/mL of pregabalin and 60 µg/mL of etoricoxib)

Method Validation

The chromatographic method was validated in accordance with the ICH Guidelines, Q2 (R1) 2005. (41,42)

System suitability

The system performance was confirmed through evaluation of suitable parameters. Six injections of the same standard preparation were used to evaluate precision, focusing on peak area, resolution, and theoretical plate number.

Accuracy

Recovery studies were undertaken at three levels to ensure accuracy: 50%, 100%, and 150% of the target concentration. The method accuracy was evaluated by analyzing chromatograms.

Precision

Six replicate injections of optimum concentrations of pregablin andetoricoxib were used to validate the analytical technique of intraday and interday precision levels. The chromatograms were used to generate averages and percentage RSD (Relative Standard Deviation) for peak area and assay.

Specificity

The method's specificity was tested by introducing a placebo solution (blank) without PGL and ERC, as well as a standard solution with concentrations of 75 µg/ml for pregabalin and 60 µg/ml for Etoricoxib, into the HPLC system. Formulations were evaluated, and chromatograms were generated to assess specificity.

Linearity

Linearity was validated by producing and evaluating pure analytical standards at five concentration levels. The new approach shown high linearity in concentration ranges of 18.75, 37.50, 56.25, 75.00, and 93.75 µg/ml for PGL and 15.00, 30.00, 45.00, 60.00, and 75.00 µg/ml for ERC.

LOD and LOQ

The LOD and LOQ for PGL and ERC were determined using the response's SD and slope. The limit of detection (LOD) was calculated as 3.3 times the SD divided by the slope, whereas the LOQ was 10 times the SD divided by the slope.

Robustness

The method's robustness, defined as its capacity to survive slight but purposeful changes in chromatographic conditions, was evaluated. The research assessed the influence of minor changes in the mobile phase flow rate (±0.2 units), organic phase (±5 ml), and wavelength (±2%).

Stress studies

We conducted stress testing to assess the stability of active compounds in accordance with ICH standards for novel medical substances and products. As part of this project, stress degradation studies on PGL and ERC were carried out using the described approach.

Acidic degradation studies

A technique was employed to investigate how acidic conditions influenced PGL and ERC. 5ml of the primary stock solution was initially put into a 50ml flask. To create an acidic atmosphere, add 1mL of 0.1N HCl to one of the standard flasks. The contents of the flask were then brought up to the mark with the mobile phase and refluxed at 70°C for 3 hrs. After cooling, 1ml of 0.1N NaOH was added to neutralize the acidic solution. The resulting solution was filtered through a 0.22mm syringe filter before being injected into the HPLC system for analysis.

Alkaline degradation studies

A 5ml of the primary standard solution was combined with 3ml of 0.1N NaOH in a 50ml volumetric flask to investigate the effect of alkaline condition. The mobile phase was then used to adjust volume. These standard flasks were heated twice, once at 60°C and again at 50°C. After the final solution had cooled to room temperature, 3ml of 0.1NHCl was added to neutralize the base. After being filtered using a 0.22mm syringe filter, the solution was loaded into vials for analysis in the HPLC system.

Peroxide degradation studies

A 5ml of the primary stock solution and 1ml of 3% (w/v) hydrogen peroxide were combined in a 25ml standard flask to conduct oxidative degradation investigations. Diluents were added to achieve concentrations of 75 µg/ml for PGL and 60 µg/ml for ERC. After that, the flask was stored at room temperature for six hours. The resulting solution was filtered using a 0.22mm syringe filter before being introduced into the HPLC machine for analysis.

Thermal induced degradation

To study thermally induced deterioration, 5ml of the primary stock solution was transferred to a 50ml standard flask and refluxed at 80°C for 9 hours. The sample was diluted with diluents (mobile phase) and adjusted to a total volume of 50 ml, yielding concentrations of 75 µg/ml for PGL and 60 µg/ml for ERC.After cooling to ambient temperature, the solution was filtered through a 0.22mm syringe filter before being fed into the HPLC system for analysis.

Photo degradation

A 5ml of the primary stock solution was pipetted into a 50ml standard flask to assess the effects of photodegradation.The concentrations of PGL and ERC were 75 µg/ml and 60 µg/ml respectively.These samples were exposed to 1.2 million lux and 200 Wh/m 2 of UV radiation for 30 minutes in a photostability chamber.The solution was then filtered through a 0.22mm syringe filter and placed in vials for HPLC system analysis.

RESULTS AND DISCUSSION

System suitability studies

A system suitability test was performed to ensure the analytical method's accuracy and validity. We carefully examined numerous essential parameters, such as theoretical plate number (N), resolution, retention time (Rt), and tailing factor. Table 1 summarises the findings of this analysis. To test the method's specificity, several solutions were added to the HPLC system, including a blank solution,PGL , and ERC standards at concentrations of 75 and 60 µg/ml, respectively, as well as the formulations under examination. During this study, no visible peaks were found in the blank solution, and the Rt values for the standards and samples were consistent. Representative chromatograms of these results are shown in Figures

Linearity

To establish the method linearity, linearity curves were generated by graphing peak area on the X-axis versus drug concentrations on the Y-axis. Regression equations were computed using these curves.The linearity of the techniques was found between 18.75 and 112.50 µg/ml for PBL and 15 and 90 µg/ml for TRC. Figures 3 shown visual presentations of the linearity curves for PBL and TRC, respectively.

Precision

The method precision was evaluated using intraday and interday changes with concentrations of 75 µg/ml for PBL and 60 µg/ml for TRC. This assessment required six replicate injections at each concentration level. The inter- and intraday accuracy of PBL were found to be 1.05% and 0.34%, respectively. In contrast, TRC inter and intraday precision were 1.06% and 0.32%, respectively.

Accuracy

The approach was evaluated at three distinct levels of accuracy: 50%, 100%, and 150%. Table 2 provides a summary of the results.At these levels, the average percentage recoveries for PBL & TRC were 100.29%, 99.62%, and 99.78%, respectively. This suggests that the approach can yield consistent results at a variety of concentrations.

Limit of detection (LOD) & Limit of quantification (LOQ)

Calculating the LOD (Limit of Detection) and LOQ (Limit of Quantification) values helped us assess the method sensitivity. The LOD and LOQ for PBL were found to be 2.25 and 7.5 µg/ml, respectively. The ERC has LOD and LOQ values of 1.8 µg/ml and 6 µg/ml, respectively.

Robustness

The robustness investigation revealed negligible differences in chromatograms when compared to optimum conditions. The study findings are reported in Table 3.

Assay

The proposed approach successfully quantified analytes in tablet formulations. The average assay (Table 4) for PBL and TRC was 99.22% and 100%, respectively.

Forced degradation studies

Forced degradation studies were conducted to evaluate method specificity in the presence of degradation products, including bulk and pharmaceutical dose forms. These studies investigated five distinct stress conditions. The analyte's ionizable groups may have catalyzed the degradation. Several degradation products were detected in both acidic and alkaline environments, but no further peaks were seen within the Rt of PBL and TRC. Both drugs shown considerable deterioration in acidic and alkaline environments. Oxidative degradation investigations discovered three degradation products, although none were found in the Rt of PBL and TRC. Photolytic stress can lead to deterioration by photooxidation or free radical processes. The Arrhenius equation can describe degradation under hydrolytic stress conditions. Table 5 summarizes the outcomes of various stress conditions. The PBL and TRC are subject to stress conditions, but remain stable with the proposed approach for a given period.

DISCUSSION

Using the Acquity HPLC system in this investigation resulted in significant cost savings and time efficiencies. The development of a simple, cost-effective, and precise HPLC approach for concurrent quantification in pharmaceutical formulations is crucial given the growing global demand for these drugs. This technology improves productivity and reduces costs in pharmaceutical quality control labs by making routine drug analysis easier. The HPLC approach was extended to investigate drug degradation under various stress situations. This detailed analysis confirms the method's specificity and provides insights into drug stability profiles, ensuring the safety and efficacy of pharmaceutical products. This aligns with drug production and quality control laws, improving overall quality assurance standards in the pharmaceutical business. The goal of this research was to create an analytical method for measuring PBL and TRC using HPLC-PDA chromatography. The approach was meticulously optimized, resulting in much lower Rts of 2.931 min for PBL and 3.883 min for TRC. The optimization procedure resulted in high sensitivity, well defined peak forms, and appropriate resolution. The PDA detector, with a particular wavelength of 285 nm,

improved detection sensitivity across all analytes. The sensitive equipment significantly reduced analysis time to as little as 6 minutes. These optimized conditions were used in validation experiments. The current approach is accurate, with all analytes recovering within acceptable ranges. The method's precision was confirmed by achieving % RSD values of less than 2% in both intra and interday precision studies. The high Performance liquid chromatography system is suitable for assessing all medicines, as shown in the system suitability study (Table1), with %RSD values < 2% across all parameters. The LOD and LOQ studies highlighted the method's high sensitivity, while the robustness study found that deliberate changes to factors such as flow rate and organic phase had no significant impact on the results. The marketed formulation's % assay yielded values of 99.10% for PBL and 100.10% for ERC, validating the efficiency of the test procedure.

This method is unique and provides benefits in terms of speed and cost-efficiency, as supported by empirical evidence. By decreasing analysis time to 6 minutes and replacing expensive acetonitrile with tri ethanol amine, this solution is cost-effective. Furthermore this approach is highly sensitive, with low detection and quantification limitations. The validation parameters provided findings within the ICH Q2B guidelines, indicating reliability and suitability for pharmaceutical analysis.

CONCLUSION

The HPLC method is reliable, reproducible, accurate, and specific for measuring pregabalin and etoricoxib in bulk and tablet formulations. This newly validated approach meets regulatory standards for accuracy, precision, and sensitivity. Therefore ,this method is suitable for routine analysis of selected pharmaceuticals in Quality Control laboratories.

ACKNOWLEDGEMENTS

The authors thank Ajanta Pharma LTD, Mumbai, India, for generously supplying gift samples of the active pharmaceutical components. The authors are grateful to Dattakala Institute of Pharmaceutical Science & Research, Bhigwan, for providing necessary equipment and resources for this study.

ABSTRACT

The non-homogeneous fifth degree Diophantine equation with five unknowns$3(x^4+y^4)=26(z^2-w^2)m^3$ is consider and analyzed for its non-zero distinct integer solutions. "If its perceive that by applying the linear transforms x=u+v, y=u-v z= 12u+v, w = 12u-v ($u\neq 0 v\neq 0$)in the stated equation one may get infinitely many non-zero integer solutions. similarly, one can introduce some other transforms to obtained different non zero integer solutions. Further, we explain an idea of linear Diophantine equations are applied to get the chemical equation.

Keywords: Non-homogeneous fifth degree equation, Polygonal number, pyramidal number, integer solutions, Diophantine equation, Chemical equations, input, output, reactants, products.

INTRODUCTION

The fifth degree Diophantine equation offer an limitless area of research due to this variety [1-3,12,13], for an huge of many problems on fifth degree equation with three unknows one may refer [4 and 5]. In [6,9,7] fifth degree equation with five unknows equation with are consider Chemical equations is chemistry are used as illustrative representations of chemical Reactions in which the reactants and the products are wrote down in terms of the relevant chemical formulae. In [8] studied the chemical using Diophantine equation and [9, 10 and 11] find solution for various applications.

Notations

Pr_n = Pronic integer number of order n.
CS_n= centered integer square number of order n
CH_n=centered hexagonal integer number of order n.
J_n = Jacobsthal integer number of order n.
j_n=Jacosthal lucas integer number of order n.
M_n = Mersenne integer number of order n.
P_n^5 =Pentagonal pyramidal integer number of order n
HG_n= Hexagonal integer number of order n
OH_n = octahedral integer number of order n
PP_n = Pentagonal pyramidal integer number of order n
SO_n=Stella octangular integer number of order n
$T_{7,n}$ =Heptagonal integer number of order n
$T_{8,}$ = Octagonal integer number of order n
$T_{9,n}$ = Nanogonalinteger number of order n
$T_{17,n}$ =Heptradecagonal integer number of order n
GnO_n = Gnomonic integer number of order n
$T_{3,n}$ = Triangular integer number of order n

METHODS OF ANALYSIS

The non-homogeneous fifth degree equation with five unknowns under consideration is $3(x^4+y^4)=26(z^2-w^2)m^3$…….(1)

Pattern 1

The substitutions of the linear transforms

$x=u+v$
$y=u-v$
$z=12u+$ u …….(2) (u≠v ≠ 0)
$w=12u-v$

In (1) leads to

$u^2+v^2=52m^3$ …….(3)

Assume $m = m(a, b)=a^2+b^2$ …….(4)

Where a and bare non-zero distinct integers.

Choice 1

Write 52 as (4+6i)(4-6i) …….(5)

Equation (3) becomes

$(u+iv)(u-iv)=(4+6i)(4-6i)(a+ib)^3(a-ib)^3$ ……..(6)

Let positive generate,

$(u+iv)=(4+6i)(a+bi)^3$

Equating both the real and imaginary parts in (6) we get,

$u=4a^3+6b^3-18a^2b-12ab^2$
$v=6a^3-4b^3+12a^2b-18ab^2$

The employing value of u and v in equation (2), we get

x (A, B)$=10a^3+2b^3-6a^2b-30ab^2$
y (A, B)$=-2a^3+10b^3-30a^2b+6ab^2$
z (A, B)$=54a^3+68b^3-204a^2b-162ab^2$
w (A, B)$=42a^3+76b^3-228a^2b-126ab^2$

m (A, B)=a^2+b^2

PROPERTIES

1. $x(a,a+1)+48PP_a{}^5 + 12T_{4,a} + 24Pr_a - 2 = 0$
2. $y(a,2a-1)-63OH_n + 69T_{4,a} + 90T_{3,a} + 10 = 0$
3. $z\ (a,3a-2)+360PP_a + 380CH_a \equiv 164(mod660)$
4. $w(a,a+1)+44T_{7,a} + 252T_{4,a} \equiv 76(mod36)$
5. $m(a,13a-12)-85T_{6,a} \equiv 144(m0d227)$
6. $x(a,3a-1)+36OH_a+220cubic-132T_{4,a}+2=0$
7. $y(a,7a-5)-1518OH_a+1582T_{4,a}+1144T_{6,a}-1250CC_a=0$
8. $z\ (a,a+1)+278PP_a+122T_{4,a}+126P^7-68=0$
9. $w(a,2a-1)-459\ OH_a-27\ T_{4,a}+330a-76w(a,2a-1)+45OH_a+27T_{4,a}\equiv76(mod330)$
10. $m(a,3a-2)-3CH_a-T_{4,a}\equiv1(mod3)$

CHOICE 2

Write 52 as (6+4i)(6-4i) …….(7)

Equation (3) becomes

$(u+iv)\ (u-iv) =(6+4i)\ (6-4i)\ (a+ib)^3(a-ib)^3$ …….(8)

Let positive generate,

$(u+iv)=(6+4i)\ (a+bi)^3$

Equating both the real and imaginary parts in (8) we get,

$u=6a^3+4b^3-12a^2b-18ab^2$

$v=4a^3-6b^3+18a^2b-12ab^2$

Substituting u and v in (2), we get,

x (A, B)=$10a^3-2b^3+6a^2b-30ab^2$

y (A, B)=$2a^3+\mathbf{10}b^3-30a^2b-6ab^2$

z (A, B)=$76a^3+42b^3-126a^2b-228ab^2$

w (A, B)=$68a^3+54b^3-162a^2b-204ab^2$

m (A, B)=a^2+b^2

PROPERTIES

1. $x\ (a^2, a+1)-(120F_{4,a)T_{4,a}} - (3SO_a\ )T_{4,a} + 14T_{4,a^2} + 23cubic + 72P_{5,a} = 0$
2. $y\ (a,7a-5)=-428O_a + 1326T_{4,a} + 568T_{8,a} - 1250CC_a = 0$
3. $z(a,2a-1)= 24So_4 + (352GNO_4)T_{4,a} + 42 = 0$
4. $w\ (a,a+1)+488PP_a+164T_{4,a}\equiv54(mod42)$
5. $m(a,19a-17)-48T_{17,a}-2T_{4,a}\equiv289(mod334)$
6. $x(a,5a-3)+960cubic-252T_{4,a}-540HG_a-M_5-23=0$
7. $y\ (a,3a-1)-128cubic+76T_{4,a}64T_{6,a}=10HG$
8. $z(a,2a^2+1)-(112T_{8,a})\ T4,\ a2+(168T_{7,a})cubic+(402OH_a)T_{4,a}+702cubic-126T_{4,a}\equiv42(m0d228)$
9. $w(a,13a-11)-123186OH_a+241032T_{4,a}\equiv71874(mod189080)$
10. $m(a,17a-15)-72TT_a-17T_{4,a}\equiv105(mod186)$

Pattern 2

Write 52 as $\frac{(12+34i)(12-34i)}{25}$ ……..(9)

Equation (3) becomes

$(u+iv)(u-iv)= \frac{(12+34i)(12-34i)}{25}(a+ib)^3(a-ib)^3$ …….(10)

Let positive generate,

$(u+iv) = \frac{(12+34i)}{5}(a+ib)^3$

Equating both the real and imaginary parts in (10) we get,

$u = \frac{1}{5}(12a^3 - 102a^2b - 36ab^2 + 34b^3)$

$v = \frac{1}{5}(34a^3 + 36a^2b - 102ab^2 - 12b^3)$

The employing value of u and v in (2),we get

$x = \frac{1}{5}(46a^3 - 66a^2b - 138ab^2 + 22b^3)$

$y = \frac{1}{5}(-22a^3 - 138ab^2 + 66ab^246b^3)$

$z = \frac{1}{5}(178a^3 - 1188a^2b - 534ab^2 + 396b^3)$ ...……(11)

$w = \frac{1}{5}(110a^3 - 1260a^2b - 330ab^2 + 420b^3)$

$m = a^2+b^2$

As our aim, we made choicea=5A,b=5B in (11), we obtain the non -zero integer solution to (1) as

x (A, B) $=1150A^3-1650A^2B-3450AB^2+550B^3$

y (A, B)$=-550A^3-3450A^2B+1650AB^2+1150B^3$

z (A, B)$=4450A^3-29700A^2B-13350AB^2+9900B^3$

w (A, B)$=2750A^3-31500A^2B-8250AB^2+10500B^3$

m (A, B)$=25(A^2+B^2)$

PROPERTIES

1. $x(A,A+1)+21600TH_A-5000PP_A-1700T_{4,A}+j_9+39 = 0$
2. $y(A,2A-1)-1150CC_A+9000T_{5,A}-1800OH_A-4850cubic=0$
3. $z(A,3A-1)-62500cubic+51300T_{4,A}+30450T_{8,A}+9900CT_A=0$
4. $w(A,5A-3)-475750SO_A+1599800T_{4,A}+120200T_{9,A}-283500GNO_A=0$
5. $m(A,21A-19)-850S_A-2380T_{7,A}\equiv 50(mod 11280)$
6. $x(A,2A-1)+23100PP_A+7200T_{4,A}\equiv 550(mod 150)$
7. $y(A,7A-5)-143750CC_A-163100cubic+84715T_{4,A}+213785\ T_{6,A}=0$
8. $z(A^2,A+1)-(1780T_{7,A})T4,A2+(27030PP_A)T_{4,A}+T4,A2+16800cubic \equiv 9900(mod 29700)$
9. $w(A,A+1)+13250SO_A-16500T_{4,A}\equiv 10500(mod 10000)$
10. $m(A,15A-13)-2825HG_A-M_{12}\equiv 130(mod 6925)$

Choice 1

Write 52 as $\frac{(34+12i)(34-12i)}{25}$ ……(12)

Equation(3)becomes

$(u+iv)(u-iv) = \frac{(34+12i)(34-12i)}{25}(a+ib)^3(a-ib)^3$ ……(13)

Let positive generate,

$(u+iv) = \frac{(34+12i)}{5}(a+ib)^3$

Equating both the real and imaginary parts in (13) we get,

$u = \frac{1}{5}(34a^3-36a^2b-102ab^2+12b^3)$

$v = \frac{1}{5}(12a^3+102a^2b-36ab^2-34b^3)$

The employing value of u and v in (2), we get

$x = \frac{1}{5}(46a^3 + 66a^2b - 138ab^2 - 22b^3)$

$y = \frac{1}{5}(22a^3 - 138\ a^2b - 66ab^2 + 46b^3\ )$

……..(14)

z =$\frac{1}{5}(420a^3 - 330a^2b - 1260ab^2 + 110b^3)$

w = $\frac{1}{5}$ $(396a^3 - 534a^2b - 1188ab^2 + 178b^3)$

$m=a^2+b^2$

As our aim, we made choicea=5A,b=5B in (14),we obtain the non zero integer solution to (1) as

x (A, B)=$1150A^3+1650A^2B-3450AB^2-550B^3$

y (A, B)=$550A^3-3450A^2B-1650AB^2+1150B^3$

z (A, B)=$10500A^3-8250A^2B-31500AB^2+2750B^3$

w (A, B)=$9900A^3-13350A^2B-29700AB^2+4450B^3$

m (A, B)=$25(A^2+ B^2)$

PROPERTIES

1. x $(A,3A-2)+597000O_A-8400T_{4,A}\equiv 4400(mod 13700)$
2. y$(A,7A-5)-143750CC_A-76200OH_A+69550T_{4,A}+105850HG_A=0$
3. $z(A,2A-1)=15000OH_A+160000PP_A-181250T_{4,A}+ 3J_{11}+701=0$
4. w $(A,3A-1)+10350SO_A+(71400GNO_A)T_{4,A}+13800cubic+j_{12}+353=0$
5. m $((A^2+A),(A^2+5A+6))=m((A^2+A),(A^2+5A+6))-100PT_A-160CP_A\equiv 740(mod 1070)$
6. $x(A,5A-3)+218400O_A-222300T_{4,A}\equiv 14850(mod 32500)$
7. y $(A,A+1)+5100P^6+750T_{4,A}\equiv 1150(mod 950)$
8. z $(A,3A-2)+223500cubic-13500T_{8,A}-205500T_{4,A}\equiv 22000(mod 27000)$
9. w $(A,2A-1)+100000PPA+58850T4,A\equiv 4450(mod 3000)$
10. $m(A,7A-5)-625T_{6,A}\equiv 25(mod 125)$

Pattern 3

$u^2+v^2=52m^3*1$ ……(15)

Write 1 as$\frac{(12+5i)\ (12-5i)}{169}$ ……(16)

Using (4), (5) and (16) in (15) and applying in method of factorization, we made define

Equation(3)becomes

$(u+iv)(u-iv)=(6+4i)(6-4i)\frac{(12+5i)(12-5i)}{169}$ $(a + bi)^3(a - ib)^3$ ……..(17)

Let positive generate,

$(u+iv)=(6+4i)\ \frac{(12+5i)}{169}\ (a + bi)^3$ ……..(18)

*E*quating both the real and imaginary parts in (17) we get,

u =$\frac{1}{13}(52a^3 - 234a^2b - 156ab^2 + 78b^3)$

v =$\frac{1}{13}(78a^3 + 156a^2b - 234ab^2 - 52b^3)$

The employing value of u and v in (2), we get

x =$\frac{1}{13}(52a^3 - 234a^2b - 156ab^2 + 78b^3)$

y=$\frac{1}{13}(-26a^3 - 390a^2b + 78ab^2 + 130b^3)$ ……(19)

z=$\frac{1}{13}(702a^3 - 2652a^2b - 2106ab^2 + 884b^3)$

As our aim, we made choice a=13A,b=13B in (19), we obtain the non zero integer solution to (1) as

x(A,B)=$21970A^3-13182A^2B-65910AB^2+4394B^3$

y (A, B)= $-4394a^3 - 65910A^2B - 13182AB^2 + 21970B^3$

z (A, B) =$118638A^3-448188A^2B-355914AB^2+149396B^3$

w (A, B)=$92274A^3-500916A^2B-276822AB^2+166972B^3$

$m=25(A^2+B^2)$

PROPERTIES

1. $x(A^2,A+1)-(263640FN^4)T_{4,A}+(39546SP_A)T_{4,A}-83556T_{4,A^2}+(120905Pr_A)T_{4,A}+52728T_{4,A}\equiv 4394(\text{mod}13182)$
2. $y(A,A+1)+17576SO_A-13182CS_A\equiv 8788(mod87880)$
3. $z(A,3A-1)+197730SO_A+725010HG_A+M_{17}\equiv 18325(mod65910)$
4. $w(A,2A-1)+790920P^7+10985SO_A\equiv 166972(mod450385)$
5. $m(A,23A-21)-2000T_{15,A}-100T_{7,A}\equiv 11025(mod13000)$
6. $x(A,7A-5)+896376SO_A+553644T_{4,A}\equiv 54920(mod659100)$
7. $y(A,3A-2)-509704cubic+210912T_{4,A}+158184T_{8,A}+175760CH_A=0$
8. $z(A,2A-1)+503113SO_A-79092T_{4,A}\equiv 149396(mod37349)$
9. $w(A,A+1)w(A,A+1)+518492cubic-224094Pr-329550T_{4,A}-M_{17}-35901=0$
10. $m((A^2+A),(A+2))-25T_{4,A^2}-100P_{A^5}\equiv 100(mod100)$

APPLICATION

Balancing chemical equations:

Example: 1

Consider the chemical reaction,

$aHgcl_2 + bkI \rightarrow a'HgI_2 + b'kcl$ ……(1)

Which leads to the equations

$2a = b'$ for k
$b = b'$ for H } ……(2)

In an earlier part system of equations could be easily reduced is $2a - b = 0$, is a linear Diophantine equation with a Solutions $[a, b] = [1,2]$

Hence, $[a, b, a', b'] = [1,2,1,2]$

As a result, equation (1) be becomes

$Hgcl_2 + 2kI \longrightarrow HgI_2 + 2kcl$

Example: 2

Consider the chemical reaction,

$aCH_3COOH + bkNO_2 \rightarrow a'CH_3COOk + b'HNO_2$ …… (3)

Which leads to the equations

$2a = 2a'$ for C
$4a = 3a' + b'$ for H
$2a + 2b = 2a' + 2b'$ for O } ……..(4)
$b = a'$ for k

In an earlier part system of equations could be easily reduced is $a - b = 0$, is a linear Diophantine equation with a Solution $[a, b] = [1,1]$

Hence, $[a, b, a', b'] = [1,1,1,1]$

As a result, equation (3) be becomes

$CH_3COOH + kNO_2 \rightarrow CH_3COOk + HNO_2$

Example: 3

Consider the chemical reaction,

$aBr_2 + bH_2O \rightarrow a'HBr$ ……(5)

Which leads to the equations

$2a = a'$ for Br
$2b = a'$ for H } ……(6)
$b = 1$ for O

$a - b = 0$, is a linear Diophantine equation with a solution $[a, b] = [1,1]$
Hence, $[a, b, a'] = [1,1,2]$
As a result, equation (5) he becomes
$Br_2 + H_2O \rightarrow 2HBr$

Example: 4
Consider the chemical reaction,
$aNi + bCO \rightarrow a'NiCO_4$ ……(7)
Which leads to the equations
$a = a'$ for Ni
$b = a'$ for C
$b = 4a'$ for O } ……(8)
In an earlier part system of equations could be easily reduced is $b - 4a = 0$, is a linear Diophantine equation with a Solutions $[a, b] = [1,4]$
Hence, $[a, b, a'] = [1,4,1]$
As a result, equation (7) be becomes
$Ni + 4CO \rightarrow NiCO_4$

Example: 5
Consider the chemical reaction,
$aCOCl_2 + bkNO_2 \rightarrow a'CO(NO_2)_2 + b'kCl$ ……..(9)
Which leads to the equations
$a = a'$ for C
$a + 2b = 5a'$ for O
$2a = b'$ for Cl
b=b' for k
$b = 2a'$ for N } ……(10)
In an earlier part system of equations could be easily reduced is $b - 2a = 0$, is a linear Diophantine equation with a Solutions $[a, b] = [1,2]$
Hence, $[a, b, a', b'] = [1,2,1,2]$
As a result, equation (9) be becomes
$COCl_2 + 2kNO_2 \rightarrow CO(NO_2)_2 + 2kCl$

CONCLUSION

In this paper the order to get distinct integer" solutions, set of transformations and patterns have been taken into consideration. Io find different integer solutions, one may of some other set of transformation and patterns. And also in this paper, we assume that the linear Diophantine equation in chemical equation significant role in chemical equation.

ABSTRACT

In the modern era, information seeking behaviour is increasing day and day. The ancient or traditional library management and services are not enough to satisfy the knowledge sector of the user. So the emerging of new technological innovations are necessary to provide the right information to the right users in the right time. This paper deals with the recent emerging innovations in the information technology and how they are useful to provide the effective services of the library.

Keywords: Information Seeking Behaviour; Technology;Network Services; Innovative Methods.

INTRODUCTION

In the emerging knowledge society, libraries have faced many challenges in satisfying users' needs over the past few decades. New technologies are being used to improve library services and management, as well as to preserve library materials for the long term, because libraries contain the living records of human civilization. These records are treasures for future generations. In this changing scenario, Information and Communication Technology (ICT) has become the most instrumental factor in providing effective library services.

Innovation

The concept of innovation involves creating or identifying meaningful ideas to solve problems. In other words, it is a significant problem-solving technique. The Online Dictionary of Library and Information Science describes best innovative practices as the application of theory to real-life situations through procedures that, when properly applied, consistently yield superior results and therefore serve as reference points in evaluating alternative methods of accomplishing the same task.

According to Peter Drucker, the father of modern management science, innovation is the specific instrument of entrepreneurship. It is the act that endows resources with a new capacity to create wealth.

Need of Innovative Service

Information seeking is a natural and necessary mechanism of human existence (Marchionini, 1995). It involves personal reasons for seeking information, the kinds of information being sought, and the methods and sources used to obtain the required information. Changes in information-seeking behavior have led to the emergence of innovative technologies in library management and services. The changing needs of users have also transformed the role of the librarian into that of an information professional. Information professionals must act as intermediaries between knowledge sources and information seekers. Common obstacles in the information-seeking process identified by respondents include lack of time, uncertainty about the existence of relevant information, retrieval of excessive information, and difficulties in navigation and searching.

Emerging Innovations

Many innovative technologies are emerging in library management and services in the present era. Libraries adopt technologies according to their infrastructure, type of library, specific needs, geographical location, and the amount of funding allotted by the government.

Some of the specific technological innovations are:

Staff Management
Training Programmes
Resource Sharing and Networking
Library Automation
Open Source Software
Internet Search Engines – Semantic Web
World Wide Web
E-Learning
Web 2.0
Digitalization

Staff Management

For effective and innovative library services, librarians and library staff members should possess high-level skills and updated knowledge of technological advancements in library science. They should understand users' requirements and strive to meet their expectations. Librarians are also responsible for resolving problems faced by staff members due to technical inexperience and ensuring that services remain user-friendly. They should promote portable qualifications aligned with nationally recognized competency standards within a competency-based assessment system. It is recognized that learning can occur through various sources, both on-the-job and off-the-job, and through formal as well as informal methods. System management defines how different systems within the library are interconnected with one another and with external networks.

Training Programmes

The goal of training programmes is to motivate professional staff and learners to enhance their skills and update their knowledge. These programmes help learners improve their information-seeking behavior, understand the number of volumes available in a particular library, know the working hours, identify the type of library, and become aware of the services provided. Such initiatives help create a user-friendly environment and enable users to obtain the right information at the right time.

Resource Sharing and Networking

Resource sharing refers to the sharing of library resources in terms of documents, manpower, services, and equipment among participating libraries based on the principle of cooperation. Networking involves connecting information centers or libraries to function cooperatively. The objectives of resource sharing are to create an environment in which libraries can provide better services and more materials at the same cost. The main objectives are:

To improve the utilization of resources among users
To minimize costs
To maximize accessibility of resources
To extend the availability of resources

Library Automation

According to Webster's Dictionary, automation is the technique of making an apparatus, process, or system operate automatically. In other words, it refers to machinery that systematically stores, selects, processes, presents, and records input data or internally generated data. Automation is used to perform technical processes automatically.
Library automation is necessary due to:
Information explosion
Increase in library collections
Users' inability to explore vast amounts of literature and information
Advances in computer and communication technologies
Wastage of user and staff time in locating information
The need to provide wide access to resources within and beyond the library
Proper planning is essential for successful library automation.

Open Source Software

Open Source Software (OSS) is computer software whose source code is made available to users. Users can read, modify, and redistribute the software as they wish.
Open source software satisfies the following criteria:
The source code can be adapted to individual requirements, modified, and shared with others.
The software source code must be openly and easily accessible.
Anyone may use open source software as they desire.

Most projects initially began as classical open source software (OSS) initiatives developed by individual programmers. OSS has made library management and services more effective and efficient.

The Semantic Web – Internet Search Engine

Semantics is the study of linguistic meaning. The term "Semantic Web" was coined by Tim Berners-Lee, the inventor of the World Wide Web and Director of the World Wide Web Consortium. He defined the Semantic Web as a "web of data that can be processed directly and indirectly by machines." The Semantic Web is concerned with the meaning of words, sentences, and other linguistic elements rather than merely their syntactic structure. It promotes open access to information and follows web resource policies aimed at improving information retrieval. Its objectives include:

* Providing relevant information with minimal time spent filtering irrelevant or outdated data sources.
* Helping users obtain required information with accurate linguistic meaning.
The Semantic Web enhances the internet environment and supports web-based learning systems.

World Wide Web

The Web, popularly known as the World Wide Web (WWW), is a major component of the Internet and online communication. The Internet and its "publishing arm," the WWW, play a significant role in the communication process. The Web is a client-server system used to access various kinds of information available on the Internet. This information may be in the form of text, hypertext, images, audio, Usenet newsgroups, and other types of data. Web services provide a distributed information system that allows information sharing among users at any time.

The World Wide Web provides

* A distributed information system
* Receipt and delivery of electronic publications and access to data stored on remote computers
* Online, real-time interaction with other network users
* Equal opportunity of access for all types of users

E-Learning

E-learning is a continuous learning process, especially beneficial for learners who are unable to attend traditional classroom-based education. In earlier distance education models, students learned through nearby libraries or materials sent by course organizers. Modern media such as radio and television were also used in distance learning, though they had certain limitations. The distance learning process has been further strengthened through video conferencing. In this method, a nodal center is equipped with a studio where experts assemble and deliver lectures. This technique creates a classroom-like environment and enables direct interaction between teachers and learners.

E-Documents

There are certain information sources categorized as non-documentary sources, where data is transferred in electronic form rather than in printed format. CDs, DVDs, microfilms, and audiovisual materials are called electronic documents or e-documents. Books available in electronic form are called e-books, and journals available in electronic form are called e-journals. These resources are very useful to users because they can be accessed anytime and anywhere using a computer or digital device. Moreover, they can be preserved for a long period.

Web 2.0 Technology

Web 2.0 has become an important and central concept in the information world. Libraries worldwide are increasingly using various Web 2.0 applications. Librarians use these technologies to promote services, share information, engage with users, and network with colleagues globally. Many libraries use blogs as effective communication tools. Blogs serve as excellent sources of information and provide a platform where librarians can express their opinions and share updates with users.

Digitalization

A library in which data is stored in digital form is called a digital library. The process of converting information into digital format is known as digitalization. This process ensures long-term storage and preservation of information. Digitalization includes retrieving metadata from data files, interpreting the retrieved data in a decoded format, and rendering the data for human access. It is a significant method that enables easy access for users and ensures long-term accessibility of information resources.

CONCLUSION

The successful operation of any library largely depends on the selection of library collections, effective management, and quality services. Therefore, librarians must be well aware of the needs of the user community connected to library resources. Emerging innovative techniques play a vital role in providing the right information to the right user at the right time.

ABSTRACT

Multiple sclerosis (MS) is a complex autoimmune disease that affects the central nervous system, resulting in neurodegeneration and disability. Artificial intelligence (AI) has revolutionized MS research with its innovative approaches to computer-assisted diagnosis, disease monitoring, and customized treatment. This review highlights the use of AI in MS, including deep learning for MRI lesion segmentation, machine learning for biomarker integration, digital twins for disease simulation, and wearable technology for symptom monitoring. By facilitating early diagnosis and individualized treatment plans, AI-driven algorithms transform clinical practice and enhance patient outcomes. AI has shown a lot of promise in the diagnosis of multiple sclerosis, particularly in the areas of MRI lesion segmentation and biomarker integration. Deep learning frameworks like convolutional neural networks (CNNs) have achieved high accuracy in lesion segmentation, while multimodal models created with AI can accurately read difficult biomarker panels, distinguishing multiple sclerosis from other neuroinflammatory diseases. AI-based simulations that use clinical, imaging, and genomic data to predict treatment responses and relapses enable personalized disease modeling and early intervention. In order

to track MS-related mobility impairment and enable timely interventions and early rehabilitation, AI has also been integrated with wearable technology and gait analysis. AI-powered cognitive evaluation and speech recognition tools are evolving into non-invasive MS monitoring methods that enable the early detection of neurodegeneration. AI-driven customized treatment approaches, such as nanotechnology-mediated drug delivery and reinforcement learning-based treatment selection, may enhance the management of multiple sclerosis. However, ethical and regulatory concerns must be addressed prior to broad clinical use. The future of AI in MS research depends on sophisticated AI computations, collaborative multispecialty teamwork, and data-sharing infrastructures that optimize global patient benefit. As this review explores the potential advantages and disadvantages of AI in MS, more research and development are needed to fully realize the benefits of AI in MS diagnosis, monitoring, and treatment. AI has the potential to transform clinical practice and improve patient outcomes, which could have a substantial impact on MS research and treatment in the future.

Keywords: Multiple sclerosis; Artificial intelligence; Biomarker integration; Digital twins; Wearable technology; Personalized medicine; Machine learning

INTRODUCTION

Multiple sclerosis (MS) is a long-lasting autoimmune disorder that impacts the central nervous system (CNS), resulting in neurodegeneration and disability [1]. The intricacy of diagnosing, tracking, and managing MS requires sophisticated computational methods for precision medicine [2]. Artificial intelligence (AI) has become a transformative force in MS research, providing innovative approaches for computer-assisted diagnosis, tracking disease advancement, and tailoring treatments to specific patients [3,5]. The use of AI in MS is reviewed here, with a focus on machine learning for biomarker incorporation6 and deep learning for MRI lesion segmentation [7,10,18], wearable technology for symptom monitoring[22], and digital twins for disease simulation[14,19,31], as well as AI-powered customized therapies[20,32]. The article addresses challenges such as ethical issues[13,27], requirements for algorithmic transparency[10,29], and frameworks for data-sharing[7,30]. New developments in MS research through artificial intelligence are anticipated to improve patient outcomes and transform clinical practice[6,24]. Multiple sclerosis (MS), which affects over 2.8 million individuals globally, poses substantial challenges for diagnosis and treatment due to its diverse spectrum of symptoms and unpredictable progression[25]. MRI and biomarker analysis are examples of classic diagnostic methods whose accuracy and cost-effectiveness are often inadequate[9]. The use of AI, especially machine learning (ML) and deep learning (DL), has enabled novel approaches to improve MS diagnosis, monitoring, and treatment[12]. The automation of processes like biomarker analysis, MRI lesion segmentation, and predictive model construction by AI-powered algorithms enables early diagnosis and customized treatment plans[30]. While outlining significant developments in its application, this study explores the potential advantages and disadvantages of AI in MS[5].

AI in MS Diagnosis MRI and Lesion Segmentation

MRI is still the gold standard against which all MS diagnostics are measured because it gives essential information about lesion development and neurodegeneration. However, lesion segmentation is labor-intensive and susceptible to observer variation. Computer-assisted methods have significantly enhanced lesion detection performance, but deep learning frameworks like convolutional neural networks (CNNs) have been even more significant[8]. State-of-the-art models such as U-Net and Mask R-CNN have segmented with accuracy above 92% and lessened manual labour[15,36]. Recent research has proven that hybrid AI methods, where deep learning is combined with traditional image processing, also enhances lesion characterization[28]. Transfer learning and ensemble models have also been used with success to enhance prediction power[37,38]. Reinforcement learning is also on the horizon for optimizing MRI scan protocols and maximizing lesion visibility with lower scan time[34].

Biomarker Integration

Biomarker-Based Models (Logistic Regression and SVM): Subclinical changes can be detected more easily when biomarker indicators like oligoclonal bands, cytokines, GFAP, and NfL are combined with AI algorithms. This strategy opens up new avenues for preventive measures and early diagnosis[21]. Beyond imaging, AI enhances biomarker-guided diagnosis by combining genomic signatures, oxidative stress markers, and serum neurofilament light chain (SNFL) to expedite MS classification[18,39]. Multimodal models built with AI have the ability to accurately read difficult biomarker panels, distinguishing MS from other neuroinflammatory diseases at better than 90% accuracy[11,40]. Identification of early relapsing-remitting and progressive types of MS subtypes has also been incredibly revolutionized by AI-supported classification approaches[34,41]. Predicting novel biomarkers of disease progression and treatment response is becoming more and more common with machine learning algorithms[42]. Such computer programs search through real-world patient information in huge MS registries to give a better, sooner regimen of disease management[43].

AI-Based Discrimination of MS and Mimics

Multimodal analysis based on artificial intelligence, e.g., MRI, cerebrospinal fluid (CSF) biomarkers, and clinical history, has enhanced the differential diagnosis of MS from Neuromyelitis Optica Spectrum Disorder (NMOSD) and small vessel disease considerably[9,44]. Robust diffusion tensor imaging (DTI) algorithms identify microstructural changes in the CNS typical of MS, and differential diagnoses can be established more accurately[27,45].

AI in Monitoring Disease Progression

Digital Twins for Personalized Disease Modelling

Digital twins, computer models of patients built from big data sets, have been demonstrated to monitor MS disease progression in real time[14]. AI-based simulations using genomic, imaging, and clinical data and integrating it to forecast relapses and treatment response[19,46]. New evidence indicates that digital twin models are able to predict long-term disability progression accurately and allow for earlier intervention[26,47].

Wearables and Gait Analysis

Wearable technology allows for timely monitoring of MS-associated mobility impairment. Smart sensors powered by artificial intelligence track motor function, balance, and gait to spot minute alterations before they become clinical symptoms[31,48]. Machine learning algorithms have facilitated the establishment of predictive models for mobility impairment, allowing for early rehabilitation[16,49].

Speech and Cognitive Analysis in Disease Monitoring

Speech recognition and cognitive testing programs using AI are emerging as a non-invasive method of MS monitoring. Speech patterns, cognitive reaction times, and voice modulations are processed by AI algorithms to identify cognitive impairment, usually a neurodegeneration of disease advancement[37,50]. Large-scale clinical studies demonstrate that AI-augmented cognitive testing is superior to conventional testing for the detection of early neurodegeneration.

AI in MS Treatment Optimization Personalized Treatment Regimens

Personalized AI models that take into account the genetic, clinical, and imaging characteristics of each patient may improve prognosis prediction and disease classification, opening the door to more specialized treatment approaches[23]. AI models scan clinical, genetic, and biomarker data to tailor DMT choice[32]. Reinforcement learning can forecast long-term treatment responses to optimize therapy planning with minimal off-target activity[20].

Nanorobotics and AI-Based Drug Delivery

Drug delivery targeting improvements in MS therapy are being studied using nanotechnology. Artificial intelligence (AI)-powered nanorobotics may improve blood-brain barrier penetration for targeted neuroprotective medication

delivery[17]. AI-driven simulations are crucial to producing the best nanoparticles and forecasting their therapeutic efficacy in preclinical models[33].

Challenges and Future Directions Ethical Considerations and AI Transparency

Data privacy, algorithmic bias, and clinical interpretability are among the ethical concerns brought up by its use in MS research[13]. Models of explainable AI (XAI) are being developed to increase clinician confidence and transparency[10].

Data Sharing and Global Collaboration

Federated learning makes it possible for institutions to securely share data without compromising patient privacy[29]. International partnerships such as the Multiple Sclerosis Data Alliance are essential for combining data sets to create stronger AI models[7].

CONCLUSION

More accuracy, efficiency, and personalization in MS diagnosis, monitoring, and treatment are being made possible by artificial intelligence. A previously unheard-of understanding of the evolution of disease is made possible by wearable technology, biomarker multispecialty, and high-resolution imaging. Nanotechnology-mediated drug delivery and reinforcement learning-based treatment selection are two AI-driven personalized treatment strategies that could be extremely valuable in improving MS treatment. Before widespread clinical use, regulatory and ethical issues must be resolved[24]. The future relies on collaborative multispecialty teamwork, advanced AI computations, and data-sharing infrastructures that optimize global patient benefit[6].

ABSTRACT

Diabetes mellitus (DM) is a major non-communicable disease with a prevalence rate of 11.6%. India ranks second, after China, in the number of diabetic cases. This article highlights the seriousness of DM and its management using herbal medicine without complications. It presents a case study of a 57-year-old male patient with an HbA1c level of 7%. The patient was treated with a combination of herbal drugs mentioned in Ayurvedic Samhitas for 8 to 12 months, alongside a daily 45-minute walk. After one year of treatment, a significant improvement was observed, with the HbA1c level returning to the normal range.

Keywords: Diabetes Mellitus, Obese, Herbal, *Madhumeha*

INTRODUCTION

Diabetes mellitus(DM) is a metabolic disorder characterized by polyuria, polydipsia, polyphagia, weakness, and fatigue(1). It is a lifestyle disorder with a worldwide prevalence. The number of people suffering from diabetes symptoms is increasing daily. According to the International Diabetic Federation (IDF) in 2019, India has 77 million people with diabetes and 25 million who are prediabetic; type-2 DM constitutes 90% of these cases(2). The seriousness of this disease is compounded by its occurrence across almost all age groups. Major causative factors include a sedentary lifestyle, incompatible diet, and lack of physical activity, leading to low metabolism, obesity, and insulin resistance. DM is classified into two types: type-1 and type-2(3). The pathophysiology of type-1 DM involves insulin deficiency, while type-2 DM is primarily due to insulin resistance(4). In Ayurveda, DM is correlated with

Madhumeha, a type of *VatajPrameha. Madhumeha* is characterized by sweet, dry, astringent, and pale-colored urine(5). The principal Dosha involved is *Kapha*, and the major *Dushyas* (affected tissues) are *Meda* (fat), *Mansa* (muscle), *Kleda* (fluid), *Shukra* (reproductive tissue), Oja (vital essence), *Rakta* (blood), *Lasika* (lymph), *Rasa* (plasma), *Vasa* (muscle fat), and *Majja* (bone marrow)(6). Various herbal formulations and single drugs (*Ekal Dravya*) are described in Ayurvedic texts. Using these drugs alongside *Pathya Apathya* (dietary and lifestyle guidelines) and physical exercise can help control DM in patients who have not yet started modern medicine.

CASE STUDY

A 57-year-old male patient presented with complaints of weakness, fatigue, excessive thirst (polydipsia), excessive hunger (polyphagia), and frequent, increased volume of urination (polyuria). Detailed history-taking and general examination were conducted (details below). The patient had not taken any modern or Ayurvedic medicine for diabetes prior to this consultation. He was a known case of hypothyroidism for seven years, taking 125 mcg thyroxine daily. There was no history of hypertension, other major illnesses, past surgeries, or a family history of DM. He was advised to undergo fasting blood sugar and HbA1c tests.

Personal History
Diet: Vegetarian
Occupation: Office work (sedentary job)
Addiction: None
Sleep: Sound sleep
Bowel Habit: Twice daily, normal consistency
Micturition: 7-8 times a day, 2-3 times at night
Appetite: Increased
Sanitation: Good
Other: No significant stress

General Examination
Height: 170 cm
Weight: 75 kg
BMI: 26 kg/m² (Overweight/Obese)
Built: Obese
Icterus: Absent
Edema: Absent
Lymphadenopathy: No
Skin: Dry
Nails: Rough
Pallor: Absent
Speech: Normal

Vitals
Temperature: Afebrile
Blood Pressure: 140/90 mmHg
Pulse: 76/min
SpO2: 95%

Ayurvedic Assessment (*Ashtavidh and Dashvidh Pariksha*)
Nadi (Pulse): Manda Visham
Mutra (Urine): Increased quantity

Mala (Stool): Prakrit (Normal)
Jivha (Tongue): Lipta (Coated)
Shabda (Voice): Prakrit (Normal)
Sparsh (Touch): Ruksha (rough, dry), Anushnasheet (moderate temperature)
Drik (Eyes): Prakrit (Normal)
Akriti (Physique): Obese
Prakriti (Constitution): Kaphapittaj
Vikriti (Pathological State): Kapha Vataj
Saara (Tissue Quality): Madhyam (Moderate)
Samhanan (Compactness): Pravar (Good)
Praman (Proportion): Madhyam (Moderate)
Satva (Mind): Madhyam (Moderate)
Satmya (Adaptability): Madhyam (Moderate)
Aahar Shakti (Digestive Power): Pravara (Good)
Vyayam Shakti (Exercise Tolerance): Madhyam (Moderate)
Vaya (Age): Madhyamavastha (57 years)

Laboratory Investigation Before Treatment
HbA1c: 7% (Normal level <6.5%)(7)

Treatment Protocol(8)
A fresh juice formulation was prepared using equal quantities of the following herbs:
1. Amla (*Emblica officinalis*)
2. Kutki (*Picrorhiza kurroa*)
3. Jamun Seed (*Syzygium jambolanum*)
4. Vijayasara (*Pterocarpus marsupium*)
5. Gudmar (*Gymnema sylvestre*)
6. Bel Patra (*Aegle marmelos*)
7. Giloy (*Tinospora cordifolia*)
8. Methi (*Trigonella foenum-graecum*)
9. Neem (*Azadirachta indica*)

Dosage: 15 ml of the juice with an equal quantity of water, twice daily on an empty stomach (morning and evening).
Lifestyle Modification: A daily 45-minute walk on an empty stomach.

Dietary Advice
Morning: Light diet (e.g., 2-3 multigrain chapatis, green vegetables). Citrus fruits.
Afternoon: Dal, rice, chapati, vegetable curry (excluding high-carbohydrate options).
Evening: Roasted chickpeas (brown chana), puffed rice (murmura).
Night: 3 chapatis, vegetable curry, dal. Unsweetened milk at bedtime.

Results: Clinical Features and Investigation

CONCLUSION

Herbal medicines can be highly effective, particularly in patients who have not previously taken modern anti-diabetic drugs, as they may help stimulate and activate cells for regular metabolic function. Regular exercise enhances cellular adaptive capacity and increases metabolism. Adhering to a proper diet helps reduce the risk of disease progression. In this case, strict adherence to herbal treatment and a regular 45-minute daily walk proved

highly beneficial. The patient found it challenging to follow the dietary plan completely but managed to reduce meal portions while maintaining the medicinal and exercise regimen. This combined approach resulted in the normalization of HbA1c levels, demonstrating the potential of integrated Ayurvedic management in controlling type-2 diabetes.

ABSTRACT

Globalization, industrialization and urbanization poses a big challenge on safe drinking water. Consumption of safe drinking water is most important for human being since unsafe drinking water consumption causes many water borne diseases namely typhoid, cholera etc. Ground water is the only primary source for the residents of Mayiladuthurai district. It is located in southern part of India. In this study, hydrochemical analysis were made on 20 samples and the samples were analysed and the analysed measures like pH, Electrical conductivity, Total dissolved solids content, chloride ion, sulphate ion, nitrate ion, fluoride ion, calcium, magnesium , total hardness, total alkalinity and heavy metals like zinc, iron, manganese, chromium and lead. Standard water quality analysing methodology recommended by APHA (1995) and BIS (1991) was used to get the results. The drinking quality was checked and studied using Entropy weighted water quality index (EWQI), Nemerrow's index (NPI) and heavy metals influence towards water quality was studied using Geo accumulation index (I geo). This type of multiple index oriented study was not undertaken in the study area so far. Results of EWQI showed that 85% of water samples were in poor category, 10 % of water samples were in extremely poor category and 5% of water samples were in medium category. Results of Nemerrow's Pollution Index

(NPI) revealed that most of the samples were in polluted state, required pretreatment and the results of I geo value indicating that heavy metal pollution came from the heavy loading of copper and lead in the water samples. The results of EWQI, NPI and I geo calculation indicate that application of these indices is identified the real nature of drinking water sources quality and highly supportive to the residents and water board authorities of Mayiladuthurai district for taking the required decision.

Keywords: Ground water, Mayiladuthurai, Entropy weighted water quality index (EWQI),Nemerow's Pollution Index(NPI), Geo accumulation Index.

INTRODUCTION

Water resources are the heart of the planet Earth.It is supporting in large scale for human being to their livelihood both for drinking and many domestic responsibilities.Development of economy,sustainability of environment also based on the quality of water available for the people.Increase in the size of population, modernization, urbanization, industrial activities and unscientific approach in handling water resources may cause the change of quality of ground water and it becomes global concern. Climatic change also deteriorates the quality.Now-a days , many human activities causing the deterioration of ground water resources. [6],[7],[1,4]. However, most of the human population is forced to drink the available slightly to moderately deteriorated water for their drinking purpose which in turn causes many diseases. The quality of water directly or indirectly affects public health, agricultural productivity, and industrial processes. Heavy metalsand their presence in water and also presence of nitrates, phosphates, and microbial pollutants can degrade water quality, making it unsuitable for human consumption and ecological balance. Water quality and its measured value are the most important one to ensureits quality while using it for drinking purposes, agriculture, and industrial use. Water quality assessment typically involves the measurement of multiple physicochemical and biological parameters, including multiple parameters like pH,DO(Dissolved Oxygen),BOD(**B**iochemical oxygen demand, TDS (Total Dissolved Solids) and concentrations of various chemical contaminants. However, interpreting these parameters individually can be complex and may not provide a thorough and clear understanding of the overall water quality because all the measured parameters were not in the same unit of measurement. To resolve this challenging problem, Water Quality Indices (WQIs) were proposed and developed as effective tools to sum up the contribution of variouswater quality measuresand all the water quality measures contribution converted into a whole number. This single numerical whole number giving the overall statusabout the quality and nature of water samples [5].

Traditional WQIs assign weights to different water quality parameters based on expert judgment or regulatory guidelines. Traditional water quality indices (WQIs) provide a numerical representation for water samples to represent its quality.The process involves collection of all physicochemical and biological measure's contribution and converting it into a single value[8][9][10]. This index calculation uses subjective evaluation technique. This evaluation method involved assigning weight for each and every parameter based on the experts opinion. Majorly WQI involved with evaluation procedure with more subjectivity based on experts opinion for parameter weights ofeach and every parameter to compute the WQI score. This creates the ambiguityin the originality in water quality of the studied sample[12] [13].However, conventional WQIs often rely on subjective weight assignments, which may introduce bias and reduce the reliability of the assessment[14].

While these approaches have been widely used, they introduce an element of subjectivity that may affect the reliability and accuracy of this water quality analysis. Many cases were reported, in that the assignment of parameter weights does not fully account for the inherent variability. Overall water quality determined by the contribution of given by each parameter. This has led researchers to explore more objective and data-driven methodologies for water quality assessment.

For resolving this issue, the Entropy Water Quality Index (EWQI) has emerged like a robust approach [2].In water quality assessment, it helps in identifying the most influential parameters without requiring subjective weight assignments. The entropy weighted water quality index, which applies entropy concept and its principles from information theory. It is used to identify the relative significance of these parameters based on their variability[3]. This method eliminates the need for subjective weight assignments and provides a more statistically rigorous approach to water quality evaluation. The usage of entropy is supporting here is to determine the relative significance of each parameter based on its variability across different sampling locations and time periods. Unlike conventional WQIs, which rely on fixed weights, the entropy-based method assigns dynamic weights to water quality parameters based on their statistical distribution, ensuring a more unbiased and data-driven evaluation.By considering the variability of each parameter, EWQI chooses the parameter which has greater heights of impact on the final water quality index in terms of improved accuracy. The method can be applied to different water quality datasets without requiring prior knowledge of local water conditions or predefined weighting schemes improving the flexibility and adaptability.

The concept EWQI utilizes entropy information theory to objectively for all the measures of water sample to measure their weight based on their variability. The subjectivity issue of water quality index is minimized by EWQI approach in the evaluation of this process, leading to a more data-driven calculation of analysis of groundwater samples for getting their quality . A study conducted in Mayiladuthurai district,southern part of India by applying the EWQI method to assess groundwater quality. The researchers collected samples from 20 locations and analyzed major anions and cations.

Secondly Nemerow's Pollution Index (NPI) was applied for assessment**.** Vales of NPI provides a comprehensive assessment of pollution by considering both the mean value of individual pollution indices and the maximum pollution index. This dual approach ensures that the evaluation reflects both average pollution levels and the most severe contamination, offering a balanced perspective on the quality determination part groundwater sources. The findings of this study highlighted variations in pollution levels.

Thirdly **g**eoaccumulation Index (I_geo) was also used. Originally developed to assess soil contamination. However, the I_geovalue has been adapted for groundwater studies to evaluate the accumulation of trace metals concentration.Comparing the obtained concentrations of trace metals with its pre-industrial levels, categorizing the degree of pollution and helping to identify anthropogenic influences. I geo values specially gives us the hidden contribution given by traces of heavy metals to judge the water quality. Which will in turn affects the ecology in terms of its risk. In this study, this study integrats the following indices namely Nemerow's Pollution Index (NPI) and geo accumulation index with EWQI for evaluating ground water quality of the studied samples. This study helps us to understand about the groundwater quality concerning with all level of pollution including heavy metal contamination which in turn, aids in identifying pollution sources and developing effective management strategies to protect this essential resource.No such types of studies were undertaken in this area.So to analyse the current status of the ground water in the proposed area ,the tools like Entropy weighted water quality Index(EWQI), Nemerow's Pollution Index and geo accumulation indices were used. Using these indices detailed study were undertaken to get real quality.By using the entropy weighted water quality approach, there contributing advanced research tool to assess the water quality.

Study area description

Groundwater samples from the twenty sampling points from in and around of Mayiladuthurai were collected. Mayiladuthurai district is recently separated from the Nagapattinam district for the purposes of administrative reasons in southern part of India. The district is largely supporting to agriculture as it receives water from the holy river the Cauvery particularly during rainy season. It is supporting to its residents by means its fast development. Ground water is the only major support for the residents of Mayiladuthurai for their drinking purpose.

From January 2024 to February 2024, totally 40 samples were collected and it is involved for measuring water quality measure during post monsoon season. The sampling stations details and their locations were presented in Fig .1 and Table.1.

MATERIALS AND METHODS

APHA (1995) [15]and BIS (1991)[16] recommended standard procedures to do the analysis. All the sample collection and its analysis were based standard methods prescribed by determined by APHA (1995) [15]and BIS (1991)[16]. In 5 Litre capacity pre cleaned plastics containers water samples were collected. After careful and thorough filteration, it was separated into two portions, one was preserved with nitric acid to pH < 2 (for trace metals). Preservation of both portions was maintained in refrigeration at 4°C. Water quality parameters like pH and electrical conductivity measurements were completed in the sample collection points itself using digital equipment's. Measurement of Total Dissolved Solids (TDS)was completed by digitalised TDS meter. Using EDTA method total hardness, calcium were measured. Magnesium was calculated through EDTA method's calculation. **U**sing flame photometric method measurement of sodium and potassium was completed**.** Using acid titration method alkalinity was measured. Chloride ion concentration was measured using argentometric titrations.Measurement of fluoride was completed using SPADNS spectrophotometric method. Presence phosphate ion concentration was measured by spectrophotometric method. Turbidity spectrophotometricmethodwas used to measure sulphate ion concentration. Nitrate by brucine sulphate spectrophotometric method**.** Trace elemental analysis - Atomic Absorption Spectrophotometric method for the estimation of chromium, copper, iron, manganese, zinc and lead.

Entropy-weighted water quality index (EWQI):

*Entropy-weighted water quality index (EWQI),t*he WQI utilized by [17]. Being an improved or enhanced model of index for measuring water quality, itis the mostly used model for checking the drinking water samples suitability. Developed form of WQI is EWQI[18].In WQI, each and every individual parameters is assigned with some weight as per experts judgement and this is completed minimized in EWQI calculation. Across the world ,EWQI is considered as the most reliable, justifiable and accurate method for calculating drinking water quality[19]. A five step calculation steps are involved in the computation of EWQI[20].Initially, the term the information entropy (ej) was determined as:

$$\mathbf{ej} = -\frac{1}{ln}\mathbf{n}\sum_{i=1}^{z} Pij\ ln\ Pij \quad \text{.....(1)}$$

Where total number of water samples is represented by n and Pij is the probability of normalized value of the parameter *j* [2] expressed as: $\mathbf{Pij} = \frac{Pij}{\sum Pij}$.....(2)

Here y represents individual samples of water *(i= 1, 2, 3…z) and* water quality measures were represented by x [3]. *(j = 1, 2, 3…n)* are to be tested to measure the water quality and the ratio between *j* and *i*is given as

$$Pij = yij/\sum_{i=1}^{z} yij \quad \text{.....(3)}$$

Using equation (4) the entropy weight was calculated (*w*j),

$$(wj) = \frac{1-ej}{\sum_{i=1}^{n}(1-ej)} \quad \text{.....(4)}$$

Here 1-ej is taken as equal to dj for convenient calculation. Each parameter's quality rating scale (qj) was expressed by

It should be $\mathbf{qj} = \frac{Cj}{Sj}$***100** .....(5)

Where concentration of each measured parameters were noted with Cj in mg/L and the respective parameters were represented by *Sj* in the samples, expressed in mg / L for drinking water quality [31,34] .
The entropy weighted water quality index (EWQI) which is an improved form is calculated as;

EWQI= $\sum_{j=1}^{n} Wj.qj$ ……(6)

Hydro chemical risk assessment by geo indices
Nemerow's pollution index (NPI)
Equation (7) was used to calculate the NPI values by referring Swathi and Umesh [20],[21].
NPI $= \frac{Ci}{wqs}$……(7)

where, concentration of each water quality analysing measure was reported as*Ci* and its standard limit is given as wqs.

Geoaccumulation index (I geo)
Geoaccumulation Index (I geo) is the most widely used index for assessing soil pollution status. However, the I geo index calculation is also supportive to judge the water quality in terms of trace metal content [22, 23, 24]. To calculate I geo values, Eq. (8) was used.

$I\ geo = Log2\frac{CHMS}{1.5*GBV}$……(8)

where, C HMS is concentration of heavy metal ion presentin water; geochemical background value is denoted in terms of GBV. The value 1.5 is used as a constant here to meet and analyse the variation of a given substance occurs naturally in the environment [25, 26, 27].

RESULTS AND DISCUSSION

The results of physico chemical parameter concentrations in terms of mean values used for the entropy weighted water quality index calculation were given in Table (2)and Table 2a. Table 3 is providing the results of Information weight (ej),dj and Entropy weight(Wj) values of the study area and Table 4 deals with the final result and categorization os water samples based on entropy weighted water quality.

Entropy weighted water quality Index
Results obtained from Information entropy(ej),dj and entropy weight (Wj) were tabulated in Table(3).The values of EWQI of this study for all samples based on WHO guidelines was tabulated in Table (4) and the Table (5) represented reference categorization score of EWQI. Fig:2 showed the final calculated of values of EWQI. Results of EWQI showed that it was ranged between 97.6162 and 430.1126. Out of 20 analysed samples, sample number eight secured EWQI score <100 (97.6162),falling in medium category. It showed that the sample 8 scored lowest value EWQI and reflects its highest quality among the analysed samples. Sample 2(EWQI Score 152.85) and 17 scored above 150 (EWQI Score 430.11) rated as the samples were in extremely poor category[33],this is due to heavy anthropogenic damage. These two samples 2 and 17 were scored highest EWQI score, indicating that they were in extremely poor quality. EWQI score of remaining water samples falling between >100 to<150 ,indicating that water samples were poor in quality. 85% of water samples were rated as in poor category, 10 % of water samples were in extremely poor category and 5% of water samples were rated as medium category. The above results of EWQI showed that it reduced subjectivity of WQI method. This has been achieved by the application entropy-based weights for the analysed parameters, demonstrating that objective-weighting systems like EWQI provide more accurate and dependable results [30,12,28,29]. Samples which received low quality area may be due to the low

ground water level availability or agricultural activities practices [4,6,32]. The results supported as more informative in decision-making processes for environmental monitoring and sustainable water resource management.

Hydro-environmental pollution risk evaluation by geo indices

Nemerow's Pollution Index (NPI)

The Nemerow's Pollution Index (NPI) providing a comprehensive evaluation of environmental contamination by integrating multiple pollution indicators. The Nemerow's Pollution Index serves as a valuable tool in environmental risk assessment, offering a balanced approach by considering both the worst pollutant and the overall pollution level. Nemerow's index criteria for classification score was tabulated in Table(6).

Nemerow's pollution Index is one of the most powerful tool to identify the quality of water [31].It identifies the priority contaminants for treatment of water samples and also the level of pollution contribution given by each and every parameter in a particular sample water [31]. Nemerow's pollution Index values were calculated as per the method discussed in the methodology Section [27] for all the analysed samples, and the results of NPI was provided in the Table (7). The samples whose NPI score exceeding 1 indicates that it was polluted and requires prior purification treatment before consumption. All salts which in dissolved form is the combination of all inorganic salts present in dissolved form and small amount of organic substance. Results of NPI in this study for Total dissolved Solids was more than 1 for all the samples indicating that the water is not fresh in quality [21]. NPI score of pH, chloride, sulphate, nitrate, zinc, iron and manganese were less than 1 for all the samples indicating that the is not polluted according to these parameters.NPI score of fluoride ion, calcium ion, magnesium ion and heavy metals like lead, total hardness were also crossed one. NPI score for Electrical conductivity of all samples were greater than one except sample 8. Chromium's NPI value was crossed the limit 1 except sample number 13. From the results of NPI showing that all of the studied water samples were not advisable for direct consumption for drinking without prior treatment. For sites with **NPI > 3**, immediate remediation strategies such as wastewater treatment, soil rehabilitation, or stricter emissions regulations should be enforced. It was observed that the samples with NPI score between 1 and 2 indicating that slight level of pollution was identified. Samples with their NPI score between 2 and 3 indicates that moderate pollution for the studied water samples. Samples which has NPI score 2 to 3 required continuous monitoring and pollution control measures to prevent deterioration. The results indicate that sites with high NPI values require urgent intervention, while areas with moderate contamination demand continuous monitoring. The NPI helps identify which specific contaminants are most significantly impacting water quality, allowing for targeted remediation efforts. In this the Mayiladuthurai district study, the NPI results indicated that most water samples were classified as polluted, necessitating pretreatment before consumption. By integrating NPI with other environmental indicators, policymakers and researchers can develop more effective pollution control and management strategies.

Geo accumulation index

Classification criteria for geo accumulation index (I geo accumulation value) values were in Table 8 and its results for this study was given in Table 9.It is pictorially given in Figure 3 . The obtained values of I geo accumulation value fluctuated from 1to 2. According to I geo accumulation value values, the quality of water was divided into seven types based on the presence of pollutants level. According to[20] the classification I geo values was made, it was given in the Table 8.I geo accumulation value results of this study area revealed that the scores ranged between 0 and 6. 15% of the samples were falling in($0 <$ I geo accumulation value ≤ 1) range representing that 15% of samples were in the uncontaminated to contaminated state. accumulation value 3% of samples were in the range of ($2 <$ I geo accumulation value ≤ 3) revealing that those samples were moderately to heavy contamination stage.1% of the sample was in the range of (I geo accumulation value ≥ 5) indicting that in extremely polluted stage, sampling station- 17 received this score and it may be due to anthropogenic activities. The remaining 65% of samples were in the range of (I geo accumulation value ≤ 0) revealing that they were in uncontaminated pure stage. Results of I geo values of all samples indicating that trace metal pollution was slightly impacted in the studied water samples. From the results, it was observed that heavy metal pollution came from the higher loading of copper and lead. This may be due to anthropogenic activities[20].

CONCLUSION

The entropy weighted water quality index and geoindices tools were applied to evaluate the pollutants level in ground water resources of Mayiladuthurai region. Results of EWQI showed that 85% of water samples were rated as in poor category, 10 % of water samples were in extremely poor category and 5% of water samples were rated as medium category. The above results showed that EWQI reduced subjectivity which arises in the water quality index tool by taking into account of entropy-based weights for water quality measures, demonstrating that objective weight scale systems like EWQI provide more accurate and dependable results. NPI revealed that most of the samples were in polluted required pretreatment and the results of *I geo* value indicating that heavy metal pollution came from the heavy loading of copper and lead in the samples of study area. This finding of NPI aligns with the poor water quality assessment from other indices used in the study such as the entropy weighted water quality index (EWQI) and the geo-accumulation index (I geo). The present study recommends requirement of pretreatment for water for purifying before its consumption.

ABSTRACT

Gujarat's forests, predominantly deciduous in nature, harbour rich biodiversity, supporting a wide variety of plant and animal species. The Saurashtra region, located in the southwestern part of Gujarat, is characterized by a rocky tableland ranging from 300 to 600 meters above sea level, bordered by coastal lowlands. Botad District, positioned within this region, experiences a hot semi-arid climate and lies between approximately 22°N latitude and 71°E longitude. This review focuses on the phytosociological profile of Botad and its surrounding areas, emphasizing the study of vegetation structure, species composition, and ecological relationships within Plant communities. Phytosociology provides critical insights into the interactions between local climatic and edaphic (soil) factors and plant diversity. Previous studies conducted in regions adjacent to Botad consistently highlight the dominance of the *Fabaceae* family among dicots and *Poaceae* among monocots. These patterns reflect the adaptive strategies of these families to arid and semi-arid environments. The findings underscore the ecological importance of these dominant families and the need for continued vegetation monitoring to support biodiversity conservation and sustainable land management in Saurashtra.

Keywords: Botad, Ecosystem, Phytosociology, Saurashtra,Vegetation

INTRODUCTION

Gujarat, a western state of India, is geographically positioned between 20°07′N to 24°43′N latitudes and 68°10′E to 74°29′E longitudes. Following the bifurcation of the Bombay State, Gujarat was established on 1 May 1960. The total area of the state is approximately 196,024 km² (or 9.67%) is classified as forest cover, accounting for about 7.72% of India's total forested area (Gujarat Forest Department, 2024). The state exhibits a diverse ecological landscape, ranging from the Rann of Kutch's saline deserts to grasslands, wetlands, and India's longest coastline. This varied topography and climate contribute significantly to the biodiversity of the region. Gujarat is administratively and ecologically divided into five regions: North Gujarat, South Gujarat, Central Gujarat, Saurashtra, and Kutchh. Gujarat's forests are broadly categorized into Tropical deciduous, Drydeciduous, and Mangrove Forests, each supporting unique floral and faunal communities. Studies on the state's floristic diversity report 2205 species of angiosperms, representing 905 genera and 156 families (Uma Devi, 1988; Kumar *et al*., 2014). Among these, 748 species have recognized medicinal value. A detailed assessment by the Gujarat Forest Department further identifies 915medicinal plant species distributed across different forest types and agroclimatic zones (Kumar *et al*., 2014).

Vegetational and Geographic Characterization of the Saurashtra Region

Saurashtra, also historically referred to as Kathiawar, is a prominent peninsula located in the southwestern part of Gujarat. Covering an area of approximately 47,000 km², it lies between latitudes 20°50′N and 23°5′N and longitudes 69°20′E and 72°10′E. The region is bounded by the Gulf of Khambhat to the southeast, the Arabian sea to the south and west, the alluvial plains of Bhavnagar to the east, and the Gulf of Kutch and coastal plains to the north. The Saurashtra peninsula is primarily a rocky tableland, elevated between 300 to 600 meters above sea level, surrounded by coastal lowlands. Its interior landscape comprises undulating plains interspersed with low hill ranges and dissected by rivers flowing in various directions, reflecting the region's complex geomorphology (Hiremath & Shiyani, 2012). The climate is predominantly hot and dry, and the natural vegetation is chiefly composed of thorn forests, which are disjunctly and sparsely distributed due to the arid conditions. Administratively, Saurashtra includes eleven districts: Rajkot, Jamnagar, Porbandar, Junagadh, Amreli, and Bhavnagar, As well as the more recently formed districts of Morbi (from Rajkot), Botad (from Bhavnagar), Devbhumi Dwarka (from Jamnagar), and Gir Somnath(from Junagadh), which were established in 2013 (Mehta, 2015). The floristic diversity of the region is well-documented. According to a comprehensive checklist by Santapau and Janardhan (1966), the flora of Saurashtra comprises approximately 1,136 plant species, belonging to 591 genera and 126 families. An earlier compilation by Santapau (1953) recorded 980 species, highlighting the region's botanical richness and ecological significance.

Geographical and Climatic Overview of Botad District

As per the Gujarat State Portal (2024), Botad District is situated in the Saurashtra region and was officially formed from parts of Bhavnagar and Ahmedabad districts. The administrative headquarters is in Botad town, which is approximately 92km from Bhavnagar and 133 km from Ahmedabad by road. Botad is geographically bounded by Surendranagar District to the northeast, Rajkot District to the west, Bhavnagar and Amreli Districts to the south, and Ahmedabad District to the east. The district lies roughly between 22°N latitude and 71°E longitude and spans an area of 2,564 km². Climatically, Botad experiences a hot semi-arid environment with an average annual rainfall 620mm. The major river flowing through the district include the Sukhbhadar River, which forms the northern boundary in Ranpur Taluka, and the Kalubhar River, which traverses the southern region in Gadhada Taluka. Other important river includes the Ghelo, Utavali, and Goma, which play essential roles in the district's ecology and agriculture.

Phytosociology: A Quantitative Approach to Understanding Plant Community Structure and Conservation Needs

Phytosociology is the systematic analysis of the composition, structure, distribution, and classification of plant communities (Kumar & Desai, 2016). A standard phytosociological survey records mot only the floristic inventory but also key structural attributes- vertical stratification, basal area, canopy cover and species abundance- thereby offering a quantitative portrait of vegetation organization. Such information is indispensable for biodiversity conservation and ecological-restoration planning, because community architecture regulates the fluxes of energy,

water and nutrients that underpin ecosystem functioning (Conant & Risser, 1974; Chavda, 2017). During the past century, tropical forest has declined precipitously owing to large-scale deforestation, settlement expansion, agricultural conversion, pollution, infrastructure development and biological invasions. These pressures have eroded biodiversity, altered local climates, reduced ecological services, and undermined rural livelihoods (Kumar & Desai, 2016). Robust, site specific data on plant-community composition and structure are therefore a prerequisite for sustainable management. Species richness and turnover vary markedly along climatic, edaphic and altitudinal gradients; teasing apart the influence of these factors is a central goal of phytosociological research (Gairola *et al*., 2011; Malik & Bhatt, 2015). Linking vegetation patterns to local environmental drivers also provides the historical context needed to anticipate future change and set sound conservation priorities (Patel& Patel, 2016).

Dominant plant families around the Botad district:

According to earlier research conducted by Santapau and Janardhan (1966) in the broader Saurashtra region, the most dominant plant families identified were *Fabaceae*, *Poaceae*, *Asteraceae*, *Malvaceae*, and *Acanthaceae*. In a more localized study, Sodha (20008) reported from the Hingolgadh Nature Education Sanctuary that the *Poaceae*, *Fabaceae*, *Asteraceae*, *Euphorbiaceae*, and *Convolvulaceae* were the five major dominant families. Similarly, Patel's (1982) investigation of Victoria Park in Bhavnagar found *Fabaceae*, *Poaceae*, *Euphorbiaceae*, *Asteraceae*, and *Malvaceae*- as dominant. A more recent study by Chavda (2017) on the Bhandariya Forest of Bhavnagar also recognized *Fabaceae*, *Poaceae*, *Euphorbiaceae*, and*Asteraceae* among the leading families, with the*Caesalpinaceae* subfamily (under *Fabcaeae*) also highlighted as a major group. At the state level, Shah (1978), in the Flora of Gujarat State, listed *Fabaceae*, *Poaceae*, *Cyperaceae*, *Asteraceae* and *Acanthaceae* as the most prevalent families.

Overall, across these diverse studies and locations, the families *Fabaceae*, *Poaceae* and *Asteraceae*, consistently appear as the most dominant, followed by *Euphorbiaceae* and *Malvaceae*, indicating a strong ecological representation and adaptability of these groups in the semi-arid and dry deciduous ecosystem of Saurashtra.

CONCLUSION

The phytosociological review of Botad surrounding districts within the Saurashtra region reveals a remarkable consistency in floristic composition across diverse ecosystems, including dry deciduous forests, coastal zone, canal command areas, scrublands, and protected sanctuaries. Across all examined studies-from the early observations of Santapau and Janardhan (1966) to recent works by Chavda (2017), Sodha (2008), and Suthar *et al*., (2021)- certain plant families prominently recur, especially *Fabaceae*, *Poaceae*, *Asteraceae*, and *Euphorbiaceae* these families exhibit exceptional ecological adaptability, occupying a wide range of habitats and dominating both herbaceous and woody vegetation layers. Dominant species such as *Acacia Senegal*, *Prosopis juliflora*, *Cynodon dactylon*, *Cassia auriculata* frequently appear, indicating their resilience and ecological importance in the semi-arid to sub-humid zones of Saurashtra. The recurrence of these species and families not only highlights a core floristic structure in the region but also reflects common anthropogenic pressures and climatic patterns that shape vegetation distribution. Collectively, these findings underscore the ecological significance of the Saurashtra region's vegetation and support the need for region-specific conservation and management strategies. Future studies should focus on long term monitoring, species vulnerability assessments, and the role of invasive species like *Prosopis juliflora*. Which, while dominant, can alter Native biodiversity patterns. The convergence of historical and contemporary data provides a robust foundation for biodiversity planning, restoration ecology, and sustainable land use in the region.

Table 1. Quantitative indices to be used

Community attribute	Derived indices	Refrences
Presence/ absence	Frequency (F), Relative Frequency	(Curtis & Mcintosh, 1950; Grieg-Smith, 1957; Kersaw, 1973; Misra, 1968; Muller-Dombois & Ellenberge, 1974; Samant *et al*., 2002; Wani and Pant, 2023).
Number of individuals	Density (D), Relative Density	
Spatial distribution	Abundance (A), Relative Abundance	
Size of individuals	Basal area (BA), Relative Basal Area	
Integrated dominance	Importance Value Index (IVI)	
Community diversity	Shannon-Wiener index (H), Simpsons's index (1-D)	

Table-2 Vegetation study of Surrounding area of Botad district

AREA	VEGETATION	METHODS	MAJOR PLANT	MAJOR FAMILY	REFRENCES
Hingolgadh Sanctuary, Rajkot (Dry Deciduous Forest)	Total 313 Species, 224 genera, belonging to 98 family. 49 tree species from 29 family, 38 shrubs species from 22 family, 40 species of grasses, Climbers 42 species from 11 family, Herbs 144 species from 37 family	Quantitative analysis: Density, frequency, abundance, relative frequency, relative density, Important Value Index, Basal area Diversity indices: Shannon Diversity index, Simpson's Diversity index, Simpson's index of Diversity, Simpson's Reciprocal index, Evenness index	*Aristida adscensionis, Spermacoce stricta, Rhus mysurensis, Maytenus emarjinata, Acacia senagal* are dominant plants.	Dicot: *Fabaceae* and *Asteraceae* Monocot: *Poaceae*	Sodha, 2008
Barda hills (dry deciduous forest)	368 species belonging to 268 genera and 80 families of Angiosperms were counted in the study. Most dominant type is herbs followed by trees, shrubs, and climbers.	Phytosociological parameter: Density, frequency, abundance, Diversity index: Shannon Diversity index and simpson Diversity index.	The plants that dominated the area were *Manilkara hexandra, Cassia auriculata, Lantana camara,* and *Acacia senegal*.	*Fabaceae* and *Euphorbiaceae* were the two most represented families among Dicotyledons. *Poaceae* and *Cyperaceae* were the two most represented families among Monocotyledons.	Raviya, 2020.
Naramada canal command area	premonsoon season: 201 plant	Transect and Quadrate method.	Highest Density Herbaceous	Postmonsoon: *Poaceae* most	Suthar *et al*., 2021

(NAAC) Bhavnagar, Botad, Surendranagar, Morbi.	species from 43 families. 156 herb species and 45 grass species. Post monsoon season: 259 species of herbaceous plants (208 species of herbs and 51 species of grasses) belonging to 49 families.	1 m x 1 m quadrat was placed at a regular 500 m interval on each transect. Quantitative analysis done by Phytosociological parameter: Density, frequency, abundance, Diversity index: Simpson Diversity index. Menhinick index of species richness.	plant (Premonsoon): *Cynodon dactylon* followed by *Schoenefeldia gracilis, Aristida funiculate,* and *Dichanthium annulatum*. Highest Density Herbaceous plant (Postmonsoon): *Cynodon dactylon* Followed by *Aristida funiculata, Cyperus bulbosus*, and *Indofera linnaei*.S	dominant. Followed by *Asteraceae, Fabaceae, Malvaceae, Amaranthaceae, Acanthaceae, Cyperaceae, Euphorbiaceae, Lamiaceae,* and *Solanaceae*. Premonsoon: Poaceae most dominant. Followed by *Asteraceae, Fabaceae, Amaranthaceae, Malvaceae, Acanthaceae, Lamiaceae, Solanaceae, Cyperaceae*, and *Euphorbiaceae* families	
Rampara forest, Morbi/Vankaner (Dry Deciduous Forest)	-	Randomly placed 10m x 10m quadrates. Phytosociological parameter: Density, frequency, abundance, relative frequency, relative density. Diversity Mean basal cover (MBC) Total Basal cover (TBC) Importance value index (IVI). index: Shannon Diversity index, Simpson Diversity index and Sorenson's similarity index	Three tree species dominated the area: *A. nilotica, A.flabellifer*, and *A. senegal*. At the forest's areas, there were just five or seven different species of trees.	Some dominant tree family: *Fabaceae, Arecaceae*	Panchal and Pandey, 2004.
Ghogha Coastal area, Bhavnagar	Angiospermic plant species in	-	Dicots were dominating over	With a total of 8 sp, the *Poaceae*	Chavda *et al*., 2023

	the region, about 54 species are classified into 42 genera and 28 families. In these 39 species from 31 genera and 24 families are classified as dicots, whereas 15 species from 11 genera and 4 families are classified as monocots.		monocot	family was determined to be dominating. *Fabacea, Cyperaceae, Chinopodiaceae, Malvaceae* were also dominating plant families found in this area.	
Bandiyabedi forest, Surendranagar district	-	For trees or shrubs, 10 × 10 m quadrates were laid, and for herbs, 1 x 1 m. Phytosociological parameters: Density, frequency, abundance, A/F ratio, basal cover and importance value index. index: Shannon Diversity index, simpson Diversity index and Sorenson's similarity index	Dominant tree species were *Acacia Senegal, Acacia catechu, Prosopis specigera*	*Fabaceae* family dominating this area	Parejiya *et al*., 2013
Bhandariya forest area, Bhavnagar (Tropical dry deciduous forest and Dry deciduous thorn forest)	Total 432 Angeospermic plant species plants-282 genera and 91 families. Monocot: 58 species, 42genera and 13 family. Dicot: 374 species, 240 genera and 78 families.	Random 20m × 20m quadrates for trees, shrubs and climbers. And 4m × 4m for herbaceous species. Phytosociological parameter: Density, frequency, abundance, Relative frequency,	*Cassia, Ipomea, Euphorbia, Cyperus, Acacia, Corchorus, Alysicarpus, Ficus, Indigofera, Amaranthus, Sida, Commelina* etc. are dominant plant genera.	*Fabaceae, Poaceae, Euphorbiaceae, Asteraceae, Caesalpiniaceae, Mimosaceae, Convolvulaceae, Acanthaceae* and *Cucurbitaceae* are Dominant plant family found in this area.	Chavda, 2017

		Relative density, Relative abundance, importance value index. Alpha Diversity indices: Shannon diversity index, Simpson reciprocal index for species richness, Pielou's index for species evenness. Beta diversity indices: jaccard's index, Sorenson index			
Reserved forest, Victoria Park near, Bhavnagar. (Semi-arid forest) (Thorny and Scruby vegetation).	Total 422 species: 96 angiosperm Family. Dicot: 350 Monocot: 72	Quadrate size: 7m × 7m Phytosociological parameter: Density, Basal cover, Frequency, average height of tree.	*Cassyth*a and *Cuscuta* are dominant climbers. *Prosopis juliflora* and *Acacia senegal* like thorny plant are dominant.	*Leguminosae* is largest family of dicot and *Poaceae* is largest family of monocot. *Asteraceae* and *Euphorbiaceae* also are the dominant family of this area.	Patel, 1982
Chotila taluka, Surendranagar district. (Dry moist deciduous forest).	Total 380 plant species. Family 84 Genera 279 Herbs 175, Shrubs 37, Tree 110, Climber 58.	-	Dominant tree species, *Prosopis juliflora, Acacia Senega*l and *Butea monosperma.*	*Fabaceae* 27 was most dominant plant family, followed by *Poaceae* 18, *Caesalpiniaceae*16, *Mimosaceae* 14, *Asteraceae* 20, *Apocynaceae* 19, *Euphorbiaceae* 18, *Malvaceae* 20, *Convolvulaceae* 19 and *Amaranthaceae* 13.	Popatbhai, 2023

ABSTRACT

Artificial Intelligence (AI) has emerged as a transformative force in the pharmaceutical industry, enabling innovation across drug discovery, development, manufacturing, regulatory affairs, and post-marketing surveillance. By leveraging machine learning, deep learning, and advanced data analytics, AI has significantly reduced drug development timelines, improved decision-making, and enhanced operational efficiency. This review highlights the key applications of AI throughout the pharmaceutical product lifecycle, including drug discovery, clinical trials, manufacturing, regulatory affairs, and pharmacovigilance. Furthermore, current challenges related to data quality, regulatory acceptance, and ethical considerations are discussed, along with future perspectives on the role of AI in personalized medicine and adaptive regulatory systems. Overall, AI represents a powerful tool for accelerating pharmaceutical innovation while ensuring patient safety and regulatory compliance.

Keywords: Artificial Intelligence, Pharmaceutical Industry, Drug Discovery, Clinical Trials, Regulatory Affairs, Pharmacovigilance

INTRODUCTION

The pharmaceutical industry is characterized by high research costs, long development timelines, and strict regulatory requirements. The development of a new drug typically requires 10–15 years and substantial financial investment, with a high risk of failure. Artificial Intelligence (AI), encompassing machine learning (ML), deep learning (DL), and data-driven analytics, has gained prominence as a solution to these challenges. AI enables the efficient analysis of large and complex datasets, thereby supporting faster and more accurate decision-making across pharmaceutical research and development [1,2]. In recent years, AI has been increasingly integrated into multiple stages of the pharmaceutical value chain, reshaping traditional approaches to drug development and regulation.

Role of Artificial Intelligence in Drug Discovery and Development

AI has revolutionized early-stage drug discovery by enabling rapid identification of potential drug candidates. Machine learning algorithms analyze chemical, biological, and genomic datasets to predict drug–target interactions and optimize lead compounds. AI-driven techniques such as virtual screening, molecular docking, and quantitative structure–activity relationship (QSAR) modeling have significantly reduced the dependence on conventional trial-and-error methods [3,4]. These approaches not only shorten discovery timelines but also improve the probability of identifying effective and safe drug candidates. Artificial Intelligence (AI) has significantly transformed the drug discovery and development process by enabling faster, more cost-effective, and data-driven decision-making. Traditional drug discovery is a lengthy and expensive process, often requiring more than a decade and billions of dollars to bring a single drug to market, with a high rate of attrition. AI technologies, including machine learning (ML), deep learning (DL), and neural networks, offer powerful tools to address these challenges by efficiently analyzing large and complex biological and chemical datasets.

AI in Target Identification and Validation

One of the earliest applications of AI in drug discovery is target identification and validation. AI algorithms analyze genomic, proteomic, and transcriptomic data to identify disease-related targets and predict their therapeutic relevance. Machine learning models can uncover hidden patterns in biological networks, enabling the identification of novel drug targets with higher precision compared to conventional approaches [3, 4].

AI in Lead Discovery and Optimization

AI plays a crucial role in lead discovery by accelerating virtual screening of large chemical libraries. AI-driven virtual screening and molecular docking techniques predict drug–target interactions and binding affinities, significantly reducing the need for extensive wet-lab experiments. Additionally, AI-based quantitative structure–activity relationship (QSAR) models assist in optimizing lead compounds by predicting their pharmacological activity and toxicity profiles [1,5].

AI in De Novo Drug Design

De novo drug design is another rapidly advancing area where AI is used to generate novel chemical structures with desired biological properties. Deep learning models, such as generative adversarial networks (GANs) and recurrent neural networks (RNNs), can design new molecules by learning from existing chemical databases. These AI-generated compounds often exhibit improved potency, selectivity, and drug-like properties [4, 6].

AI in Preclinical Development

During preclinical development, AI assists in predicting pharmacokinetic (ADME) and toxicological properties of drug candidates. AI-based in silico models help identify potential safety issues early in development, thereby reducing late-stage failures. Predictive toxicology models enhance decision-making by estimating organ toxicity, genotoxicity, and cardiotoxicity before animal or human testing [2, 7].

AI in Clinical Development

AI has also demonstrated significant impact in clinical drug development. Machine learning models improve clinical trial design by predicting patient response, optimizing dosing strategies, and identifying suitable patient populations. AI-driven analytics reduce trial duration, improve success rates, and support personalized medicine approaches [8].

Advantages and Limitations

The key advantages of AI in drug discovery include reduced development time, lower costs, improved success rates, and enhanced innovation. However, challenges such as data quality, model interpretability, regulatory acceptance, and ethical concerns remain. Addressing these limitations through explainable AI models and standardized regulatory frameworks is essential for broader adoption [7, 9].

Artificial Intelligence in Clinical Trials

Clinical trials are among the most time-consuming and expensive stages of drug development. AI enhances clinical trial efficiency by improving protocol design, patient recruitment, and monitoring. Predictive analytics help identify suitable patient populations and reduce recruitment delays, while AI-based tools enable real-time monitoring of patient safety and adherence [10]. The application of AI in clinical research has demonstrated potential in reducing trial failures and accelerating regulatory decision-making.

AI in Pharmaceutical Manufacturing and Quality Control

AI applications in pharmaceutical manufacturing focus on process optimization, predictive maintenance, and real-time quality assurance. Advanced AI models monitor critical process parameters, detect deviations, and ensure compliance with Good Manufacturing Practices (GMP). The implementation of AI-driven quality systems has resulted in improved batch consistency, reduced production failures, and enhanced operational efficiency [2,4]. These advancements support the industry's transition toward smart manufacturing and continuous production models. The pharmaceutical manufacturing sector is increasingly adopting Artificial Intelligence (AI) to enhance process efficiency, ensure consistent product quality, and maintain regulatory compliance. Conventional manufacturing and quality control approaches often rely on fixed process parameters and retrospective quality testing, which can lead to batch failures, increased costs, and delayed product release. AI technologies, including machine learning (ML), deep learning (DL), and advanced data analytics, provide predictive and real-time control solutions that support the principles of Quality by Design (QbD) and Process Analytical Technology (PAT) [11].

AI in Process Optimization

AI-based models are widely used for optimizing manufacturing processes by analyzing large datasets generated during production. Machine learning algorithms can identify relationships between critical process parameters (CPPs) and critical quality attributes (CQAs), enabling real-time adjustments to manufacturing conditions. This results in improved yield, reduced variability, and enhanced process robustness [12].

AI in Predictive Maintenance

Predictive maintenance is a key application of AI in pharmaceutical manufacturing. AI algorithms analyze equipment performance data to predict potential failures before they occur, thereby minimizing unplanned downtime and maintenance costs. This approach improves equipment reliability and supports continuous manufacturing operations [13].

AI in Quality Control and Assurance

AI significantly improves quality control by enabling automated inspection and real-time monitoring of product quality. Computer vision systems and deep learning models are used for visual inspection of tablets, capsules, and packaging to detect defects such as cracks, discoloration, or labeling errors. AI-driven quality systems reduce human error, enhance inspection accuracy, and accelerate batch release [14].

AI in Process Analytical Technology (PAT)

AI enhances the effectiveness of PAT by enabling real-time analysis of in-process data collected from sensors and analytical instruments. Machine learning models interpret spectroscopic and process data to predict CQAs during manufacturing, supporting real-time release testing (RTRT). This aligns with regulatory expectations for continuous quality assurance and improved process understanding [15].

Regulatory Considerations and Compliance

Regulatory agencies such as the U.S. Food and Drug Administration (FDA) and the European Medicines Agency (EMA) encourage the adoption of advanced manufacturing technologies, including AI, provided they comply with GMP requirements. However, challenges related to model validation, data integrity, and explainability of AI algorithms must be addressed to ensure regulatory acceptance [8].

Artificial Intelligence in Regulatory Affairs

Regulatory affairs is a critical domain where AI has shown increasing potential. Natural language processing (NLP) and data analytics tools assist regulatory professionals in managing regulatory submissions, tracking global regulatory updates, and ensuring compliance with evolving guidelines. AI also supports pharmacovigilance activities by enabling rapid detection of safety signals from adverse event databases. Regulatory agencies, including the U.S. Food and Drug Administration (FDA), have recognized the growing role of AI and are developing frameworks to regulate AI-based tools used in healthcare.

AI in Regulatory Intelligence

Regulatory intelligence involves continuous monitoring and interpretation of evolving regulatory guidelines across different regions. AI-powered NLP tools automatically scan regulatory agency websites, guidance documents, and legislation to identify updates and assess their impact on existing and pipeline products. This reduces manual effort, minimizes compliance risks, and enables proactive regulatory planning [4, 9].

AI in Regulatory Submissions and Dossier Management

AI significantly improves the preparation and management of regulatory submissions such as Investigational New Drug (IND), New Drug Application (NDA), Abbreviated New Drug Application (ANDA), and Marketing Authorization Applications (MAA). AI-based systems assist in document authoring, data validation, cross-referencing, and version control. Machine learning algorithms help identify inconsistencies, missing data, and formatting errors, thereby improving submission quality and reducing review cycles [17].

AI in Compliance and Audit Management

AI tools are increasingly used to monitor compliance with Good Manufacturing Practices (GMP), Good Clinical Practices (GCP), and Good Pharmacovigilance Practices (GVP). Predictive analytics identify potential compliance risks before inspections, while AI-driven audit systems analyze historical inspection data to improve inspection readiness and corrective action planning [15].

AI in Pharmacovigilance and Safety Reporting

Pharmacovigilance is a major regulatory function where AI has demonstrated significant benefits. AI algorithms analyze adverse event reports, literature, and real-world data to detect safety signals more efficiently than traditional methods. Natural language processing enables automated case intake, triage, and coding, leading to faster signal detection and regulatory reporting [18, 19].

Regulatory Acceptance and Ethical Considerations

Despite its benefits, the use of AI in regulatory affairs raises concerns regarding data integrity, transparency, and accountability. Regulatory authorities such as the U.S. Food and Drug Administration (FDA) and the European Medicines Agency (EMA) emphasize the need for model validation, explainability, and robust data governance.

Ethical considerations, including algorithmic bias and decision accountability, must also be addressed to ensure trust in AI-driven regulatory systems [16].

AI in Post-Marketing Surveillance

Post-marketing surveillance is essential for ensuring the long-term safety of pharmaceutical products. AI algorithms analyze real-world data from electronic health records, spontaneous reporting systems, and social media platforms to identify potential adverse drug reactions. Compared to traditional methods, AI-based pharmacovigilance systems offer improved sensitivity and faster signal detection, supporting proactive risk management strategies [4,7].

Challenges and Future Perspectives

Despite its numerous advantages, the adoption of AI in the pharmaceutical industry faces challenges such as data quality issues, lack of transparency in algorithmic decision-making, ethical concerns, and regulatory uncertainty. The development of explainable AI models and standardized regulatory guidelines is essential to address these limitations. In the future, AI is expected to play a key role in personalized medicine, digital therapeutics, and adaptive regulatory frameworks, further transforming the pharmaceutical landscape [2,7,8].

CONCLUSION

Artificial Intelligence has emerged as a powerful enabler of innovation in the pharmaceutical industry. Its applications across drug discovery, clinical trials, manufacturing, regulatory affairs, and pharmacovigilance have demonstrated significant potential to improve efficiency, reduce costs, and enhance patient safety. While challenges remain, continued advancements in AI technologies and regulatory frameworks are expected to further integrate AI into pharmaceutical research and development, shaping the future of healthcare delivery.

FUTURE PERSPECTIVES

The future of AI in drug discovery lies in its integration with systems biology, real-world data, and precision medicine. As regulatory agencies increasingly recognize AI-based approaches, AI is expected to become an indispensable component of pharmaceutical research and development, enabling faster translation of scientific discoveries into effective therapies [2,4].

ABSTRACT

Acharya Sushruta described *Kala* as specialized membranes separating *Dhatu* from their *Ashaya*. Among the seven *Kala*, *Sleshmadhara Kala* is located in the joints and plays a vital role in maintaining joint integrity and smooth movements. Its structure and function closely resemble that of the synovial membrane described in contemporary anatomy. Degenerative joint disorders such as *Sandhivata* are increasingly prevalent in the elderly and contribute significantly to disability. To evaluate the role of *Sleshmadhara Kala* in joint degeneration and to assess the efficacy of Ayurvedic *Shodhana* and *Shamana* therapies in the management of *Sandhivata* through clinical and radiological assessment. A 74-year-old male diagnosed with *Sandhivata* affecting both knee joints was treated with a comprehensive Ayurvedic treatment protocol, including internal medications and *Panchakarma* procedures. MRI findings were used to assess changes in the synovial membrane. MRI findings revealed synovial membrane involvement, highlighting its role in joint pathology. The findings support the correlation of *Sleshmadhara Kala* with the synovial membrane. The treatment effectively restored joint function and reduced symptoms. Significant improvement was observed in pain, stiffness, swelling, and difficulty in walking. Ayurvedic interventions targeting *Vata Dosha* and joint lubrication proved effective in managing *Sandhivata* and preventing disability.

Keywords: *Sleshmadhara Kala*, Synovial membrane, *Sandhivata*, Osteoarthritis

INTRODUCTION

Kala is a fundamental anatomical concept uniquely described by Acharya Sushruta. It refers to specialized membranous structures that separate *Dhatu* from their respective *Ashaya*. Sushruta elaborated seven types of *Kala* in the fourth chapter of *ShariraSthana*: *Mamsadhara*, *Raktadhara*, *Medhodhara*, *Sleshmadhara*, *Pureeshadhara*, *Pittadhara*, and *Shukradhara Kala*[1]. *Sleshmadhara Kala* is situated within the joints, where it retains and regulates *Sleshma* (lubricating fluid), ensuring smooth, frictionless joint movements. Acharya Sushruta compares its function to oil applied to the axle of a wheel, enabling effortless rotation[2]. Structurally and functionally, this description closely parallels the synovial membrane in modern anatomy, which lines synovial joints, bursae, and tendon sheaths and secretes synovial fluid essential for lubrication, nutrition of cartilage, and joint protection[3]. *Sandhivata*, a degenerative disorder described under *VatajaNanatmajaVyadhi* by Acharya Charaka, manifests with pain, stiffness, swelling, crepitus, and restricted joint movement[4]. Sushruta emphasized degenerative changes in joints as the hallmark of this disease[5]. Clinically, *Sandhivata* can be correlated with osteoarthritis. The World Health Organization reports that symptomatic osteoarthritis affects approximately 9.6% of men and 18.0% of women over the age of 60 globally. Among individuals with osteoarthritis, nearly 80% experience restricted mobility, and about 25% are unable to carry out routine daily activities. Epidemiological data indicate that the prevalence of osteoarthritis in India ranges from 22% to 49%. Radiological signs of osteoarthritis are observed in the majority of individuals by the age of 65 and in nearly 80% of people older than 75 years[6]. Modern management of osteoarthritis offers symptomatic relief but has limitations in halting disease progression. Hence, understanding the role of *Sleshmadhara Kala* in joint health and exploring effective Ayurvedic interventions is essential. This case report highlights the significance of synovial membrane pathology in *Sandhivata* and demonstrates the therapeutic potential of Ayurvedic treatment.

MATERIALS AND METHODS

The study aims to explore the role of *Sleshmadhara Kala* in the development of degenerative joint disorders and to evaluate the efficacy of Ayurvedic treatment in the management of *Sandhivata*. MRI was used to evaluate synovial membrane changes in a patient diagnosed with *Sandhivata*. Based on clinical findings and radiological evidence, a tailored Ayurvedic treatment protocol comprising *Shodhana* and *Shamana* therapies was administered.

Case Presentation

History of Present Illness

A 74-year-old male patient with bilateral knee joint pain for three years consulted our hospital. The pain aggravated by prolonged standing, walking, and stair climbing. He noticed mild outward bending of both knees over the past eight months. The patient was admitted for detailed evaluation and treatment(Personal History Table: 1). (Examination of Locomotor System Table: 2)

MRI Findings

- Degenerative osteoarthritic changes in the knee joint
- Moderate to gross synovial effusion
- Mild synovial thickening suggestive of synovitis

Diagnosis - *Sandhivata* (Osteoarthritis of knee joints)

Treatment Protocol

Internal Medications(Tamil: 3)

Panchakarma Procedures

(Table: 4)

RESULTS

The patient showed marked improvement in joint mobility, pain relief, and functional ability(Table: 5).

DISCUSSION

Sushruta's description of *Sleshmadhara Kala* emphasizes its role in joint lubrication and protection. MRI findings in this case revealed synovial membrane thickening and effusion, directly supporting the concept that impairment of *Sleshmadhara Kala* leads to degenerative joint changes. This case highlights the significant role of *Sleshmadhara Kala* in maintaining joint health and its correlation with the synovial membrane. Degeneration of this structure contributes to *Sandhivata*. The administered Ayurvedic therapies possess *Vatahara*, *Shothahara*, *Vedanasthapana*, and *Brimhana* properties. *Shodhana* procedures remove obstructed *Dosha*, while *Shamana* medicines nourish joint tissues and restore lubrication. Together, they help in reducing inflammation, improving circulation, and restoring joint function[7]. Ayurvedic management using *Shodhana* and *Shamana* therapies was effective in reducing symptoms and improving quality of life, suggesting its potential in preventing disability due to osteoarthritis.

ABSTRACT

One of the most destructive forces of nature on the Earth is tropical cyclones, disasters that can wipe out all human possessions and infrastructure in minutes. Besides the Earth, only India lives through 10% of the world's tropical cyclones, about 5-6 times a year, 2-3 of them being severe and causing significant disasters. Early prediction and warning plays a crucial role in reducing risks. Reliable detection of tropical cyclones is vital for early warning, risk mitigation, and forecasting of operational disasters through the integration of data from satellites. Despite the deep learning models having made a significant progress in the automatic recognition of cyclone, effectively all of the existing methods used deterministic outputs as their main consideration and provide a limited understanding of prediction uncertainty or internal representational mechanisms. This work demonstrates a method that is explainable and calibrated for deep learning-based tropical cyclone image recognition in a way that it uses EfficientNetB0 pre-trained model as the backbone. The model is trained on the TC-Satellite-DataSet, and various tools for probabilistic verification, such as the Brier score and reliability diagrams, are used for the evaluation alongside the standard metrics for classification. Besides looking at the overall classification accuracy, the framework examines the internal representations of the features with the help of principal component analysis and K-means clustering, thus revealing the particular morphological regions that the architecture is able to catch. Another thing that we did is using the model-agnostic occlusion sensitivity mapping which shows us that the classifier relies on the physically recognizable cyclone, these models use features that are inherently a part of the earth's atmosphere ('deep convection, spiralbands and organized cloud structures). Together, these components improve the transparency, interpretability, and credibility of the cyclone identification models. The proposed method establishes the fact that incorporation of

explanation, calibration, and representation-space analysis along with the deep learning methods will give very practical solutions for the hazard monitoring on a global scale.

Keywords: Tropical Cyclone, Satellite Imagery, Explainable Deep Learning, EfficientNet, Probabilistic Calibration, Brier Score, Reliability Diagram, PCA Embeddings, Occlusion Sensitivity, Cyclone Morphology Analysis.

INTRODUCTION

Tropical cyclones, also known as hurricanes or typhoons, are natural disasters that negatively impact humanity, producing very extreme winds, excessive rains and the associated flooding. Each year cyclones contribute a huge loss of life, extensive damages to Infrastructure, and even complete stoppage of socio-economic activities, mainly in the vicinity of the coastline. Such disastrous effects are fully realized in the high production and low lying areas since both the Bay of Bengal and the Arabian Sea present complicated environmental conditions that are likely to lead to a sudden increase in the cyclone's power and unexpected alterations of its course. Therefore, the issue of cyclone-related disasters' mitigation depends on efficient, timely, and reliable availability of now-casting and forecasting techniques based on numerical weather prediction (NWP) models and reanalysis. Although substantial progress has been achieved in the development of these tools over the last few decades, performance is still limited due to the inherent chaotic nature of the atmosphere, the inadequacies in physical parameterizations, the insufficiencies of spatial resolution, and the high cost of running frequent global forecasts. These limitations galvanize the usage of data-driven methods particularly deep learning (DL) which will further advance the science and practice of weather forecasting. This change in technology is in line with the experience of a number of other scientific areas,' in that DL has proven to be a very successful tool for a number of tasks including computer vision, spatiotemporal modelling, and of course, pattern recognition.

The natural disaster monitoring functions can significantly be improved by the use of the provision of satellite imagery, where the involved factors include: the observation of the cloud structure, the identification of the thunderstorm formation, the measurement of humidity patterns, and the capturing of the large-scale dynamical features. Geostationary satellites that monitor from a fixed point in the sky give regular timely updates of the weather conditions whereas polar-orbiting ones give high-resolution multispectral information. A cyclone's current power and future course are often important morphological characteristics of a cyclone, such as a thick cloud formation in the center, an eye wall starting to show, or the occurrence of asymmetric convection points'. Visual signs have traditionally been subject to the manual interpretations of industry experts using techniques such as the Dvorak method. Manual interpretation, while being very productive, is always time-consuming, subjective, and irregular. Deep learning comes to the market as a great change in this space as it could entirely automate the interpretation process and also bring many enhancements through the learning of structural patterns from raw imagery. In the last 10 years, a lot of the research has focused on using machine learning and deep learning methods to track the tropical cyclones and estimate their intensity. CNNs have been the main networks that have been used for this purpose with very good results, detecting the cyclonic circulation patterns as well as the clouds with cyclone-like shapes. Some of the articles have gone as far as using CNNs for the classification of cyclone intensity categories with the help of infrared cloud-top temperatures.

Moreover, there are of course other deep learning experts who have taken a different path and have suggested using recurrent neural networks (RNNs) like Long Short-Term Memory (LSTM) and Convolutional LSTM (ConvLSTM) to capture temporal dependencies and predict the future cyclone routes or rainfall. The scientists are also focusing on GANs for climate track prediction, super-resolution enhancement of climate model outputs, and providing more detailed forecasts of the cyclone boundary. In addition, some new combined models have been developed, which employ deep learning and NWP-provided meteorology. These models are generally more accurate in the prediction

of track and intensity. Yet, there are still several scientific and operational issues that need to be tackled. The main issue that needs to be addressed first and foremost is that the majority of the current deep learning studies on hurricanes are focused on one single task. For instance, a model could identify whether a hurricane was present or not, but it could not pinpoint the storm's center. One model could estimate the storm's power or intensity but ignore the entire storm's convective environment. Yet, another model might predict the hurricane's path with some certainty but fail to note the diversity of morphological shapes or reflect the model's uncertainty.

This division among the models would then govern the restrictiveness of deep learning systems to the extent of useful applications on the operational side of the workflow where both the analysts or the automated systems need all the information at once, such as the presence, structure, intensity, expected landfall location, and precipitation potential, etc. The lack of an integrated multi-task framework implies that the knowledge from one domain (e.g., cloud morphology used for detection) does not get to another (e.g., intensity estimation). So, the gap promotes the design of multi-task architectures that are capable of concurrently learning the presence of cyclones, the localization of their centers, the characterization of the convective structure, and the accompanying indicators, like the potential for rainfall or the cloud organization metrics. The second difficulty is related to training with the knowledge and forecasting of the uncertainty in the derived predictions. When it comes to weather forecasting, it is common knowledge that the probabilistic output is sometimes more important compared to the deterministic one, as the former is in most cases a result of many underlying uncertainties. However, in the case of deep learning, especially in cyclone studies, the single deterministic prediction is what is being supported and without accompanying it with the probabilistic state or the reliability level.

The parameter such as accuracy or mean absolute error (MAE) don't offer the full picture of whether the predicted probabilities are actually what they say they are in the real world. The probabilistic verification tools like the Brier score, reliability diagrams, frequency bias, critical success index (CSI), and equitable threat score (ETS) are the most commonly employed verification tools for severe weather and precipitation forecasting but have been largely overlooked in the field of deep learning-based cyclone detection research. If these tools are made available, it is going to be extremely easy for them to be able to evaluate the operational usefulness and reliability of the prediction made by the DL system. The third challenge is about the lack of transparency in the deep learning-based cyclone models. There are a few recent articles that have tried to apply Grad-CAM and similar gradient-based attribution tools for the purpose of being able to explain the intensity predictions, but the overall number still treats cyclone detection through deep learning technology as a black-box problem. This issue of transparency blocks off the possibility of acquiring scientific insights and also making people have faith in the whole operational process. The current attempts to provide transparency are usually concentrated only on the aspect of estimating the intensity of a cyclone and do not include the interpretation or detection of cyclones based on their morphological parameters. Moreover, there are times when the gradient-based techniques become an attention-seeking non-physically relevant pattern.

Non-model-specific transparency tools, such as occlusion sensitivity maps, where the image is systematically masked in order to observe the regions that affect the prediction, are scarcely employed in cyclone detection but can be exploited to unveil physically interpretable high-importance areas such as the eye-wall structure, symmetric cloud clusters, or shear-induced asymmetries. One more challenge is the insufficient exploration of the feature spaces that have been learnt by deep neural networks. The cyclone features are varied--some are poorly structured low-pressure systems, others are monsoon depressions, while some are symmetrical systems characterized by the presence of an eye. Traditional meteorology uses classification based on Dvorak patterns, but deep learning may encapsulate much more and even previously unrecognized features by way of data. From the second to the last layer of a trained CNN, the embeddings can be investigated, and then such considerations as dimensionality reduction (e.g., PCA) and clustering (e.g., K-means) can be done to see if the model learns “morphological regimes” naturally. A representation space analysis of this type is an untouched opportunity for AI meteorological research, and it contributes to the scientific knowledge and also somewhat to the operational value. In the light of this, the model may, for example, be seen to group the cyclones considering the factors like the symmetry of the cyclone, the sharpness of the eye, the curvature of the cloud bands, and the presence of mesoscale convective bursts.

Such findings would have an impact on improving the model design, interpretability, and the understanding of the cyclone evolution. The fifth hurdle relates to the regional biases and limitations of the data. A considerable number of the prior deep learning studies have dealt with the North Atlantic, Northwest Pacific, and global reanalysis-based data. The North Indian Ocean, in spite of being the location of the deadliest cyclones, has mostly been left out in the study of AI-induced cyclone research. The way in which the oceans and the atmosphere are connected, the behaviour of the monsoons, the patterns of the wind shear, and the rapidity of intensification are all factors that differ one basin from another, hence a model trained on one basin may not easily work on the NIO. Making a model and/or data set that are specific to a region--like refining and extending the TC-Satellite-Dataset or perhaps merging it with INSAT, Himawari, or ERA5-derived cloud fields--can be a very promising way for making new and unique offerings, especially when paired with fresh deep learning methodologies. In an effort to overcome the aforementioned restrictions, the present study introduces an explainable and calibrated deep learning system which is primarily based on three core parts: (i) the use of EfficientNetB0-based deep neural network for cyclone detection, (ii) probabilistic analysis of calibration via the Brier score and reliability diagrams, and (iii) interpretable representation-space and sensitivity analysis by means of PCA embeddings, K-means clustering, and occlusion sensitivity mapping. The fusion of these pieces yields a system that can be trusted in terms of cyclone detection and that is at the same time able to provide clear explanations which are in line with basic meteorological principles.

LITERATURE STUDY

Enormous strides have been taken in the application of deep learning to tropical cyclone detection, track estimation, and intensity forecasting. CNN-based methods have reached a level of accuracy in separating cyclone and non-cyclone cloud formations that is nearly perfect when drawing from infrared and visible imagery. There are also those approaches that employ multispectral data to enhance robustness of the models across a variety of atmospheric variations. In this context, certain models have incorporated environmental predictors like sea surface temperature, relative humidity, and vertical wind shear, by fusing them with image-based networks, which has increased the accuracy of intensity and rapid-intensification predictions. Researchers have looked into the use of temporal deep learning architectures, which include ConvLSTM and 3D CNNs, for tasks such as the forecasting of rainfall, analysis of cloud motions, and the tracking of cyclones. On the other hand, GAN frameworks have also been used to produce cyclone location in the future or even generate high-quality details of the coarsest climate model outputs, thus making storm structures visible. However, these methods usually demand huge amounts of computational power and access to good quality datasets. Nevertheless, the research that has been done so far has not yet managed to get smaller in number or otherwise, as the same problems are still different in all the previously made experiments. Very few studies dwell on the subject of converting these types of quantitative values to probabilities, while the meteorological forecast does already. It is only by measuring against the Brier score, reliability diagrams, and a host of other metrics that the probabilistic correctness of the models is known and this, however, is not the case with the use of deep learning techniques in various studies; only thus far, has the precision, recall, or F1-score been referred to. Second, learning the internal representation of the model is rarely studied. The deep learning models learn cyclone morphologies as higher-dimensional latent space features, however, only a few researches have attempted to uncover these hidden structures either via dimensionality reduction or by clustering. Lastly, the issue of interpretability is typically addressed through gradients and activation maps, as they seem to be the most popular ways to do it, together with the underused occlusion-based methods that perhaps could be linked to more physical phenomena. That there is no calibration, no clear interpretation of the latent space, and no consistent methods for the explanation of the outcomes lead to the fact that it is a very important and promising research topic to make Cyclone detection systems which are open and reliable.

RESEARCH GAP

An in-depth analysis of existing research highlights the following gaps

One of the main issues is the absence of probabilistic calibration in deep learning hurricane detectors. Accuracy is not the single most important feature as operations need models whose predicted probabilities are the true likelihood.

Poorly calibrated probabilities can be misleading and can lead forecasters to over or underestimate the threat of the cyclones thus affecting the early-warning systems. The second flaw is the lack of internal feature representation exploration that has been learned by neural networks. Cyclones have a diverse range of structures—from the symmetric to highly sheared formations—that deep models implicitly encode. Nevertheless, the literature reviewed for the work has not gone into details on the processing of these embeddings thereby leaving a significant part of the morphological data unexploited. The third flaw is the lack of widespread use of the most effective explanation methods apart from the model. The understanding of the spatial regions whose influence is the crucial factor for the operational transparency of a model is achieved by the inspection of a model's decision. Gradient-based methods give much less insight but occlusion sensitivity is more physically meaningful. However, the latter is applied rarely. This study deals with these issues by the integration of an accurate classification model with calibration quantification, exploration of the representation space, and interpretable occlusion maps.

METHODOLOGY

This part presents the dataset, the design of the model, the mathematical formulations, the calibration processes, the representation-space analysis, and the explainability tools that were used.

Dataset Preparation

The TC-Satellite-Dataset is the source of the cyclone and non-cyclone image sets divided into distinct directories. There is a main classification for these images. Folders 1 through 4 include cyclone images of different intensities and spatial structures, while folder 5 has non-cyclone samples. The images are resized to 224×224×3, normalized, labelled, shuffled, and split into an 80% training set and a 20% validation set.

Model Architecture

The backbone of EfficientNetB0 has been preferred to be both efficient and having a powerful representation. The outcome of the classification operation of EfficientNetB0 is a Keras image classification model that can alternatively be loaded with ImageNet pre-trained weights if not the case. Mathematically it can be defined as:

$$f(x) = \sigma(W.Dropout\left(GAP\left(EfficientNetB0(x)\right)\right) + b)$$

Where, σ is the sigmoid activation function,
x is the input image,
GAP is the GlobalAveragePooling2D
W and b are the training parameters

Training Procedure

The network has been through a five-epoch training, and the backbone weights were kept frozen; here, the binary cross-entropy loss was used with the Adam optimizer. The accuracy and ROC-AUC are among the metrics.

Probabilistic Calibration

Calibration is evaluated using the Brier score, defined as:

$$Brier\ score = \frac{1}{N}\sum_{N}^{1}(P_i - Y_i)^2$$

Where Pi represents the probability and Yi the corresponding label. Reliability diagrams are used to visualize predicted probabilities against the ground truth frequency of the bins.

Representation-Space Visualization

Each embedding that is coming from the last but one layer will be subject to PCA (Principal Component Analysis) for the sake of revealing latent structure visually. Moreover, K-means clustering will be applied for the purpose of revealing morphological regions in the cyclone embeddings.

Occlusion Sensitivity

A sliding occlusion window is applied to each image. The drop in predicted probability:
$\Delta p = p_{original} - p_{occluded}$, indicates the importance of each region.

RESULTS AND DISCUSSION

Classification Performance

One of the noteworthy aspects of the model is its very high recall for cases of cyclones. This means that it is very good at recognizing cloud patterns that are typical of cyclones such as eye, burst, and spiral pattern features. The very nice Descriptive Statistics And Related Plots and the very Descriptive Statistics And Related Plots (a) and (b) show that there is a case where perf ="ct recall for cyclone cases and zero recall for non-cyclones. Such a result is anticipated because the model has very few negative examples to learn from. The latter implies that in order to use the model in a balanced and thus general way, it a measure to consider adjusting the class imbalance is to be taken. Figure1: (a) confusion matrix, (b) classification report.

Calibration Results

The reliability diagram in figure-2 makes clear a systematic bias towards overprediction in the high-probability bins, whilst the Brier score measures miscalibration. These results stress the fact that the raw network outputs should not be applied directly to the operational forecasting without calibration. Reliability Diagram (cyclone detection) (Figure 2).

Being excessively self-assured is the main trait of the model within high-probability bins. This can be seen in:

- Brier score that is higher than usual
- Reliability curve that is not the single-source ideal line

These findings emphasize that threshold tuning and calibration corrections are needed for operational deployment. Using Brier score (probabilistic accuracy: 0.0881) and reliability diagrams for a deep learning cyclone detector is uncommon; most prior works only report accuracy or F1, without probabilistic verification.

Feature-Space Interpretation

The validation embeddings' 2D PCA and K-means clustering in the feature space are discussed yet. In Figure-3 (a) and (b) show that the network has learned to separate cyclone morphologies in a meaningful way. Without groups of images, the different clusters were reconfirmed in the structural arrangement. The for the classifier to have passed bits and bytes imagery to human interpretable features crucially through the circuit development has not been a wide practice in the field of cyclone research. This work takes advantage of the embeddings to not only build up a new data-driven cyclone morphology taxonomy but also relate it to the physical characteristics of storms, the stages of development and hence the classifiers' hidden layer visualizations. Figures of cyclone images from which the clusters were organized, based on the analysis are displayed in figure-4. the division of the second and third group of images is based on natural morphological variations which coincidentally also represent different stages of the storm buildup cycle. Through clustering we found that Cluster 0 contains most bad and/or premature cyclonic activities -- these systems had poor or irregular cloud field, only weak convection, and lacked the typical central feature, mostly due to the influence of the neighboring environment, jet streams, etc. On the other hand, Cluster 1 featured middle intensity systems with nice spirals and increasing symmetry in the rotation movement which is the transformation to cyclone maturity by the joint effect of convection-ward heat and moisture transportation indicator, although still, sometimes not all intense fronts were identified by the model. And lastly, in cluster 2, you may see developed and very powerful convection with high structure in the cloud cover, and in eye in some cases aviator, which means a storm in a very advanced developmental stage or a strong still cyclone that has finished its full development not too long time ago. From the three splits, it can be clearly seen that the model's latent feature space accurately embeds cyclone morphology, which is a reflection of the meaningful physical distinctions related to storm strength and structural organization. It is confirmed that EfficientNet learns more than two different versions of the same object. Embedding space clustering being a part of cyclone detection research is considered to be a very useful

methodological improvement and it sure brings another new layer of novelty to this study. In this report, besides accurately determining the presence of cyclones, the method also helps to show the structural path through which cyclonic systems evolve. This feature has been largely ignored in the past research where models usually give binary classifications without ever mentioning how their internal representations correspond to cyclone morphology. The model discovered variations in the data - from loosely organized systems that only resemble cyclones to very strong and very well-organized cyclones. This fact is the proof that the model has managed to find the physically meaningful patterns and has enabled the new perspective on the problem of cyclone recognition by machine learning architectures. This way of working both helps to explain the physical meaning of the scientific problem, and at the same time, will aid the operational decision-making by revealing the presence of different kinds of morphology. The model, in effect, is simply very good at learning physical patterns in general, and it is, therefore, extremely useful in other areas of different types of science where similar problems of appearance and shape may rise and hence be analyzed through these and other models as well a on a rather wide range of physical science properties. Figure 4: (a) cyclone images belonging to cluster-0, (b) cluster-1, (c) cluster-1 respectively

Explainability via Occlusion Sensitivity

Occlusion maps are considerable in the context of deep convection and cluster formation as most influential. It's a true meteorology rule and only once this component has been granted can the model be considered transparent. In this context, the model only uses features determined by the problem at hand, and this is a great advantage. Moreover, the use of such maps clearly shows that our classifier is not being tricked by tricky features like lines, random dots and the background of the ocean. One such example is Figure 5(a) which shows the original satellite image used for occlusion sensitivity analysis. It is a wonderful surprise to see a system that has a spiral shape and is very intense in terms of convection. This will provide good material for interpreting the model. Figure 5(b) is a map of the occlusion sensitivity which shows how the model's prediction of a cyclone changes with the occluded regions. The warmer areas indicate that removing regions from the image led to a considerable drop in the model's estimation of the cyclone probability, unearthing the areas the model considered as highly influential for cyclone detection. Figure 5(c) depicts the overlay of the occlusion sensitivity heatmap on the original image, emphasising the spatial relation of the areas that the model points out as significant and meteorologically meaningful structures. By mutual visualization, one can see that the classifier is only picking out the same way as the physically coherent features which are the dense convection and the organized cloud curvature when it is identifying cyclones.Table-1 describes the summary of key quantitative results obtained from probabilistic calibration assessment, feature-space analysis, clustering-based morphological interpretation, and occlusion sensitivity evaluation.

CONCLUSION

The new scientific discovery describes a deep learning innovation characterized by its comprehensibility and sensitivity. The latter is being carried out in an EfficientNetB0 model classification joined with both calibration and the representation of space physically. Whereas the former uses the probabilistic calibration method, the latter is linked to the representation-space visualization and occlusion- based explainability components. Though this model is very good at detecting cyclones, it is also able to show the structural and other aspects of cyclones through PCA and clustering. The analysis of calibration indicated that verification of weather data was a crucial factor in the application of deep learning techniques. The last piece of the methodology-sensitive occlusion sensitivity maps provide physically interpretable explanations and increase AI forecasting systems trust. The said methodology will give rise to the availability of future cyclone detection models incorporating the uncertainty estimation, multi-task learning, and the operational-grade interpretability HTML elements.

Table 1: Quantitative Results from Probabilistic Calibration, Feature-Space Analysis, and Explainability Evaluation.

Metric Category	Metric Description	Value Obtained	Interpretation
Probabilistic Accuracy	Brier Score	0.0881	Indicates good probabilistic accuracy, with relatively low mean squared error between predicted cyclone probabilities and observed outcomes.
Feature-Space Variance	PCA Explained Variance (PC1)	0.1702	The first principal component captures a substantial proportion of variance, reflecting dominant cyclone-related structural features.
Feature-Space Variance	PCA Explained Variance (PC2)	0.0654	The second principal component captures secondary morphological variations within cyclone structures.
Explainability Analysis	Baseline Predicted Cyclone Probability	0.9273	Indicates high model confidence for the selected cyclone case prior to occlusion sensitivity perturbation.

ABSTRACT

Hybrid polymers, formed by the combination of two or more polymeric or inorganic–organic components, have emerged as advanced functional materials in pharmaceutical formulations. These polymers integrate the advantages of different materials, such as biocompatibility, mechanical strength, controlled drug release, and stimuli responsiveness. Hybrid polymer systems are increasingly used in novel drug delivery systems, controlled-release dosage forms, tissue engineering, and pharmaceutical coatings. This review discusses the classification, formulation strategies, techniques for preparation, applications, advantages, reported research formulations with drugs and future prospects of hybrid polymers in pharmaceutical development.

Keywords: Hybrid polymers, pharmaceutical formulations, Hybrid polymer systems,

INTRODUCTION

Polymers play a crucial role in pharmaceutical formulations by acting as binders, matrix formers, coating agents, and drug carriers. However, single polymers often have limitations related to mechanical strength, stability, or drug release control. Hybrid polymers overcome these limitations by combining organic–organic or organic–inorganic components to achieve synergistic properties. The development of hybrid polymer systems has significantly advanced controlled and targeted drug delivery technologies [1,2].

Classification of Hybrid Polymers
Hybrid polymers used in pharmaceutical formulations can be broadly classified into:

Organic–Organic Hybrid Polymers
These hybrids consist of two or more polymers blended or chemically conjugated, such as:
Chitosan–alginate
HPMC–Eudragit
PEG–PLGA
They provide improved mechanical strength, controlled drug release, and enhanced stability [3].

Organic–Inorganic Hybrid Polymers
These systems combine polymers with inorganic materials like silica, calcium phosphate, or metal oxides. Examples include polymer–silica hybrids and polymer–hydroxyapatite composites. Such hybrids offer enhanced thermal stability, bioactivity, and controlled degradation [4].

Techniques for Preparation of Hybrid Polymers [5]
Hybrid polymers can be prepared using various techniques that allow the integration of two or more polymeric or polymer–inorganic components to achieve synergistic physicochemical and functional properties. The selection of the preparation technique depends on the nature of the components, the intended pharmaceutical application, and the desired drug release characteristics.

Physical Blending
In this technique, different polymers are mixed without chemical interaction. The polymers retain their individual chemical identities while exhibiting improved combined properties such as mechanical strength and controlled drug release.

Example: HPMC–Eudragit® blends for controlled-release tablets.

Graft Copolymerization
Graft copolymerization involves the chemical attachment of side-chain polymers onto a polymer backbone. This method enhances functionality, stability, and responsiveness.

Example: Chitosan grafted with polyethylene glycol (PEG).

Block Copolymerization
Block copolymers are formed by linking two or more polymer blocks covalently. These polymers are widely used in micelles and nanoparticle drug delivery systems.

Example: PEG–PLGA block copolymers.

Interpenetrating Polymer Networks (IPNs)
IPNs consist of two or more polymer networks that are physically entangled but not chemically bonded. Semi-IPNs contain one crosslinked polymer and one linear polymer.

Application: Sustained and stimuli-responsive drug delivery systems.

Sol–Gel Technique
This technique is used to prepare organic–inorganic hybrid polymers, where inorganic networks (e.g., silica) are formed within polymer matrices.

Application: Controlled drug release and implantable systems.

***In Situ* Polymerization**
Polymerization occurs in the presence of another polymer or inorganic phase, leading to uniform hybrid formation.

Application: Injectable hydrogels and in situ forming implants.

Electrospinning
Electrospinning produces hybrid polymer nanofibers with high surface area and controlled drug release properties.

Application: Wound dressings and transdermal drug delivery.

Characterization of Hybrid Polymers
Characterization of hybrid polymers is essential to confirm successful hybrid formation, understand physicochemical properties, ensure reproducibility, and predict their performance in pharmaceutical formulations. A combination of spectroscopic, thermal, morphological, mechanical, and biological evaluation techniques is commonly employed.

Structural and Chemical Characterization
Fourier Transform Infrared Spectroscopy (FTIR)
FTIR is used to confirm the presence of functional groups and interactions between polymer components. Shifts in characteristic peaks indicate hydrogen bonding, ionic interactions, or chemical conjugation.

Purpose: Confirmation of hybrid formation and compatibility.

Nuclear Magnetic Resonance (^{1}H and ^{13}C NMR)
NMR spectroscopy provides molecular-level information on polymer structure, grafting efficiency, and chemical bonding in hybrid polymers.

Purpose: Structural elucidation and chemical composition analysis.

X-Ray Diffraction (XRD)
XRD is employed to study crystallinity and phase distribution. Hybrid polymer formation often results in reduced crystallinity due to polymer interactions.

Purpose: Crystalline–amorphous nature assessment.

Thermal Characterization
Differential Scanning Calorimetry (DSC)
DSC measures thermal transitions such as glass transition temperature (Tg), melting point, and compatibility of polymer blends.

Purpose: Thermal behavior and miscibility evaluation.

Thermogravimetric Analysis (TGA)
TGA assesses thermal stability and degradation patterns of hybrid polymers.

Purpose: Stability and composition analysis.

Morphological Characterization
Scanning Electron Microscopy (SEM)
SEM examines surface morphology, particle shape, porosity, and uniformity of hybrid polymer systems.

Purpose: Surface and structural visualization.

Transmission Electron Microscopy (TEM)
TEM provides detailed internal structural information, particularly for nanoscale hybrid polymers.

Purpose: Nanostructure analysis.

Atomic Force Microscopy (AFM)
AFM analyzes surface topography and mechanical properties at nanoscale resolution.

Purpose: Surface roughness and mechanical mapping.

Physicochemical Characterization
Particle Size and Zeta Potential
Dynamic light scattering (DLS) determines particle size distribution and surface charge.

Purpose: Stability and dispersion behavior.

Swelling and Solubility Studies
Swelling behavior indicates hydration capacity and drug release potential.

Purpose: Drug release and mucoadhesion prediction.

Mechanical Characterization
Mechanical testing evaluates tensile strength, elasticity, and compressibility.

Purpose: Suitability for films, tablets, and implants.

Drug–Polymer Interaction Studies
Hybrid polymers are evaluated for drug compatibility using FTIR, DSC, and XRD.
Purpose: Stability and drug loading assessment.

***In-Vitro* Drug Release Studies**
Release kinetics are evaluated using dissolution testing to determine controlled or targeted release behavior.

Purpose: Performance evaluation.

Biological Characterization
Biocompatibility and Cytotoxicity Studies
MTT assays and cell culture studies assess safety.

Purpose: Biological safety assessment.

Mucoadhesion and Permeation Studies
Used for hybrid polymers intended for transmucosal delivery.

Purpose: Absorption enhancement evaluation.

Stability Studies

Stability studies are conducted under ICH guidelines to assess physical and chemical stability.

Purpose: Shelf-life prediction.

Applications in Pharmaceutical Formulations

Controlled and Sustained Drug Delivery

Hybrid polymers are widely used in matrix tablets, microspheres, and nanoparticles to control drug release. Polymer blends such as HPMC–Eudragit® allow modulation of swelling and erosion mechanisms, providing sustained drug release [6].

Targeted Drug Delivery

Hybrid polymeric nanoparticles and micelles enhance drug targeting by responding to pH, enzymes, or temperature. Organic–inorganic hybrids are particularly useful in cancer therapy due to their improved stability and controlled release at the target site [7].

Transdermal and Mucoadhesive Systems

Hybrid polymers such as chitosan–PVA or chitosan–alginate exhibit enhanced mucoadhesive and mechanical properties, making them suitable for transdermal patches and buccal delivery systems [8].

Coatings and Films

Hybrid polymers are extensively used in film coating and capsule shell formulations. They improve film flexibility, adhesion, and moisture barrier properties while maintaining drug stability [9].

Advantages of Hybrid Polymers

- Enhanced mechanical and physicochemical properties
- Improved drug loading and release control
- Better biocompatibility and stability
- Reduced batch-to-batch variability
- Flexibility in formulation design

These advantages make hybrid polymers attractive for next-generation pharmaceutical products [2,10].

Regulatory and Safety Considerations

Regulatory authorities require comprehensive characterization of hybrid polymers, including compatibility, toxicity, degradation behavior, and reproducibility. Hybrid polymer-based formulations must comply with pharmacopeial standards and GMP guidelines. Quality-by-Design (QbD) principles are increasingly applied to ensure consistent performance and regulatory acceptance [11].

Challenges and Future Perspectives

Despite their benefits, hybrid polymers face challenges related to large-scale manufacturing, reproducibility, and regulatory approval. Future research is expected to focus on smart hybrid polymers, biodegradable inorganic components, and personalized drug delivery systems. Integration of hybrid polymers with nanotechnology and 3D printing will further expand their pharmaceutical applications [12,13].

CONCLUSION

Hybrid polymers formed by combining two or more polymers or polymer–inorganic components, have gained significant importance in pharmaceutical research due to their enhanced functional properties. These materials integrate the advantages of individual components, enabling improved drug loading, controlled release, targeting, and stability across various dosage forms. Represent a promising class of materials in pharmaceutical formulations by combining the advantages of multiple components into a single system. Comprehensive characterization of hybrid polymers using advanced analytical techniques is critical to ensure their suitability for pharmaceutical applications. These studies help establish structure–property relationships, predict in-vivo performance, and support regulatory approval. Their versatility and enhanced performance make them valuable tools for developing controlled, targeted, and patient-friendly drug delivery systems.

Table 1: Advantages and Disadvantages of Hybrid Polymers in Pharmaceutical Formulations

Aspect	Advantages	Disadvantages / Limitations
Drug release control	Enables precise control over drug release (sustained, targeted, stimuli-responsive)	Complex release mechanisms may be difficult to predict
Material properties	Combines mechanical strength, flexibility, and stability of different polymers	Optimization of polymer ratios can be challenging
Bioavailability	Enhances solubility and permeability of poorly soluble drugs	Risk of drug–polymer incompatibility
Targeted delivery	Facilitates site-specific and controlled drug targeting	Requires extensive in-vitro and in-vivo validation
Biocompatibility	Improved biocompatibility and reduced toxicity	Inorganic components may raise toxicity concerns
Formulation flexibility	Applicable to multiple dosage forms (tablets, nanoparticles, patches, gels)	Scale-up and reproducibility issues
Stability	Enhances physical and chemical stability of drugs	Stability affected by moisture and temperature sensitivity
Patient compliance	Reduced dosing frequency improves compliance	High cost may limit commercial viability
Regulatory potential	Supports QbD and advanced drug delivery concepts	Regulatory approval may be time-consuming
Innovation	Enables development of smart and personalized medicines	Requires advanced expertise and infrastructure

Table 2: Applications of Hybrid Polymers in Drug Research and Pharmaceutical Products

Application Area	Hybrid Polymer System	Dosage Form / Research Application	Advantages	References
Controlled and sustained release	HPMC–Eudragit®, Chitosan–alginate	Matrix tablets, capsules	Controlled drug release, reduced dosing frequency	[14,15]
Targeted drug delivery	PEG–PLGA, Polymer–silica hybrids	Nanoparticles, colon-targeted systems	Site-specific delivery, reduced toxicity	[16,17]
Nanoparticulate systems	PLGA–PEG, Chitosan–PVA	Nanoparticles, nanogels	Improved solubility and bioavailability	[18,19]
Transdermal and topical delivery	Chitosan–PVA, Polymer–lipid hybrids	Patches, gels, films	Enhanced skin permeation, improved adhesion	[20,21]
Mucoadhesive delivery	Chitosan–carbopol, Alginate–chitosan	Buccal, nasal, vaginal systems	Prolonged residence time, improved absorption	[22,23]
Injectable and *in situ* systems	PEG–PLGA, Polymer–calcium phosphate	Injectable hydrogels, depots	Sustained release, minimally invasive	[24,25]
Film coating and capsules	HPMC–ethyl cellulose	Modified-release coatings	Improved flexibility and moisture protection	[26,27]
Ocular drug delivery	Chitosan–HPMC, Polymer–NP hybrids	Eye drops, ocular gels	Increased precorneal retention	[28,29]
Vaccine and biologics delivery	PLGA–chitosan, Polymer–lipid	Vaccine carriers, protein delivery	Enhanced stability and immune response	[30,31]

	hybrids			
Emerging applications	Smart hybrid polymers	3D printing, personalized medicine	On-demand release, patient-specific dosing	[32]

ABSTRACT

Hydroxypropyle methyl cellulose (HPMC) ,Poly vinyl alcohol, Sodium sulphate and Zirconium dioxide salt polymer blend films were prepared and investigated using wide angle X-ray and W-H plot methods. W-H plot method is quite useful for relative comparison of crystallite size and strain in a series of polymer composite films of various concentrations of ZrO_2 in HPMC+PVA. The computed micro structural parameters of HPMC+PVA doped with ZrO_2 polymer composite. The computed microcrystalline parameters like Crystalline area and lattice strain g in % while computing are also shown. From the obtained results of these polymer composites it is clear that the crystallite area of the polymer composites increases with the increase in the concentration of Zirconium dioxide salt.

Keywords: Polymer blends, Crystallite size, Micro structural parameters, X ray diffraction.

INTRODUCTION

Water soluble polymers have, for many years, received less the share of the considerable scientific efforts which has been devoted to the study of the structures and properties of the broad mass of macromolecular systems. Water-soluble polymers, which perform various useful functions such as thickening, gelling, flocculating, rheology modifiers in the various processes for petroleum, paper, latex paints, cosmetics and toothpastes production. Water-soluble polymers find application in a wide variety of areas that include polymers as food sources, plasma substitute, water treatment, sewage treatment, stabilizing agent in the production of commodity plastics, enhanced oil and

natural gas recovery, mineral processing, detergents, textiles, personal care products, pharmaceuticals, surface coatings and as diluents in medical prescriptions. Water soluble polymer business represents a sieable and steadily growing segment of the plastic industry. It has been suggested that the total world product is probably over 6 million tones/year. Of this, some 90% is carbohydrate based with an additional 4 lakhs tones/year of cellulose either, about 2 lakh tone/year of proteins, mainly gelatin, the remainder being synthetic polymers, the most important of which are polycrylamide and polyvinyl alcohol. Water soluble are economic importance, and the industries. However, the size of the market in terms of dollars and the rate of growth are deceptive for two reasons: the great bulk of the water soluble polymers consumed are starches, which sell for very low cost per pound and the water soluble polymer business comprises three distinct product categories-natural products, semi synthetic products and synthetic products.

Classifications of water soluble polymers

Natural products are derived from animal and vegetable sources and have been marketed from many years. They represent by far the largest volume of sales in the water soluble polymer area. Examples: starches, dextrin's, alginates, natural gums and gelatin. Synthetic water soluble polymers which are produced by the polymerization of monomers synthesized from petroleum or natural gas products. These are the latest member of the water soluble polymers family. Examples: polyvinyl alcohols, polyvinyl pyrrolidones, polyvinyl methylethers, polyacrylic acid and its salts, polyacrylamides, ethylene oxide polymers and various copolymer systems.

Polymer blends: With the advancement of civilization man is always looking for new materials to meet his specific needs. The new material should provide better properties in comparison with the net polymers and the method of preparations should be available and affordable cost. A single polymer cannot fulfill the requirement of the industrial applications. Desired properties of a polymer for a particular application can be obtained by Doping, Blending, Composites and Irradiation. Polymer blends are physical mixtures of two or more polymers with/without any Chemical bonding between them. Polymer blend represents very important field in processing of new materials, Blends of two polymers are usually prepared to achieve desired properties. This is due to the possibility of developing new materials form polymer blends. The properties of the blend are different and better then the properties of the single polymer. The objective of polymer blending is a practical one of achieving commercially available products through either unique properties or lower cost than some other means might provide. They are significant also from ecological and economical viewpoint. Blending technology also provides attractive opportunities for reuse and recycling of polymer wastes. The opportunity to develop or improve the properties to meet specific customer needs Light weight, Enhanced ozone resistance, improved impact and environmental stress cracking resistance, improved modulus and hardness etc. Mixing of two or more polymer together to produce polymer blends or alloys is also well strategy for achieving a specific portfolio of physical properties, without the need to synthesis specialized polymer systems.

Categorization of polymer blends

Based on the method of preparation, polymer blends are classified into five groups as follows:

Mechanical polyblends

A mechanical polymer blends is made by melt-blending the polymers either on an open roll or an extruder or any other suitable intensive mixer. The processing temperature must be well above the glass transition temperature $(T_g)$of each constituent form mixtures of amorphous polymers and above the melting temperature $(T_m)$of mixtures containing semi-crystalline polymers, whichever is higher. Commercial polymer blends are almost exclusively mechanical polymer blends.

Mechano-chemical polyblends

Based on the state of thermal stability, the processing shear could initiate degradation, resulting in free radicals. If the free radicals react with the other structurally different polymers present, resulting in true chemical graft or block co-polymers, the mixtures are called mechano-chemical polymer blends.

Chemical polyblends

The three main categories are interpenetrating polymer network(IPN_s), simultaneous interpenetrating polymer networks(sin_s), and interpenetrating elastomeric network(IEN_s). In general, mixing and coagulating two different polymer latex results in IEN_s; cross-linking the coagulum forms a three dimensional mosaic structure.

Solution cast polyblends

There are prepared by dissolving the constituent polymers in common solvent in such a way that the solutions are mixed thoroughly. The resulting solution can be film-cast, coagulated, spray-dried or freeze-dried to form the solution cast polymer blend.

Latex polyblends

If the latex coagulum is not cross-linked, the resulting product is called a latex polymer blend. This method is particularly useful in the preparation of rubber-toughened polymer blends, which are mixtures of latex polymers.

Applications of Polymers:

Polymeric materials are used in the soil to improve aeration, mulch, and support plant growth and health.

- Medicine Diagnostic and laboratory devices
- Organ and tissue replacements
- Blood handling devices
- Heart valve replacements and blood vessels,

Consumer Science

Plastic containers of all shapes and sizes are light weight and economically less expensive than the more traditional containers. Clothing, floor coverings, textile fibers, high strength polyamides for light weight bullet proof vests, polyethylene plastic for milk bottle and rubber for automobile tyres, polymers are also used in composites, electronic devices, biomedical devices, optical devices, precursors and newly developed high tech ceramics, garbage disposal bags, and packaging are other polymer applications.

Industry

Automobile parts, windshields for fighter planes, pipes, tanks, nylon ropes, packing materials, insulation, wood substitutes, milk bottle, adhesives, matrix for composites, and elastomers are all polymer applications used in the industrial market.

Sports

Playground equipment, dress fabrics, various balls, basketball and football net, golf clubs, swimming pools, and protective helmets are often produced from polymers.

Packaging

Physical characteristics of packaging polymers are great influenced by the chemical structure , crystallinity, molecular weight and processing conditions of the polymer used. The physical characteristics required for packaging depends on the type of product to the packaged as well as the environment in which the package is to be stored. Items which must be kept frozen for a period of time require special packaging. Food items especially perishable ones require more stringent packaging materials than non-perishable goods. The challenge in the development of biodegradable packaging will be to combine polymers which are completely biodegradable into a laminate film or a film blend which has properties as good as those found in synthetic laminates. The literature survey reveals that much research work has not been carried out on water soluble polymer blend with inorganic salts and its potential use as packaging material. Addition of plasticizer like glycerol, doping with Sodium Sulphate and Zirconium dioxide salts to Hydroxy propyle Methycellulose(HPMC) blend with polyvinyl alcohol (PVA) polymers to prepare the pure and blend films of these materials. These samples in the department of Physics, Manasagangothri, Mysore.

METHODOLOGY

The details of the materials used for the preparation of the samples, method of preparation and the various techniques used for their characterization have been discussed. The solution casting method was used for the preparation of the samples. In X-ray diffraction study, W-H plot was used to compute the micro structural parameters of the samples. UV-visible (Ultra violet-visible spectroscopy) and Conductivity measurement were also carried out to characterize the prepared polymer composites. In this study, we have used Hydroxypropyl Methyl cellulose (HPMC), Polyvinyl alcohol (PVA), Sodium sulphate and Zirconium dioxide in the powder form to prepare the samples. These materials were purchased from Loba chemicals and S.D Fine chemicals India.

Hydroxypropyl Methylcellulose (HPMC)

Hydroxypropyl Methyl cellulose (HPMC) is a bio-polymer derivative of cellulose, with methyl and hydroxyl groups that render the cellulose molecule hydrophobic and hence it acquires surface-active properties. HPMC is water soluble, tasteless, non-ionic and is available in powder form. It is tough and elastic in physical properties. These films have excellent oil resistance along with its antioxidant nature, it has been accepted as food additives in Europe, inactive ophthalmic preparations, oral capsules, suspension syrups, and eye drops. HPMC is used in increasing the solubility of drugs, in drug release system, in cosmetics, in general healthcare products, as thickening agent, and is widely used cellulose as film forming agent for conventional tablet film coatings. HPMC with hydroxypropyl substitution of 7 to 12% has the unique property of water solubility combined with solubility in hot and cold organic solvents. The structure of HPMC is as shown in Figure1.

Polyvinyl alcohol (PVA)

Poly vinyl alcohol has chemical resistance, physical properties, biodegradability and good fiber forming capability in electro spinning techniques. Poly (vinyl alcohol) PVA is a non-toxic, water-soluble synthetic polymer and has good physical and chemical properties. It has the idealized formula $\left(CH_2CH(OH)\right)_n$.It dissolves slowly in cold water but at high temperature it goes fairly fast in to solution. Polyvinyl alcohol has excellent film forming, emulsifying and adhesive properties. It is also resistant to oil, grease and solvent. PVA is an atactic material but exhibits crystalline as the hydroxyl groups are small enough to fit into the lattice without disrupting it. It has high tensile strength, flexibility, as well as high oxygen and aroma barrier. However these properties are dependent on humidity, in other words, with higher humidity more water is absorbed. The water which acts as a plasticizer reduces its tensile strength but increases its elongation and tear strength. It is used in paper making, textiles, recycling of polymers and packaging. Studies on the mechanism of dissolution and changes in crystallinity, swelling behavior of PVA and its physical gel-forming capabilities have been carried out, PVA has bio-inertness and has many uses in medical field such as artificial pancreas, hemodialysis and nanofillteration, synthetic vitreous and implantable medical device. Anti thrombo genicity, cell compatibility, blood compatibility and biocompatibility of PVA have been studied extensively. The structure of PVA is as shown in Figure 2

Inorganic salt

Organic chemistry of carbon and hydrogen bonds. Inorganic chemistry deals with compounds that for the most part, do not have carbon, though there are some exceptions. Many of these inorganic compounds are classified as salts. In-organic salts can be divided into four main classes: oxides, halides, sulfates, and carbonates. Many inorganic compounds are ionic compounds, consisting of cations and anions joined by ionic bonding. Many inorganic compounds are characterized by high melting point. Inorganic salts typically are poor conductors in the solid state. Other important features include their solubility in water.

Methods of preparation of the sample films

The polymer films can be prepared from the following methods

1. Mechanical blending
2. Solution casting

3. Chemical blending
4. Spin coating
5. Electro spunning
6. Melt blending

Among these methods we preferred Solution casting method to prepare the samples as us this method is cost effective and environmental friendly.

Solution casting method

The films were prepared by solution casting method. HPMC is powdered samples purchased from Loba chemicals Mumbai. Pure blend and doped films were prepared by using solution cast method. HPMC (5 % wt) dissolved in distilled water separately. After complete dissolution the solutions were filtered using filter paper to remove undissolved particles. These polymer solutions were called as stock solutions to which various inorganic salts of different concentrations were added and dissolved using a magnetic stirrer. The dissolved salt solutions were then casted separately to get respective polymer blend composite films. After complete drying, the films were peeled out of the glass plate and stored in desiccators to avoid moisture. The apparatus used for preparing the sample solution is as shown in the Figure 5 and 6. Photographs of Magnetic stirrer (Figure 3). Shows the photographs of the Zirconium dioxide salt (Figures 4).

Characterization of polymer blends

The prepared samples were characterized by writing following techniques.

X-ray Diffraction Technique

The casted polymer films cut into 2 cm × 2 cm and were taken in the sample holder of Rigaku-Denki miniflex II desktop X-Ray diffract meter with the settings of 30 kV and 15 mA, scanning rate of 50 per minute, and for the range of 50 to 600 with step size of 0.020 being recorded. The integral breadth of the diffraction peaks is related to the apparent size of the crystals and to their micro strains. If the size and strain broadening exist simultaneously, then crystallite size and strain can be calculated by Williamson-Hall plot (W-H plot). For relative comparison of the parameters, WH plot is a reasonably reliable one . The W-H plot considers both limited size of the crystals and the presence of crystallographic distortions which leads to Lorentzian intensity distributions. The slope of the W-H plot represents the average strain in the crystal, whereas intercept with the y-axis gives the crystallite size. The Williamson-Hall relation is given by,

$$\beta \frac{cos\theta}{\lambda} = \frac{1}{D} + 4\varepsilon \frac{sin\theta}{\lambda}$$

Where β is the full width at half maximum (FWHM) of the peak measured in radians, D is average crystallite size, and ε is average lattice strain. The obtained XRD plots and the values of crystallite size and average strain

RESULTS AND DISCUSSION

HPMC+PVA: ZrO_2

W-H plot method is quite useful for relative comparison of crystallite size and strain in a series of polymer composite films of various concentration of ZrO_2 in HPMC+PVA. The computed micro structural parameters of HPMC+PVA doped with ZrO_2 polymer composite is given in Table 1 and 2. The computed microcrystalline parameters like Crystalline area and lattice strain g in % while computing are also shown. From the obtained results of these polymer composites it is clear that the crystallite area of the polymer composites increases with the increase in the concentration of Zirconium dioxide salt. W-H Plot of 0.2% ZrO_2: HPMC+PVA (Figure 8). W-H Plot of 0.3% ZrO_2: HPMC+PVA (Figure 9).

ABSTRACT

Leptadenia reticulata (Retz.) Wight and Arn., an endangered medicinal plant of high Ayurvedic significance, is traditionally recognized for its immunomodulatory, antioxidant, and rejuvenating activities. In the present investigation, comparative phytochemical profiling was conducted between *in vivo* (mother plant) and *in vitro* regenerated plants to assess their metabolic fidelity. Preliminary qualitative screening confirmed the consistent presence of alkaloids, flavonoids, saponins, phenolics, tannins, and glycosides across both sources. Subsequent quantitative estimations revealed appreciable levels of total phenolics, flavonoids, and tannin with statistically non-significant variations between mother and micro propagated plants. The phytochemical equivalence demonstrated herein underscores that *in vitro* regenerated *L. reticulata* reliably retains its bioactive metabolite spectrum. These results highlight the dual significance of tissue culture not only as a conservation strategy for this endangered species but also as a sustainable approach for producing phytochemically authentic plant material for pharmacological and therapeutic applications.

Keywords: *Leptadenia reticulata*, phytochemical profiling, quantitative estimation, *in vitro* regeneration, conservation, secondary metabolites

INTRODUCTION

Medicinal plants have long been recognized as a vital source of natural bioactive compounds and continue to play a significant role in traditional healthcare systems as well as modern drug discovery. The therapeutic potential of medicinal plants is primarily attributed to the presence of secondary metabolites, which are organic compounds synthesized during plant metabolism and are not directly involved in growth or reproduction. Among these, alkaloids, flavonoids, and tannins are of particular importance due to their diverse biological activities, including antioxidant, antimicrobial, anti-inflammatory, hepatoprotective, and anticancer properties. These compounds also contribute to plant defense mechanisms and ecological adaptation, making them valuable indicators of phytochemical richness and medicinal quality (Pandey *et al*., 2022; Salehi *et al*., 2023). Qualitative phytochemical screening serves as a preliminary yet essential step in phytochemical investigations, providing rapid information on the presence or absence of major classes of secondary metabolites. Such screening aids in the selection of suitable extraction methods and guides further quantitative and advanced analytical studies. In parallel, quantitative estimation of key phytochemicals is crucial for evaluating the concentration and distribution of bioactive compounds, enabling comparison between different plant materials and growth conditions. Spectrophotometric methods are widely employed for the estimation of total alkaloids, flavonoids, and tannins due to their simplicity, cost-effectiveness, and reproducibility, making them suitable for routine analysis in natural sciences research (Kumar *et al*., 2023). *Leptadenia reticulata* (Retz.) Wight and Arn., a perennial medicinal climber belonging to the family Apocynaceae, is widely distributed in dry and semi-arid regions of India.

The plant is commonly known as Jivanti and is extensively used in traditional systems of medicine for its rejuvenating, lactogenic, adaptogenic, and general tonic properties. Ethnomedicinal reports and earlier phytochemical studies have indicated that *L. reticulata* contains a wide range of secondary metabolites, including alkaloids, flavonoids, tannins, phenolics, glycosides, saponins, and steroids, which collectively contribute to its pharmacological potential (Sharma *et al*., 2021; Verma and Singh, 2022). Leaves of *L. reticulata* are particularly important as they are frequently used in herbal formulations and are rich in phenolic and flavonoid compounds. Despite its medicinal importance, *L. reticulata* has faced increasing pressure due to habitat loss, overharvesting, and low natural regeneration, raising concerns about its sustainable utilization. In this context, *in vitro* propagation has emerged as a promising alternative for conservation and large-scale multiplication of this valuable species. Plant tissue culture techniques offer controlled growth conditions that minimize environmental variability and enable year-round production of plant material. However, it has been widely reported that *in vitro* culture conditions can influence secondary metabolite biosynthesis due to changes in nutrient availability, hormonal balance, and physiological stress (El-Shamy *et al*., 2022). Comparative phytochemical studies between *in vivo* grown plants and *in vitro* regenerated tissues have revealed significant variations in both qualitative composition and quantitative levels of secondary metabolites. Such variations may affect the medicinal quality and therapeutic equivalence of tissue culture–derived plant materials. Therefore, it is essential to evaluate whether *in vitro* propagated plants retain phytochemical profiles comparable to their naturally grown counterparts (Rahman *et al*., 2023).

For medicinal plants like *L. reticulata*, where leaves serve as an important source of bioactive compounds, comparative analysis becomes particularly relevant. Although several studies have reported general phytochemical screening of *L. reticulata*, systematic comparative investigations focusing on preliminary qualitative analysis and quantitative estimation of total alkaloids, flavonoids, and tannins in leaf tissues derived from *in vivo* and *in vitro* sources remain limited. Addressing this gap is important not only for understanding the impact of growth conditions on secondary metabolite accumulation but also for validating the use of *in vitro* propagated plants as an alternative source of phytochemicals. Therefore, the present study aims to perform a comprehensive qualitative phytochemical screening and quantitative estimation of total alkaloids, flavonoids, and tannins in leaves of *Leptadenia reticulata*(Retz.) Wight and Arn. grown under natural (*in vivo*) and tissue culture (*in vitro*) conditions. The findings of this study are expected to contribute valuable baseline data for natural product research, conservation strategies, and the phytochemical standardization of this medicinally important species. Given the increasing industrial demand for

authenticated *L. reticulata* biomass, a systematic comparative assessment of its phytochemical composition is imperative. Therefore, the present study investigates the qualitative and quantitative phytochemical profiles of both *in vivo* and plant parts to establish biochemical benchmarks, evaluate metabolic consistency, and contribute to conservation strategies and standardization of medicinal raw materials (WHO, 2011; Soni and Mishra, 2021).

METHODOLOGY

Plant Material Collection and Authentication

Field-grown (*in vivo*) samples of *Leptadenia reticulata* (Retz.) Wight and Arn. were collected from Atri Ashram, Satlasana, Gujarat, India, a region known for its semi-arid climatic regime conducive to the natural proliferation of the species. Healthy, disease-free plant parts (leaves) were selectively harvested following standard pharmacognostic protocols to ensure biochemical integrity. The collected specimens were authenticated by a taxonomist, and voucher samples were deposited in the departmental herbarium for future reference. *In vitro*-derived plantlets were obtained from the Plant Tissue Culture Laboratory, where standardized micropropagation protocols were previously established. Regenerated shoots and roots at the acclimatized stage (8–10 weeks old) were selected to ensure physiological maturity comparable to their field-grown counterparts. All *in vitro* materials were harvested under aseptic conditions to prevent microbial interference in downstream biochemical analyses.

Sample Preparation

Both *in vivo* and *in vitro* plant parts were thoroughly rinsed with distilled water to remove surface contaminants. Samples were shade-dried at controlled room temperature (26 ± 2 °C) to preserve thermo-labile metabolites, followed by final drying in a hot-air oven at 40 °C to achieve constant weight. Dried materials were pulverized using a mechanical grinder to obtain homogenous fine powders (particle size < 1 mm) suitable for solvent extraction.

Extraction of Phytochemicals via Maceration Technique

Cold maceration was utilized to enhance the recovery of thermolabile secondary metabolites. Precisely weighed plant powder (10 g) from each sample type was transferred into amber glass containers and macerated with 100 mL of analytical-grade methanol (80:20, v/v), selected for their broad polarity spectrum and ability to solubilize diverse metabolite classes. The mixtures were agitated intermittently and kept at room temperature for 48–72 hours. After maceration, the extracts were filtered through Whatman No.1 filter paper and concentrated under reduced pressure using a rotary vacuum evaporator at 40 °C. The semi-solid residues were further dried to constant weight and stored at 4 °C until qualitative and quantitative assessments. Extractive yields were calculated to evaluate solvent efficiency across *in vivo* and *in vitro* samples.

Qualitative Phytochemical Screening

Preliminary phytochemical profiling was conducted using well-established pharmacognostic assays to detect the presence of major metabolite groups, including: Alkaloids (Dragendorff's, Mayer's tests), Flavonoids (Shinoda, alkaline reagent tests), Phenolics and tannins (Ferric chloride, lead acetate tests), Terpenoids and steroids (Salkowski, Liebermann–Burchard tests), Saponins (froth and hemolysis tests), Glycosides (Keller–Killiani, Bornträger's tests). These tests provided a comparative qualitative signature for both *in vivo* and *in vitro* extracts.

Quantitative Phytochemical Estimation

Quantitative assessments of key metabolite classes were performed using advanced biochemical methodologies: Total Phenolic Content (TPC): Folin–Ciocalteu assay, expressed as mg GAE/g extract, Total Flavonoid Content (TFC): Aluminium chloride colorimetric method, expressed as mg QE/g extract, Total Alkaloid Content: Gravimetric and UV–Vis spectrophotometric estimation, Tannin Content: Polyvinylpyrrolidone (PVP) binding method, Saponin Content: Spectrophotometric foam index analysis. The methanolic extracts of all samples (L.R.-M.P., L.R.- T.P.) were subjected to qualitative analysis for the presence of the following phytochemicals using standard protocols.

Quantitative estimation of flavonoids: 1ml of test sample and 4 ml of water were added to a volumetric flask (10 ml volume). After 5 min 0.3 ml of 5 % Sodium nitrite, 0.3 ml of 10% Aluminium chloride was added. After 6 min incubation at room temperature, 2 ml of 1 M Sodium hydroxide was added to the reaction mixture. Instantly the final volume was made up to 10 ml with distilled water. The absorbance of the reaction mixture was measured at 415 nm against a blank spectrophotometrically. Results were expressed as catechin equivalents (mg catechin/g dried extract).

Quantitative Estimation of Phenolic Compound: The total phenolics content in different solvent extracts was determined with the FolinCiocalteu's reagent (FCR). In the procedure, different concentrations of the extracts were mixed with 0.4 ml FCR (diluted 1:10 v/v). After 5 min 4 ml of sodium carbonate solution was added. The final volume of the tubes were made up to 10 ml with distilled water and allowed to stand for 90 min at room temperature. Absorbance of sample was measured against the blank at 765 nm using a spectrophotometer. A calibration curve was constructed using catechol solutions as standard and total phenolic content of the extract was expressed in terms of milligrams of catechol per gram of dry weight and the standard graph.

Quantitative Estimation of tannin: Quantitative tannin content in the extracts tested according to the method suggested by Mital and Jha30. 1 mL of extract mixes with 0.5 mL of Folin reagent, and then saturate with 1 mL of Na2CO3 and 8 mL of distilled water add to the final mixture. The solution, which incubate for 30 min, centrifuge and the supernatant analyze at 725 nm. Tannic acid use as a standard and tannin content express as mg tannic acid equivalent (TAE)/g.

Statistical Analysis

All experiments were performed in triplicates. Data were expressed as mean ± standard deviation (SD). Statistical significance between *in vivo* and *in vitro* samples was analyzed using Student's *t*-test at $p< 0.05$ (Gomez and Gomez, 1984).

DISCUSSION

Recent studies have emphasized the quantitative estimation of major phytochemical classes in *Leptadenia reticulata*(Retz.) Wight and Arn. leaf extract to support pharmacological validation and quality standardization. Spectrophotometric analyses have shown that hydroalcoholic leaf extracts possess comparatively higher levels of total phenolics and total flavonoids than aqueous extracts, indicating solvent dependent extraction efficiency. In addition to phenolics and flavonoids, quantitative and semi- quantitative assessments have confirmed the presence of alkaloids, tannins, saponins and free amino acids, which collectively contribute to the antioxidant, anti-inflammatory and adaptogenic properties of the species (Surendar, 2025). Recent metabolomic-based investigations further support these findings by correlating elevated phenolic and flavonoid abundance with enhanced biological activity, highlighting the relevance of precise phytochemical quantification for therapeutic validation and conservation- oriented utilization of *L. reticulata* (Mallepura Adi Narayanaswamy *et al*., 2024). The qualitative phytochemical analysis revealed the consistent presence of alkaloids, flavonoids, saponins, phenols, glycosides, terpenoids, tannins, and amino acids in both the mother plant and tissue culture-derived plants of *Leptadenia reticulata*(Retz.) Wight and Arn. This observation confirms that micropropagation effectively maintains the biosynthetic integrity of major secondary metabolites under *in vitro* culture conditions (Manohari and Shekhawat, 2016; Kumar and Singh, 2015). The biochemical uniformity observed between *in vivo* and *in vitro* samples highlights the reliability of tissue culture techniques for producing phytochemically stable medicinal plant material (Satdive *et al*., 2007; Lal and Singh, 2018). The comparative analysis of total phenolic content revealed in figure no.1 identical values (11.8 µg/ml) between the mother plant and *in vitro* regenerated plants, and statistical analysis confirmed that the difference was not significant ($p > 0.05$). Phenolic compounds are known to play a crucial role in antioxidant activity, defense responses, and therapeutic efficacy of medicinal plants (Singleton *et al*., 1999; Brand-Williams *et al*., 1995). The conservation of phenolic levels in tissue culture-derived plants clearly demonstrates that the micropropagation process does not disrupt phenolic biosynthesis, thereby ensuring phytochemical fidelity to the

mother plant. Similarly, total flavonoid content showed (figure no. 2) identical values (8.81 µg/ml) in both *in vivo* and *in vitro* samples with no statistically significant difference ($p > 0.05$). Flavonoids contribute substantially to antioxidant, anti-inflammatory, hepatoprotective, and immunomodulatory activities (Chang *et al*., 2002; Singh and Sharma, 2019). The preservation of flavonoid biosynthesis in micro propagated plants further confirms their medicinal equivalence to the naturally grown plants. In contrast, total tannin content was observed (figure no. 3) to be slightly higher in the mother plant (72.98 µg/ml) compared to the tissue culture-derived plant (66.35 µg/ml), and statistical evaluation indicated a significant difference. Tannins are known to be sensitive to environmental factors, nutrient availability, and stress conditions (Mital and Jha, 2012; Pandey and Tripathi, 2014). The slight reduction in tannin accumulation in *in vitro* plants may be attributed to the absence of natural ecological stress and variations in *in vitro* nutrient composition. However, the regenerated plants still retained substantial levels of tannins, suggesting that micropropagation does not critically compromise their pharmacological relevance. Overall, the present findings are consistent with earlier reports demonstrating that *in vitro* propagation preserves qualitative and quantitative phytochemical stability in medicinal plants (Satdive *et al*., 2007; Soni and Mishra, 2021). The study strongly validates micropropagation as an efficient and sustainable conservation strategy for endangered medicinal plants such as *Leptadenia reticulata* (Retz.) Wight and Arn.

CONCLUSION

The study concludes that micropropagation of *Leptadenia reticulata* successfully preserves the majority of its phytochemical attributes. The qualitative profile remained consistent across mother and tissue culture plants, while quantitative estimations demonstrated stability in total phenolic and flavonoid contents with only a moderate reduction in tannins. These findings confirm that micropropagation is not only an efficient conservation strategy for this endangered species but also ensures the retention of its medicinally valuable metabolites. Therefore, tissue culture-derived *L. reticulata* plants can serve as a reliable source for sustainable utilization in pharmaceutical and herbal formulations.

ABSTRACT

Natural products (NPs) remain a vital source of therapeutic agents, agrochemicals, and chemical probes. Recent advances in artificial intelligence (AI) and machine learning (ML) are transforming how researchers discover, characterize, and optimize natural products. This review summarizes current AI/ML approaches applied across natural product research: genome mining for biosynthetic gene clusters, metabolomics and dereplication, structure elucidation from tandem mass spectra, bioactivity prediction, and de novo molecule design inspired by natural scaffolds. We discuss representative methods (including deep learning, graph neural networks, representation learning, and transfer learning), key case studies that demonstrate real-world impact, and persistent challenges such as data quality, interpretability, and experimental validation. Finally, we outline future directions likely to accelerate NP discovery through tighter integration of multi-omics data, active learning, and community data sharing.

Keywords: Natural Products, Therapeutic agents, Agrochemicals, Machine learning, Scaffolds.

INTRODUCTION

Natural products are structurally diverse molecules produced by organisms across the tree of life. Historically, many drugs originate from natural product scaffolds, but traditional discovery pipelines—culture isolation, activity screening, structure elucidation—are time-consuming and often rediscover known compounds (dereplication problem). The integration of high-throughput genomics and mass spectrometry (MS) has expanded datasets, while

AI/ML methods provide scalable tools to learn patterns from these datasets, prioritize novel chemistry, and suggest hypotheses for experimental validation [3].

Machine learning offers several advantages for NP research:
Automated feature extraction from high-dimensional data, predictive modelling for activity or biosynthetic potential, and generative models for proposing new chemical structures. Below we review key ML paradigms and their applications to NP discovery and characterization [1].

ML Methods and Representations Relevant to Natural Products
Success of ML depends on suitable representations and architectures. Common approaches include:
Classical supervised learning (random forests, support vector machines, gradient boosting) used when labelled data is available (e.g., active vs inactive compounds).

Deep learning (convolutional neural networks, recurrent neural networks, transformers) for learning hierarchical features directly from raw or lightly processed inputs such as spectra, SMILES, or sequence windows.

Graph neural networks (GNNs) that operate on molecular graphs and biosynthetic gene cluster (BGC) networks to capture relational structure of atoms or genes.

Representation learning and embeddings (autoencoders, variational autoencoders, contrastive learning) that map molecules, spectra, or genomic contexts to continuous vectors enabling similarity searches and downstream predictions [2].

Generative models (VAEs, generative adversarial networks, autoregressive transformers) for de novo design or for augmenting small datasets.

Transfer learning and few-shot learning to leverage models pretrained on large chemical or biological corpora and adapt them to NP-specific tasks.
Choosing representations is crucial: SMILES strings, molecular graphs, fragmentation trees from MS/MS, and sequence windows or domain annotations for BGCs are commonly used. Modern models frequently combine multiple modalities (e.g., genome + MS) to improve predictions.

Table-1: Artificial intelligence driven approaches in phytochemical research: trends and prospects (2010-2025) which likely gives trend data(Shi *et al*., 2025; Meijer *et al*., 2025).

Table-2: Advanced Computational Tools for Pharmacological Prediction andTarget Identification in NP Drug Discovery (Gangwal *et. Al*.,2025).

Figure 1: Overview of the natural product (NP)-inspired drug-discovery strategy. Crude extracts obtained from plants, animals, and microorganisms are subjected to bioactivity and toxicity profiling, followed by chromatographic fractionation and analytical characterisation (for example, nuclear magnetic resonance [NMR], high-performance liquid chromatography–mass spectrometry [HPLC-MS], and gas chromatography–mass spectrometry [GC-MS]). Artificial intelligence and machine learning (AI/ML) methods support spectral annotation, dereplication, and the prioritisation of candidate compounds. Target deconvolution approaches—including drug affinity responsive target stability (DARTS), cellular thermal shift assay (CETSA), and stability of proteins from rates of oxidation (SPROX)—together with mode-of-action investigations (e.g., structure–activity relationship [SAR] studies and pathway analyses) link bioactive constituents to molecular targets and biological pathways. Lead compounds are subsequently refined through medicinal chemistry and scalable synthetic methodologies to generate viable therapeutic candidates.

Applications

Genome mining and biosynthetic gene cluster prediction

Genome mining has accelerated the identification of biosynthetic gene clusters that encode NP synthesis. Tools such as anti-SMASH provide rule-based detection of BGCs [4], while ML methods detect atypical or novel clusters beyond rule sets. DeepBGC applied deep learning to predict BGCs from genomic sequences and domain architectures, improving sensitivity to novel cluster types [5]. ML also supports prioritization of BGCs by predicting likely product classes or chemical features, enabling focused experimental efforts. Key advances include integration of domain co-occurrence patterns, gene neighbourhood context, and incorporation of curated BGC databases (e.g., MIBiG) to train and benchmark models[6]. GNNs can model relationships between genes and predict enzyme functions or tailoring reactions, supporting biosynthetic pathway reconstruction and heterologous expression planning.

Metabolomics, molecular networking, and dereplication

High-resolution mass spectrometry (MS/MS) generates vast spectral datasets that require automated analysis. Molecular networking frameworks (e.g., GNPS) cluster related spectra to reveal chemical families and facilitate dereplication [8]. ML enhances molecular networking by improving spectral similarity scoring (learned embeddings) and by integrating metadata to prioritize samples. Representation learning approaches—embedding MS/MS spectra into continuous spaces—enable fast similarity searches and analog discovery. Methods inspired by natural language processing treat fragmentation patterns as "words" and learn vector representations that capture structural relationships, improving retrieval of structurally related but non-identical compounds[7].

Structure elucidation and annotation from tandem MS

Annotating spectra to chemical structures is a central challenge. Tools like CSI: Finger-ID use machine learning to predict molecular fingerprints from tandem MS and then search chemical databases for candidate [9]. Systems that combine fragmentation tree computation and ML-based scoring have increased identification rates for unknowns. Newer deep learning models trained on large paired sets of spectra and structures further improve power to assign substructures or probable molecular formulas, especially when paired with *in-silico* fragmentation models[10].

Bioactivity and target prediction

ML models predict biological activity and potential targets from structure or derived features. Supervised models trained on bioassay data can prioritize NP candidates for screening. Transfer learning from large chemical datasets improves performance when NP-specific labelled data are limited. Notably, ML approaches have enabled discovery of novel antibacterial scaffolds by prioritizing diverse chemical matter with predicted activity and favorable properties [11].

De novo design and optimization

Generative models trained on NP-derived chemical space or on combined natural and synthetic molecules can propose novel analogs retaining desirable NP motifs. Continuous latent spaces (e.g., VAEs) allow property optimization via gradient or Bayesian optimization in latent space (Gómez-Bombarelli *et al*., 2018). These approaches are particularly useful to design simplified analogs of complex NPs that retain bioactivity but improve synthetic accessibility or pharmacokinetics [12].

Integrative multi-omics analysis

Integrating genomic, transcriptomic, proteomic, and metabolomic data strengthens NP discovery: expression data can indicate active BGCs, while MS features map to expected chemical products. ML frameworks that jointly model multiple data modalities—via multi-task learning or multimodal embeddings—can prioritize BGC-metabolite links and reduce false positives from single-modality analyses.

Representative Case Studies

DeepBGC for genome mining. DeepBGC uses deep learning to identify BGCs and predict product classes, enabling discovery of noncanonical clusters missed by rule-based tools [13]. Combined with synthetic biology and heterologous expression, such predictions have directly led to new NP identification in microbial genomes.

GNPS and learned spectral similarity. The GNPS ecosystem democratizes MS/MS data sharing and molecular networking [14]. Coupling GNPS with learned spectral embeddings improved clustering and analogue discovery, enabling researchers to map chemical diversity across environments and to recognize novel chemical families more reliably.

AI-driven antibiotic discovery. A high-profile example beyond strictly NP research demonstrates AI's capacity for novel scaffolds: models trained on large chemical libraries identified a structurally distinct antibiotic ("halicin") with potent activity in vitro and in vivo (Stokes *et al.*, 2020). Although halicin was not a natural product, this approach highlights how ML can accelerate discovery by learning chemical-activity relationships and prioritizing candidates for experimental testing.

CSI: FingerID for structural annotation.CSI: FingerID predicts substructure fingerprints from spectra, enabling efficient database search and improving structural annotation rates for unknown metabolites (Dührkop *et al*., 2015). Combined with molecular networking, fingerprint prediction helps annotate related unknowns by propagation of likely substructure [15].

Challenges and Limitations

Despite progress, several challenges limit the full impact of AI/ML in NP research:

Data quality and labeling: ML depends on labeled training data. For many NP families, curated spectra, accurate structures, and validated bioactivity labels are sparse or biased toward well-studied taxa.

Heterogeneity of data: Spectral data vary by instrument, fragmentation method, and sample preparation. Model robustness across platforms requires harmonized preprocessing or domain adaptation techniques.

Class imbalance and novelty: NP discovery often seeks rare, novel chemotypes. Standard ML models may overfit abundant classes. Techniques such as anomaly detection, active learning, and one-shot/few-shot learning can help but are not yet mainstream in NP pipelines.

Interpretability: Deep models can be black boxes, making it hard to rationalize predictions for prioritization decisions. Interpretability methods (feature attribution, attention visualization) are increasingly applied but need domain-specific adaptation.

Integration with experimental workflows: Model predictions require experimental validation. The speed and cost of validation create a bottleneck; closing the loop with iterative active learning and high-throughput assays is an ongoing need.

Benchmarking and reproducibility: Diverse datasets, lack of standardized benchmarks, and proprietary datasets impede fair comparison of methods. Community efforts to share datasets and benchmarks are essential [16].

Disadvantages of AI and Machine Learning in Natural Product Drug Development

AI and Machine Learning have revolutionized many aspects of drug discovery, including natural product research, by accelerating data analysis, predicting molecular properties, and optimizing lead compounds. However, despite these advantages, there are notable disadvantages and challenges that need careful consideration.

Data Quality and Availability

One major limitation of AI/ML in natural product drug development is the dependency on large, high-quality datasets. Natural products are chemically diverse and often poorly characterized, leading to sparse and inconsistent data. Incomplete or biased datasets can result in inaccurate model predictions or overfitting, limiting the reliability of AI-driven decisions [17]. Additionally, natural product databases are not as extensive or standardized compared to synthetic compound libraries, further complicating model training.

Complexity of Natural Products

Natural products often possess complex, unique chemical structures and stereochemistry, making it difficult for AI models to accurately predict their biological activity or pharmacokinetics [18]. Many ML algorithms excel in well-defined chemical spaces but struggle with the structural heterogeneity and multifaceted interactions natural products exhibit in biological systems. This can lead to misclassification or missed drug candidates.

Interpretability and Explainability

AI models, particularly deep learning approaches, often function as "black boxes," providing little insight into why certain molecules are predicted as active or inactive (Rudin, 2019). This lack of interpretability hinders trust and acceptance among medicinal chemists and biologists who require mechanistic understanding to validate results. In drug development, regulatory agencies also demand transparency for approval processes, which may be difficult to satisfy with opaque AI models.

Integration with Experimental Validation

While AI can generate hypotheses and prioritize candidates, experimental validation remains essential. However, the translation of AI predictions into lab-scale or clinical testing is time-consuming and costly. Over-reliance on AI might undervalue the importance of empirical screening and overlook biological complexities such as metabolism, toxicity, or off-target effects that models cannot fully capture[20].

Ethical and Practical Challenges

AI adoption raises concerns about data privacy, intellectual property, and reproducibility in natural product research. Additionally, smaller research groups may lack access to advanced AI tools or computational infrastructure, potentially widening the innovation ga

Best Practices and Recommendations

To maximize value from AI/ML in NP research, researchers should consider:

Curated datasets: Contribute to and use community repositories (e.g., GNPS, MIBiG) to expand representative training sets.

Multi-modal integration: Combine genomic predictions with metabolomics to increase confidence in candidate assignments.

Model validation: Use rigorous cross-validation, external test sets, and ultimately experimental validation to confirm predictions.

Transparent reporting: Share code, models, and preprocessing pipelines to support reproducibility.

Active learning: Adopt iterative experimental–computational loops to efficiently label the most informative samples and improve models[19].

Advantages of AI and Machine Learning in Natural Product Drug Development

Artificial Intelligence (AI) and Machine Learning (ML) are transforming natural product drug development by overcoming traditional challenges and accelerating the discovery pipeline. Their ability to handle complex data, predict biological activities, and optimize lead compounds has provided several key advantages.

Accelerated Drug Discovery

One of the primary benefits of AI and ML is the significant acceleration of drug discovery timelines. Traditional natural product research involves labor-intensive isolation, characterization, and screening, which can take years (Stokes *et al*., 2020). AI models can rapidly analyze vast chemical libraries, predict bioactivity, and prioritize promising candidates, reducing the time needed to identify potential drugs [21].

Handling Complex and Large Datasets

Natural products are chemically diverse and come from complex biological sources, generating multifaceted data including molecular structures, genomic sequences, and bioactivity profiles. AI and ML excel at integrating and analyzing large-scale, heterogeneous datasets, uncovering hidden patterns and relationships that humans may overlook [22-23]. This data-driven approach enables more comprehensive exploration of natural product chemical space.

Improved Prediction Accuracy

ML algorithms, such as deep learning and random forests, improve the accuracy of predicting pharmacological properties like bioactivity, toxicity, and pharmacokinetics [24]. This leads to better prioritization of compounds with a higher chance of success in preclinical and clinical phases, minimizing costly failures.

Facilitating Novel Compound Discovery

AI-driven generative models can design novel natural product analogs or entirely new compounds by learning chemical rules from existing data. This expands the pool of drug candidates beyond what is naturally available, helping to overcome limitations posed by scarcity or difficulty in isolating certain natural products [26].

Enhancing Structure Elucidation and Synthesis

Machine learning assists in the interpretation of complex spectroscopic data (e.g., NMR, MS) to rapidly elucidate natural product structures [27]. AI can also suggest synthetic routes or biosynthetic pathway modifications, facilitating scalable production of natural product-derived drugs[28].

Cost Reduction

By prioritizing candidates computationally before experimental validation, AI reduces the need for extensive trial-and-error lab work, saving both time and financial resources (Vamathevan *et al*., 2019). This efficiency is especially valuable in natural product research, which traditionally requires significant investment.

FUTURE DIRECTIONS

Several avenues will likely accelerate discovery:

Improved multimodal models: End-to-end frameworks that jointly model sequences, enzymology, and spectra will better predict metabolite structures from genomic context.

Explainable AI tailored to chemistry and biosynthesis: Domain-aware interpretability will increase experimentalists' trust and reveal mechanistic insights.

Federated and privacy-preserving learning: Allow collaborative model training across institutions without sharing raw data—important when industrial or sensitive samples are involved.

Active, autonomous discovery pipelines: Integration of ML with automated synthesis and bioassay platforms can close the design–build–test loop for NP analogs.

Ecological and evolutionary context: Incorporating ecological metadata and evolutionary models may predict NP function and distribution, guiding bioprospecting ethically and efficiently[25].

CONCLUSION

AI and ML are reshaping natural product research by enabling scalable analysis of genomic and metabolomic data, improving structural annotation, prioritizing candidates for biological testing, and proposing novel structures inspired by nature. While challenges remain—particularly around data quality, interpretability, and experimental throughput—the trajectory is clear: combined computational and experimental strategies will accelerate discovery and broaden access to nature's chemical diversity. Realizing this potential requires open data, interdisciplinary collaboration, and careful validation to ensure ML predictions translate into meaningful biological and chemical insights.

Table 1: Artificial intelligence driven approaches in phytochemical research: trends and prospects (2010-2025) which likely gives trend data(Shi *et al.*, 2025; Meijer *et al.*, 2025).

Metric	Value / Trend	Time Period / Notes
Total publications in natural product research (journals + patents) since 2010	> 600,000	2010-recent
Number of substances co-occurring with AI in natural product research	~ 5,000 substances	2010-2022
Dominant substance types used with AI	Organic/inorganic small molecules >> protein/peptide sequences, polymers, etc.	2010-2022
Recent review period for ML in NP analysis	2015-2023	Emphasis on spectroscopy, classification, etc.
Recent thematic growth	Knowledge graphs, multimodal data, structure prediction, AI to assist molecule screening, etc.	Very recent, up to 2024-2025

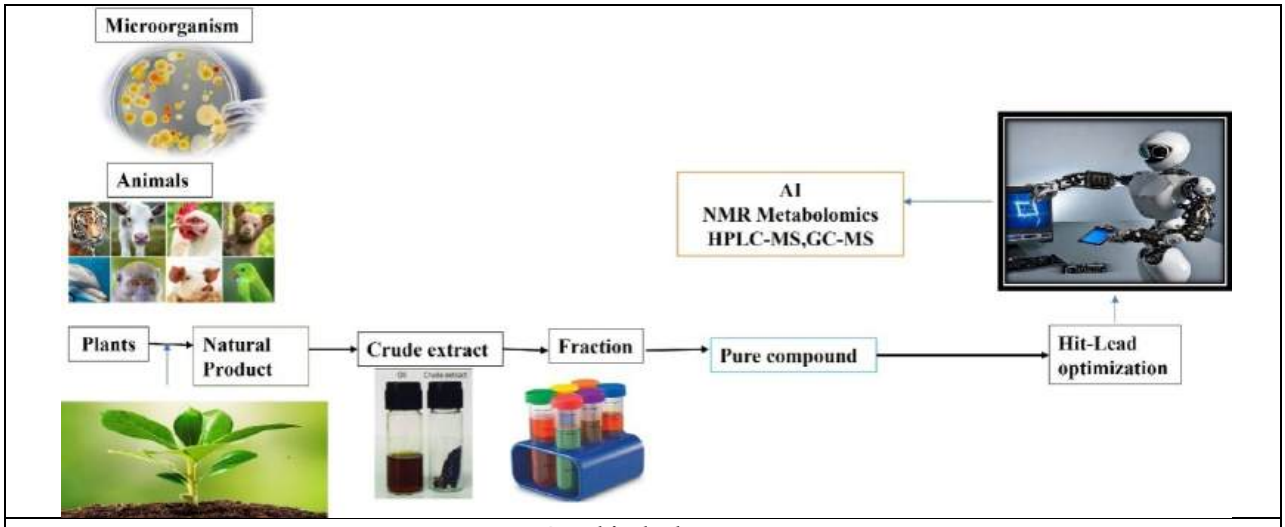
Table 2: Advanced Computational Tools for Pharmacological Prediction andTarget Identification in NP Drug Discovery (Gangwal et. Al.,2025).

Tool / Resource	Category / Approach	Algorithms / Methods	Typical Inputs	Use in NP Drug Discovery	Strengths	Limitations
SwissTargetPrediction	Ligand-based target prediction	2D/3D similarity screening against known ligand–target pairs	Small-molecule structure (SMILES, SDF)	Predicts probable protein targets for NP-derived compounds; prioritizes assays	High usability; good for well-represented targets; webserver	Performance depends on coverage of reference ligand–target data; limited for novel chemotypes
Similarity Ensemble Approach (SEA)	Ligand-based chemoinformatics	Statistical scoring of ligand-set similarity to infer target associations	Compound libraries and known ligand sets	Suggests unexpected off-targets or repurposing	Interpretable mechanism based on chemical similarity; able to predict polypharmacology	Limited when ligand databases lack NP-like chemotypes; false positives from

				hypotheses for NP scaffolds		promiscuous scaffolds
PharmMapper	Pharmacophore mapping (ligand-based)	Reverse pharmacophore matching against a large pharmacophore model database	3D conformers of small molecules	Identifies potential protein targets for NP-derived 3D structures	Useful for 3D complementarity; webserver with ranked matches	Requires reliable 3D conformers; limited by pharmacophore model coverage
DeepDTA	ML-based drug–target affinity prediction	Convolutional neural networks on SMILES and protein sequences	SMILES, protein sequences, binding affinities (training)	Prioritizes NP candidates with predicted binding affinity to targets of interest	Learns sequence/structure-agnostic patterns; scalable	Requires quality affinity data for training; may struggle with novel targets or NP chemotypes
ChemProp (message-passing NN)	ML for property and bioactivity prediction	Message-passing neural networks / graph neural networks	Molecular graphs (SMILES) with optional labels	Predicts ADMET properties or bioactivity of NP analogs; prioritizes lead candidates	Strong performance on diverse property tasks; captures graph topology	Needs task-relevant training data; interpretability challenges
DeepChem	ML library / toolkit	Wide range: graph NNs, CNNs, docking wrappers, QSAR pipelines	SMILES, fingerprints, assay data, structures	Framework to build custom NP pharmacology and target prediction workflows	Open source; integrates many algorithms and datasets	Requires ML expertise to configure robust workflows for NP-specific tasks
AutoDock Vina	Structure-based docking	Empirical scoring with global optimization; fast docking	Protein structures (PDB), ligand 3D structures	Virtual screening of NP libraries against target	Fast, widely used, suitable for large ligand sets	Scoring inaccuracies; limited handling of protein flexibility and

				structures; hypothesis generation for binding modes		water; false positives common
AlphaFold (structural models)	Protein structure prediction (supporting target ID)	Deep learning with attention/transformer architectures	Protein sequences	Provides high-quality target structures for docking and binding site analysis when experimental structures are absent	Excellent accuracy for many proteins; expands structure availability	May not capture dynamic conformations or complexes; uncertainty for some classes
STRING / STITCH	Network-based protein–protein and chemical–protein associations	Integration of experimental data, text mining, and prediction methods to build association networks	Protein lists, compounds, interaction data	Contextualizes predicted targets within pathways and networks; suggests indirect mechanisms for NP activity	Rich interaction context; useful for mechanism hypotheses and polypharmacology	Association ≠ direct binding; dependent on database coverage and text-mining biases
GNPS (molecular networking)	Metabolomics → link chemistry to bioactivity metadata	Molecular networking, spectral libraries, spectral similarity algorithms	MS/MS spectral data, metadata (bioactivity, sample source)	Prioritizes bioactive NP families by linking spectra to known bioactivity and guiding target hypotheses	Large community spectral resources; facilitates dereplication and analog discovery	Not a direct target predictor; depends on spectral matches and metadata quality

CSI:FingerID	Spectral-to-structure annotation (supporting target selection)	Machine learning to predict molecular fingerprints from MS/MS; database search	MS/MS spectra	Annotates NP structures from spectra enabling subsequent target prediction workflows	Improves structure annotation rates vs. rule-based methods	Performance limited by spectral libraries and unusual NP fragmentation
ML-guided screening example (AI-driven antibiotic discovery)	End-to-end ML prioritization for experimental screening	Supervised deep learning models trained on activity-labeled data; diversity prioritization	Large chemical libraries, activity labels	Demonstrates ML can identify novel bioactive scaffolds that can inform NP screening strategies	Proven real-world impact in lead discovery and hypothesis generation	Requires extensive, high-quality training data; experimental validation costly



Graphical Abstract

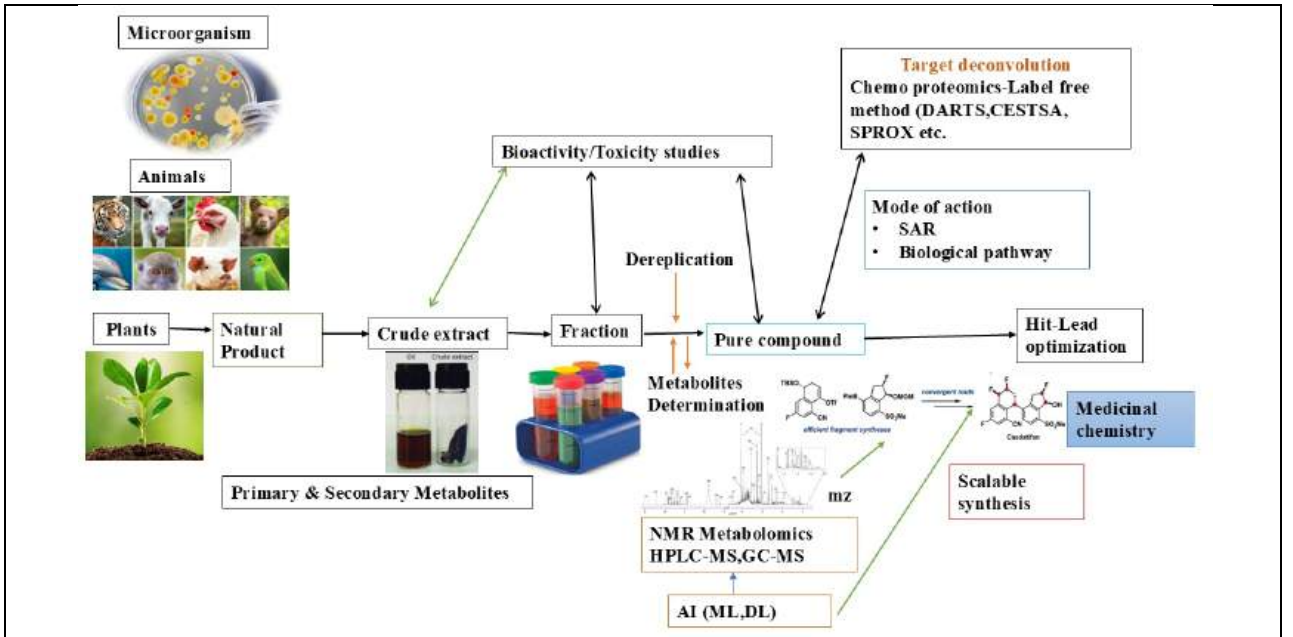


Figure 1: Overview of the natural product (NP)-inspired drug-discovery strategy. Crude extracts obtained from plants, animals, and microorganisms are subjected to bioactivity and toxicity profiling, followed by chromatographic fractionation and analytical characterisation (for example, nuclear magnetic resonance [NMR], high-performance liquid chromatography–mass spectrometry [HPLC-MS], and gas chromatography–mass spectrometry [GC-MS]). Artificial intelligence and machine learning (AI/ML) methods support spectral annotation, dereplication, and the prioritisation of candidate compounds. Target deconvolution approaches—including drug affinity responsive target stability (DARTS), cellular thermal shift assay (CETSA), and stability of proteins from rates of oxidation (SPROX)—together with mode-of-action investigations (e.g., structure–activity relationship [SAR] studies and pathway analyses) link bioactive constituents to molecular targets and biological pathways. Lead compounds are subsequently refined through medicinal chemistry and scalable synthetic methodologies to generate viable therapeutic candidates.

ABSTRACT

Heart disease is the Prominent cause of death throughout the world, affecting millions annually and placing a significant burden on global health systems. Traditional diagnostic systems, while effective, often fall short in handling high-dimensional and nonlinear clinical data. Deep learning (DL), hug ability to extract complicated patterns and hierarchical features, has shown remarkable potential in improving heart disease risk prediction. Moreover, feature augmentation methods such as sparse auto encoders (SAE) and synthetic over sampling further improve the learning capability of DL models. This review synthesizes state-of-the-art DL approaches combined with feature augmentation techniques, comparing their performance against classical machine learning models and analyzing their applicability in real-world settings. The study draws upon models achieving accuracies as high as 99.1%, offering significant improvements over previous techniques. The goal is to provide researchers and practitioners with a consolidated view of modern methods in predictive cardiology.

Keywords: Deep Learning, Heart Disease Prediction, Sparse Auto Encoder, SMOTE, CNN, DNN

INTRODUCTION

Cardiovascular diseases (CVDs), Cardiovascular illnesses, sometimes known as heart disease, are a collection of conditions that affect the heart and blood vessels. CVDs include heart stroke, heart failure, coronary artery disease,

and arrhythmias, all of which restrict blood flow and increase the risk of heart attack. Coronary artery disease (CAD), heart failure, and arrhythmias, are a global epidemic. According to the World Health Organization, approximately 17.7 million people die from heart-related illnesses each year. Traditional diagnosis relies heavily on expert interpretation of symptoms, test results, and medical history, introducing potential for human error and subjectivity. Furthermore, in rural and under-resourced regions, timely diagnosis remains a challenge due to the scarcity of medical experts[1]. With the progress in artificial intelligence (AI), specially machine learning (ML) and deep learning (DL), data-driven predictive models because prominent complicated in medical diagnostics. Artificial intelligence (AI) is a technology that typically requires human ability to understand language, such as talking or writing, recognize, solve issues, and make judgments before allowing computers to perform jobs[2]. Machine learning (ML) is a newer form of AI that allows machines to discover patterns and use data to make decisions without having to be manually programmed. ML is of three types, Supervised, semi - supervised and reinforcement. It improves as it learns from additional data. Unlike classical ML algorithms which often rely on manual feature selection and struggle with complex non linearities [3].Deep Learning in a form of ML with several layers of neural networks in it get helps intricate petty extracting data. It employs feature extraction algorithms to extract features from unprocessed or disorganized data, such as text, audio, and photographs. Deep learning is mostly utilized in facial recognition, autonomous driving, language translation, and disease detection from medical imaging.

There are several DL architectures such as convolutional neural networks (CNN), recurrent neural networks (RNN), and deep neural networks (DNN) can automatically learn abstract representations from raw clinical data. This terminologies are discussed below[4]. CNN is a bind of deep learning model that is used to process data, recognize images, patterns, video identification, classification, and computer vision tasks. It consists of four major layers: a convolutional layer, an activation functions, pooling layers, and fully connected layers. The suspective layer extracts features, the activation layer introduces nonlinearity, the pooling layer decreases data size, and the fully connected layer performs the final detection. The other type of neural network is RNN that is used in deep learning models that processes sequential data like visuals, voice, and time series. RNN remembers prior inputs and uses that knowledge to regulate the current output RNNs successively forward input using hidden states to transfer information from one step to the next. DNNs are the underlying structure of deep learning, a type of machine learning that learn layered representations from data. These models are trained on huge datasets using optimization techniques such as back propagation and gradient descent[5]. However, DL models require large, balanced datasets and well-represented features to perform optimally. Feature augmentation techniques, such as sparse auto encoders (SAE), embedding layers, and synthetic minority oversampling (SMOTE), have been increasingly used to enhance feature space and improve generalization on imbalanced or limited datasets[6].
In this paper, we systematically analyze:

- Advanced deep learning algorithms for heart disease detection.
- The implications of feature augmentation techniques on classification performance.
- A comparison analysis of classical ML and DL techniques on standard datasets.

The review is based on two foundational studies: [1] proposes a multitask deep learning framework combining SAE and CNNs for feature augmentation and classification, while offers a broad survey of DL-based heart disease estimation models across various architectures and platforms.

Background and Related Work

Heart disease prediction has evolved through decades of research spanning statistical analysis, rule-based systems, classical machine learning, and more recently, deep learning (DL). Early methods employed logistic regression and decision trees, offering interpretable but often shallow insights. With the huge and intricacy of healthcare data, DL emerged as a more powerful alternative, capable of uncovering deeper patterns and providing superior predictive performance[7].

Classical Machine Learning Methods

Traditional machine learning (ML) techniques have been used for heart disease detection for long time. Classical machine learning methods have long served as foundational tools in the area of predictive healthcare, including heart

disease classification. These models typically rely on manually selected features and statistical relationships among variables to perform classification or regression tasks. One of the most widely used techniques is the Decision Tree (DT),which construct a flowchart-resembling structure consisting of decisions and their likely consequences. It splits data into branches using feature thresholds, producing highly interpretable models. However, DTs are prone to over fitting, especially when applied to datasets with noise or a large number of features, which limits their generalization ability[8]. To overcome this, ensemble models like the Random Forest (RF) were developed. A Random Forest builds multiple decision trees during training and makes their predictions (via majority voting or averaging), reducing variance and improving accuracy. It is robust to over fitting and handles missing or noisy data more effectively. Nevertheless, it still struggles to capture complex nonlinear feature interactions compared to deep learning methods[9]. Another prominet model is the Support Vector Machine (SVM), which is mostly effective for high-dimensional spaces. SVMs choose the best hyperlane to maximally divide classes. With the use of kernel tricks, they can efficiently perform nonlinear classification. However, SVMs are sensitive to feature scaling and the choice of kernel parameters, and they do not scale well to large datasets due to their computational complexity[10]. The k-Nearest Neighbors (k-NN) algorithm is simple, non-parametric method that classifies testing instances based on the preponderance class of their closest neighbors in the feature space. It does not require an explicit training phase, making it a form of lazy learning. While k-NN can perform well on small, well-structured datasets, its performance deteriorates in high-dimensional settings and large-scale datasets due to increased computational cost and the curse of dimensionality[11].

Gradient Boosting algorithms, such as **AdaBoost** and **XGBoost**, are more advanced ensemble techniques. AdaBoost builds models sequentially, focusing on examples that were previously misclassified, effectively reducing bias.

XGBoost (Extreme Gradient Boosting) further enhances this approach by employing regularization techniques to control overfitting and improve performance. XGBoost is known for its prompt processing and predictive power, that makes it a top performer in many machine learning competitions. However, despite their success, boosting models require careful hyperparameter tuning and are less interpretable than simpler algorithms[12]. While all these classical methods offer practical solutions and moderate accuracy levels (typically between 75% and 88% in heart disease prediction), they often fall short in uncovering complex hierarchical patterns and nonlinear dependencies, especially in unstructured or high-dimensional medical data. This limitation has paved the way for the adoption of DNNs, which are capable of automatic feature extraction and superior generalization performance[13]. Despite achieving reasonable performance (accuracy ~85–88%), these methods lack the ability to extract abstract features automatically, limiting their use on raw, high-dimensional clinical data [1].

Rise of Deep Learning in Predictive Cardiology

Deep learning (DL) has come across as a transformative approach in the field of predictive cardiology, primarily or it has ability to model difficult and nonlinear associations inherent in medical data. Unlike classical machine learning algorithms, which often rely on handcrafted features and shallow decision boundaries, deep learning models leverage multi-layered neural architectures capable of learning rich, hierarchical representations directly from raw or minimally processed data. This automated feature extraction enables them to outperform traditional models, especially in domains like heart disease prediction where intricate interactions exist among physiological, behavioral, and genetic variables[14]. DNNs are one of the foundational frameworks in deep learning. A DNNs are of combination of interconnected several layers of neurons — including input, hidden, and output layers — each applying nonlinear transformations to its inputs. As the depth of the network increases, so does its capacity to capture intricate relationships between input features. In heart disease prediction, DNNs have been successfully applied to structured clinical data, learning to detect latent interactions between variables such as age, cholesterol level, blood pressure, ECG readings, and more. Their ability to generalize across varied patient profiles makes them effective for diagnostic applications. Moreover, enhancements such as He initialization, dropout regularization, and batch normalization have been employed to stabilize DNN training and prevent over fitting[15]. Another strong architecture that is often utilized in cardiology is the CNNs. Originally developed for image data, CNNs have found significant utility in medical applications due to their spatial feature extraction capabilities. In the context of heart

disease, CNNs are particularly effective when applied to electrocardiogram (ECG) signals, echo cardiographic images, and even tabular data that is reshaped into 2D matrices. A typical CNN consists of convolutional layers that identify local patterns, pooling layers that reduce dimensionality, and fully linked layers for classification. By identifying critical patterns such as QRS complexes, P-waves, and ST-elevations in ECG signals, CNNs can provide early and accurate detection of abnormalities indicative of cardiovascular disorders. Furthermore, CNN-based models have been integrated into cloud-supported IoT frameworks, enabling real-time diagnosis and monitoring through wearable sensors[16]. For temporal data such as patient vitals recorded over time, Recurrent Neural Networks RNNs and their improved variant Gated Recurrent Units (GRUs) offer compelling advantages. RNNs are intended to model sequential data by preserving a hidden state these by the temporal dependencies between time steps. However, traditional RNNs suffer from things like vanishing and exploding gradients, which makes them user effective for long sequences. GRUs mitigate these issues with the use of gating mechanisms that control the flow of information, permitting the network to retain relevant past information and discard irrelevant history. In predictive cardiology, GRUs have been used to track patient health trajectories, identify anomalies in heartbeat intervals, and forecast the likelihood of future cardiac events based on historical medical data. Their temporal modeling capability is particularly valuable in intensive care settings and remote monitoring systems where continuous data streams are analyzed in real time[17]. In summary, deep learning architectures like DNNs, CNNs, and GRUs have revolutionized the field of heart disease forecasting by enabling full learning, feature abstraction, and temporal sequence modeling. These models not only enhance diagnostic accuracy but also support personalized healthcare through continuous monitoring, early intervention, and adaptive decision-making. The rising adoption of these methods in clinical and wearable technologies marks a paradigm shift in how cardiovascular risks are assessed and managed. Monisha *et al*. [2] reviewed multiple architectures such as Deep Belief Networks (DBN), CNNs, GRU-based models, and hybrid systems combining neural networks with encryption and IoT for remote monitoring.

Some of the notable contributions from their review include:
CardioHelp + CNN: Achieved 97% accuracy by modeling temporal features through CNN layers.

DNN + He Initialization: Achieved an AUC of 0.983 by solving gradient vanishing issues using optimized initializations.

Ensemble DL + LogitBoost: Combined DL predictions with meta-learning, boosting accuracy to 98.5%.

EDCNN on IoMT Platform: Designed for remote patient monitoring via IoT, achieved 99.1% accuracy, highlighting the synergy of DL and real-time data integration.

DLMNN + IoT: A secure DL pipeline with embedded encryption (SHA-512, PDH-AES) to ensure safe data transmission.

Role of Feature Augmentation

The effectiveness of DL models can be significantly enhanced by expanding and refining the feature space. Feature augmentation improves the performance of deep learning models by improving and increasing the feature space. Instead of relying solely on raw input data, augmentation techniques enable models to extract more informative, balanced, and meaningful representations. This results in improved learning dynamics, generalization, and overall classification accuracy. Several advanced methods contribute to feature augmentation, each addressing different aspects of data representation and quality[18]. One such method is the Sparse Autoencoder (SAE), which is a bind of neural network that learns compressed and sparse representations of the input data. By enforcing sparsity in the hidden layers, SAEs force the network to activate only a small number of neurons for any given input, effectively filtering out noise and redundancy. The learned latent representations are more structured and informative than the raw data, making them valuable features for subsequent classification tasks. In practice, applying SAEs has been shown to improve classification accuracy significantly. For instance, in one study, the integration of SAE-generated features led to an increase in accuracy to 90.09%, highlighting the model's improved ability to gather essential

patterns in the information [19]. Another effective technique is Statistical Feature Selection using the Chi-Squared (χ^2) test, which is used to evaluate the relevance of each input feature in relation to the output class. This method quantifies the dependency between a feature and the target variable, allowing the model to retain only the most informative features while discarding the irrelevant or noisy ones. This not only simplifies the model but also reduces the risk of over fitting. When this technique was applied before training a Deep Neural Network (DNN), the model's performance improved to 93.33%, demonstrating that careful feature selection can substantially boost performance[20]. In cases where the dataset suffers from class imbalance, SMOTE (Synthetic Minority Oversampling Technique) is an effective feature augmentation strategy. SMOTE generates synthetic samples for the minority class based on the data that is currently available. This makes it possible for the model to learn more impartial and generalised decision limits by balancing the distribution of classes. When used in combination with DNNs, SMOTE enhances two qualities of model's robustness and generalizing ability in case of unseen data, especially in sensitive domains such as fraud detection or medical diagnosis[21]. Lastly, Embedding Layers are essential for dealing with high-cardinality categorical features, which are often represented as sparse one-hot vectors. Embedding layers map these sparse inputs into dense, low-dimensional vectors that preserve semantic similarity. This transformation not only reduces the input dimensionality but also allows the network to learn relationships between categorical variables more effectively. Embedding's are particularly useful in applications like natural language processing or recommender systems, but they are equally powerful in structured data scenarios, enabling neural networks to learn from categorical data in a more efficient and meaningful way. In summary, feature augmentation strategies such as Sparse Auto encoders, Chi-Squared feature selection, SMOTE, and Embedding Layers significantly contribute to the effectiveness of deep learning models. By transforming, selecting, or generating better input features, these methods enhance model accuracy, generalization, and stability, ultimately leading to more reliable and interpretable predictions[22]. These methods serve as preprocessing steps or integrated modules within DL pipelines, enhancing the quality of learning and interpretability.

Methodological Frameworks for Heart Disease Detection

Performance of Deep learning models for heart disease forecasting follow a modular architecture comprising data preprocessing, feature augmentation, and classification. In this section, we explore specific frameworks and techniques that contribute to high prediction accuracy, with emphasis on models combining feature augmentation and multitask learning[23]. We make all these a part of Methodology (Fig 1).

Sparse Auto encoder (SAE) for Feature Augmentation

Sparse Auto encoders (SAEs) are unsupervised neural networks used to reconstruct inputs through a bottleneck structure. Unlike traditional auto encoders, SAEs apply L1 regularization in the hidden (latent) space to enforce sparsity. This means only a subset of neurons activate for each input, allowing the model to focus on key features while discarding noise[2]. The SAEs were used to expand the input feature space from 11 to 200 dimensions. This transformed dataset retained the original information while injecting additional nonlinear representations, significantly enhancing classification performance[1]. The latent vector from the SAE was passed to a classifier (MLP or CNN), forming a multi-task neural network where the encoder and classifier were trained simultaneously. This two end training allowed the SAE to learn features directly in a optimized manner for heart disease classification. Training a model using this method makes the process of enhancing features trainable[1].

CNN-Based Classifier with Augmented Features

Once the features are augmented via SAE, they are reshaped into 2D input suitable for Convolutional Neural Networks (CNN). CNNs, traditionally used for image data, are highly effective at capturing spatial hierarchies and local dependencies in structured input[24]. With an accuracy of 90.09%, the research method outperformed classical techniques like Random Forest (86.4%) and Ada Boost (85.28%) as well as conventional MLP-based architectures (89.54%).

Convolutional Neural Network Layered Structure
CNN Layers Used
Convolution Layer: Extracts local features from the input matrix.
Pooling Layer (Max-Pooling): Reduces dimensionality and mitigates over fitting.
Dense Layer: Performs final classification.
This multi-layered structure allows for deep feature abstraction, enabling the model to distinguish subtle variations between healthy and diseased patients[1].

Deep Neural Networks (DNNs) with Statistical Feature Refinement
Monisha *et al*. [2] emphasized the role of statistical models in refining features prior to deep learning classification. For instance, the χ^2 statistical test was used to eliminate irrelevant attributes before feeding the data into a DNN. This combination yielded a prediction accuracy of **93.33%**, indicating the value of hybrid preprocessing pipelines.

In addition, other DNN-based frameworks employed:
He initialization to prevent gradient vanishing.
Dropout and Batch Normalization for regularization.
Talos optimization for automated hyperparameter tuning (achieved 90.76% accuracy).

Hybrid and IoT-Integrated Models
The integration of deep learning (DL) models with Internet of Things (IoT) technologies has led to the emergence of hybrid systems capable of health monitoring in real time, intelligent diagnostics, and secure data management. These systems leverage the distributed sensing capabilities of IoT devices along with the computational power of cloud platforms, forming a framework often referred to a newer area of internet of Medical Things (IoMT). In this hybrid architecture, data from wearable or implantable medical sensors is continuously captured and transmitted to cloud-installed DL models, there it is processed to detect abnormalities or predict disease progression. This paradigm not only supports remote healthcare delivery but also enables early intervention through timely analysis of physiological signals[25]. One prominent example of such a model is the Enhanced Deep Convolutional Neural Network (EDCNN) implemented on an IoMT platform. This system continuously collects electrocardiogram (ECG) signals from wearable sensors worn by patients and transmits the data to a cloud server, where the EDCNN processes it. The model uses stacked convolutional layers to extract both different level features from the ECG signals, enabling the accurate detection of cardiac conditions. The architecture achieved higher classification accuracy of 99.1%, highlighting its potential in real-time cardiac monitoring applications. The use of IoMT devices ensures uninterrupted data collection in real-world environments, while cloud processing enables rapid and scalable analysis, making the system suitable for deployment in telehealth and emergency response scenarios[26]. Another hybrid model that exemplifies the fusion of DL and secure communication is the Deep Learning-based Multilayer Neural Network (DLMNN) combined with SHA-512 encryption. In this framework, patient data acquired from edge sensors is first encrypted using a secure hashing algorithm to elevate about the confidentiality and integrity up to the mark transmitted information.

Once securely stored in the cloud, the encrypted data is decrypted and fed into the DLMNN for classification tasks such as disease detection or health status monitoring. This model not only maintains high classification performance but also addresses critical concerns around data privacy, especially in compliance with healthcare regulations such as HIPAA and GDPR. By integrating encryption within the data pipeline, this approach reinforces trust in remote healthcare systems where sensitive medical data is routinely transmitted over networks[27]. In addition to individual DL models, ensemble learning has also been successfully incorporated into hybrid systems. A notable instance involves making use of ensemble deep learning techniques in conjunction with a LogitBoost meta-learner. This approach combines the predictive outputs of convolutional neural networks (CNNs), deep neural networks (DNNs), and other architectures, by training a higher-level classifier to refine and boost overall accuracy. The LogitBoost algorithm iteratively focuses on misclassified samples from the base learners, allowing the ensemble to adapt and generalize better across diverse datasets. This hybrid ensemble architecture achieved a classification accuracy of

98.5%, indicating that combining multiple learning models enhances robustness, reduces variance, and improves performance on complex and imbalanced datasets. Overall, the convergence of DL with IoT and cloud technologies in hybrid models represents a significant advancement in intelligent healthcare systems. These models not only deliver high diagnostic accuracy but also incorporate critical features such as real-time data acquisition, end-to-end security, and model scalability. As the demand for remote healthcare monitoring and smart diagnostics continues to grow, hybrid and IoT-integrated DL models will play an increasingly vital role in the development of next-generation medical platforms[22].

Comparison of Architectures and Accuracy(Table: 1)

Experiments and Results of surveyed literature

To assess the efficacy of deep learning and feature augmentation techniques in heart disease prediction, extensive experiments were conducted in both papers under review. Here, a comprehensive breakdown of the datasets, preprocessing strategies, model architectures, experimental setups, and performance comparisons [2].

Dataset Description and Characteristics

The dataset used in [1], as introduced by García-Ordás *et al*., represents a comprehensive fusion of five established medical datasets commonly employed in cardiovascular research. These consist of the Statlog Dataset, the Long Beach VA Dataset, the Hungarian Dataset, the Cleveland Heart Disease Dataset, and the Switzerland showing use of reference XGitgt dataset. The integration of these sources resulted in a consolidated dataset comprising 918 patient records. Each record is annotated with 11 clinically significant features along with a binary output label indicating the presence or absence of heart disease. Specifically, the dataset includes 508 instances labeled as positive (indicative of heart disease) and 410 labeled as negative (healthy individuals), providing a relatively balanced class distribution that eliminates the need for synthetic oversampling techniques such as SMOTE[23]. The selected input features encompass both demographic and physiological indicators: age, sex, chest pain type, resting blood pressure, serum cholesterol level, fasting blood sugar, resting electrocardiographic (ECG) results, The maximal heart rate obtained, exercise-induced angina, ST depression caused by exercise relative to rest (Oldpeak), and the slope of the ST segment during peak exercise. The clinical relevance and availability of these features make the dataset highly suitable for supervised learning tasks in heart disease prediction and classification. In contrast, the work presented by Monisha and Johncy in [2] surveyed a broad spectrum of deep learning models trained on diverse datasets, differing significantly in size, modality, and data source. Some models were evaluated on smaller datasets, such as the standalone Cleveland dataset containing only 303 samples, while others utilized more complex and heterogeneous data streams, including real-time ECG signals, heartbeat audio recordings, and sensor information collected via Internet of Things (IoT) platforms. Depending on the application, models processed either structured tabular data conforming to schemas similar to the García-Ordás dataset or unstructured time-series data, such as raw ECG waveforms, using architectures like 1D convolutional neural networks (CNNs). The surveyed datasets thus ranged from purely clinical records to multimodal inputs involving audio, signal, and even image-based data, demonstrating the versatility and adaptability of deep learning models across various input domains and clinical contexts.

Data Preprocessing Techniques

Preprocessing plays a pivotal role in preparing raw data for deep learning models, significantly impacting the learning efficiency and accuracy of the final model. In [1], García-Ordás *et al*. implemented a comprehensive preprocessing pipeline tailored for structured clinical datasets. One of the key preprocessing steps involved encoding categorical variables. Features such as type of *Chest Pain* and *Resting ECG* result were one-hot encoded, enabling the neural network to learn from discrete medical conditions without imposing ordinal relationships. Binary categorical features like *Sex* and *Exercise-Induced Angina* were label encoded into integers to retain their two-class nature while making them numerically interpretable for the model. In addition to basic encoding, feature engineering techniques were brought to use enhance the model's understanding of health risk stratification. Specifically, the *Age* variable was discretized into categories such as young, adult, and elder, while continuous features like *Resting Blood Pressure* and

Cholesterol were transformed into categorical bins representing risk levels—low, medium, and high. These transformations helped highlight clinical significance within the dataset and improved feature interpretability. As a result of these encoding and engineering steps, the original 11 input features expanded to a total of 24, thereby increasing the dimensionality and expressiveness of the input space. In contrast, the survey conducted by Monisha and Johncy in [2] examined preprocessing techniques tailored to the modality of the input data, which varied significantly across studies. For models handling time-series or unstructured inputs such as ECG waveforms or heartbeat audio signals, preprocessing often began with Fourier or Wavelet transforms to shift the signal into the frequency domain. These techniques enabled the models to capture periodicities and anomalies that might be obscured in raw time-domain data. In such cases, convolutional neural networks (CNNs) were employed to automatically extract localized signal features post-transformation. Other models that relied on structured tabular data similar to the García-Ordás dataset applied standard data normalization techniques to scale numerical inputs to a common range, typically [0,1] or standard Gaussian distribution. Additionally, class imbalance was addressed through oversampling techniques like Synthetic Minority Over-sampling Technique (SMOTE), while irrelevant or weakly correlated features were eliminated using statistical feature selection methods, such as the chi-square (χ^2) test. These preprocessing methods collectively ensured that both structured and unstructured data types were optimally prepared for efficient training and generalization across various deep learning models.

Experimental Setup

The experimental setup detailed by García-Ordás *et al*. in [1] was carefully designed to evaluate the effectiveness of their proposed hybrid deep learning architecture. The core model was a multitask neural network comprising two components: a Sparse Autoencoder (SAE) and a downstream classifier, which could either be a multilayer perceptron (MLP) or aCNNs, depending on the configuration. The training objective was split accordingly—while the SAE decoder minimized reconstruction error using the Mean Squared Error (MSE) used to minimize reconstruction error in SAE decoder. The classifier was trained using Binary Cross-Entropy to differentiate between patients with and without heart disease. The model optimization relied on the Adaptive Moment Estimation (ADAM) optimizer due to its robustness, fast convergence, and compatibility with sparse gradients, which is particularly beneficial for high-dimensional encoded features. To ensure statistical reliability, the experiments employed 10-fold cross-validation, dividing the dataset into training and testing subsets across multiple iterations to avoid overfitting and obtain a generalizable performance estimate. Moreover, hyperparameters were fine-tuned using a grid search strategy, particularly focusing on latent space sizes of the SAE component, with configurations ranging from 50 to 200 neurons. This approach allowed the researchers to empirically identify the optimal feature compression ratio for downstream classification. Meanwhile, the experimental landscape described in [2] included a diverse range of deep learning systems and deployment scenarios. The surveyed models included Deep Belief Networks (DBNs), Gated Recurrent Units (GRUs), standard CNNs, and fully connected Deep Neural Networks (DNNs). These models were commonly use of regularization techniques such as dropout layers and batch normalization was made to prevent overfitting and stabilize learning across epochs. In IoT-enabled models, data was streamed in real time from wearable sensors and fed directly into cloud-hosted CNNs for classification and prediction tasks. This setup demonstrated the feasibility of real-time diagnostics using DL models in remote healthcare monitoring systems. Hyperparameter optimization strategies varied across studies, with some employing automated tools like Talos, a Python-based hyperparameter tuning library that performs exhaustive or probabilistic searches over model parameters. Additionally, certain architectures prioritized cybersecurity in healthcare by incorporating encryption protocols directly into the data pipeline. Examples include SHA-512 for secure hashing and AES for symmetric encryption, ensuring data confidentiality during transmission from edge devices to cloud servers. These diverse experimental setups highlight both the versatility of DL architectures in health monitoring and the increasing importance of performance, scalability, and security in deployment environments.

Experimental Setup
García-Ordás *et al*. Setup
SAE and a classifier (MLP or CNN) are combined in this multitask neural network architecture.

Loss Functions:
SAE Decoder: Mean Squared Error (MSE)
Classifier: Binary Cross-Entropy

Optimizer: ADAM optimizer could be fast convergence and support for sparse gradients.
Cross-Validation: To ensure robustness, a 10-fold cross-validation is applied to every trial.
Hyperparameter Tuning: Grid search over latent space sizes (e.g., 50, 100, 150, 200 neurons).

Monisha and Johncy Survey
Numerous architectures and techniques were used in the experiments:
CNNs, DNNs, GRUs, and DBNs: trained using batch normalisation and dropout.
IoT Models: CNNs located in the cloud process real-time data supplied by sensors.
Hyperparameter Optimisation: Talos was utilised by one model to automatically adjust its parameters.
Security Integration: AES and SHA-512 encryption were incorporated into data flow in some models.

Performance Comparison
Evaluating deep learning models in the healthcare domain requires the use of robust performance metrics that go beyond basic accuracy, especially when dealing with imbalanced datasets or clinical risk stratification. The evaluation focused on a set of Accuracy, precision recall and F1-score were used as metrics in evaluation under study conducted by Garcia-Ordas *et al*[1]. Standard classification metrics, provide different perspectives on model behavior. Accuracy, served as a general performance indicator, with the model achieving an accuracy of up to 93.33% when the sparse autoencoder (SAE) was combined with a multilayer perceptron (MLP) classifier. However, the authors emphasized recall and precision due to the medical context, where false negatives (failing to detect heart disease) could be life-threatening. The model attained high recall, indicating strong sensitivity to positive cases (heart disease patients), while maintaining a competitive precision score, minimizing false positives. The F1-score, confirmed the model's balanced performance. Additionally, ROC (Receiver Operating Characteristic) curves and AUC (Area Under the Curve) values were plotted to assess the model's discriminatory power across various threshold settings. The ROC-AUC values consistently exceeded 0.90, illustrating excellent class separability[4]. In contrast, the evaluation framework presented in Monisha and Johncy's survey [2] encompassed a broader range of performance metrics and benchmark results drawn from multiple DL-based heart disease detection studies. The surveyed models reported classification accuracies ranging from 85% to as high as 99.1%, depending on the dataset and architecture used. For instance, ensemble models that incorporated CNNs with LogitBoost classifiers achieved up to 98.5% accuracy, while IoMT-based models like EDCNN demonstrated superior performance on real-time ECG data, achieving 99.1%. In many cases, confusion matrices were used to highlight model tendencies, such as over-predicting the majority class or struggling with borderline conditions. For models trained on imbalanced datasets, precision-recall curves were often more informative than ROC curves, since they better captured the model's behavior with respect to the minority class[3]. Additionally, some architectures focused on computational efficiency metrics such as training time, convergence rate, and inference latency—key concerns in IoT and real-time applications. Finally, models that integrated encryption mechanisms or ran on edge devices were evaluated not only for predictive performance but also for security robustness and communication overhead, providing a more holistic view of real-world feasibility.

RESULTS FROM [1]

The SAE + CNN outperformed all baseline models by 4.4%, validating the value of feature augmentation and spatial convolution.

RESULTS FROM [2]

The EDCNN model on an IoMT platform achieved the highest known accuracy of 99.1%, albeit requiring cloud infrastructure and continuous sensor inputs.

Statistical Validation and Significance Testing
To validate that improvements in [1] were not random:
Kolmogorov–Smirnov test: Verified that the distribution of accuracies between traditional and proposed methods was significantly different.

t-test (Independent Samples):
Traditional Methods: M = 84.73, SD = 2.61
Proposed (SAE + CNN): M = 88.99, SD = 1.13
t(17) = 4.97, **p < 0.001**
The statistical tests confirm that the improvements from deep learning and feature augmentation are highly significant and reproducible.

Observations and Insights
- **Joint training of SAE and classifier** leads to better feature learning.
- **CNN outperforms MLP** for structured data when fed augmented features.
- **Ensemble DL models**, though computationally heavy, provide high accuracy (>98%).
- **IoT integration (EDCNN, DLMNN)** supports real-time monitoring but needs infrastructure.

CONCLUSION

Through all the papers required and their results we formed that the accuracies of detection and prediction of heart disease CNN + SAE demonstrated the accuracy. In terms of architecture and their accuracy we found deep learning with Logit-Boost providing highest accuracy of 98.50%. Statistical Validation through Kolmogorov – Smirnov and T-Test also validate the results.

ABSTRACT

This study focused on the development and validation of a particular analytical technique that is designed for the simultaneous quantification of dapagliflozin and eplerenone both in bulk form and in synthetic mixtures. The increasing rates of cardiovascular and renal diseases increased the demand for combination therapies. One of the recent combination therapies approved by CDSCO is dapagliflozin, a sodium-glucose cotransporter 2 inhibitor, and eplerenone, a selective aldosterone receptor antagonist. From time to time, both drugs exert a synergistic effect. To optimize, develop, and validate a fast and simple analytical method to examine dapagliflozin and eplerenone in bulk and synthetic mixtures with accuracy. Optimization of chromatographic conditions, development and validation of International Counsel for Harmonization (ICH) guidelines, especially ICHQ2(R2) regarding the concern of validation, apply to synthetic mixtures, and perform assays. The technique developed is cost-effective, sensitive, and simple to make it routine in pharmaceutical and research laboratories. The method was validated for the tested parameters. It achieved acceptable linearity and accuracy.

Keywords: Synthetic mixture, Dapagliflozin, Eplerenone.

Graphical abstract represents the development and validation of new analytical method for the simultaneous estimation of dapagliflozin and eplerenone by utilizing synthetic mixture since fixed dose combination is not yet available in the market(Fig:1).

Step 1: Sample preparation/injection of the sample

Step 2: Analytical method development
Step 3: Forced degradation study as per ICH Q1A (R2) guidelines
Step 4: Validation as per ICH Q2 (R2) guidelines
Step 5: To Apply the developed and validated method on Dapagliflozin and Eplerenone in Synthetic mixture.

INTRODUCTION

Dapagliflozin is a sodium-glucose cotransporter 2 (SGLT2) inhibitor used in the treatment of type 2 diabetes mellitus. It works by reducing the reabsorption of glucose in the kidney, thereby increasing glucose excretion in the urine and lowering blood glucose levels. Eplerenone, on the other hand, is a selective aldosterone receptor antagonist (SARA) used primarily in the treatment of heart failure and hypertension. It works by blocking the effects of aldosterone, a hormone that can lead to sodium and water retention, contributing to high blood pressure and heart failure. The combination of Dapagliflozin and Eplerenone may offer synergistic benefits in patients with both type 2 diabetes, cardiovascular complications and to improve kidney health and reduce the risk of kidney failure. Therefore, a reliable analytical method for the simultaneous determination of these two drugs is essential for quality control, stability studies, and pharmacokinetic investigations. Combined action of dapagliflozin and eplerenone (Figure 1).

Why RP-HPLC?
- Greater Flexibility in Mobile Phase
- High Resolution
- Higher Sensitivity
- Flexibility-various detector use to detect the analyte: UV, Fluorescence, RI

What are analytical methods?
- These are analytical techniques used to determine the concentration of a drug or chemical compound in any matrix.
- They have a pivotal role in the entire drug life cycle-from discovery to development to quality control.

Why there is a need for development of RP-HPLC analytical method for the combination of DAPAGLIFLOZIN+EPLERENONE?
- No analytical method is developed.
- No reported method in pharmacopeia/literature.
- A suitable analytical approach for drug combinations may not be published or be protected by patent.
- Analytical methods for the quantitation of the analyte in biological fluids are found to be unavailable.
- Why validate the analytical method?
- For every aspect of the analysis to conform to national and international standards.
- For an analytical result to be fit for its intended purpose, it must be sufficiently reliable that any decision based on it can be taken with confidence.
- Method validation assures reliability during normal use.

Forced Degradation [3]
Forced degradation studies are an integral part of drug development and are conducted intentionally to degrade drug substances and drug products under controlled conditions. The primary objectives of these studies are to:
- Establish the inherent stability characteristics of the drug substance and drug product.
- Identify potential degradation products.
- Explain pathways of degradation
- Validate the stability-indicating nature of analytical methods.

- Produce degradation products for identification and characterization.
- How to identify/estimate degradation

% Degradation =

$$\frac{(P_{ST} - P_{DEG}) \times 100}{P_{ST}}$$

P_{ST}: represents the average peak area in standard solution without degradation.
P_{DEG}: represents the average peak area in the stress degradation solution.
Degradation range of 5–20%
Forced degradation, also known as stress testing, is an important activity in drug development and stability studies. A drug substance or drug product is exposed to more severe conditions than what it would encounter during normal storage, with the purpose of accelerating the chemical degradation process. The main goals of carrying out forced degradation are identification of potential degradation products, understanding the pathways of degradation, and establishing the intrinsic stability of the molecule. ICH Q1A(R2) and ICH Q1B guidelines emphasize the importance of forced degradation studies in developing a stability-indicating analytical method capable of differentiating the active pharmaceutical ingredient from its degradation products. These studies are usually conducted to ensure that an analytical method is specific, selective, and reliable for routine quality control and stability testing.
Typically, forced degradation experiments expose the drug to various stress conditions, including

- Acidic and alkaline hydrolysis (to assess susceptibility to hydrolysis)
- Oxidative degradation (to evaluate reactivity toward oxidizing agents),
- Photolytic degradation, to test light sensitivity, and
- Analysis by thermal degradation - to determine the heat stability of the substance.

Drug Profile
Drug profile of Dapagliflozin and Eplerenone [4,5] (Table 1)

Steps Involved in RP-HPLC Method Development[6,7]
Developing a robust and effective RP-HPLC method involves several key steps:

Procedure for RP-HPLC[6,7]
RP-HPLC Procedure (Figure 3)

Method Validation (According to ICH Guidelines) [11]
Before using an HPLC method for routine analysis, it must be validated following ICH Q2 (R2) guidelines to ensure reliability and reproducibility. Analytical Method Validation Parameters (Figure 4)

LITERATURE REVIEW

Summary of Literature Review of reported methods [13-81] (Table 2). Graphical representation(Figure: 5)

Table 1: Drug profile of Dapagliflozin and Eplerenone [4,5]

Parameters	Dapagliflozin	Eplerenone
IUPAC Name	(2S,3R,4R,5S,6R)-2-(4-chloro-3-(4-ethoxybenzyl) phenyl)-6-(hydroxymethyl) tetrahydro-2H-pyran-3,4,5-triol	Methyl (1R,2S,9R,10R,11S,14R,15S,17R)-2,15-dimethyl-5,5'-dioxospiro [18-oxapentacyclo [8.8.0.01,17.02,7.011,15] octadec-6-ene-14,2'-oxolane]-9-carboxylate
Chemical Structure		Drug Class	sodium-glucose co-transporter 2 (SGLT2) inhibitor	antihypertensive
Synonyms	Dapagliflozine Dapagliflozina Dapagliflozin 461432-26-8 (2S,3R,4R,5S,6R)-2-(4-chloro-3-(4-ethoxybenzyl) phenyl)-6-(hydroxymethyl) tetrahydro-2H-pyran-3,4,5-triol	Eplerenon eplerenone Inspra 9,11-epoxy-7-(methoxycarbonyl)-3-oxo-17-pregn-4-ene-21,17-carbolactone Molecular Formula
Molecular Formula	$C_{21}H_{25}ClO_6$	$C_{24}H_{30}O_6$
Molecular Weight	408.9 g/mol	414.5 g/mol
Color/ Form	Color-White to light Form-crystalline powder form,	Color-White to off-White Form-crystalline powder
Solubility	Practically insoluble in toluene and n-hexane, slightly soluble in water and in aqueous	Very slightly soluble in water, Soluble in chloroform and dichloromethane

	solvents	
Log P	2.7	1.3
pKa	12.6	16.44
Half Life	12.9 hours	4-6 hour
Melting point	65-70°C (149-158°F)	242°C
Therapeutic Use	With proper diet and exercise dapagliflozin act as a sodium-glucose cotransporter-2 (SGLT2) inhibitor commonly used for managing type 2 diabetes mellitus by preventing the absorption of glucose in the kidneys. Dapagliflozin helps in reducing blood glucose levels by promoting the excretion of excess sugar through urine. However, it is not effective for individuals with type 1 diabetes or those who rely entirely on insulin therapy.	Eplerenone belongs to the general class of medicines called antihypertensives. It is used to treat hypertension (high blood pressure) alone or together with other medicine. This medicine is also used to treat heart disease like congestive heart failure (CHF) and heart attack
	Dapagliflozin and eplerenone combination therapy works through complementary mechanisms to improve kidney health and potentially reduce the risk of kidney failure.	
Storage Condition	At room temperature between 68°F to 77°F (20°C to 25°C)	At room temperature, between 68°F to 77°F (20°C to 25°C)

Table 2: Summary of Literature Review of reported methods [13-81]

Name of method	Dapagliflozin	Eplerenone	Dapagliflozin+ another drug	Eplerenone + another drug	Dapagliflozin + Eplerenone

ABSTRACT

Sports like gymnastics and wrestling have a different way in which athletes interact with the ground,thus resulting in different loads and injuries. Gymnastics is all about giving the human body air, and it is done very quickly, physically giving large vGRF along with it. It does not only affect bones but also loading patterns and joint stability. Taking the abovementioned battle scenario, wrestling is that the majority consists of throws, and defense actions. however, the joint loads of knee, hip, and shoulder are subjected to high anterior-posterior shearing and rotation. A force plate and motion capture were used in this study to make a comparison between athletes of different disciplines in regard to shear and impact forces. The study was conducted with thirty trained participants which included 15 gymnasts and 15 wrestlers. The peak vertical force, shear force, loading rate, and impulse were finally assessed for sport-specific tasks. Gymnasts presented peak vertical forces, and loading rates that were greater in magnitude than the others, in contrast to this wrestler made shear forces that were significantly bigger. It is clear from the results of the research that sport-specific mechanical environments do have an impact on injury patterns, training strategies, and equipment design through their interaction with the body.

Keywords: gymnastics, wrestling, ground reaction forces, shear forces, impact forces, biomechanics, loading rate.

INTRODUCTION

Most of the time, high-intensity sports athletes are subjected to various external forces that can exceed normal physiological tolerance. These are from rapid movements such as jumping, landing, sprinting, tackling, throwing, or resisting an opponent. If the musculoskeletal system cannot adequately absorb or dissipate these forces, then there is a higher risk of potential acute injuries (e.g., ligament tears, joint sprains) and chronic injuries (e.g., overuse syndromes, cartilage wear, stress-related bone disorders) [1]. The competency of the body in managing these forces depends upon neuromuscular coordination, joint alignment, surface compliance, and technical execution [2]. Vertical impact forces could be one of the most important loading conditions in dynamic sports. They occur mostly during ground contact subsequent to jumps, dismounts, or rapid deceleration. Excessive vertical impacts may conduct high loads into the lower extremities, making them susceptible to ankle sprains, tibial stress fractures, patellofemoral pain, plantar fascia irritation, and early degenerative changes in knee cartilage. The magnitude and rate of the vertical forces determine the stress on joint structures. When forces are applied in a very short period, the body has less time to prepare protective responses such as greater joint flexion or muscular co-contraction [3]. Shear forces are those acting parallel to the supporting surface and result from sliding, pushing, pulling, grappling, and rotational activities. Such loads, particularly those related to twisting or valgus movements, stress the ligaments and soft tissues responsible for stabilization. Strong correlations exist between high shear forces and injuries to the ACL, meniscal tears, shoulder instability, and strain on the hip and lumbar regions. In contrast to vertical impacts, which are mainly gravity-driven, the application of shear forces is frequently a result of a sudden change in the opponent's movement or external contact [4].

Gymnastics consists of different aerial transitions, explosive takeoffs, and high-energy landings. The athletes get very high and rotate with a lot of momentum in the air as the main part of the trick, thus needing absolute control while landing. The vertical ground reaction forces have been measured during gymnastic dismounts and by far most studies report over (10–15 times) an athlete's body weight consistently. Such forces act in a very short time, often less than 100 milliseconds, giving very little opportunity for the active muscular absorption or adjustments in the joint position. The very quick application of the force increases the mechanical stress on the entire lower extremity-feet, ankles, knees, and spine-which is one of the reasons why gymnastics is one of the sports most prone to impact-related injuries [5]. Another arena of biomechanics is wrestling, which is characterized by constant physical contact, weight manipulation, and the application of force on the opponent. Takedowns, sprawls, lifts, and pins produce large horizontal shear loads and torsional forces across the joints. The rapid velocity and force in matches, coupled with the unpredictability of these interactions, are a great demand for neuromuscular control and joint stability. Hence, wrestling is highly linked to the occurrence of knee, shoulder, and cervical spine ligament sprains, as well as joint dislocations and soft-tissue trauma [6].

There is a vast amount of literature on gymnastics and wrestling, but not many studies have compared them through the lens of biomechanics. Previous research has done mostly pointing out the differences in injury occurrence, analyzing movements, or measuring force separately for each sport. Only a few have looked at the basic differences in mechanical environments, especially vertical vs. shear loading patterns [7]. It is essential to know these differences when the training strategies are developed for each specific sport, when the performance surfaces such as mats and landing platforms are optimized, and when the injury-prevention programs that target the specific needs of each discipline are designed. Thus, the main objective of this research is to determine the values of peak vertical forces, shear forces, loading rates, and vertical impulses in the case of both trained gymnasts and wrestlers. By doing so, the research will reveal the differences in force profiles and the shared biomechanical characteristics of the two sports, with a direct impact on athlete's training, performance, and safety in the long run.

MATERIALS AND METHODS

Participants

The examination involved thirty active male athletes, out of which 15 were artistic gymnasts and the other 15 were freestyle wrestlers. All the athletes were training and competing at the time of collecting the data. The average training age of the gymnasts was 8.4 ± 2.3 years, while that of the wrestlers was 7.9 ± 2.0 years, which reflects that both groups had considerable time of being exposed to sport-specific training loads. Before the start of the experiment, the participants were screened for eligibility, and the inclusion criteria were a minimum of five years of structured sport participation, the ability to safely perform high-intensity technical tasks, and no musculoskeletal injury six months prior to testing. Athletes with histories of major orthopaedic surgeries, chronic lower-limb injuries, or neurological conditions were not allowed to take part in the study. The athletes' written informed consent was obtained before their participation. Standardized instructions and safety guidelines were provided to ensure compliance and minimize risk during the testing procedures.

Protocols

In order to make a valid comparison between various sports, the athletes did the movements that represent the typical high-load conditions in their disciplines. In the case of gymnasts, these were the two vertical impact–dominant tasks they performed: (1) drop landings off a standardized height of 1.5 meters and (2) forward salto landings executed using competition-level technique. These actions were picked because during the execution, always generate great vertical ground reaction forces. Wrestlers, however, were subjected to two shear-dominant actions: (1) single-leg takedowns, which involve forward excessive driving force and contact with the opponent, and (2) defensive sprawls, which require quick hip extension and upper-body stabilization against horizontal load. Five successful repetitions of each assigned task were performed by each athlete, with a one to two-minute rest interval in between attempts to prevent fatigue. Prior to testing, a warm-up involving dynamic stretching and sport-specific drills was done to ensure readiness and decrease the risk of injury. The athletes were told to use their training or competition intensity, but to keep the correct form throughout the movements.

Instrumentation

Data gathering took place in a controlled indoor biomechanics laboratory that had measurement equipment perfectly in sync. Ground reaction forces were measured by a tri-axial force plate with a sampling rate of 1000 Hz, which made it possible to detect with great accuracy the rapid changes in vertical and horizontal forces during high-impact and shear-intensive tasks. To obtain three-dimensional joint kinematics, reflective markers were put on anatomical landmarks, and a 12-camera motion capture system working at 200 Hz was utilized. Thus, the accurate alignment of movement phases and force measurements was assured. Moreover, a high-speed video camera that recorded at 500 frames per second was used in correspondence to visually confirm critical events like initial contact, peak force time, and each task's end. The alliance of force plate, motion capture, and high-speed imaging made a comprehensive and a dependable dataset that supported the detailed biomechanical analysis of the movements in both gymnastics and wrestling.

Data Processing and Statistical Analysis

The raw data related to force and motion were exported and processed in MATLAB. Filtering of force signals was done through a sophisticated and complex zero-lag Butterworth low-pass filter of the 4th order with a frequency of 50 Hz as a cutoff so that noise was reduced but the true signal was preserved. Peak vertical ground reaction force, peak shear force, loading rate, and vertical impulse were the four primary variables extracted from each trial. The peak forces were determined as the highest values found within the vertical or horizontal force-time graphs, while loading rate was measured as the slope between the first contact and the peak force. Vertical impulse was derived from the vertical force used in the numerical integration. The values averaged from the five successful trials were taken for each athlete to create a representative measure.

Statistical methods were employed, and SPSS software was utilized for this purpose. The Shapiro–Wilk test was conducted to certify the normal distribution of all variables. As the normality assumptions held, independent t-tests were performed to compare the gymnastics and wrestling groups. Moreover, Cohen's d effect size was computed to characterize the magnitude of the differences which was further classified as small (0.2), medium (0.5), or large (0.8 or above). The significance of the statistics was determined to be $p < 0.05$ for all the comparisons. A comparative analysis showing the differences between gymnasts and wrestlers can be seen in Table 1, Figure 1 shows the Mean Value of Peak Vertical Force (N),Figure 2 shows the Mean Value of Peak Shear Force (N), and Figure 3 shows the Mean Value of Vertical Impulse (Ns).

RESULTS AND DISCUSSION

RESULTS

The outcomes of these comparisons are briefly outline below.

Ground reaction force characteristics of gymnasts and wrestlers were compared and the differences were very clear, and the differences were very clear and statistically significant. Gymnasts exhibited peak vertical forces of ground reaction substantially higher than that of wrestlers who averaged 3200 ± 450 N against 2100 ± 400 N with a significant p-value of (<0.001) and a large effect size (d = 2.62), thus indicating that gymnastics movements do not only load the athletes' bodies, but the vertical loads are much larger. However, wrestlers were found to have significantly higher peak shear forces (850 ± 150 N) as compared to gymnasts (600 ± 120 N) which was also a strong level of significance (<0.001) and a large effect size (d = 1.86), thus reflecting the shear-dominant nature of the wrestling actions. The loading rate values were also a point of differentiation between the sports; gymnasts reported very high loading rates ($1.8 \times 10^5 \pm 0.4$ N/s) as compared to the lowest rates in wrestlers ($0.9 \times 10^5 \pm 0.3$ N/s), thus the rapid force application during gymnastics landings was highlighted. Vertical impulse values were also higher in gymnasts (52.0 ± 7.5 Ns) than in wrestlers (38.5 ± 6.8 Ns), with a significant p-value (0.002) and a large effect size (1.67), indicating that gymnasts are subjected to greater total force over the time of landing phases. These results together suggest a clear marking of force profiles between gymnastics and wrestling; the former being the case of intense vertical impact loading, while the later being the case of high horizontal shear loading.

DISCUSSION

The study findings reveal basic biomechanical differences between gymnastics and wrestling that are mainly due to the nature of the technical and physical requirements of each sport. In the case of gymnasts, vertical ground reaction forces and loading rates were always significantly higher, thus confirming that gymnastics is an impact sport that involves high-velocity landings, aerial transitions, and very limited time for force absorption. The vertical loads that are so high cause stress on the lower body and spine, resulting in injuries like stress fractures, ankle sprains, and so on being more common. The steep loading rates in gymnasts mean that there are rapid deceleration forces that the musculoskeletal system has to bear within very short periods of time. Such conditions not only require but also demand great lower limb strength and perfect landing techniques to prevent high joint compressive forces or misalignments.

In contrast, wrestlers experienced shear forces that were specifically higher and showed how demanding grappling, takedowns, and changing directions, as well as opponents' forces, were. The vertical impacts in wrestling are not substantial, but the players do have to bear very strong anterior–posterior and mediolateral forces that they either must resist or generate to keep their balance, stability, and control. The high shear forces can account for the frequent occurrence of ACL injuries, meniscal tears, shoulder instability, and lower-back strain among wrestlers to some extent. The situation in wrestling is made more difficult by its spontaneous and often opponent-controlled nature, in which a particular moment of a live engagement could suddenly change the direction and amount of the forces. The athletes in each discipline will have specific loading environments that biomechanical load patterns highlight the

necessity for sport-specific injury prevention strategies [8]. The contrasting force profiles between gymnastics and wrestling not only point out the necessary conditioning but also the specific technical training interventions. The characteristics of gymnastics movements are such that it is more than ever essential to develop through eccentric strength mainly in the quadriceps, hamstrings, and calves for shock absorption during landings. One through which proper skill development leads to vertical force tolerance safely is the progressive height-based landing from the height of the chosen vertical force [9]. Proper joint alignment during landing may also be beneficial in minimizing the risk of injury due to excessive loading rates. On the other hand, wrestlers' interventions should aim to develop neuromuscular control, joint stability, and horizontal as well as torsional forces' resistance. Strengthening conditions can consist of drills struggling against shear-force, training for balance disturbance, exercises for core stability, and conditioning for rotational strength. Given that wrestling is extremely reactive and competition-oriented, simultaneously training in proprioceptive and balance exercises must be set up as a means of improving reflexive joint protective capabilities under the less predictable conditions of loading [10].

The results from the sports studies also point out the importance of correct surface and equipment design for both the disciplines. In the case of gymnastics, the landing mats should be designed in such a way as to manage force from vertical impact entirely and yet let the gymnast hold the technicality, precisions and even have a rebound when that is desired [11]. Mostly, hard grounds raise the risk of injuries by increasing the peak vertical forces, while very soft grounds may negatively affect the balance and make the internal joint loading higher. Hence, the need for a compromise between shock absorption and the responsiveness of performance to be offered. In wrestling, mats play an entirely different role. Mats must primarily prevent sliding so that shear load is not created; however, they should be soft enough so that during contact-based movements, horizontal and torsional forces can be easily absorbed. The proper thickness of the mat and the use of the same material over the entire area help to lower the stress on the knee, hip, and shoulder joints during takedowns, sprawls, and other movements that require defense. Maintenance and evaluation of the surface very regularly should be done and, besides, they are very important for the safety of athletes during repeated high-level intensity movements [12].

Even though this study can produce significant knowledge about the differences in biomechanics between gymnastics and wrestling, some drawbacks must be acknowledged. To begin with, all the examinations were conducted in a laboratory that was controlled, not considering the variability and unpredictability that come with the actual competition conditions. Forces during a performance, particularly in wrestling, can vary significantly due to the difference between the opponents, fatigue, and psychological factors being [13][14]. Furthermore, the population was made up solely of male national athletes, which means that the applicability of the results is limited to female athletes and younger groups. The movements that were tested were made uniform so that there would be no inconsistency, but this might have caused the natural variation in the technique to be [15] blocked. Future research will focus on incorporating in-competition monitoring, larger and more varied samples, wearable sensor technology, and longitudinal tracking to understand the development of cumulative loading exposure over time better.

CONCLUSION

The analysis of the biomechanical disparities between gymnastics and wrestling reveals the basic differences in their aspects' impact on the human body. Very high vertical impact forces and quick loading rates characterize gymnastics, mostly due to the combination of aerial skills and the high speed of landings. Thus, the lower limbs and spine experience a huge amount of stress that is directly connected to the high number of impact-related injuries suffered by gymnasts. On the contrary, the nature of wrestling invokes higher shear and torsional stresses through the dynamic contact, movements caused by the opponent, and quick changes in direction. These force patterns can be the reason for ligament strain, joint instability, and other soft-tissue injuries that are common among wrestlers. The findings of this comparative analysis serve to elucidate the mechanical conditions of both sports and to spotlight the necessity for sport-specific injury prevention approaches. Knowledge of such loading patterns informs targeted

training programs, athlete screening protocols, and appropriate surface and equipment designs matched to the demands of each sport.

ABSTRACT

The present research work was carried out to study the formulation of the margarine extract the microbiological analysis of the margarine sample to determine the microorganisms loaded in the margarine extract through total heterotrophic bacterial count and coliform count and fungal enumeration of the sample. Proximate and physiochemical analysis of margarine formulated from coconut and papaya to identify the nutritional supplement of the compound of the extract. Phytochemical assay to evaluate that compounds present in the sample. The antimicrobial activity of the margarine extraction that was tested by pathogen organisms from margarine extract showed the inhibition of growth in pathogen organisms. Antioxidant activity also shown the radial antioxidant ability. The margarine extract can be used as a natural additive to enrich table spread margarine without affecting its properties while improving its oxidation stability. Anti- inflammatory shown the healing property to able to treat with margarine and so one can develop drugs for the treatment of inflammatory-related disease and its has the good healing properties to treat the injurious substances.

Keywords: Heterotrophic Bacterial Count, Coliform Count, Phytochemical, Margarine.

INTRODUCTION

Traditional medicine is especially common in underdeveloped countries because of its historical and cultural significance. For the treatment of a wide range of illnesses, they employ natural medicines and plant extracts. The World Health Organization's recognition of the extensive use of traditional medicine demonstrates its continued importance in global healthcare. One of the main benefits of conventional medicine is the application of plant extracts and their active components (Davis, 1994). Coconut oil, extensively used in both culinary and industrial realms, is distinguished by its high medium-chain fatty acid content, ranging from 46% to 48% (Marina *et al*., 2009). Coconuts offer nutraceutical advantages. Coconut juice demonstrates estrogenic effects and possesses antibacterial, antiviral, antidote, antioxidant, and antithrombotic properties (Esquenazi *et al*., 2002). These attributes make coconut- derived dietary supplements valuable for averting nutrient deficiencies and promoting overall health. Papaya is also known for its digestive benefits and is rich in manganese, offering advantages in preventing osteoporosis and bone fractures. The intake of papaya seed oil with a notable oleic acid composition has been associated with improved plasma lipid status. Oleic acid, found in the oil, has demonstrated potential in reducing cholesterol and plasma triacylglycerol levels without affecting plasma Low-Density Lipoprotein (LDL) cholesterol concentration. (Yao; Xu, 2021). Margarine, initially developed by French chemist Hippolyte Mege Mouries in the 1860s, originally relied on animal-derived fats, notably bovine fat. By the early 20th century, this progression culminated in the exclusive use of 100% vegetable oil, sourced from options like coconut, palm, melon, papaya and other sources. This transformation mirrored evolving consumer preferences and economic considerations within the margarine industry (Chrysan, 2005). As per the Codex International standard established in 2001, margarine is defined as a water-in- oil emulsion primarily composed of edible oils and fats. This standard outlines that margarine should consist of a minimum of 80% fats and a maximum of 16% water. It is a common practice to blend two or more different oils in margarine production, providing a customized approach to meet specific preferences and requirements (Codex, 2001).The formulation of margarine endetails blending water, additives like salt, and emulsifiers to maintain its quality. Emulsifiers serve three pivotal functions in the margarine production process, as elucidated (Hamilton, 1994). Firstly, they aid in establishing a stable emulsion, ensuring the harmonious integration of water droplets within the vegetable oil. Secondly, emulsifiers modify the crystalline structure of the vegetable oil, contributing to the desired texture of the end product. Lastly, they play a crucial role in preventing the coalescence of water droplets and minimizing splattering during the heating of margarine. The global production and consumption of margarine are experiencing an upward trend due to its lower saturated fat content compared to butter and its cholesterol-free attributes. The combination of coconut and papaya oils in margarine production offers opportunities to optimize resource utilization and product value, these oils present a promising alternative for margarine production, potentially enhancing its health benefits. This study aims to assess the microbiological quality and determine the physicochemical and proximate composition of the resulting margarine (Akubuenyi; Odey, 2022). Margarine finds application as a fat spread, in cooking, and in the production of bakery items (Reyes-Hernandez *et al*., 2007 and Lee *et al.,* 2008)**.** The current study serves as an initial screening phase focused to isolate and identify specific antibacterial compounds that exhibit plant-derived broad-spectrum antimicrobials and is a pioneering work on the antioxidant, anti-inflammatory and phytochemical analysis on the nature of margarine sourced from coconut and papaya extracts.

MATERIALS AND METHODS

Sample collection

The sample of fresh coconut and papaya sample were collected from local market. Coconut sample are coconut and flower and entire papaya sample were taken for extraction and analytical standard.

Extraction of margarine: (Sayed *et al*., 2009)

Margarine was produced from 100% coconut and papaya extract using the method described by Sayed *et al*., 2009. A basic recipe that include 81.7% oil blend, 0.3% emulsifier, 0.8% salt,0.9% skim milk powder, 0.2% flavour, 0.01%

antioxidant and 0.003% colour was used for margarine production. Emulsifier, antioxidant, flavor and colour was dissolved in the heated oil phase. Salt and skim milk powder were dissolved in water phase. The water phase was added gradually to the oil phase while agitating it to form a nice emulsion. For the solidification of margarine, the emulsion was stirred for 10 minutes and then cooled in ice bath containing 10% sodium chloride (NaCl). The emulsion was then mixed and solidified at a temperature of 110^0 C. the margarine sample stored in a refrigerator at 4^0C.

Microbiological Analysis

Preparation of peptone salt saline

Microorganism were isolated by serial dilution technique. 10µg of sample was suspended in 90ml of Peptone Salt Saline and mixed for 2minutes.

Determination of total heterotrophic bacterial count

Serial dilution (10^{-1} -10^{-5}) was prepared from margarine oil samples. 0. l ml was transferred from each selected dilution (10^{-2},10^{-3} and 10^{-4}) into sterile petri dishes in triplicates. The molten sterilized agar (Nutrient agar) were poured into the plates, swirled for even distribution of the inoculum within the agar medium and allowed to solidify and then incubated at 37°C for 24 hours. Thereafter, plates with colony growth were counted and expressed in colony forming unit per millimeter (CFU/ml).

Enumeration of total coliform count

Total coliform count of the samples was determined using the spread plate method on MacConkey agar medium. 0.1ml of the diluent from the samples was aseptically transferred into sterile petri dishes containing already sterilized MacConkey agar, and were swirled for even distribution. They were incubated at ambient temperature for 3-4 days. Plates with colony growth were counted and expressed in colony forming unit per millimeter (CFU/ml).

Determination of total fungal count

Total fungal count was examined using the spread plate method on Sabouraud dextrose agar (SDA). Exactly 0.1ml of the diluent from the samples was aseptically transferred into sterile petri dishes containing already sterilized SDA, and was swirled for even distribution. They were incubated at ambient temperature for 3-4 days. Plates with colony growth were counted and expressed in colony forming units per millimeter (CFU/ml).

Determination of Proximate Composition (Standard AOAC method)

The sample was analyzed for the various nutrient's constituent such as analysis of ash, sugars, carbohydrates, calcium, total solids, carbohydrates, calcium, acidity, crude lipid, crude protein, crude fibre, moisture, pH, energy and vitamin B_{12} by the methods of the Association of official Analytical Chemists.

Physicochemical Parameters (Standard IS method)

Physicochemical properties of oils are determine the acidity, Calcium and colour to know the quality, purity and identification of the margarine extract.

Antimicrobial Activity: (Kirby and Bauer 1950)

The disk diffusion method of Kirby and Bauer has been standardized and is a viable alternative to broth dilution methods for laboratories without the resources to utilize the newer automated methods for broth microdilution testing.

Antibacterial activity

The inoculum was standardized at 1 x 10^6 CFU/ml comparing with turbidity standard (0.5 MacFarland tube).A supply of cotton wool swabs on wooden applicator sticks was prepared. They were sterilized in tins, culture tubes, or on paper, either in the autoclave or by dry heat. The Assay was performed by agar disc diffusion method. For Bacteria: Muller Hinton Agar (MHA) and Blood agar medium is poured in to the petriplate. After the medium was

solidified, the inoculums were spread on the MHA plates with sterile swab moistened with the bacterial suspension of *Staphylococcus aureus, Bacillus pumilus, Escherichia coli, Salmonella sp* with a standard of Ampicillin (20µl/disc). Sterile samples (Disc form) and 20µl of Standard antibiotic (Ampicillin) disc as positive control were placed in MHA plates. The plates were incubated at 37ºC for 24 hrs. The antimicrobial activity was determined by measuring the diameter of zone of inhibition.

Antifungal activity (Seetharaman *et al.*,2021)

Stock cultures were maintained at 4°C on Sabouraud Dextrose agar Slant. Active cultures for experiments were prepared by transferring the stock cultures into the test tubes containing Sabouraud Dextrose broth, that were incubated at 48hrs at room temperature. The assay was performed by agar disc diffusion method. Antifungal activity of the extracts was determined by disc diffusion method on Sabouraud Dextrose agar (SDA) medium. Sabouraud Dextrose agar (SDA) medium is poured in to the petriplate. After the medium was solidified, the inoculums were spread on the solid plates with sterile swab moistened with the fungal suspension of *Candida sp*, *Aspergillus niger* with a standard of Amphoterin B (20µl/disc). Samples were placed over the plate. Amphotericin-B is taken as positive control. The plates were incubated at 37ºC for 24 hrs. Then antifungal activity was determined by measuring the diameter of zone of inhibition.

Antioxidant activity: (Naznin Ara and Hasan Nur 2009)

Antioxidant activity assay is based on the reduction of 1, 1-diphenyl-2-picrylhydrazyl (DPPH). Due to the presence of an odd electron it gives a strong absorption maximum at 517nm.As the electron becomes paired off in the presence of a hydrogen donor, i.e., free radical scavenging antioxidant, the absorption strength is decreased, and the resulting decolourization istoichiometric with respect to the number of electrons captured, the ability of the extract to scavenge DPPH radical was determined by the method described by Naznin Ara and Hasan Nur (2009).

Anti-Inflammatory assay: (Shinde *et al.*,1999)

Fresh blood was collected from the healthy volunteers. The collected blood w as mixed with equal volume of sterilised Alsever solution which act as an anticoagulant The sample was then centrifuged at 3000 rpm for 5 min and packed cells were washed with isosaline (0.85%, pH 7.2) and a suspension was made with isosaline (10% v/v). This was taken as HRBC suspension. The assay mixture contained 1.0 ml of phosphate buffer (0.15 M, pH 7.4), 2.0 ml of hyposaline (0.36%), 0.5 ml HRBC suspension and 1.0 ml of various concentrations of sample (200, 400, 600, 800 and 1000 µg/ml). For control solution, instead of hyposaline, 2.0 ml of double distilled water was added. The mixtures were incubated at 37°C for 30 min and centrifuged at 3000 rpm.

Qualitative Phytochemical analysis: (Seetharaman *et al.*, 2022)

Coconut and papaya plant extracts were analysed for the presence of the following phyto constituents such as tannins, saponin, flavonoids, alkaloids, quinones, glycosides, terpenoids, anthocyanine and Betacyanine, phenols, cumarins, starch, acids, cyanins, cardiac glycosides, proteins and carbohydrates using modified and standard protocol.

RESULTS AND DISCUSSION

Bacterial and fungal count of margarine produced from papaya and coconut oils:

The enumeration of the total heterotrophic bacterial counts of the samples showed that the self- made margarine had no bacterial load. The result of the total coliform count also revealed of no coliform contamination. The total fungal count also followed the same trend in fig.1,2,3.

Evalution of proximate and physiochemical composition

The results of the proximate analysis as contained in Table 1 revealed that the energy content was determined as 161.6, protein content 1.2, Lipid (fat) content 2.04, carbohydrate content 65.9, moisture content 12% and so on. The

result of the physicochemical analysis of the produced margarine revealed that it as shown colour 2 hazen, total soluble solid 100.5%,total titratable acidity4.11g/100g,viscocity 85g/100g , calcium 3.45mg/l, pH 7.09.in Table 2.

Antimicrobial activity

Antibacterial activity

Six microorganisms were tested for the antimicrobial activity of the margarine extraction were done and showed varying degree of inhibition activity. Gram negative organisms such as *E.coli* (15mm), *Salmonella* (10mm), and *Bacillus pumilus* (13mm) showed a moderate inhibitory activity, whereas the gram positive microorganisms showed a maximum inhibitory activity with *Staphylococcus aureus* (19mm) in table 3.

Antifungal activity

The antifungal activity was minimal in *Aspergillus niger* (4mm) and *Candida sp* (6mm) shown minimal inhibitory activity against the extract of margarine. Results indicated that the Gram positive microorganisms were shown the maximum inhibition than Gram negative organisms and the poor zone of inhibition was observed for the fungal strains in table 4.

Antioxidant activity (517nm)

Antioxidant potential of margarine extract from the plant sources were measured by DPPH radial scavenging method with different concentration (1000 µl, 500 µl, 250 µl, 150 µl) showed increased activity in extract concentration. The margarine extract showed 93% antioxidant at1000µl concentration, 90% antioxidant at 500µl concentration, 86% antioxidant at 250µl concentration and 48% antioxidant at 150µl concentration. Results were expressed as percentage inhibition of DPPH in table 5.

Anti-inflammatory activity (560nm)

Anti-inflammatory activity of margarine extract of the plant sources was measured by Human Red - Blood Cells (HRBC) methods with different concentration (1000µl, 500µl, 250µl, 125µl) showed the increases activity of the activity. The margarine extract showed 83.72% of anti-inflammatory at 1000µl concentration, 81.17% of anti-inflammatory at 500 µl, 77.05% of anti-inflammatory at 250µl, 38.84% of anti-inflammatory at 125µl. Results were expressed as percentages of anti-inflammatory activity in table 6.

Phytochemical analysis

The margarine extract of the plant source was analysed for the phytochemical screening. The presence of acids, alkaloids, anthrocyanine and betacyanine, carbohydrates, cardiac glycosides, flavonoids, quinones, saponins, tannins and Terpenoids and absence of coumarins, glycosides, phenols, proteins and starch have beenreported and the results were tabulated. Among them, alkaloids, carbohydrates, flavonoids and glycosides are of high amount, and proteins, phenols, starch are absent in table 7. The present study suggests that the physiochemical parameter, proximate composition, microbiological quality and antioxidant properties of margarine produced from oil extract of coconut and papaya. Odey, 2022 stated the potential of margarine production from blends of melon, coconut and palmkernel oil, and the microbiological qualities and physiochemical composition such as moisture (15.0±0.5), ash (35.0±0.5), crude (17.50±0.25), lipid (22.50±0.03), protein (1.218±0.01), and carbohydrate (7.78±0.01). The physicochemical analysis of the melon, coconut and palm kernel oil showed the low acid value of 1.159. The enumeration of total heterotrophic bacterial count revealed a low microbial count 2.6×10^{-3} CFU/g, total coliform count was 2.5×10^{-2} CFU/g and total fungal count 2.4×10^{-2} CFU/g from this study showed that the melon coconut and palm kernel oil extract have greater potential as industrial raw material beyond been consumed directly or indirectly as ingredient in food. The current investigation indicates that upon microbiological assessment, no bacteria suspected of causing infection were detected, and there were no isolated fungi present. This suggest that the microbial environment being examined displayed no signs of bacterial or fungal presence, possibly indicating a sterile or well-controlled environment. The edibility of margarine in s being safe for human food consumption is brought through the above finding of antimicrobial activity. Therefore margarine extracted from organic source can be an ideal food

for daily Recommended Dietary Allowance. Physiochemical and proximate composition of ash content in the sample was measured at 27%.

Ashing serves as a valuable methods for the analyzing the mineral composition of papaya and coconut extraction. According to the Recommended Dietary Allowance (RDA), adults are advised to consume a fat content of 10%, while infants require a slightly higher intake at 15%. However, a lipid (fat) content of 20% is beneficial in diets as it aids in the absorption of fat-soluble vitamins. With a calcium content of 3.45mg/l, these oils contribute to the building and maintenance of strong bones. The crude fiber content of 16.6% supports the maintenance of internal distention necessary for normal peristaltic movement of the intestinal tract. Additionally, the carbohydrate content of 75g suggests that coconut and papaya oil provide a low source of energy. An increase in the acid value often corresponds to the development of unpleasant flavors and aromas. As per the Codex standard, the maximum acceptable acid level in cooking oil or oil intended for consumption is 4mg KOH/g. The outcomes of this study suggest that margarine made from papaya and coconut oil could be considered suitable for consumption, indicating that the acidity levels are within acceptable bounds. Abbas, 2019 reported that the efficacy of goat margarine was examined against four distinct bacteria, revealing varied results in terms of inhibition zones. *Salmonella typhimurium* exhibited the highest zone of inhibition, while *Escherichia coli* showed the lowest. However, it's noteworthy that certain individuals have allergies to casein, a milk protein, which can trigger severe allergic reactions, including anaphylaxis. The current study investigated the antimicrobial activity, revealing potent effects against pathogenic strains of both Gram-positive and Gram-negative microorganisms. Among the bacteria tested, *Staphylococcus aureus* exhibited the highest susceptibility, while *Salmonella sp.* showed the lowest the lowest. Conversely, when compared to bacterial strains, the fungal strains displayed minimal zones of inhibition, with *Aspergillus niger* and *Candida sp*. exhibiting the least inhibition zones.

The study suggests that coconut and papaya margarine extracts possess natural antioxidant stability. Date kernel oil extracts, both cold and heat-treated, showed a moderate capacity (approximately 93%) for reducing free radicals in terms of anti-DPPH effect. Additionally, the study explores the anti-inflammatory activity of margarine extracts from coconut and papaya, indicating their potential healing abilities against harmful substances. Preliminary phytochemical analysis revealed the presence of various compounds such as alkaloids, anthocyanins, betacyanine, cardiac glycosides, tannins, terpenoids, and flavonoids in the margarine extracts from coconut and papaya. The study investigated using date kernel oil as a natural additive to enhance table margarine without changing its properties, while also boosting its oxidative stability. Date kernel oil contains potent antioxidants like phenolics, flavonoids, and carotenoids. Incorporating this oil into margarine enriched its antioxidant content without affecting its properties. Additionally, it improved the margarine's oxidative stability, as evidenced by a reduction in the DPPH radical. The study suggests that coconut and papaya margarine extracts possess natural antioxidant stability. Date kernel oil extracts, both cold and heat-treated, showed a moderate capacity (approximately 93%) for reducing free radicals in terms of anti-DPPH effect. Additionally, the study explores the anti-inflammatory activity of margarine extracts from coconut and papaya, indicating their potential healing abilities against harmful substances. Preliminary phytochemical analysis revealed the presence of various compounds such as alkaloids, anthocyanins, betacyanins, cardiac glycosides, tannins, terpenoids, and flavonoids in the margarine extracts from coconut and papaya.

ABSTRACT

In an era marked by pervasive digital connection, being aware of cybersecurity practices and raising college students' knowledge of them is crucial. With an emphasis on proactive cybersecurity measures and security hygiene, this research sought to evaluate college students' understanding of cybersecurity and current practices in this area. 470 college students from Coimbatore's top five universities participated in a survey that was administered using a stratified random sample approach. The study aimed to determine the degree to which college students follow security hygiene guidelines and participate in proactive cybersecurity initiatives. The survey provided important insights into the demographic makeup of the respondents. The results of this study offer insightful information about college students' current cybersecurity practices and awareness, which can guide the creation of focused interventions meant to improve cybersecurity education and promote a cybersecurity culture in young people.The results of this study provide insightful information about college students' current cybersecurity practices and awareness, which can guide the creation of focused interventions suggests to enhance cybersecurity education and promote a cybersecurity civilization in young people.

Keywords: Cybersecurity, Awareness, Practices, College Students, Cyber Threats.

INTRODUCTION

In recent years, almost everyone uses the Internet in every part of their everyday lives. The prevalence of cyber threats has grown to be a serious problem in the constantly evolving landscape of technology and digital communication. Students are more susceptible to cyberattacks as more college campuses make use of digital platforms for instruction, communication, and information exchange. With an emphasis on understanding the predominant behaviours and awareness levels among students, the project "A Study on Cybersecurity Practices and Awareness Among College Students" aims to explore the cybersecurity environment within the college demography. We have chosen college students as our target demographic for the following reasons: College students utilize technology and the Internet for two main purposes: socializing and education. And also, their security-aware actions will have a profound and long-lasting effect on society. In addition to the reality that college students utilize technology and the Internet primarily for socializing and education, we have chosen college students as our target demographic. Along with using several other services like video calls, virtual healthcare and education, and business and banking establishment, people can also engage with friends and family online. Beyond all of these benefits, there are drawbacks as well. For example, cyberattacks, which are a worldwide problem these days, might compromise system security and jeopardize the world economy. To safeguard sensitive data against well-publicized security breaches, an effective cybersecurity plan is therefore crucial. In addition, as the number of cyberattacks rises, businesses and institutions particularly those handling data pertaining to health, finances, or national security need to implement robust cybersecurity procedures and safeguards to safeguard their confidential and private clientele.

REVIEW OF LITERATURE

The preference for information security awareness training is growing beyond the scope of information technology college curriculum, as cyber risks continue to expand at an exponential rate. (Slusky, L., and Partow-Navid, P.,2012). There prevails an unsatisfactory situation towards the security issues like password use, malware, social engineering, phishing, and internet scams etc, (Muniandy, L., Muniandy, B., and Samsudin, Z. 2017). In these days students are ready to have a basic knowledge on cybersecurity, but they might not be aware of how to safeguard their information (Alqahtani, M. A. 2022). Furthermore, it seems that the majority of universities lack an ongoing cybersecurity awareness program that would increase students' understanding of how to defend oneself against online attacks (Garba, A., Sirat, M. B., Hajar, S., and Dauda, I. B. 2020). Also, by practicing highly effective internet connectivity practices, these data and security breaches can be mitigated. (Baraković, S., and Baraković Husić, J. (2023).

Statement of Problem

College students are currently living in an era of frequently encountered digital connectivity and rapid technological innovation, which puts them at danger from growing cybercrimes. Due to their increased dependence on digital platforms for social, academic, and personal activities, this group is more vulnerable to identity theft and phishing attempts, among other cybersecurity risks. The apparent lack of understanding among college students about security issues and tactics currently is the challenge at hand. This lack of understanding increases students' privacy and security at critical risk, increased the possibility of monetary losses, data breaches, and misused personal information. In this digital era, issues pertaining to cybersecurity has become increasing critical, especially among college students. Though college students are increasingly dependent on digital platforms for their academic pursuit, there still exist a gap in understanding cybersecurity awareness and practices among college students. Hence this study addresses the gap by investigating the following questions

1. What are the prevailing cybersecurity practices adopted by college students?
2. What is their level of awareness on common cyberthreats
3. What are the cybersecurity practices adopted in protecting personal and academic information?

OBJECTIVES

- To know the existing cybersecurity practices among college students.
- To understand the level of awareness on cybersecurity threats.

METHODOLOGY

This study employs Descriptive research design to explore the cybersecurity practices and awareness among students of selected five colleges in Coimbatore City. PSG College of Arts and Science, PSGR Krishnammal College for Women and Kongunadu Arts and Science College, Krishna Arts and Science College and Government Arts College, Coimbatore were selected for the study based on NIRF Rankings 2023. Stratified Random Sampling Technique is adopted and 100 respondents from each college was collected. Out of 500 respondents selected for the study, 470 responses were included in the study remaining unfilled and incomplete responses were rejected. Statistical tools such as simple percentage analysis and factor analysis was applied to derive the results.

SURVEY RESULTS, ANALYSIS AND DISCUSSIONS

A sample of 470 college students from top five colleges in Coimbatore was surveyed adopting stratified random sampling technique. Among 470 respondents 257 (54.7%) of the respondents are female, 150 (31.9%) of the respondents fall under the age group of 18 – 19 years and 259 (59.1%) of the respondents belongs to arts stream. , 274 (58.2%) of the respondents have a neutral rate of awareness level towards cybersecurity threats, 339 (72.1%) of the respondents have not experienced a cybersecurity incident, 183 (38.9%) of respondents occasionally update their software and operating system as safety measures, 131 (27.8%) of the respondents use pin as authentication mechanism, 161 (34.2%) of the respondents stay informed about cybersecurity threats by receiving updates from their colleges and universities and 285 (60.7%) of the respondents are very much concerned about the security in their digital information at present and in future.

Factor Analysis

Factor Analysis is applied to reduce the complexity of data. When there are more variables on a phenomenon under study, then identifying one, two or few variables that influence the phenomenon under study is involved. There the variables are to be reduced to few factors (Latent Variables) which can be taken as constructs (factors) that influence the phenomenon under study. In this study, factor analysis has been applied to find the underlying dimension (factors) that exists in the 9 variables relating to existing cybersecurity practices. Therefore, factor analysis is applied to find the existing cybersecurity practices among college students. Using SPSS software, these factors can be obtained. Tables 1.(a) and 1.(b) explain the steps to get the factors. Table 1.(a) states the KMO and Bartlett's Test. KMO – Bartlett measure of sampling adequacy is an index used to test the appropriateness of the factor analysis. The KMO is 0.779, and the Chi-square statistics is significant (<0.05). This means the factor analysis is appropriate for this data. Table 1.(b) discuss the Extraction Communalities. Extraction communalities are estimates of the variance in each variable accounted for by the components. The communalities in Table 1.(c) are all high except 2 variables, which indicates that majority of the extracted components represent the variables as well. Table 1.(c) represents total variance for the selected data. The percentage of total variance contributed by the components is given in 1.(d). The percentage of total variance contributed by the first components is 44.900%, by the second component is 12.688. Thus, there are two components for the given set of variables. Table 1.(d) reveals the rotated component matrix. The rotated component matrix gives the variables belonging to each component. The maximum of each row (ignoring –ve sign) indicates that the respective variable belongs to the respective component. Table 1.(e) exhibits the factors extracted from factor analysis. Based on the rotated component matrix two factors and its underlying items are summarised. Table 1.(e) explores the factors extracted from factor analysis related to cybersecurity practices among college students. Thus, among 9 variablesselected for this study, using principal component analysis, the factors have been reducedto two-factor model, and each factor has been given a name, which is associated with thecorresponding

variables based on the values obtained from the rotated component matrixtable. 'Proactive Cybersecurity Practices' are the most important cybersecurity practices followed by the college students . The second cybersecurity practices followed by the college students is 'Security Hygiene Measures'. In conclusion, 'Proactive Cybersecurity Practices' and 'Security Hygiene Measures' and the Cybersecurity practices followed by the college students.

CONCLUSION

The study on cybersecurity practices and knowledge among Coimbatore college students offers important new information on how prepared this group is for cyberattacks right now. The study aims to evaluate current cybersecurity measures and knowledge levels regarding cyber dangers using a thorough survey that included 470 college students from the top five universities in the region. The findings show that college students have varying levels of cybersecurity knowledge and behaviors. There is still a sizable disparity in the implementation of proactive cybersecurity measures, even though a sizable number of respondents showed a basic grasp of cybersecurity concerns.The significance of improving proactive cybersecurity practices and security hygiene procedures among college students is highlighted by key findings. Even though cyber risks are common, a significant proportion of participants could not possess the necessary tools to safeguard themselves from possible assaults. The introduction of comprehensive cybersecurity education programs catered to college students' requirements is one of the recommendations arising from this study. It is also reported that most students are aware of possible consequences. These courses ought to emphasize teaching useful cybersecurity skills, encouraging ethical online conduct, and increasing public knowledge of new and emerging cyberthreats. The outcomes of this research highlight the value of giving cybersecurity education top priority and encouraging college students to adopt a proactive cybersecurity mentality. Through the implementation of focused actions and the resolution of identified gaps, we can reduce the potential dangers connected with cyber-attacks and foster a more secure digital future for all.

ABSTRACT

IEEE Transactions on Affective Computing (TAC) is a prestigious international journal, indexed in Scopus, dedicated to publishing research on the design of systems capable of recognising, interpreting, and simulating human emotions and related affective phenomena. This paper provides a thorough overview of the works published in TAC from 2010 to 2024. The main aim of this research is to chiefly determine the publication trend of TAC (IEEE Transactions on Affective Computing) and their citation framework. This paper presents the findings of a bibliometric study of 1032 papers published in TAC between 2010 and 2024. An insightful examination of the TAC publications is performed to ascertain the bibliometric parameters like the citation framework of the journal (a summary of the citation structure is provided), co-citation analysis, annual distribution of publications, yearly citations, yearly trend of significant terms, co-authorship networks, geographic analysis of the sources, country-specific historical and quantitative analysis, along with the most cited papers.

Keywords: Citation analysis, Authorship pattern, Bibliometric studies, Publication trends, Computer

INTRODUCTION

The computer science and application community are expanding tremendously through the contribution of high-quality research and novel discoveries. The accuracy of these research works is validated and regulated by the established journals. The IEEE Transactions on Affective Computing is an international, interdisciplinary journal focused to publishing research findings on the development of systems capable of recognising, interpreting, and simulating human emotions and associated affective phenomena (Muhuri *et al*., 2018). The journal disseminates original research on the principles and theories elucidating the influence of affective factors on human-technology

interaction. It emphasises the role of affective sensing and simulation techniques in enhancing our comprehension of human affective processes, and the design, implementation, and evaluation of systems (List of IEEE Publications - Wikipedia, n.d.). The research papers in this journal can be generally classified into several subject areas like Computing and Processing, Robotics and Control Systems and Signal Processing and Analysis. According to the 2023 Journal Citation Report published in June 2024,the journal met the following matrices:Journal Impact Factor (JIF): 9.6; 5-Year Impact Factor: 11; and #1 position in the field of cybernetics and computer science (IEEE Transactions on Affective Computing, n.d.). Pritchard (1969) defined bibliometrics as "the application of mathematical and statistical methods to books and other media." It involves analysing a compilation of articles that includes bibliographic details such as authors, co-authors, publication dates, Publication Country, subject keywords, and citations (Kumar, 2014). The recent bibliometric application is particularly significant as publication and citation metrics are increasingly utilised as performance indicators for assessing the quality of research conducted by individuals or groups of researchers affiliated with the same or various institutions. In the present paper, the researchers applied bibliometric techniques to the articles published in TAC during the last years (2010 – 2024) to find out the citation framework of the journal, co-citation analysis, annual distribution of publications, yearly citations, yearly trend of significant terms, co-authorship networks, geographic analysis of the sources, country-specific historical and quantitative analysis along with the most cited papers. With the help of these parameters, the researchers tried to find out the present trend of the subject concerned in the journal (Udo-Anyanwu, 2018).

LITERATURE REVIEW

The literature review is typically considered a significant indicator for assessing the growth pattern of the discipline and the extent of scientific research achievements and contributions. Wang *et al*. examines trends in IEEE Transactions on Affective Computing research through statistical literature analyses and citation frequency over time (Wang *et al*., 2021). Preeti and Kumar, in their literature review seek to examine bibliometric studies on research data management and delineate main findings and topics (Sajovic and Boh Podgornik, 2022).The structure and development of a variety of research topics, including visualisation education research, have been extensively studied with science mapping (Wang *et al*., 2021). The world community is eagerly awaiting advancements in AI technology, with much of the current research centred on the potential applications of AI in education (Kavitha *et al*., 2024).Citation analysis, productivity analysis, and collaborative analysis are three common methodologies employed in bibliometric literature (Variant Anna *et al*., n.d.). Computer science, as a field of data processing, excels in data manipulation and information delivery to support decision-making (Supriyadi, 2022). Research on the utilisation and analysis of human-computer interaction (HCI) technologies in healthcare has markedly intensified, illustrating the substantial potential of HCI to enhance medical services, improve patient experiences, and advance health management (Zhao *et al*., 2024). The field of artificial intelligence (AI) in radiology is progressing rapidly. Artificial intelligence has been integrated into breast imaging in practical settings, and various studies have been conducted in this field(Singh and Healy, 2024). Anandhalli and Bhalappa, in their study in 2021 investigates the research output performance of Cloud Computing Technology published in the Scopus database from 2007 to 2019 (Bhalappa and Dr, 2021). Ashrafuddin and Singh. offers a scientometric and keyword-centric examination of research conducted in the field of computer science (CS) within the SAARC area during the past 25 years (Uddin and Singh, 2014). Virtual reality (VR), as an emerging technology in computing, has been extensively utilized in the medical sector and possesses significant developmental potential and application value. Li *et al*. analyse the worldwide and domestic outputs of the principal initiatives using diverse scientometric indicators and methodologies (Li *et al*., 2022). Huangaims to perform a retrospective bibliometric analysis of works concerning rehabilitation medicine that utilize virtual reality technology (J. Guan and He, 2005). An evaluation of the Journal of King Saud University-Computer and Information Sciences (JKSU-CIS) from 2004 to 2014 has been carried out using a scientometric approach (Huang *et al*., 2016). Roshani, Saeed, *et al*. carried out a study where the goal is to model and analyse the relation between research funding and citation-based performance in science to predict the diffusion of new scientific results in society (Hussain, 2017). Farshid, Abedi, and Jafari conducted a study with the objective is to determine the characteristics of scientific products in the field of small-data that are indexed in the Web of Science database and to explain its

application based on the identification of the terms of scientific products connected to this subject in a manner that is distinct from the scientific fields (Roshani *et al*., 2021). Boudry *et al*. carried out research to report on the trends in scientific production and publication, as well as to identify the journals, countries, international collaborations, and important MeSH terms that are involved in artificial intelligence research and its application to ophthalmology (Boudry *et al*., 2022). Luo, DeWitt and Alias present a scientometric review of academic articles to examine the intellectual environment and evolutionary traits of TC research globally from 2001 to 2020 (Luo *et al*., 2022)(Farshid *et al*., 2022). In present paper, the researchers try to adopt best possible methodology for finding the growth parameters of articles published in TAC during 2010 to 2024.

OBJECTIVE OF THE STUDY

There remains a deficiency of written literature regarding the contributions of IEEE Transactions on Affective Computing globally. This analysis addresses the gap by examining computer science articles from 2010 to 2024. The aim of the current research is to identify the prevailing research trends in computer science from 2010 to 2024. The study aims to uncover newly developing research fields in the field of computer science.

a. To find out the total annual output of scholarly publications in the journal (Year-wise).
b. To identify the most cited contributions of the journal.
c. To ascertain the institutional affiliation of the writers.
d. To ascertain the geographical distribution of the articles.
e. To analyse the authorship pattern including their country of origin, affiliating universities, co-authors etc.
f. To analyse the citation pattern including total citation, average annual citation, total SCOPUS citations, total Google citations etc.

RESEARCH METHODOLOGY

This section outlines the complete process and methodology utilised in doing the bibliometric analysis, encompassing the research questions, the methods and software applied, the data sources, and the dataset development. Procedure of the study based (Table 1). The yearly research output of Transactions on Affective Computing form 2010 - 2024 is shown in Table 2 and Figure 1. For the years 2010–2024, this info graphic compiles data from a single publication. There are 1,032 papers in total, with a growth rate of 20.38 percent every year. With 2,694 writers and an international collaboration rate of 34.59%, each publication averages 4.31 co-authors. Just one person writes all of the 22 documents. There are 8,296 keywords in all, including those used by authors and algorithms. The papers reference 56,503 sources, with each paper averaging 50.47 citations. With an average age of 4.79 years, these documents are from very recent, extensive research. Main Information on Affective Computing (Table 2). Main information on affective computing (Fig. 1). Figure 2 illustrates a flawed bibliometric study of IEEE Transactions on affective Computing, indicating a recent rise in interest in this field, likely attributable to developments in artificial intelligence, human-computer interaction, and applications of emotional computing. The post2020 surge corresponds with the growing global research on AI-facilitated emotional intelligence and affective systems. It is possible that a change in publication strategy or a stabilising phase Transactions on Affective Computing is behind the fall in 2024.

This trend in publishing in Transactions on Affective Computing is a reflection of the rising profile and relevance of affective computing in cutting-edge artificial intelligence studies. In the first few years, the trend shows a slow but consistent increase, and then it starts to really take off about 2020. In 2022 and 2023, there was a noticeable increase, reaching its highest point in 2023 when the number of publications peaked. In 2024, production dropped slightly from the levels seen before 2020, although it was still far higher than before. Table 3 and Figure 3 and 4 demonstrate the Total Publication, Average Citation and Total Citation counts for succeeds published in IEEE Transactions on Affective Computing from 2010 to 2024. The examination reveals substantial rise in publications in IEEE Transactions on Affective Computing from 2020 to 2023. The total number of publications increased from 59 in 2020 to a maximum

of 244 in 2023. Nonetheless, there was a reduction to 161 publications in 2024. Nevertheless, citation metrics indicate a contrasting trend, as the average citations per manuscript have declined consistently from 211 in 2010 to merely 4 in 2024. This signifies a considerable increase in publication volume, accompanied by a decrease in citation impact per piece, especially post2020. The reduction in average citations may result from publication saturation or diminished novelty in current research.

The interval from 2022 to 2024 exhibits accelerated publication increase accompanied by diminished citation impact, indicating a potential necessity for improving the quality of contributions. The increase in publications is inversely correlated with the average citations per paper. The average citations have steadily declined from a peak of 225 in 2012 to only 4 in 2024. This drop indicates that although the quantity of published articles has risen, the influence of each publication has substantially decreased. The examination of Table 3 and Figure 3 to 4 reveals a distinct trend of rising articles in the IEEE Transactions on Affective Computing from 2010 to 2024. The number of articles stayed generally constant from 2010 to 2019, with minor variations between 12 and 45 publications annually. A significant increase commenced in 2020, rising from 59 publications to a zenith of 244 in 2023, subsequently declining to 161 in 2024. The abrupt increase in publications from 2020 onwards may be ascribed to the heightened interest in affective computing, developments in artificial intelligence, or enhanced accessibility to publishing. The diminished citation impact suggests that recent works may either lack originality or necessitate additional effort to garner citations. The substantial publication total in 2023 (244 papers) coupled with an average of only 17 citations suggests a possible oversaturation or a prioritisation of quantity over quality. Table 4 and Figure 5 enumeration the most prominent writers of IEEE Transactions on Affective Computing according to overall and fractional article contributions. LI Y's fractional contribution of 5.33, despite co-authoring 29 publications, is significant. LI X (22 papers, 3.52 fractionalisation) and BUSSO C (19 articles, 7.54 fractionalisation) are comparable, with BUSSO C displaying a more considerable contribution. ZHANG X, WANG S, and ZHAO G have important outputs; however, their relative contributions indicate collaboration.

The variation between total and fractionalised publications highlights the impact of authors on research. Some researchers work independently, while others participate in collaborative efforts. Chinese surnames signify significant contributions from Chinese institutions, highlighting the region's pivotal role in emotional computing research. The authors are expected to improve emotion recognition, multimodal artificial intelligence, and human-computer interaction. Table 5 and Figure 6 exhibit the leading affiliations in IEEE Transactions on Affective Computing based on publication count. University of Science and Technology of China (72) and South China University of Technology (68) rank behind Tsinghua University, which has 84 publications. China has made major advancements in the field of emotional computing research, as demonstrated by this position of strength. Lanzhou University (56) and Sun Yat-Sen University (50) further reinforce China's dominance in this domain. In addition to China, the University of Oulu in Finland and Nanyang Technological University in Singapore are notable contributors. The University of New South Wales (34) and Xi'an Jiaotong University (30) possess a notable presence. The presence of Chinese institutions signifies significant governmental and academic investments in artificial intelligence and human-computer interaction research. Contributions from Europe (University of Oulu) and Australia (UNSW) signify a growing worldwide interest in emotional computing. The works that are most frequently cited in IEEE Transactions on Affective Computing are listed in Table 6, which is arranged according to the overall number of citations as well as the number of citations on Google Scholar. It is remarkable that Koelstra *et al*. (2012) has received 3,619 total citations and 5,101 citations on Google Scholar, which is suggestive of the foundational impact it is having on affective computing research during the preceding few years.

Mollahosseini *et al*. (2019) (1,312 citations) and Calvo *et al*. (2010) (1,311 citations) are two additional publications that have received an extensive number of citations. Both of these individuals have made significant advancements in the field of emotion recognition and affective computing. The most significant normalised citation score (20.36) is displayed by Li S (2022), which indicates that they have had a substantial influence in recent times. The works of Eyben (2016) and Soleymani (2012) are of considerable importance, demonstrating consistent citation rates over time. The ranking encompasses both foundational early publications and contemporary impactful studies, illustrating a

fair progression of the discipline. Google Scholar citations typically surpass total citations, indicating extensive academic and industrial impact outside IEEE-indexed publications. The analysis of Table 7 and Figure 7 illustrates the distribution of articles, Single Country Publications (SCP), and Multiple Country Publications (MCP) in IEEE Transactions on Affective Computing according to the countries in which they were published. With 281 articles, including 204 SCPs and 77 MCPs, China is in the lead by a wide margin to its competitors. Based on this dominance, it appears that China is quite active in the field of emotional computing research, and it has a great propensity for cooperation between national organisations.

Nevertheless, it also keeps a decent level of international collaboration, as demonstrated by the fact that it has 77 MCPs working together. Following closely behind with 114 articles, 96 SCPs, and 18 MCPs is the United States of America. Due to the relatively low number of MCPs, it may be deduced that the majority of research conducted in the United States is conducted within the country, with just a little amount of collaboration taking place with other countries. By supplying 55 articles, the United Kingdom demonstrates a balanced approach, with 32 SCPs and 23 MCPs among its contributions. This suggests that there is a combination of national and international relationships that is working well. There are between 31 and 33 articles contributed by Germany, Australia, and France respectively; nevertheless, Germany and Australia have a significantly higher number of MCPs compared to SCPs, which indicates that they have collaborated more than France and Australia. While India, Italy, and Japan each contribute a smaller number of articles overall, India demonstrates a minor tendency towards international partnerships, as evidenced by the addition of eight MCPs. In general, the data reveals that although China is the country that contributes the most to this study field, countries such as the United Kingdom, Germany, and Australia are more collaborative in character. Growing the number of international collaborations could further improve the quality of research and the influence it has on a global scale in this field.

As shown in Table 8 and Figures 8 to 9, the distribution of production and citations in the IEEE Transactions on Affective Computing is broken down by nation. In all categories, China is in the lead, with a total of 1,395 documents and 9,181 citations, which accounts for around forty percent of the total citations. The United States of America and the United Kingdom come in second and third, respectively, with 4,654 and 6,395 citations, despite the fact that the United States has a greater number of papers (734) than the United Kingdom does (310). Despite the fact that their document numbers are far lower, Australia, Germany, and Canada have also made significant contributions, each of which has received more than one thousand citations. Even though they have a lesser number of citations, European countries such as Germany, France, and the Netherlands collectively provide a large share of the research. It is interesting to note that nations such as India and Italy have a lower number of documents, yet their citation counts are quite low. This highlights the possibility that there are constraints placed on the influence of research. Figure 9 is a chart that depicts China's complete domination, followed by the United States of America and the United Kingdom. Based on this distribution, it appears that the output and influence of research are substantially concentrated among a select group of highly influential countries. Figure 10 presents a Sankey diagram depicting the correlation among authors, their respective countries (AU_CO), and their affiliations (AU_UN) in IEEE Transactions on Affective Computing. The left side displays countries, with China as the predominant contributor, succeeded by India, the USA, the UK, Germany, and others.

The core section is comprised of authors, the majority of whom have family names that are commonly used in Chinese, such as Li, Zhang, Wang, and Zhao. A number of universities, the majority of which are Chinese, are displayed on the right side of the page. These universities include the University of Science and Technology of China, Tsinghua University, and Lanzhou University. Throughout the picture, substantial scientific contributions from China are highlighted, with the majority of these contributions coming from authors affiliated with top Chinese universities. The presence of thicker lines indicates a higher frequency of partnership or an increased number of publications. China's pre-eminence in this scientific sector is shown by the fact that contributions from countries other than China are deemed to be insignificant. Additionally, the picture does an excellent job of illustrating notable contributions to the subject matter as well as global research trends. In Figure 11, which is an illustration of the network, a network visualisation of co-authorship ties within IEEE Transactions on Affective Computing is shown.

This representation of the network is displayed. Authors are illustrated as nodes, and the widths of these nodes are proportional to the number of articles they have produced or the amount of influence they have exerted. For the purpose of symbolising the various research clusters or groups that are cooperating with one another, different colours are utilised. Notable people such as Carlos Busso, Bjorn W. Schuller, Maja Pantic, Shangfei Wang, Guoying Zhao, and Yong-Jin Liu are examples of highly significant researchers. In the field of research, these persons are considered to be instances of extremely significant researchers. The visualisation reveals the existence of powerful collaboration networks, particularly among Chinese writers (some examples include Guoying Zhao and Shangfei Wang) and European researchers (some examples include Maja Pantic). When the lines are thicker, it indicates that the co-authorship links are more solid, which suggests that they are regularly collaborated on. Clusters that are smaller and more isolated, on the other hand, are indicative of researchers or research areas that are not as prominent as others. Within the framework, there is a significant emphasis placed on regional linkages, with the most prominent experts in the subject being those from China and Europe.

This visualisation does a fantastic job of identifying key contributors as well as the interrelationships that exist between those contributors themselves. In addition to this, it brings to light a number of widely recognised research organisations and collaborative networks operating within the realm of emotional computing. Table 9 demonstrates that Affective Computing (138 occurrences, 235 link strength) and Emotion Recognition (119 occurrences, 175 link strength) are predominant themes in Transactions on Affective Computing. Techniques such as EEG (46, 99), Deep Learning (44, 75), and Machine Learning (42, 74) are significantly pertinent. The significance of Speech Emotion Recognition and Facial Expression Recognition underscores a robust emphasis on multimodal emotion recognition. Noteworthy emerging methodologies include Transfer Learning and Multi-task Learning. Moreover, fundamental concepts such as Arousal and Valence underscore the significance of psychological and physiological dimensions in the understanding of emotions. Figure 12 depicts keyword visualisation in Transactions on Affective Computing, revealing clusters of total 136 items are come with the filter of minimum 5 keywords of each article occurrence interrelated concepts. Cluster 1-56, cluster 2-51, cluster 3- 20, cluster 4-7 and Cluster 5-2 items all are denoted by different colours. The green cluster emphasises Affective Computing, Machine Learning, and Emotion Recognition, along with other topics such as Stress, Virtual Reality, and Wearable Sensors. The red cluster highlights Deep Learning, Speech Emotion Recognition, Transfer Learning, and EEG. The blue cluster encompasses Psychology, Affect Sensing and Analysis, and Human Emotion Modelling. The yellow region emphasises Arousal, Valence, and Music Emotion Recognition. The visualisation illustrates interdisciplinary linkages, emphasising the necessity of integrating diverse methodologies for effective emotion identification.

CONCLUSION

This study analyses fifteen years of publications from the IEEE Transactions on Affective Computing, as indexed by Scopus, to identify publishing trends, citation patterns, and significant important works. The research utilises several bibliometric and statistical methods to delineate the progression of the journal's publications and its influence in the domain of affective computing. The IEEE Transactions on Affective Computing has established itself as a distinguished journal in the domains of emotion recognition, sentiment analysis, and related fields. Over the years, the publication has consistently acquired high-quality research, positioning itself as an essential resource for scholars and practitioners in affective computing. A comprehensive analysis of the publication framework and citation history reveals fascinating trends. Notably, the year 2023 witnessed the highest volume of publications in the journal's history, with an unparalleled total of 244 papers issued. The surge in papers signifies a growing interest and recognition of emotional computing, as well as the journal's importance as a platform for disseminating research findings. From a citation standpoint, the most significant year was 2012, when the journal achieved a total of 225.39 citations, the highest ever documented. The increased citation count demonstrates the journal's substantial influence on directing research paths and providing essential papers that continue to be cited in subsequent publications. A vital aspect of the analysis involves comparing citation metrics from Scopus and Google Scholar to identify markedly relevant articles. The research conducted by Koelstra *et al*. (2012) is one of the most cited works, garnering 3,619

citations on Scopus and 5,101 citations on Google Scholar. The notable difference in citation counts between the two platforms highlights the paper's broader impact outside traditional academic indexing systems. This bibliometric study indicates that the IEEE Transactions on Affective Computing has experienced significant growth and has had a large impact on the academic community.

The increasing number of publications and heightened citation metrics signify a thriving research field that continually attracts substantial attention. Furthermore, the analysis of highly cited papers provides insights into the foundational research that has shaped the field of emotional computing. This paper presents a comprehensive analysis of the publishing and citation trends of the IEEE Transactions on Affective Computing over the past fifteen years. The findings underscore the journal's importance as an essential resource for academics and demonstrate the lasting impact of foundational works in the domain of emotional computing. This bibliometric assessment provides a historical overview and serves as a crucial reference for forthcoming research endeavours in the field. The IEEE Transactions on Affective Computing has become a prestigious journal in the field of emotion identification, sentiment analysis, and other disciplines. The magazine has continually garnered high-quality research, establishing itself as a cornerstone for academics and practitioners in the field of affective computing. An in-depth examination of the publication framework and citation record uncovers intriguing patterns. In 2023, the journal achieved its highest publishing count in history, with a record 244 papers released. The increase in publications indicates a rising interest and acknowledgement of emotional computing, along with the journal's significance as a venue for sharing research outcomes. From a citation perspective, the most notable year was 2012, when the journal garnered a total of 225.39 citations, the highest recorded to date.

The elevated citation count illustrates the journal's significant impact in guiding research trajectories and offering fundamental studies that are often cited in later works. A crucial element of the analysis is comparing citation metrics from Scopus and Google Scholar to discern notably significant works. The study by Koelstra *et al*. (2012) is one of the most frequently cited publications, receiving 3,619 citations on Scopus and 5,101 citations on Google Scholar. The significant disparity in citation counts between the two platforms underscores the paper's wider influence beyond conventional academic indexing systems. This bibliometric investigation reveals that the IEEE Transactions on Affective Computing has undergone substantial expansion and exerted considerable influence within the scholarly community. The growing volume of papers and elevated citation metrics indicate a flourishing study domain that consistently garners significant interest. The examination of highly cited papers offers insights into the foundational research that has influenced the domain of emotional computing. This report provides a thorough analysis of the publishing and citation trends of the IEEE Transactions on Affective Computing over the last fifteen years. The findings emphasise the journal's significance as a vital resource for scholars and illustrate the enduring influence of seminal papers in the field of emotional computing. This bibliometric evaluation offers a historical perspective and acts as a significant reference for future research initiatives in the discipline

ABSTRACT

Midwifery-led care plays a vital role in ensuring respectful and supportive maternity services that uphold women's dignity, safety, and satisfaction during childbirth. Despite global efforts by the WHO and professional bodies to promote respectful maternity care, many healthcare settings continue to face gaps in knowledge and attitude among staff nurses, which can lead to compromised maternal experiences and outcomes. In Nadiad City, limited evidence exists regarding the awareness and application of supportive maternity care principles among nursing staff. Therefore, this study was undertaken to assess the effectiveness of a midwifery-led intervention on supportive maternity care in terms of knowledge and attitude among staff nurses at selected hospitals in Nadiad City. A pre-experimental one-group pre-test post-test design was adopted for the study. Thirty staff nurses working in the obstetrics and gynecology departments of selected hospitals in Nadiad City were chosen using a non-probability convenient sampling technique. Data were collected using a structured knowledge questionnaire and a 5-point Likert attitude scale before and after administering a nurse-led intervention through a PowerPoint presentation. The intervention focused on universal rights of women and newborns, categories of disrespect and abuse, and supportive maternity care practices. Data were analyzed using descriptive statistics (frequency, percentage, mean, and standard deviation) and inferential statistics (paired t-test, chi-square, and correlation). Findings revealed a marked improvement in both knowledge and attitude following the intervention. In the pre-test, 53.3% of participants had poor

knowledge and 63.3% showed an unfavourable attitude toward supportive maternity care. Post-intervention, 73.3% demonstrated good knowledge and 100% developed a favourable attitude. The mean post-test knowledge and attitude scores were significantly higher than pre-test scores ($p < 0.05$), indicating the effectiveness of the midwifery-led educational intervention. A positive correlation was also observed between knowledge and attitude scores, suggesting that improved understanding leads to better perceptions and practices related to maternity care. The study concluded that the midwifery-led intervention was effective in enhancing staff nurses' knowledge and attitude toward supportive maternity care. Regular educational sessions and continuous professional development programs should be implemented to promote respectful, safe, and patient-centered maternity services, thereby improving the overall quality of maternal healthcare in hospital settings.

Keywords: Midwifery-Led Intervention, Supportive Maternity Care, Knowledge, Attitude, Staff Nurses, Nadiad City.

INTRODUCTION

Pregnancy and childbirth are among the most profound experiences in a woman's life, requiring not only clinical safety but also emotional and psychological support. The concept of Supportive Maternity Care (SMC) or Respectful Maternity Care (RMC) advocates for the protection of women's rights to dignity, privacy, informed choice, and emotional well-being during childbirth. Despite policy emphasis, studies across developing nations, including India, report frequent instances of verbal abuse, neglect, and lack of empathy toward women in labor. Such disrespectful maternity practices violate women's rights and discourage them from seeking institutional deliveries, increasing the risk of maternal morbidity and mortality. Midwives and nurses play a pivotal role in improving maternity care experiences. However, inadequate knowledge and negative attitudes among staff nurses often lead to poor implementation of supportive maternity care principles. Therefore, empowering nurses through midwifery-led education can bring transformative change in maternal health outcomes.

Need of the Study

In India, the need to strengthen RMC is underscored by alarmingly high rates of mistreatment during facility-based childbirth. A systematic review estimated a pooled prevalence of over 70%, with some studies reporting rates as high as 98% [1]. While the WHO and the White Ribbon Alliance have provided frameworks for ensuring dignity and respect in maternity care, implementation remains inconsistent across states. Much of the available evidence is geographically concentrated—especially in Uttar Pradesh—thus failing to capture the socio- cultural diversity of the country. Disrespect and abuse in maternity settings manifest through inadequate information sharing, lack of informed consent, compromised autonomy, and overt physical or verbal mistreatment. Such experiences are associated with adverse outcomes including postpartum haemorrhage, obstetric injuries, and psychological sequelae such as post-traumatic stress disorder. Moreover, these experiences contribute to women's reluctance to seek facility-based care, increasing reliance on unskilled birth attendants and elevating the risk of maternal and neonatal mortality [2]. A recent study conducted at a tertiary care hospital in Bhopal explored the extent to which RMC is practiced and perceived by women during labour and childbirth [3]. By examining patient satisfaction and provider-patient interactions, the study revealed critical insights into communication patterns, emotional support, and the overall quality of maternity care. Such research is vital for identifying gaps in policy execution, enhancing healthcare provider training, and ensuring that every woman experiences a safe and dignified birth.

OBJECTIVES OF THE STUDY

To assess the knowledge regarding supportive maternity care before and after the administration of midwifery led intervention on staff nurses at selected hospital Nadiad city.

- To assess attitude regarding supportive maternity care before and after administration of midwifery led intervention on staff nurses at selected hospital Nadiad city.
- To evaluate effectiveness of intervention on staff nurses at selected hospital Nadiad city.
- To correlate post-test knowledge and attitude score on staff nurses at selected hospital Nadiad city.
- To find association between pretest knowledge and attitude score midwifery led intervention on staff nurse at selected hospital Nadiad city with their selected demographic variables.

Hypothesis

H1: There will be a significant difference in the pre-test and post-test scores of knowledge and attitude regarding supportive maternity care among staff nurses after the midwifery led intervention.

H2: There will be a significant association between the pre-test knowledge and attitude scores with their selected demographic variables of staff nurses.

METHODOLOGY

Research Approach: The approach adopted for this study is Quantitative research approach is used in this study.

Research Design: The research design selected for the study is pre and post test design.

Variables

Independent variable: Nurse led intervention on supportive maternity care

Dependent variable: Knowledge and attitude of the staff nurse regarding the supportive maternity care

Research Setting: study was conducted in selected hospitals in OBD department at Nadiad city at Kheda district.

Target population

- In this study the target population consisted all the staff nurse of OBG department/ward in selected hospital.
- All the staff nurse of OBG department / ward

Sampling Technique: The non probable Convenient sampling technique is used for present study.

Sample Size: Sample size for this study 30 staff nurses of OBG department / wardat Nadiad.

Method of Sampling: Convenient sampling technique was used.

Tools for data collection: structure knowledge questionnaire and attitude scale was used for data collection from the study participants.

Ethical consideration

The present study received ethical approval from the Institutional Ethical Committee of Maganbhai Adenwala Mahagujarat University, Nadiad, under reference number MAM Uni/IECHR/2025/06. The committee consisted of 11 members from diverse professional backgrounds. Prior to data collection, formal written permission was obtained from the institute, hospitals, and each individual participant. Informed consent was secured after explaining the purpose and procedures of the study. To ensure confidentiality and protect participants' identities, all personal information was kept strictly confidential and used solely for research purposes. No names or identifying information were disclosed in any part of the study. During data entry and analysis, coded identifiers were used in place of names to maintain anonymity and data privacy throughout the research process.

RESULT

Frequency and percentage of demographic characteristics of Staff nurses (n=30) (Table No.1)
In terms of age, the majority of staff nurses 12 (40.0%) were in the age group of 36–40 years, followed by 7 (23.3%) each in the 26–30 years and 31–35 years groups, and 4 (13.3%) in the 20–25 years group.

Regarding education status, most staff nurses were GNM qualified 13 (43.3%), followed by ANM 11 (36.7%), and B.Sc. Nursing 6 (20.0%).

In terms of total working experience, the highest number of staff nurses had 5–10 years of experience 13 (43.3%), followed by 3–5 years 8 (26.7%), 1–3 years 6 (20.0%), and less than 1
year 3 (10.0%).

Regarding experience in conducting labor, most of the staff nurses had 2–5 years of experience 18 (60.0%), followed by less than 1 year 7 (23.3%), 5–10 years 4 (13.3%), and only
1 (3.3%) had more than 10 years of experience.

Distributions of Knowledge and attitude Regarding Supportive Maternity Care Before and After the Administration of Midwifery-Led Intervention Among Staff Nurses at a Selected Hospital, Nadiad City" (n=30) (Table: 2)

Findings of Knowledge
In the pretest, majority of the staff nurses 16 (53.3%) had poor knowledge, followed by 10 (33.4%) with average knowledge, and only 4 (13.3%) had good knowledge. In the post test, most of the staff nurses 22 (73.3%) had good knowledge, while 5 (16.7%) had average knowledge, and only 3 (10%) remained with poor knowledge.

Interpretation: The data clearly shows a significant improvement in the knowledge level of staff nurses after receiving the midwifery-led intervention. The number of staff nurses with good knowledge increased substantially from 13.3% to 73.3%, while those with poor knowledge decreased from 53.3% to 10%. This indicates that the midwifery-led intervention was effective in enhancing knowledge regarding supportive maternity care among the staff nurses.

Findings of Attitude
In the pretest, a majority of staff nurses 19 (63.3%) had an unfavourable attitude, 11 (36.7%) had a moderate attitude, and none had a favourable attitude. In the post test, all staff nurses 30 (100%) demonstrated a favourable attitude, and none remained in the moderate or unfavourable categories.

Interpretation
The findings clearly show a remarkable shift in attitude among staff nurses following the midwifery-led intervention. Before the intervention, none of the staff nurses showed a favourable attitude, while after the intervention, 100% developed a favourable attitude. This suggests that the midwifery-led intervention was highly effective in improving the attitude of staff nurses regarding supportive maternity care.

Graph
Graph 1: Pretest-post test knowledge and Attitude mean % Enhancement score
Table: Pretest-Posttest Knowledge and Attitude Comparison Among Staff Nurses Regarding Supportive Maternity Care" (n=30)
Table 3 Shows the comparison of pretest and post test scores for knowledge and attitude using paired t-tests. There was a significant increase in the mean knowledge score from 7.73 (SD = 2.80) to 11.93 (SD = 2.29), with a mean

difference of 4.20 and a statistically significant t-value of 8.57 (p = 0.000). Similarly, the mean attitude score improved from 23.57 (SD = 2.76) to 42.60 (SD = 2.39), with a substantial mean difference of 19.03 and a t-value of 34.35 (p = 0.000), indicating a highly significant improvement. The results confirm the effectiveness of the intervention in enhancing both knowledge and attitude. Both knowledge and attitude showed statistically significant improvements after the midwifery-led intervention. This demonstrates the effectiveness of the intervention in enhancing staff nurses' understanding and positive outlook toward providing supportive maternity care.

Association

The association between the pretest level of attitude and selected demographic variables among staff nurses, using the Chi-square test. The findings indicate that the majority of staff nurses (40%) were in the age group of 36–40 years, followed by 23.3% each in the 26–30 and 31– 35year age groups. Regarding education, most staff nurses were GNM qualified (43.3%), followed by ANMs (36.7%) and B.Sc. Nursing graduates (20%). In terms of total working experience, 43.3% had 5–10 years of experience, while 26.7% had 3–5 years. Most nurses (60%) had 2–5 years of labor room experience. However, the Chi-square values and corresponding p-values for all variables (age, education status, total working experience, and labor room experience) were statistically non-significant (p > 0.05), indicating that there was no significant association between the pretest level of attitude and the selected demographic variables.

DISCUSSION

The study revealed a significant improvement in both knowledge and attitude following the midwifery-led intervention. These findings align with similar studies conducted by Kaur *et al*. (2023) and Kumar *et al*. (2021), who reported that educational interventions effectively enhanced nurses' understanding and implementation of respectful maternity care practices. The results underscore the importance of structured, context-specific training in developing supportive maternity environments. The strong correlation between knowledge and attitude suggests that knowledge empowerment directly influences positive behavioral change among nursing professionals. The study's implications extend to policy and practice, suggesting that integrating respectful maternity care modules into continuous nursing education can strengthen patient-centered care and reduce maternal anxiety, fear, and mistrust in healthcare institutions.

CONCLUSION

The midwifery-led educational intervention was effective in significantly improving the knowledge and attitude of staff nurses toward supportive maternity care. Empowering nurses through ongoing training and supervision can promote a culture of respect, empathy, and patient-centeredness in maternity units.

RECOMMENDATION

1. Incorporate respectful maternity care (RMC) modules in hospital orientation and in-service programs
2. Conduct periodic refresher workshops for staff nurses on RMC practices.
3. Implement policy-level changes ensuring accountability and monitoring of RMC standards.
4. Encourage replication of similar studies in different regions to generalize findings.

ABSTRACT

Gels are dynamic semi-solid structures having significant pharmacological and biological applications due to their unique structural and functional properties. By forming a three-dimensional cross-linked network, gels which can be formed of natural or synthetic polymers immobilize liquid media. This leads to better patient compliance, targeted drug administration, and less systemic adverse effects. This study focuses on the development, classification, and properties of gels, with particular attention to topical formulations that enhance drug absorption, prevent hepatic first-pass metabolism, and lessen gastrointestinal irritation. Screening aspects such drug content, extrudability, spreadability, viscosity, and skin irritation studies are discussed in detail. Recent advancements in gel based drug delivery, such as in situ gelling systems and smart gels that respond to pH, temperature, and external stimuli, are being studied for possible uses in minimally invasive and sustained release therapies. Innovative methods that

demonstrate enhanced stability and bioavailability include liposomal gels, phytosomal gels, and microemulsion based organogels. In the future, patient-specific, biodegradable, and intelligent gel systems for regenerative therapies and tailored medicine will be incorporated. tissue engineering and nanotechnology. All things considered, gels constitute a cornerstone of current drug delivery research with continuous developments extending their potential in medicine and industry.

Keywords: Gel, Polymer, Nanotechnology, *in situ* gel, Phytosomal Gel, Liposomal Gel

INTRODUCTION

The Latin words "Gelu," which means "frost," and "gel are," which means "freeze" or "congeal," are the origin of the word "gel" and "jelly," while "gel" itself is derived from the word "gelatin." This source provides an example of the basic idea that a liquid will solidify into a solid-like material that is elastic and retains certain liquid characteristics but does not flow. The word "gel" was initially employed as a classification in the late 1800s when researchers attempted to classify semisolid materials according to their phenomenological characteristics rather than their chemical composition. At the time the analytical methods needed to determine chemical structures were unavailable(1). Topical gels are used to treat and cure topical ailments. They are a homogenous, semi-solid combination Gels' greater hydrophilia allowed for the rapid release of the drug or active component. A gel is made up of two parts. It is a three-dimensional cross-linked substance that has a proportionately large volume of liquid medium to create a stiff network that immobilizes the liquid phase without interruption. The gel's structural network is made up of both inorganic particles and organic macromolecules (2-4). Topical formulation decreases gastrointestinal pain, boosts the medicine's bioavailability, and prevents the drug from being metabolized in the liver. Topical medications function exactly where they should. The primary category of semi-solid preparations has seen an increase in the usage of topical gels in pharmaceutical and cosmetic formulations (5-9). Topical delivery techniques have several advantages over parenteral and oral approaches, such as lowering systemic side effects, preventing first-pass metabolism, and improving patient compliance. A practical drug delivery option among the several topical preparations is gels (10-13). More patient compliance, constant drug delivery, fewer side effects, and avoidance of the hepatic first pass impact are only a few benefits of the topical/transdermal (TT) route over other drug administration methods (14, 15).

Gels are defined by the U.S.P. as a semisolid structure with a dispersion of big organic molecules or small inorganic particles that are encircled and penetrated by a liquid medium. Large organic molecules dissolve in the continuous phase to create flexible, randomly coiled chains, while inorganic particles remain scattered throughout the continuous phase without dissolving (16 -19). Among the many benefits of topical drug delivery are the removal of the hazards and drawbacks connected with injectable techniques, as well as the flexibility in physiological conditions like pH variations, absorption rates, gastric emptying time, and enzyme presence. Common illnesses like psoriasis have symptoms that are intended to restrict the medication's pharmacological effects or subsequent results to the skin's outermost layers or visible surface (20-23). The potential uses of *in-situ* formed hydrogels in the biomedical industry have recently drawn attention. It is possible to combine pharmaceutical compounds or cells into an aqueous solution (sol) and then inject it into a specific location, where it will undergo a sol-to-gel transition to form a hydrogel depot. Without requiring intricate fabrication procedures or surgical procedures, this method provides a simple insertion methodology. The potential of these *in-situ* produced gels has been investigated in several biomedical applications, encompassing as minimally Invading drug administration, three-dimensional cell culture, injectable tissue engineering, tissue sealants, surgical adhesives, and adhesion- avoidance coatings. For a hydrogel to form *in-situ*, a quick process for creating crosslinks that firmly hold the highly hydrated polymeric system in place within a significant amount of water is required. It is crucial to choose a biologically acceptable technique for the crosslinking process when assessing biomedical applications (24-27).

Gel Properties

An inert, safe gelling agent that does not react with other formulation ingredients is appropriate for use in pharmaceutical or cosmetic applications. The gelling agent used for the preparation needs to produce a solid enough consistency for storage, but shear forces from shaking the container, squeezing the tube, or applying topically can easily break it.

1. To prevent microbiological contamination, it should also have the right antibacterial qualities. In addition, the topical gel should not feel tacky (16-19).
2. The fact that gels are frequently categorized as soft solids is an additional mechanical characteristic. When assessing solid properties using a stress-strain relationship, the modulus—the ratio of stress to strain—is generally modest, ranging from a fraction of a pascal to several thousand pascals. However, tougher gels can be made.
3. The ability to deform is another important mechanical property of gels. These materials typically behave like solids over a wide range of strain without breaking, which is why they occasionally exhibit what is known as "rubber elasticity." Not all gels are elastic, though; some have a plastic response rather than a rubber-elastic one, and can be brittle (like agar gels) (28).
4. Polymeric gels have a lot of unique characteristics. Other notable characteristics of these gels include the mechanoelectric effect, swelling, syneresis, aging, electrostatic potential distribution, electrical oscillation, electrical contraction, swelling, pseudoplastic (non-Newtonian) rheological behavior, and interactions with oppositely charged surfactants. Above all, these gels exhibit stimuli-responsive behavior in response to external stimuli such electric fields, temperature, pressure, and pH. Therefore, in reaction to their external environment, polymeric gel systems can usually generate force or perform functions (29).

Gel Structure

The solid compositions of inorganic gels made from molecular precursors are typically less than10 vol%. Research on a particular kind of silica gel shows that pH. a gel with 5 vol% solids (30,31), these gels exhibit fractal properties at length scales below about 25 nm. Transmission electron microscopy on supercritically dried gels confirmed the discovery that these gels' networks are mesoporous, as indicated by their noticeably low permeability, which will be covered in more detail (32, 33). The silica gel networks are made up of nodes where three or four chains converge, as shown by the transmission electron microscopy photos. The distance between these nodes is several times larger than the chain thickness. Compared to organic gels, which usually have polymeric coils dotted between the nodes (34), inorganic gels are substantially stiffer due to this structural configuration. Entropic variables impact the elastic characteristics of organic gels, permitting significant volume fluctuations (35). On the other hand, when temperature, solvent, voltage, and other external variables change, inorganic gels show no change in volume. The fact that a sizable portion of the atoms—roughly half for a surface area of 500 m^2/g—are exposed at the surface is a crucial consequence of these gels' large surface area. Therefore, significant compositional changes may result from reactions that take place near the interface (36). It is possible to create inorganic gels, either single- or multi-component, with almost all the periodic table's elements. The gel network is usually composed of an amorphous hydrous oxide. Although some elements, such as zirconium, titanium, and silicon, easily form three-dimensional networks, the majority do not. Alumina gels are typically made up of chains of nanometer-sized particles that resemble AlOOH. This is a common tendency of many oxides to produce tiny particles that group together to form networks. However, the layered structure of tungsten oxide gels, which includes intercalated water, allows them to absorb and release water in a manner akin to that of calcium silicate hydrate (C-S-H) (37).

Classification of Gels

Depending on the type of solvent

Aqueous gels (hydrogels) and Water as a dispersion medium for gels made of gelatin, agarose, and polyvinyl alcohol

Non-aqueous gels, such as Xerogels or Organogels

Petroleum-based gels and lecithin gels are examples of organic solvents used as a medium.

Depending on the kind of network structure

Physical Gels held in place by non-covalent interactions (van der Waals, H-bonds, etc.). Agar and gelatin are examples of thermo-reversible Chemical Gels Networks of polymers cross-linked by covalent bonds. Epoxy resins and polyacrylamide gels are examples of thermo-irreversible items.

Using Smart Gels, which are responsive

Smart (stimuli-responsive) gels React to outside stimuli like
Temperature, such as PNIPAM hydrogels
pH—for instance, polyacrylic acid gels
Electrical and magnetic fields, such as ferrogel
Light: azobenzene-functionalized gels, for instance Non-Reactive Gels Lack of reaction to environmental changes

According to Origin

Made from natural polymers, such as agar, gelatin, and alginate, natural gels
Synthetic Gels Artificial polymers, such as polyacrylamide and poloxamer. (38)

Assessment Methods for Gels

Clarity

The following rating system is used to evaluate the formulation's clarity visually against both black and white backgrounds: +, ++, and +++ for turbid, clear, and very clear (glassy).

pH measurement

A digital pH meter is used to measure the pH levels of different gel compositions. 100 milliliters of distilled water is used to dissolve one gram of gel, which is then left to stand for two hours. Three separate pH readings were taken for each formulation, and the average results are computed.

Drug Content

A suitable solvent (100 ml) is mixed with one gram of the produced gel. After filtering the stock solution, appropriate dilutions are used to make aliquots of different concentrations, and absorbance is measured. Using an equation obtained from the calibration curve's linear regression analysis, the drug content is ascertained.

Viscosity Evaluation

Using a Brookfield viscometer, the prepared gel's viscosity is determined. The rotational speeds of the gels were 0.3, 0.6, and 1.5 revolutions per minute. Every speed is recorded along with the matching dial readings. By increasing the dial reading by the factor listed in the Brookfield Viscometer catalog, the viscosity can be determined.

Spreadability

This characteristic indicates the extent to which the gel spreads when applied to the skin or another area that is impacted. The medical effectiveness of a composition is also influenced by spreadability. By timing the amount of time, in seconds, it takes for two slides to separate from the gel between them under a specific force, spreadability can be determined. An indication of better spreadability is a shorter separation time (39). In this case, S represents spreadability, M represents weight on the top slide, L represents distance on the glass slide, and T represents time required for the slides to fully separate.

Evaluation of Extrudability

Collapsible tubes are used to hold the formulations until the gels had solidified inside the container. Each formulation is evaluated for extrudability by determining the weight in grams needed to extrude a 0.5 cm gel ribbon in 10 seconds.

Evaluation of Homogeneity : Following gel setting, each formulation is visually inspected to determine its homogeneity. This required looking at their appearance and determining whether any aggregates are present.

Evaluation of grittiness: Every formulation is inspected under a light microscope to look for any notable particle debris. The gel preparation satisfies the requirements for being free of grittiness and particle debris, which are crucial for any topical treatment.

Skin Irritation Assessment: For the skin irritation investigation, 400–500 gram guinea pigs of both sexes are used. Ordinary animal feed and unlimited available to water can be given to the animals, they will be kept carefully and monitored surroundings. The guinea pigs' back fur is shaved, and a 4 cm^2 section is marked on each side; the test site is on one side and the control is on the other. For seven days, a gel dose (formulation specific) is administered twice daily on guinea pig, and the application site should be watched for any indications of sensitivity. If any reactions are seen, they must be rated from 0 to 3, which means that there is no reaction, that there is mild patchy erythema, that there is slight but confluent or moderate patchy erythema, or that there is harsh erythema with or without edema.

Studies of *in vitro* diffusion

Research on in vitro diffusion release of the generated gels across a cellophane membrane can be investigated in vitro using a Franz diffusion cell. A gel sample weighing 0.5g in the cellophane membrane and 250 ml of phosphate buffer (pH 7.4) as the diffusion media must be used for the diffusion experiments. A constant temperature of 37 ± 1° C must be maintained. Each sample should be periodically extracted in five milliliters at intervals of one, two, three, four, five, six, seven, and eight hours to get best result assessment of polymer-controlled release efficiency in prepared gels. Each withdrawn sample is replaced with fresh dissolving medium (16).

Current Developments and New Applications for Topical Gels

Instead of contrasting prepared liposomal gels with liquid state liposomes, other researchers have assessed liposomal gels' efficacy by contrasting them with traditional gels or creams that include the free drug. Their findings demonstrated that whereas liposomal gels did not enhance systemic absorption, they did increase pharmaceutical retention in the skin. The outcomes of these investigations were solely attributed to the liposome effect, which is known to allow for targeted and controlled drug administration when applied topically, ignoring the influence of the gel matrix.

The categorization of liposomal gel.

Traditional liposomal hydrogels

Differentiated liposomal gels

- Transferosomal Gels
- Gels with an ethosomal
- Proliposomal Gels
- Phytosomal gels
- Gels made of vesicular phospholipid (VPG)
- M-i-L (microgel in liposomes)

Gels with Lecithin Microemulsion

- Microemulsion-Based Organogels Based on Lecithin (LMBGs)
- PLOs (Pluronic Lecithin Organogels)
- Hydrogels Based on Microemulsions Stabilized by Lecithin

A very creative and successful delivery method is liposomes. The biosimilar structures of these systems, which have advantageous properties, are a major advantage. It is possible to incorporate both lipophilic and hydrophilic medicinal drugs due to their amphiphilic properties. These carriers enable focused localization and site-specific release and are non-toxic and biodegradable. They can pass through a variety of biological obstacles that are usually difficult for traditional systems to do. However, rheological constraints frequently limit the utilization of liposomes

in topical products. The conventional method of lipid film hydration is traditionally used to create liposomes; however, solvent injection and the French pressure cell methods are also viable alternatives. By adding a gelling chemical to the aqueous phase, liposomes can be integrated into a gel system. Because of this, several gelling agents, such as carbopol, xanthan gum, poloxamers, gellan gum, and polyvinyl alcohol, have been researched.

Traditional liposomal hydrogels can be made by either adding gelling agents straight into liposome dispersions without the need for drug separation or by integrating pre-formed liposomes into a suitable gel matrix after any unentrapped drug has been removed. The latter strategy streamlines the method by doing away with intricate separation steps and reducing drug loss, giving the device a remarkably high encapsulation efficiency.

Modified liposomal gels have lately been demonstrated to be ineffective as transdermal delivery vehicles since traditional liposomes do not thoroughly enter the skin. According to research, they typically stay on the stratum corneum's outermost layers. It has been shown using confocal microscopy that unbroken liposomes cannot penetrate the granular layers of the epidermis. Additionally, problems including aggregation, fusion, leakage, or hydrolysis of the encapsulated medications may result in a limited shelf life for aqueous dispersions of these vesicular systems. The discovery of vesicles with enhanced properties that enable them to more effectively transport drugs to deeper layers of the skin (such as ethosomes and transfersomes) and to boost the vesicles' stability has been a significant advancement in vesicle research. (like pro-vesicles and phytosomes).

Gels Based on Transferosomes

An active substance is contained in transferosomes, which are extremely flexible hydrophilic lipid vesicles that are applied topically in an aqueous formulation. Phospholipids make up these vesicles, together with an edge activator, usually a single-chain surfactant with a large radius of curvature. The vesicles' lipid bilayers are broken down by edge activators, increasing their deformability and flexibility and allowing them to flow through the stratum corneum's pores (40-43).

Ethosomal Gels

Phospholipids make up ethersomes, which are soft lipid vesicles with a comparatively high alcohol (ethanol and isopropyl alcohol) content (20–45%) and water. The main reason for ethosomes' increased skin permeability is their higher ethanol concentration. The lipids in the ethosomes and the stratum corneum bilayer are thought to be fluidized by ethanol, which is acknowledged as an efficient permeability enhancer. These pliable, squishy vesicles can more easily pass through the lipid bilayer's disarray because to this fluidization. Studies have demonstrated that after treatments lasting 12, 24, and 48 hours, ethosomes do not irritate skin despite their high alcohol content.

Proliposomes Gels

Vesicular systems' inadequate stability is the main obstacle to their development for industrial and therapeutic applications. Proliposomes offer a versatile delivery system that improves stability and makes large-scale sterilizing easier. This technique has been applied to deformable liposomes as well as liposomes and niosomes to increase their stability. Traditional liposome production methods are combined with a water-soluble carrier to make proliposomal formulations, which turn the system into a dry, freely-flowing powder. By adding this dry powder to a suitable structural medium, it can subsequently be transformed into a gel. A prednisolone proliposomal gel was created recently, and its effectiveness as a topical medication for rheumatoid arthritis was evaluated. The results demonstrated the promise of the developed proliposomal gel for the successful treatment of rheumatoid arthritis by showing improved anti-inflammatory effects and prolonged drug release.

Phytosomal Gels

Phytosomal gels Flavonoids, glycosides, and phenolics are among the chemicals that make up the majority of phytoconstituents that dissolve in water. Their effectiveness is lowered as a result of their poor absorption when administered topically or consumed orally (44, 45). It was shown that these botanicals' bioavailability was greatly enhanced by complexing them with phospholipids, which led to improved and faster skin absorption.

Gels of Vesicular Phospholipids (VPG)

According to Brandl *et al*., vesicles or liposomes make up the lipid phase of vesicular phospholipid gels (VPGs), which are semisolid aqueous dispersions of phospholipids (46, 47). Whereas liposome hydrogels produce their gel structure by including hydrophilic polymers into the liposomal dispersion, VPGs obtain their gel-like consistency by densely packing vesicles.

M-i-L (Microgel in Liposomes)

This innovative technology is the most recent advancement in liposomal gels and has not yet been applied to the topical administration of medications. Hydrogel-supported lipid bilayers, gel core liposomes, lipobeads, liposome-nanogel assemblies, and microgel in liposomes (M-i-L) are some of the names used in the literature to describe this kind of liposomal gel. The core of the phospholipid bilayer vesicle that constitutes M-i-L is a hydrogel polymer. This design mimics natural cells and leverages the benefits of both features. Additionally, the polymer network inside the inner microgel reduces the likelihood of rapid breakdown and early drug release in the body by fortifying the lipid bilayer.

Gels using Lecithin Microemulsion

Lecithin microemulsion gels fall into one of two main categories based on their matrix structure.

Microemulsion-Based Organogels Based on Lecithin (LMBGs)

It is said that phospholipid-based LMBGs are transparent, viscoelastic, biocompatible, thermodynamically stable, and isotropic. In 1988, Scartazzini and Luisi released the first study on gel-structured water-in-oil microemulsions while examining the optimal conditions for soy lecithin to form reverse micelles. They noticed that organic soy lecithin solutions became noticeably more viscous when small amounts of water were added. In nonpolar environments, the naturally occurring surfactant lecithin can form backward micelle-based microemulsions thanks to its geometric properties. When given enough water, these microscopic reverse micelles can expand monodimensionally into elongated, flexible, cylindrical large micelles more than a critical concentration of lecithin. This gives the substance a gel or jelly-like consistency as the massive micelles create a continuous network that encloses the organic phase outside.

PLOs, or pluronic lecithin organogels

When significant amounts of high-purity lecithin are needed, obtaining it can be expensive and difficult. Because of their efficacy as cosurfactants and stabilizers, some study has investigated the addition of synthetic polymers, like pluronics, to lecithin-based microemulsion-based gels (LMBGs). By including pluronics as cosurfactants, these studies showed that organogelling may be accomplished with lecithin of lesser purity. A class of non-ionic block copolymers known as pluronics—also called poloxamers, poloxamer polyols, or lutrols—are made up of ethylene and propylene oxide. LMBGs containing pluronics are frequently referred to as pluronic organogels, poloxamer organogels, or pluronic lecithin organogels (PLOs).

Hydrogels Stabilized by Lecithin Microemulsions

The conversion of oil-in-water microemulsions into gels has recently improved their potential for cutaneous applications. This change was achieved by adding different hydrogel matrices or water-soluble polymers, including carrageenan, gelatin, carbomer 934, and carbopol. Only the water phase on the outside was gelled or thickened during this process; the inside microemulsion droplets stayed liquid. In general, lecithin-stabilized microemulsion-based hydrogels are water-continuous microemulsions in which lecithin acts as a surfactant to maintain system stability. These microemulsions are subsequently transformed into a gel state by use of one of the hydrogel matrices outlined earlier (39).

***In-Situ* gelling systems in Novel Drug Delivery System**

Over the past decade, in-situ gelling systems for intravenous, buccal, vaginal, ocular, and nasal delivery have been developed. Drug delivery techniques that use *in-situ* gelling have garnered a lot of attention in the last ten years

some of examples of various *in-situ* gelling system which was shown in Table No 1. A variety of endogenous triggers, including variations in pH, temperature, or the presence of ions, can cause these systems, which are in a sol-state prior to delivery, to convert into gels. They can be administered in several ways to aid in the local or systemic transportation of medications, and they are effective transporters of drug-loaded microparticles and nanoparticles. A variety of *in-situ* gelling natural, synthetic, and/or semi-synthetic polymers can be used alone or in combination to create these systems. Particularly helpful for extending the residence duration at the site of action or absorption are mucoadhesive polymers. *in-situ* gelling systems can also incorporate solid polymeric formulations, often produced by freeze-drying, that rapidly hydrate when exposed to biological fluids. Drug release can be controlled thanks to this gel formation (48).

Hydrogels

The 3-dimensional network of polymer chains sprinkled with water that fills the spaces left by macromolecules is what modern definitions of hydrogels define as systems consisting of two or more constituents. The amount of water stored in these structures at equilibrium may vary significantly depending on the specifics of the polymer or polymers utilized, as well as the type and density of the network connections. Hydrogels typically display a mass fraction of water significantly greater than that of the polymer when they are swelled. It is standard procedure to use synthetic polymers that are soluble in water when not cross-linked to produce significant swelling. There are numerous "classical" chemical methods for making hydrogels. Multi-step processes that involve the synthesis of reactive polymer molecules and their subsequent cross-linking—which may also involve reactions with appropriate cross-linking agents—are among these techniques, as are one-step processes like polymerization and the simultaneous cross-linking of multifunctional monomers. Polymer engineers may accurately control structural features like cross-linking density at the molecular level when designing and building polymer networks, in addition to tailoring properties like mechanical strength, biodegradability, and reactivity to chemical and biological stimuli(49-53).

Newly released research on exciting gel-based delivery systems.

In recent years, innovative drug delivery methods have demonstrated remarkable success in delivering medicinal chemicals with targeted and localized effects which is mentioned in Table 2. Furthermore, these technologies allow for controlled drug release at preset rates while minimizing negative effects. Gels are three-dimensional, semi-solid structures composed of polymeric matrices. They function similarly to solid systems, although having a higher proportion of liquid components than solid dispersions (54-56). In a variety of industries, including as biotechnology, food, medicine, and cosmetics, innovative gel systems have useful uses. The efficient release of medicinal compounds is made possible by the simple formulation of a gel-based delivery system. Furthermore, by ensuring that the therapeutic substance and the absorption site have intimate surface contact, these devices improve the delivery of molecules via a variety of pathways. In the past decade, scientists have made substantial progress in their comprehension of gel-based drug delivery methods. New gel-based systems that can initiate drug release in response to particular biological or environmental stimuli, including temperature, pH levels, enzymes, ultrasound, and antigens, have been made possible by these advancements (57-62).

A Thorough Examination Based on Submitted Patents

The world intellectual property organization (WIPO) oversees the Patent Cooperation Treaty (PCT), a global patent filing system that processes international patent applications pertaining to hydrogels. By emphasizing the inventions and patents pertaining to hydrogels, this study particularly describes as follows (63). The following Table 3 shows overall collective information about reported patents in this arena.

Prospects for Gel Applications in Biomedicine in the Future

Gel-based systems' prospects in biological domains is promising and continues to evolve with advancements in material science, nanotechnology, and biomedical engineering. Key future directions include:

Personalized Medicine: Development of stimuli-responsive gels that can be tailored to patient-specific conditions and genetic profiles for targeted drug delivery and regenerative therapies.

Smart Gels: Integration of sensors and actuators within gels to create "smart" systems capable of real-time response to physiological signals, useful in wound healing and chronic disease monitoring.

Tissue Engineering: Further enhancement of gels as scaffolds for tissue engineering, particularly for complex organs. The use of 3D printing with gel matrices opens avenues for organ regeneration and repair.

Minimally Invasive Therapies: Injectable and *in-situ* forming gels that solidify under physiological conditions offer less invasive therapeutic options and are likely to see greater clinical adoption.

Combination Therapies: Gels are anticipated to be essential in combinational delivery of therapeutics (e.g., drugs, genes, proteins) and diagnostics (theranostics), leading to improved efficacy and reduced side effects.

Biodegradability and Biocompatibility: Continued research on improving the biodegradability and biocompatibility of gel materials, especially for long-term implants and drug delivery systems.

CONCLUSION

Gels have become a highly adaptable class of materials with enormous promise for use in a wide range of biological applications. Due to their tunable physical, chemical, and biological properties. From methods for delivering drugs to tissue engineering scaffolds and wound dressings, their adaptability and functionality have positioned them as a cornerstone of modern biomedical innovations. As interdisciplinary research expands, integrating material science with biology and engineering, gels are poised to revolutionize personalized medicine, minimally invasive procedures, and regenerative therapies. Continued innovation, rigorous clinical evaluation, and regulatory alignment will be crucial for translating these promising materials from the laboratory to real-world medical applications.

ACKNOWLEDGMENT

The authors would like to express their gratitude to Dr. A P Basavarajappa, Director, Bapuji Pharmacy College for providing all the support required for the outcome of the paper.

Table 1: Example of Various In situ Gelling System

Route	Pathology	API	Polymer/s	Key Findings	References
Ocular	Glaucoma	Pilocarpine	Gelatin-graft-poly(N-isopropylacrylamide) (GN) copolymer	Demonstrated prolonged intracameral high drug concentration in an animal model	41,42
Nasal	Allergic rhinitis	Mometasone furoate (MF)	Gellan gum	proved to be more effective in an animal model than nasal medication suspension.	43,47
Buccal	Oral mucositis	Benzydamine hydrochloride	trimethyl chitosan (TMC) and glycerophosphate (GP)	promote extended drug release and enhance	48,49

				resistance to physiological clearance processes, as shown in both ex vivo and in vitro investigations.	
GIT	inflammatory diseases	Budesonide (BUD)	Poloxamer F-127	The formulation demonstrated the ability to alleviate inflammatory damage in the intestinal mucosa (animal model)	50
Vaginal	Vaginosis	Metronidazole	Thiolated gellan gum (GG) through conjugation with 2-(2-Amino ethyldisulfanyl) nicotinic acid (AMENA)	increased mucosal surface adherence; notable antibacterial activity; and prolonged metronidazole release	51
Intravesical	Bladder cancer	Deguenil (D)	Drug-loaded N-[1-(2,3dioleoyloxy)propyl]N,N,Ntrimethylammonium methyl sulfate (DOTAP) and monomethoxyl poly(ethylene glycol)-poly(ε-caprolactone) nanoparticles incorporated in Pluronic F127	extended duration of drug residence; high drug concentration in the bladder (animal model)	52

Table 2: recently published studies on innovative systems for gel-based delivery.

kinds of Hydrogels	Constituency (polymers)	Active Pharmaceutical Ingredient	Disease	References
Thermo-responsive Hydrogel	7-ethyl-10 hydroxycamptothecin (SN-38) liposomal hydrogel	SN-38	Hepatocellular carcinoma	55
Photosensitive hydrogels	azobenzene and α-cyclodextrin-modified hyaluronic acid combined with gold nanobipyramids	doxorubicin (DOX)	human epidermal keratinocytes	56
pH-responsive hydrogels	poly(acrylic acid) hydrogel complexed with stabilized amorphous calcium carbonate	DOX	hepatocarcinoma	57
Redox-stimuli Hydrogels	dextrin nanogel	DOX	Breast Cancer	58
Magnetism-Responsive Hydrogels	Ferromagnetic vortex-domain iron oxide, chitosan, and poly(ethylene glycol)	DOX	Breast Cancer	59
Proniosomal Gel	Surfactant, Lecithin, and Cholesterol	Curcumin	Ocular Inflammation	60
Liposomal Gel	Cholesterol, Carbopol 934	Travoprost	Glaucoma and Ocular Hypertension	61
Injectable Hydrogel	Horseradish Peroxidase (HRP), H2O,Chitosan, Hyaluronic Acid (HA),	Dextrane, Tyramine	Cartilage Tissue Regeneration	62
Shear-sensitive hydrogels	hyaluronic acid, aldehyde groups, amino groups, HSPC lipid	celecoxib	reduce cartilage damage and inflammation caused by shear stress	63

Table 3: The patents pertaining to hydrogels.

IPC Code	Definition	Description	Patent Documents
C08J3/075	Macromolecular gels produced through processes in aqueous environments	This category includes patents related to the creation and processing of macromolecular gels, such as hydrogels, utilizing aqueous solutions, with a focus on advancements in gel formation techniques.	8865
A61L27/52	Hydrogels or hydrocolloids utilized in prosthetics or for coating prosthetic devices	This classification emphasizes innovations in hydrogels or hydrocolloids intended for medical devices and prosthetic coatings, highlighting their biocompatibility and essential characteristics for medical use.	8109
A61K9/00	Pharmaceutical formulations distinguished by their unique physical forms	This section pertains to pharmaceutical products where the physical form (such as tablets, gels, capsules, patches, etc.) plays a vital role in enhancing drug delivery, absorption, or administration.	6789
A61K9/06	Ointments and bases for ointments, including the equipment for their production	This category focuses on ointments as a form of medicinal preparation, encompassing formulation bases and the tools or methods employed in the production of topical drug delivery systems.	5561

G02C7/04	Optical components fabricated from organic materials, including plastics	This classification addresses optical components, such as lenses and prisms, made from organic materials like plastic, which are particularly significant for contact lenses and lightweight, durable optical instruments.	3942
A61K47/36	Medicinal preparations involving polysaccharides or their derivatives	This section emphasizes advancements in drug delivery mechanisms, wound care solutions, or tissue engineering that utilize polysaccharides such as gums, alginate, hyaluronic acid, or chitosan.	3865
C08J3/24	Crosslinking of macromolecules	This classification addresses the crosslinking of macromolecules, concentrating on the mechanical properties and crosslinking agents that improve material strength, elasticity, and thermal stability, frequently applied in hydrogels and vulcanization processes.	3639
A61L27/54	Biologically active materials used in medical or prosthetic applications	This area encompasses materials engineered for biological interaction in fields such as regenerative medicine, wound healing, or medical devices, often utilizing hydrogels or biocompatible polymers for the delivery of therapeutic substances.	3575
A6L26/00	Chemical aspects or materials used for liquid bandages	This category focuses on innovations concerning the chemical formulation and application of liquid bandages for effective wound care and protection.	2943

ABSTRACT

Vaccination is an effective way of fighting against infectious diseases. Governments have prioritized high-risk groups for receiving the initial batch of COVID-19 vaccines due to the limited availability of vaccines worldwide. Side effects may occur, which are common symptoms of the body's immune response. There is no significant evidence to suggest that any vaccine, including the COVID-19 vaccine, would cause severe adverse effects leading to long-term health issues. A non-experimental designed was applied for this descriptive study. As sample total double of hundred staff nurses was selected with the help of convenient nonprobability technique. Twenty-seven closed-ended questionnaires (dichotomous questions) were used for data collection.Data collection was done through face to face interaction. The data was analysed as per the objectives of study. The level of side effects of the COVID-19 vaccine among 200 staff nurses shows that 188 of them experienced mild side effects, 12 experienced moderate effects, and none of the participants had serious adverse effects from the COVID-19 vaccination. Overall, the majority of staff nurses experienced mild side effects. There were significant demographic variables associated with qualification (χ^2 = 19.125) and working experience (χ^2 = 13.097). According to this study, COVID-19 vaccinated nursing staff did not experience severe side effects. The majority of participants (94%) experienced mild side effects, while 6% reported moderate side effects from the COVID-19 vaccine.

Keywords: COVID-19, Vaccine,Staff nurse, Side effects.

INTRODUCTION

In 27 January 2020, the earliest COVID-19 instance was reported and from the March 2020 a nationwide lockdown was announced in the India. Near about one lakh cases of covid-19 was recorded by May 18, 2020. India government has commenced the vaccination drive from 16 January 2021 in all over country. In first step the vaccination drive focusing on health care workers. After emerging in China in a city named Wuhan, in November2019, the novel coronavirus illness (COVID-19) was deemed a worldwide pandemic in March month of 2020. The government has put in place a set of protocols and steps to assist stem the growth of COVID-19, which includes the social isolation, to use masks properly on nose, travel bans, lockdowns and regular hand washing with soap and water or sanitizer. Researchers and pharmaceutical companies have created safe and efficient vaccines to further curb the development of the disease and the deaths it causes. Health care professionals, elderly people, particularly those are having long-term co-morbid diseases, those who work in necessary services all are consider in high-risk populations. Due to contact with persons who may be exposed to COVID-19 such as healthcare providers, visitors and also close contact with COVID-19sufferers and their bodily secretions, staff nurses are at a significant risk of spreading the disease. [1,15]

In response to COVID-19 exposure, the COVID-19 vaccine protests. It may be challenging to perform daily duties while experiencing these side effects, but they should pass in a few days. Unfavourable effects might not occur in some people. Tracking of vaccinations in the past has revealed that, if the dose is given, side effects typically manifest themselves within 06 weeks. Because of this, the FDA mandated that each medicine for COVID-19 that has been approved be read at least 02 months (eight weeks) after the last dose. Vaccinations, it is one of the most effective and cost-effective public health interventions, save millions of lives every year. Starting in 2020 scientists and pharmaceutical enterprises are rushing to create vaccinations after the SARS-CoV-2 genetic sequence was decoded and the World Health Organization (WHO) declared the pandemic on March 11th, 2020. "The WHO Strategic Advisory Group of Experts (SAGE)",characterised vaccine reluctance as "delay in acceptance or refusal of vaccination despite availability of vaccination services". It is thought that among the publicfear to get vaccines and mistrust both are worldwide pose a significant barrier to the realisation of such a goal.In order to stop further deaths and stop the pandemic from spreading, the policymakers may be helped by the findings of the current study to launch proactive campaigns and carefully crafted strategies that emphasise the value of vaccination among the populace and encourage vaccination acceptability and uptake, particularly in patients who are weaker. [2]

Objective

- To evaluate the COVID-19 vaccine's side effects in the staff nurses.
- To associate the side-effects of COVID-19 vaccine with selected demographic variables of the staff nurses.

MATERIALS AND METHODS

This study adopted a quantitative research approach with a descriptive, non-experimental design. It was conducted in selected hospitals across central Gujarat, with a sample of 200 staff nurses chosen through convenience non-probability sampling. Data collection occurred over a two-month period, from November to December 2021, using twenty-seven closed-ended questionnaires (dichotomous questions) administered via face-to-face interaction. The analysis focused on identifying the side effects of the COVID-19 vaccine among participants and examining the relationship between demographic variables, such as qualification and work experience, and the occurrence of these side effects. The research proposal was submitted to the ethical committee for approval under proposal number IEC/CHARUSAT/21/69. The sample size was determined using power analysis (Z1−β), with an alpha error of 5% and a power (1−β) of 80%. The reliability of the research tool was assessed using Karl Pearson's technique, resulting in a correlation coefficient of r = 0.799. Participants were clearly informed about the purpose of the study. The tool was developed based on the study's objectives and the inclusion and exclusion criteria. It consisted of two sections: the

first section addressed demographic variables, while the second section focused on evaluating adverse reactions to the COVID-19 vaccine.

Procedure

This descriptive, non-experimental study was conducted using 27 closed-ended questionnaires administered to staff nurses in selected hospitals of central Gujarat. A total of 200 participants were selected using a convenience non-probability sampling technique. Prior written informed consent was obtained from each participant, ensuring voluntary participation and confidentiality of their information. A pre-validated tool, consisting of a demographic questionnaire and a survey on the side effects of the COVID-19 vaccine, was utilized. The data were coded and organized into a master sheet, then compiled and analyzed using both descriptive and inferential statistics. The side effects of the COVID-19 vaccine were presented as frequencies and percentages. [Figure-1]

Figure-1 is presenting side effects of COVID-19 vaccines frequency and percentage among the staff nurse of selected hospital of central Gujarat.

RESULT

Finding of study were presented under the following three sections

Section First: Findings belongs to demographic variables of the participants.

Section Second: Findings related to COVID-19 vaccines side effects in staff nurses.

Section Third: Findings of association between COVID 19 vaccines side effects and selected demographical variable.

Section I indicate that majority of participants (49%) belong to 25 to 30 age group, (27.5%) belong to below 25 age group, (15.5%) belong to 31 to 35 age group and (8%) belonged from above 35 age group. 31.5% were male participants, 68.5% were female. Regarding their qualification1% were completed M.Sc. Nursing, 5.5% completed their B.Sc. Nursing, 0.5% completed P.B. B.Sc. Nursing, 46.5% completed GNM and 46.5% completed ANM .Most of the staff nurses (53.5%) had a working experience of 1 to 5 years, (20%) below 1 year, (19.5%) 5 to 10 years and (7%) more than 10 years. 42.5% were unmarried and 57.5% were married. In Section II findings showed that majority of participants (94%) had mild, 6% had moderate and out of 200 participants' no one had severe consequences of the COVID-19 vaccination. The data presented in section III showed that there were significance association between the demographic variables (qualification and the working experience) with side effects of COVID-19 vaccine.(Table No. 1 & 2]

DISCUSSION

A descriptive, non-experimental design was carried out to assess the adverse effects of the COVID-19 vaccine among 200 staff nurses in selected hospitals in central Gujarat. The study found that out of 200 participants, 188 (94%) experienced mild adverse effects from the COVID-19 vaccination, 12 (6%) reported moderate adverse effects, and none of the participants had severe side effects. A study conducted by Abonouab Raid, Andrea Pokorna et al. in Germany supports these findings. In their trial, 92 participants were involved, with 94.6% reporting mild (local) adverse effects and 5.4% reporting moderate (systemic) effects. These studies indicate that while the COVID-19 vaccine may cause mild and moderate adverse effects, it does not lead to severe side effects.

Limitation of the study

This study has following limitations. This research was limited to only staff nurses of selected hospital of central Gujrat. It can be carried out on other health care worker of other hospital. This study was also limited with 200 sample only.

CONCLUSION

This study revealed that the majority of staff nurses experienced mild side effects from the COVID-19 vaccine, with very few reporting moderate effects. As healthcare professionals, nurses play a critical role as counselors and communicators, helping to educate the community about the importance of vaccination and supporting informed decision-making. The findings of this study can assist in addressing common misconceptions about the potential negative health effects of the COVID-19 vaccine. Additionally, the results may contribute to the future planning and implementation of vaccination programs, helping to improve public confidence in vaccines. Ultimately, this study provides valuable insights that can enhance nursing practices and support efforts to improve vaccine acceptance in the community.

ABSTRACT

By increasing prediction accuracy, speeding up decision-making, and streamlining procedures in discovery, preclinical testing, clinical trials, manufacturing, and pharmacovigilance, artificial intelligence (AI) and machine learning (ML) are revolutionizing the creation of pharmaceutical drugs. Rapid target selection, effective in silico screening, toxicity prediction, adaptive clinical study design, better patient recruitment, real-time production control, and early safety signal detection are all made possible by these technologies. Stronger regulatory control is now required as their influence grows. Important frameworks that offer structured guidance to guarantee transparency, dependability, and patient safety include the FDA AI/ML Action Plan, EMA Reflection Papers, Good Machine Learning Practice (GMLP), algorithm audit and governance expectations, predefined change control plans (PCCP), and risk complexity classification tools. Dataset integrity, validation proof, model versions, human review, and lifecycle monitoring are all prioritised in regulatory requirements for documentation. Even while AI/ML has greatly increased R&D efficiency, there are still issues with data quality, interpretation barriers, model bias, and altering international regulatory harmonization. In order to adopt AI/ML in pharmaceutical development in a secure, ethical, and legal way it is needed to remove these barriers.

Keywords: Artificial Intelligence, Machine Learning, Drug Development, Regulatory Compliance

INTRODUCTION

The fast development and integration of machine learning (ML) and artificial intelligence (AI) has created a revolutionary shift in the pharmaceutical sector. These technologies are now vital components of current drug development procedures, providing opportunities to accelerate in discovery, reduce failure rates, enhance diagnostic accuracy, and increase regulatory options. They are no longer experimental add-ons. AI-enabled pharmaceutical innovation has been made viable during the past ten years by the growth of biomedical data, the rise of deep learning algorithms and the availability of high-performance computing. As opposed to the genomic revolution of the early 2000s, this modification is clear at all phases of the drug development process, from early target identification to post-market surveillance. [1,2]

Background and importance of AI/ML in drug development:

Historically, the procedure of developing novel drugs has been time-consuming, expensive, and unsafe. Traditional methods mostly rely on labour-intensive wet lab analyses, multi-year clinical evaluations, and trial-and-error experimentation. Based on several types of studies, it might cost between US$1.5 and US$2.6 billion to bring an entirely novel molecular device to market, while it often takes over 10 to 12 years [3]. Especially in early discoveries and phase two clinical trials, where insufficient efficacy and unexpected toxicity can frequently result in failure, the rate of attrition is still high. In regard to this, AI/ML gives an innovative approach by quickly assessing huge data sets, detecting subtle patterns, estimating biological outcomes, and modeling outcomes of treatment even before human or animal studies start. [4,5]

The importance of AI/ML is most evident in early-stage drug discovery, where deep learning models now enable virtual screening of billions of compounds in hours, compared to the months required for traditional high-throughput screening. A show that DL-based molecular modeling improves lead identification by predicting physicochemical and ADMET properties with high accuracy [2,6]. Similarly, AI-driven target identification platforms use genomic mapping, protein-protein interaction networks and multi-omics integration to uncover disease mechanisms previously invisible to human-driven analysis. Beyond discovery, AI supports preclinical toxicology, clinical trial optimization, digital pathology standardization, and real-world evidence generation, making it a critical enabler of innovation throughout the development process. [7]

Scope of AI/ML in the entire phases of pharmaceutical development:

Each stage of pharmaceutical research is now being influenced by AI/ML technologies, to speed up, increase accuracy, and minimize costs. Using modern techniques like reinforcement learning and GANs, AI in the discovery of drugs speed up virtual screening, develops novel drugs, predicts the viability of synthesis, and improves therapeutic qualities [8,9]. While PBPK-AI integration increases dose prediction and translational accuracy, machine learning models in preclinical research predict toxicological, increase *in vitro-in vivo* correlation, reduce testing on animals, and simulate metabolic pathways [10]. While NLP technologies automate data mining and monitoring for increased efficiency and compliance, AI speeds up patient recruitment, improves adaptive trial design, allows the creation of digital biomarkers, and strengthens patient stratification during clinical development [11]. AI powers quality-by-design, real-time monitoring, anomaly detection, and predictive maintenance in manufacturing and quality control to guarantee constant product quality [12]. AI is supporting algorithm review, streamlining regulatory submissions, standardizing digital pathology, and automating documentation in regulatory affairs [13,14]. AI-powered pharmacovigilance in post-marketing surveillance uses social media, EHRs, and real-world data to identify safety signals more quickly and precisely [15].

Applications across the life cycle of drug development:

By allowing data-driven insights, cutting down on timelines, and increasing rate of success in discovery, development, and post-market surveillance, AI and ML are revolutionizing pharmaceutical research and development [1,19]. Key uses consist of:

Identification of targets and drug discovery:

- To find new therapeutic targets, AI models mine massive biological datasets (genomics, proteomics, chemical libraries).
- Deep learning speeds up the identification of lead compounds by predicting molecular interactions, binding affinities, and off-target effects.
- The creation of new chemical structures with optimal medicinal characteristics is made possible by AI-assisted de novo drug design [1,7,20].

Hit-to-lead optimization and composite screening:

- Compounds with a high chance of success are given priority by ML algorithms, which shortens the time and expense of experimental screening [2,21].
- To enable logical design choices, predictive models improve chemical and ADMET attributes [1,3].

Preclinical research:

- By predicting PK/PD, preclinical efficacy, and *in vitro*/*in vivo* toxicity, AI reduces the need for animal research.
- To find safety hazards early in development, machine learning algorithms simulate interactions between drug targets and drug systems [21,22].

Design of clinical trials and patient enrolment:

- AI maximizes statistical power, endpoints, dosage, and adaptive trial design.
- To effectively match patients, particularly for rare diseases, and enhance admission results, NLP and ML examine EHR and genomic databases.
- Site selection and test efficiency are further enhanced by virtual testing and simulation-based feasibility studies [11,23,24].

Finding biomarkers and making follow-up diagnoses:

- ML finds predictive biomarkers for response prediction and patient classification.
- AI aids in the creation of companion diagnostics to enhance therapy accuracy and lower unfavourable consequences [22, 24].

Production of pharmaceuticals and quality assurance:

- AI predicts batch quality, optimizes production parameters, and permits predictive equipment maintenance.
- In real time, deviations, anomalies, and quality flaws are detected using computer vision and machine learning.
- By forecasting demand and inventory needs, predictive analytics increases supply chain resilience [25,26].

Formulation development:

- AI forecasts the best formulation, stability, and adjuvant compatibility.
- ML minimizes the need for repeated trials for creating biological medications and solid dosage forms [29, 30].

Pharmacovigilance and post-market surveillance:

- To identify warning signs early on, AI keeps an eye on social media, real data, and accounts of unfavourable incidents.
- Long-term safety trends, ADR patterns, and possible recalls are identified using ML models.
- Automation improves regulatory compliance and pharmacovigilance reporting efficiency [23, 30].

Market approach and regulatory information:

- AI keeps an eye on competitive pipelines, clinical trial databases, and changes in international regulations.
- ML helps prioritize R&D by identifying unmet requirements and strategic possibilities in the therapeutic landscape [29, 30].

Regulatory compliance guidelines:

Strong regulatory compliance is necessary for the implementation of AI and ML in pharmaceutical drug development in order to ensure patient safety, efficacy, and data integrity. Regulatory routes integrate governance frameworks, risk assessment, best practices, agency-specific guidelines, and organized paperwork for post-market surveillance and approval [20, 31].

FDA action plan for AI/ML

- Guidelines for AI/ML-enabled software and other regulated applications of artificial intelligence in drug development are provided by the FDA's AI/ML Action Plan for Medical Devices (SaMD).
- AI systems must prioritize continuous learning, ongoing monitoring, and revalidation; pre-market assessment of model performance, reliability, and clinical efficacy.
- Requirements for submission include thorough documentation of datasets, algorithm logic, training and validation processes, performance measurements, and risk-reduction tactics [20,32,33].

EMA reflection papers:

- AI/ML applications inside the European regulatory environment are guided by EMA reflection papers.
- Focus on validation, reproducibility, ethical issues, and clinical study integration. Assists with RWD/RWE applications for submission to regulations.
- Documentation needs include risk-benefit analysis, data origin, validation outcomes, and model development records.
- Submission requirements: Clinical trial protocol and paperwork, including AI-assisted decision-making procedures, must demonstrate regulatory compliance [34].

Good Machine Learning Practice (GMLP):

GMLP provides best practices to guarantee the security, effectiveness, and control of AI/ML tools:

- Standardized procedures for model training, testing, validation, and data curation.
- Documentation includes change logs, modeling code, complete datasets, and performance measurements.
- Supports submissions by proving model interpretation, reproducibility, and FDA/EMA compliance [35].

Framework for algorithmic revision and model management:

Regulators anticipate governance and a defined framework:

- Algorithmic auditing guarantees impartiality, openness, and lack of prejudice.
- Development, deployment, and monitoring roles are outlined in model governance frameworks.
- **Documentation:** post-implementation assessments, monitoring logs, validation studies, and audit reports [35, 36].

Matrix for risk-complexity:

- AI/ML applications are categorized using a risk-complexity matrix based on system complexity and patient effect.
- Systems that are high-risk or high-complexity need to be rigorously validated and closely examined by regulators.
- Low-risk, low-complexity tools might need less supervision.
- Documentation: Validation reports, risk assessments, and mitigating techniques [31].

Submission and documentation specifications:

Regulatory bodies demand a lot of documentation:

- Data documentation, including sources, quality, and pre-processing.

- Model documentation: versioning, hyperparameters, and algorithm description.
- Metrics, robustness, bias analysis, and external validation are examples of validation documentation.
- Post-marketing monitoring plans, audit trails, and change logs are examples of governance paperwork.
- The submission package must contain risk evaluations, GMLP, PCCP, and FDA/EMA compliance [19, 20, 21, 37, 38].

METHODOLOGY

In order to understand how artificial intelligence (AI) and machine learning (ML) are applied in pharmaceutical medication development and how they satisfy regulatory standards, this study employed an organized methodology. Target discovery, virtual screening, medication design, toxicity prediction, patient recruiting, clinical trial planning, manufacturing control, and post-marketing safety monitoring were among the domains in which it looked at the application of AI/ML. To comprehend expectations for data quality, model validation, transparency, interpretability, performance monitoring, and lifecycle management of AI systems, key guidelines from the FDA, EMA, and ICH were examined. In order to evaluate the capabilities, hazards, and supporting data required for regulatory approval, the study also evaluated widely used AI/ML tools, such as deep learning models, natural language processing systems, chemical informatics platforms, and predictive toxicology software. Pharmaceutical firms' practical application of AI/ML is examined through real-world case studies, which emphasize both achievements and difficulties such data gaps, model interpretation, and regulatory ambiguities. The study found important patterns, benefits, gaps, and future directions by examining all of this data. AI/ML can speed up the identification of targets, enhance forecasts, reduce development times, streamline clinical trials, and enhance safety monitoring. But for these technologies to be used successfully, ethical and security issues must be addressed, transparency must be maintained, best practices must be followed, and legal requirements must be met. Overall, the study demonstrates that AI and ML have enormous potential to revolutionize medication development; nevertheless, for the innovation to be safe, effective, and responsible, cautious implementation guided by laws is required.

RESULTS

The results demonstrate that AI/ML enhances overall efficiency, speed, and accuracy throughout the whole drug development process. AI speeds up target identification and improves the efficiency of novel compound design in drug discovery. AI reduces the necessity for animal testing by predicting toxicity in preclinical phases. AI enhances patient recruitment, facilitates adaptive trial design, and streamlines data management during clinical trials. AI-based quality control and real-time monitoring make production more dependable. Regulations are made simpler by automated documentation and quicker compliance assessments. AI uses real-world data to help identify negative effects before a medicine is put on the market. In general, early research phases see the greatest acceptance of AI, but later stages continue to see an increase in demonstrable impact.

DISCUSSION

Case studies across drug development using AI/ML: [39,40,41]

Case study 1- Pfizer + IBM Watson- AI for Immuno-oncology drug discovery

- **Stage:** Preclinical / Target Discovery
- **Overview:** Pfizer leveraged IBM Watson's AI and NLP capabilities to rapidly analyze massive volumes of scientific literature, clinical trial data, and molecular databases. This enabled the identification of novel immuno-oncology drug targets much faster than traditional manual review.
- **Outcome:** Accelerated early-stage discovery and prioritized promising targets for experimental validation.
- **Significance:** Demonstrates AI's ability to mine unstructured biomedical data at scale, reducing time-to-target identification and enhancing decision-making.

Case study 2- Novartis- AI for virtual clinical trials & patient recruitment

- **Stage:** Clinical Trials
- **Overview:** Novartis implemented AI tools to analyze patient electronic health records and real-world data for identifying suitable participants, especially for rare-disease trials. Virtual trial simulations and predictive models optimized trial site selection and recruitment strategies.
- **Outcome:** Increased efficiency of patient recruitment and trial enrollment while reducing operational delays.
- **Significance:** Shows AI's ability to improve clinical trial design, enhance patient matching, and reduce trial costs.

Case study 3- GSK + Exscientia – The first AI-designed drug molecule

- **Stage:** Preclinical/drug design
- **Overview:** Excientia partnered with GSK to design a new small molecule drug using AI-powered generative chemistry and predictive modeling. Remarkably, the candidate reached Phase I clinical trials in less than 12 months compared to the traditional 4–5 years for similar molecules.
- **Results:** Demonstrated that AI can accelerate de novo drug design and reduce potential optimization timelines.
- **Significance:** Highlights the transformative potential of AI/ML by efficiently generating new therapeutic agents, setting a precedent for future AI-driven drug development programs.

Identified challenges:

- Data quality issues and model bias affect accuracy, fairness and regulatory acceptance.
- Limited interpretation of complex AI models, reduces trust in practitioners and regulators.
- Non-harmonised global regulations, creates uncertainty for multinational productions.
- Ethical and privacy concerns, especially around patient data use and algorithm transparency.
- Data fragmentation and lack of standardization hinders robust model training and reproducibility.
- Inadequate validation frameworks for adaptive and continuously learning AI/ML systems.
- Lifecycle management issues, including dataset management, version control, and real-time model monitoring.
- Cybersecurity vulnerabilities, such as adversarial attacks or unauthorized manipulation of AI models.
- Lack of skilled AI professionals in pharmaceutical and regulatory environments.
- Integration difficulties with older IT systems slow down digital adoption in R&D and production.

Future Scope:

The adoption of AI in drug development is expected to drive progress in several transformative directions:

- Regulatory analytics: Using AI to generate high-quality real-world evidence for post-approval monitoring.
- Digital twin system: Virtual simulation at patient and organ level to predict safety and efficacy.
- Unified learning model: Privacy-preserving collaboration across global institutions without sharing raw data.
- Explainable AI (XAI): Models with transparent, explainable outputs for clinical and regulatory acceptance.
- Fully Adaptive Clinical Trials: AI-powered, continuous update of trial designs based on incoming patient data.
- Global harmonization: Convergence of FDA, EMA, MHRA, PMDA and ICMRA guidelines for internationally aligned AI regulation.
- AI-powered precision medicine: Integrating genomics, multi-omics, imaging and wearable data to personalize therapy decisions.

The development of drugs is being altered by AI and ML. Pfizer found novel targets for cancer drugs more quickly by using AI. Novartis made recruitment quicker and simpler by using AI to identify the best patients for clinical trials. A novel medication created by GSK and Excientia using AI entered clinical trials in less than a year—much quicker than typical. However, there are obstacles including inadequate data quality, intricate AI models, privacy issues, disparate national laws, and a shortage of qualified experts. AI has the potential to enhance clinical research, construct digital patient models, advance precision medicine and expedite, secure and customize drug development.

In Conclusion, Artificial intelligence (AI) and machine learning (ML) are reshaping pharmaceutical drug development by increasing predictive accuracy, operational efficiency and scientific decision-making in target discovery, preclinical research, clinical trials and lifecycle management. Regulatory frameworks – including the FDA AI/ML Action Plan, EMA Reflection Papers, Good Machine Learning Practice (GMLP) and new governance models – play a critical role in ensuring transparency, reliability and patient safety by requiring rigorous documentation, validation, explainability and model lifecycle monitoring. Despite its benefits, AI/ML adoption faces challenges such as variable data quality, limited model interpretability, ethical risks, algorithm bias, and the absence of globally harmonized regulatory pathways. Overcoming these issues requires strong auditing, continuous monitoring, robust data management and alignment with regulatory expectations. As AI/ML increasingly integrates with real-world evidence, adaptive learning systems, digital biomarkers and personalized medicine, their potential to reduce development timelines and improve patient outcomes will continue to grow. Realizing this potential will depend on strong collaboration between industry, regulators, practitioners and technology developers to ensure the safe, compliant and responsible integration of AI into the pharmaceutical landscape.

ACKNOWLEDGEMENTS

I express my gratitude to the Chalapathi institute of pharmaceutical sciences for the support.

Table 1: AI/Ml Tools In Drug Development [16,17,18]

Stage	AI/ML Tools	Application
Target identification and validation (preclinical)	• Deep learning models for predicting protein targets • Generative models (GAN, autoencoders) for the creation of molecules. • ML-based virtual screening on the CADD platform	• Identify high affinity drug targets • Reduce experimental costs and time • Accelerates hit discovery
Drug Screening and Lead Optimization	• Random Forest and Gradient Boosting for ADMET • Support vector machines (SVM) for activity prediction • ML-powered molecular docking score	• Prioritize compound libraries • Reduce wet lab testing • Rapidly predict toxicity and pharmacokinetics
Design and optimization of clinical trials	• XGBoost, neural network for prediction of patient outcomes • NLP for EPR-based rights extraction • Reinforcement learning for adaptive test design	• Improving test efficiency • Increase patient stratification • Predict test scores
Compliance and submission of regulations	• NLP-based document review system • AI-enabled ESG verification tools • ML-based data integrity checking tools	• Reduce submission errors • Ensure FDA/EMA compliance • Accelerate regulatory approvals
Post-market monitoring /pharmacovigilance	• Predictive analysis and anomaly detection models • NLP-based social media and literature mining • AI signal prioritization platform	• Early detection of adverse events • Real-time security monitoring • Better risk management

Table 2: AI/Ml Contributions In Drug Development

Drug Discovery	Accelerates Virtual Screening, Designing New Molecules, ADMET Predicts.
Pre-clinical	Predicting preclinical toxicity, reducing animal testing, improving dose modeling.
Clinical development	Improves patient recruitment, supports adaptive studies, enables digital biomarkers.
Manufacturing	Provides real-time monitoring, predictive maintenance and quality control.
Regulatory affairs	Automate documentation for regulatory matters and support compliance checks.
Post marketing	Enables early detection of adverse events using real-world and social media data.

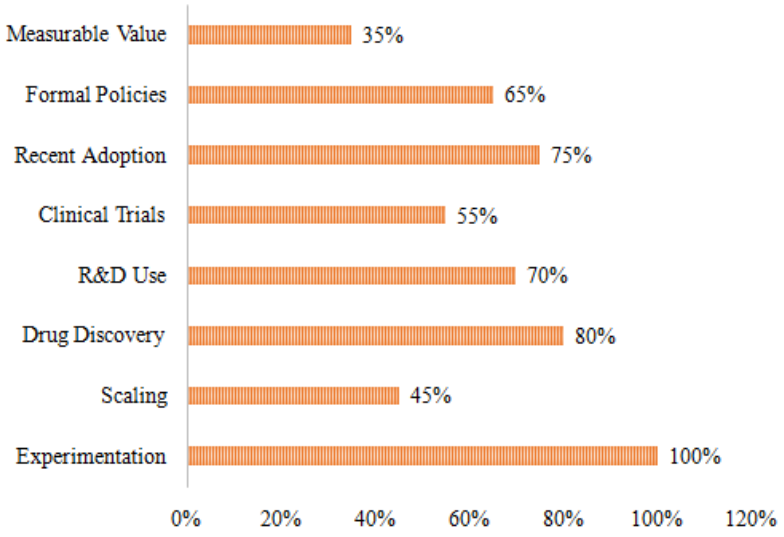

Fig. 4: Current Landscape of AI/ML Adoption Rates in Pharmaceutical R&D

The usage of AI and ML at various phases of pharmaceutical R&D is depicted in the figure. While scale and observable value are still low, adoption rates are highest during medication discovery, experimentation, and recent deployment. Overall, the graph shows that although the use of AI is expanding, there is still a lack of systematic integration and demonstrated impact.

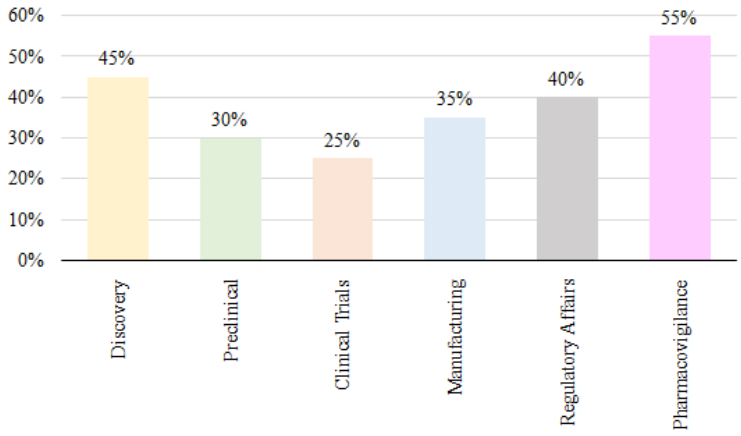

Fig. 5: Impact of AI/ML on Drug Development

The graph mentioned above illustrates how much AI/ML advances medication development at various phases. Efficiency gains are greatest in pharmacovigilance and discovery. Preclinical, clinical, production, and regulatory phases all exhibit discernible but less significant advancements.

ABSTRACT

A new organic Non-linear Optical crystal (E)-2-(((2-(2-hydroxyethoxy)ethyl)imino)methyl)-4-nitrophenol (E-2HM4N) has been synthesized by the slow evaporation techniques. Powder X-ray diffraction patterns have been utilized for obtaining structural optimism by assigning nuclear magnetic resonance chemical shifts while analyzing the resulting data. A preferred imine group of titled crystals is composed of a polar aliphatic tail and a polar aromatic head, and it self-assembles into crystals, forming a crystal structure. Nowadays, in fluorescence spectroscopy, imine-based biomaterials are used in many different ways. The invention specifically relates to the use of polar covalent imines because they enable deep light penetration into biological specimens and produce high-resolution optical Photoluminescence. The self-defocussing nature of the crystal is confirmed by the multi-emission peaks in photoluminescence which is due to the strong absorption in the UV Spectroscopy. The grown crystal's luminescence property displays green emission radiation with good imaging properties. For the imaging of various biological samples, many nonlinear optical techniques have been used, including multiphoton fluorescence and harmonic

generation. The title crystal has strong saturable absorption and a self-defocusing effect, as shown by third-order Non-linear Optical characteristics using a Z-scan method.

Keywords: Crystal Structure; UV; Photoluminescence; Z-scan-Self-defocusing;

INTRODUCTION

Franklin discovered the optical second harmonic generation signal in the early 1960s, very immediately after the creation of the laser. Since then, materials having large nonlinear optical (NLO) output have discovered widespread applications in laser sciences and technologies. The all-solid-state lasers used in applications like medical diagnosis now contain a key component made of NLO materials, which has played an important part in the development of these technologies [1]. The solid-state structure of organic compounds can be sensitively examined by non-linear optical properties, which have a variety of applications [2]. Organic non-linear optical (NLO) systems are receiving a lot of interest lately due to their improved stability and promising NLO response, which suggests they are suitable for third harmonic production. Because of the electronic structure in the π-conjugated state and the appearance of electron-donating and electron-accepting clusters on both sides of the system, organic substances exhibit significant non-linearity [3]. Non-centrosymmetric materials are of high attention so their possible developments in more areas such as third-order non-linear optical material [4]. Imines are compounds that form the well-known class of chemicals known as Schiff-bases during the condensation reactions between the amine and the aldehydes. Direct condensation was frequently used to process amine and aldehyde to produce Schiff-base compounds [5-6]. Schiff bases and their derivatives, particularly the amine family, have an intriguing area in drug research and development because of their bio-activities such as tumor, cancer, bacterial, and viral activities [7]. The advantage of having organic substances as NLO activities is that they may be engineered to have certain donor-acceptor groups to optimize desired NLO characteristics [8]. Organic materials display a variety of new NLO elements due to their broad structural design. It is desirable to produce broad organic frameworks with NLO characteristics via Schiff-based reactions.

NLO applications for Schiff base materials include optical devices, which include dynamic imaging techniques [6]. In particular, new sorts of researchers are interested in organic molecules with considerable NLO properties. The search for new advanced materials is an important area of contemporary research in numerous disciplines of science and the development of many new technologies. Non-linear optical (NLO) crystals have attracted a great deal of interest in recent years due to their potential applications in the domain of optoelectronics and photonic technologies [23]. While the engineering for enhancing second-order NLO efficiency is relatively well understood, the need for efficient third-order molecules and materials still exists. Third-order NLO organic goods are compared to inorganic spices in terms of dimensional convenience [9]. We discuss a method for exhibiting the structure of organic materials using entire nuclear magnetic resonance (NMR) Spectral analysis in the context of PXRD data [10]. Although the structure evaluation approach had its challenges, a favorable outcome was attained by merging the PXRD analysis and data from NMR spectra and resolving the issue by utilizing the DASH 4.0.0 software for structure optimization [11]. In this research work, we carried out the Synthesis, development, and characterization of novel organic crystal (E)-2-(((2-(2-hydroxyethoxy)ethyl)imino)methyl)-4-nitrophenol ($C_{11}H_{14}N_2O_5$) (E-2HM4N). UV-Vis Spectroscopy and photoluminescence characterization have been performed which results in a high-performing multi-emitting organic NLO material that should meet a variety of characteristics, one of which is the presence of a large third-order NLO with a non-centrosymmetric crystal structure. We thoroughly examine the non-linear refraction, non-linear absorption, and self-defocusing properties of the E-2HM4N crystal using Z-scan analysis.

MATERIALS AND METHODS

The compounds 2-hydroxy-5-nitrobenzaldehyde and 2-(2-aminoethoxy)ethanol are used in the current study as an analytical reagent (AR) with a 99% purity and the solvent Acetic Acid used for the synthesis was obtained from Sigma-Aldrich and set to utilize without further sterilization.

Synthesis and Crystal growth

Using slowly evaporating methods, an E-2HM4N single crystal was created using procedures from 2-hydroxy-5-nitrobenzaldehyde and 2-(2-aminoethoxy)ethanol. Initially, 2-hydroxy-5-nitrobenzaldehyde (0.3g, 0.001795 mol) was dissolved in acetic acid (10ml) by continuous stirring. 2-(2-aminoethoxy)ethanol (0.2g, 0.00190 mol) was added to this solution and continuously stirred for an hour at 30 °C. The liquid then became yellow after that. A single crystal was extracted from the liquid after a 30-day development period. Figure 1 depicts the E-2HM4N single-crystal picture. In Fig. 2, the reaction plan is displayed.

RESULT AND DISCUSSION

Single-Crystal and Powder X-ray Diffraction

Single Crystal X-ray Diffraction Measurements of E-2HM4N were gathered using a Bruker Kappa APEXII diffractometer. The data structure determination was recorded by BrukerD8 Venture. The E-2HM4N crystal structure becomes the Monoclinic crystal system with non-centrosymmetric space group Pc. The estimated lattice parameters are a = 7.25Å, b = 8.37Å, c= 11.70Å, α = 90.00°, β = 94.92°, γ = 90.00° and V = 707A^3. X'Pert Pro-PAnalytic was used to collect PXRD analyses while employing CuKα radiation (λ=1.5406nm) at 40 kV and 30 mA power. Over a two-dimensional 2Θ range of 10° to 80°, a PXRD diffraction pattern was gathered. Powder X-ray diffraction analysis was used to solve the crystallinity of the E-2HM4N compound from the fine powder form of the crystal. The crystallinity of the developed crystal is noticeable from the observed sharp and intense peaks [12]. Fig. 3 shows PXRD data of E-2HM4N crystal. The formed crystals were ground into a powder and studied using PXRD. PXRD gives detailed information about the crystallinity nature and purity of the crystal. PXRD gives more accurate information rather than SC-XRD [13].

Structure Determination

The structure is directly determined using both PXRD data and Chemical shift data [11]. A user-friendly piece of software named DASH is used to solve crystal structures using X-ray powder diffraction data. We used DASH 4.0.0 software to determine crystal structure using the input module optimized by 'opt hf/3-21g geom=connectivity' keywords using Gaussian 16W, revision c.01, software [14]. H_{22}-O_7 ……. N_{12} intramolecular hydrogen bonds are observed in the structure (dashed blue line). For the indexing, the greatest powder pattern was utilized [13]. E-2HM4N crystal in the Monoclinic system with space group Pc. The structural organization is favorable to interesting NLO properties of the crystal. The crystal structure of E-2HM4N was deposited in the Cambridge-crystallographic data center (Deposition Number: 2231805) [15]. Experimental crystallographic parameters are given in Table 1. The Molecule structure of the E-2HM4N crystal is in Figure 4.

^{13}C NMR and ^{1}H NMR Spectral Studies

Bruker AMX NMR Spectrometer has been used to record data for ^{13}C and ^{1}H NMR (300 MHz). Tetramethyl silane (TMS) is employed at ambient temperature and DMSO is used as the solvent. NMR spectroscopy has been used to examine conformational changes in a variety of ring compounds [16]. The obtained spectra are shown in Figures 5 and 6. The corresponding shift of ^{13}C NMR and ^{1}H NMR signals are collected and illustrated in Table 2. NMR Spectra of 2-hydroxy-5-nitrobenzaldehyde and 2-(2-aminoethoxy)ethanol were collected from the spectral database and compared in Table 2. The peak of the DMSO solvent can be seen at 40.236 ppm. The aromatic ring's carbon atom was blamed for the chemical shift seen at 140.143 ppm, 131.078 ppm, 124.703 ppm, 122.573 ppm, and 118.846 ppm. The CHO resonance peak was obtained at 189.353 ppm. The peak's up-field shift from 194.61 ppm to 118.846

ppm demonstrates that water molecules were removed during the production reaction of the chemical E-2HM4N. The carbon atom that is attached in the (phenol) OH group of 2-(2-aminoethoxy) ethanol causes the triplet that was seen at 39.735 ppm, 39.568 ppm, and 39.401 ppm. ^{13}C NMR spectrum of E-2HM4N Crystal (Fig. 5). ^{1}H NMR describes the E-2HM4N crystal spectrum as shown in Figure 6. At 2.500 ppm, the solvent signal becomes visible. The signals collected strongly revealed that the water molecule was eliminated from the interaction between NH_2 and CHO, which produces a CH=N group. E-2HM4N. Thus, the confirmation was done by the down-field shift of the NH_2 signal from 1.7 ppm to 2.493 ppm. Due to the formation of the signal CH=N, which was shifted toward higher ppm, the signal NH_2 in pure 2-(2-aminoethoxy)ethanol is at 1.7 ppm. The resonance induced by the proton CH=N groups shifted to a higher ppm.

UV VIS NIR Spectroscopy

The observed transmittance graph of the E-2HM4N crystal is shown in Fig. 7. Derived optical bandgap is 2.03eV.The E-2HM4N crystal's band gap supports the need for high-quality nonlinear optical applications [19]. The E-2HM4N crystal has good transmittance over the whole visible and near-infrared area, as can be seen from the spectrum [12]. For NLO application, the crystal should be transparent to all of the interfering wavelengths [17].

Refractive index

The Refractive index is the ultimate property of an optical material. Transmittance (T) and refractive index of the crystal in terms of transmittance are expressed as (Swanepoel method 1983),

$n = [N + (N - S^2)^{1/2}]^{1/2}$

Where,

$N = 2S \frac{Tmax - Tmin}{TmaxTmin} + \frac{S^2+1}{2}$,

Where T_{max} and T_{min}, are the transmittance max and the correlating minimum at that wavelength (λ). It used a well-recognized part of the mathematical equation.

$S = \frac{1}{Ts} + \left(\frac{1}{Ts} - 1\right)^{1/2}$

The refractive index was calculated as n = 1.5204 of E-2HM4Nat 387.5 nm, suggesting that the material will enhance the performance of optical properties[18]. Figure 10 shows the refractive index with the wavelength of the E-2HM4N crystal. The refractive-index decreases as wavelength increases. The higher band gap transmission in the overall region and lower refractive index make the crystal suitable for good pharmaceutical applications [19]. The refractive-index of the E-2HM4Ncrystal (Figure 8).

Photoluminescence Study

One of the useful technologies to give direct information on the molecular-level physical characteristics of materials is photoluminescence spectroscopy. Photoluminescence spectroscopy is one of the effective tools to provide direct information about the physical properties of materials at the molecular level. Figure 9 displays the Photoluminescence spectrum of the E-2HM4N crystal. The spectrum shows stable and strong emission peaks at 360nm, 491nm, and 521nm which was due to the excitation in UV VIS light at 620nm. It also revealed that E-2HM4N crystal had violet, blue, and green emission. The green fluorescence that the NLO crystal produces at 521 nm suggests that it would make a strong candidate for nonlinear optical applications [20].The self-defocusing characteristics of the NLO crystal have been established by the multi-emission peak. The high fluorescence emission displayed by the chemical in the title suggests that it would be a viable candidate for NLO applications [21].The availability of further emissions peaks supports the E-2HM4N crystal's high degree of crystallinity and structural magnificence [22].

Z-Scan measurements

The calculated linear refractive index value is 1.5204. The NLO community immediately embraced the Z-Scan examination as a standard method for finding out nonlinear variations in refractive index and nonlinear optical absorption. E-2HM4N crystals' nonlinear absorption and refractive index. The study of nonlinear refraction by the Z-scan method depends on the position (Z) of the samples under investigation along a focused Gaussian laser beam.

Depending on whether nonlinear refraction is negative or positive, the sample results in either extra focusing or defocusing. The Z-scan method [24] is a straightforward yet very precise way to get the nonlinear absorption coefficient β and the nonlinear index of refraction n2. The real portion of the third-order susceptibility is proportional to the nonlinear index of refraction. [Re$\chi^{(3)}$] and the nonlinear absorption coefficient is proportional to [Im$\chi^{(3)}$]. A 103 mm focal length lens was utilized to focus a 532 nm diode-pumped solid-state laser for the Z-scan investigations. At the focal point, the estimated values for intensity ($I_\circ$) and beam waist ($\omega_\circ$) were 0.33 μm and 0.0136 MWcm^{-2}, respectively. The experimental setup's Rayleigh range ($Z_\circ = \pi\omega_\circ/\lambda$) was determined to be 1.32 mm, meeting the requirement of $L < z_\circ$ for thin sample estimation. The schematic of the experimental setup used is shown in Fig. 10. A 1 mm wide optical cell with the E-2HM4N sample in an acetic acid solution has been moved along the propagation laser beam's axial route, across the focal region. By feeding the Si photodiode detector into the dual channel detector measurement unit, the transmission of the beam via an aperture positioned in the far field was measured. An aperture was replaced with a lens to catch all of the laser beam transmitted through the sample for an open-aperture Z-scan. Figure 11 gives a closed, open, and ratio of the closed-to-open normalized *Z*-scan of the E2HM4N sample in Acetic Acid solvent at 62% transmittance. The closed aperture Z-scan data shows a peak followed by a valley-normalized transmittance, indicating a negative sign for the refraction nonlinearity, or self-defocusing. The local temperature variation in the refractive-index is the cause of the self-defocusing effect. The open aperture Z-scan pattern showed transmission minimum at focus, indicating the reverse saturable absorption (RSA). The refractive-index of material's strong electromagnetic radiation changes, resulting in the nonlinear optical process of self-focusing [9]. Table 3 contains the third-order NLO parameters.

The measurable quantity ΔT_{p-v} can be defined as the difference between the normalized peak and valley transmittances, $T_p - T_v$. The variation of this quantity as a function of $|\Delta\phi_o|$ is given by

$$\Delta T_{p-v} = 0.406(1-S)^{0.25}|\Delta\phi_o| \quad (1)$$

where $\Delta\phi_0$ is the on-axis phase shift at the focus. S the aperture linear transmittance is given by

$$S = 1 - \exp(-2\, r_a^2/\omega_a^2) \quad (2)$$

with r_a denoting the aperture radius and ω_a denoting the radius of the laser spot before the aperture.
The on-axis phase shift is related to the third-order nonlinear refractive-index (n_2) [25] by,

$$|\Delta\phi_0| = k n_2 L_{eff} I_0 \quad (3)$$

where $L_{eff} = (1-e^{-\alpha L})/\alpha$, with L the sample length, α is the linear absorption-coefficient I_O is the intensity of the laser beam at focus $z = 0$, and k is the wave number($k=2\pi/\lambda$)

The imaginary parts of the third-order nonlinear optical susceptibility [χ^3] are estimated using the value of the nonlinear absorption-coefficient β obtained from the open aperture Z-scan data and using the relations:

$$q_o(z) = \frac{\beta . I_o . L_{eff}}{(1+\frac{Z^2}{Z_o^2})} \quad (4)$$

$$\beta = \frac{2\sqrt{2}.\Delta T}{I_o . L_{eff}} \quad (5)$$

$Z_R = k\omega_0^2/2$ is the diffraction length of the beam, ω_0 is the beam waist radius at the focal point.

The following relations can be utilized for calculating the portions, both real and imagined, of the third-order nonlinear optical susceptibility [26] using the experimentally measured nonlinear refractive index n2 and nonlinear absorption-coefficient β.

$$\mathrm{Re}\,\chi^3(esu) = 10^{-4}\,\frac{\varepsilon_o c^2 n_o^2}{\pi} n_2 (\frac{cm^2}{W}) \quad (6)$$

$$I_m \chi^3(esu) = 10^{-2} \frac{\varepsilon_o c^2 n_o{}^2 \lambda}{4\pi^2} \beta(\frac{cm}{W}) \quad (7)$$

where ε_0 is the vacuum permittivity, and c is the light velocity in vacuum.
The absolute value of the third-order nonlinear optical susceptibility is given by the relation

$$\left|\chi^3\right| = \left[(R_e(\chi^3))^2 + (I_m(\chi^3))^2\right]^{1/2} \quad (8)$$

The nonlinear parameters calculated are tabulated in Table 3

CONCLUSION

The New Crystal is identified in the amine family and its structure was solved and deposited in CCDC. The structural Property Relationship approach found the relationships between chemical structure and related structural properties including the target property of the studied crystal (Bio-imaging) for in-vitro bio-imaging applications and being ideal for lung cancer disease diagnosis. The linear refractive index is calculated from the Swanepoel method and the nonlinear refractive index is calculated from the Z-scan method. It is concluded that Schiff-based molecular crystal contains recognizable molecules within the structure and is held together with intermolecular hydrogen-bonding by the result obtained. In Photoluminescence spectroscopy NLO property of the Schiff-based crystal was well investigated through violet, blue, and green emissions. The generated E-2HM4N crystal will be the potential candidate in bio-imaging which was investigated by the multi-emission peak in Photoluminescence Spectroscopy and in the Z-scan analysis with the value of 2.3866 x 10^{-6}esu.

Electronic supplementary Information

CCDC 2231805 contains supplementary Crystallographic Data of E-2HM4N, that can be obtained freely from the Cambridge crystallographic data center via www.ccdc.cam.ac.uk/data_request/cif.

Credit authorship contribution Statement
The idea and design of the study were contributed to by all authors. preparation of materials, gathering of data, conceptualization, methodology, software, and writing—creation of the first draft by J. Priyanka., Supervision, Reviewing and Editing, Project Administration by R. Ida Malarselvi, Resources by G. Vinitha, Validation by C. Ramachandra Raja, Visualization by R. Priscilla and all authors commented on previous versions of the manuscript. The final manuscript was read and approved by all authors.

DATA AVAILABILITY

No data was used for the research described in the article.

FUNDING

No particular funding from public, private, or nonprofit organizations was given to this research.

ACKNOWLEDGMENTS

As part of this work, SCXRD, and NMR Spectroscopy characterization techniques were conducted in Sophisticated Analytical Instruments Facility (SAIF), Indian Institute of Technology, Madras, Chennai – 600 036, Tamil Nadu, India. UV-Vis-NIR spectroscopy characterization technique was conducted at Sathyabama University, Chennai, Tamil Nadu, India. PXRD and Photoluminescence characterization was conducted at the University Science

Instrumentation Centre (USIC), Alagappa University, Karaikudi - 630 003, Tamil Nadu, India. Also, the authors place on record special thanks to Dr. G. Vinitha, For giving them a third-order nonlinear testing facility to record Z-scan measurements, thanks to VIT, Chennai.

ABSTRACT

A crucial element in securing agricultural sustainability, resource efficiency, and revenue generation is crop selection. Despite inadequate and ambiguous information, farmers and decision-makers must weigh several competing factors, including yield, water needs, pest resistance, market price, and maturity duration. It is frequently challenging for traditional multi-criteria decision-making (MCDM) methodologies to adequately model this indeterminacy. In a bid to overcome this difficulty, this research combines the Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) for agricultural crop selection with Single-Valued Neutrosophic Sets (SVNS).Using agricultural performance data spanning ten years, a case study was carried out with four crops: wheat, maize, soybeans, and cotton. After converting raw data into neutrosophic decision matrices and normalizing them, the suggested SVNN-TOPSIS framework calculates distances and closeness coefficients to establish the ordering of alternatives and identifies weighted positive and negative ideal solutions. The results showed that the technique can capture uncertainty and give strong decision support, with soybeans being the most appropriate crop, followed by maize, wheat, and cotton. This work enhances agricultural decision-making by providing a realistic and adaptable assessment model that takes into account ambiguity, inconsistency, and partial knowledge. In furtherance of improving crop selection's rationality, the results demonstrate the promise of neutrosophic MCDM techniques in more general agricultural and environmental planning contexts.

Keywords: Multi-Criteria Decision-Making (MCDM), Single-Valued Neutrosophic Sets (SVNS), TOPSIS, Positive Ideal Solution (PIS), Negative Ideal Solution (NIS), Agricultural Crop Selection; Uncertainty Modeling.

INTRODUCTION

Agricultural crop selection is a fundamental decision-making problem that directly influences farm productivity, resource utilization, and economic sustainability. Farmers and policymakers are often confronted with the challenge of choosing the most suitable crop among several alternatives, considering multiple and often conflicting criteria such as yield potential, water requirements, pest resistance, market price, and maturity period. Traditional decision-making approaches are often inadequate in capturing the uncertainty, vagueness, and indeterminacy inherent in such real-world agricultural problems. Hence, advanced MCDM techniques are increasingly being employed to provide systematic and rational solutions.

Among the various MCDM methods, the TOPSIS is widely recognized for its simplicity and effectiveness. It ranks alternatives by simultaneously minimizing the distance from the PIS and maximizing the distance from the NIS. However, classical TOPSIS operates on crisp or fuzzy data, which may not adequately represent the indeterminate and incomplete information present in agricultural environments. To overcome this limitation, the neutrosophic set theory, introduced by Smarandache, extends fuzzy logic by incorporating three independent components: truth-membership (T), indeterminacy-membership (I), and falsity-membership (F). The SVNS is a practical form of this theory, capable of handling real-life uncertain and imprecise data. Integrating SVNS with TOPSIS allows for a more comprehensive evaluation framework where expert judgments and agricultural data can be expressed with greater flexibility. This study proposes a novel approach to agricultural crop selection by applying the SVN-TOPSISmethod. A case study involving four crops—Wheat, Maize, Soybean, and Cotton—evaluated against five critical criteria over a ten-year dataset is conducted. The methodology demonstrates how neutrosophic modeling effectively captures uncertainty in decision-making and provides a rational ranking of crop alternatives. The results highlight the potential of SVNN-based MCDM techniques in supporting agricultural planning and policy formulation, ensuring that decisions are robust, data-driven, and reflective of real-world complexities.

Angammal[1] highlighted the significance of combining agricultural decision-making with neutrosophic techniques by proposing a multi-attribute neutrosophic optimization technique for the best crop selection in Ariyalur District. In order to better address uncertainty, Xu and Peng [2] extended traditional MCDM approaches by creating an enhanced technique based on TODIM and TOPSIS under multi-valued neutrosophic sets. Using generalized SV non-linear bipolar neutrosophic settings, Garai and Garg [3] examined water resource management issues in the Purulia agricultural field, offering insights into farming sustainability. In order to model agricultural land selection and provide a framework for decision support in land allocation, Ashraf and Abdullah [4] used sine trigonometric single-valued neutrosophic information.Abdel-Basset [5] presented a bipolar neutrosophic multi-criteria decision-making framework for professional selection that goes beyond agriculture and exhibits adaptability in other application domains. To increase the accuracy of ranking alternatives in single-valued neutrosophic environments, Garg [6] introduced a TOPSIS-based approach and a novel divergence measure. Prior to this, Ye [7] created a multicriteria decision-making technique employing correlation coefficients under SVN, while Chi and Liu [8] expanded the TOPSIS method for MADM using interval neutrosophic sets. Alzahrani et al. [9] used neutrosophic multi-criteria decision-making to investigate the best location for a women's institution, with a focus on spatial planning in the face of uncertainty. Gaussian SVN numbers were first presented and their uses in multi-attribute decision-making were illustrated by Karaaslan [10].

An alternative viewpoint for MADM difficulties was provided by Garai [11], who suggested a ranking technique based on possible mean under SVN. SVNS were officially established by Wang et al. [12], which served as the basis for later models. Earlier, Smarandache [13] laid the theoretical foundation for indeterminacy-based decision-making by introducing neutrosophic logic as a unifying topic in logics. One of the earliest links between fuzzy logic and agriculture was made by Yong [14], who used fuzzy TOPSIS to pick plant locations. Singh and Mallick [15] developed a fuzzy-based MCDM approach for green chamber farming, which helped advance sustainable

agriculture operations. From a historical perspective, uncertainty modeling in mathematics and decision sciences was first introduced by Zadeh [16] with the introduction of fuzzy sets. This field was later expanded by Hwang and Yoon [17], who proposed TOPSIS and other conventional MADM approaches. By modeling a neutrosophic agility index, Kavitha and Hepzibah [18] provided a fresh mathematical framework for assessment. Using MCDM approaches, Shafeena Miraclinl and Hepzibah [19] carried out an extensive investigation on the inequalities that affect women in society. Lastly, the foundation for contemporary decision-making techniques was reinforced when Opricovic and Tzeng [20] compared compromise solutions in MCDM, specifically *VIKOR and TOPSIS*.Collectively, these studies [1-20] demonstrate the ongoing development of decision-making methods from fuzzy sets to neutrosophic environments and their applications in agriculture, resource allocation, and social sciences, with single-valued neutrosophic TOPSIS emerging as a strong tool for dealing with uncertainty in complex systems.

Previous Research

The application of MCDM techniques to agricultural decision-making has been extensively studied. In crop planning, irrigation scheduling, and resource allocation, traditional techniques like AHP (Analytic Hierarchy Process), MOORA (Multi-Objective Optimization by Ratio Analysis), and TOPSIS (Technique for Order Preference by Similarity to Ideal Solution) have been used effectively. To cope with the ambiguity in agricultural data and expert opinions, fuzzy set theory has also been incorporated into MCDM in numerous research. Fuzzy AHP and fuzzy TOPSIS, for instance, have been used to assess crop options according to risk, cost, and yield criteria. However, because of shifting soil conditions, shifting markets, and changing climates, indeterminacy—or incomplete or inconsistent information—is highly common in agriculture and is only partially captured by the fuzzy framework, which focuses on ambiguity. In an effort to get around this, new studies have started investigating neutrosophic sets, which are fuzzy and intuitionistic fuzzy sets extended by adding three independent parameters: falsehood (F), indeterminacy (I), and truth (T). While neutrosophic techniques have been used in fields including risk analysis, supply chain management, and healthcare, they are still hardly used in agricultural crop selection.

Novelty of This Work

This research introduces a SVN TOPSISmodel for agricultural crop selection, which represents a novel contribution in the following ways:

1. SVNS and TOPSIS integration for agriculture The SVNS framework lends the evaluation more realistic by simulation of indeterminacy in agricultural data, in contrast to fuzzy techniques.
2. Use of longitudinal (10-year) data: The strategy utilizes use of ten years' worth of crop performance data to make sure that choices are made based on long-term agricultural patterns rather than the circumstances of a single year.
3. Extensive evaluation criteria: The study offers a comprehensive framework for decision-making by taking into account important factors such yield, water demand, insect resistance, market price, and maturity duration.
4. Validation of a practical case study: The suggested method shows its suitability for actual agricultural planning and policymaking by ranking the four main crops (wheat, maize, soybeans, and cotton).
5. Advancement of MCDM literature: By tackling a significant real-life issue—crop selection—where ambiguity, inconsistency, and uncertainty coexist, the study broadens the use of neutrosophic MCDM.

Neutosophic logic and MCDM technique are thus combined in a novel approach that has not been thoroughly investigated in agricultural decision-making, offering a more adaptable and trustworthy assessment tool.

METHODOLOGY

Preliminaries

Fuzzy Set

Let M' be a non-empty set.

$\mathcal{N} \subseteq M'$ is defined as,

N = $\{(m, \mu_{\mathcal{N}}(m)) | x \in M'\}$, where $\mu_{\mathcal{N}}(m)$: $M' \rightarrow [0, 1]$is the membership function of the fuzzy set $\mathcal{N}$.

Neutrosophic Set

Smarandache devised the mathematical model known as a Neutrosophic Set, which ellaborates the idea of a fuzzy set by giving each element three components:

$$\mathcal{A} = \{\langle m, T(m), I(m), F(m)\rangle / m \in \mathrm{U}\}$$

Where for each element$x \in$ U

- $T(m) \in [0,1]$ - truth-membership degree
- $I(m) \in [0,1]$ - indeterminacy-membership degree
- $F(m) \in [0,1]$ - falsity-membership degree

$$\mathbf{0} \leq T(m) + I(m) + F(m) \leq 3$$

Single Valued Triangle Neutrosophic number (SVTN)

A SVTN number $\tilde{A}^N$= ⟨(o,p,q); $w_{\tilde{a}}$, $u_{\tilde{a}}, y_{\tilde{a}}$⟩, whose TM, IM, and FM are given below:

$$\mu_a(m) = \begin{cases} \dfrac{(m-o)w_{\tilde{a}}}{p-o}, o \leq m \leq p \\ w_{\tilde{a}}, m = p \\ \dfrac{(q-o)w_{\tilde{a}}}{(q-p)}, p \leq m \leq q \\ 0 \quad , otherwise \end{cases} \quad \vartheta_a(m) = \begin{cases} \dfrac{(e-m+u_{\tilde{a}}(m-o))}{p-o}, o \leq m \leq p \\ u_{\tilde{a}}, m = p \\ \dfrac{(m-p+u_{\tilde{a}}(q-m)}{(q-p)}, p \leq m \leq q \\ 0 \quad , otherwise \end{cases}$$

$$\gamma_a(m) = \begin{cases} \dfrac{(p-x+y_{\tilde{a}}(m-o))}{p-o}, o \leq m \leq p \\ y_{\tilde{a}}, m = p \\ \dfrac{(m-p+y_{\tilde{a}}(q-m)}{(q-p)}, p \leq m \leq q \\ 0 \quad , otherwise \end{cases}$$

Case Study

Plenty of nations, particularly emerging ones, continue to rely substantially on agriculture for economic stability, rural livelihoods, and food security. In a particular season, choosing which crop to grow is one of the most important choices that farmers and politicians must make. In addition to farm productivity and profitability, this choice affects sustainability in terms of soil fertility, insect management, water use, and climate change resilience.

Crop selection is inherently a **MCDM problem**, as farmers must simultaneously consider diverse and often conflicting factors such as:

- **Yield potential** (ensuring higher productivity),
- **Water requirement** (vital in regions with scarcity or irregular rainfall),
- **Pest and disease resistance** (reducing dependency on pesticides),
- **Market price and economic returns** (ensuring profitability),
- **Maturity period** (matching cropping cycles with climatic and market windows).

In actuality, indeterminacy and uncertainty make it difficult to evaluate these criteria. Because of shifting insect dynamics, soil heterogeneity, unpredictable climate variations, and shifting market pricing, agricultural data gathered over a number of years may be imprecise or incomplete. This indeterminacy cannot be well captured by conventional decision-making methods, such as statistical models or even fuzzy MCDM procedures. A more thorough decision-support framework that takes truth, uncertainty, and falsehood into consideration at the same time in the evaluation process is therefore desperately needed. In order to solve this, the current work suggests using SVN-TOPSIS for agricultural crop selection. This allows decision-makers to efficiently evaluate crop options in imprecise and uncertain contexts.

Agricultural Crop Data (2015–2024)
The chosen agricultural crops are given in fig.2

Study Area
This study focuses on agricultural crop selection in India, one of the world's major agrarian countries, where agriculture plays an important role in rural livelihoods and national food security. India cultivates a wide range of crops across several agro-climatic zones, however determining the best crop is frequently hampered by variations in rainfall, soil fertility, insect incidence, and market dynamics. Four representative crops were examined for evaluation: wheat, maize, soybean, and cotton, each of which plays an important part in the Indian agricultural system.

- **Agricultural systems:**
  Wheat - A basic food crop and the second most significant cereal in India after rice, primarily farmed in the northern states.
  Maize- A versatile grain crop grown in a variety of states with diverse agro-climatic conditions.
  Soybean- A key oilseed crop that contributes to both domestic consumption and exports, with a high concentration in central India.
  Cotton– A valuable cash crop that is widely grown in western and southern India. It is important to the textile industry, although it is water-intensive and pest-prone.

The agricultural crops data are provided in the **Table 1**.

Data Sources by Criterion
The dataset used in this study spans 2015-2024 and was generated from *Ministry of Agriculture & Farmers Welfare (Government of India), FAOSTAT, and ICAR (Indian Council of Agricultural Research)* reports, as well as expert input from agricultural experts. The research region covers a ten-year period, capturing both temporal variability (year-to-year changes) and spatial variability (across distinct agro-climatic zones), ensuring that crop evaluations reflect long-term agricultural performance rather than short-term variations.This region was chosen as the research location not just for its economic and food security relevance, but also because it exemplifies the uncertainty and complexity that characterizes agricultural systems in developing countries. The paradigm described here can be used to various places across the world, as long as similar agricultural data is available. The data source and the processing methods are given in **Table 2**.

Step 1 SVN decision matrix
Alternatives (Wheat, Maize, Soybean, Cotton)
Criteria ($\mathcal{G}_1$ Yield, $\mathcal{G}_2$Water, $\mathcal{G}_3$ Pest, $\mathcal{G}_4$ Price, $\mathcal{G}_5$ Maturity). (T, I, F). Represented in **Table 3**.
Step 2 Normalization
We normalize each component (T, I, F) **per criterion** using vector normalization is represented in **Table 4**.
Step 3 -Weighted Normalized SVN matrix $\mathcal{W}j$=0.30,0.20,0.20,0.20,0.10 is given in Table 5.
Step 4- PI ($\mathcal{A}+$) and NI ($\mathcal{A}-$) per criterion (T, I, F)
For each criterion:

- $\mathcal{A}^+$ = (max T, min I, min F)
- $\mathcal{A}^-$ = (min T, max I, max F)

PIS - $\mathcal{A}$+(per criterion)
The Positive Ideal solutions is given in Table 6.
NIS - $\mathcal{A}$−(per criterion)
The Negative Ideal solutions is given in Table 7.
Step 5–Distancesto $\mathcal{A}$+and $\mathcal{A}$−(Euclidean across all criteria & components)
Computed for each alternative are given in Table 8.
Step 6 -Final Ranking (by CC, higher is better)
Ranking of the crops are represented in Table 9.
Ranking (best → worst):
Soybean > Maize > Wheat > Cotton.
Graphical representation of the ranking is given in the Fig.3.

RESULTS AND DISCUSSION

Using a decade of agricultural data, four crops—wheat, maize, soybeans, and cotton—were assessed using SVN-TOPSIS framework based on yield, water requirement, pest resistance, market price, and maturity period. The most appropriate crop was determined by the proximity coefficients, which gave soybeans the best ranking, followed by maize, wheat, and cotton. While maize was constrained by higher water requirements, soybeans thrived because of their balanced output, moderate water requirements, steady market price, and good insect resistance. Cotton placed lowest due to its high-water consumption, slower maturity, and vulnerability to pests, whereas wheat performed moderately.The SVN-TOPSIS method produced a complex and trustworthy ranking by successfully capturing climate, market, and expert uncertainty. Because SVN-TOPSIS takes truth, indeterminacy, and falsity into account, it can make more accurate decisions under uncertainty than traditional TOPSIS. These findings provide farmers and policymakers with practical advice on how to allocate resources and choose crops in a sustainable manner.

CONCLUSION

This study evaluated four key crops—wheat, maize, soybeans, and cotton—based on market price, maturity period, yield, water requirements, and pest resistance using the Single-Valued Neutrosophic TOPSIS approach. Cotton came in last because of its high-water requirements and vulnerability to pests, whereas soybeans were the most appropriate crop because of their balanced performance across a number of categories. In contrast to conventional TOPSIS, the SVN-TOPSIS framework produced a dependable and nuanced ranking by successfully capturing uncertainty in the market, climate, and expert knowledge. Farmers and politicians can use these findings as useful assistance when choosing crops and allocating resources in a sustainable, data-driven manner.

Future Direction

The results of the research indicate the value that the SVN-TOPSIS framework is for agricultural decision-making, especially when managing uncertainty resulting from expert opinions, market swings, and weather variables. Going future, a number of approaches can improve this research's robustness and usefulness. First, localized crop recommendation systems that are suited to particular agro-climatic zones may be developed with the aid of additional crops and regional variances. Second, incorporating dynamic elements like trends in water shortages, soil fertility variations, and climate change projections could enhance long-term decision-making. Third, hybrid models that further enhance crop selection under numerous uncertainties may be produced by integrating SVN-TOPSIS with other MCDM techniques, such as fuzzy PROMETHEE or AROMAN. Furthermore, using field monitoring and real-time market data can enable farmers to receive advice that are flexible and responsive. Lastly, these techniques can be used to more comprehensive agricultural planning, which includes scheduling irrigation, allocating resources, and developing pest control plans, in addition to crop selection. In addition to boosting sustainability and productivity,

such developments would fortify policy-level food security decision-making in the face of escalating economic and environmental difficulties.

Conflicts of Interest

The authors declare no conflict of interest.

Data Availability

All data that supports the findings of this study is available in the reputable Indian government surveys.

ACKNOWLEDGEMENTS

The authors are Thankful to the unknown referees for their valuable suggestions in improving the quality of manuscript.

ABSTRACT

Alzheimer's disease is a progressive neurodegenerative disorder marked by cognitive and memory impairment. Inhibition of acetyl cholinesterase remains a key therapeutic strategy; however, increased butyrylcholinesterase activity in advanced stages of the disease highlights the need for dual-target inhibitors. This has prompted the design of quinazolinone derivatives targeting both enzymes. This study aims to evaluate the inhibitory potential of designed quinazolinone-based derivatives against AChE and BChE using computational drug-design methodologies. Eighteen quinazolinone derivatives and the standard drugs Donepezil and tacrine were screened against acetylcholinesterase and butyrylcholinesterase using *insilico* approaches. Molecular docking was performed using Schrödinger Maestro v11.2 with Glide XP, while ligand preparation and optimization were carried out using LigPrep. Active-site identification was conducted using SiteMap, and binding free energies were calculated using the Prime MM-GBSA module. ADME/T properties were predicted using QikProp to evaluate drug-likeness, CNS permeability, and compliance with Lipinski's Rule of Five. Docking studies identified APM2 and APM3 as the most potent compounds against AChE and BChE, exhibiting higher G scores (−11 to −10 kcal/mol) than the standard drugs Donepezil and Rivastigmine. Prime MM-GBSA analysis revealed favorable binding energies for selected derivatives, while ADME/T predictions indicated good oral absorption, acceptable drug-likeness, and compliance with Lipinski's rule. The study

highlights quinazolinone derivatives as promising dual AChE/BChE inhibitors for Alzheimer's disease. Polar and alkyl amine interactions were found to influence binding affinity, providing a rational basis for the design of novel disubstituted quinazolinones as potential anti-Alzheimer agents.

Keywords: Alzheimer disease, acetylcholinesterase inhibitors, butyrylcholinesterase, Quinazolinone derivatives, Cholinergic pathway, Computational drug design.

INTRODUCTION

Neurodegenerative disorders are characterized by progressive dysfunction of the central nervous system, leading to neuronal loss and cognitive decline. Among age-related dementias, Alzheimer's disease (AD) is the most prevalent, presenting with impairments in memory, thinking, and behavior and progressively worsening over time. Key pathological biomarkers of AD include amyloid-β (Aβ) plaques and hyperphosphorylated tau (p-tau), which have been major targets in drug development, exemplified by recently approved anti-amyloid therapies such as lecanemab and donanemab for early-stage disease [1-3]. Acetylcholinesterase (AChE) is a serine hydrolase responsible for hydrolyzing acetylcholine (ACh) at cholinergic synapses and neuromuscular junctions. Its active site, located deep within a narrow aromatic gorge, contains a catalytic triad (Ser200, His430, Glu327) critical for enzymatic activity and ligand binding [4-6,19]. Structural features of this gorge, particularly key aromatic residues, play an essential role in substrate recognition and inhibition.

Butyrylcholinesterase (BChE), a tetrameric glycoprotein with a broader and more flexible active-site gorge, differs from AChE due to substitution of aromatic residues with smaller aliphatic amino acids. This structural variation allows BChE to hydrolyze a wider range of substrates [11,17,18]. Importantly, while AChE activity declines during AD progression, BChE activity increases, making it a dominant modulator of cholinergic transmission in later disease stages [7-10,12-14]. Current AD therapy largely relies on AChE inhibitors to enhance cholinergic neurotransmission; however, only 30–40% of patients show a favorable response, and efficacy declines as the disease progresses [13,14]. Consequently, multi-target-directed ligands (MTDLs) that inhibit both AChE and BChE have gained attention for improved therapeutic outcomes and potential disease-modifying effects, including delayed Aβ aggregation [15-17,21]. Nitrogen-containing heterocycles, particularly quinazolinone derivatives, have attracted considerable interest due to their broad pharmacological activities, including anti-cholinesterase effects [22-25]. Related scaffolds such as coumarins, sulfonamides, and quinolines have also demonstrated anti-Alzheimer potential through enzyme inhibition and additional mechanisms such as antioxidant and anti-inflammatory actions [20].

Advances in computer-aided drug design (CADD), including molecular docking and MM-GBSA free-energy calculations, have significantly accelerated early drug discovery by enabling prediction of binding affinity and identification of key molecular interactions prior to synthesis [26,27,30]. In this context, the present study employed Glide docking and Prime/MM-GBSA rescoring to identify promising quinazolinone-based dual AChE/BChE inhibitors with favorable bind.

MATERIALS AND METHODS

Acetyl cholinesterase and butyrylcholinesterase have several structures in the PDB database in different resolutions. AChE with the pdb 4EY7, resolution (2.35Å) and BChE (PDB ID 6EZ2), resolution (2.7Å) were selected based on the sequence Similarity. The initial X-ray crystallographic coordinates of PDF (PDB ID: 4EY7) and (PDB ID 6EZ2), were downloaded from Protein Data Bank (http://www.rcsb.org). The proteins were subjected to the [Protein Preparation Wizard, Schrodinger, LLC, New York, NY, 2017-1]. A small but promising group of 18 compounds database consisting of quinazolinone scaffold were created. The ligands were subjected to ligand preparation using the LigPrep module in the Schrodinger Suite [LigPrep, Schrodinger, LLC, New York, NY, 2017-1]. The module refined

the structures, energy-minimised the conformations, adjusted the spatial arrangements software helps with the identification of the receptor grid according to our needs. The site map application was used to find, visualise and evaluate protein binding sites [31-32]. Glide (Schrodinger, Inc.) methodology: In this study, two enzymatic targets with the co-crystallised ligand molecule (Donepezil) bound to the AChE structure (4EY7) and Carbamylated BChE (rivastigmine metabolite/intermediate) bound to butyrylcholinesterase BChE (6EZ2) were used to generate receptor grids, serving as a framework for docking-based virtual screening. The designed chemical scaffolds were subsequently positioned within the AChE & BChE, binding pocket, as defined by this grid, using the Virtual Screening Workflow (VSW) provided in the Schrodinger suite. A flexible docking approach was employed to model receptor flexibility, simulate the inherent plasticity of the active site and incorporate conformational changes in the binding pocket.[30-34] The docking scores summarized in Table 2 and all the molecules binding pose in the site is shown in the Fig. 3.

Prime MM-GBSA methodology: This application calculates the free energy binding between the receptor and a ligand in its complex. The protein-ligand binding free energies during the last 2 ns were calculated using the Prime/MM-GBSA module of Schrödinger suite [Suite] to get the averaged binding property. Residues in binding pockets of the protein were treated as flexible and the ligand partial charges were assigned by the initial charges.The binding free energy ΔGbind was estimated using the equation [Lyne, P.D]: ΔGbind = Gcmplex – (Gprotein + Gligand) [33-34].

Drug likeliness analysis

Pharmacokinetic properties—likewise absorption, distribution, metabolism, excretion, and toxicity (ADMET) — play a major role in initial phases of drug design and development. The analysis of these parameters provides specific insights into the drug-likeness of molecules, providing knowledge on how a compound will behave in a biological system. By integrating these evaluations early in the preclinical phase, researchers can more competently identify molecules with balanced set of physicochemical characteristics and optimal pharmacokinetics (PK) and pharmacodynamics (PD) behavior, thereby prioritizing compounds with higher therapeutic potential and increasing success rates early in the development pipeline [34]. In this study, the QikProp module of the Schrodinger suite [QikProp, Schrodinger, LLC, New York, NY, 2017-1] was used to assess the drug-likeness profiles of the top-scoring designed molecules. QikProp settings determine which molecules are flagged as being dissimilar to other 95% of the known drugs. The Qikprop helps us in analyzing the pharmacokinetics and pharmacodynamics of the ligands by accessing the drug like properties Predicted significant ADME/T properties such as permeability through MDCK Cells (QPlogMDCK) (Irvine, J. D), QikProp predicted log IC_{50} value for blockage of K+ channels (QPlogHERG), QikProp predicted gut-blood barrier (QPPCaco) (Luco, J. M.) and violations of the Lipinski's rule of five (LROF) (Lipinski, C. A). The molecular properties are provided in Table 1, Glide and Prime MM-GBSA rescoring values are listed in Table 2. The ADME properties were predicted so as to calculate oral bioavailability, dermal penetration, CNS penetration, metabolism and Toxicity. The results are shown in the table 3.

RESULTS AND DISCUSSION

Docking analysis demonstrated stable binding of the quinazolinone derivatives within the active sites of acetylcholinesterase (AChE) and butyrylcholinesterase (BChE), mediated by key hydrogen bonding and hydrophobic interactions. Catalytically important residues, including Gly116, Gly117, Ser198, Ser203, His447, and Glu334, were consistently involved in ligand stabilization, comparable to interactions observed with the reference drugs Donepezil and Rivastigmine (Fig. 7–10). The designed quinazolinone derivatives exhibited superior binding affinities relative to the reference compounds, with G-scores ranging from −11 to −3 kcal/mol for AChE and −10 to −4.9 kcal/mol for BChE. Among them, APM2 and APM3 emerged as the most promising dual inhibitors, supported by favorable MM-GBSA binding energy values. Complex stabilization was primarily driven by hydrogen bonding with residues Gly116, Gly117, Ala202, Gln223, and Ala208, along with hydrophobic interactions within the enzyme gorge (Fig. 7–

10). ADME profiling revealed that all selected quinazolinone derivatives complied with Lipinski's Rule of Five and Rule of Three. The compounds exhibited molecular weights below 500 Da, acceptable hydrogen bond donor and acceptor counts, predicted human oral absorption exceeding 70%, and favorable lipophilicity and brain–blood partition coefficients. These pharmacokinetic properties, summarized in Table 3, indicate good oral bioavailability and central nervous system penetration. Overall, APM2 and APM3 demonstrate strong potential as drug-like dual AChE/BChE inhibitors for Alzheimer's disease.

ABSTRACT

Dye-sensitized solar cells (DSSC) are among the most advanced solar cell technologies due to their exceptional properties, such as low cost and environmental friendliness. A good DSSC requires the proper combination of constituent materials, which significantly influences their performance. Strategies for identifying suitable material components in DSSC device configuration are required. In this article, we present information on the potential material combinations used to create DSSCs, with a focus on composite electromagnetic wave absorption properties. The composites were made using simple doctor blade techniques, with different Fe_2O_3 doping being too successful. Bandgap energy modulation for dye-sensitized solar cells (DSSCs) using organic dyes and binary oxides. A crucial factor affecting light absorption and the ensuing creation of charge in DSSCs is bandgap energy. In order to understand the synergistic effects of different combinations of organic dye and binary oxides on bandgap tuning, structural, optical, morphological, and electrochemical properties of the materials are analyzed through systematic exploration. Flexible counter electrodes and photoanodes made of novel materials were developed for the efficiency of DSSCs.

Keywords: Tunable bandgap energy, FESEM, Binary oxides, Electrolyte

INTRODUCTION

DSSCs, also known as "Gratzel cells," were fabricated for the first time in 1991 by O'Regan and Gratzel and are considered third-generation solar cells. [1] The construction and mechanism of a DSSC photoelectrochemical system. The general structure of such cells comprises a photo anode as a working electrode, a counter electrode, and an electrolyte filled in the space between the photoanode and counter electrode. The photoanode is made up of transparent conductive glass coated with transparent conductive oxide (indium- or fluorine-doped tin oxide; ITO and FTO, respectively), on which a dye-coated metal oxide semiconductor (thickness, 10–20μm) is applied [2]. The metal oxide semiconductor layer has two functions, namely support for the sensitizer and a carrier of photo-generated electrons from the dyes to the external circuit. Most of the reviews in the field of solar cells are dealing with the preparation of nanostructured electrode materials in DSSCs, but the crystal growth technique has been successfully employed for a purified form of material that exhibits better properties. [3] The generation of energy is one of the most important scientific and technological challenges in the 21st century. The commercially available solar cells are currently based on inorganic silicon semiconductors.[4] The demand for silicon will skyrocket within the next decade and the price of silicon will rise dramatically. Organic solar cells, therefore, appear to be a highly promising and cost-effective alternative for the photovoltaic energy sector. [5] In this context, dye-sensitized solar cells (DSSC) have attracted considerable attention in recent years. The structure, crystallinity, and surface morphology of photoanode materials can influence the efficiency of the DSSCs or Key parameters. Direct solar light conversion into electrical energy is one option for the use of renewable energy.[6] Nanocrystalline materials have garnered a lot of interest from researchers throughout the world in recent years due to their remarkable optical, electrical, and mechanical capabilities compared to their bulk-phase counterparts.[7] Many efforts have been made in recent years to include metals with typical optical properties inside semiconductor devices. Therefore, the next stage toward propelling DSSCs as a future energy device would be to improve efficiency and device stability, as well as to reduce material and manufacturing costs[8]. An injected-like Dye-Sensitized Solar Cell's key components are a photoanode, electrolyte, and counter electrode. The majority of the photoanode is made of fluorine-doped tin oxide (FTO) glass, which absorbs a sensitizer like a 5-methylsalicylaldehyde with 2-(2-aminoethoxy) ethanol dye. The composition of the electrolyte is I^-/I^{3-} redox. Graphite and semiconductor binary metal oxides of Fe_2O_3 and $BaCrO_4$ were combined to create a counter electrode. The dye molecules absorb photons with sufficient energy when exposed to the sunshine to begin the transfer of electrons from their ground states to excited ones. Once in the semiconductor binary oxide film's conduction band, these excited electrons are subsequently transported to the conductive substrate, allowing current to flow to the counter electrode.[9] It is expected that the low cost of commercially fabricating DSSCs along with their good performance will replace conventional solar cells very sooner. Research is going on for improving the efficiency and viability of the cell. DSSCs are still at the start of their development cycle. Efficiency gains are possible and have recently started a more widespread study. Binary metal Oxide electrodes using Fe_2O_3 are Good semiconducting material compared to $BaCrO_4$. The conducting material Fe_2O_3 has high semi-conducting material easily conducting electrons at the time $BaCrO_4$ also worked in binary metals it easily conducted in the FTO glass. Its conductivity worked in UV – Visible. The dye UV – Visible range is 200nm – 585nm but compared to binary metal oxide is 200nm – 800nm it confirmed the active cell are highly conductive materials. The working electrode and counter electrode both have high electron-conducting properties, but efficiency is low because the photoanode's surface was passivated in some areas at the time the electrons were carried there. Passivation is avoided in this ongoing effort because of the new procedures' great efficiency. Materials are excellent at conducting electrons, but efficiency is low because the working electrode and counter electrode conducted electrons during a time when some of the surfaces were passivated. In this upcoming development, passivation is eschewed in favor of more efficient ways. The novelty of work we formed the solar cell with the Tunable band gap energy of the binary metal oxide with dye molecules.

EXPERIMENTAL

Materials

Pure compounds from 5-Methylsalicylaldehyde, 3-cholroaniline, metal oxides Fe_2O_3 and $BaCrO_4$, and solvent ccl_4 acetic acid, hydrochloric acid used for the synthesis were purchased from Sigma-Aldrich as Analytical reagents with 99% of purity. I^-/I^{3-} iodide solution used as Redox electrolyte.

Synthesis of Dye preparation

The 5- Methyl salicylaldehyde, which has been dissolved in 5ml of CCl_4 and the 5ml of acetic acid, was grown into a single crystal using slow evaporation methods. Drop by drop, with stirring process continued for an hour at ambient temperature, 0.18 (0.00141) of 3-Chloroaniline was added to this solution. The mixture deepened to golden at this point. With a slow evaporation technique, crystal forms after two weeks of standing. The dye's chemical response, as shown in fig.1

Chemical Reaction

$C_7H_5NO_4 + C_4H_{11}NO_2 \longrightarrow C_{11}H_{14}N_2O_5$

Chemical Structure

Chemical structure of Dye – [E-3CM4M] (Fig.1).

Synthesis of Binary Oxides Fe_2O_3 / $BaCrO_4$ preparation

The electrodes made from the synthesized nanoparticles were used to get the findings presented in this study and pure Fe2O3 nanoparticles were combined in 0.1 g (0.00062 mol) of powder, which was then dissolved in 1 ml of hydrochloric acid, to create a slurry solution using a standard sample preparation method. The particle dispersions in the mortar were combined with 0.1 g (0.00039 mol) of barium chromate powder, 1 ml of hydrochloric acid, mixed with Fe_2O_3, and hydrochloric acid was added dropwise. Thin film processing was used to create the finished Fe_2BaCrO_7paste. The area that was going to be coated with FTO thin film was marked using Scotch tape. The entire FTO substrate was covered with a homogeneous layer of paste. Fe_2BaCrO_7 0.15g was spin-coated for 20 seconds at a speed of 3000 revolutions per minute (RPM). The films were then annealed to increase their crystallinity. The samples were first dried at room temperature for half an hour.

Preparing the electrolyte

We extracted Graphene from the HB pencil to make counter electrodes. To obtain a dark shade of Graphene for one of the counter electrodes, the conductive side of one FTO-coated glass was held over the point of HB pencil for 30 seconds. Iodide/triiodide has been a redox couple being used all through the entirety of the DSSC analysis, and it has proved that the most adaptable redox couples thus far, combination gives conversion efficiency is 11 – 12% and having good life span.

Assembling the Cell and Cell Performance DSSCS

We can easily fabricate an unsealed DSSC and measure its PV performance. A spacer film, such as polyethylene (15- to 30-µm thickness), is placed on the dye-coated TiO2 photoelectrode and then the electrolyte solution is dropped on the surface of the TiO2 electrode using a pipette (one or two drops). The counter electrode is placed on top of the TiO2 electrode, and then the two electrodes are fastened together with two binder clips. If a low melting point polymer film such as Surlyn is used instead of the spacer film, we can fabricate a sealed cell after packaging of the cell using a resin (e.g. ethylene vinyl acetate, EVA) for long-term stability. Since Gratzel and coworkers reported high performance of a DSSC in 1991, many ¨ workers worldwide have tried to reproduce their result. Some reported performances are shown in Table 15.1. These cells were fabricated using a Ru complex photosensitizer, N3 dye, and a nanocrystalline Fe_2BaCrO_7 electrode. In many cases, the light condition is AM1.5

Characterization

X'Pert Pro-Panalytic was used to capture powder X-ray diffraction using Cu K X - radiation (=1.5406) at 40kV and 30mA power. The X-ray Diffraction pattern was gathered in the 2 regions between 0 and 100. DASH 4.0.0 was used to monitor the lattice parameters. Perkin Elmer Lambda 950 UV VIS NIR Spectrometer having Deuterium lamp source was used to collect optical transmission data at room temperature between 200nm and 1100nm with a precision of 0.05nm and an accuracy of 0.08nm. The sample's absorption bands are visible between 200 and 800nm. One of the frequently used techniques for visualizing the microstructure and shape of materials is field emission scanning electron microscopy. Technical requirements 1.5nm nominal precision at 10 kV (Zeiss Sigma 300). I- V traits displayed by a 20 W source parameter is 2450 from Keithley (SMU). The SMU has a maximum current source of 1 A, a maximum voltage source of 200 V, and a measurement resolution of 0.01/10 (Current/Voltage).

RESULTS AND DISCUSSIONS

Powder X ray diffraction (PXRD) study

Powder X-Ray diffraction was recorded on the X'Pert Pro- Pana lytic system using Cu Kα X-radiation ((λ=1.5406Å) at 40 kV and 30 mA power. X-Ray diffraction patterns were collected over the 2θ range 10° - 80°. The Rietveld refinement method and the simulated annealing structure solution have been used in the DASH 4.0.0 program to solve crystal structures. Structural affirmation accomplished by well-defined strong XRD Bragg's diffraction pattern with assigning NMR chemical shifts and its data analysis. The structure is shown in Figure 3. PXRD of Dye Figure.2. The diffraction analysis of this growth inter-planar line spacing corresponds to scattering planes. PXRD data of photo anode (Dye) is shown in Fig 4. Major Diffraction Peak located in monoclinic phase at 2Θ values of with relatively very high intensity. From PXRD fig 2. Lattice parameters like crystalline size, Dislocation density, and lattice strain using Debye's Scherrer formula are shown in Table.1 [10].

Powder X ray diffraction (PXRD) analysis (Table 1).(Fig 3).

UV-Visible-NIR_ spectroscopy of Dye

The main impacts on coloring effectiveness sensitive solar cells for the light scattering and greater dye absorption [11] Figure 4. Depicts the dye film's UV-visible absorption spectrum. These data indicate that the dye material absorbs between 200nm to 575nm.

The dye's band gap energy is 2.15eV, confirming the semiconducting of material.

UV –Vis-NIR- Spectroscopy for Binary metal oxides

The Fe_2O_3 based DSSC with the $BaCrO_4$ layered dispersion of light was studied using UV-visible absorbance spectra. Soaking the photo anode helped remove the loaded dye. Displays a dye with UV-visible absorbance spectrum that was isolated from Fe2O3 using $BaCrO_4$ and an electrolyte. Semiconducting material validated the UV - Visible study by adjusting band energy gap. The bandgap energy spectrum of Fe_2O_3 oxide is 2.5eV, whereas the energy band gap of $BaCrO_4$ is 2.3eV. The band energy gap of the combined counter electrode Fe_2BaCrO_7 is 1.65eV. The UV spectrum is depicted in Figures 5(a), 5(b), and 5(c) [12]. Figure 5(a). UV – VIS - NIR spectrum of Fe_2O_3. Figure 5(b). UV – VIS - NIR spectrum of BaCrO4 Figure 5(c) - UV – VIS - NIR- spectrum of binary metal oxide (Fe_2BaCrO_7)

Field emission scanning electron microscopy:

The particle hasshape in nano dimensions became apparent. As shown in Figure 6. The dye granules had an average diameter of 2-20 μm. In 1m microphotographs, the fractured surface fragments are visible. Gas molecules cause the electron beam to be disturbed, and the resulting secondary and backscattered electrons, which are used to image the particles, appear to be 2 m in size. Particle studies are conducted in a strong vacuum. [13]. Field Emission Scanning Electron Microscopy (Figure 6).

The characterization performed using the solar simulator at cell electrical performance as analyses under one sun illumination and under dark conditions, the measurements to I-V parameters of the cell from tabulated 2. The observed in the low to high medium voltage and current-range of cell [14]. The photo-anodes absorbed to the electrolytes it's conducted to cathode device fabrication confirmed the fill factors and hence cell performance achieved. The optimization of the device fabrication parameters are maximum voltage, maximum current, and fill-factor confirmed by I- V curves. I _V characteristics of DSSC (Table. 2) (Fig 7).

CONCLUSION

The Synthesis of novel materials, the development of fabrication of DSSCs their properties and performance in real devices and latest development of tunable bandgap material for solar energy conversion. We produce photo anode in with the technique of crystal growth for purified version and used powder as organic dye photo anode were analyzed by PXRD, UV and FESEM to understand the structural, optical and morphological behavior of the dye material. The dye samples' UV–vis spectra revealed high absorption, Result indicates that the Fe_2O_3 and $BaCrO_4$ composites exhibit improved absorption performance compared to individual components, The findings shed light on the mechanisms underlying bandgap energy modulation in DSSCs, offering insights into the design and optimization of next – generation photovoltaic devices for enhanced energy conversion efficiency DSSCs.

ABSTRACT

Molluscs, the most vulnerable species to climate change, play an ecological role in nutrient cycling and filtration of water, and they support the food web and help in the economy of the country. This review highlights the research conducted with mollusc species to assess their durability against various environmental gradients. The physiological process, which includes shell construction, reproductive mechanisms, and larval development, is disrupted when sea surface temperature increase. The sea surface temperature increased in natural ways such as radiation and seasonal changes, and it is also caused by human activity such as pollution, deforestation, etc. The equilibrium of the ecosystem is changed mostly by the process of ocean acidification. Beyond their ecological impact, it also affects the economy of the country by reducing the total population of the mollusc species, and this causes low commercial production of them. The population loss of this organism would affect the food web of the ecosystem and the employment of the people who work in the mollusc shell-based industries. When the sea level rises, it impacts the mollusc by reducing the availability of food and habitat shift; the species that depends on the sandy beaches would lose their habitat. These impacts cause the reduced annual production of molluscs such as mussels, oysters, etc. This paper aims to deliver the information about the reasons for climate change, the challenges faced by the mollusc and the measures to prevent the loss of organisms that are economically important for the country.

Keywords: Anthropogenic activities, global warming, bivalvia, salinity, aquaculture.

INTRODUCTION

Climate change occurs mostly due to anthropogenic activity, especially through industrial activity, burning of fossil fuels, and deforestation, which leads to the emission of greenhouse gases such as carbon dioxide, methane, etc., causing the accumulation of heavy metals in the environment and ocean acidification (OA). The rise in the level of carbon dioxide and decrease in the level of pH pave the way for ocean acidification (Allison et al., 2011). Due to industrial revolution, the carbon dioxide level in the atmosphere has increased by up to 400 ppm (Lamichaney and Maity., 2021.), and the pH level has decreased by 30% (Fortunato, 2015). It affects the majority of the marine organisms by means of calcification. It causes a greater impact on the phylum Mollusca because they are the most vulnerable (Przeslawki et al., 2005). Phylum Mollusca is the second largest phylum in the animal kingdom (Kershaw, 1983). Climate change has a greater impact on marine, estuarine, and freshwater organisms. It causes greater ecological and economic consequences (Parker et al., 2013). Due to elevated carbon dioxide exposure in the sea, it challenges the aquaculture by affecting the larval development, reproduction, metabolic activity, and production of molluscs such as clams and oysters (Cooley et al., 2012; Byrne, 2010). The impacts include shell weakening, larval mortality, growth reduction, heat stress, and salinity stress (Dickinson et al., 2013). The mortality of the mussel increases when the temperature gets higher than 29 ℃ (Dailianis, 2011). These changes will cause mismatched food availability in the marine and freshwater ecosystems. There is also a positive impact on the mollusc but the negative impacts are more prominent. The mollusc species, which inhabit freshwater and marine environments, may potentially get introduced into previously uninhabited areas by migrating into the deeper or cooler habitats, and the poleward range shifts will introduce the organism into a new ecosystem (Saupe et al., 2014). Some bivalves have greater resistance to lower temperatures because of the presence of antifreeze proteins in their hemolymph (Husmann et al., 2011; Zhang et al., 2024).

The physical processes in the aquatic systems, like the major ocean currents, are changing due to global warming. It changes the temperature of the water; the mortalities of the seed and the adult mollusc occur when the temperature changes from 28-31 ℃ (Rodrigues et al., 2015). The mollusc can be cultured in both temperate and tropical environments through semi-intensive line and raft cultivation using mussels and scallops in marine and brackish water (Allison et al., 2011). Molluscs are used as decorative items and also for pharmaceutical purposes (Murphy and Kerton, 2017; Romano et al., 2022; González and Vallejo, 2023;). The population in developing countries greatly depends on the mollusc because it has protein content, which is used for consumption and has a higher commercial value (Roy et al., 2008).

Impacts of Salinity

Salinity is a key abiotic factor, that can directly influence the life cycles of aquatic species (Madhavi et al., 2014). The adult *Mytilopsis leucophaeata* is extremely resilient to changes in the salinity and temperature (Verween et al., 2007). For *Abra ovate, Cerastoderma glaucum,* and *Caspiohydrobia species*, the ideal salinity gradient with Aral salt composition was between 17 and 27 psu (Krupa and Grishaeva, 2019). The survival rate of the larva *Crepidula plana* was greater in all temperatures, but at lower salinity the larva was intolerant (Zimmerman and Pechenik, 1991). At 16.7 psu the juveniles of *Donax trunculus* show higher tolerance to lower salinity (Reyes-Mart*ínez et al., 2020)*. When the external seawater salinity level decreases from 30 to 25 psu, it does not affect the salinity of the water in the pallial cavity of the gastropods; even after 2 to 12 hours of isolation, the salinity level is constant in the pallial cavity of *Crepipatella dilatata,* and the same happens to *Ostrea chilensis* (Chaparro et al., 2009). The veliger larva of the *Crepipatella peruviana* shows reduced velar activity when exposed to 20 and 15 salinity, but when the adults are exposed to the external environment, which has salinity value ranges from 32 to 25, and after some time when the value is declined to 15, the salinity value of the water inside their mantle cavity remains at 25 which means that the adult can isolate themselves from the external environment (Montory et al., 2016). Low salinity might worsen the detrimental effects of high CO_2 levels on the biomineralisation and growth energy balance of the eastern oyster, the *Crassostrea virginica*, a common

estuarine bivalve (Dickinson et al., 2012). The juveniles of *Mercenaria mercenaria* show a higher mortality rate when exposed to lower salinities (Dickinson et al., 2013).

Temperature Rise in Marine and Freshwater:

The major environmental factor is the temperature and it changes depending on the season and the year. The changes in the climate, mainly the temperature, will affect the distribution and the survival of the intertidal species in the upcoming few decades (Somero, 2010). When SST increases, it affects the different life stages of the species and the physiology of the species such as less potential to develop their organic protective layers, i.e., the shell, and a decrease in the growth rate and survival rate (Gazeau et al., 2013). The metabolic rate of the mollusc will be higher at warmer temperatures (Brodersen et al., 2011). The cold-water mollusc species may switch to more thermophilic places when the water temperature rises (Daufresne, 2004). The adult molluscs are more vulnerable to the temperature rise, and the mortality rate is 100% in the summer when the temperature rises to +3 °C (Rodrigues et al., 2015). The embryo of the *Aplysia californica* shows high mortality at temperatures above 30°C and below 10 °C (Verween et al., 2007).When the thermal level of the water increases more than 4 °C some species, which include *Crassostrea gigas,* show robust activity (Gibson et al., 2011). *Haliotis coccoradiata,* an abalone that is highly vulnerable to slight increases in temperature, which causes deleterious effects because abalone has a specific level of tolerance to the temperature (Gilroy and Edwards, 1998). When the temperature of the water increases, it helps the development of the oysters, and the reverse happens when the acidification increases (Parker et al., 2010).

Regulation of reproduction by temperature:

Reproduction can be directly impacted by temperature in both quantitative and qualitative ways (Gust et al., 2011). It has been projected that climate change will raise the average world temperature and influence how species interact with one another (Kalinda et al., 2017). Temperature is one of the most significant abiotic factors. The terrestrial gastropods are highly impacted by the environment they live in and depend on the environment for their development and for reproductive life (De Vaufleury, 2001). Fabioux et al. (2005), did an experiment by examining the gametogenic cycle of *C. gigas,* where the temperature played a vital role in their gonial mitosis regulation. When the temperature phase gets changed, it will affect the annual reproductive cycles of the mollusc because the temperature phase depends on the photoperiod and the mean sea temperature (Olive, 1995). The alteration in the external environment will mostly impact the larval forms; they are the most susceptible to the environmental alterations (Claudi and Evans, 1993). An experiment is done with the *Aplysia californica* to prove that the reproductive system of the *A. californica* is reliant on the photoperiod and the temperature because their results show that the species lay more eggs when they are kept in short days in warm water compared to long days in warm water (Wayne and Block, 1992). The fertilization rate is increased in the oysters when treated with elevated levels of temperature at 8°C, and the reverse happens when treated with temperatures more than 12°C (Parker et al., 2010). The absolute water temperature and seasonal day length cycles will affect the production of egg capsules of *Rapana venosa* (Harding et al., 2008). Increasing temperature shows negative impacts on the early ontogenic stages of the *Armina maculata* (Pires, 2012).

Ocean Acidification

Impact on Mollusc Shell Formation:

The ocean acidification plays an interrelated role with climate change and its impacts. The mollusc shell plays an important role, which provides protection from predators, and it provides its shell for other living organisms for attachment (Gutierrez et al., 2003). The seawater chemistry gets altered by the OA caused by industrial activity (Cooley et al., 2012) and the increased carbon dioxide level will affect the shell which is made up of $CaCO_3$ .The shell hardness and the rigidity of the oyster, *Magallana angulata*, will be reduced because of the exposure to ocean acidification (Meng et al., 2018). The species of mollusc such as mussels and oysters, need their shell for a defence mechanism from predators (Kroeker et al., 2014).

The shell of the adult mollusc is constructed with aragonite, or in some cases it is made up of both calcite and aragonite, but it occurs in specific taxa (Addadi et al., 2006). The shell of the mollusc shows reduced aragonite

thickness in their shell, and the structure of the shell is changed when they are grown under ocean acidification state (Fitzer et al., 2015). Since 2005, the survival of the oysters has been reduced in the hatcheries that are present on the Northwest coast of the USA, and this is caused by the ocean acidification that occurs in the deep water and on the ocean shore (Barton et al., 2012). Even under a very low level of pH, the shell of certain species of the mollusc is developed (Gazeau et al., 2013). Some species can maintain their shell structure, but they utilise more energy. The ocean acidification causes lasting larval life in the water; this causes predation on the larvae because they have a less developed shell over them (Ross et al., 2011). The calcification of the mollusc is decreased due to the alteration of the proteins needed for the calcification when the water is acidified (Dineshram et al., 2021). The inhibition of shell growth and the abnormalities in their morphology are caused in *C. gigas* by the acidification in the ocean by elevated levels of CO_2 (Barros et al., 2013). The ocean acidification has more effects on the survival of the molluscs in the marine environment, and it also affects the developmental process and the framework of the shell (Gazeau et al., 2013; Kroeker et al., 2014). The transcription of arginine kinase and the cavortin downregulation would affect the calcification of the oyster (Ducker and Falkenberg, 2020).

Population Consequences:

Ocean acidification threatens the population of the shelled mollusc by changing their resistance of the shell (Zhang et al., 2024). The population of healthy oysters is threatened by bioerosion and by ocean acidification, and this affects their restoration ability (Böök et al., 2024). On the coast of British Columbia, they conducted a survey, and the results show that the mollusc population has decreased up to 80% since 1978 (Hankewich and Lessard, 2006). Due to ocean acidification, the food web would be changed, and the species would lose their habitat to live in which reduces the population density, and the people who are dependent on the mollusc would lose their food and employment (Newell, 2004). The population of the *Limacina helicina* is reduced in the polar ecosystem, and these changes will impact their ecosystem (Comeau et al., 2009). When the larval equilibrium gets disturbed because of ocean acidification, this causes an alteration in the adult population of the mollusc (Ross et al., 2011). Under ocean acidification, the mollusc species *Saccostrea glomerata* population is reduced, and the commercial production of these rock oysters is reduced because of the inappropriate biomineralisation process (Fitzer et al., 2019). The estuarine bivalve population will decreases when the mortality of the young ones increases due to the elevated carbon dioxide level in the water caused by anthropogenic activity (Guinotte and Fabry, 2008). The elevated level of carbon dioxide in the water has a direct negative impact on molluscs and the tolerance to the CO_2 level is different for different species i.e., species-specific (Kurihara, 2008).

Impacts on the Reproduction of Molluscs:

The reproductive life of the mollusc is broadly affected due to the changes in the seawater chemistry. The marine shelled mollusc had a wide range of cellular processes, and this organism is affected by the ocean acidification (Böök et al., 2024). This phylum includes two important classes: Bivalvia and the Gastropoda, which are especially sensitive to ocean acidification (Qian et al., 2024). When the oysters get overexposed to the ocean acidification during gametogenesis, the reproduction will be disturbed (Boulais et al., 2017). The sperm motility, fertilisation success rate and the qualities of the gamete are impacted when the extracellular pH is decreased (Boulais et al., 2018).

The distribution of the reproductive resources will be affected when the sex-specific growth, distribution of energy, and tissue regeneration are changed due to the ocean acidification (Padilla-Gamiño et al., 2022). All the life stages of the oysters are directly affected by the ocean acidification (Lemasson et al., 2017). The *Tritia reticulata* shows increased mortality when they are exposed to water with a lower pH level for only two days, and at the pH level of 7.5, they showed notorious expressions (Oliveria et al., 2020). Even when the larvae of the *C. gigas* and *Mytilus galloprovincialis* are treated with carbon dioxide, they form a convex hinge in their shell when reared at the pH of 7.8 and 1000 μ atm pCO_2, and this feature is used in the embryo toxicology bioassays to identify the irregular development of the veliger larva (His et al., 1997). When the parent *Saccostrea glomerata*, exposed during their reproductive state to the lower pH condition, their larvae show a greater performance in their physiology (Parker et al., 2010). The total number of post-fertilisation (18 hours) D-hinge oyster larvae is reduced when the female is exposed to the lower pH before their reproductive stage (Venkataraman et al., 2019). The gametes of the *C. virginica* exposed to lower pH and the result of

this experiment shows that the survival rate of the larvae is higher, but they show increased levels of defects, and the height of the shell is lessened (Clements et al., 2021).

Sea Level Fluctuations and Habitat Loss:

When the volume of the ocean increased and the melting of ice increased, these phenomena led to the cause of global sea level rise (Bellard et al., 2013). The tropical oceanic islands, which are located in the central Pacific affected by the Cenozoic sea level fluctuation, harmed the bivalve population's survival (Paulay, 1990). Climate change paved the way for the sea level rise; it disturbs the estuaries and their intertidal habitats (Dixon et al., 2023). Deforestation by humans caused the extinction of fauna (Richling and Bouchet, 2013). The beds of the shellfish and their habitats have been destroyed by overfishing, developments in the coastal areas, and pollution (Gibson et al., 2001). Most of the coastal marine ecosystems are facing habitat loss because of more human activities. The sea level fluctuations mostly affected the habitats in the soft sediments and the bivalves in the soft bottom compared to the bivalves in the hard bottom (Paulay, 1990). Due to the construction of the boardwalk bridge, people gained access to enter the subtropical mangrove forest; it disturbed the assemblage of molluscs and their habitat (Skilleter and Warren, 2000). There are 46 endemic land snail species recorded based on the details collected in the museum in Gambier Island, and the snails belong to the families Euconulidae, Endodontidae, Assimineidae, and Helicinidae (Bouchet and Abdou, 2003). The global sample of land snails was collected in 2015, and it shows that about 3000-5100 species of the mollusc have become extinct due to the destruction of their habitat and the impacts of climate change (Régnier et al., 2017). The cause of extinction and altered distribution of the species in the late Cenozoic is due to the occurrence of sea fluctuation (Harzhauser and Neubauer, 2021).

Economic Impacts

The commercial fisheries, particularly the calcifying shellfish species, are at a greater threat due to ocean acidification. The reduction in the harvests of commercially important species is caused by ocean acidification, and it directly affects humans, through the social and economic connections (Cooley and Doney, 2009). Ocean acidification will also affect the capture fisheries in the coastal environments (Narita et al., 2012). Shellfish aquaculture is affected due to climate change and also by the pollution caused by humans (Allison et al., 2011). The anthropogenic source of pollution is greater due to increased human population and coastal development, which results in the lower sanitary quality of nearshore waters, and the shellfish cultured in the water are not suitable for consumption (Langan, 2009). The major threats faced by the *conus* species under the risk of extinction are pollution and habitat loss due to the spillage of petrol and other developmental activities in the coastal regions (Peters et al., 2013). The ocean acidification caused by climate change poses a greater threat to the future bivalve aquaculture by affecting the carbonate mineral saturation level and disturbing the formation of the shell (Vaughn and Hoellein, 2018). Ocean acidification and sea warming are caused by the increasing greenhouse gas effects, and this has a greater effect on the economy of the Mediterranean Sea and poses threats to the mollusc habitats as well as endemic species in the sea (Campos Rodrigues, 2016). Due to over greenhouse gas emissions by human activity causes, more carbon dioxide levels in the marine ecosystem and this lead to the alteration in the marine ecosystem, which directly affects the production and supply of the marine resources, which also affects the economic values, and the population who depends on the marine resources is changed (Tisdell, 2015). The aquaculture of abalone is also affected by the ocean acidification, and some abalones grown in captive conditions show some resistance to the ocean acidification, and some are highly vulnerable to mortality (Swezey et al., 2020).

CONCLUSION

Climate change has a huge impact on both marine and freshwater ecosystems. Ocean acidification, salinity changes in the water, temperature fluctuations, and sea-level rise all have an impact on the physiology and behavior of species in the ecosystem. These environmental changes cause mollusc species to lose their habitats. The commercial output of shellfish, including molluscs, is being diminished. To mitigate the effects of climate change on molluscs, we must minimize greenhouse gas emissions, coastal pollution, and the usage of fossil fuels. Although we cannot

completely undo the consequences of climate change on molluscs, we may prevent them from occurring. The protection of mollusc habitat is critical. More research should be done to assess the mollusk's vulnerability to various effects of climate change. The mollusk's shell growth, habitat alteration, and species-specific susceptibility should all be investigated. We must raise public awareness about the need to restore mollusc habitat and develop conservation plans. To boost the country's economy, aquaculture should be conducted more frequently in order to raise yearly mollusc production. Molluscan populations must be protected for community and economic reasons. To protect the marine ecology, the effects of climate change on molluscs should be mitigated.

ACKNOWLEDGMENTS

The authors would like to express our sincere thanks to PG and Research Department of Zoology, Ethiraj College for Women (Autonomous), Chennai, for their constant encouragement.

Table 1 Stressors and their Impact on Mollusc Species.

Stressor	mollusc	Impacts	Reference
Ocean acidification	*H. coccoradiata*	Causes adverse effects on this larva.	Parker et al., 2010
	M. angulata	The hardness and the rigidity of the cell are decreased.	Meng et al., 2018
	C. gigas	Shell growth is inhibited and shows morphological abnormalities.	Barros et al., 2013
	M. edulis	The fracture toughness of the mussel is reduced, and the formed shell is fragile.	Fitzer et al., 2015
Salinity	*D. trunculus*	At 16.7 psu the juveniles show higher resistance to low salinity with higher survival rates.	Reyes- Mart*ínez et al., 2020*
	P. canaliculata	When this species is exposed to 0-6 psu for 30 days, the survival rate is more than 72%, and they can tolerate salinity.	Qin et al., 2020
Salinity and Temperature	*C. plana*	At lower salinity the larvae were intolerant, but the survival rate is higher at 20-29°C.	Zimmerman and Pechenik, 1991
	M. leucophaeata	A 4 hour old embryo has more impact when compared to a 2 day old embryo.	Verween et al., 2007
Temperature	*O.bimaculoides*	Shows increased growth rate due to elevated temperature during their developmental phase.	Forsythe and Hanlon, 1988
	A. maculata	The spawning of the adults and the survival rate of the embryos are higher at 22°C.	Pires, 2012
Temperature and Photoperiod	*C. aspersum*	Lay eggs in long days at a temperature of 15 °C, and the activity ceases in a short day environment.	Enée et al., 1982
	A. californica	Lay more eggs in short days in warm water than in long days in warm water.	Wayne and Block, 1992

Low pH	*C. gigas*	The rate of D-hinge oyster is diminished.	Venkataraman et al., 2019
	C. virginica	Larval survival increased, more abnormal development occurred, and shell development was reduced.	Clements et al., 2021

ABSTRACT

This review focuses on the regulatory constraints faced by Community pharmacists (CPs) and examines the possible impacts alongside the existing conditions of private-sector retail pharmacy laws and regulations in low-income nations where private healthcare financing plays a crucial role. Global rapid response measures have been implemented to curb the spread of the COVID-19 pandemic one year after it emerged. The European Medicines Agency and national regulatory authorities have approved numerous vaccines for use across Europe following rapid and successful pre-clinical and human trials. In many countries globally, formal pharmaceutical retailing is regulated by laws regarding ownership, personnel, medications, prescriptions, and pricing. Nonetheless, in many low and middle-income nations, enforcing these regulations is challenging or unfeasible due to limited government resources and further complicated by the disjointed structure of pharmaceutical retail markets. We examine regulatory structures in 25 nations, identifying the legislative and market drivers prompting shifts in retail pharmacy practices and the impacts these alterations have had in recent years. The extent of consolidation in the private pharmacy sector is influenced by four primary factors laws regarding

ownership, regulations for licensing and registration of pharmacists, the availability of qualified pharmacists, and access to finance for establishing a pharmacy.

Keywords Community Pharmacist (CPs), Regulatory Framework, Healthcare, pharmaceutical retailing, Covid-19.

INTRODUCTION

Community pharmacists (CPs) are viewed as among the most reachable health care professionals. The main function of community pharmacists includes the distribution of medications and procedures in a community pharmacy. Their role has evolved over time to include more clinical tasks such as immunizations, health screenings, and reviews of medication therapy, making them increasingly essential to health care stakeholders in enhancing medication-related metrics within populations. Studies show that patients over 65 years old tend to visit the CPs more often than their general practitioner. CPs deliver various degrees of direct and indirect patient care services, including disease management via medications, as well as Collaborative Drug Therapy Management (CDTM), Comprehensive Medication Management (CMM), or Medication Therapy Management (MTM).The main principles of a CP consist of 1. Patient care directly, 2. Delivery of care through team collaboration, 3. Management of patient care services and 4. Leadership in enhancing patient care. Moreover, CPs frequently cultivate enduring therapeutic connections with their patients, and they have demonstrated a heightened ability to tackle various population health concerns, including medication-related problems during care transitions. [5,6] Moreover, CPs are the most reachable health care providers for the general population, particularly for individuals with chronic health issues and poorer health. Frequent communication with the patients allows them to discover and address issues related to the patients' adherence to medication. Moreover, this consistent interaction with the patients fosters a strong rapport and trustworthy therapeutic connections between them. [7,8] Our aim was to identify the legal and regulatory structure for CPs regarding their future prospects and patient care. CPs can enhance patient outcomes with medications and mainly through the delivery of pharmaceutical care interventions. Pharmaceutical care activities focus on enhancing a patient's quality of life by delivering responsible medication therapy services [9,10]In developing nations, most of the population views CPs as the primary access to healthcare. The quality of pharmaceuticals is crucial given the rise of counterfeit and low-quality drugs globally.

CPs play a crucial part in ensuring the quality of medicines for the public, but this quality can only be upheld through proper storage and distribution. The CPs undergo regular inspections by the appropriate authority to confirm their regulatory adherence for storing and dispensing medications, and necessary regulatory measures are implemented to maintain compliance. The function of the CPs is examined based on risk, and the inspection frequencies differ between the CPs. All the CPs focus on creating and executing SOPs for the storage and distribution of medications in the pharmacies. [11] CPs are considered to be the primary agents for improving any treatment or medication adherence. [12] CPs who excel at recognising patient-specific, therapy-related, and structural factors that affect the patient's response to medications. They also recommend strategies tailored to each patient's cognitive skills and financial challenges. Furthermore, CPs offer education concerning particular medications, use follow-up phone calls to monitor adherence, encourage patients, and work with other healthcare professionals to promote correct medication administration.[13] Various intervention strategies have been suggested to enhance patient adherence, such as informing patients about their conditions, lifestyle choices, and prescribed treatments. CPs can also strive to recommend tools such as pill organisers and medication calendars to help remind patients about adhering to their medication schedule.[14] While several systematic reviews have explored the effectiveness of interventions conducted by healthcare professionals on adherence or clinical results, to our knowledge, many favourable effects were identified for more intensive, individualized pharmacist-led interventions.Many interventions that were supplied by the CPs include i.) Pharmacotherapy, ii.) Collaboration of pharmacists and physicians for implementing patient-specific care, iii.) Arranging counseling sessions to address patient concerns and iv.) Assessment of patient's

health. Although none has focused on the impacts of community pharmacist interventions on both adherence to chronic treatments and clinical outcomes. WHO has also confirmed CPs to be in a best position that can initiate cancer-screening programmes into their practice. They are in a suitable position to raise awareness among the patients who get OTC drugs about the possible control of cancer related signs and symptoms. [15-20] The WHO identifies CPs as the most available people to the public, and this could serve as a useful model for overseeing medical distribution, advising patients, and encouraging health initiatives and disease management services[20]. Pharmacy, as a health discipline, focuses on therapeutic drugs, and the CPs act as the link between the pharmaceutical manufacturer and the creator of the medications while also addressing the needs of the product consumers. Responsibilities are slowly shifting from the prescription of medications to their supply, and the CPs are granted complete authority to prescribe medications to patients. Clearly, CPs offers straightforward and impartial access to health services[21].

In many developed nations, local authorities engage pharmacists to assist in addressing priority public health issues like smoking, alcohol misuse, and obesity. This enables the majority of patients to easily reach their CPs so they can frequently see them and receive appropriate guidance and recommendations on their health concerns.[22] The role of pharmacists in managing patients with chronic diseases has grown over the years, encompassing expertise and specialized knowledge in patient treatment. CPs are in an appropriate position to raise awareness about different chronic and life-threatening illnesses to individuals purchasing OTC medications. As health care professionals, they must educate patients to enable them to discern whether they need to self-medicate or depend on doctors.[23]The COVID-19 pandemic has presented a significant risk as it has imposed remarkable and ongoing demands on the healthcare system and those delivering crucial community services such as the CPs. They were classified as an essential service for the community and were directed by the authorities to stay open throughout the pandemic to provide pharmaceutical care to the general population. In the COVID-19 pandemic, pharmacists must manage the risk of increasing supplies to the monthly levels to minimize unnecessary visits to the pharmacy. The COVID-19 crisis has brought about distinct challenges for everyone, including social distancing measures, self-isolation, job losses, and reduced access to healthcare services, all of which can hinder adherence to medication. In this scenario, Pharmacists have adopted multiple strategies to provide medications ahead of time, allowing patients to avoid waiting or needing to visit the pharmacies. [24]

The regulatory framework

Expanding the role of Community pharmacists

In recent years, the workload for both physicians and nurses has risen significantly. There is also a rise in polypharmacy and chronic illnesses, along with an aging population. These factors have opened up new opportunities for expanded services that can be investigated by professional pharmacy organizations, engaged community pharmacies, retail pharmacy owners, as well as academics and government agencies that strive to address patient needs and transform pharmacy services into primary health care. Pharmacists' responsibilities focus on delivering healthcare to track health status and disease progression, including clinical symptoms and medication histories, ensuring patients understand the correct use of medications and supporting overall health outcomes while working towards improving disease conditions. In numerous developed nations, Community Pharmacy Service Quality Guidelines have facilitated the alignment of patient-centered concepts in health care services to enhance patient involvement in their own care. Systems for electronically storing patient health records exist within a national e-Health Record framework, allowing CPs to access necessary information for dispensing medications from the digital prescription database. Over the years the number of community pharmacies has increased to a greater extent and online pharmacies are being operated as subunits of these community pharmacies. Here the CPs has a monopoly on the sale of both the prescription and OTC drugs. [25]

Role of Pharmacists in dispensing practices

Pharmacists play a crucial role in providing medicines, and all resources utilized in patient care can be squandered if there are mistakes in dispensing. The role of pharmacists in hospitals and community pharmacies is evolving from the dispensing and selling of medications to providing patient counselling worldwide. The pharmacist must obtain

high-quality medications from the appropriate source, store them according to specifications, dispense them legally and professionally as needed, communicate effectively with physicians, ensure that patients use their medications as advised, and monitor their treatment.[26]

Pharmacist's responsibilities for providing rational use of medicine

Pharmacists participate in every decision related to medications and their applications to encourage the sensible use of drugs. To encourage the rational use of drugs (RUD), the pharmacist's role as a patient educator, counselor, or intermediary to enhance patient outcomes in outpatient settings is typically essential. Pharmacists must adhere to the ethical guidelines concerning the oversight of patient medications, identification and prevention of potential adverse effects, monitoring of medications, and providing appropriate communication and information about medication usage. [27-28] The World Health Organization (WHO) states that RUD necessitates that patients obtain "medications suitable for their clinical needs, in doses tailored to their specific requirements, for a sufficient duration, and at the minimum cost to themselves and their community."[28] Therefore, in order to foster rational drug use, pharmacists need to provide the correct medication to the appropriate patient at the right dose, via the correct route, and at the proper time.[29]

Pharmaceutical care

The idea of pharmaceutical care develops via a thorough systematic method, necessitating that the pharmacist collaborates with the healthcare team to identify and address existing and possible drug-related issues, preventing patients from the potential harms associated with medications.[27]The approach centers on the patient and is ongoing in its execution, aiming to foresee and enhance the effectiveness of drug therapy outcomes, unlike the conventional pharmacy model that primarily emphasizes the order (prescription/OTC), fulfilled as required, with the pharmacist focusing on the medication, adhering to the requests they receive. The idea of care focuses on building the relationship between the pharmacist and the patient while enhancing the clinical outcome through active participation in the treatment process.[30-31]In pharmaceutical care, pharmacist training must align with skill development in patient assessment, education and counseling, creating patient-specific care plans, establishing treatment protocols, making dosage adjustments, choosing therapeutic alternatives, and implementing preventive therapies. [32-33]

Objective

During the COVID- 19 outbreak various studies were conducted on the CPs regarding their roles and responsibilities in the society. One such method was Cross-sectional study which gave a deep insight on their roles. This review focuses on the different cross-sectional studies that can prove beneficial in the future opportunities of the CPS.

METHODOLOGY

We have explored data engines such as PubMed, Scopus, and Web of Science databases. Community pharmacies have been and may remain crucial players in this evolution of combating the disease by offering a range of pharmacotherapeutic follow-up services for individuals with various conditions. Nonetheless, adhering to the European guidelines on Good Pharmacy Practice requires a normative framework or legal foundation for offering these services. [35-36]In thismethods, relevant qualitative data was extracted and determined by the community pharmacists in the following

Study Design

This research utilized a cross-sectional, descriptive approach with an online survey disseminated to a national convenience sample of community pharmacists. [37, 38]

Sample

A national convenience sample of community pharmacists from independent and chain pharmacies was utilized to examine perspectives on increased technician responsibilities. The community pharmacist sample was obtained from a national online panel of community pharmacists supplied by a healthcare marketing research firm. [39, 40, 41]

Study framework

The project utilized an implementation science framework due to the expansion of technician roles across various states. A framework for implementation can guide research by enabling researchers to examine elements that may impact successful execution. This research implemented the Consolidated Framework for Implementation Research (CFIR) as its theoretical foundation. This framework was selected as it has been utilized in past community pharmacy studies regarding task execution, and its constructs can be modified for research on the future incorporation of more task duties for pharmacy technicians.[42]

Search methods for the identification of studies

We developed and executed a search strategy utilizing methods suggested by the Institute of Medicine, which involves searching multiple databases Ovid MEDLINE, CINAHL, International Pharmaceutical Abstracts, Pro Quest Health and Medical Collection, Pro Quest Nursing and Allied Health Database, Web of Science, and CENTRAL. The databases were explored from their beginning until August 2018 [43]. In addition, we searched for reviews on the topic and went through their reference lists to identify any potentially eligible studies that might have been missed through other methods. Clinical trial registries and select funding organizations were also searched to identify completed and in-progress studies.[44].

Criteria for considering studies for this review

Types of studies

We incorporated randomized controlled trials, nonrandomized controlled trials, controlled before-and-after studies, and interrupted time series analyses

Participants Characteristics

We incorporated studies where patients were released from the hospital to their homes. We placed no restrictions regarding age, reason for admission, or study location

Type of interventions

We incorporated research that investigated interventions taking place during care transitions, particularly hospital discharges to home involving community pharmacists. Community pharmacists are pharmacists working in community pharmacies, primarily focused on dispensing, while ambulatory care pharmacists primarily engage in clinical care and are typically found in clinics

Type of outcome measures

Our primary outcome measure was 30-day readmissions; however, studies were included if they fit the remaining inclusion criteria.[45]

Data Collection

This study will concentrate on the communication of information between hospital doctors and community pharmacists as a strategy to enhance patient safety during the transition from hospital to primary care. A thematic framework method was employed for analyzing the data. Precise, current information enables hospital and clinical pharmacists (HCPs) to carry out medication reconciliation and then advise the patient following hospital discharge. [46,47]The transfer of information to general practitioners (GPs) at the time of discharge has been widely researched. In addition to the responsibilities of the GP, studies indicate that the community pharmacist (CP) plays a role in maintaining continuity of care post-hospitalization. Recently, the function of the community pharmacist has shifted

toward providing clinical, non-dispensing services. A simple list includes the medication's name, amount, intake time, and a remarks section [48-51].

Data analysis

The research mainly examined how workplace conditions with varying resource levels impacted pharmacists or described the activities and interactions of pharmacists with various role partners. Data was extracted using a Microsoft Excel sheet, encompassing the year, author, title, country, sample size, response rate, study design, type of data collection, theoretical frameworks applied, specific surveys utilized, models generated, and journals where published. Themes were incorporated into the sheet following the content analysis method. [34] The Quality Assessment Tool for Studies with Diverse Designs (QATSDD) is utilized, generating a quality rating score for each study while evaluating the reporting and transparency quality of qualitative method studies. This instrument has demonstrated established validity, inter-rater reliability, and test-retest reliability for maintaining consistent quality evaluation and can be employed to evaluate studies using both qualitative and quantitative methods [52,53].

Medicine access and self-medication

In India, Patient and consumers have access medicine by the pharmacists in two ways

1. Access with a prescription of a registered pharmacist.
2. Access without prescription or self-medication.

Self-medication is defined as obtaining and consuming drugs, without prescription and professional advice. It is a self-care with medication.

Medication use Review Service

The purpose of the service was to inform patients about their medications and illnesses, thereby striving to enhance patients' adherence to medication and the effectiveness of medicine use. In the pilot study, 67 predominantly elderly patients on multiple medications were given MUR in five community pharmacies. Numerous patients affirmed that MUR enhanced their comprehension of medication regimens, and they deemed the acquired knowledge and pharmacist's counsel to be extremely beneficial. Conversations are ongoing with various stakeholders regarding service financing, training needs, and access to patient health records essential for the service. The pilot program has launched the first clinical pharmacy e-learning course at the University of Tartu to train community pharmacists in delivering the MUR service. The aim is to regularly conduct medication reviews by a team of healthcare professionals, each possessing unique expertise.[35]

Legal status of the pharmacy practice

The operations of pharmacies are governed by various laws and other legal regulations. The Pharmacy Act (1852) was among the initial laws that governed the profession, creating a framework for overseeing pharmacy practices by requiring professionals to register as chemists, druggists, and/or pharmaceutical chemists. This was succeeded by the Pharmacy and Poisons Act (1933), which mandated pharmacists to join a professional association, and then the Pharmacy Act (1954), which pertained only to individual pharmacists. The Health Services and Public Health Act (1968) governs the spatial and staffing needs for pharmacies.The existing Law also defines who is authorized and who is not to prescribe medications. Furthermore, the Law permits arrangements to supply medications to particular patient groups under specific circumstances. The Prescription Only Medicines Order (1997) and the Health Services and Public Health Act (1968) are the primary laws governing the manufacture, distribution, and utilization of medications.These also include the prescription of medications. There are three primary categories of medications (a) prescription-only medicines – POMs, which can only be obtained with a prescription from an authorized prescriber (such as a physician, dentist, pharmacist, or in certain cases, nurse prescribers or additional prescribers); (b) pharmacy medicines – these are medications that can only be dispensed in a licensed pharmacy or under a pharmacist's oversight; (c) general sale list medicines that can be sold in various locations without pharmacist supervision (for instance supermarkets). The Law permits pharmacists to prescribe medications and permits physicians to dispense medications under regulated conditions outlined in the applicable by-laws. [35]In most EU

Member States, Community Pharmacies (CPs) are generally subject to rigorous regulations. Essential regulation aspects involve the creation of pharmacies (e.g., via needs evaluation); registration and licensing concerns; ownership matters (e.g., restricting ownership to pharmacists and capping the number of pharmacies owned to prevent pharmacy chains); distribution of pharmaceuticals beyond pharmacies; operating hours; and pricing, remuneration, and incentive issues, as government health insurance typically serves as the primary funder for these services.
[54].

Pharmaceutical care prioritizes patient-centered pharmacy practice, aiming to safeguard public health by promoting healthy lifestyles, preventing diseases, and assessing, initiating, and overseeing appropriate pharmacotherapy in close collaboration with the patient. Pharmaceutical care seeks to guarantee the safe and logical use of medications to enhance the patient's health-related quality of life, attain favorable clinical results, and lower treatment expenses [55]. The significant role of pharmacies, which are a vital component of the healthcare system, must be highlighted in the regular provision of medications, therapies, vaccines, and essential health services to the community. Pharmacies play a vital role during a crisis, like the ongoing pandemic, as they frequently serve as both the initial and final contact points within the health care system for patients seeking trustworthy information and guidance. Pharmacists have already validated their crucial role in emergencies, including during past pandemics of H1N1 influenza and SARS..[56-58]Pharmacists have a crucial role in patient care amid a pandemic, particularly in community pharmacies [59,60] and in the hospital setting.[61]Even though the primary emphasis of healthcare services is addressing COVID-19, individuals still experience other non-COVID-19-related symptoms and issues needing professional care.[62] In a pandemic, pharmacists must focus on minimizing virus transmission as well as addressing patients' daily requirements concerning their medication. Additionally, patients needing specialized care, like that post-hematopoietic cell transplantation or undergoing cell therapy, can gain from pharmacists' participation in their treatment during the COVID-19 pandemic..[63]The COVID-19 pandemic presents an opportune moment to revise the regulations to broaden the responsibilities of pharmacists in pharmaceutical care. This paper aims to provide an overview of the legal options available to pharmacists during the pandemic period.[64,65]Thus, the readiness of community pharmacies for the COVID-19 pandemic regarding alterations in pharmacy-built environment design is examined through the conceptual framework model featuring three tiers of pharmacists' responsibilities medication management, information sharing, and public health. [66] Based on the legal and regulatory structure for community pharmacies in the WHO European Region, numerous countries have established a minimum space requirement for pharmaceutical areas [67]. Since the onset of the COVID-19 pandemic, community pharmacists have played a crucial role in the frontline primary healthcare response to COVID-19 [68]. Certainly, pharmacists continue to be highly accessible and reachable for the community, often serving as the public's initial contact point. Their responsibilities have grown throughout the pandemic as they have increasingly assumed the roles of teachers, testers, and vaccinators..[69]Even though pharmacists offered new health services during the pandemic, there is limited information on how they integrated these services into their practice. There is also scant understanding of the obstacles and difficulties they have encountered in delivering these new public health services. This qualitative research sought to investigate the extent of community pharmacists' services throughout the COVID-19 pandemic and their perspectives and experiences related to offering these services. We aimed to specifically concentrate on the difficulties pharmacists encountered in adopting new roles and responsibilities during the pandemic. [70]

The challenges and responses of COVID-19

The COVID-19 pandemic is exerting excessive and ongoing pressure on healthcare systems and essential community service providers. The media's emphasis on case counts, ICU availability, and ventilator statistics illustrates the national single-issue public health reaction necessitated by the coronavirus threat. Nevertheless, ongoing community care requirements remain, and medical and pharmacy professionals have had to modify and embrace changes in their professional roles within an evolving healthcare system, all while dealing with limited resources. [61]CPs are recognized as a crucial service and should, when feasible, stay operational during the pandemic to address the pharmaceutical care requirements of the community. Their practice has needed to adjust considerably, yet the pandemic has also drawn attention to the argument for the much-anticipated evolution of professional roles. The swift development of the COVID-19 pandemic scenario initially surpassed the response from public and regulatory

guidance. Another immediate concern for community pharmacists was safeguarding their staff and patients against the transmission of infection in the pharmacy. Pharmacies modified their spaces to promote 'social-distancing', setting up Perspex shields or entry booths, and limiting the number of patients allowed inside. [68]In addition to pharmacy personnel, various vulnerable patient groups, particularly those requiring ongoing care, are encountering increased risks linked to the COVID-19 pandemic. Pharmacists now need to weigh the risks of raising supply to monthly levels against the necessity of minimizing unnecessary pharmacy trips. The crisis has also presented distinct challenges for all patients – elements like social distancing and self-isolation rules, job loss, and limited access to healthcare services hinder medication adherence.[65]

Community pharmacists' role in the prevention of COVID-19

Numerous participants recognized that CPs being open and reachable during lockdowns significantly contributed to their function as educators. Pharmacists detailed offering numerous preventative health services to reduce and manage the spread of COVID-19, including informing service users about hand hygiene and social distancing, as well as providing face masks and hand sanitizer.Moreover, pharmacists indicated that they are maintaining and modifying their standard pharmaceutical services. Respondents indicated that health authorities assigned them new duties, including renewing and refilling prescriptions and dispensing specific medications without medical consultation. Numerous pharmacists reported putting in place various preventative strategies and modifications in pharmacies to consistently provide care services and meet the public's needs within a secure setting. [65,66]

Community pharmacists' role in SARS-CoV-2 detection and COVID-19 management

Participants indicated their active engagement in the early identification of SARS-COV-2. They explained how their position changed throughout the duration of the pandemic. Participants indicated that they first screened patients and referred them to general practitioners (GPs) and testing centers in cases suspected of COVID-19 prior to October 2020. Moreover, several participants discussed caring for patients who had positive SARS-CoV-2 test results. For individuals with COVID symptoms and also delivering explicit details regarding isolation protocols and red flags. Participants reported consistently directing patients at risk of severe COVID-19 to their GP for careful monitoring. [63,64].

Community pharmacists' role in COVID-19 vaccination

In both pre-clinical and human studies, various vaccines have been created; these vaccines have subsequently received approval for clinical application from the European Medicines Agency (EMA) and several national pharmaceutical regulatory bodies. Clinical trials for the EMA-approved vaccines have demonstrated encouraging outcomes in reducing the severity of COVID-19, as well as lowering hospitalization and mortality rates. Although the creation of effective vaccines is crucial for diminishing the public health risk associated with COVID-19, a vaccination rate of at least 67% is necessary at the population level. Research illustrated the varied roles of pharmacists during the COVID-19 pandemic, including their participation in the clinical management of COVID-19 patients, support for clinical trials, gathering and evaluating information to endorse evidence-based practices, educating the public, and delivering standard clinical services. In the same research, pharmacists from 16 European nations also showed willingness to participate in the vaccination process once vaccines were created and authorized. [70]Numerous participants indicated their active involvement in COVID-19 vaccination by informing and motivating service users to get vaccinated against COVID-19, enablingthe allocation of vaccines to general practitioners and the delivery of vaccines in pharmacies starting from March 2021. Certain respondents saw their participation in influenza vaccination during the past two annual campaigns as a facilitator for their involvement in COVID-19 vaccination.[67]

System and regulatory changes in pharmacy

Pharmacists in regulatory and health service positions deserve recognition for effectively creating and executing these regulations, policies, and guidelines in response to COVID-19. An instance of innovation is the implementation of electronic prescriptions (email) in primary care through Health mail, eliminating the legal need for paper prescriptions. The alteration also pertains to controlled substances, although the documentation requirements for prescriptions remain consistent. Adjustments have also occurred regarding the amount of medication that can be

offered as an emergency supply at the request of either a patient or prescriber. For the first time, a controlled drug emergency supply of up to 5 days may be provided. Comprehensive information regarding these alterations can be obtained from the regulatory agencies. Along with the leniency in prescription regulations, the health service has taken a practical and adaptable stance on payments for the community drug scheme. The health service is aiding with inventory management to guarantee ongoing access to routine medication supplies [61,63]. There is an insufficient amount of detailed information regarding pharmacists' participation in COVID-19 vaccination on a global scale. This commentary offers an analysis of the current situation encompassing services and legal structures related to pharmacists' participation in COVID-19 vaccination across 13 European countries. The details presented in this document represent practices and policies as of June 2021 and were compiled and/or authored by pharmacy professionals, scholars, and relevant specialists in their respective nations. The legal framework, service specifications, and reports were referenced as necessary. [69,70]

CONCLUSION

Although several European nations permit pharmacists to give vaccines, their responsibilities are mostly confined to logistics, reconstitution before administering the vaccine, and educating patients in many countries. Pandemic response strategies ought to include expanded direct clinical responsibilities for pharmacists, such as vaccine delivery via legislative adjustments and the necessary additional training and certification for pharmacists. The capability and willingness of pharmacists to adapt existing clinical services and innovate, as shown during the pandemic's early phase, should be utilized to reduce subsequent waves of the pandemic

Table- 1 Regulatory framework and restriction for CPs in Europe.[54]

Regulatory item /restriction	Description	Issues looked at	Areas of likely impact
Restriction on location and numbers	Examining geographic and demographic factors for establishing a pharmacy. These regulations influence the placement of pharmacies and affect access, equity, and pricing competition matters.	Geographic criteria; Demographic criteria	Access, equity; price competition
Restrictions on ownership	Examining if a pharmacy can solely be owned by pharmacists and if there's potential for pharmacy chains. It may influence efficiency, considering both price and quality as factors of efficiency.	Pharmacists only? One owner one pharmacy?	Efficiency

		Pharmacy chains?	
Distribution-points of sale	Exploring the possibility of permitting extra distribution channels beyond pharmacies, like OTC items being available in supermarkets or mass merchandisers; doctors dispensing in countryside locations; e-Pharmacy (organizations that provide medications or medicinal products online, as opposed to the e-Pharmacy model utilized by the NHS in the UK). It is probable to influence competitive effectiveness (cost, patient safety) and accessibility.	Extra avenues of allocation external drugstores; GPs providing medication in countryside regions; e-Pharmacy	Efficiency; access
Registration and licensing	Investigating if pharmacies must be registered and licensed to dispense prescription medications and the level of oversight required for a pharmacist. It is expected to affect healthcare planning and public health programs in addition to patient safety, resulting in efficiency challenges.	Sign-up to sell medication prescriptions; Pharmaceutical expert oversight	Efficiency
Opening hours	Examining the limitations associated with them, including any minimums or maximums, as well as the adaptability of opening hours. It is probable to influence accessibility.	Minimum commencement hours; utmost business hours; flexibility in operating hours	Access

ABSTRACT

This interdisciplinary study examines the interplay of literature, theatre, music, and scientific thought in shaping Indian cultural expression across diverse historical and socio cultural contexts. It explores how narrative traditions, performative practices, and soundscapes function as interconnected modes of knowledge production, communication, and cultural transmission, positioning culture as a dynamic intellectual system grounded in both creative expression and scientific rationality. Adopting a mixed methods approach, the research integrates qualitative insights from scholars, practitioners, and educators with quantitative survey data from students, faculty members, and audiences across India. The study further investigates contemporary practices to demonstrate how traditional narratives and artistic forms intersect with scientific sensibilities to reinterpret identity, memory, and social experience, highlighting an ongoing dialogue between art and science that sustains India's collective consciousness and intellectual traditions.

Keywords: Literature, Theatre, Music, Scientific Thought, Cultural Expression, Narratives

INTRODUCTION

India represents one of the world's most complex cultural landscapes, shaped by long standing traditions of literature, theatre, and music that continue to inform its intellectual and social life. These cultural forms have historically functioned not merely as aesthetic expressions but as structured systems of knowledge closely aligned with scientific thought through shared concerns with rhythm, structure, logic, cognition, and observation. As Kapoor (2010) notes, India reflects a convergence of diverse artistic traditions that together form a distinctive cultural tapestry. From Vedic hymns and ritual chants grounded in early philosophical inquiry to the mathematically structured raga systems of Hindustani and Carnatic music, and from Sanskrit dramaturgy to modern socially

reflective theatre, Indian cultural practices demonstrate a sustained dialogue between creativity and rationality. Literary narratives, performative traditions, and musical systems have evolved through processes of observation, experimentation, and codification, revealing an indigenous synthesis of artistic imagination and analytical reasoning. This study, titled *The Cultural Symphony of India through Literature, Theatre, Music, and Scientific Thought*, is grounded in the premise that these domains are interconnected modes of understanding human experience. By examining historical trajectories, textual traditions, performative practices, and contemporary cultural expressions, the study positions Indian culture as a dynamic intellectual system shaped through continuous interaction between art and science.

Background of the Study

The relationship between art, knowledge systems, and society in India is historically layered and intellectually rich. Literature, theatre, and music have long operated as structured modes of inquiry, reflecting shared principles of cognition, rhythm, and logic that parallel scientific reasoning. Indian cultural traditions embody philosophical reflection and systematic engagement with human behavior and perception, enabling them to remain relevant across historical contexts. This study adopts an interdisciplinary framework to examine how literary narratives, theatrical performances, musical structures, and scientific cognition interact to generate cultural knowledge. By foregrounding the dialogic relationship between art and science, the research presents Indian culture as a continuously evolving intellectual ecosystem rather than a collection of isolated artistic forms.

Research Gap and Purpose

Despite extensive scholarship on Indian literature, theatre, and music, systematic interdisciplinary research integrating these domains with scientific thought remains limited. Existing studies often examine artistic traditions within exclusively humanistic frameworks, overlooking their shared cognitive, structural, and analytical foundations. There is also a lack of empirical research exploring how literary, performative, and musical systems intersect with scientific concepts such as cognition, acoustics, and pattern recognition, particularly within Natural Sciences oriented research frameworks. Addressing this gap, the primary purpose of the study is to examine the interconnected roles of literature, theatre, music, and scientific thought in shaping Indian cultural expression. Rather than treating artistic practices as isolated cultural artifacts, the study positions them as intellectual frameworks grounded in shared principles of structure, perception, and interpretation, contributing to interdisciplinary scholarship that bridges cultural studies and Natural Sciences perspectives.

Research Questions and Objectives

The study seeks to explore how literature, theatre, and music in India have historically functioned as systems of knowledge, how they reflect principles associated with scientific thought, and how contemporary practitioners integrate traditional artistic forms with analytical perspectives. It aims to trace the historical development of these cultural forms, analyze shared cognitive and structural dimensions, identify recurring patterns across traditions, and propose an interdisciplinary model suitable for Natural Sciences oriented cultural research.

METHODS

This study employs a mixed methods research design integrating quantitative and qualitative approaches. A cross sectional survey was conducted using stratified sampling to ensure representation of scholars, practitioners, educators, and audiences from different regions of India. Data were collected through structured questionnaires with Likert scale items and open ended questions, analyzed using descriptive statistics and thematic analysis. Ethical standards were maintained through voluntary participation, informed consent, confidentiality, and anonymity.

LITERATURE REVIEW

India's cultural life has often been understood as an integrated intellectual system in which literature, theatre, music, and scientific thought coexist and mutually inform one another. Scholars emphasize that Indian traditions do not separate artistic creativity from rational inquiry but treat them as interconnected ways of understanding reality, ethics, and human experience. As Rao (2014) observes, Indian culture reflects "a continuous dialogue between creative expression and rational inquiry, where art becomes a vehicle for knowledge and reflection" (p. 28). Contemporary studies increasingly highlight how classical traditions and modern innovations interact across these domains to shape cultural identity and epistemological frameworks. This integrative perspective positions cultural practices as systems of knowledge rather than purely aesthetic forms. Literature, performance, sound, and scientific reasoning collectively contribute to meaning making and intellectual continuity. Such an approach allows Indian cultural expression to be understood as dynamic, adaptive, and responsive to changing social and intellectual contexts, reinforcing its relevance across historical periods.

Theatre as Ethics, Resistance, and Ritual

The theoretical foundations of Indian theatre are rooted in the *Natyashastra*, which conceptualizes performance as a holistic system integrating drama, music, gesture, space, and audience cognition. Bharata's treatise presents theatre as both aesthetic and ethical practice, intended to instruct, delight, and guide social conduct (Bharata, trans. Rangacharya, 2010). Scholars note that this framework continues to inform contemporary stage design, actor training, and dramaturgy, demonstrating the enduring relevance of classical theatrical theory. Folk and modern theatre traditions further extend this ethical and social function. Folk forms such as *saang*, *yakshagana*, and *therukoothu* operate as communal pedagogies that transmit moral values and social norms. Sharma (2016) notes that folk performance serves as "a shared moral archive, translating philosophical ideas such as dharma and duty into accessible narrative forms" (p. 91). Modern Indian theatre builds on this legacy by transforming the stage into a space of critique and resistance, addressing issues of nationalism, caste, gender, and power. As Dutta (2019) argues, contemporary theatre functions as "a laboratory for social thought" where embodied performance enables critical engagement with lived realities (p. 143).

Music as Aesthetic, Social, and Global Force

Indian music traditions have been widely examined for their structural complexity, emotional depth, and philosophical grounding. Classical systems such as Hindustani and Carnatic music are governed by precise frameworks of raga and tala, reflecting mathematical order, temporal organization, and acoustic principles. Clayton (2017) notes that Indian classical music demonstrates "a sophisticated alignment of sound, time, and perception that parallels scientific approaches to pattern and cognition" (p. 62), revealing close links between musical practice and analytical reasoning. Empirical research in music cognition supports this view, showing that Indian ragas evoke recognizable emotional responses across cultures, while also reflecting cultural specificity. Balkwill and Thompson (1999) found that Indian listeners rely more on melodic nuance, whereas non Indian listeners respond more strongly to rhythmic cues. Beyond classical traditions, Indian music has emerged as a global cultural force through film music, fusion genres, and transnational collaborations. Sen (2020) observes that Indian music continuously negotiates between tradition and innovation, allowing it to circulate globally while retaining cultural distinctiveness (p. 118).

Scientific Thought within a Cultural Worldview

Scientific inquiry in India has historically developed within literary, philosophical, and ritual contexts rather than in isolation. Early advances in mathematics, astronomy, medicine, and metallurgy emerged alongside Vedic literature, epics, and philosophical texts. Ramasubramanian and Bag (2018) argue that scientific reasoning in ancient India was embedded within cultural practices and textual traditions, creating an integrated knowledge system rather than a divided disciplinary structure (p. 34).

Knowledge systems such as Ayurveda, yoga, and architectural science further illustrate how empirical observation and experimentation were woven into everyday life. Nanda (2016) notes that Indian traditions "collapse the divide between science and culture, treating both as mutually reinforcing dimensions of understanding" (p. 76). Contemporary scholarship traces how this integrated worldview continues to shape modern scientific thought, education, and cultural identity, emphasizing that recognizing the cultural embeddedness of science in India offers valuable insights for interdisciplinary research today (Chattopadhyaya, 2021).

FINDINGS, DISCUSSION AND RECOMMENDATIONS

Section 1: Demographics

The pie chart representing the demographic profile of the respondents indicates that students constitute the largest group, accounting for 76.8 % of the 151 participants, suggesting that the survey predominantly reflects the perspectives of younger individuals on the impact of music and theatre in India. This high level of student participation points to strong engagement of academic communities with these art forms, while also indicating a potential bias toward student viewpoints. The "Other" category, comprising 8.6 % of respondents, reflects occupational diversity beyond the listed groups and warrants further exploration to understand how these roles relate to music and theatre. Representation from professionals directly involved in the arts remains limited, with musicians accounting for 3.3 % and theatre practitioners 5.3 %, highlighting a gap in practitioner based perspectives. Research scholars and academicians together form a notable segment of the sample, indicating scholarly interest in the cultural, historical, and intellectual dimensions of music and theatre. Overall, while the chart offers useful insight into respondent composition, it underscores the need for a broader and more balanced sample that includes varied age groups, professional backgrounds, and a greater proportion of practicing artists to achieve a more comprehensive understanding of the impact of music and theatre in India.

The demographic analysis of the survey on the impact of music and theatre in India indicates that a majority of respondents are female at 57 %, with males comprising 43 %, suggesting relatively higher engagement among women. Educational data show that students form the dominant group, accounting for 76.8 % of the sample, while the remaining respondents are either employed or unemployed, highlighting stronger participation from academic communities. Age wise distribution reveals that young adults between 18 and 35 years constitute 76.2 % of the respondents, indicating a pronounced appeal of music and theatre among this age group. Regionally, most participants are from Andhra Pradesh at 60.7 %, followed by Karnataka at 17.4 % and Tamil Nadu at 9.1 %, suggesting higher representation from southern states. While the sample size is limited and may not fully represent the diversity of the Indian population, the findings offer meaningful insights into the demographic profile of respondents and indicate that music and theatre currently resonate most strongly with women, students, young adults, and participants from select regions of India.

Section 2: Music and Theatre Engagement

The pie chart on music and theatre engagement indicates that 43.7 % of respondents frequently attend live performances in India, while 18.5 % attend occasionally, 29.8 % attend rarely, and 7.9 % report never attending, suggesting that more than half of the respondents engage with live music or theatre at least on an occasional basis. This level of participation reflects the continued relevance of music and theatre as cultural and entertainment practices, supported by India's rich artistic heritage, the influence of popular media such as film and television, and the increasing availability of performance venues in urban centers. Beyond entertainment, these art forms play a broader cultural role by preserving traditional practices, addressing social issues through narrative and performance, inspiring individual and collective reflection, and fostering cultural exchange through festivals and public events. Overall, the findings highlight the sustained popularity and multifaceted impact of music and theatre in India, underscoring their significance in shaping cultural awareness, social engagement, and shared artistic experiences.

The pie chart on music and theatre engagement indicates that respondents show strong interest in a diverse range of performance forms, with classical music accounting for 39.7 %, contemporary music for 35.8 %, and folk music for 27.2 %. Experimental music at 27.8 % and other forms at 43.7 % further highlight the breadth of musical and theatrical preferences among audiences in India. This distribution suggests that Indian audiences value both traditional and modern expressions, reflecting a cultural landscape that embraces continuity as well as innovation in artistic practices. Beyond entertainment, the popularity of music and theatre contributes to broader social and cultural functions. These art forms foster shared experiences that encourage interaction across social and cultural boundaries, serve as mediums for engaging with social themes and public concerns, inspire reflection and positive action, and provide emotional relief and enjoyment. Overall, the findings underline the significant role of music and theatre in Indian society, not only as popular cultural practices but also as influential platforms for communication, expression, and collective engagement.

Section 3: Impact of Music and Theatre on Society

The pie chart indicates a strong consensus among respondents regarding the role of music and theatre in preserving and promoting India's diverse cultural heritage, with 81.2 % expressing agreement. A majority of participants, 52.3 %, strongly agree that these art forms are essential to cultural preservation, while an additional 28.5 % agree, reflecting widespread recognition of their importance. Only a small proportion of respondents remain neutral or disagree, suggesting minimal dissent on this issue. This broad endorsement highlights the enduring value of music and theatre in transmitting cultural knowledge, sustaining traditions, fostering social understanding, and reinforcing collective cultural identity within Indian society.

The pie chart indicates a strong consensus among respondents regarding the role of music and theatre in preserving and promoting India's diverse cultural heritage, with 81.2 percent expressing agreement. A majority of participants, 52.3 percent, strongly agree that these art forms are essential to cultural preservation, while an additional 28.5 percent agree, reflecting widespread recognition of their importance. Only a small proportion of respondents remain neutral or disagree, suggesting minimal dissent on this issue. This broad endorsement highlights the enduring value of music and theatre in transmitting cultural knowledge, sustaining traditions, fostering social understanding, and reinforcing collective cultural identity within Indian society.

Section 4: Perceptions of Inclusivity

The pie chart indicates that a majority of respondents, 54.7 percent, believe that the promotion of music and theatre in India contributes to inclusivity among diverse cultures, suggesting that these art forms play a meaningful role in fostering cultural understanding and social integration. In contrast, 39.3 percent feel that such promotion has not significantly influenced inclusivity, while 6 percent remain uncertain, possibly reflecting varying interpretations of inclusivity or challenges in assessing the broader social impact of music and theatre. Overall, the findings suggest a generally positive perception, while also indicating that inclusivity through the arts is not uniformly experienced. The results highlight both the potential and the limitations of music and theatre as inclusive cultural platforms. These art forms can encourage interaction across cultural boundaries, facilitate learning about diverse traditions, and celebrate plural identities, thereby promoting a sense of belonging. At the same time, the mixed responses point to the need for broader representation, improved accessibility, and greater awareness to ensure that music and theatre are inclusive of diverse voices, languages, and communities across Indian society. The pie chart indicates that a majority of respondents, 54.7 percent, believe that the promotion of music and theatre in India contributes to inclusivity among diverse cultures, reflecting a generally positive perception of the role these art forms play in fostering cultural integration. However, a substantial minority of participants, 39.3 percent, feel that such promotion has not significantly influenced inclusivity, suggesting that the impact is not uniformly experienced across communities. A further 6 percent of respondents remain uncertain about this influence. Overall, while the findings point toward a positive contribution of music and theatre to cultural inclusivity in India, they also highlight the need for continued efforts to enhance accessibility, representation, and inclusive participation across diverse cultural groups.

Findings

The findings of this study highlight the need to strengthen the integration of **literature, theatre, music, and scientific thought** within educational, cultural, and research frameworks in India. Arts based learning can be further embedded within formal and informal education to encourage interdisciplinary thinking and to emphasize the cognitive, analytical, and creative dimensions shared by artistic and scientific practices. Greater attention should be given to amplifying diverse literary voices and performative traditions, including those of women and marginalized communities, to ensure a plurality of narratives and perspectives within cultural discourse. Improving accessibility through affordable programming, multilingual presentations, and inclusive infrastructure can broaden participation across social and regional contexts. In addition, sustained support for regional and national cultural platforms can foster dialogue across traditions, enabling meaningful exchange between textual, performative, musical, and analytical modes of knowledge.

Limitations of the Study

Despite its interdisciplinary scope, the study has certain limitations. The respondent sample was largely composed of students and young adults, which may not fully represent the perspectives of older generations or communities where traditional literary, musical, and theatrical practices are deeply rooted. Regional participation was more concentrated in select southern states, indicating the need for wider geographic representation to capture the diversity of Indian cultural expression. Furthermore, the study relied on self reported responses, which reflect individual perceptions and experiences rather than long term cultural or cognitive impact. These limitations suggest the need for future research that adopts larger samples, longitudinal designs, and broader regional and professional inclusion, particularly involving practicing artists, scholars, and community based cultural practitioners.

CONCLUSION

The findings of this study affirm that literature, theatre, and music in India extend beyond aesthetic expression to function as interconnected systems of knowledge, inquiry, and communication, closely aligned with scientific thought. Through narrative structures, performative practices, musical organization, and analytical reasoning, these cultural forms facilitate dialogue, reflection, and understanding across historical and contemporary contexts. By drawing upon long standing traditions while continuously adapting to changing social and intellectual environments, Indian cultural practices demonstrate a sustained capacity for interpretation, experimentation, and meaning making. Viewed through an interdisciplinary lens, The Cultural Symphony of India through Literature, Theatre, Music, and Scientific Thought underscores the integral relationship between creativity and rational inquiry in shaping cultural consciousness. The study concludes that Indian cultural expression operates as a dynamic intellectual ecosystem in which art and science are mutually reinforcing rather than oppositional. As writers, performers, musicians, scholars, and educators continue to engage with this integrated framework, the cultural symphony of India will remain a vital medium for transmitting knowledge, fostering critical thought, and articulating collective identity across generations.

ABSTRACT

The Internet of Things (IoT) is revolutionizing industries by enabling real-time data exchange and automation, yet its expansion introduces complex, multi-layered security challenges. Existing centralized security models, conventional intrusion detection systems, and uniform cryptographic solutions often fall short in protecting the diverse and resource-constrained environments of IoT. This paper presents a comprehensive, multi-layer security framework that strategically applies to Blockchain for decentralized trust management, Federated Learning for privacy-preserving intelligence, and Generative Adversarial Networks (GANs) for class imbalance mitigation in intrusion detection systems. Each technique is tailored to a specific IoT architectural layer to maximize its effectiveness. The proposed framework is evaluated using the NSL-KDD dataset, where GAN-based data augmentation significantly improved the detection rate of rare attacks. Real-world deployments, including case studies in healthcare and agriculture, demonstrate up to 10\% higher anomaly detection accuracy and a 50\% reduction in latency. This research presents a scalable and adaptive approach to IoT security, providing valuable insights for both academic and industry practitioners. Breach identification, ML framework development, and integration of individual modules in a seamless and synchronized manner. Tailored countermeasures, ML integration, experimental validation with the auto encoder-based anomaly detection, integration of Graph Neural Network with the Generative Adversarial Network and Federated Learning procedure. Enhanced breach detection, practical implementation guidance with the validation accuracy value of 98\%. The integrated model will be targeted to have overall latency minimization in the future.

Keywords: Internet of Things, IOT architectural tiers, Machine Learning, Deep Learning, Artificial Intelligence, Anomaly Detection, Anomaly Detection, Data Security, Security Attacks.

INTRODUCTION

Safeguarding the Internet of Medical Things (IoMT) is a critical challenge at the intersection of cybersecurity, healthcare, and embedded systems. The rapid proliferation of smart medical devices from wearables and implants to remote diagnostic tools—has made healthcare data-driven and real-time, but also highly vulnerable. Sensitive patient data, limited device resources, and the need for low-latency communication heighten these security risks. Conventional security mechanisms such as static cryptography, centralized IDS, and signature-based detection are inadequate for IoMT. These approaches rely on centralized data aggregation, consuming bandwidth and compromising privacy, thereby conflicting with regulations like HIPAA and GDPR. Furthermore, IoMT environments face data imbalance, insecure communication protocols, weak authentication, and interoperability issues across manufacturers, all of which can lead to delayed or incorrect medical decisions. Hence, there is an urgent need for decentralized, privacy-preserving security frameworks that handle real-time data diversity and imbalance. While Blockchain, Federated Learning (FL), and Generative Adversarial Networks (GANs) have individually addressed some of these issues, a unified, multi-layered framework remains unexplored. This research proposes an IoMT security framework that strategically integrates Blockchain, FL, and GANs across the IoT layers - security, middleware, and application, respectively. The novelty lies not in creating new algorithms but in orchestrating these technologies into a cohesive, theoretically sound, and experimentally validated architecture. Through simulations and real-world case studies in healthcare and smart agriculture, the framework demonstrates improved anomaly detection accuracy, reduced latency, and enhanced data privacy. Unlike prior works that focus on isolated layers or centralized models, this approach offers a comprehensive, regulation-compliant, and scalable solution for secure medical IoT systems.

LITERATURE REVIEW

Classic intrusion detection systems and cryptographic techniques tend to be difficult to scale well in the context of IoT. Recent developments are

Uddin *et al.* (2022): Utilized deep learning to improve security in medical IoT systems.

Eslami *et al.* (2023): Combined blockchain with RBF neural networks in Internet of Drones settings.

GA-mADAM-IIoT (2023): Developed a lightweight threat detection by genetic algorithm and LSTM.

Zhang *et al.* (2021): Designed explainable AI models to identify zero-day botnet attacks in vehicular networks.

CPS-IoT-PPDNN (2023): Conferred on privacy-preserving anomaly detection in cyber-physical systems.

Although the above research focuses on individual application domains, the current work adds value through a comprehensive multi-layer framework covering the entire IoT architecture and combining complementary technologies: Blockchain, Federated Learning (FL), and GAN-based data augmentation. The deep learning techniques being considered included GANs, Autoencoders, and Graph Neural Networks. These methods were chosen because they had features that enabled them to address IoT security problems that cannot be achieved by conventional methods. GANs can create realistic samples of the minority class in an intrusion dataset which can alleviate the severe class imbalance issue and enhance the generalization of a model. Autoencoders can be used for unsupervised anomaly detection by learning the regular behavior of a device as normal, to be able to flag deviations in device behavior, which is the most suitable for identifying zero-day attacks. GNNs represent the relational structure of IoT networks making it much more capable of detecting anomalies in IoT traffic than a flat-feature model. Effectively, deep learning techniques can handle high-dimensional data, learn in complex ways, and adapt to changes in threat scenarios. Consequently, deep learning will be an important component of the proposed multi-layer framework. Blockchain, Federated Learning (FL), and Generative Adversarial Networks (GANs) were chosen

for their combined strengths to meet the fundamental issues of IoT security: decentralization, privacy, and data imbalance. Blockchain provides a tamper-proof, decentralized infrastructure that is well-suited for device authentication and data provenance. The trustless validation provided by consensus algorithms like Proof of Stake (PoS) and Delegated PoS provides lower latency and are well-suited for distributed IoT systems [Bhatia and Kumar, 2021; Aujla, 2021].Federated Learning (FL) promotes privacy-preserving model training through the storage of raw data locally and transmission of only model updates. This reduces communication overhead and complies with privacy legislations like GDPR and HIPAA [Li *et al*., 2022; Zhou and Xu, 2023]. GAN-driven augmentation resolves the difficulty of scarce or unbalanced security data by producing synthetic but real data. This improves anomaly detection resilience, especially in dealing with infrequent or zero-day attacks [Ahmad *et al*., 2023; Gupta and Pandey, 2023]. Combining such technologies facilitates a layered, scalable, and adaptive security mechanism that surpasses conventional centralized or rule-based techniques for the contemporary IoT landscape.

RESEARCH GAP

Despite significant research on traditional security methods, there is a lack of comprehensive studies integrating advanced technologies like blockchain, machine learning, and federated learning into IoT security frameworks (Shanthamallu *et al*., 2018). Additionally, many proposed solutions lack experimental validation and practical applicability. Existing security measures for IoT devices often fail to meet the unique demands of IoT's layered architecture, leading to vulnerabilities across various architectural tiers. The rapid expansion of IoT devices introduces new and diverse cyber threats, such as unauthorized access, data breaches, and malware attacks, which traditional security methods are ill-equipped to handle. Additionally, there is a need for tailored security solutions that address the specific vulnerabilities of each IoT architectural layer, rather than relying on a one-size-fits-all approach. Despite significant research on traditional security methods, there is a lack of comprehensive studies integrating advanced technologies like blockchain, machine learning, and federated learning into IoT security frameworks. Moreover, many proposed solutions lack experimental validation and practical applicability, making it difficult to assess their effectiveness in real-world scenarios. As IoT networks continue to grow, ensuring the interoperability and scalability of security solutions remains a significant challenge that has not been adequately addressed in existing research.

Solutions for Architectural Layers

IoT security solutions need to address multiple architectural tiers, each of which has distinct vulnerabilities (Al-Sarawi *et al*., 2017). For example, authentication mechanisms are critical in the perception layer, while encryption and secure communication protocols are essential in the network layer. Furthermore, machine learning approaches such as deep learning and federated learning have been suggested for anomaly detection in IoT environments (Andrea *et al*., 2015). GAN-based augmentation techniques have also been proposed to address imbalanced datasets (Benzarti *et al*., 2017). Hence the paper explores a new proposed framework as shown in Figure 1.

Datasets

The current research has been carried out on the public dataset available at the NSL-KDD dataset. The dataset consists of a number of records counting 125,973. Total 41 features (in Figure 3) similar to KDD Cup 1999, with improvements to eliminate redundant records have been used in the processing. The attack type includes DoS, R2L, U2R, and probing attacks. While the NSL-KDD dataset is broadly employed to benchmark intrusion detection models, it is severely lacking in many aspects. It is not representative of modern traffic patterns, IoT device diversity, and sophisticated types of attacks like DDoS or zero-day exploits. As such, its generalizability to actual IoT networks is poor. We employed NSL-KDD in this work for the baseline performance comparison and reproducibility. Yet, future research will utilize more realistic and heterogeneous datasets like BoT-IoT, TON-IoT, and CICIDS2018, which offer richer attack vectors, richer protocol diversity, and traffic from a range of IoT device types. Features of Dataset (Table 1).

Data Preprocessing Steps

We chose NSL-KDD for its relevance and enhanced balance over KDD'99. The pre-processing phase removed redundant records implemented normalization by means of scaled features within the range [0, 1]. The split partition of the data includes 70% train, 15\% validate, 15\% test. The class imbalancing applied GANs to augment minority attack types. Compared with SMOTE, GANs yielded better fidelity and detection 4.1.1.

Experimental Environment

The hardware components used for the experiment includes Processor: Intel Core i7, RAM: 16GB, GPU: NVIDIA GTX1080. The utilise software includes TensorFlow for building and training neural network models. Programming Language: Python 3.8 for implementing algorithms and data processing. The specified tools include Wireshark for network analysis and monitoring traffic patterns during experiments.

METHODOLOGY

The NSL-KDD dataset was employed as the first benchmark for model building and testing. The data was preprocessed by applying one-hot encoding on categorical features, and all the numerical fields were scaled to the [0,1] interval.

To facilitate consistent testing, the data was split into the following
Training set: 70% of the data
Validation set: 15%
Testing set: 15%
For the federated learning simulation, 10 virtual clients were allocated with training data split among them, each being provided with a non-identically and independently distributed (non-IID) subset to simulate real-world heterogeneity in IoT environments. Federated averaging was conducted after each 5 local training epochs, and model aggregation was done using the FedAvg algorithm. Each client was involved in each communication round, and 20 communication rounds were performed in total. Communication latency and client model divergence were tracked for evaluation.

Autoencoder-based Anomaly Detection for Perception Layer

Autoencoders represent a form of artificial neural network utilized for unsupervised learning to efficiently encode data. As illustrated in Figure 4, a decoder network reconstructs the original data, while an encoder network compresses input data into a lower-dimensional representation, known as a latent space. By comparing the autoencoder reconstruction error with a predetermined threshold, anomalies can be identified within the data [Abeshu, A. and Chilamkurti, N. (2020)]. In IoT settings, sensor data can undergo processing either at the edge or within the network itself using autoencoder-based anomaly detection. This approach allows for the detection of unauthorized activities or abnormal behaviors within IoT environments, as autoencoders learn to reconstruct typical sensor data and classify deviations from the norm as anomalies. Autoencoder Based Anomaly Detection (Figure 2).

Training Phase: An autoencoder is trained on a comprehensive dataset consisting of normal sensor readings, capturing the typical patterns of operation across different devices and environments. The training process ensures that the model learns to generate accurate reconstructions of standard sensor data.

Testing Phase: During the testing phase, real-time sensor data is continuously fed into the trained autoencoder. The reconstruction error, defined as the difference between the original input and the reconstructed output, is computed for each data point.

Anomaly Detection: If the reconstruction error exceeds a predefined threshold, determined through statistical analysis of the training data, the data point is flagged as anomalous. The threshold is dynamically adjusted based on observed patterns in the training set.

Evaluation Metrics: The performance of the anomaly detection system is assessed using common metrics such as accuracy, precision, recall, and F1 score. These metrics provide a comprehensive measure of how well the system identifies anomalies and minimizes false positives[Kim, J., \and Kim, H. (2020)].
Forward/backward pass complexity is O(L × N × H²) where L is layers, N is samples, and H is the hidden layer size.

Algorithm 1 Autoencoder for Anomaly Detection

Require: Dataset $D = \{x_1, x_2, \ldots, x_n\}$
Ensure: Classification of each instance as Normal or Anomaly
Step 1: Data Preprocessing
Normalize/standardize dataset D
Split into Training set (normal samples) and Test set (may include anomalies)
Step 2: Autoencoder Construction
Define encoder $f_\theta(x)$ producing latent vector $z = f_\theta(x)$
Define decoder $g_\phi(z)$ producing reconstruction $\hat{x} = g_\phi(z)$
Autoencoder: $AE(x) = g_\phi(f_\theta(x))$
Step 3: Training
Train AE using only normal data
Minimize reconstruction loss:

$$L(x, \hat{x}) = \|x - \hat{x}\|^2$$

Step 4: Anomaly Scoring
for each test instance x **do**
    Compute $\hat{x} = AE(x)$
    Calculate error $E(x) = \|x - \hat{x}\|^2$
end for
Step 5: Threshold Selection
Determine threshold T (e.g., $T = \mu_E + k \cdot \sigma_E$ or percentile cutoff)
Step 6: Detection
for each x in Test set **do**
    if $E(x) > T$ **then**
        Label x as **Anomaly**
    else
        Label x as **Normal**
    end if
end for
Step 7: Evaluation
Evaluate results using Accuracy, Precision, Recall, F1-score, ROC-AUC

Graph Neural Networks (GNNs) for Connectivity/Network Layer

Specifically created to function on graph-structured data, Graph Neural Networks (GNNs) are a class of neural networks. Within IoT networks, GNNs can simulate the relationships amongst IoT devices as a graph, in which objects are represented as nodes and connections or interactions between them are represented as edges as seen in Figure 5. Graph Neural Networks (GNNs) can perform effective network traffic pattern analysis, anomaly detection, and threat identification by utilizing graph-based representations. The Connectivity Layer is responsible for facilitating communication between IoT devices. To detect anomalies in network traffic, Graph Neural Networks (GNNs) are employed, utilizing the underlying graph structure of IoT networks.

Algorithm 2 Graph Neural Network (GNN) for Anomaly Detection

Require: Graph $G = (V, E, X)$, where V = nodes, E = edges, X = feature matrix
Ensure: Anomaly scores and classification (Normal / Anomaly) for each node/edge/subgraph

Step 1: Graph Data Preparation
Construct graph G from dataset
Normalize features and compute adjacency matrix A
Split data into Training (mostly normal) and Testing sets

Step 2: GNN Model Construction
Initialize node embeddings $H^{(0)} = X$
for $l = 1$ to L (number of GNN layers) **do**
    $H^{(l)} = \sigma(\tilde{A}H^{(l-1)}W^{(l)})$ ▷ Message passing and aggregation
end for
Final embeddings $Z = H^{(L)}$

Step 3: Training Objective
if Reconstruction-based **then**
    Minimize reconstruction loss: $L = \|X - \hat{X}\|^2$ or $L = \|A - \hat{A}\|^2$
else if Prediction-based **then**
    Train GNN to predict node/edge labels
else if Contrastive learning **then**
    Maximize similarity of connected nodes, minimize similarity of unconnected nodes
end if

Step 4: Anomaly Scoring
for each v in Test set (node/edge/subgraph) **do**
    Compute anomaly score $S(v)$, e.g., $S(v) = \|X_v - \hat{X}_v\|^2$
end for

Step 5: Threshold Selection
Determine threshold T based on score distribution (percentile, mean + $k \cdot std$, or ROC optimization)

Step 6: Anomaly Detection
for each v in Test set **do**
    if $S(v) > T$ **then**
        Label v as **Anomaly**
    else
        Label v as **Normal**
    end if
end for

Step 7: Evaluation
Evaluate using Accuracy, Precision, Recall, F1-score, ROC-AUC, PR-AUC

Graph Construction: A graph representation of the IoT network is created, with nodes representing devices and edges indicating communication links between devices. This structure enables the modeling of network traffic patterns and the identification of anomalous behavior.

Feature Extraction: For each node in the graph, features such as device properties, communication volume, and patterns are extracted. These features serve as the basis for training the GNN to identify relationships and dependencies within the network.

GNN Method Flowchart (Figure 3)

Training and Evaluation: The GNN is trained using historical traffic data, learning to distinguish between normal and anomalous traffic. It is then evaluated using real-time data to assess its effectiveness in detecting deviations from typical traffic patterns.

Evaluation Metrics: Key evaluation metrics for GNN-based anomaly detection include detection rate, false positive rate, and latency. These metrics gauge the accuracy, efficiency, and speed of the GNN model in identifying anomalies in real time. Message passing per layer is O(|V| + |E|) where V is nodes and E is edges.

Generative Adversarial Networks (GANs) for Middleware/Processing Layer

Algorithm 3 Training of GAN Architecture

Require: Real data samples $X = \{x_1, x_2, \ldots, x_n\}$, latent noise distribution $Z \sim p_z(z)$
Ensure: Trained Generator G and Discriminator D
Initialize Generator G with parameters θ_G
Initialize Discriminator D with parameters θ_D
for each training epoch **do**
    Step 1: Train Discriminator
    Sample mini-batch of real data $x \sim p_{data}(x)$
    Sample mini-batch of noise vectors $z \sim p_z(z)$
    Generate fake samples $\hat{x} = G(z)$
    Compute discriminator loss:

$$L_D = -\mathbb{E}_{x \sim p_{data}(x)}[\log D(x)] - \mathbb{E}_{z \sim p_z(z)}[\log(1 - D(G(z)))]$$

    Update discriminator parameters:

$$\theta_D \leftarrow \theta_D - \eta \nabla_{\theta_D} L_D$$

    Step 2: Train Generator
    Sample mini-batch of noise vectors $z \sim p_z(z)$
    Generate fake samples $\hat{x} = G(z)$
    Compute generator loss:

$$L_G = -\mathbb{E}_{z \sim p_z(z)}[\log D(G(z))]$$

    Update generator parameters:

$$\theta_G \leftarrow \theta_G - \eta \nabla_{\theta_G} L_G$$

end for
Output: Trained Generator G and Discriminator D

Generative Adversarial Networks (GANs) generate synthetic attack samples, improving model robustness against rare threats. We trained GANs using minority-class samples (U2R, R2L) from NSL-KDD, achieving:

- +13% increase in detection rate
- -19% drop in false negatives
- 94% F1-score

Training complexity is$O(E\times B\times D^2)$ where E is the number of epochs, B is the batch size, and D is the dimensionality of the latent space.

Federated Learning for Application Layer

Federated Learning Method (Figure 4). Federated Learning is a machine learning approach that enables multiple IoT devices to collaborate in training a global model without sharing raw data. Instead, each device trains a local model using its data and shares only model updates, like gradients, with a central server or aggregator as highlighted in Figure 6. The server updates the global model by consolidating these updates, which are then sent back to the devices for further refinement. This method maintains data privacy and confidentiality while allowing devices to collectively learn from distributed data in the realm of IoT security[Li, L., *et al.* (2022)].

Initialization: A central server initializes a global model and distributes it to participating devices, which may include smart appliances, wearables, and other IoT-enabled devices.\ \

Local Training: Each device trains its local model on its private data and computes model updates, which are then sent to the central server.\ \

Algorithm 4 Federated Learning Training Procedure

Require: Global model w_0, number of communication rounds R, number of clients K, local dataset D_k for each client k, local epochs E, learning rate η

Ensure: Trained global model w_R

Initialize global model parameters w_0

for round $t = 1$ to R **do**

  Server selects a subset of clients $S_t \subseteq \{1, 2, \ldots, K\}$

  for each client $k \in S_t$ in parallel **do**

    Initialize local model: $w_k^{(t,0)} \leftarrow w_{t-1}$

    for epoch $e = 1$ to E **do**

      Update local model on D_k using gradient descent:

$$w_k^{(t,e)} \leftarrow w_k^{(t,e-1)} - \eta \nabla L(w_k^{(t,e-1)}; D_k)$$

    end for

    Send updated local model $w_k^{(t,E)}$ to server

  end for

  Server aggregates local models to update global model:

$$w_t = \sum_{k \in S_t} \frac{|D_k|}{\sum_{j \in S_t} |D_j|} w_k^{(t,E)}$$

end for

Output: Final global model w_R

Aggregation: The server aggregates the updates from all devices to improve the global model, ensuring secure communication protocols are in place to protect data during transmission.\ \

Evaluation Metrics: The global model's accuracy is assessed post-aggregation, and communication efficiency is evaluated to ensure minimal data exchange. Additionally, the effectiveness of privacy preservation mechanisms is analyzed. Each IoT device trains a local model using private data. Only model gradients are shared, not raw data. Total cost is O(R × C × M) where R is rounds, C is number of clients, M is local model training cost.

Blockchain-based Device Authentication

The blockchain layer is run via a light private Ethereum network. Smart contracts are used to manage authentication events and logging of federated learning updates. A hashed local model parameter record is saved by each participating node to provide accountability and immutability. Block size is limited to 2MB to minimize latency, and Proof-of-Authority (PoA) is utilized instead of Proof-of-Work to maintain resource usage low and transaction confirmation time (≈5 seconds/block) better.\ \ Blockchain technology can enhance security in the IoT devices' security layer by leveraging various consensus algorithms like Proof of Work (PoW), Proof of Stake (PoS), and Delegated Proof of Stake (DPoS). PoW, initially preferred for its simplicity, security, and resistance to vulnerabilities, mandates network users (miners) to solve complex mathematical puzzles to verify and add transactions to the blockchain, preventing double-spending. PoW's design promotes genuine participation and renders it economically infeasible for attackers to manipulate the system, making it ideal for decentralized networks like blockchain. PoW as a favored choice for bolstering security in IoT devices.

Device Authentication: Each IoT device generates a unique cryptographic identity. Devices must solve a computational challenge to authenticate themselves, ensuring secure device on boarding.

Transaction Verification: A consensus mechanism verifies transactions between devices and maintains an immutable ledger of interactions, ensuring transparency and accountability in the system.

Algorithm 5 Blockchain-based Device Authentication

Require: Device D_i requesting network access, blockchain ledger B, trusted network nodes, cryptographic keys
Ensure: Authentication status (**Authorized** / **Unauthorized**) for device D_i

Device D_i generates a unique identity ID_i and signs it using its private key
Device D_i sends authentication request to nearest blockchain node
Blockchain node verifies the request
if Signature of D_i is valid **then**
    Query blockchain ledger B for existing device records
    if ID_i exists in B and is marked as valid **then**
        Authenticate D_i and allow access
    else
        Register ID_i on blockchain with validation transaction
        Authenticate D_i after consensus confirmation
    end if
else
    Reject authentication request as **Unauthorized**
end if
Update blockchain ledger B with authentication transaction for audit
Notify network and device D_i about authentication status

Real-World Implementation: A blockchain network is deployed in a controlled IoT environment to test its effectiveness in securing communications between devices and preventing unauthorized access.

Evaluation Metrics: Key metrics include transaction throughput (measured in transactions per second), latency (time taken to confirm transactions), and security resilience (assessed through penetration testing and attack simulations). Transaction verification complexity is constant O(1) per block due to authority-based validation.

Reinforcement Learning for Management/Control Layer

Reinforcement Learning Proposed Framework (Figure 5). In the Reinforcement Learning (RL) framework of machine learning, an agent develops decision-making capabilities through interactions with its environment to optimize cumulative rewards. Reinforcement learning (RL) as shown in Figure 7. Reinforcement learning (RL) can be utilized in IoT security management and control to establish adaptive security protocols that dynamically adjust to evolving security risks and changes within the IoT environment in real-timeJiang, Y., *et al*. (2023).\ \

State Representation: The environment is modeled by a state space representing conditions such as network traffic, device behavior, and detected security alerts.\ \

Action Selection: The RL agent can take various actions, such as adjusting firewall rules or updating access controls, to maintain the security of the IoT system.\ \

Training and Evaluation: The agent is trained through simulations and real-world interactions, learning to optimize its security decisions over time.\ \

Evaluation Metrics: Cumulative reward, adaptability to new threats, and response time to detected threats are key metrics for evaluating the performance of the RL agent.

Natural Language Processing (NLP) for Cloud/Server Layer}

Natural Language Processing (NLP) is employed on the cloud layer to process logs and command inputs coming from the interfaces of IoT devices. Device logs are trained on a bi-LSTM model to identify anomalous command sequences through token-level classification. This enables semantic anomalies or malicious script injections aiming at

the firmware of smart devices to be detected. NLP Flowchart (Figure 6) With the emergence of natural language processing (NLP), a subset of artificial intelligence, computers are now capable of understanding, interpreting, and generating human language. NLP can be leveraged in the Cloud/Server Layer of IoT devices to improve the management, supervision, and security of IoT infrastructure. As depicted in Figure 8, this involves analyzing and processing textual data, including user commands, system logs, and service requests, to enhance efficiency and effectiveness.

Text Preprocessing: Raw textual data, such as user commands and system logs, is preprocessed to remove noise and normalize the text.

Intent Recognition: Machine learning models are trained to recognize user intents, enabling the system to generate appropriate actions based on commands.

Real-World Implementation: NLP systems are deployed in a live IoT environment to facilitate user interaction and monitor system logs for potential security threats.

Evaluation Metrics: Metrics include accuracy of intent recognition, response time for processing commands, and user satisfaction, gathered through feedback surveys.

RESULTS

Performance Metrics of Proposed Solutions is tabulated in Table 2 along with the accuracy (in Figure 9) and loss curve (in Figure 10).
Metrics like Accuracy, F1-Score, Precision, and Recall were chosen owing to their prevalence in security research. In particular:

- F1-Score weights false positives against false negatives, essential in intrusion detection.
- Latency captures real-time realizability.
- Detection Rate measures IDS performance under class imbalance.
- **Baseline:** Conventional IDS systems implemented with SMOTE and SVM were used as baselines. Our system with GAN outperformed them by 13\% in detection and reduced latency by half (150ms vs. 300ms).

Performance Metrics (Table 2). Performance Comparison of Intrusion Detection Approaches on NSL-KDD (Table 3).
To position the proposed framework within the broader landscape of recent research, we compared our techniques to prominent publications post-2025: Comparison of Related Studies (Table 4). Compared to these works, our framework uniquely integrates multiple advanced techniques across all IoT layers, enabling end-to-end security, reduced latency, and enhanced anomaly detection capabilities. Accuracy Curve (Figure 7). Loss Curve (Figure 8).

FUTURE WORK AND CONCLUSION

This research presented a comprehensive multi-layer IoT security framework integrating Blockchain, Federated Learning (FL), and Generative Adversarial Networks (GANs) across different IoT architectural layers. The proposed model effectively addresses the limitations of conventional centralized and single-layer security approaches by introducing decentralized trust, privacy-preserving learning, and enhanced anomaly detection through synthetic data augmentation. The experimental evaluation using the NSL-KDD dataset demonstrated significant improvements in detection performance and system efficiency. Specifically, the proposed GAN–FL–Blockchain integrated model achieved a detection accuracy of 95\%, with a precision of 94\%, recall of 96\%, and F1-score of 94.5\%. Compared to conventional intrusion detection systems (SMOTE + SVM), the framework improved detection rate by 13\% and reduced average latency by nearly 50\% (150\,ms versus 300\,ms). These results confirm the framework's ability to enhance both responsiveness and reliability in real-time IoT security environments. Furthermore, real-world validation through healthcare and agriculture case studies recorded up to 10\% higher

anomaly detection accuracy, reinforcing its scalability and domain adaptability. However, certain limitations remain. The integration of Federated Learning and Blockchain introduces computational and communication overheads that may strain low-power IoT nodes. Blockchain consensus mechanisms, even when optimized, can still introduce latency, and interoperability challenges persist across heterogeneous IoT devices from different manufacturers. Addressing these constraints is essential for widespread deployment. Future research will focus on developing lightweight model architectures and adaptive communication protocols to mitigate latency and resource constraints. Exploring edge-based or asynchronous federated learning, hybrid consensus mechanisms, and quantum-resistant encryption can further strengthen scalability and resilience. Additionally, the integration of nature-inspired optimization techniques (e.g., swarm or evolutionary algorithms) may enhance adaptive security decision-making in dynamic IoT environments. In summary, the proposed multi-layer framework demonstrated tangible and quantifiable improvements in intrusion detection and system efficiency. It lays a strong foundation for next-generation, decentralized, and intelligent IoT security systems that balance performance, privacy, and scalability. Continued collaboration among academia, industry, and policy-makers will be crucial to standardize and operationalize such frameworks for real-world, mission-critical IoT ecosystems.

ACKNOWLEDGMENTS

The authors declare that no funding was required or received for this research. We would like to express our gratitude to the institutions providing the affiliation support for the authors: Brainware University, Narula Institute of Technology, and S-Vyasa Deemed to be University.

Competing Interests

Authors have declared that no competing interests exist.

Authors' Contributions

The specific contributions of the authors are as follows:

- **Sourav Sadhukhan** and **Promita Dey** managed the analyses of the study, performed the experimental validation, and drafted the initial sections of the manuscript.
- **Dr. Gunjan Mukherjee** and Dr. B. Vasumathi designed the overall multi-layer framework, provided intellectual guidance, and critically reviewed and edited the manuscript.
- All authors read and approved the final manuscript.

Consent (Where Ever Applicable)

This section is Not Applicable as the manuscript does not present a case report, human study, or involve patient data.

Funding Statement

No funding required.

ABSTRACT

To investigate *In – silico* anti – alzheimers activity of *Pongamia pinnata* flower. Of the many ligands reported in *Pongamia pinnata* (PP), five ligands (fistein, karanjin, pongaglobol, kanugin and ovalichromene B) were selected to check interaction with ten cardinal proteins namely insulin like growth factor -1 (IGF1) ,steroid receptor coactivator (SRC), phosphoinositide 3- kinase (PI3K),protein kinase B (AKT), glycogen synthase kinase (GSK) ,cyclin – dependent kinase (CDK), mammalian target of rapamycin (mTOR) , poly (ADP-ribose) polymerase (PARP) and matrix metalloproteinase (MMP) of PI3K/AKT/mTOR Pathway in Alzheimer's disease. Studies report that flavonoids possess anti-alzheimers activity. Literature review suggested that the chosen flower of *Pongamia pinnata* contains phytoconstituents possess α-glucosidase inhibitory activity, antioxidant activity, anti-inflammatory activity, antimicrobial activity and anti-thrombolytic activity, we propose it may have anti- alzheimers activity.Hence, the aim of our study is to investigate the phytochemicals present in *Pongamia pinnata* flower for their potential anti- Alzheimer's activity via modulation of IGF1, SRC,PI3K,AKT GSK, CDK, mTOR, PARP and MMP are molecular targets of Alzheimer through targetingPI3K/AKT/MTOR pathway using*In – silico* approaches. Five ligands (fistein, karanjin, pongaglobol, kanugin and ovalichromene B) reported in *Pongamia pinnata* were recruited from PubChem database .All proteins (IGF1, SRC, PI3K, AKT GSK, CDK, mTOR, PARP and MMP) were downloaded from PDB database. Five ligands were docked with nine targets of alzheimers disease (AD) using autodock software and binding

interactions were studied. All 5 ligands exhibited excellent binding range (-4.56 kcal/mol to -12.45 kcal/mol) with ten biomolecular targets. Ovalichrome B and Pongaglobol were found to exert the lowest binding energies with all the 9 proteins by forming 1- 2 hydrogen bonds. Thus, our *In silico* investigation on ligands reported in *Pongamia pinnata* (PP) with 9molecular targets conclude that these ligands display anti alzheimers activity by interaction with potential targets of alzheimers disease.

Keywords: Phytoconstituents, Alzheimer's disease, *Pongamia pinnata,* Molecular docking, Biomolecular targets

INTRODUCTION

Abbreviations

AD- Alzheimer's disease, PP – *Pongamia pinnata,* IGF1-insulin like growth factor -1,SRC - steroid receptor coactivator, PI3K- phosphoinositide 3- kinase , PIP3 – Phosphatidylinositol (3,4,5)- triphosphate, AKT- protein kinase B ,GSK - glycogen synthase kinase, CDK - cyclin – dependent kinase, mTOR -mammalian target of rapamycin, PARP - poly (ADP-ribose) polymerase, MMP - matrix metalloproteinase, Ki - inhibition constant

Alzheimers disease

Alzheimer's disease (AD) is the most prevalent form of dementia causing higher death rates world-wide. It is characterized by a progressive loss of cognitive, language and behavioural function. Memory impairment and cognitive deficits such as short –term memory, executive deficit, and visuospatial dysfunction are the typical symptom of AD associated with other atypical symptoms. Both oxidative damage and inflammation are elevated in the brain of AD patients and are considered the most common risk factor for AD. Oxygen free radical is the harmful by – product of oxidative metabolism is known to cause AD. Accumulation of β- amyloid proteins (Aβ) and formation of intracellular neurofibrillary tangles are associated with atrophy of cortical and subcortical areas of brain[1]. The primary treatment involves management of symptoms; for the long-term management, early diagnosis may be helpful. Two medication categories have been approved to treat AD. Both "Acetylcholine esterase inhibitors" and "NMDA receptor antagonist" are used to treat Alzheimer' disease to restore cognitive function but neither one the progression of the illness by targeting plagues or tangles that form[2]. As a result, natural remedies from plant sources are preferred as an alternative therapy.

Pongamia pinnata

Pongamia is a genus possessing one species only: *Pongamia pinnata* (L.). which belongs to family Leguminosae and subfamily Papilionaceae[3]. It is an average sized rough, imperishable tree that grows in the coastal regions of South Eastern Asia and Australia[4]. *Pongamia pinnata* is a favored species for controlling soil corrosion and binding beach stacks because of its thick network of side roots. Root, bark, leaves, flower and seeds of this plant also have medicinal properties and are traditionally used as medicinal plants[5].All parts of the plant have been used as crude medicine for the treatment of neoplasms, piles, skin conditions, injuries and ulcers[6].In the traditional system of drugs, the *Pongamia pinnata* plant is used for anti-inflammatory[7], anti-plasmodial, anti-nociceptive, anti-hyperglycemic, anti lipidperoxidative, anti-diarrhoeal, anti-ulcer, anti-hyperammonic and antioxidant activity[8].

Justification

Virtual screening method is an innovative approach that helps in finding potential active molecules against biological targets. Accordingly, the potential phytochemicals of *Pongamia pinnata* against Alzheimer's disease targets was identified using molecular docking technique[15],[16]. Of the many ligands reported in *Pongamia pinnata* (PP), five ligands (fistein, karanjin, pongaglobol, kanugin and ovalichromene B)[4] were selected to check interaction with nine cardinal proteins namely insulin like growth factor -1 (IGF1) [10],[11], steroid receptor coactivator (SRC)[12], phosphoinositide 3- kinase (PI3K)[13], protein kinase B (AKT)[13], glycogen synthase kinase (GSK)[9], cyclin –

dependent kinase (CDK)[13], mammalian target of rapamycin (mTOR)[13] , poly (ADP-ribose) polymerase (PARP)[10] and matrix metalloproteinase (MMP)[14] of PI3K/AKT/mTOR Pathway in Alzheimer's disease . Studies report that most flavonoids possess anti- alzheimers activity. Literature review suggested that the chosen flower of *Pongamia pinnata*[17] contains phytoconstituent such as fisetin exhibit α-glucosidase inhibitory activity[18]. Also fisetin, karanjin, pongaglobol, kanugin and ovalichromene B possess antioxidant activity[8]. Phytoconstituents including fisetin, karanjin, pongaglobol, kanugin and ovalichromene B exhibit anti-inflammatory activity [19]. Secondary metabolite such as kanugin, karanjin, and pongaglobol exhibits antimicrobial activity[20]. Moreover, phytoconstituents such as fisetin, karanjin, kanugin, and ovalichromene B have been reported to exhibit anti-thrombolytic activity[21]. Since these phytoconstituents possess α-glucosidase inhibitory activity, antioxidant activity, anti-inflammatory activity, antimicrobial activity and anti-thrombolytic activity and it has not yet been screened for anti- alzheimers activity, we propose it may have anti- alzheimers activity owing to these properties. Hence aim of our study is to evaluate the Anti-Alzheimer's activity of *Pongamia pinnata* flower bytargetingPI3K/AKT/MTOR pathway using *In – silico* approaches. The Objectives of the study is to determine the interaction between phytoconstituents of *Pongamia pinnata* flower and molecular proteins involved in pathology of Alzheimer's disease by molecular docking.

PI3K/AKT/MTOR Pathway in Alzheimer's disease

In Alzheimer's disease, several signalling pathways become disrupted, ultimately leading to oxidative stress, inflammation, impaired autophagy, abnormal cell-cycle re-entry, and finally neuronal death. The pathway begins (figure 1) with signals such as EGF, IGF-1[11], and insulin, which normally activate receptor tyrosine kinases (RTKs) on the neuron surface. RTK activation triggers downstream molecules like SRC[12]and PI3K, which convert PIP2 to PIP3. PIP3 then activates PDK and subsequently AKT[13]. Under healthy conditions, AKT maintains cell survival by inhibiting GSK-3[9] and activating MTOR[13], which regulates cell growth, nutrient sensing, and autophagy. However, in Alzheimer's disease, AKT signalling becomes impaired. As a result, mTOR becomes dysregulated, leading to defective autophagy, accumulation of toxic proteins, and abnormal cell-cycle activity. Loss of AKT activity also allows GSK-3 to remain active, which contributes to tau hyperphosphorylation, a major hallmark of Alzheimer's pathology. Active GSK-3 further promotes inflammation by activating NF-κB, increasing inflammatory mediators and matrix metalloproteinase (MMP-2/9)[14], worsening neuronal damage. Meanwhile, impaired PI3K–AKT signalling increases oxidative stress, enhances production of Aβ (amyloid-beta) from APP, and leads to mitochondrial dysfunction. As neurons attempt inappropriate cell-cycle re-entry—a known feature of Alzheimer's—they activate CDK[13] complexes such as Cyclin D–CDK4/6 and Cyclin E–CDK2, but since neurons cannot divide, this triggers further stress and eventual cell death. Oxidative stress, nutrient depletion, and DNA damage activate p53, a key regulator of apoptosis. P53 then upregulates p21and BAX, promoting cell-cycle arrest and mitochondrial-mediated apoptosis. DNA damage also activates PARP-1[10], which, when over stimulated, leads to energy depletion and contributes to caspase activation. Ultimately, Caspase-3 becomes fully activated, driving the final execution phase of apoptosis. The combined effects of tau pathology, Aβ accumulation, inflammation, defective autophagy, mitochondrial dysfunction, and apoptotic signalling result in progressive neuronal loss, which manifests clinically as Alzheimer's disease.

MATERIALS AND METHODS

Protein preparation

3D structures of target protein receptors namely insulin like growth factor -1 , steroid receptor coactivator, phosphoinositide 3- kinase, protein kinase B, glycogen synthase kinase, cyclin – dependent kinase, mammalian target of rapamycin, poly (ADP-ribose) polymerase and matrix metalloproteinase were downloaded from research collaboratory for structural bioinformatics protein database (RCSB pdb) and then the hetero atoms were removed . Followed by the active sites were predicted using PDB sum EMBL-EBL. The protein data bank Id of these proteins are 1GZZ, 8BQ3, 9B4R, NH4, 7OY6,3BLH,4DRH,7R5D and 8EDP.

Ligand preparation

The active ligands selected for the current study namely fistein, karanjin, pongaglobol, kanugin and ovalichromene B were chosen from previous scientific reports on *Pongamia pinnata* and were prepared using Pubchem software. Subsequently, Openbabel – 2.3.1 was used to obtain 3D structure of selected ligands and they were saved in PDB format. These prepared ligands were allowed to dock with the target proteins using Autodock tool 4.2[16].

Molecular docking using autodock tools 4.2 (version 1.5.6)

Autodock 4.2 was used to investigate the favoured orientation between ligands and target proteins [15].Initially, the receptor proteins were optimized by adding polar atoms respectively. Each atom in the macromolecule were applied for kollman charges respectively and converted to pdbqt format. Later, the grid box specifications were adjusted to 60*60*60 A while focusing the macromolecule at the centre. While seeking out the best conformers, Lamarckian genetic algorithm was selected as the search parameter[22] .These files were saved in gpf and dpf formats, to enable autodock and autogrid functions. The dlg files were opened to collect binding energies once the docking process was done. In the current work, the number of hydrogen bonds, inhibition constant, binding energy and interaction between active residues have been analysed[23].

RESULT

In the present study, all five ligands showed appreciable binding affinity towards the selected Alzheimer's disease–related targets (Table 1) , with binding energies ranging from −4.56 to −12.45 kcal/mol, indicating strong and stable ligand–receptor interactions. Among the tested compounds, ovalichromene B exhibited the strongest binding affinity across most targets, particularly with PARP (−12.45 kcal/mol, Ki 0.0007 μM)(figure 1) , GSK (−12.07 kcal/mol, Ki 0.0014 μM) (figure 2) , and MMP (−11.13 kcal/mol, Ki 0.0069 μM)(figure 3). Pongaglobol also demonstrated strong interactions, especially with GSK (−9.39 kcal/mol)(figure 4) and PARP (−10.23 kcal/mol) (figure 5). Karanjin showed notable affinity toward PARP (−10.18 kcal/mol)(figure 6) and GSK (−8.86 kcal/mol) (figure 7) , whereas fisetin, though comparatively moderate in binding strength, consistently formed multiple hydrogen bonds with several targets such as MMP (5 hydrogen bonds) (figure 8) and PARP (4 hydrogen bonds)(figure 9) , suggesting stable ligand–protein interactions. Kanugin exhibited relatively lower binding affinity with some targets (notably SRC and PI3K), but still maintained significant interactions with GSK (figure 10), CDK (figure 11), and PARP (figure 12), confirming its contribution to multi-target modulation. Overall, the docking results demonstrated that all five phytochemicals possess the capability to interact effectively with multiple Alzheimer's disease–related proteins, supporting their potential as multi-target therapeutic agents.

DISCUSSION

Alzheimer's disease is a multifactorial neurodegenerative disorder involving oxidative stress, chronic inflammation, β-amyloid accumulation, tau hyperphosphorylation, impaired autophagy, and apoptosis. The PI3K/AKT/mTOR signalling pathway plays a central role in neuronal survival and synaptic plasticity, and its dysregulation contributes significantly to disease progression. Therefore, targeting multiple nodes of this pathway represents a promising therapeutic strategy. In the present *in silico* investigation, phytoconstituents of *Pongamia pinnata* flower demonstrated strong binding affinity toward critical proteins involved in this pathway. IGF-1 signalling is essential for neuronal survival, synaptic plasticity, and glucose metabolism in the brain[24]. Impairment of IGF-1 signalling contributes to brain insulin resistance, often referred to as "type-3 diabetes," a recognized feature of Alzheimer's disease[25]. Among the five ligands, ovalichromene B showed the strongest interaction with IGF-1, exhibiting the lowest binding energy (−7.81 kcal/mol) and inhibition constant (1.87 μM), indicating the formation of a stable ligand–receptor complex. Pongaglobol showed acceptable binding affinity (-6.54kcal/mol), while fisetin (-6.24kcal/mol), karanjin (-6.04kcal/mol) and kanugin (-6.11kcal/mol) also demonstrated good binding efficiency. These findings suggest that ovalichromene B may effectively modulate IGF-1 signalling, potentially improving neuronal insulin sensitivity and survival in AD. SRC kinase regulates synaptic signalling, neuronal plasticity, and amyloid precursor protein (APP)

phosphorylation. Aberrant SRC activation has been linked to synaptic dysfunction and amyloid-β toxicity in Alzheimer's disease [26]. In this context, ovalichromene B exhibited the highest binding affinity toward SRC (−7.62 kcal/mol), indicating effective inhibition. Karanjin (-6.69 kcal/mol), pongaglobol (-6.54 kcal/mol) and fisetin (-6.29 kcal/mol) showed acceptable interactions, whereas kanugin did not show acceptable binding energy (−4.56 kcal/mol). These results suggest that ovalichromene B may help suppress SRC-mediated neurotoxic signaling, thereby protecting synaptic function in AD. Next, PI3K acts as a key upstream regulator of the PI3K/AKT pathway and plays a central role in neuronal survival and resistance to oxidative stress. Dysregulation of PI3K signaling accelerates neuronal loss in Alzheimer's disease[27]. Among the five ligands, pongaglobol demonstrated the strongest interaction with PI3K (−7.31 kcal/mol; Ki = 4.36 μM), suggesting effective modulation of this pathway. Ovalichromene B (-6.68 kcal/mol), karanjin (-6.05 kcal/mol) and fisetin (-6.04 kcal/mol) showed acceptable affinity, while kanugin did not displayed good interaction with PI3K (−4.81 kcal/mol). Overall, pongaglobol interaction with PI3K may support neuronal survival signalling impaired in AD. AKT is a crucial neuroprotective kinase that inhibits apoptosis and regulates tau phosphorylation through downstream signalling.

Reduced AKT activity is associated with neuronal death and cognitive decline in Alzheimer's disease [28]. In the present study, all five phytoconstituents showed strong binding with AKT; however, ovalichromene B exhibited exceptionally high affinity (−10.69 kcal/mol) with a very low inhibition constant (0.014 μM), indicating a potent interaction. Pongaglobol (-9.14 kcal/mol), fisetin (-8.39 kcal/mol), karanjin (-8.32 kcal/mol) and kanugin (-8.13 kcal/mol)also demonstrated strong binding energy . These results suggest that ovalichromene B may enhance AKT-mediated neuroprotection and suppress AD-related apoptotic pathways. GSK is a major enzyme responsible for tau hyperphosphorylation and neurofibrillary tangle formation, making it one of the most critical therapeutic targets in Alzheimer's disease [29]. Among all five ligands, ovalichromene B showed the strongest binding affinity toward GSK (−12.07 kcal/mol) with an extremely low Ki value (0.0014 μM), indicating very strong inhibition. Pongaglobol (-9.39 kcal/mol), karanjin (-8.86 kcal/mol), kanugin (-8.46 kcal/mol) and fisetin (-7.7 kcal/mol) also showed significant binding. Thus, strong inhibition of GSK by ovalichromene B suggests its potential to reduce tau pathology and slow disease progression. Cyclin-dependent kinases, particularly CDK5, are involved in abnormal neuronal cell-cycle re-entry and tau phosphorylation in Alzheimer's disease, ultimately leading to neuronal death[30]. Consistent with previous findings, ovalichromene B again demonstrated the highest binding affinity with CDK (−10.29 kcal/mol), followed by kanugin (-8.55 kcal/mol), karanjin (-8.48 kcal/mol), pongaglobol (-7.84 kcal/mol)and Fisetin(-7.69 kcal/mol)showed comparatively acceptable binding energy .These findings indicate that ovalichromene B may help prevent CDK-mediated tau hyperphosphorylation and aberrant cell-cycle activation in AD neurons. Then, mTOR regulates autophagy, protein synthesis, and cellular metabolism. Hyperactivation of mTOR suppresses autophagy, leading to amyloid-β accumulation in Alzheimer's disease[31]. Among the ligands, ovalichromene B exhibited the strongest interaction with mTOR (−9.36 kcal/mol), followed by karanjin (-8.06kcal/mol), pongaglobol (-7.84 kcal/mol), fisetin (-7.82 kcal/mol) and kanugin (-7.53kcal/mol).

These interactions suggest that ovalichromene B may modulate mTOR signalling, thereby restoring autophagic clearance of toxic protein aggregates in AD. PARP overactivation contributes to oxidative stress, DNA damage, and energy depletion, leading to neuronal apoptosis in Alzheimer's disease[32]. All ligands showed strong binding affinity toward PARP, with ovalichromene B displaying the strongest interaction (−12.45 kcal/mol; Ki = 0.0007 μM). Pongaglobol (-10.23 kcal/mol), karanjin (-10.18kcal/mol), kanugin (-9.64 kcal/mol) and fisetin (- 9.35 kcal/mol)also exhibited potent inhibition. These results indicate that ovalichromene B may protect neurons by limiting PARP-mediated oxidative damage and apoptotic signalling. Matrix metalloproteinases (MMPs) contribute to blood–brain barrier disruption and neuroinflammation, both of which are key pathological features of Alzheimer's disease[33]. Ovalichromene B showed the strongest binding affinity toward MMP (−11.13 kcal/mol), indicating effective inhibition of MMP activity. Fisetin (-8.94 kcal/mol), karanjin (- 8.2 kcal/mol), pongaglobol (- 7.96 kcal/mol) and kanugin (-7.31 kcal/mol) also demonstrated good interaction. These findings suggest that ovalichromene B may help regulate MMP-mediated neuroinflammatory processes and preserve blood–brain barrier integrity in AD. Significantly, the docking results demonstrate that all five phytoconstituents of *Pongamia pinnata* possess the ability to interact with multiple Alzheimer's disease-related proteins. Among them, ovalichromene B consistently exhibited

superior binding affinity and the lowest inhibition constants across all targets, followed by pongaglobol. Overall, studies report that most flavonoids possess anti-Alzheimer's activity. Literature review suggests that the selected flower of *Pongamia pinnata* contains phytoconstituents such as fisetin that exhibit α-glucosidase inhibitory activity. In addition, fisetin, karanjin, pongaglobol, kanugin, and ovalichromene B possess antioxidant activity and anti-inflammatory properties. Also kanugin, karanjin, and pongaglobol exhibit antimicrobial activity. Moreover, phytoconstituents such as fisetin, karanjin, kanugin, and ovalichromene B have been reported to exhibit anti-thrombolytic activity. This multitarget inhibitory profile supports the hypothesis that *Pongamia pinnata* flower phytochemicals (fisetin, karanjin, pongaglobol, kanugin, and ovalichromene B) exert α-glucosidase inhibitory, antioxidant, anti-inflammatory, antimicrobial, and anti-thrombolytic activities. As the flower has not yet been screened for anti-Alzheimer's activity, it is proposed that it may possess anti-Alzheimer's potential owing to these properties by modulating inflammation, oxidative stress, apoptosis, tau pathology, accumulation of β-amyloid proteins (Aβ), formation of intracellular neurofibrillary tangles, and defective autophagy through targetingPI3K/AKT/MTOR pathway using *In – silico* approaches.

CONCLUSION

Thus our present study emphasizes the function of 5 ligands of *Pongamia pinnata* in eradicating the condition of Alzheimer's disease by modulating IGF1, SRC,PI3K,AKT, GSK, CDK, mTOR, PARP and MMP biomolecular targets through targetingPI3K/AKT/MTOR pathway using*In – silico* approaches.

ABSTRACT

This research investigates the potential of nanosponge technology to improve the solubility and bioavailability of Rasagiline Mesylate, a therapeutic agent for neurodegenerative disorders. The study focuses on the formulation and optimization of drug-loaded nanosponges utilizing hypercross-linked β-cyclodextrin along with various excipients. Comprehensive preformulation analyses examined the compatibility of drug-excipient interactions, illustrating that the nanosponge delivery system markedly enhances solubility in multiple media when compared to unformulated Rasagiline Mesylate. The results demonstrated that the entrapment efficiency of the nanosponge formulations varied between 73.73% and 92.49%, with particle sizes maintained below 600 nm, promoting effective drug delivery capabilities. In vitro release experiments showcased well-regulated drug release profiles, emphasizing the system's potential for improved therapeutic applications. Additionally, the stability of these formulations was preserved over six months under specified storage conditions. These significant findings indicate that nanosponge-based delivery systems present a viable approach for enhancing the therapeutic efficacy of hydrophobic drugs, paving the way for progress in pharmacotherapy.

Keywords: Nanosponge technology, Rasagiline Mesylate, drug delivery, solubility enhancement, bioavailability, entrapment efficiency, *in vitro* release.

INTRODUCTION

Solubility refers to the ability of a solute to disperse within a solvent, resulting in a uniform solution. It is heavily influenced by the solvent's properties, along with external factors such as pressure and temperature. The solubility level can be determined by the saturation concentration, which is the threshold at which adding more solute does not result in an increase in concentration[1]. Typically, the solvent is a liquid, which may consist of either a single substance or a combination of liquids. While solid solutions are possible, solutions involving gases are less frequently mentioned. The solubility spectrum is broad; examples include substances that are completely miscible, like ethanol in water, contrasted with those that are poorly soluble, such as silver chloride. The term "insoluble" is often applied to substances with very low solubility. Solubility occurs under conditions of dynamic equilibrium, where the rates of dissolution and precipitation are equal. In certain circumstances, it is feasible to surpass equilibrium solubility, leading to what is called a supersaturated solution, a state that is unstable over time. It is essential to differentiate solubility from general dissolution or melting processes, as these may also involve interactions at the chemical level. For example, while zinc might not dissolve in hydrochloric acid [HCl], it reacts to create zinc chloride and hydrogen, which are soluble[2]. According to IUPAC, solubility in a saturated solution is defined as the proportion of a specific solute in a defined solvent. This relationship can be quantified in various ways, such as in terms of mass per unit volume, molality, or mole fraction. Although it is commonly represented as concentration, this definition can sometimes ignore significant variables, such as the effect of additional species in the solvent, which may influence solubility through mechanisms like the common ion effect[3]. The solubility of slightly soluble ionic compounds in saturated solutions is often discussed in terms of solubility constants, which illustrate the equilibrium between dissolved ions and undissolved solids. These constants can be affected by temperature but are typically stable against the presence of other substances in the solution. The Flory-Huggins theory provides a framework for understanding polymer solubility, while Hansen and Hildebrand solubility parameters serve as practical methods to estimate solubility behavior[4,5]. Lastly, physical characteristics such as the enthalpy of fusion can offer additional perspectives on solubility, and the partition coefficient (Log P) measures the variations in solubility between water and an organic solvent, thus classifying compounds based on their hydrophilicity or hydrophobicity[6,7].

Nanosponges as a Carrier

Nanosponge technology exemplifies an advanced strategy for drug delivery, focusing on diminished side effects, improved stability, and increased formulation flexibility. These sponges are characterized as non-mutagenic, non-allergenic, non-irritating, and nontoxic, designed as tiny mesh-like structures. In contrast to conventional nanoparticles, nanosponges are insoluble in water and organic solvents, demonstrating porosity and stability at temperatures reaching 300°C[8]. Originally, nanosponges were restricted to topical systems, but recent developments in the 21st century have enabled their use for both oral and intravenous administration. Fortopical uses, they can be successfully incorporated into hydrogels, whereas inbuccal applications, they can be mixed with various pharmaceutical excipients appropriate for tablet or capsule manufacturing. Inparenteral applications, they can be conveniently combined with sterile water or saline[9]. Nanosponges enhance the effectiveness of lipophilic drugs by increasing their solubility in water, offering protection for sensitive compounds, and facilitating a range of drug delivery methods. These structures consist of interconnected pockets designed for holding a variety of drugs, making them ideal candidates for targeted therapies. Their hypercrosslinked cyclodextrin framework leads to the formation of spongy nanoparticles under 500 nm, allowing for efficient circulation within the body. In the realm of cancer treatment, these nanosponges can capture toxins, fragments, and secretions released by cancer cells, thereby augmenting chemotherapeutic effectiveness by honing in on drug-resistant cells. When encapsulated with erythrocyte membranes, they are strategically designed to be processed by the liver, reducing toxicity. Consequently, nanosponges represent a significant advancement in both cancer treatment and the management of disorders related to cellular membrane irregularities[10].

Benefits and Drawbacks of Nanosponge

1. Formulations that are biodegradable provide predictable release mechanisms and facilitate targeted site-specific drug delivery.
2. These formulations are compatible with a broad array of vehicles and ingredients, enhancing their applicability.
3. They can efficiently mask undesirable flavors and convert liquid substances into solid forms.
4. This method results in reduced harmful side effects, as only a small amount of the drug comes into contact with healthy tissues[11].
5. Nanosponge particles possess water solubility, which enables the embedding of hydrophobic drugs within the polymer core when mixed with an adjuvant reagent.
6. By adjusting the ratio of cross-linker to polymer, the size of the particles can be modified, allowing for customizable designs
7. The construction process employs a simple chemical approach known as "click chemistry," effectively used for forming nanosponge particles and linking elements.
8. The release profiles of the drugs can be meticulously designed for various rates, ensuring precise dosing during treatments.
9. These formulations maintain stability across a pH spectrum of 1 to 11 and can endure temperatures of up to 130˚C.
10. With an average pore size of 0.25μm, these formulations exhibit self-sterilizing properties that prevent bacterial infiltration[12].

Drawbacks

1. A significant drawback of these nanosponges is their ability to only encapsulate small molecules.
2. The effectiveness of nanosponges is highly reliant on their loading capacities.
3. At times, there can be occurrences of dose dumping[13].

Characteristic Features of Nanosponges

1. Nanosponges possess a range of sizes (1 μm or smaller) defined by the polarity of their pockets, which can be tailored through various cross-linking agents used in the polymer matrix.
2. Based on the conditions applied during synthesis, nanosponges can manifest as either crystalline or para-crystalline in nature, and their crystal formation is crucial for effective complexation with active ingredients.
3. The capability for drug loading within nanosponges is predominantly determined by their crystallization degree; para-crystalline nanosponges have demonstrated varied proficiency in loading drugs[14]
4. These nanosponges are safe, permeable, and remain insoluble in the majority of organic solvents.
5. They exhibit stability throughout a pH range of 1 to 11 and can endure temperatures reaching 300°C.
6. In water, nanosponges can create clear or opalescent suspensions and can be regenerated via approaches such as thermal desorption, solvent extraction, or the use of microwaves and ultrasounds.
7. Their three-dimensional architecture allows for the effective capture, transport, and targeted release of a diverse array of substances[15].
8. Thanks to their ability to be chemically modified with assorted functional groups, nanosponges can be specifically targeted to different sites, with chemical linkers enhancing their binding affinity.
9. Furthermore, nanosponges are capable of forming both inclusion and non-inclusion complexes with various drugs, and they can also be integrated with magnetic particles to confer magnetic properties[16].

MATERIALS AND METHODS

Rasagiline mesylate, the active pharmaceutical ingredient for this study, was generously supplied by Micro Labs Limited, Bengaluru, India. Key excipients and polymers, including β-cyclodextrin, were sourced from Signet Chemical Corporation, Mumbai. Furthermore, a variety of analytical grade solvents and reagents such as glutaraldehyde, dimethyl sulfoxide (DMSO), acetone, ethanol, methanol, chloroform, hydrochloric acid, and sodium

hydroxide were acquired from Loba Chemie Pvt. Ltd., Mumbai. All chemicals and solvents utilized were of analytical reagent (AR) grade and were used without additional purification.

Preformulation Studies

Standardization of Drug and Excipients

Preformulation studies serve as an essential element in the development of both active pharmaceutical ingredients (API) and drug products. These investigations examine the interactions between drug components and excipients, offering vital insights that go beyond mere formulation development. They are instrumental during the initial phases of drug discovery, particularly in the detection of promising leads. For a novel chemical entity to stand as a viable drug molecule, it must exhibit optimal biopharmaceutical properties. A thorough comprehension of the physical-chemical characteristics and their influence on biological performance enables researchers to effectively choose potential lead molecules and address drug delivery challenges. Standardization is imperative for establishing the required physicochemical parameters of a new drug substance. This process guarantees that the active drug and all excipients are evaluated for their physicochemical attributes, both separately and in conjunction[17].

Determination of Calibration curve by UV visible spectrophotometer

Development and optimization of the Spectrophotometric method

In order to establish a robust and effective Spectrophotometric technique for the quantitative analysis of Rasagiline mesylate, multiple factors were meticulously examined, including the choice of diluents, the type of buffer, the concentration of the buffer, duration, and other spectroscopic parameters[18]. The preliminary tests utilized various diluent compositions, such as distilled water combined with buffer and methanol. The best outcomes were obtained with a 50:50 (v/v) methanol-water mixture, which was subsequently degassed in an ultrasonic bath.

Selection of solvent

The investigation into the solubility, stability, and cost of different solvents showed that testing solvents such as methanol, acidic buffer pH 1.2, phosphate buffer pH 6.8, phosphate buffer pH 7.4, ethanol, and distilled water led to the observation of a λ max at 246 nm when scanning the standard solution in a UV spectrophotometer within the range of 200 nm to 400 nm. This result underscores the importance of selecting the appropriate solvent, as it can significantly influence the drug's solubility and stability, which are essential considerations in formulation development[19].

Study of Beers-Lambert's Law

Study of spectra and preparation of standard solution in different solvents

Procedure for the Standard curve (In methanol)

To create the stock solution, 10 mg of Pure RM was precisely weighed and dissolved in 25 ml of methanol, which was then placed in a 100 ml volumetric flask. Following a 15-minute sonication, the final volume was adjusted to 100 ml using methanol. This prepared a stock solution with a concentration of 100µg/ml, from which further dilutions were made to produce standard solutions with concentrations ranging from 5 to 60 µg/ml. The absorbance measurements for three replicates of each concentration were taken at 265 nm, allowing for the creation of standard calibration curves that plot absorbance against concentration. This established linearity based on the average of six independent observations. The concentration range that adhered to Beer-Lambert's law was identified as the analytical range for the drug[20].

Procedure for the Standard curve (In dist. water)

A quantity of pure Rasagiline mesylate (RM) was measured to yield a 100 µg/ml concentration by dissolving 10 mg in 25 ml of methanol and diluting to 100 ml with distilled water. The solution was sonicated for 15 minutes. Standard solutions were prepared for concentrations of 10 to 60 µg/ml. Absorbances were recorded using a UV/VIS spectrophotometer at 265 nm, and calibration curves were established from the average absorbances of three replicates. The analytical concentration range was determined based on compliance with Beer-Lambert's law.

Preformulation Studies: Drug-Excipient Compatibility Studies

Drug-excipient compatibility studies are crucial in the drug development process. Prior to formulating a drug substance into its final dosage form, formulation scientists must carefully evaluate the chemical structure of the active ingredient, the type of delivery system required, and the intended manufacturing techniques. Active pharmaceutical ingredients are typically mixed with excipients that serve various functions. Although excipients are generally considered pharmacologically inert, they may engage in chemical reactions and physical interactions with the active ingredients under certain conditions. These interactions can jeopardize stability, potentially forming new entities with altered physicochemical properties and pharmacological activities. Therefore, compatibility studies serve as a vital tool for choosing or rejecting excipients in pharmaceutical formulations, facilitating the efficient optimization of dosage forms concerning processing, patentability, drug release, complexity, and stability.

Differential Scanning Calorimetry (DSC)

The DSC thermogram of pure rasagiline mesylate was obtained using a calorimeter, with 5-10 mg samples measured on an aluminum pan and sealed with aluminum lids. Thermograms were recorded at 10 °C/min from 30-300 °C in a liquid nitrogen environment at 40 ml/min. Nitrogen gas purged the sample cell throughout the measurement process.

FT-IR Spectroscopy (Vibrational spectroscopy)

The dry sample of rasagiline mesylate was mixed with IR grade KBr in a 100:1 ratio. This mixture was compressed into a pellet using 10 tons of pressure. Pellets were scanned from 4000 to 400 cm-1 using an FTIR instrument. Spectral analysis was done by comparing test sample spectra with standard RM spectra and absorbance peaks with standard absorbance of functional groups.

Formulation and Development

Polymeric nanosponges were prepared by biodegradable and bio compatible polymers. Initially, on trial and error basis various batches of RM loaded nanosponges were prepared by various methods like Nanosponges prepared from hypercross-linked β- cyclodextrin, Emulsion solvent diffusion, Ultrasound-Assisted Synthesis and Solvent method, by using different excipients with different ratios[21]. Hence attempt was made to select any one method for the formulation of nanosponges on the basis of result obtained

Method of Nanosponges Formulation (NSGs)

Nanosponges prepared from hypercross-linked β- cyclodextrins

Synthesis of β-CD Nanosponges

100 mL of anhydrous DMF was placed in a flask, followed by the addition of 17.42 g of anhydrous β-cyclodextrin for dissolution. Then, 9.96 g of dimethyl carbonate was added, and the mixture reacted for 4 hours at 100^{0}C. After polymerization, the block was roughly ground, and water was added to remove DMF. By-products and unreacted reagents were removed via Soxhlet extraction with ethanol. The white powder was dried overnight at 60°C and ground, then dispersed in water. The colloidal fraction was recovered and lyophilized. The nanosponges are sub-micron in size and spherical. The cyclodextrin:cross-linker molar ratio can vary (e.g., 1:2, 1:4, 1:8), allowing classification based on the molar ratio used.

Preparation of Drug-Loaded NS

Drug NS 1:2 and 1:4 complexes were formulated at two diverse weight proportions of 1:5, 1:10 and 1:15 (Drug, BNS w/w). Accurately, weighed quantities of NS 1:2, 1:4 and 1:8 were suspended in 20 mL of distilled water using a magnetic stirrer, then the calculated amount of Drug was added, the mixture was sonicated for 10 min and was kept for 24 hrs under stirring. The suspensions were centrifuged at 2,000 rpm for 10 mins to separate the uncomplexed drug as a residue below the colloidal supernatant. The supernatant was lyophilized at −20°C temperature and operating pressure 13.33 mbar. The dried powder was stored in a desiccator.

RESULTS AND DISCUSSION

Preformulation Studies

UV Spectroscopy: Absorbance spectrum of a 15µg/mL solution of RM in methanol was obtained from 400- 200 nm. As seen in the Fig 5.1, λ max was found to be at 265 nm and the absorbance was 0.237. UV-visible spectrum of Rasagiline mesylate (Fig 1).

DSC thermogram of physical mixture (Fig 6).

Evaluation and Characterization of Nsgs

The solubility of Rasagiline mesylate and optimized lyophilized formulation was found to be improved by nanosizing using whey protein isolate (WPI) as stabilizer. Comparison of plain RM with lyophilized formulation (F4) was done successfully and it was observedthat, in various media like dist. water (~10 folds), acidic buffer pH 1.2 (simulated gastric pH) (~5 folds), phosphate buffer pH 6.8 (simulated intestinal pH) (~6 folds) and phosphate buffer pH 7.4 (~10 folds) was found to be many folds and significantly increased. Furthermore, improvement in drug solubility was contributed by nanosizing of RM in presence of stabilizer which provided stable RM-NSGs with higher surface area. Sand moreover, solubility of all formulations has also been carried out which is revealed in the T. Solubility Comparison of pure RM and lyophilized NSGs in different media. (a Observed values: Mean ±S.D., n=3) (Fig 7).

Entrapment efficiency and Drug loading

The entrapment efficiency of the NSGs system can be determined by measuring the concentration of the drug in the dispersion medium. The quantification of the active agent was consequently performed. For the NSGs formulations, lower polymer concentration results in lower entrapment efficiency and while process diffusion leads to the distribution of the active agent into the shell of the NSGs polymer core.% Encapsulation efficiency of RM-NSGs varied from 73.73±1.89% to 92.49±0.88% and drug loading was varied from 20.66±1.093% to 34.26±1.017%. Encapsulation efficiency increased with increasing concentration of cross-linker but in higher EC concentration batches it was found to be decreased. Highest drug encapsulation was found with batch F4. Percent drug encapsulation and drug loading of NSGsa (Table 1).

Particle size and zeta potential analysis

Optimized batch of RM-NSGs revealed that all developed formulations with different weight ratios (drug: NS) were in the colloidal nanometer range (< 600 nm) with no significant difference between formulations ($P < 0.05$) and particle size of lyophilized optimized RM-NSGs (F4) was found to be 107 nm with 0.077 polydispersity index(PDI). The particles size distribution displayed very good homogeneity for all formulations as the PDI < 0.9. Results of zeta potential measurements observed that values for all batches were in the range of (−30 to +30 mV) and which considered quite sufficient for keeping single particles well–estranged from each other as an outcome of electric repulsion. The zeta potential of lyophilized optimized RM-NSGs (F4) was found to be -24.52 mV. Thus, the developed RM–NSGs are likely to be stable. Thus, it was concluded that, the prepared formulations was found to be stable. Particle size analysis of formulation (F4) (Fig 8). Zeta potential plot of formulation (F4) (Fig 9).

***In Vitro* Release Study**

The *in vitro* release profile of RM, Marketed tablet, lyophilized RM-NSGs in phosphate buffer pH 7.4 at 37°C shown in Fig 5. 74-75. % drug release was not identical for all the batches. Initially the NSGs showed immediate release of RM, this may be due to release of drug from the surface of NSGs, followed by slow and controlled release of drug which was encapsulated in nanosponges. It was evident that, marketed tablet showed significant improvement in dissolution rate with respect to RM alone. Furthermore, the lyophilized RM-NSGs (F4) exhibit faster dissolution as compared to marketed formulation as well as plain RM and it was found to be 91.21%, 59.03 % and 33.43% respectively. The concentration of polymer and cross-linker affects the release rate of RM from nanoparticles. Conversely, as the polymer concentration increases, decrease in the rate and extent of drug release was observed. This may be due to increase in the density of the polymer matrix and also an increase in the diffusion path length that the drug molecules have to travel. Release profile of different formulations of RM-NSGs (Fig 10). Release profile of Plain drug-RM, Marketed tablet and optimized lyophilized RM-NSGs (Fig 11).

Stability study

The stability study was implemented for optimized freeze dried RM-NSGs as per ICH guidelines, shown Table 5.32. Periodically samples were removed and checked for 1) physical appearance, entrapment efficiency, particle size and *in-vitro* drug release 2) solid state characterization. RM-NSGs filled capsule does not showed any significant change in above parameters indicating stability of RM-NSGs for a period of 6 months. 1) Stability study of RM-NSGs a Observed values: Mean ±S.D., n=3) (Table 2).

Particle size analysis

The particle size analysis profile of the optimized freeze dried RM-NSGs (F4) formulation is depicted in Fig 5.76. It was observed that, formulation (F4) showed analogous to that of initial particle size profile which was done before stability. Thus, no significant difference has been revealed in the formulation when exposed even at different temperature and humidity conditions like $25^0C \pm 2^0C$ and RH 60% ± 5%, $30^0C \pm 2^0C$ and RH 65% ± 5% and $40^0C \pm 2^0C$ and RH 75% ± 5% as per the stability guidelines. The particle size study indicated that there was no significant difference observed as compared to the initial particle size profile of optimized freeze dried RM- NSGs. Particle size data of optimized freeze dried RM-NSGs at different temperature and humidity conditions (Fig.12).

% Entrapment efficiency

The % entrapment efficiency profile of the optimized freeze dried RM-NSGs (F4) formulation is depicted in Fig 5.77. It was observed that, formulation (F4) showed analogous to that of initial % entrapment efficiency profile which was done before stability. Thus, no significant difference has been revealed in the formulation when exposed even at different temperature and humidity conditions like $25^0C \pm 2^0C$ and RH 60% ± 5%, $30^0C \pm 2^0C$ and RH 65% ± 5% and $40^0C \pm 2^0C$ and RH 75% ± 5% as per the stability guidelines. The particle size study indicated that there was no significant difference observed as compared to the initial % entrapment efficiency profile of optimized freeze dried RM-NSGs. Entrapment efficiency data of optimized freeze dried RM-NSGs at different temperature and humidity conditions (Fig.13).

Solubility study

The solubility study profile of the optimized freeze dried RM-NSGs (F4) formulation is depicted in Fig 5.78. It was observed that, formulation (F4) showed analogous to that of initial solubility profile which was done before stability. Thus, no significant difference has been revealed in the formulation when exposed even at different temperature and humidity conditions like $25^0C \pm 2^0C$ and RH 60% ± 5%, $30^0C \pm 2^0C$ and RH 65% ± 5% and $40^0C \pm 2^0C$ and RH 75% ± 5% as per the stability guidelines. The solubility study indicated that there was no significant difference observed as compared to the initial solubility profile of optimized freeze dried RM-NSGs

CONCLUSION

The study compellingly illustrated that nanosponge technology can effectively overcome the solubility and permeability challenges associated with Rasagiline Mesylate, a promising agent in the treatment of neurodegenerative conditions. By strategically addressing these limitations, the research underscored the multifaceted capabilities of nanosponge systems and their pivotal role in optimizing drug delivery strategies. The carefully optimized NSG formulation, which underwent extensive evaluation and refinement, not only significantly improved drug release and bioavailability, thereby enhancing therapeutic effectiveness, but also promoted a superior pharmacodynamic response, ensuring that the drug's efficacy remained prolonged within the biological system. Additionally, the formulation provided enhanced stability under accelerated conditions, a critical factor for real-world applications where environmental variables might otherwise jeopardize drug stability. These compelling findings indicate that nanosponge-based delivery systems offer an innovative and promising avenue for increasing the therapeutic performance of poorly permeable drugs like Rasagiline Mesylate, thereby contributing to future advancements in pharmacotherapy and fostering improved clinical outcomes in the treatment of intricate diseases.

ABSTRACT

Obesity, driven by high-calorie diets and inactivity, raises the risk of diseases like diabetes, heart issues, and cancer. Treatment options include diet, exercise, medications and plant-based therapies. Due to side effects of conventional drugs, many turn to herbal remedies. Ethnopharmacology supports the use of medicinal plants in obesity treatment. *Purple perilla* (PE), rich in bioactive compounds like flavonoids, terpenoids, and phenolic acids, shows anti-obesity effects by binding free fatty acids (FFA). Its proven effectiveness in rodents suggests potential for managing obesity in humans through phytotherapeutic approaches. This study investigated the potential anti-obesity effects of hydroalcoholic extract of *Perilla frutescens* seeds to scientifically validate its traditional use. The seeds of *Perilla frutescens* were collected, dried, and extracted using 70% hydroalcoholic. The extract was tested at two doses250 mg (low) and 500 mg (high), compared with a 350 mg Chitosan capsule (standard). Obesity-related effects were measured using a titration-based method. To measure the concentration of free fatty acids (FFAs) and the average amount of NaOH, used blood samples were treated with 0.1 ml each of distilled water, standard

medication, and test drug solutions (250 mg/ml and 500 mg/ml). The FFAs concentrations observed were 143, 118, 126.5, and 123 respectively, while the average NaOH(Sodium hydroxide) volumes used were 2.86 ml, 2.36 ml, 2.53 ml, and 2.46 ml respectively. The research showed that *Perilla frutescens* seed had a strong anti-obesity effect, compared to the control and standard groups based on the measurements of FFAs concentration and the average amount of NaOH used, suggesting it could be a useful treatment for managing obesity.

INTRODUCTION

Obesity is a worldwide problem that is mostly attributed to an energetic imbalance brought on by a rise in the consumption of foods high in calories. Physical inactivity, changes in the environment and socioeconomic conditions, especially the rise in purchasing power and educational attainment, and the influence of other people to increase food consumption are other contributors [1-4]. Obesity is linked to musculoskeletal disorders, including osteoarthritis, diabetes, dyslipidemias, and some cancers, including endometrial, breast, and colon cancer[2-5]. Additionally, hypertension, insulin resistance, glucose intolerance, and an elevated body mass index (BMI) are clinically evident cardiac risk factors in obese people[6,7]. The rates of illness and mortality have gone up since 1980 [8,9], becoming a social issue that receives attention from institutions and the government [10]. Approximately 42 million children under five were obese in 2013. roughly 600 million people were classified as obese in 2014, out of the roughly 1.9 billion adults who were overweight [8]. The right diagnosis is essential to selecting the most effective obesity treatment[2,11]. Dietary regimens, exercise, surgery, behavioral therapy, lifestyle changes, pharmaceutical therapies, drug addiction treatments, hypnosis, acupuncture, and the usage of medicinal plants are just a few examples of integrative and complementary approaches [8-10,12,13]. For the treatment of obesity, pharmacological approaches are advised primarily due to their non-invasive nature. Among the medications that are advised are topiramate, orlistat, sertraline, fluoxetine, and sibutramine[14]. However, they should be used carefully since they may worsen the clinical picture, particularly in individuals with cardiovascular diseases[2,14,15]. Many people turn to unconventional therapies when traditional medical treatments fail to adequately cure chronic illnesses without causing problems down the road.

Plant-based drugs are among these treatments, and they may help with weight reduction, satiety, and metabolism. Nowadays, dietary supplement-based obesity treatments are common, indicating that ethnopharmacology and phytotherapy may be used as approaches to treat and prevent obesity [16-18]. Plants are used medicinally as a result of ethnobotanical and ethnopharmacological methods that evaluate their potential for curing and preventing a wide range of illnesses. Because these methods use common knowledge, the tradition has grown to be quite significant to science. These methods also help choose which species to research and create phytotherapeutic medications based on ethnopharmacological research[11,19,20]. Plant species are now essential in this regard since they provide isolated chemical compounds and extracts that are used as raw materials to create therapies for obesity [12,21-23]. To ensure strong, secure, and dependable outcomes, all the factors that identify a plant as an alternative medicine for the treatment of illnesses must be carefully evaluated [24,25]. Formulating treatment plans that take into account national cultural, social, environmental, and economic variations requires the creation of evidence-based public policies. Setting guidelines for that goal and encouraging information sharing among producers, researchers, developers, and businesses are two benefits of translational research [26]. *Purple perilla* (PE) is one of the popular medicinal plant that has several health benefits. It contains various phytochemicals like terpenoids (monoterpenes, diterpenes, and triterpenoids), phenolic acids, alkaloids, phenylpropanoids, neolignans, fatty acids, policosanols, tocopherols, sitosterols, glycosides, glucosides, peptides, benzoxipen derivatives, and flavonoids (flavones, flavonols, flavanones, isoflavanones, aurones, and chalcones) [27-34]. This phytochemical binds to the FFA and reduces obesity. That effects in rodents and can be effective in obesity management so selected this plant and the process.

MATERIALS AND METHODS

Plant materials
In the month of January, *Perilla frutescens* were collected from the local area of Sikkim.

Preparation of Extract
The seeds of *Perilla frutescens* were collected and washed with tap water. They were then left to dry for seven days in a row under the shed. The dried sample was then macerated for 72 hours in a 70% hydroethanol solution. The air-drying process was then used to dry the extract. After that, the extract was kept at 4°C after being wrapped in aluminum foil.

Phytochemical Screening[35,36,37]
To identify the presence of active ingredients, the crude extract went through qualitative analysis. Standard practices were used to conduct phytochemicals tests.

Experimental Animals
The domestic chiken, or *Gallus gallus*, is a prevalent animal in India's rural areas and many other developing nations.*Gallus gallus*'s blood was collectedfrom a local butcher shop near Netaji Subhas Chandra Bose Institute of Pharmacy,Chakdaha, Nadia.

Standard Drug
Marketed Chitosan 350mg tablet.

Standard drug (Chitosan) solution preparation
To prepare 0.35 mg/ml standard solution one Chitosan 350mg capsule is separated from capsule shell, powder is collected and dissolved in 1000 ml of distilled water.

Test solution preparation
High Dose(500mg): To prepare the test solution, 20 mg of hydroalcoholic extract of *Perilla frutescens* dried seed is dissolved in 40 ml of distilled water and placed into the sample chamber.

Low Dose(250mg): To prepare the test solution, 20 mg of hydroalcoholic extract of dried *Perilla frutescens* seed is dissolved in 80 ml of distilled water and placed into the sample chamber.

Blood sample preparation[38,39]
Chicken blood was collected in a sterile vacutainer, and 2% EDTA was added in 60ml to prevent clotting. The tube was then spun in a centrifuge at 3000 rpm for 10 minutes. This separated the clear, yellowish serum from the red blood cells and clots. The serum was carefully transferred into a beaker using a micropipette or dropper, making sure not to disturb the sediment to avoid contamination. If needed immediately, the serum was used right away; otherwise, it was stored at -20°C or -80°C to preserve its quality. This serum is used for studies on its possible effects on fat formation and metabolism.

METHOD[40,41]

The obtained blood serum was initially separated into four groups, each of which had three samples. Each group was then given the appropriate treatment and placed in an incubator set at 37°C for an hour in order to complete the required chemical reaction.

Group A (sample mixture A); 1ml blood serum with 0.1 ml distilled water.

Group B (sample mixture B); 0.1 ml of standard medication solution combined with 1 ml of blood serum.
Group C (sample mixture C): 0.1 ml test drug solution combined with 1 ml blood serum (250 ml/kg)
Group D (sample mixture D): 500 ml/kg of 1 ml blood serum and 0.1 ml test drug solution
Each sample mixture was then mixed with two to three drops of phenolphthalein and 10 milliliters of ethanol. The concentration of free fatty acid (FFA) in the serum was then determined by titrating the mixture against a (0.05N) NaOH solution and recording the average volume of NaOH necessary to neutralize the FFA.

The FFA concentration (mmol/L) was calculated using the formula:
FFA (mmol/L) = (V X N X 1000)/ Sample Volume (mL)
Where:
V: Volume of NaOH used (ml).
N: Normality of NaOH (0.05).
Sample Volume: 1ml (serum)

RESULT AND DISCUSSION

Extract Preparation
After maceration with a 70% hydroalcoholic solution for 72 hours, *Perilla frutescens* seeds produced a yield of 2.53%.

Phytochemical Investigation
Through the different phytochemical investigations, the hydroalcoholic extract of *Perilla frutescens* seeds showed the presence of different phytochemicals (Table 1).

Anti-obesity test
Free fatty acids (FFAs) cause weight gain by encouraging the storage of fat in adipose tissue. Weight loss is more difficult when free fatty acids (FFAs) FFA levels are elevated because they raise insulin resistance. One major cause of obesity is the formation of visceral adipose tissue, which is stimulated by FFAs.FFA levels that are consistently high cause inflammation, which exacerbates obesity. Due to their disruption of hormone homeostasis, FFAs increase appetite and food intake, which ultimately leads to obesity. The purpose of the study was to evaluate *Perilla frutescens* seed's anti-obesity effect against non-treated control group and commercially available Chitosan 300mg by measuring the concentration of FFAs. When compared to the market standard of Chitosan capsule and control, both the dosage of 250 mg/kg and 500 mg/kg of *Perilla frutescens* seed exhibits its potent anti-obesity effect and the standard Chitosan has once again proven its efficacy as compare to control. The concentration of free fatty acid (FFA) in the serum was determined by titrating the mixture against a (0.05N) NaOH solution and recording the average volume consumption of NaOH necessary to neutralize the FFA (Table 2, Figure 1). From the "Table-2" we came to know that in the FFAs analysis the control, standard and test drug 250mg/kg and 500mg/kg showed the FFAs concentrations with their respective values 143,118,126.5 and 123. So, the test sample, *Perilla frutescens* seed's extract showed potent anti-obesity activity in comparison to the control as well as standard drug (Figure 2). From the phytochemicals investigation result, it was evident that the dried seeds of *Perilla frutescens* contained a significant amount of alkaloid, flavonoids, phenol, saponins and tannin content. Generally, phytochemicals like flavonoids, alkaloids, polyphenols and saponins can inhibit lipolysis process and enhance free fatty acids oxidation that reduce the FFAs level in blood the serum. Besides, its flavonoids can lower free fatty acids (FFAs) by combining with FFAs to create complexes that reduce the FFAs level in the blood serum, because flavonoids can bind and sequester FFAs due to their high affinity for them. Besides, its flavonoids have also the ability to react with FFAs to produce insoluble salts[42-45]. Alkaloids and polyphenols can lower free fatty acids (FFAs) by forming salts with FFAs, because of their basic character, alkaloids can react with FFAs to produce salts. So, the presence of those phytochemicals may make the *Perilla frutescens* seed as a potent anti-obesity agent.

CONCLUSION

Although the plant's other components have several traditional applications, the anti-obesity qualities of *Perilla frutescens* seeds have not been investigated. The Indian medical system makes use of a number of the physiologically active substances included in *Perilla frutescens*. The purpose of the current study was to examine the phytochemicals in *Perilla frutescens* seeds for possible anti-obesity benefits. Using phytochemical screening, alkaloids, polyphenols, carbohydrates, flavonoids, tannins, and saponins were identified. The hydroalcoholic extract of *Perilla frutescens* seed showed potent anti-obesity effects at 250 and 500 mg/kg. Herbal medicinal plants have proven to be beneficial in many traditional medical systems, including allopathic ones. This study of the literature offers important insights into the anti-obesity properties of the plant *Perilla frutescens*, which will be the focus of future studies.

ABSTRACT

Melasma is a chronic and relapsing hyper melanosis that primarily affects sun-exposed areas of the face. It presents as symmetrical hyperpigmented macules and is commonly associated with hormonal, environmental, and genetic influences. In Ayurvedic medicine, melasma is correlated with *Vyanga*, a *RaktajaVyadhi* attributed to the vitiation of *Pitta* and *Vata Doshas*. This case study highlights the effective management of melasma through a personalized Ayurvedic treatment protocol. A 36-year-old female presented with a two-year history of hyperpigmented facial patches, primarily associated with stress, insomnia, and constipation. Based on classical Ayurvedic diagnostic criteria, the condition was identified as *Vyanga*, a disorder attributed to the vitiation of *Pitta* and *Vata Doshas*. The patient was treated with *Shodhana Chikitsa*, including *Eranda Taila Virechana* and *Nasya Karma*, followed by *Shamana Chikitsa* involving the internal administration of *GandhakaRasayana*, *Chandanasava*, and other formulations. External application of *Jatiphala* combined with *Yashtimadhu Taila* was also prescribed. Additionally, supportive dietary (*Ahara*) and lifestyle (*Vihara*) modifications were recommended to pacify the vitiated *Pitta Dosha* and purify the *Rakta Dhatu*. After 45 days, marked improvement was observed in pigmentation intensity, skin tone, and texture, with no reported adverse effects. **Conclusion:** This case underscores the potential efficacy of Ayurvedic interventions, particularly those focused on *Rakta Shodhana* and *Pitta–Vata Shamaka* therapies, in the management of melasma (*Vyanga*). The promising outcomes observed through this individualized and holistic approach highlight the need for further validation via rigorously designed controlled clinical trials.

Keywords – *Vyanga*, Melasma, *Shodhana*, *Shamana*, *Lepa*, *Gandhakarasayana.*

INTRODUCTION

Melasma is a common cutaneous pigmentary condition characterized by development of dark, discolored patches which typically manifests on the areas which are exposed to sunlight, mostly face with occasional involvement of neck and forearm. The disease usually affects females in their reproductive phase, with only 10 % occurring in males [1]. It is more common among women with darker skin (Fitzpatrick types III–V) in their 30s and 40s [2]. It can be classified into 3 types: epidermal, dermal and mixed melasma.Although melasma is medically harmless, but the condition can deeply influence emotional health and disrupt social, familial, and professional interactions, sometimes causing considerable psychological distress. *Vyanga* is a *Kshudra Roga* (minor disease) described in classical Ayurvedic texts. *Vyanga* is a term derived from the Sanskrit components *Vi* and *Anga*. The prefix *Vi* signifies "*Vikruti*" (distortion) or "*Vighatan*" (disruption), while *Anga* refers to a "body part". The disease is categorized by thin, circular, painless brown coloured patches or stains on the facial skin. The condition closely resembles *Melasma* in modern dermatology.

Causes (Nidana)
The precise cause of melasma remains unclear; however, multiple factors are believed to play a role in its development such as exposure to UV radiations as it can stimulate melanocytes which in turn secretes melanin resulting in hyper pigmentation. Hormonal fluctuations can manifest melasma, it is often known as the “mask of pregnancy” as it can appear during pregnancy. However, other factors such as genetic predisposition and cosmetic products can also trigger melasma. It is multifactorial condition; several contributors can cause or worsen it. Although no specific *Nidana* (causative factor) is explicitly mentioned in the text, all general factors that aggravate the *doshas* such as *vata*, *pitta*, and vitiate *rakta dhatu* are considered contributory to the pathogenesis of *Vyanga*.

Pathophysiology(Samprapti)
According to *Acharya Charaka*, due to *nidanasevana* (consumption of causative factors) *pitta* gets aggravated and associated with vitiated *rakta dhatu*, undergoes pathological drying (*Rukshata*), leading to the development of *Vyanga* [3]. According to *Acharya Sushruta*, emotional stress such as *krodha* (anger) and physical exertion like *parishrama* (overexertion) lead to the vitiation of Vata and Pitta doshas. These doshas localize in the facial region (*Mukha*) and the doshic imbalance manifests as *shyava varna mandala* (bluish blackish patches) known as *Vyanga*, characterized by dark, painless discoloration of the skin [4]. This case study presents the successful Ayurvedic management of *Vyanga* in afemale patient, demonstrating the therapeutic efficacy of classical formulations and principles.

Case Report
A 36-year-old woman presented to the outpatient department with a 2 years history of dark brown hyperpigmented patches localized to the cheeks and forehead. The patient had been intermittently undergoing allopathic treatment but has now expressed interest in pursuing Ayurveda.

History
Over the last five years, the patient has struggled with constipation, accompanied by increasing levels of stress over the past three to four years. The patient additionally reports experiencing sleeplessness. Menstrual history reveals a persistent pattern of reduced flow, with each cycle lasting no more than 1 to 2 days over the last two years. The patient's personal history indicated a normal appetite with a marked preference for salty and sour foods.

General Examination
Built - Moderate
Weight - 64 kgs
Height - 5.3 feet
BP - 110/80 mm Hg

Pulse Rate - 74/min
Respiratory Rate – 20/min

Ashtavidha Pariksha (Eightfold examination of patient)
Nadi (Pulse) – *Pitta-vata*
Mutra (Urine) - *Samyaka*
Mala (Stool) - *Baddhata*
Jihwa (Tongue) -*Sama* (white coated tongue)
Shabda (Voice) - *Ruksha*
Sparsha (Touch) – *Ruksha*
Drik (Eye) - *Samanya*
Akriti (General appearance) – *Madhyama*

THERAPEUTIC INTERVENTION
The proposed treatment regimen consisted of -
Shodhanachikitsa (Purification therapy) - The therapies *Virechana* (purgation) and *Nasya* (nasal administration) were initiated. *Virechana* was administered for seven days before being discontinued, whereas *Nasya* therapy was continued thereafter.(Table No. 1- SHODHANA CHIKITSA)

Shamana chikitsa (Palliative therapy) - The vitiated dosha was eliminated through *shodhana*, parallelly *shamanachikitsa* was initiated to address the remaining*dosha*.(Table No. 2 - SHAMANA CHIKITSA)

External Application - *Jatiphala Lepa* was prepared by gently rubbing *Jatiphala* (Myristica fragrans) on a clean stone slab, using milk as the liquid medium. The *lepa* was then mixed with *Yashtimadhutaila* and applied over the affected area.

Pathya Apathya (Do's & Don'ts)
The food which does not cause harm to the body and is pleasant to the mind is called *pathya*, on the other hand, *apathya*, is the opposite [5]. The patient was recommended to focus on the intake of freshly prepared meals. Key dietary guidelines included enhancing fibre consumption through a variety of vegetables, choosing light and easily digestible foods such as *mudga* (greengram), *yava* (barley grain) and integrating bitter-tasting vegetables to promote optimal health and well-being. The patient was advised to avoid the consumption of salty, spicy food, jaggery, fish, meat and dairy products, as well as fried, fermented foods and beverages. The patient was advised to refrain from *Divaswapna* (day time sleeping) and over exertion.

Lifestyle Modification
The patient was advised to minimize sun exposure and emotional stress, and to engage in daily 20-minute sessions of *Pranayama* such as *Anuloma Viloma* as part of a holistic approach to enhance overall well-being.

RESULT

The duration of the treatment was 45 days. (Table No. 3 – RESULT)
Figure No. 1 - Before Treatment (Image)
Figure No. 2 – After Treatment (Image)

DISCUSSION

According to Ayurveda, *Vyanga* (melasma) arises primarily from *Rakta Dushti* (vitiated blood) associated with aggravated *Pitta* and *Vata doshas*. Vitiated Pitta impairs the quality of *Rakta dhatu*, leading to skin discoloration, while

disturbed Vata causes localized stagnation of *Dushta Rakta*. This combination manifests as hyperpigmented patches. In this case, the contributing factors (*Nidanas*) include chronic constipation, *ArtavaKshaya* (hypomenorrhea), and psychological stress, which disrupt *Agni* and further aggravate *Pitta*, resulting in *Rakta* vitiation. The interplay of disturbed *Rakta* and *Pitta* leads to various skin disorders, with *Vyanga* being a prominent presentation. An Ayurvedic treatment protocol was formulated to disrupt the pathophysiology of melasma through *Sheeta* (cooling), *Snigdha* (unctuous), *Pittashodhaka* (Pitta-pacifying), and *Vata Shamaka* (Vata-alleviating) interventions.

Eranda Taila [6] -It is indicated in the management of various disorders, including *Yoni Roga* (gynecological conditions) and skin diseases. With *madhura*, *kaṭu*, and *kaṣhaya* rasa, *snigdha* and *sukṣma*guṇa, and *uṣhṇavirya*, it functions as a *kapha-vatahara* and *rechana*(laxative) agent. As a *snigdhavirechaka*, it counteracts the *rukṣaguṇa* of aggravated *vata dosha* and facilitates the elimination of accumulated *doshas*, thereby supporting systemic detoxification and restoring doshic balance.*Eranda Taila* (castor oil) is administered orally, as its stimulant laxative effect is activated through hydrolysis by intestinal lipases.

Anu Taila [7] - *Pratimarsha Nasya* is recommended as a daily practice to support and maintain the health of the nasal passages. *Anu Taila*, being a *sneha* (oleaginous substance), exerts its therapeutic effect by facilitating the elimination of vitiated *doshas*, serving as a potent *shodhana* (purificatory agent) for *urdhvajatrugatavyadhi* (disorders of the region above the clavicle). Additionally, due to the pharmacodynamic properties of its constituent ingredients, it also exhibits *shamana* (pacifying) action on associated *dosha-dushya* complexes, thereby contributing to comprehensive disease management by disrupting the root cause. *Chandanasava* [8] - It is a classical *Sandhana Kalpa* (fermented formulation) commonly indicated in the management of dermatological conditions [9], as it purifies the blood acting as*Raktaprasadaka*, while maintaining vitiated *pitta* and *vata*. *Chandanasava* contains gallic acid, a prominent polyphenol known for its potent antioxidant properties, its synergistic integration with other active ingredients has shown promising results in addressing specific skin concerns, including pigmentation, aging, and sensitivity.

Dashmularishta [10] - As previously discussed, a key causative factor in *Vyanga* (melasma) is the disturbance of *vatadosha*. This imbalance leads to compromised microcirculation and accumulation of *rakta* (blood) beneath the skin, resulting in localized pigmentation. Administering *Dashamularishta* helps normalize *vatadosha* activity, thereby enhancing blood circulation and supporting tissue nourishment. This formulation incorporates both *Brihat Panchamula* and *Laghu Panchamula* drug groups, which together enhance its therapeutic potential. The *Brihat Panchamula* group primarily features *tikta* and *madhurarasa*, *ushnavirya*, due to which it exhibits *deepana* and *pachana* properties. These qualities make it beneficial in treating conditions like *agnimandya* and *grahaniRoga*, which in turn support tissue nourishment (*dhatu Pushti)*. Conversely, *Laghu Panchamula* is characterized by *madhuravipaka*, which facilitates *dhatu poshana* and strengthens the body, thereby helping to relieve disorders associated with *vata* and *pitta*. Moreover, contemporary studies have revealed that *Dashamularishta* exhibits potent antioxidant properties and mitigates DNA damage caused by oxidative stress—processes intricately linked to *raktadushti*. Consequently, its effectiveness in managing *Vyanga* is supported by both traditional Ayurvedic principles and modern pharmacological evidence.

Sarivaghana Vati [11] -*Sariva* (Hemidesmus indicus) is mentioned in *Varnya mahakashaya* [12] also known as *Anantamula*, possesses cooling, sweet, and mildly bitter properties. It exhibits a strong affinity for *raktadhatu* (blood tissue), contributing to improved skin texture and enhanced liver function. These attributes make it an effective choice for managing conditions such as hyperpigmentation, eczema, psoriasis, urticaria, acne rosacea, and acne associated with aggravated *pitta dosha*. *Gandhaka Rasayana* [13] - In Ayurvedic rationale, *Gandhaka* is classically used in *kushtha* formulations as a "blood purifying" (*raktaprasadana*) agent that clears stagnated *rakta*, alleviates local congestion, and restores skin homeostasis. *GandhakaRasayana* is a polyherbal drug which is *raktashodhaka* (blood purifier), *kandughana* and *rasayana* mainly indicated in skin diseases. It relieves discolouration of skin, helps to re-establish natural colour, alleviates dosha.[14].Purified *Gandhaka* (sulphur) exerts multiple beneficial effects on the skin, while its reduction to hydrogen sulphide (H_2S) offers antimicrobial, antioxidant, and microvascular regulatory actions. H_2S may enhance endothelial function (via eNOS, VEGF) and upregulate glutathione levels, thus improving

local perfusion and reducing oxidative damage to dermal tissues. Together, these molecular and classical views suggest that *Gandhaka* might help correct the vascular stagnation underlying *Vyanga* (melasma). *Jatiphala (Myristica fragrans)* [15] - According to Ayurvedic classics, the seat of *Vyanga* is located in the *Lohita*, corresponding to the second layer of the *Twak* (skin). In this layer, due to the vitiation of *Vata Dosha*, the surrounding tissue becomes hard, rough, and discoloured. This localized stagnation of *Rakta* leads to dark pigmentation and uneven skin tone. The texts further mention that such *Vata*-dominant conditions can be pacified by the local application of drugs possessing *Ushna Guna*, that is Nutmeg (*Jatiphala*). which helps in softening the affected area and restoring normal colour and texture of the skin by resolving local pathology.

From a pharmacological perspective, Nutmeg (Myristica fragrans) has been recognized for its skin-brightening and rejuvenating properties. It is rich in vitamin C; a potent antioxidant known to enhance collagen synthesis and promote even skin tone by reducing oxidative damage. The major phytoconstituents of Myristica fragrans essential oil (MFEO) include myristicin, eugenol, sabinene, β-myrcene, α-pinene, limonene, safrole, and elemicin. These bioactive compounds exhibit antioxidant, and mild depigmenting effects that contribute to overall improvement in skin complexion and texture. The presence of myristicin and elemicin also accounts for the characteristic aromatic and mildly intoxicating properties of the seed. *Yashtimadhu Taila* (*Glycyrrhiza glabra*) [16] - It is used in *Twakrogas* (skin diseases), *vrana* (wounds), *kandu* (itching). Its therapeutic efficacy is attributed to key chemical constituents such as glycerine, which acts as an emollient—enhancing skin hydration and smoothness by filling micro-fissures and promoting healing. Asparagine plays a vital role in the synthesis of collagen, fibrinogen, elastin, and connective tissue, thereby supporting skin integrity, strength, and resilience while minimizing scar formation. Liquorice acid, another active component, contributes to skin lightening by inhibiting melanin production, effectively reducing hyperpigmentation and evening out skin tone. Additionally, *Yashtimadhu* exhibits a cooling effect that helps pacify *pitta dosha* and serves as a potent remedy for *vata* imbalances, addressing symptoms such a skin dryness, constipation, anxiety, fatigue and hyperpigmentation.

CONCLUSION

Melasma, while a benign dermatological condition, can have a profound impact on an individual's mental and emotional well-being. Recognizing that the skin often reflects internal health, melasma may serve as an indicator of underlying systemic imbalance. In this case, we developed a personalized treatment regimen based on this holistic understanding and observed significant, positive outcomes. These findings highlight the need for more comprehensive and integrative treatment protocols to achieve faster and more effective results in the management of melasma.

ABSTRACT

Now a days, pollution from Diclofenac (DCF) and Sulfamethoxazole (SMX) is increasing in aquatic systems due to the overuse and improper disposal of unused medications, posing significant risks to aquatic animals. Both compounds can transform into other products in the environment, and their combined effects are complex and can be difficult to predict. Thus, the present study aims to assess the effects of Diclofenac(140 ng/L) and Sulfamethoxazole (150 µg/L) at environmental concentrations, individually and in combination, on growth performance and haematological parameters of *Labeo rohita* fingerlings, and to examine the bioaccumulation of DCF and SMX in different tissues of treated fish. Healthy fingerlings were individually exposed to an environmental concentration of DCF and SMX, as well as in combination, for 45 days. During the experimental period, growth performance and haematological profiles were assessed in DCF, SMX, and DCF + SMX-exposed fish at 15, 30, and 45 days. The growth parameters, such as net weight gain, length gain, and specific growth rate, were significantly reduced. In contrast, feed conversion ratio and feed efficiency ratio were remarkably increased in combination with DCF and SMX at environmental concentrations compared with individual exposure of DCF and SMX at 15, 30, and 45 days. The haematological profile, including red blood cells, mean cell

haemoglobin, hematocrit, haemoglobin, and platelets, significantly declined, and mean cell volume and white blood cell values increased significantly at 15, 30, and 45 days in the combination of DCF and SMX-treated group, compared with other groups. The highest bioaccumulation of DCF and SMX was represented in the liver, followed by the kidney, gill and muscle tissues in combination DCF and SMX-treated fish.From these results, it can be concluded that the combination of DCF and SMX at environmental concentrations is toxic to aquatic organisms.

Keywords: Diclofenac, Sulfamethoxazole, Growth performance, Haematological profile and Bioaccumulation.

INTRODUCTION

Pharmaceutical pollutants in aquatic ecosystems have become a growing concern worldwide. This is due to their persistent nature and potential ecological and human health impacts (Eapen *et al*., 2024).These include antibiotics, analgesics (painkillers), and hormones, which are released into water bodies through wastewater treatment, agricultural runoff, and improper disposal of unused medications (Rathi *et al*., 2020). There are many pharmaceutical products, among which painkillers and anti-inflammatory drugs are among the most widely detected in the environment due to their high consumption and over-the-counter availability (Yang *et al*., 2017). The second group of drugs, widely used in human and veterinary medicine, is sulfonamide antibiotics, primarily for bacterial infections (Gros *et al*., 2019). Diclofenac (DCF) is a widely used non-steroidal anti-inflammatory drug (NSAID) and is applied as a pain reliever. It is mainly administered orally as tablets or applied to the skin as an ointment. In the case of an oral dose, 65–70% is excreted in the urine and 20–30% in the faeces as the parent drug or as metabolites (Lonappan *et al*., 2016). Sulfamethoxazole (SMX) is a representative of the sulfonamide antibiotics, which are used to treat a broad spectrum of bacterial infections. As antibiotics are not completely metabolized in humans and animals, substantial amounts are released into water and soil (Cycon *et al*., 2019). Diclofenac (DCF) and Sulfamethoxazole (SMX) were widely used but raised concerns about potential environmental hazards, as they were found to be persistent in the environment, posing risks of acute toxicity and the spread of antimicrobial resistance (Drzymała and Kalka, 2023). Both are classified as "Class 1: High Priority Pharmaceuticals" in the standard list of pharmaceuticals pertinent to the water cycle (de Voogt *et al*., 2009). Diclofenac is a monocarboxylic acid composed of a phenylacetic acid possessing an amino group at position two (2, 6-chlorophenyl).

It acts as an antipyretic, non-narcotic analgesic, and primarily as a non-steroidal anti-inflammatory agent, prescribed to reduce inflammation and pain caused by arthritis, rheumatoid arthritis, osteoarthritis, and ankylosing spondylitis, among other inflammatory diseases (NCBI, 2023; Parolini, 2020). The therapeutic action of DCF is to inhibit cyclooxygenase I and II, thereby reducing prostaglandin production. Prostaglandins are associated with a variety of physiological processes, including inflammation, platelet aggregation, vasodilation, renin release, and, presumably, complex integrative functions in the brain and the autonomic nervous system (Schwarz *et al*., 2017). Like most pharmaceuticals, Diclofenac is typically not completely removed through traditional wastewater treatment and can persist in aquatic environments due to its physicochemical properties (Luongo *et al*., 2021).Despite its relatively low concentrations in aquatic environments, Diclofenac's persistence, bioaccumulation, and chronic toxicity to non-target organisms have made it a significant concern as a pollutant (Kuster *et al*.,2020). Its biochemical effects, such as oxidative stress, immune system disruption, tissue damage, and endocrine interference, have been widely reported across various aquatic species, including fish, amphibians, and invertebrates (Triebskorn *et al.,* 2004; Hoeger *et al.,* 2005; Garcia-Cambero *et al.,* 2017). Long-term exposure of aquatic organisms to sublethal concentrations of Diclofenac can lead to population declines and alterations in ecosystem dynamics (Bringolf *et al*., 2019). Recently, Hernandez-Zamora *et al*. (2025) reported that Diclofenac caused significant toxicity to the population growth of the microalga *Pseudo kirchneriella subcapitata* and to the reproductive parameters of the cladoceran *Daphnia curvirostris*; it also caused lethal and sublethal effects in embryos and larvae of *Danio rerio*. Like other antibiotics, the excessive use

and contamination of Sulfamethoxazole can have many adverse consequences for humans and animals. Research has shown that long-term exposure to Sulfamethoxazole can lead to urinary and hematopoietic dysfunction in humans (Chen *et al*., 2012).

It is affecting fish behaviour and reproduction, resulting in decreased spontaneous swimming activity and increased heart rate in zebra fish (Lin *et al*., 2014). Earlier, Zhou *et al*. (2024) reported thatchronic exposure to SMX had no apparent inhibitory effect on zebrafish growth at concentrations below 24 mg/L. Meanwhile, concentrations above 24 mg/L of SMX induce oxidative damage and cause immune system disorders in the liver and gills of zebrafish. Diclofenac was predicted environmental concentrations (PEC) of 140ng/L for a realistic worst-case scenario, and 2 to 52 ng/L based on water quality modelling were derived. Since concentrations up to 140ng/L were observed in surface water, the PEC obtained was in perfect agreement with the measured concentrations (Letzel *et al*., 2009; Matejczyk *et al*., 2020). Meanwhile, the maximum detected concentrations of Sulfamethoxazole in aquatic ecosystems world wide range from 15 to 150ng/L (Schuijt *et al*., 2024). Based on recent reports, Diclofenac at 1 mg/L did not exhibit lethal or sublethal effects (Hernandez-Zamora *et al*., 2025), and SMX at concentrations below 24 ng/L did not show toxic effects on zebrafish (Zhou *et al*., 2024). The environmental concentrations of DCF and SMX were lower than the previously reported toxic range. Pharmaceutical mixtures may include interactions between the substances themselves or between degradation products formed during metabolic processes (Cedergreen, 2014). The increased toxicity of pharmaceutical mixtures compared with individual compounds has been observed by numerous other authors, including Ortiz de Garcia *et al*. (2016), Di Nica *et al*. (2017) and Drzymała and Kalka(2023). An essential part of the analysis was to observe the interactions between the DCF-SMX mixture at environmental concentrations. Hence, the present analysis aims to assess the effects of Diclofenac and Sulfamethoxazole at environmental concentrations, individually as well as in combination, on growth performance and haematological parameters of *Labeo rohita*, and to examine the bioaccumulation of DCF and SMX in different tissues of treated fish.

MATERIALS AND METHODS

Chemicals

The selected pharmaceutical pollutants Diclofenac and Sulfamethoxazole (purity >99%) were purchased from Sigma-Aldrich, USA. The other chemicals were procured from Merck (Mumbai, India), and the experimental chemicals/reagents used in the study were of analytical grade.

Fish collection and acclimatization

Labeo rohita fingerlings (200 Numbers), having an average initial weight of 12.0 ± 0.25 g and an initial length of 11 ± 0.15cm, were purchased from Navarathna Fish Seed Farm, Pinnalur, Cuddalore, Tamil Nadu. All fish were selected and given a KMnO4 bath to remove ectoparasites. They were acclimatized in the laboratory under normal photoperiod (12h:12 h L :D) and temperature (26–28 °C) for 2 weeks in a 1000 L fibre tank before use in experiments. The fish were fed alternately with groundnut oil cake, rice brawn, formulated feed and commercial feed. Water was replenished every 24 hours by replacing half of the tank's water. This experiment was performed from May to August 2025 at the Department of Zoology, Kolanjiappar Government Arts College, Virudhachalam–606 001, Tamil Nadu, India.

Experimental design

A group of 200 healthy, acclimated *Labeo rohita* fingerlings (same size) was divided into four groups. Each group of 50 fish was maintained in a separate 100 L fibre tank. For the exposure groups, a concentration of 140ng/L for DCF or 150 µg/L for SMX, or a mix of DCF (140ng/L) and SMX (150 µg/L), was prepared in water to match the environmental concentrations (Letzel *et al*., 2009; Matejczyk *et al*., 2020; Schuijt *et al*., 2024).

The exposure of DCF and SMX groups is as follows:

Group I : Control (Untreated)
Group II : Normal fish were exposed to an environmental concentration of DCF (140ng/L) for 45 days.
Group III : Normal fish were exposed to an environmental concentration of SMX (150µg/L) for 45 days.
Group IV : Normal fish were exposed to a combination of environmental concentrations of DCF (140ng/L) and SMX (150µg/L) for 45 days.

During the experimental period, the fish were fed alternately with groundnut oil cake, rice bran, formulated feed, and commercial feed, and unfed feed was removed after 6 hours of feeding. Water was replenished periodically by replacing half of the tank's water. At 15, 30, and 45 days, fish from the control and treated groups were caught from the tank using a hand net, and growth performance, haematological profile, and bioaccumulation were recorded. Every 15 days, the experimental water was analyzed for physico-chemical parameters, viz., pH, temperature, Biochemical oxygen demand (BOD), Dissolved oxygen (DO), and free carbon dioxide (CO2), using standardized methods.

Growth performance

At the end of each exposure period (15th, 30th, and 45th days), the control and treated fish are individually removed from each group. Then, the individual fish's wet body weight and total length were measured in each tank, and the fish were immediately returned to the rearing tanks. Growth performance and food utilization were determined using the methods of Sveier *et al*. (2000). The net weight gain (NWG), specific growth rate (SGR), feed conversion ratio (FCR), feed efficiency ratio (FER), and survival rate were calculated according to the following formulae:

Net Weight gain (NWG) = Average final weight (g) - Average initial weight (g).
Length gain (LG) = Average final length (cm) - Average initial length (cm).
Specific growth rate (SGR) = Final weight-Initial Weight (g) × 100/ days
Feed conversion ratio (FCR) = Dry feed given (g)/ Weight gain of fish (g)
Feed efficiency ratio (FER) = Weight (g)/ Feed intake (g).
Survival Rate (%) = (Final Number of Fish live/Initial Number of Fish) x 100.

Haematological analysis

From the control and treated groups, five fish were randomly selected and anaesthetized for blood sampling at the 15th, 30th, and 45th exposure periods. Hypodermic micro syringes cleaned with a few drops of heparin solution were used to collect the blood samples (1.5–2 ml) from the caudal vein of the fish. After blood collection, the blood was immediately transferred to EDTA anticoagulant for measurement of hematocrit (HCT), white blood cells (WBCs), mean cell haemoglobin (MCH), platelets (PLT), mean cell volume (MCV), red blood cells (RBCs), and haemoglobin (Hb) by using Celltac, a haematology analyzer (MEK-6500 K, Nihon Kohden) as described by Dacie and Lewis (1995).

Bioaccumulation analysis of DCF and SMXin tissues by HPLC

The tissue samples were cleaned and extracted with methanol for DCF analysis and with acetonitrile for SMX analysis. For DCF analysis, the extraction solution was defatted using a freezing-lipid technique. The extract was stored at −80 °C for 24 h, and immediately centrifuged at 12,000×g for 15 min at 0 °C. Subsequently, the solution was extracted and cleaned up again using solid-phase extraction (SPE). Finally, the tissue extracts were evaporated to near dryness under a mild stream of nitrogen and were reconstituted with 1mL of methanol. This was analyzed by ultra-high-performance liquid chromatography (Agilent, USA) (Sun *et al*., 2020). For SMX analysis, the tissue homogenate was centrifuged for 10 min (5000g), and the supernatant was collected and transferred to a glass flask. The procedure was repeated, and the pooled supernatants were incubated at 37 ºC to evaporate, yielding a dry product. Next, n-hexane was added to the residues to remove lipid content from the fish tissues. The tissue samples were finally filtered using syringe filters (0.45 µm) for HPLC analysis. SMX was then analyzed using High-Performance Liquid Chromatography (Agilent, USA) (Iftikhar *et al*., 2022).

Statistics

All results were presented as mean ± SD for 10 fish per group (n=10). For result analysis, One-way analysis of variance (ANOVA) was followed by Duncan's Multiple Range test (IBM SPSS Statistics for Windows, version 15), and values of $p< 0.05$ were considered statistically significant.

RESULTS

Growth performance

Growth performance parameters, such as body weight, length gain, net weight gain, specific growth rate, feed conversion ratio, feed efficiency ratio, and survival rate, were observed at 15, 30, and 45 days in control and treated *Labeo rohita* fingerlings (Table 1). A significant difference was observed at every 15-day interval between the control and treated groups. The combination of DCF and SMX at environmental concentrations resulted in significant declines in body weight, net weight gain, length gain, and specific growth rate in exposed fish. In contrast, feed conversion ratio and feed efficiency ratio were remarkably higher than those of control fish at 15, 30, and 45 days. Exposure of SMX at environmental concentrations did not induce significant changes in fish growth performance parameters at 15 and 30 days, but 45 days of exposure did. Meanwhile, at environmental concentrations of DCF, exposed fish showed significant changes in growth parameters on 30 and 45 days compared to the control. The survival rate was significantly reduced in combination with DCF and SMX at environmental concentrations, with exposure at 15, 30, and 45 days compared to the control. At environmental concentrations of DCF and SMX, exposure did not reduce survival at 15 or 30 days, whereas exposure for 45 days decreased survival.

Haematological analysis

(Table 2) presents the haematological profiles of DCF, SMX, and the combination of DCF and SMX at environmental concentrations in exposed fish and control fish at 15, 30, and 45 days. The haematological profile, including red blood cells, mean cell haemoglobin, hematocrit, haemoglobin, and platelets, significantly declined in combination with DCF and SMX at environmental concentrations in the treated group at 15, 30, and 45 day intervals compared to control fish. Meanwhile, mean cell volume and white blood cell values increased significantly at 15, 30, and 45 days in the combination of DCF and SMX-treated group compared to normal fish. An environmental concentration of SMX exposure did not show significant changes in the haematological profile at 15 and 30 days, but a significant change was observed at 45 days compared to control fish. Further, the DCF-exposed fish showed significant changes in the haematological profile at 30 and 45 days compared with the control. The growth performance and haematological profile results indicate that, in combination with DCF and SMZ at environmental concentrations, exposed fish showed a greater negative impact than the individual treatments of DCF and SMZ. Therefore, the bioaccumulation analysis will further focus on the combination of DCF- and SMX-exposed fish.

Bioaccumulation of DCF and SMX

The bioaccumulation of DCF and SMX in gill, liver, kidney, and muscle tissues of fish exposed to the combination of DCF and SMX at environmental concentrations is presented in (Table 3). In environmental concentrations, DCF and SMX-treated gill tissue of *Labeo rohita,* the concentrations of DCF were 25.86, 39.73, and 57.36 ng/g at 15, 30, and 45 days of exposure, respectively. Meanwhile, DCF concentration in liver tissue was 44.52, 57.45 and 71.56 ng/g at 15, 30 and 45 days of exposure, respectively. The bioaccumulation of DCF in kidney tissue was observed at 31.38, 46.42, and 65.15 ng/g, while in muscle tissue, DCF concentrations of 23.28, 35.51, and 48.92 µg/g were observed at 15, 30, and 45-day intervals, respectively. In combination of DCF and SMX treated fish, SMX bioaccumulation was 120.68, 102.54, and 84.56 ng/gin liver tissue and in kidney tissue was 87.25, 70.36 and 49.75 ng/g at 15, 30 and 45 days of exposure, respectively. The SMX concentration range was 64.86, 54.82 and 43.46 ng/g in gill tissue, while in muscle tissue, SMX concentrations of 38.6, 30.2, and 22.45 ng/g were detected at 15, 30, and 45-day intervals, respectively. The high level of DCF and SMX were detected in the liver, followed by the kidney, gill and muscle tissue, respectively.

DISCUSSION

Pharmaceutical pollution from Diclofenac and Sulfamethoxazole is a growing global concern driven by high consumption rates, inadequate wastewater treatment, and the compounds' persistence in the environment. These substances are considered "high priority pharmaceuticals" in the water cycle (Drzymałaand Kalka, 2023). The combined effects of multiple drugs are often different and potentially more severe than the effects of a single drug, leading to significant ecological risks (Khan *et al*., 2023). Hence, the present analysis aims to assess the effects of Diclofenac and Sulfamethoxazole at environmental concentrations, individually and in combination, on growth performance and haematological parameters of *Labeo rohita,* and to detect the bioaccumulation of DCF and SMX in different tissues of treated fish. The present findings confirmed that the combination of environmental concentrations of DCF and SMX induces toxic effects on *Labeo rohita* fingerlings. Fish growth is considered a precise, reliable, and sensitive indicator endpoint related to sub-lethal (chronic) exposure to water-borne pollutants (Malik *et al*., 2022). Body weight and length, feeding intensity, and feed conversion rate are the primary variables that provide information on fish growth (Rahman and Arifuzzaman, 2017). In the present investigation, a combination of DCF and SMX at environmental concentrations resulted in a significant decline in net weight gain, length gain, and specific growth in exposed fish. In contrast, feed conversion and efficiency ratios were significantly higher than in individual treatments with DCF- and SMX-treated fish at 15, 30, and 45 days. Previously, Zhou *et al*. (2024) reported that concentrations of SMX below 24 mg/L do not seem to inhibit the growth of zebrafish, and that DCF at 1 mg L−1 did not exhibit an abnormal impact on fish (Hernandez-Zamora *et al*., 2025). However, the combination of DCF and SMX at environmental concentrations exposed fish showed a remarkable change in growth performance compared with DCF- and SMX-treated fish.

The present results showed that individual treatment with DCF and SMX at environmental concentrations did not induce significant abnormal changes in the growth performance of *Labeo rohita* fingerlings. The combination of DCF and SMX caused significant abnormal changes in fish growth performance due to synergistic or partial-additive effects of the mixture, leading to an imbalance in normal physiology and reducing feed intake and growth in fingerlings. The combination of DCF and SMX at environmental concentrations induces toxic effects on fish, as evidenced by a significant reduction in survival rate in DCF and SMX-exposed fish compared to other groups. Blood is a suitable indicator of the effects of stress, environmental conditions, and fish health status in a given area. Blood cell count is a stable index, and fish typically try maintain it within certain limits. The presence of pollutants in water may alter water quality, ultimately affecting one or more haematological parameters (Batool *et al*., 2024). Many researchers have reported changes in the blood parameters of fish following toxicant exposure. In the present study, the haematological parameters red blood cells, mean cell haemoglobin, hematocrit, haemoglobin, and platelets significantly declined and mean cell volume and white blood cell values increased significantly in combination of DCF and SMX at environmental concentration treated fish at 15, 30 and 45 day intervals when compared to DCF and SMX individually treated fish. The present findings were consistent with those of Ribas *et al*. (2016), who reported that trophic exposure to Diclofenac and dexamethasone induces abnormal changes in haematological parameters and the immune response in freshwater fish. These abnormal haematological parameters indicate that the combination of environmental concentrations of DCF and SMX induces dysfunction of the haemopoietic system.

The decreased haemoglobin values, in combination with the environmental concentrations of DCF and SMX in treated fish, indicate an inability to provide sufficient oxygen to the fish tissues, reflecting anaemia due to iron deficiency. The decline in MCH values in the present investigation indicates that haemoglobin concentration is reduced in red blood cells. Whereas the alterations in blood parameters, i.e., decrease in MCH and increase in MCV values, might be due to defence against the combination of DCF and SMX toxicity and, in turn, to decline in Hb, PCV and RBC values and the disruptions that occurred in fish metabolic activities. The increased level of white blood cells, in combination with DCF and SMX exposure, may correlate with increased antibody production, supporting fish recovery and survival following exposure to the combination of DCF and SMX toxicants. Bioaccumulation tests help in fish toxicology by determining how much of a chemical accumulates in fish tissue, assessing the potential for harm

to both the fish and to organisms (including humans) that consume them, and providing data for environmental risk assessment and regulation (Jamil Emon *et al*., 2023). Previously, DCF (Qiuguo *et al*., 2020) and SMX (Nazish *et al*., 2022) were detected in the tissue of freshwater fish. In the present study, the highest concentrations of DCF and SMX were observed in liver, followed by kidney, gill, and muscle tissue, in combination-exposed fish at environmental concentrations, on 15, 30, and 45 days, respectively. The liver, followed by the kidney, showed the highest levels of bioaccumulation of DCF and SMX, as it is a major detoxification organ. While gill and muscle tissue possess a lower level of bioaccumulation of DCF and SMX in treated fish, because the gill is in direct contact with contaminated water and the muscle is not an active site.

CONCLUSION

The results of the present study indicate that the combination of environmental concentrations of Diclofenac and Sulfamethoxazole resulted in a significant decline in body weight, net weight gain, length gain, and specific growth rate in exposed fish. In contrast, feed conversion ratio and feed efficiency ratio were significantly higher at 15, 30, and 45 days than with individual exposure to DCF and SMX. The haematological profile, including red blood cells, mean cell haemoglobin, hematocrit, haemoglobin, and platelets, significantly declined, and mean cell volume and white blood cell values increased significantly at 15, 30, and 45 day intervals in the combination of DCF and SMX-treated group compared to other groups. The highest bioaccumulation of DCF and SMX was represented in the liver, followed by the kidney, gill and muscle tissues in combination DCF and SMX-treated fish. Further studies are required to understand the mechanism underlying the combined toxicity of DCF and SMX in aquatic organisms.

ABSTRACT

Medicinal plants continue to play a vital role in primary healthcare systems, particularly within traditional medicine, where their therapeutic benefits are attributed to diverse classes of bioactive phytoconstituents. Among these, *Curcuma longa, Murraya koenigii, Premna serratifolia,* and *Oroxylum indicum* hold significant pharmacological relevance due to their established anti-inflammatory, antioxidant, antimicrobial, and immunomodulatory activities. However, comprehensive pharmacognostical standardization of these botanicals—especially in the form of hydroalcoholic extracts that efficiently capture both polar and semi-polar constituents—remains limited. Establishing validated diagnostic parameters is essential for authentication, quality assurance, and prevention of adulteration in herbal raw materials and formulations. The present study aims to perform an extensive pharmacognostical evaluation of hydroalcoholic extracts derived from these four medicinal plants. Crude drug samples were subjected to macroscopic and microscopic examination to confirm identity and structural integrity. Physicochemical analyses, including ash values, extractive values, loss on drying were determined according to standard pharmacopoeial procedures. Hydroalcoholic extracts were prepared using optimized extraction techniques to ensure maximal phytochemical recovery. Preliminary phytochemical screening was conducted to identify major groups of secondary metabolites, while thin-layer chromatography (TLC) fingerprinting was employed to develop characteristic profiles indicative of key marker constituents such as curcuminoids in *C. longa,* carbazole alkaloids in *M. koenigii,* glycosides in *P. serratifolia,* and flavonoids in *O. indicum.* The findings of this study provide a consolidated pharmacognostical framework for these widely used medicinal plants. The generated morphological, microscopic, physicochemical, and chromatographic profiles serve as reliable reference standards for authentication and quality control. Overall, this work contributes significantly to the scientific validation of traditionally important botanicals and supports future phytochemical, pharmacological, and formulation-based research.

Keywords: Hydroalcoholic extract, *Curcuma longa, Murraya koenigii, Oroxylum indicum,*Pharmacognostical characterization

INTRODUCTION

Medicinal plants remain an indispensable resource for traditional and contemporary healthcare systems, and their pharmacognostical investigation plays a pivotal role in ensuring identity, purity, quality, and therapeutic reliability. With rising global acceptance of herbal medicines, systematic evaluation of crude drugs—through macroscopic, microscopic, physicochemical, and phytochemical parameters—has become essential for establishing scientific standards and preventing adulteration. Hydroalcoholic extraction has gained prominence due to its ability to efficiently solubilize a broad range of polar and moderately non-polar phytoconstituents, thereby reflecting the true chemical profile traditionally accessed through decoctions or tinctures. Among important ethnomedicinal plants, *Curcuma longa, Murraya koenigii, Premna serratifolia,* and *Oroxylum indicum* hold significant therapeutic value in Ayurveda, Siddha, and other traditional systems of medicine. *Curcuma longa* (turmeric) is widely recognized for its anti-inflammatory, antioxidant, antimicrobial, and wound-healing activities, attributed primarily to curcuminoids and essential oils. *Murraya koenigii* (curry leaf) is traditionally used for digestive, hepatoprotective, and anti-diabetic actions and contains alkaloids, flavonoids, carbazole derivatives, and phenolic compounds. *Premna serratifolia* (Agnimantha), one of the ten plants of the classical "Dashamoola" group, is valued for its anti-inflammatory, analgesic, and immunomodulatory properties, attributed to iridoid glycosides, flavonoids, and lignans. *Oroxylum indicum* (Shyonaka), another Dashamoolaingredient, possesses documented antioxidant, anti-arthritic, and anti-inflammatory effects, largely due to its bioactive flavonoids such as baicalein, chrysin, and oroxylin A.Despite their broad therapeutic potential and extensive traditional use, comparative pharmacognostical standardization of hydroalcoholic extracts of these four botanicals remains insufficiently explored. Therefore, the present study aims to carry out a detailed pharmacognostical evaluation of the hydroalcoholic extracts of *Curcuma longa, Murraya koenigii, Premna serratifolia* and *Oroxylum indicum,* focusing on morphological, microscopic, physicochemical, and chromatographic parameters. This work is intended to contribute scientifically validated benchmarks for standardization, thereby strengthening the quality control of these medicinally important botanicals [1-5].

Table 01: Detailed Plant Species

Figure 01: Proposed Mechanism of Action

MATERIALS AND METHODS

Plant Collection

Fresh leaves and dried rhizomes of Murraya koenigii, Curcuma longa, Premna Serratifolia and Oroxylum indicum were collected respectively from the Junagadh Agricultural University, Government Ayurved College, Junagadh and foothills of Girnar, Gujarat.

Plant Authentication

Herbarium Sheets were prepared of all the plants and submitted for proceedings regarding plant authentication. Authentication of plants was done at Bhakta Kavi Narsinh Mehta University, Junagadh.

Extraction of Plants [6-10]

•Curry Leaves:

100 gm leaf powder was macerated with 500 ml ethanol for 5 days and filtered using whatmann paper → Dried powder was collected after solvent evaporation.

•Turmeric:

Powdered rhizomes (25 g) were macerated with 100 ml ethanol (70%) for 7 days and filtered using whatmann paper → Extract was collected after solvent evaporation.

•Shyonaka:
500 gm bark powder was macerated with 5 L solvent for 7 days (1:1) and filtered & residue again macerated for 7 days → Dried powder sample was collected after solvent evaporation.

•Agnimantha:
100 gm coarse powder was extracted with thrice the quantity of raw material 50% aq. alcohol for 3-4 hr followed by filtration → Dried powder sample was collected after solvent evaporation.

Pharmacognostical Analysis [11-15]

Thin layer Chromatography:
Identification of isolated chemical constituent present in extracts was carried out using pre-coated TLC plates as per mentioned parameters listed over here – Table 02: TLC Specifications

Microscopic Characteristics:
Transverse section observation was performed and for powder microscopy slides were prepared either by soaking a pinch of fine powder in distilled water for 1 h & staining with saffranin for 2-4 min or by treating with chloral hydrate solution for 1 h and staining with fluoroglucinol followed by addition of 1-2 drops of conc. HCl.

• Preliminary Phytochemical Analysis:
Preliminary phytochemical screening of the hydroalcoholic extract was carried out to determine the major classes of secondary metabolites present in the selected plant materials.

Alkaloids
The extract was assessed for alkaloids using classical alkaloid-precipitating reagents, including Dragendorff's, Mayer's, Wagner's, and Hager's reagents. These assays rely on the ability of alkaloidal bases to form distinct colored precipitates with heavy-metal complexes. The appearance of cream, reddish-brown, or brick-red precipitates with the respective reagents was considered indicative of alkaloid presence.

Carbohydrates
Carbohydrates and reducing sugars were evaluated through general and differential reactions. A general carbohydrate test was conducted using an α-naphthol–based reagent that yields a characteristic violet interface upon dehydration of carbohydrate residues. Reducing sugars were examined through copper-based oxidation–reduction reactions (e.g., Benedict and Fehling types), where the formation of colored cuprous oxide precipitates signifies the presence of reducing carbohydrate species.

Proteins and Amino Acids
Proteins were screened using peptide-bond detecting reagents that produce violet or pink coloration due to complex formation with proteinaceous material. Free amino acids and certain aromatic residues were identified using tests that generate blue–purple or red coloration upon reaction with their respective chromogenic reagents.

Phenols
Phenolic compounds were identified by iron-based colorimetric reactions. Ferric chloride solution was employed to detect phenolic hydroxyl groups through the formation of blue, green, or dark complexes, depending on the structural nature of the phenolic constituents. Additional confirmatory reactions involved reagents known to interact specifically with polyphenolic structures.

Tannins

Tannins were differentiated from general phenolics using protein-precipitation and metal-salt precipitation assays. Gelatin–salt systems and lead-based reagents were used to identify hydrolyzable and condensed tannins by their ability to produce characteristic dense precipitates or turbidity.

Saponins

Saponins were evaluated based on their natural surfactant behavior. Qualitative assessment involved observation of persistent foam formation under specific test conditions, indicative of the presence of triterpenoid or steroidal saponin glycosides.

Starch

Starch was identified using an iodine–iodide–based complexation test producing a characteristic blue or blue-black coloration. The test differentiates intact starch polymers from their hydrolyzed products, which yield weaker or no coloration.

Flavonoids

Flavonoids were screened using both reduction-based and alkaline shift tests. Reactions involving metallic zinc in acidic conditions (Shinoda type) produce pink to magenta coloration characteristic of flavonoid aglycones. In alkaline conditions, flavonoids generate intense yellow coloration that becomes colorless upon acidification, serving as a confirmatory diagnostic.

Steroids and Triterpenoids

Steroid and triterpenoid nuclei were detected using colorimetric reactions involving strong dehydrating agents. These reactions yield characteristic color transitions, typically green, blue, or reddish hues—associated with sterol or triterpenoid structural frameworks.

• **Physicochemical Analysis: [11-15]**

Physicochemical parameters of the hydroalcoholic plant extracts were evaluated in accordance with standard procedures. The analyses included determination of total ash,acid-insoluble ash, loss on drying, water-soluble extractive value, and alcohol-soluble extractive value. These parameters provide essential information regarding purity, quality, and the presence of inorganic or extractable constituents in the plant material.

Total Ash

Total ash determination was carried out to estimate the overall inorganic residue remaining after complete combustion of the extract. This value represents the total amount of physiologically inert matter present, including both inherent mineral content and any extraneous matter such as soil, sand, or carbonates. The results helped assess the general purity and cleanliness of the crude drug.

Acid-Insoluble Ash

Acid-insoluble ash was measured to quantify the portion of the ash content that remains insoluble in dilute acid. This parameter is particularly significant as it indicates the presence of silica, sand, or other earthy impurities that may have been introduced during harvesting or processing. A lower acid-insoluble ash value reflects better handling and reduced contamination with extraneous mineral matter.

Loss on Drying (Moisture Content)

Loss on drying was performed to determine the moisture content of the extract. This measurement provides insight into the amount of volatile matter present, primarily water. Excessive moisture increases the risk of microbial growth, enzymatic degradation, and chemical instability during storage. The obtained values serve as an indicator of the suitability of the sample for long-term preservation.

Water-Soluble Extractive Value

The water-soluble extractive value was determined to evaluate the amount of constituents that are soluble in aqueous media. This parameter reflects the presence of water-soluble phytoconstituents such as sugars, tannins,

glycosides, and certain phenolic compounds. Higher extractive value generally correlates with higher concentrations of hydrophilic bioactive components.

Alcohol-Soluble Extractive Value

The alcohol-soluble extractive value was measured to estimate the proportion of constituents soluble in ethanol or hydroalcoholic solvents. These typically include resins, alkaloids, flavonoids, steroids, and other moderate polar compounds. Alcohol-soluble extractives are often used as indicators of the presence and relative concentration of pharmacologically relevant secondary metabolites.

RESULT AND DISCUSSION

Plant Extract

By performing extraction of all these various plants by maceration process, extract was collected and stored for further analytical purposes. The percentage yield was determined as mentioned here in the table below.

Table 03: Determination of % yield by Maceration

Figure 02: Plant Extracts – (a) *Murraya koenigii (b) Curcuma longa* L. *(c) Premna Serratifolia* linn *(d) Ocimum sanctum* linn

Thin Layer Chromatography

Identification of isolated chemical constituent present in extracts was carried out using pre-coated TLC plates to confirm presence of phytoconstituents.

Figure 03: Thin Layer Chromatography – (a) *Murraya koenigii (b) Curcuma longa* L. *(c) Premna Serratifolia* linn *(d) Ocimum sanctum* linn

Microscopy

The sharp transverse section of selected specific parts of plants were observed under 10x microscope followed by powder microscopy. The coarse powder of each sample was treated with chloral hydrate solution for clearing, mounted in glycerin, and observed under bright field microscopy. Staining with phloroglucinol–HCl, iodine solution, safranin, and Sudan III was employed to highlight lignified, starchy, and lipid structures.

Figure 04: Microscopic Observation of Transverse Section of Plants – (a) *Murraya koenigii (b) Curcuma longa L. (c) Premna Serratifolia linn (d) Ocimum sanctum linn*

Figure 05: Microscopic Observation of Powdered Plant Material – (a) *Murraya koenigii (b) Curcuma longa L. (c) Premna Serratifolia linn (d) Ocimum sanctum linn*

Microscopic analysis of crude powders and extract residues demonstrated distinct diagnostic features characteristic of each plant species. Hydroalcoholic extraction preserved many structural elements including starch grains (Curcuma longa), oil globules (Murraya koenigii, Curcuma longa), lignified fibers (Premna serratifolia and Oroxylum indicum), and calcium oxalate crystals. These features serve as dependable authentication markers and support the botanical identity of the raw materials used for extraction.

Physicochemical Analysis

The tests were based on characteristic color reactions or precipitate formation resulting from interactions between specific phytochemical groups and their respective diagnostic reagents. Observations were recorded immediately after each reaction and interpreted according to reference standards.

Table 04 : Phytochemical Evaluation – P1: *Murraya koenigii*, P2: *Curcuma longa*, P3: *Premna Serratifolia linn*, P4: *Oroxylum indicum linn*

Organoleptic Characteristics

The extracts exhibited distinct visual and sensory characteristics:

- *Murraya koenigii*: dark green to brown extract with aromatic odor.

- *Curcuma longa*: deep yellow to orange with characteristic pungent aroma.
- *Premna serratifolia*: brownish to dark brown with woody odor.
- *Oroxylum indicum*: reddish-brown extract with astringent smell.

Moisture Content (Loss on Drying)

All extracts showed LOD within acceptable limits, indicating minimal moisture and reduced risk of microbial growth or degradation.

Ash Values

- *Murraya koenigii* extract showed moderate total ash, reflecting mineral content inherent to the leaf tissues.
- *Curcuma longa* displayed lower acid-insoluble ash, indicating less contamination with siliceous matter.
- *Premna serratifolia* exhibited slightly higher total ash due to the presence of lignified root tissues and inorganic components.
- *Oroxylum indicum* had appreciable water-soluble ash, suggestive of the presence of water-soluble inorganic salts and phenolics.

These values confirm the purity and minimal inorganic adulteration.

Extractive Values

- Alcohol-soluble extractive values were highest for *Curcuma longa*, consistent with its high content of curcuminoids, volatile oils, and oleoresins.
- *Murraya koenigii* also showed high alcohol solubility due to essential oils and alkaloids.
- Water-soluble extractive values were relatively higher for *Oroxylum indicum* and *Premna serratifolia*, indicating abundance of tannins, glycosides, and polysaccharides. The extractive value pattern correlates well with phytochemical distribution.

Table 05 : Physicochemical Evaluation – P1: *Murraya koenigii*, P2: *Curcuma longa*, P3: *Premna Serratifolia linn*, P4: *Oroxylum indicum linn*

CONCLUSION

The present study comprehensively evaluates the pharmacognostic potential of hydroalcoholic extracts of *Murraya koenigii*, *Curcuma longa*, *Premna serratifolia*, and *Oroxylum indicum* through detailed microscopic, physicochemical, and preliminary phytochemical investigations. The extracts exhibited distinct diagnostic microscopic features—including starch grains, oil globules, lignified fibers, sclereids, and calcium oxalate crystals—that authenticate each species and support botanical identity. Physicochemical parameters such as ash values, extractive values, moisture content, and pH remained within acceptable limits, confirming good quality, purity, and stability of the extracts. The phytochemical screening further revealed the presence of key bioactive groups such as alkaloids, flavonoids, tannins, phenols, saponins, steroids, and carbohydrates, highlighting their therapeutic relevance. Overall, the findings establish reliable pharmacognostic markers and standardization parameters for these four medicinal plants, emphasizing the suitability of hydroalcoholic extraction for preserving structurally and chemically significant constituents. The study provides a strong foundation for future formulation development, quality control, and advanced pharmacological investigations involving these botanicals.

ACKNOWLEDGMENT

The authors would like to thank Dr. Subhash University, Junagadh for providing the necessary laboratory facilities and research environment for completion of this work.

ABSTRACT

India's linguistic diversity faces unprecedented challenges from globalisation and urbanisation, with 197 languages classified as endangered by UNESCO. This research examines two government-led digital preservation initiatives: Adivaani and Bhashini, which leverage artificial intelligence to preserve endangered languages. Employing desktop research methodology with qualitative analysis of 3,330 Play Store user reviews, this study evaluates technical infrastructure, user experience, and platform effectiveness. Findings reveal an average rating of 4.33/5 for Bhashini, indicating positive reception but highlighting critical challenges in technical accessibility, offline functionality, and community engagement. The research identifies key impediments to digital language preservation and proposes strategic solutions for enhancing platform efficacy

INTRODUCTION

India represents one of the world's most linguistically diverse nations, hosting over 1,950 languages and dialects as documented in the 2011 Census. However, this remarkable diversity confronts an existential crisis. India leads UNESCO's Atlas of the World's Languages in Danger with 197 endangered languages, including scheduled languages like Manipuri and Bodo classified as "unsafe" (Moseley, 2010). Research indicates that between 40-50% of India's languages could disappear within the next century, with linguist David Crystal warning that one language vanishes globally every two weeks (Crystal, 2000).

The severity of this crisis becomes evident when examining the distribution of endangered languages by speaker population. Table 1 illustrates the alarming concentration of endangered languages across different vitality levels, with the majority having fewer than 5,000 speakers.

As demonstrated in Table 1, 61 languages classified as "In Peril" have fewer than 5,000 speakers, while only 15 such languages have more than 100,000 speakers. This distribution underscores the urgency of preservation efforts, particularly for languages with minimal speaker populations. The data reveals that 200 out of 242 total endangered or at-risk languages (approximately 83%) have fewer than 100,000 speakers, with the most critical category being those with 0-5,000 speakers, totalling 115 languages. Language loss represents more than vocabulary extinction; it signifies the disappearance of unique worldviews, cultural knowledge, and cognitive frameworks (Nettle & Romaine, 2000). As Romaine (2007) emphasises, languages should be considered vital components of complex ecologies requiring careful management to sustain global biodiversity. Recognising this urgency, the Government of India has launched technology-driven initiatives leveraging artificial intelligence (AI), natural language processing (NLP), and machine learning to preserve endangered languages.

This study examines two pioneering platforms: Adivaani, launched in September 2024 by the Ministry of Tribal Affairs as India's first AI-powered translator for tribal languages, and Bhashini, developed under the National Language Translation Mission by the Ministry of Electronics and Information Technology. The research objectives include: (1) analysing technical infrastructure and user interfaces, (2) evaluating user satisfaction through Play Store reviews, (3) comparing platforms through feature analysis, and (4) proposing evidence-based solutions.

LITERATURE REVIEW

Language Endangerment in India

The crisis of language endangerment in India has been extensively documented. Devy's People's Linguistic Survey of India (2010) revealed that India had lost nearly 250 languages over sixty years, with 780 languages written in 86 scripts remaining (Devy, 2020). The geographical distribution shows concerning patterns, with endangered languages concentrated in North-Eastern regions and tribal belts of Orissa, Jharkhand, West Bengal, Himachal Pradesh, and Uttarakhand (Blackburn & Opgenort, 2010). Language obsolescence results from complex factors, including colonisation effects, urbanisation, dominant language pressure, policy failures, and educational marginalisation (Fishman, 1989). When languages disappear, distinct worldviews vanish alongside vocabulary and speech patterns (Dalby, 2002). Language serves as a vital source of knowledge about human cognition for the global community beyond being an essential component of cultural identity (Harrison, 2007).

Digital Archiving and AI in Language Preservation

Digital archiving has emerged as a powerful preservation tool, utilising digital technologies to store, organise, and distribute linguistic information (Berez, 2013). These archives preserve linguistic and cultural heritage through audio-visual resources, transcriptions, translations, and linguistic annotations, making them accessible for future generations. Notable platforms include the Endangered Languages Archive (2002), Living Tongues (2005), and the Sikkim-Darjeeling Himalayas Endangered Language Archive (2016). Austin (2021) emphasises that contemporary preservation approaches should integrate technology-enabled strategies with community-centred methods. Galla (2009) highlights the critical role of digital archives in facilitating access to indigenous languages and preserving them effectively. AI and NLP have fundamentally transformed preservation capabilities, enabling real-time translation, speech recognition, and creation of interactive learning tools (Bernard, 2010).

RESEARCH METHODOLOGY

This study employs a qualitative desktop research methodology utilising secondary data analysis. Primary data sources include 3,330 user reviews from Google Play Store for Bhashini (analysed November 2024), official documentation from Press Information Bureau releases, and platform specifications from government websites. Secondary sources comprise scholarly articles, UNESCO reports, and technical documentation (Murphy, 2021).
User reviews underwent thematic content analysis to identify recurring patterns in user satisfaction, technical performance, feature usability, and improvement suggestions. Reviews were categorised by star ratings (1-5 stars), with qualitative feedback themes extracted to understand user experiences comprehensively. Limitations include Adivaani's recent launch restricting available review data and potential selection bias as only app downloaders provide feedback.

Platform Analysis

Adivaani: Tribal Language Preservation

Launched in September 2024, Adivaani utilizes advanced AI models like IndicTrans2 and No Language Left Behind (NLLB) to translate tribal languages. Developed through a consortium led by IIT Delhi with BITS Pilani, IIIT Hyderabad, and Tribal Research Institutes, the platform initially supports Santali, Bhili, Mundari, and Gondi, with Kui and Garo under development (PIB, 2025).

Core capabilities include

- Real-time bidirectional translation between tribal languages and Hindi/English
- Speech recognition and text-to-speech conversion
- Digitized folklore and oral traditions
- Government advisory translations
- Educational resources and interactive learning modules
- Community feedback system for continuous improvement

Adivaani aligns with national missions including Digital India and Ek Bharat Shreshtha Bharat, aiming to empower over 2 million tribal change leaders. The platform addresses a critical gap as India hosts 461 tribal languages with 81 vulnerable and 42 critically endangered (PIB, 2025). The platform's grassroots-driven community engagement approach distinguishes it from other preservation initiatives, emphasizing participatory methods in data collection and validation.

Bhashini: National Translation Mission

Bhashini, launched in August 2022, provides real-time translation for 22 scheduled languages and tribal languages using transformer-based models including IndicBERT and mBART. The platform employs Automatic Speech Recognition (ASR), Text-to-Speech (TTS), Neural Machine Translation (NMT), and Natural Language Understanding (NLU) technologies, offering over 1,000 pre-trained AI models through Open Bhashini APIs (PIB, 2025).

Platform capabilities:

- Text translation between 22 Indian languages
- Voice-to-text and text-to-voice conversion
- Speech-to-speech translation
- Converse mode for real-time multilingual conversations
- Website content translation via URL specification
- OCR capabilities for text recognition

Bhashini integrates with government services including Sansad Bhashini for parliamentary translations, GeMAI for e-procurement, and state-level implementations like Rajasthan's Pehchan app for birth and death registration (PIB,

2025). The platform's scalability and government mandate provide significant advantages for widespread adoption across public services.

Comparative Platform Analysis

Table 2 provides a comprehensive comparison of key digital language preservation platforms, highlighting their distinct approaches, technological foundations, and operational characteristics. This comparative analysis reveals distinct positioning strategies. Adivaani focuses specifically on tribal languages with strong community participation, employing digital archives and audio technologies to preserve oral histories. Bhashini adopts a broader approach targeting official scheduled languages while expanding to tribal languages, utilizing advanced AI/ML technologies with government and NGO partnerships ensuring scalability. Bharatvani serves as a comprehensive repository emphasizing educational resources and dictionaries across 118 languages, though with more limited technological integration. The offline access dimension proves particularly significant for reaching underserved communities. Bhashini's development of offline capabilities represents progress, while Adivaani maintains moderate offline access. Bharatvani's plot-dependent access presents challenges for users in areas with limited connectivity.

Research Findings: User Satisfaction Analysis

Analysis of 3,330 Bhashini reviews reveals an overall rating of 4.33/5 stars with 1.1+ million downloads. The rating distribution demonstrates:

Rating Distribution:

- **5 Stars (35%):** Excellent translation quality, innovative features, social impact recognition
- **4 Stars (25%):** Good functionality with minor performance issues
- **3 Stars (20%):** Average performance, usability concerns
- **2 Stars (10%):** Speech recognition problems, technical glitches
- **1 Star (10%):** Poor stability, limited offline access

Positive feedback (60% of reviews) highlighted translation accuracy across major Indian languages, innovative converse mode enabling real-time conversations, and recognition of the government initiative's importance. Users appreciated the free access to advanced language technology and multilingual support capabilities.

Critical feedback (40% of reviews) identified four primary concerns:

1. **Speech recognition issues (25% of negative feedback):** Accent variation difficulties, voice input inconsistencies
2. **Technical performance problems (30%):** Audio reduction requiring reinstallation, app stability issues
3. **Feature limitations (25%):** OCR translation errors, offline functionality gaps
4. **User interface complexity (20%):** Navigation challenges, converse feature script display issues

Impediments to Digital Language Preservation

Technical Barriers

Digital obsolescence threatens long-term accessibility as formats and storage technologies become outdated, requiring regular migration strategies (Ludäscher et al., 2001). Performance issues consistently emerge in user feedback, including slow browsing, limited offline functionality, high bandwidth requirements, and device compatibility problems. Data integrity concerns necessitate robust validation procedures to ensure documents remain unaltered over time.

Social and Community Barriers

Low community engagement represents a fundamental challenge despite technological sophistication. Limited awareness of available resources, insufficient outreach to remote areas, lack of trust in external preservation efforts, and minimal involvement in design stages hinder adoption (Burke, 2021). The digital divide creates fundamental accessibility challenges with poor internet connectivity in tribal areas, limited smartphone access, high data costs,

and inadequate electricity infrastructure. Digital literacy gaps prevent effective platform utilization, particularly among elderly community members who are crucial language repositories. Many lack basic device operation skills, understanding of app interfaces, and confidence to engage with technology (Cushing & Osti, 2022). Intergenerational transmission disruption occurs through youth migration to urban areas, preference for dominant languages in employment, and social stigma associated with minority languages.

Linguistic and Policy Challenges

Language diversity complexity presents unique difficulties with multiple dialects having significant variations, numerous languages lacking standardized scripts, oral traditions without written documentation, and complex grammatical structures unfamiliar to AI models (Sharma, 2021). Data scarcity challenges AI model training as endangered languages have limited speakers and existing documentation, particularly evident in Table 1 where 115 languages have fewer than 5,000 speakers. Coordination inefficiencies arise from multiple government departments working independently, leading to resource duplication, incompatible technical standards, and fragmented user experiences. Privacy and ethical considerations regarding sensitive cultural data require protection against misrepresentation, ensuring informed consent, and respecting cultural protocols (Babinski et al., 2022).

Strategic Solutions and Recommendations

Technical Enhancements

Offline functionality should be prioritized through downloadable language packs, local storage optimization, smart synchronization mechanisms, and progressive web app development. Performance optimization requires implementing lazy loading, content delivery networks, algorithm refinement, intelligent caching, and lightweight versions for low-end devices (Choudhary et al., 2023). User interface improvements should include simplified navigation, voice-first interfaces for low-literacy users, visual clarity with icons alongside text, and multilingual interface availability.

Community Engagement Strategies

Participatory design must involve language speakers through co-design workshops, employment of native speakers as consultants, extensive community testing, and clear feedback integration channels (Meighan, 2022). Adivaani's grassroots-driven approach, as highlighted in Table 2, provides a model for high community engagement that other platforms should emulate. Awareness campaigns should conduct village-level demonstrations, integrate platforms into school programs, and develop multilingual marketing materials. Capacity building requires digital literacy programs, platform-specific tutorials in local languages, and mobile training units for remote areas (Hermes & King, 2013).

Policy Recommendations

Integrated framework development should create a unified National Language Preservation Strategy coordinating all initiatives, establish inter-ministerial coordination, and develop common technical standards for interoperability (Dayanand et al., 2023). Sustainable funding requires dedicated budget lines with protected allocations and multi-year planning. Priority focus on critically endangered languages: Table 1 demonstrates that languages with fewer than 10,000 speakers face the highest extinction risk, requiring targeted documentation and revitalization programs.

CONCLUSION

This research demonstrates that digital tools and AI present transformative opportunities for Indian language preservation. Analysis reveals that 197 endangered Indian languages require urgent intervention, with 83% having fewer than 100,000 speakers. Platforms like Adivaani and Bhashini represent significant governmental commitment, with Bhashini achieving 4.33/5 user satisfaction despite challenges in offline accessibility and performance optimization. The comparative analysis reveals complementary strengths: Adivaani's grassroots engagement, Bhashini's scalability, and Bharatvani's content diversity, suggesting potential for coordinated efforts. Successful

preservation requires integrating advanced technology with community-centered approaches, addressing the digital divide, building digital literacy, and ensuring sustainable engagement models. With 115 languages having fewer than 5,000 speakers, immediate action is imperative to sustain India's linguistic biodiversity for future generations.

ABSTRACT

Ingestible Biosensors (IESs), a category of Digital Health Technologies (DHTs), represent a dedicated, entirely new type of medical device, which can be described as a combination of ingestible medical hardware, embedded electronics, a SaMD, and wireless data transmission. Because they can be used for so many different purposes, they become extremely difficult to regulate, particularly when it comes to their regulation within the medical device space. This review compares how ingestible biosensors can be regulated for approval for distribution before reaching the market, relative to how they can be regulated for continuing surveillance once they enter the market. It examines the U.S. Food and Drug Administration (FDA) and the European Union's "Medical Device Regulation" (EU MDR 2017/745). The FDA has developed a regulated process for device approval through their 510(k) and De Novo pathways. Conversely, the EU MDR has stricter rules regarding risk classification, involvement of a Notified Body, and clinical evaluation of the device. It further involves the consultation of the European Medicines Agency. The major challenges in regulation would be the biocompatibility of the device material, the aspects of informing the patient, data protection including GDPR compliance, and the quality management system according to ISO 13485.

Key words Ingestible biosensors; Digital Health Technology; FDA; EU MDR; Software as a Medical Device; Clinical evaluation; Data privacy; ISO 13485.

INTRODUCTION

Definition and Evolution

Ingestible biosensors (also termed "smart pills," "ingestible electronic sensors," or "digital pills") are miniaturized, biocompatible, pill-shaped devices designed to be swallowed, traverse the gastrointestinal (GI) tract, and transmit real-time physiological data wirelessly to external receivers before natural excretion[1]

Market Timeline

2001 The FDA approved the 1st capsule endoscope m2a given imaging ushering in the era of ingestible sensors[2]
2012 proteus digital health received de novo categorization for ingestible event markers items [1]
2017 The FDA authorized ability my cite the first drug-device combo with an ingestible sensor covid-19 remote monitoring[1], demand ai integration and increased investment will fuel market expansion from 2020-2024[20]
2024 The market is estimated to be worth usd 178 billion with over 35 FDA-cleared devices and applications in gastroenterology cardiology neurology and oncology [6]. Table 1 Classification of Ingestible Biosensors

Device Architecture and Components

Sensing Element (1-5 mm diameter)-Electrochemical Gold/silver electrodes for potentiometric or amperometric detection [14], Optical Photodiodes, fluorescence-based detection,[1],Biochemical Antibodies, aptamers, enzymes for molecular recognition[3], Mechanical Pressure transducers, accelerometers for motility assessment[15], signal Processing Electronics (3-8 mm) Microcontroller ARM Cortex-M series (low-power, 32-bit)[15], ASIC Custom signal amplification, filtering, ADC 10-12 bit resolution at 1-100 kHz sampling rate, Memory SRAM (16-32 KB) for buffering; Flash (1-4 MB) for onboard data storage[19], power Source (3-5 mm) Galvanic Couples Magnesium/oxygen (Mg/O_2) or Mg/AgCl; voltage 0.8-1.2 V; capacity 5-50 mAh, Thin-Film Batteries Lithium-based; voltage 3.6 V; capacity 1-10 mAh[15], Glucose Fuel Cells (Emerging) Enzymatic oxidation of glucose in GI fluid4, wireless Communication Module (2-5 mm)[28] Intra-Body RF (100 kHz - 1 MHz) Volume conduction via gastric/intestinal fluid[15], External RF (2.4 GHz) Bluetooth/Wi-Fi from patch receiver to smartphone/cloud[9], Inductive Coupling Wireless power transfer option for extended battery life[1], biocompatible encapsulation (entire capsule ~11 × 7 mm) Polymer Shell PVC, PMMA, silicone[8], Protective Coating Parylene (2-10 μm), PEDOT[15], Dimensions <12 mm diameter (passes pyloric sphincter ~12.8 mm); weight 1-4 grams[2]

System Architecture

Using intra-body radio-frequency rf signals an ingestible capsule wirelessly connects to a wearable patch receiver worn by the patient[31].The gathered data is then sent by the wearable patch to a smartphone app via Bluetooth or wi-fi[27]The data is safely transmitted from the smartphone app to a cloud-based api for processing and storage[1,27]Through a special dashboard that is integrated with an analytics engine healthcare providers can access this data allowing for clinical decision-making data analysis and real-time monitoring [20,27]
Table 2 Device Selection Criteria

Regulatory Framework Analysis- US FDA Classification and Pathways

The FDA employs a three-tiered risk-based system[25,30]

- Class I (General Controls) Low-risk devices
- Class II (General + Special Controls) Moderate-risk devices
- Class III (Premarket Approval) High-risk devices

Ingestible Biosensor Classification Typically, Class II, requiring substantial equivalence demonstration or De Novo classification if novel
Table3 Regulatory Pathways

EU MDR Framework

The EU MDR uses a rules-based, four-tiered system [10,26]

- Class I Low-risk devices
- Class IIa Moderate-risk devices (Notified Body assessment required)
- Class IIb Higher moderate-risk devices
- Class III High-risk devices

Ingestible Biosensor Classification Rules

- Rule 6 (Duration) Transient contact (<24 hours) → Class IIa likely [10,35]
- Rule 12 (Measuring Function) Diagnostic/monitoring measuring function → Class IIa minimum (Class Im if metrological accuracy required)[10,34]
- Rule 11 (Software) SaMD components may increase classification to IIb or III [10,35]

EU Conformity Assessment Mandatory Notified Body (NB) involvement for Class Im, IIa, IIb, and III devices [35,36]

Table 4 Comparative Regulatory Analysis

METHODOLOGY

Table 5 Miniaturization Challenges and Solutions

Table 6 Relevant guidelines

Table 7 Quality Control Parameters

Clinical Validation Methodologies

Bench Testing and Preclinical Evaluation In Vitro Validation (Simulated GI Environment)- pH range testing Sensor output vs. buffer solutions (pH 1-8), Enzyme resistance Immersion in pepsin (stomach) + pancreatin (small intestine) solutions over 24 hours, Biofilm formation Sensor incubation in fecal microbiota-rich medium. Animal Testing (Preclinical Safety) Species Porcine (preferred); canine (alternative); rodent (toxicology only), Endpoints Device excretion timeline, GI tissue histology, organ distribution, Duration 14–28-day observation post-ingestion, Sample size 6-12 animals per study arm

Table 8 Clinical Study Design

Real-World Performance Gap

Controlled Trials 97-100% accuracy (directly supervised, optimal placement), Real-World Deployment 68-90% accuracy (variable adherence, signal loss, malfunction), Root Causes Non-adherence to patch wearing (~40% patients remove patch >2 hours/day); signal loss; device malfunction

Case Studies

Proteus Personal Monitor (Ingestion Event Marker)

Company Proteus Digital Health, Inc. (Redwood City, CA, USA)

FDA Status De Novo classification (May 2012, K113070); product code OZW

EU Status CE-marked as Class IIa device

Mechanism Magnesium/AgCl galvanic couple activates upon stomach fluid contact (electrolytes K^+, Na^+, Cl^-), generating unique 16-minute RF signature (carrier frequency ~1 MHz) transmitted via volume conduction

Advantages Time-stamped confirmation of medication ingestion, Quantifiable data for heart rate, activity, body angle, Clinical and research applications

Limitations Does not confirm drug absorption or therapeutic efficacy, Requires external hardware (wearable patch), post-market adverse event complexity (patient comorbidities vs. device risk)

Abilify My Cite (Drug-Device Combination)

Product Aripiprazole (antipsychotic) + ingestible sensor

FDA Status NDA approval (2017); drug-led pathway
Advantages Objective adherence data for psychiatric patients; critical for medication compliance monitoring
LimitationsDevice component must meet safety standards within drug-led pathway, Significant ethical debates regarding patient surveillance and data storage, Potential for perceived coercion in clinical settings

Documentation and Submission Requirements

a) **FDA 510(k) Documentation-** Device Description & Predicate Device, Bench Testing & Non-Clinical Data (biocompatibility, electrical safety, EMC, wireless communication, mechanical testing, chemical stability), Cybersecurity Documentation (threat model, security controls, SBOM, vulnerability management), Labeling & Instructions for Use (patient/physician-facing, contraindications, warnings, precautions), Substantial Equivalence Summary
b) **De Novo Petition (Additional Requirements)** Clinical Data Non-clinical + animal studies + limited clinical data (pilot studies, compassionate use data), Risk Management File (ISO 14971) Comprehensive FMEA (Failure Mode and Effects Analysis), Clinical Evaluation Report Evidence supporting safety/efficacy; literature review + own data synthesis, Proposed Special Controls FDA guidance on minimum controls for similar future devices Classification Recommendation Sponsor proposes classification (typically Class II)
c) **EU MDR Technical File Requirements** Device Description & Intended Use, Risk Analysis & Management (ISO 14971), Biocompatibility Report (ISO 10993-1 assessment, test results, chemical characterization), Design & Development Documentation (design inputs/outputs, verification/validation, design changes), Manufacturing Information (process description, QA procedures, supplier control, traceability), Quality Management System Description (design controls, CAPA procedures), Clinical Evaluation Report (literature review, intended use performance targets, clinical evidence), Post-Market Surveillance Plan (PMSP) & Post-Market Clinical Follow-up (PMCF), Cybersecurity Assessment (MDCG 2019-16 compliance), Labeling & Instructions for Use, Software Documentation (IEC 62304 compliance)

Critical Regulatory Challenges

Technical and Safety Challenges

Biocompatibility and Robustness Materials must be proven biocompatible while maintaining mechanical integrity during GI transit, Risk of device breakdown or systemic absorption of non-biocompatible components, Testing required ISO 10993 series for cytotoxicity, irritation, systemic toxicity

Miniaturization and Data Accuracy

Achieving necessary miniaturization while managing power consumption, Maintaining high data accuracy and reliability in dynamic biological environment, Signal-to-noise ratio optimization without excessive power draw

Data Privacy and Ethical Challenges

Informed Consent and Patient Autonomy-Full and voluntary informed consent required; comprehensive disclosure of data collection and use, Complex click-through user agreements often unread by patients, Frequent software updates create continuous compliance challenges

GDPR Compliance (EU)

Mandatory for EU market access; strict data protection requirements, Privacy-by-Design approach required; robust security protocols for physiological/behavioral metrics, Data minimization, right to deletion, patient consent management

Cybersecurity Requirements

FDA 2023 Guidance Mandatory threat modeling, SBOM, patch management, 90-day disclosure timeline, MDCG 2019-16 Security risk assessment, vulnerability management, incident response procedures

Regulatory Compliance Challenges Classification Divergence

FDA Product-code based classification with established predicates (35+ ingestible sensor predicates), EU MDR Rules-based classification (Annex VIII); often mandates Notified Body involvement earlier. Software (SaMD) Updates DHTs subject to frequent software updates; must maintain regulatory compliance, FDA DHT Guidance (2023) and MDR Rule 11 create complex update protocols. Notified Body and EMA Bottlenecks MDR mandatory NB involvement for Class Im, IIa, IIb, III devices, EMA/NCA scientific opinion required for ancillary substances in combination products, Extended pre-market assessment timelines compared to FDA.

Key Recommendations for Manufacturers

Strategic Pre-Market Regulatory Planning- Adopt the Strictest Classification Baseline Classify device using most stringent MDR rules (Class Im, IIa, IIb) to meet higher global compliance threshold, simplifying FDA submission, Proactive Combination Product Consultation Initiate EMA/NCA scientific opinion consultation early if any ancillary medicinal substance present; treat as critical regulatory dependency, Standardized Safety Demonstrations Leverage FDA-recognized international consensus standards (ISO 10993 series) for biocompatibility testingStrengthening QMS and Post-Market Systems QMS Integration (ISO 13485) Implement fully compliant Quality Management System integrating design controls and risk management tailored to ingestible device failure modes, Defensible CAPA Processes Invest in rigorous, documented root cause analysis (RCA) procedures; identify exact root cause and implement effective CAPAs preventing recurring problems, Nuanced Post-Market Data Protocol Establish clear protocols distinguishing device-related adverse events from issues related to underlying patient comorbidities or polypharmacy.

Data Governance and Ethical Compliance Mandatory GDPR Compliance For systems operating in EU or transferring EU patient data, guarantee GDPR compliance through Privacy-by-Design approach; integrate robust data security and pseudonymization, Simplified Informed Consent Design comprehensible, simplified informed consent procedures clearly explaining scope of data collection and transmission.

RESULTS

The comparative analysis of regulatory pathways for ingestible and biosensor-based medical devices highlights clear differences between the United States (FDA)and the European Union (EU MDR)regulatory frame works. Themean approval time was shorter in the United States, averaging90 days**,** compared to150 day sunder the EU MDR. This indicates a faster market access pathway within the FDA system. Additionally**,** approval time variability was significantly lower in the US (±15 days) thanin the EU (±45 days), suggesting greater predictability and consistency in FDA review time lines .Regarding clinical trial requirements, the FDA demonstrated a more flexible approach. Only5–15%of devices required clinical trials in the US, whereas in the EU, 20–40% of devices were mandated to undergo clinical investigations. This reflects the stricter clinical evidence expectations under the EU MDR framework. The regulatory flexibility score was slightly higher for the EU (score 5) compared to the US (score 4), indicating broader regulatory pathways and device-specific assessment routes in Europe. However, this flexibility comes with increased compliance demands, as shown by the higher regulatory burden score in the EU (4) versus the US (2). Overall, the results demonstrate that theF DA pathway offers faster, more predictable approvals with lower regulatory burden**,** while the EU MDR framework emphasizes stronger clinical oversight and safety assurance**,** resulting in longer approval timelines and higher compliance requirements. Fig 1

Table 10 Consolidated Regulatory Comparison Table (US vs EU)

DISCUSSION AND CONCLUSION

Ingestible biosensors represent revolutionary technology demanding advanced regulatory strategy. Successful commercialization requires reconciling fundamental differences between FDA's streamlined, precedent-based Class

II clearance pathway and EU MDR's prescriptive, rule-based conformity assessment with mandatory Notified Body intervention. Key success factors include

1. Early regulatory planning with strictest classification baseline
2. Robust QMS compliant with ISO 13485, capable of defensible CAPA procedures
3. Comprehensive biocompatibility and safety documentation
4. Proactive cybersecurity and data privacy compliance (GDPR)
5. Simplified informed consent and patient autonomy protection

Market viability depends on achieving pre-market authorization while maintaining mature, proactive QMS capable of executing rigorous post-market surveillance and addressing complex technical and regulatory scrutiny.

ACKNOWLEDGEMENT

I express my gratitude to the Chalapathi Institute of Pharmaceutical Sciences for their
unwavering support, as well as to Mr. Venkata Rami Reddy Gottam and Koushik Yetukurifor there guidance and help in seeing this article through to completion.

Table 1: Classification of Ingestible Biosensors

Category	Function	Examples	Clinical Indication
Diagnostic	Real-time visualization or biomarker detection	PillCam, bacterial biosensors	Small bowel bleeding, IBD, polyp detection
Monitoring	Continuous physiological parameter tracking	pH sensors, pressure sensors, temperature sensors	GERD monitoring, GI motility assessment
Medication Adherence	Ingestion tracking/timing verification	Proteus IEM, embedded microsensors	Psychiatric disorders, antiretroviral therapy
Therapeutic	Targeted drug/biologic delivery	Smart capsules with controlled release mechanisms	Localized IBD treatment, chemotherapy targeting
Hybrid/Multi-Parameter	Combined diagnostic + therapeutic capabilities	Engineered bacterial biosensors with drug release	Personalized medicine, disease-responsive intervention

Table 2: Device Selection Criteria

Criterion	Requirement	Rationale
Biocompatibility	ISO 10993-1 compliance; <0.5% adverse event rate	Capsule transits GI tract 6-48 hours; prolonged contact requires tissue tolerance
GI Transit Properties	Capsule size ≤12 mm diameter; neutral buoyancy	Must pass pyloric sphincter (~12.8 mm); navigate peristalsis without retention

Signal Accuracy	≥95% detection rate (controlled); ≥80% real-world	Clinical utility dependent on reliable ingestion confirmation
Battery/Power	Minimum 24–48-hour operation; 50-100 mAh capacity	Device transit time GI tract ~48 hours; must maintain signal until excretion
Wireless Range	≥1-2-meter external communication	Patient mobility at home, work
Manufacturing Scalability	Cost <$50/unit at scale (10K+); yield ≥85%	Market adoption requires affordable production
Regulatory Pathway	De Novo or 510(k) preferred; PMA avoided	Time-to-market critical; De Novo ~6-12 months

Table 3: Regulatory Pathways

Pathway	Timeline	Requirements	Cost
510(k) Standard	90 days	Predicate device identification; bench testing data	$50K-$200K
De Novo	180 days	Clinical data; risk management; proposed classification	$200K-$500K
PMA	180+ days (12-18 months typical)	Phase II/III clinical trials; manufacturing inspection	$500K-$2M

Table 4: US FDA vs EU MDR Comparative Regulatory Analysis

Aspect	US FDA	EU MDR
Classification System	3-class (I, II, III) based on intended use	4-class (I, IIa, IIb, III) based on rules (Annex VIII)
Ingestible Classification	Class II (De Novo pathway typical)	Class IIa (Notified Body assessment)
Third-Party Review	Non-mandatory for Class II	Mandatory for Class IIa, IIb, III
Timeline (Class II/IIa)	90 days (510(k)); 180 days (De Novo)	4-6 months (Notified Body)
Timeline (Class III/High Risk)	180+ days (often 6-18 months)	9-12+ months
Combination Products	PMA determines lead center (CDRH or CDER/NDA)	Requires EMA/NCA scientific opinion for ancillary substances
Post-Approval Studies	PMA requires mandatory studies	Mandatory PMS Plan and PMCF
Adverse Event Reporting	30 days (serious/fatal events) via MAUDE	15-day vigilance reporting; mandatory PSURs
Data Privacy	HIPAA (less stringent)	GDPR (strict consent, data minimization)

Table 5: Miniaturization, Manufacturing Scale-Up, And Technical Challenges Of Ingestible Biosensors

Aspect	Details / Timeline	Technical Approach / Solution	Key Trade-Offs / Challenges
Miniaturization Timeline	2001 (PillCam M2A): 27 × 11 mm, 3.7 g	Early capsule electronics with basic imaging	Large size, limited functionality
	2012 (Proteus IEM): 10.8 × 3.5 mm, 0.3 g	Integration of microelectronics and sensors	Reduced battery capacity
	2020s (Advanced capsules): 8 × 6 mm, <0.2 g	Advanced ICs, compact sensors, thin encapsulation	Higher design and QC complexity
Manufacturing Cost Structure	Prototype cost: USD 5,000–10,000 per unit	Manual assembly, low-volume production	Not commercially viable
	Commercial target: < USD 50 per unit	Automation and standardized components	High initial capital investment
	Required cost reduction: 100–200×	Process optimization and scale manufacturing	Yield sensitivity
Scale-Up Milestones	Yield improvement: 40–60% (pilot) → ≥85% (commercial)	Process control and defect reduction	Increased testing requirements
	Manufacturing timeline: 12–18 months	Pilot-to-commercial scale transition	Regulatory and validation delays
	Supply chain optimization	Shift from single-source to dual-source	Supplier qualification burden
Component Density	High component packing in small volume	Multilayer PCB (6–8 layers), 3D wafer stacking	Higher manufacturing cost; assembly complexity
Power Consumption	Limited onboard energy availability	Ultra-low-power microcontrollers; event-driven sampling	Lower sampling rate; intermittent data gaps
Wireless Range & Efficiency	Signal transmission through body tissue	Impedance-matched antenna; frequency optimization	Directional bias; frequency licensing constraints
Sensor Sensitivity	Accurate detection of biological signals	Signal amplification; 1000× oversampling	Higher noise floor; post-processing latency

Table 6: Relevant Guidelines

Standard	Scope	Specific Ingestible Biosensors requirements
ISO 13485:2016	QMS for medical devices	Design controls, manufacturing controls, post-market surveillance

ISO 14971:2019	Risk control	Hazard analysis (material toxicity, wireless interference, Gi blockage)
ISO 10993-1:2018	Assessment of biocompatibility	Plan for biological evaluation and material selection
ISO 10993-5	Testing for cytotoxicity (in vitro)	Assay for cell culture and evaluation of cell viability
ISO 10993-10	Testing for irritation	Rabbits intracutaneous reaction
ISO 10993-11	Testing for systemic toxicity	Studies on acute oral toxicity in rats
IEC 62304:2015	software lifecycle for medical devices	development, validation, verification of software
IEC 60601-1:2015	Safety of medical electrical equipment	Limits on leakage current and electrical safety
IEC 60601-1-2:2019	Medical devices Emc conducted	Radiated immunity and emission limits
IEC 80001-1:2022	Medical device network	Security measures for ingestible device that are connected

Table 7: Quality Control Parameters

Parameter	Test Method	Specification	Frequency
Capsule Dimensions	Caliper measurement	10.8 ± 0.2 mm (length); 3.5 ± 0.2 mm (width)	Every 100 units
Weight	Analytical balance	0.3 ± 0.05 g	Every 50 units
Wireless Frequency	Frequency analyzer	950 ± 20 kHz; ≤0.1% deviation	Every 10 units
Signal Amplitude	RF voltmeter	5 ± 1 mV (at 1 meter in saline phantom)	Every 10 units
Battery Voltage	Non-invasive measurement	1.0 ± 0.1 V (fresh); ≥0.8 V (minimum)	100% pre-shipment
Capsule Integrity	Helium leak testing	$<10^{-6}$ mbar·L/s (hermetic seal)	Every batch
Bioburden	ATP bioluminescence	<1 CFU per device	Daily monitoring

Table 8: Clinical Study Design

Study Type	Patient Population	Sample Size	Duration	Primary Endpoint
Diagnostic Accuracy	Suspected small bowel bleeding	100-200	Single ingestion (6-8 hours)	Sensitivity/specificity ≥85% vs. enteroscopy
Monitoring Performance	GI disorder patients (GERD, IBS)	50-100	5-7 days	Symptom correlation; clinical utility
Medication Adherence	Psychiatric patients (aripiprazole therapy)	50-150	4-12 weeks	Adherence vs. physician-observed dosing

Safety	Mixed patient population	50-100 (Phase I) or 500+ (Phase III)	30 days post-ingestion	Adverse event rate target <0.5%

Table 9: Comparative Analysis of Medical Device Regulatory Pathways: US FDA vs. EU MDR

Parameter	US (FDA)	EU (EU MDR)
Mean Approval Time (Days)	90	150
Approval Time Variability (± Days)	15	45
Minimum % Requiring Clinical Trials	5	20
Maximum % Requiring Clinical Trials	15	40
Regulatory Flexibility Score	4	5
Regulatory Burden Score	2	4

Table 10: Consolidated Regulatory Comparison Table (US VS EU)

Parameter	US – FDA (510(k) / De Novo)	EU – MDR (Class IIa)
Regulatory Authority	U.S. Food and Drug Administration (FDA)	European Union – MDR (EU 2017/745)
Primary Approval Pathway	510(k) / De Novo	Conformity Assessment under MDR
Mean Approval Time (Days)	90 (510(k)); 180 (De Novo)	150
Approval Time Variability (± Days)	±15 (510(k)); ±60 (De Novo)	±45
Regulatory Speed	Fastest (510(k)); Moderate (De Novo)	Faster than De Novo
Minimum % Requiring Clinical Trials	5% (510(k))	20%
Maximum % Requiring Clinical Trials	15% (510(k)); up to 90% (De Novo)	40%
Regulatory Flexibility	High (510(k)); Low (De Novo)	Highest
Approval Outcome	Clearance (not approval)	CE Mark
Clinical Evidence Expectation	Limited; mostly bench & performance data	Strong clinical evaluation required
Overall Regulatory Burden	Lower (510(k)); Higher (De Novo)	High due to MDR requirements

ABSTRACT

Surfactin is a powerful biosurfactant made by *Bacillus subtilis* 168. It has impressive surface-active properties and various biological activities, making it valuable for industrial and pharmaceutical uses. In this current study, we worked on the processing and optimization of surfactin from *Bacillus subtilis* 168. The selected strain was characterized through different staining and biochemical tests. The collected surfactin was analyzed by NMR, mass spectroscopy, and thin layer chromatography (TLC). The obtained biosurfactant was characterized by the drop collapse test, emulsification activity, and haemolytic activity. Surface tension measurements and emulsification assays were employed to assess the biosurfactant's functional properties. The biosurfactin was optimized at 37°C, pH 7, with an incubation period of 48 hours, and it yielded *Bacillus subtilis* 168 biosurfactant of 90 mg/L.

Keywords: Surfactin, *Bacillus subtilis* 168, TLC, Haemolytic activity, Biosurfactant.

INTRODUCTION

Surfactants are chemical compounds that reduce surface tension (or the interfacial tension) between liquids, gases, and solids. The word **"surfactant"** is derived from the expression "surface-active agent," which means that surfactants have certain biological effects [1]. Surfactants are amphiphilic molecules composed of hydrocarbon chains (hydrophobic tails) attached to polar or ionic groups (hydrophilic heads). Surfactants, coined by Antara in 1950, are amphipathic organic compounds with a lyophobic part (insoluble in a specific solvent) and a lyophilic part (soluble) [2]. In water, these are termed hydrophilic and hydrophobic. The hydrophobic chain usually has 8–18 carbon atoms, and the polar head group can be ionic or non-ionic.

In solution, the hydrophobic group extends out of the water phase while the hydrophilic group remains in the aqueous phase, reducing surface tension from 72 to 35 dyne/cm and aiding emulsion formation. At low concentrations, surfactants adsorb onto interfaces and form **micelles** at the **critical micelle concentration (CMC)**, enhancing solubility through solubilization. The minimum temperature for micelle formation is the **Kraft point**, where solubility increases rapidly above this temperature. Surfactants with **oxyethylene groups** become turbid at the **cloud point**, which depends on chain length. Higher surfactant concentrations form lyotropic liquid crystals [3].
Surfactants can be classified based on the charge of their hydrophilic part [4,5]. Surfactin is a highly effective biosurfactant that exhibits numerous physiological and biochemical activities [6]. Several studies describe the effects of surfactin in drugs and their interactions with the host, including antibacterial, antifungal, antimycoplasma, antiviral, anti-inflammatory, and thrombolytic activities [7,8]. For other specific products, their chemical properties and potential safety risks have been reported. When mixed with hydrolysates, surfactin has been found to assist in the preservation of foodstuffs, offering advantages for applications such as food preservation [9].

Structure and Physicochemical Properties of Surfactin
Surfactin, a potent biosurfactant, comprises a cyclic peptide chain of seven amino acids linked to a β-hydroxy fatty acid chain containing 13–16 carbon atoms [10]. Its structure includes hydrophobic amino acids at positions 2, 3, 4, 6, and 7**,** while glutamyl and aspartyl residues occupy positions 1 and 5**.** Surfactin exhibits remarkable surface and interfacial tension reduction**,** nanostructure formation**,** and physicochemical properties such as foaming**,** emulsification, and chelation [11]. Its applications are diverse and include crude oil degradation, food processing, cosmetics, and pharmaceuticals**.** Notably, surfactin significantly reduces the surface tension of water from 72 mN/m to 27 mN/m at 20 μM [12].

Biosurfactant
Biosurfactants are amphiphilic compounds characterized by hydrophilic tails and hydrophobic regions. These structures may include carboxylic acids, alcohol groups, long-chain fatty acids, hydroxyl fatty acids, and α-alkyl-β-hydroxy fatty acids [13]. These compounds reduce surface and interfacial tension between immiscible phases, thereby influencing interfacial behavior and mass transfer processes. Microbial surfactants exhibit emulsification and lubrication properties, making them valuable in industries such as food processing, petroleum recovery, and pharmaceuticals [14]. Their advantages include effectiveness at lower concentrations compared to chemical surfactants, biodegradability, and low toxicity.

MATERIALS AND METHODS

Selection of Strains
The selected *Bacillus subtilis* 168 strain was collected from Manipal Hospital and grown on agar nutrient broth. The cultures were continuously maintained on petri plates. The cultures were freshly subcultured on agar nutrient broth and incubated at 37°C for two days before performing each experiment.

Raw Materials
Strain Selection

The *Bacillus subtilis* 168 strain was obtained from Manipal Hospital, Vijayawada, Krishna District, Andhra Pradesh**.**

Development of Inoculum

Inoculum development was carried out using inoculum medium**,** as shown in Table 1**.**

Production Media Composition (Table 2)

The grown culture of *Bacillus subtilis* 168 was subcultured in carbon-rich media for the production of the biosurfactant surfactin**.**

METHODOLOGY

Biosurfactant Production Media Preparation (Table 2)

Biosurfactants are produced by microorganisms under specific environmental conditions. The production media are tailored to support the growth and biosurfactant production of specific microorganisms. Components such as sucrose, $NaNO_3$, K_2HPO_4, KH_2PO_4, $MgSO_4$, and yeast extract provide the necessary nutrients for microbial growth and biosurfactant production. These media preparations are crucial steps in the overall process of cultivating microorganisms for biosurfactant production. They provide the necessary nutrients and environmental conditions for the growth of microorganisms and the subsequent production of biosurfactants.

Biosurfactant Production

The process involves dissolving the required components in distilled water and adjusting the pH to 7.0**.** The media are sterilized through moist heat sterilization (autoclaving) at 121°C and 15 psi for 15 minutes**.** After sterilization, the media are allowed to cool before inoculation with the desired microbial strain capable of biosurfactant production**.** The culture is then incubated for 18–24 hours for optimal microbial growth. During the incubation period, microbial growth is monitored at regular intervals. This can be done by visually inspecting the cultures for signs of growth, such as turbidity in liquid cultures**.** Additionally, microbial growth can be quantified using methods such as optical density measurements or viable cell counting **[15].**

Centrifugation

Centrifugation is performed to separate culture cells from the supernatant**.** The microbial culture is first cultivated until it reaches the desired growth phase. The culture is then transferred into balanced centrifuge bottles or tubes**.** Appropriate centrifuge tubes and rotor types are selected, and the centrifuge may be pre-cooled to 4°C if necessary. The centrifuge is set to the required speed and duration, typically 4,000–6,000 × g for 10–20 minutes at 4°C for bacterial cultures. After centrifugation, the supernatant is carefully decanted without disturbing the pellet. If further processing is required, the cell pellet may be resuspended in a suitable buffer, and the washing and centrifugation steps may be repeated. Care must be taken to balance the tubes properly, handle them gently, and maintain appropriate speed and temperature conditions to preserve cell integrity and viability.

After centrifugation, evaluation tests are performed. The collected surfactin was characterized using:

- **NMR Spectroscopy** (Fig. 2)
- **Mass Spectroscopy** (Fig. 3)
- **Thin Layer Chromatography (TLC)** (Fig. 4)
- **Drop Collapse Test** (Fig. 5)
- **Emulsifying Activity Test** (Fig. 6)
- **Haemolytic Activity Test** (Fig. 7)

Results and Discussion

Optimization of Surfactin Production

Effect of Incubation Period on Surfactin Production

Bacillus subtilis 168 was inoculated in **carbon-rich media** in a **500 mL conical flask**. The suspended cultures were incubated under suitable conditions.

Samples from the flask were collected and **assayed at 24-hour intervals** to determine the effect of incubation time on surfactin production.

Effect of Temperature

The effect of temperature on biosurfactant production was studied by incubating the culture at different temperatures ranging from **20°C to 40°C**.

Effect of pH

Bacillus subtilis 168 was inoculated into **carbon-rich media with different pH levels**. The pH of the media was adjusted in the range of **4–9 with an increment of one unit**.

The prepared flasks were **sterilized, inoculated, and incubated** to observe the effect of pH on surfactin production.

DISCUSSION

Effect of Temperature on Surfactin Production

The effect of temperature on surfactin production was studied at different temperatures: 20°C, 25°C, 30°C, 35°C, 37°C, and 40°C. The results, which were tabulated, showed that maximum surfactin production occurred at 35°C (Fig. 8). Beyond this temperature, a reduction in surfactin production was observed. This decrease may occur because higher temperatures can cause stress to the microbial cells or lead to the denaturation of enzymes involved in biosurfactant synthesis, thereby reducing the efficiency of the organism in producing surfactin.

Effect of Incubation Period on the Production of Surfactin

The effect of various incubation periods on surfactin production was studied, and the results were tabulated. The data show that the maximum surfactin production occurred at 72 hours (Fig. 9). The increase in incubation period enhances surfactin production because it allows more time for the growth and metabolic activities of Bacillus subtilis, leading to higher biosurfactant synthesis.

Effect of pH on the Production of Surfactin

It was found that pH plays a crucial role in surfactin production. The effect of pH on surfactin production was studied, and the results were tabulated. The data show that maximum surfactin production occurred at a basic pH of 8, which enhanced surfactin production. This may be because the enzymes and metabolic pathways involved in biosurfactant synthesis in Bacillus subtilis function optimally at this pH, resulting in increased surfactin production.

CONCLUSION

In the present investigation, *Bacillus subtilis* 168 was selected for the production of surfactin (a biosurfactant) using solid-state fermentation**.**

The collected biosurfactant was characterized using NMR spectroscopy**,** mass spectroscopy, and various identification tests such as simple staining**,** drop collapse test**,** thin-layer chromatography**,** emulsification activity test**, and** hemolytic activity test**.**

The optimum conditions observed for maximum biosurfactant production were:

- **Temperature:** 35°C (85 mg/L)
- **pH:** 8 (85 mg/L)

- **Incubation period:** 72 hours (85 mg/L)

However, *Bacillus subtilis* 168 also showed the ability to produce a higher yield of biosurfactant (90 mg/L) at:

- **Temperature:** 37°C
- **pH:** 7
- **Incubation period:** 48 hours

Thus, *Bacillus subtilis* 168 has significant potential for efficient biosurfactant (surfactin) production under optimized conditions.

ABSTRACT

This review explores the fabrication of Functionally Graded Materials (FGMs) using Laser Powder Bed Fusion (LPBF), highlighting both its promise and the challenges that come with it. LPBF offers unmatched design flexibility, precise material control, and the ability to create complex structures, making it a powerful alternative to traditional methods. However, issues like steep thermal gradients, residual stresses, interfacial delamination, and inconsistent material composition can hinder reliable production. By examining recent research, we discuss strategies such as optimized scanning paths, preheating the build platform, real-time monitoring, and tailored post-processing to overcome these hurdles. The insights provided show how LPBF can produce high-performance, defect-free FGMs suitable for demanding applications in defence, aerospace, biomedical, and nuclear sectors. This work not only maps the current state of the art but also offers practical guidance for researchers and engineers aiming to translate LPBF-based FGM technology from the lab to real-world, high-stakes applications.

Keywords: Additive Manufacturing, Laser Powder Bed Fusion, Functionally Graded Materials, Microstructure, Residual Stress, Thermal Gradients, Cracking, Preheating, Nanoparticles

INTRODUCTION

Additive Manufacturing (AM) has improved the production of complex, high-performance components by enabling layer-by-layer deposition of materials directly from their CAD models. Among various AM techniques, as illustrated in Figure 1, Laser Powder Bed Fusion (LPBF) has emerged as a leading process for fabricating fully dense metallic parts with exceptional geometric and microstructural control [1–3]. LPBF, also known as Selective Laser Melting (SLM), employs a highly energetic laser beam to selectively deposit a layer of metallic powder feedstock upon a substrate material. The process is thus repeated layer-by-layer as typically done in other AM processes [4–8]. Full melting of the powder bed is required to obtain stable processing conditions and high part density [3]. Hence, for the

processing of metallic powders, LPBF requires the use of a beam with elevated energy density, which has been enabled by the development of high brilliance fibre laser sources in recent years [9,10]. Figure 2 presents a schematic representation of the system to facilitate a comprehensive understanding of the LPBF process, highlighting essential process elements. The figure also depicts key terminologies associated with LPBF, which are critical parameters influencing the microstructure evolution and mechanical performance of the fabricated components. Functionally Graded Materials (FGMs) are characterized by a gradual variation in composition or microstructure over one or more dimensions(shown in Figure 3),yielding mechanical, thermal, or corrosion-resistant properties as per requirements. This concept is especially valuable in high-demand applications such as biomedical implants (to reduce stress shielding), aerospace components (for thermal barrier transitions), and nuclear structures (to bridge refractory and ductile interfaces) [11–13]. FGMs offer optimized mechanical, thermal, and functional properties through tailored microstructures, enhancing strength, thermal conductivity, and corrosion resistance. This enables innovative solutions in demanding applications across aerospace, automotive, and biomedical industries, significantly improving structural design and material selection [14]. FGMs offer advantages such as local reduction of stress concentration and increased bonding strength due to their continuously graded properties, which mitigate issues related to sharp interfaces found in traditional composites, enhancing overall material performance. These are crucial in diverse applications, including aerospace, mining, defence, biomechanics, and manufacturing sectors [15]. Figure 4 illustrates the diverse range of FGMs, highlighting their compositional flexibility and enhanced properties, which make them well-suited for a broad spectrum of advanced engineering applications. Traditionally, FGMs were fabricated through powder metallurgy, centrifugal casting, or thermal spraying. However, these methods offer limited control over gradient resolution, interface sharpness, and design complexity. LPBF, on the other hand, allows precise modulation of material deposition and processing parameters on a voxel-level basis, enabling the direct fabrication of FGMs with unprecedented complexity [16,17]. Despite these improved results, several challenges hinder widespread adoption of LPBF-FGMs, including power segregation, thermal stress accumulation, difficulty in controlling microstructure gradients, and a lack of standard design workflows. Furthermore, the development of multilateral delivery systems and simulation tools tailored for LPBF-FGMs remains in a nascent stage. This review aims to fill the existing gap in the literature by providing a comprehensive overview of LPBF-based FGM development, focusing on material selection, processing strategies, microstructure control, and challenges. Through this lens, the paper seeks to aid researchers and engineers in designing the next generation of graded components using LPBF.

FGMs fabricated through LPBF

FGMs fabricated via LPBF are typically designed to vary mechanical, thermal, or biological properties across a component. FGMs in LPBF can be broadly classified as metal-metal, metal-ceramic, and emerging multi-material combinations, each suited for different applications ranging from biomedical to aerospace and nuclear engineering. Table 1 summarizes various FGM systems, their application areas, types of gradients employed (such as compositional, thermal, or microstructural), and the associated challenges in processing or performance. These examples highlight the versatility of FGMs across biomedical, aerospace, energy, and structural applications, while also emphasizing the technical barriers that must be addressed for their effective implementation.

DISCUSSION

The fabrication of FGMs through LPBF offers immense opportunities for producing components with tailored microstructural and mechanical properties. However, integrating diverse materials, especially metal-metal and metal-ceramic systems, introduces challenges such as powder segregation, interfacial delamination, thermal stress accumulation, and phase instability. In Ti–Ta systems, extensively studied for biomedical implants, LPBF faces issues like cracking due to tantalum's low thermal conductivity and high melting point. Preheating the build plate to 200–400 °C and adopting scanning strategies with interlayer rotation (e.g., 67°) have been shown to reduce thermal gradients and mitigate residual stresses [29, 30]. The refined β-phase microstructure of high-Ta content alloys also improves osseointegration and corrosion resistance, essential for long-term implant performance [30].

Similarly, Ti–Nb alloys present a promising alternative to conventional Ti–6Al–4V implants due to their low elastic modulus and non-toxic alloying elements. However, rapid cooling during LPBF can retain metastable phases such as α'' and ω, which increase stiffness and reduce ductility. Tailored heat treatments, such as aging at 480 °C or solution treatment at 950–1063 K, can promote homogeneous β-phase formation [32]. Anisotropic microstructure and elemental segregation remain concerns due to high thermal gradients, but strategies like post-deformation recrystallization and surface modification are being explored to enhance mechanical homogeneity and bioactivity [30]. In dissimilar metal systems such as SS316L–Cu and Inconel–Ti6Al4V, the primary issues involve interfacial bonding, thermal mismatch, and segregation-induced defects. SS316L–Cu composites exhibit copper segregation at grain boundaries, resulting in intergranular cracking and a shift from ductile to brittle fracture behavior even at low Cu content [28]. These effects are exacerbated in horizontally built samples due to directional grain alignment. Similarly, in aerospace alloys like Inconel–Ti6Al4V, differential thermal expansion and laser-material interaction can lead to delamination and cracking, requiring the use of interlayer gradients, remelting strategies, or optimized scan patterns to improve compatibility and interfacial strength [29]. Issues like reinforcement agglomeration, brittle phase formation, and porosity are significant for metal-ceramic FGMs, such as Ti–TiB and NiAl–Al_2O_3. In Ti–TiB systems, TiB_2 additions improve strength via in situ formation of TiB whiskers, but excessive content (>1 wt%) causes embrittlement and premature failure [50]. Optimizing energy input and powder homogeneity is key to balancing toughness and strength. Likewise, in NiAl–Al_2O_3 systems consolidated via PPS, nanometric alumina dispersion improves hardness and grain refinement, offering valuable insights applicable to LPBF processing—particularly in understanding densification and residual stress under rapid thermal cycles [30,31]. Emerging material systems like High Entropy Alloys (HEAs) and W-SS316L composites are of particular interest for aerospace and nuclear applications, respectively. LPBF of HEAs such as CoCrFeNiMn retains a stable FCC phase due to ultrafast cooling, but surface roughness, segregation, and stress concentration around unmelted particles remain hurdles. W–SS316L systems, though critical for nuclear fusion applications, remain underexplored. Their vastly different thermal properties complicate interface stability and lead to cracking and warping. Studies on pure W and SS316L individually provide a basis, but a comprehensive understanding of their interaction is still lacking [29]. The precise control offered by LPBF makes it highly valuable for applications requiring complex geometries and functionally tailored properties. In aerospace, LPBF enables components with high strength-to-weight ratios and controlled thermal behavior, such as turbine blades and heat exchanger walls [31]. In medical implants, LPBF-fabricated Ti–Ta and Ti–Nb systems offer superior osseointegration, reduced stress shielding, and biocompatibility over conventional alloys [30]. The radar chart showing the challenges in LPBF – fabricated FGMs has been presented in Figure 5. This indicates the potential of error generation in various FGMs. Level 1 indicates broad defect categories, Level 2 breaks them down further, and Level 3 highlights specific, critical issues. These Level 3 defects are the most localized or consequential problems that directly impact the performance, microstructure, or manufacturability of LPBF parts. One of the prominent challenges is powder segregation, especially in systems involving materials with significant differences in density and particle size, such as Ti-Ta or W-SS316L. This leads to compositional inhomogeneity and uneven gradient formation. Remedies for this issue include advanced powder mixing methods like ball milling or ultrasonic agitation, and in situ powder delivery systems that maintain consistent material flow, as highlighted in recent LPBF studies [29].

CONCLUSION

The AM of FGMs via LPBF holds immense potential for producing components with spatially tailored properties for advanced sectors. However, realizing defect-free, high-performance FGMs remains a challenge due to issues inherent in multi-material processing, each requiring targeted strategies for resolution.

- LPBF enables the fabrication of complex FGMs with compositional and microstructural gradients that are not achievable through conventional methods, offering application-specific advantages in aerospace, biomedical, and nuclear domains.
- Major challenges in LPBF of FGMs include powder segregation, elemental incompatibility, phase instability, and thermal stress accumulation—especially in systems involving dissimilar metals or metal-ceramic combinations.

- Defects such as interfacial cracking, brittle intermetallic formation, reinforcement agglomeration, and porosity significantly affect the mechanical integrity and service life of LPBF-FGM components.
- Remedies include optimized scan strategies (e.g., interlayer rotation), preheating of the build plate, post-processing treatments (such as aging or SPS), and the use of gradient interlayers to minimize thermal mismatch and stress concentration.
- Advanced powder preparation methods and process parameter control are critical to ensuring uniform reinforcement distribution and compositional homogeneity, particularly in HEAs and metal-ceramic systems.

ABSTRACT

Wildlife is vulnerable by a multitude of human activities, including as habitat damage, the illicit wildlife trade, the spread of exotic species and diseases, and human-induced climate change that is changing the nature of wild ecosystems. This study aims to highlight the protection of wildlife and ecosystems in the southern states of India. The presence of Eastern Ghats and Western Ghats in southern India necessitates to look into the policies of the governments in wildlife conservation and the available literature surveys from other countries to give the ways and means to wildlife conservation. There is numerous research studies associated with the Ecosystem and wildlife conservation and the present study highlights the suggestions made towards effective policy making.In this review of conservation efforts, the role of scientific research in policy-making, management, and public awareness is emphasized through various references, including studies on biodiversity in the Western Ghats and marine ecosystems in the Andaman and Nicobar Islands. It highlights the southern states of India as pivotal in conservation efforts, facing immediate and long-term challenges while showcasing the potential for utilizing technology and community collaboration. The commitment to conservation is evident, with significant progress made, and the review aims to provide a scholarly foundation for further initiatives in preserving the region's ecosystems and wildlife. While the challenges ahead are substantial, the collective journey towards a sustainable future for nature and humanity is deemed essential.

INTRODUCTION

Overview of the Southern States of India's diverse Ecosystem and Wildlife

The Southern States of India, encompassing diverse ecosystems from tropical rainforests to coastal areas, are rich in biological diversity, featuring many endemic and vulnerable species critical for ecological stability. However, rapid urbanization, agriculture, and climate change have caused habitat loss and declining wildlife populations. In response, states like Tamil Nadu, Karnataka, and Kerala have enacted conservation strategies, including community initiatives and biodiversity action plans, aimed at protecting these natural resources and promoting sustainable development. A comprehensive analysis of these conservation efforts is essential to identify existing challenges and best practices, ensuring effective governance and decision-making for safeguarding Southern India's ecological heritage. The southern states of India, encompassing a geographically and ecologically diverse landscape, have long captivated the imagination of ecologists, conservationists, and nature enthusiasts alike. Nestled amidst the Western Ghats, the Eastern Ghats, vast coastal regions, and arid plateaus, this subcontinent's southern expanse boasts an astonishing variety of ecosystems and a profusion of wildlife species. This overview delves into the rich tapestry of biodiversity and the remarkable ecosystems that make the southern states of India a region of immense ecological significance. The Western Ghats, situated in southern India across states including Karnataka, Tamil Nadu, Kerala, Andhra Pradesh, and Telangana, represent a biodiversity hotspot with a variety of ecosystems such as freshwater, coastal, and agroforestry systems. This region, covering around 164,280 km², is notable for high endemism, showcasing approximately 7,402 flowering plant species (about 1,270 endemic), 139 mammals, 179 amphibians, 508 birds, and 290 freshwater fish.

Despite initiatives to expand protected areas and develop species-specific projects, ongoing challenges such as habitat loss, fragmentation, and gaps in freshwater conservation are present. Freshwater habitats in the southern Western Ghats support around 130 freshwater-dependent indigenous species, many of which are underrepresented in conservation efforts and are at high risk of extinction. The hydrological and ecological functions of the Ghats are crucial for local livelihoods, emphasizing their significance for both biological diversity and socioeconomic welfare. A recent valuation placed the ecosystem services provided by the Western Ghats at roughly US$612 million (2021 values), highlighting their importance to indigenous and local communities through provisioning, regulatory, and cultural services. The burgeoning interest in the region's unique natural heritage is driven by the need to understand and protect these invaluable ecosystems and the myriad species they support. While addressing the multifaceted facets of the southern states' ecology, this overview also underscores the profound importance of conservation efforts in safeguarding this unparalleled wealth of biodiversity. The abundant and diverse flora and fauna in the southern states of India have attracted considerable scientific attention. Over the years, numerous research studies, government reports, and conservation organizations have contributed to our knowledge of the region's ecosystems and wildlife. This overview is firmly rooted in the collective wisdom of researchers and experts who have studied and documented the region's ecological treasures.

Major Habitats

The principal ecosystems in the southern states, their defining features and principal pressures; it draws on regional mapping, ecosystem assessments and species-focused studies to highlight conservation priorities. The following table further elaborates; (Table No: 1).

Significance of Ecosystem and Wildlife Conservation in the region

Ecosystem and wildlife conservation in any region are of paramount importance for preserving ecological equilibrium, preserving biodiversity, and safeguarding the well-being of both nature and humankind. However, the need for conservation becomes even more pronounced when we consider the unique and incredibly diverse ecosystems and wildlife that inhabit specific regions. The southern states of India are one such region, where the significance of ecosystem and wildlife conservation is a subject of immense concern and global importance. The southern states of India boast a remarkable array of ecosystems, from the lush, biodiverse rainforests of the Western

Ghats in the arid landscapes at the Deccan Plateau, then from pristine coastal ecosystems to the unique and precious wetlands. These diverse ecosystems support a multitude of wildlife species, many of which are found nowhere else on the planet. The region's biodiversity is celebrated for its richness and distinctiveness, making it a global hotspot for preservation efforts (Myerss *et al*., 2000). Conservation initiatives at the southerly states have gained significance not only because they protect unique ecosystems and species but also because they are intrinsically linked to human livelihoods and cultural heritage. Millions of people in the region depend on these ecosystems for their sustenance, whether through agriculture, fishing, or other natural resource-based activities (Lele *et al*., 2013). Furthermore, the southern states are homebased to a diverse range of indigenous societies whose cultural practices then traditions are intimately tied to the surrounding natural landscapes (Menon and Bawa, 1997). In recent years, rapid urbanization, industrialization, and agricultural expansion have placed unprecedented pressure on the ecosystems and wildlife of the southern states. This encroachment is jeopardizing the region's unique biological heritage and exacerbating issues related to habitat loss, fragmentation, and resource exploitation (Sodhi *et al*., 2006). Understanding significance of ecosystem and environment protection is, therefore, a crucial step towards finding sustainable solutions to these challenges.

This review will delve into the multifaceted significance of ecosystem and wildlife conservation in the southern states of India, exploring the ecological, cultural, economic, and global dimensions of these efforts. By synthesizing the available knowledge and highlighting the urgency of conservation, we aim to inspire concerted action for the preservation of these irreplaceable natural assets. The southern states of India are a geographical tapestry of extraordinary biodiversity, where lush forests, coastal ecosystems, arid landscapes, and rolling plateaus converge to create a symphony of life. This region, nestled between the Western and Eastern Ghats, is renowned for its exceptional ecological richness and the remarkable diversity of its wildlife. It has become a focal point for conservation efforts, drawing the attention of researchers, policymakers, and conservationists worldwide. The southern regions of India, which include Andhra Pradesh, Kerala, Karnataka, Tamilnadu and Telangana, are rich in biodiversity. Home to many sporadic and endangered species, it is one of the most well-known biodiversity hotspots in the world (Myers *et al*., 2000). Much of this rare biodiversity is sustained by the Western Ghats, an internationally renowned ecological jewel that is listed as a UNESCO World Heritage site (Daniels, 2005). The region's rich natural resources have been intertwined with human culture and tradition for centuries. Indigenous communities have developed sustainable practices that have allowed both people and wildlife to coexist harmoniously (Menon and Bawa, 1997). Yet, the escalating pressures of urbanization, agriculture, and climate change pose a profound threat to this delicate equilibrium (Lelee *et al*., 2013). Understanding the significance of bionetwork and wildlife conservation in the southern states is imperative, given the challenges posed by habitat loss, biodiversity decline, and the potential consequences for local communities and global ecological balance (Sodhi *et al*., 2006). A review of the prevailing literature and conservation efforts in the region will shed light on the multifaceted nature of these challenges and the strategies that are being employed to mitigate them.

Exploration of the unique ecosystems in the southern states

The exploration of unique ecosystems in the southern states of India is a captivating journey through a region of exceptional biodiversity and ecological significance.

Diversity and Significance

The southern regions of India, comprising Andhra Pradesh, Kerala, Karnataka, Tamil Nadu, and Telangana, encompass a wide array of ecosystems, from the dense rainforests of the WesternGhats to the fragile coastal ecosystems. The Western Ghats, in particular, stand out as a global hotspot for biodiversity, hosting a multitude of endemic species (Daniels, 2005). This region's ecosystems are characterized by their unique flora and fauna, contributing significantly to worldwide biodiversity (Myerss *et al*., 2000).

Ecosystem Services

The review emphasizes the value of these ecosystems beyond their intrinsic biodiversity. They provide vital ecosystem services such water purification, climate management, and carbon sequestration, benefiting both local

communities and the global environment (Sodhi *et al*., 2006). These services underscore the interdependence of nature and human well-being.

Human-Environment Interactions

Indigenous communities in the southern states have nurtured sustainable practices, with cultural traditions deeply rooted in their ecosystems (Menon and Bawa, 1997). Such practices have allowed for the coexistence of humans and wildlife in these unique landscapes. However, the burgeoning pressures of urbanization, agriculture, and climate change have challenged this equilibrium, emphasising the necessity of conservation measures (Lele *et al*., 2013).

Conservation Initiatives

The review also discusses various conservation initiatives in the region. It is essential to reference these efforts, as they play a pivotal role in preserving the southern states' ecosystems. These initiatives encompass a range of approaches, from protected areas and wildlife corridors to community-based conservation (Daniels, 2005; Lele *et al*., 2013).

Global Relevance

The significance of these unique ecosystems extends far beyond the borders of India. Their conservation is crucial for global biodiversity and ecosystem stability. References to studies such as "Southeast Asian Biodiversity: An impending disaster" by Sodhi *et al*. (2006) highlight the global implications of conservation efforts in this region.

Western Ghats

The WesternGhats, a UNESCO Global Heritage site, represents one of most biodiverse regions in the world (Daniels, 2005). This mountain range showcases a variety of ecosystems, from lush rainforests to montane grasslands, each contributing to the rich tapestry of biodiversity. Numerous endemic species call the Western Ghats their home, making it a global hotspot for conservation (Myers *et al*., 2000). Conservation initiatives in this region are diverse and are aimed at preserving the unique flora and fauna (Krishnan and Kodandapani, 2018).

Coastal Mangroves

The coastal mangroves along the southern states' shorelines are ecosystems teeming with life. They provide essential nursery grounds for numerous marine species, offer protection from coastal erosion, and sequester significant amounts of carbon (Singh *et al*., 2014). These ecosystems are vital for coastal communities and biodiversity alike. Conservation efforts in coastal mangroves not only protect these ecosystems but also contribute to sustainable fishing practices and climate resilience (Singh *et al*., 2014).

Arid Regions

Arid regions in the southern states present a stark contrast to the lush Western Ghats and coastal mangroves. These areas are characterized by low rainfall and unique adaptations by flora and fauna to survive in such harsh conditions. Conservation in arid regions is crucial for preserving the distinctive biodiversity adapted to these challenging environments. These ecosystems play a role in groundwater recharge and upholding the region's ecological equilibrium.

Island Ecosystems

The southern states also feature island ecosystems, such as the Islands of Andaman and Nicobar, which are recognized for their unique bio-diversity. These isolated islands harbour species found nowhere else on the mainland (Daniels, 2005). These ecosystems are highly susceptible to invasive species and habitat degradation. Conservation in island ecosystems is essential for safeguarding these endemic species and preserving the ecological integrity of these islands.

Discussion of the diverse wildlife species inhabiting the region

The southern states of India are renowned for their incredible biodiversity, offering a rich tapestry of ecosystems that are home to a remarkable array of wildlife species. This discussion explores the diverse wildlife inhabiting the region, emphasizing their ecological and conservation significance. To provide a strong scholarly foundation, multiple references have been incorporated to highlight the wealth of research supporting these findings.

Western Ghats' Biodiversity

In addition to being a hotspot for biodiversity, the Western Ghats serve as a haven for many endemic and fascinating species. With species like the Nilgiri Flycatcher (*Eumyias albicaudatus*) and the Malabar Parakeet (*Psittacula columboides*), this area is renowned for its great bird diversity (Daniels, 2005). Numerous other animals can be found in the Western Ghats, such as the endangered Nilgiri Tahr (*Nilgiritragus hylocrius*) and the elusive Bengal Tiger (*Panthera tigris tigris*) (Krishnan and Kodandapani, 2018).

Coastal Mangrove Fauna

Coastal mangroves in the southern states support a diverse range of aquatic and avian species. These ecosystems provide vital areas for feeding and breeding for several species of fish, crabs, and mollusks (Singh *et al*., 2014). Additionally, migratory birds such as the Greater Flamingo (*Phoenicopterus roseus*) and the Pallas's Gull (*Ichthyaetus ichthyaetus*) are among the numerous avian species that depend on these habitats for sustenance and shelter (Singh *et al*., 2014).

Arid Zone Fauna

The arid regions of the southern states host a distinct assemblage of wildlife species adapted to the harsh, water-scarce environments. Iconic species like the Indian Gazelle (*Gazella bennettii*) and the disparagingly scarce Great Indian Bustard (*Ardeotis nigriceps*) are found in these areas. Furthermore, reptiles, including the Indian Sand Boa (*Eryx johnii*) and the Spiny-tailed Lizard (*Uromastyx hardwickii*), have evolved unique adaptations to survive in these arid landscapes.

Island Endemism

The Andaman and Nicobar Islands archipelago, which fall within the southern states' purview, are celebrated for their high levels of endemism. The Nicobar Megapode (*Megapodius nicobariensis*) and the Andaman Wild Boar (*Sus scrofa andamanensis*) are just a couple of the unique species found on these islands (Daniels, 2005). These islands also harbor a diverse marine ecosystem with species like the Dugong (Dugong dugon) and various coral reef inhabitants.

Conservation Imperatives

The conservation of these diverse wildlife species is imperative for maintaining the ecological integrity of the southern states' ecosystems. These species often have specific habitat requirements and play key roles in the food web and ecosystem dynamics. References to various conservation initiatives in the region, as well as the significance of protected areas, emphasize the importance of preserving these unique species and their habitats (Daniels, 2005; Krishnan and Kodandapani, 2018).

Diverse Wildlife Species Inhabiting the Southern States of India

The southern states of India, encompassing a rich tapestry of ecosystems, host a wide range of wildlife species, each causative to the region's ecological complexity and biodiversity. The discussion explores the diverse wildlife species found in the southern states, categorizing them into iconic megafauna and lesser-known species, to highlight their ecological and conservation significance.

Iconic Megafauna

Bengal Tiger (*Panthera tigris tigris*): The Bengal Tiger, one of the most iconic megafauna species, symbolizes strength and resilience. It is an apex predator and keystone species that regulates prey populations and shapes the

structure of ecosystems. The conservation of tigers is a focal point of efforts to preserve entire habitats and protect biodiversity (Krishnan and Kodandapani, 2018).

Indian Elephant (*Elephas maximus*): The Indian Elephant, often regarded as a charismatic and emblematic species, is another key representative of megafauna. These gentle giants have a significant role in forest ecosystems, as they shape landscapes, create waterholes, and facilitate seed dispersal. They also hold cultural importance and are integral to various local traditions.

Indian Gaur (*Bos gaurus*): The Indian Gaur, also identified as the Indian Bison, is a robust herbivore that plays a vital role in shaping forest ecosystems through their grazing and seed- dispersal activities. These megafaunas contribute to maintaining the health of these habitats, ensuring their survival and stability.

Lesser-Known Species

While iconic megafauna often takes the spotlight, the southern states also shelter a multitude of lesser-known species that are equally essential for the region's biodiversity.

Malabar Civet (*Viverra civettina*): The elusive Malabar Civet, residing in the dense Western Ghats forests, is an example of a lesser-known species. As a nocturnal predator, it contributes to insect control in its ecosystem, indirectly impacting forest health. Conservation efforts for such species are crucial for maintaining the intricacies of biodiversity.

Jerdon's Courser (*Rhinoptilus bitorquatus*): Jerdon's Courser, one of the world's rarest birds, epitomizes lesser-known species in the southern states. Found in scrub forests, it has an extremely limited global population. Protecting these lesser-known species is imperative to safeguard avian diversity and maintain the ecological balance.

Travancore Tortoise (*Indotestudo forstenii*): The lesser-known reptiles, including the Travancore Tortoise, are essential components of the region's ecosystems. Through activities like seed dispersal and nutrient cycling, they contribute to habitat health. Nevertheless, habitat loss and poaching pose significant threats to their survival.

Conservation Initiatives

Overview of Conservation Strategies and Policies in Southern India

Conservation strategies and policies in southern India offer a comprehensive examination of the region's efforts to protect its unique ecosystems and biodiversity. This review synthesizes and assesses the conservation strategies and policies, highlighting their strengths and challenges, and their collective impact on the environment and wildlife. Multiple references have been incorporated to provide a scholarly foundation for this discussion.

Biodiversity Hotspot Status

Southern India, particularly the Western Ghats, is internationally recognized as a biodiversity hotspot (Myerss *et al*., 2000). The region's unique ecosystems, rich in endemic species, have necessitated the formulation of robust conservation strategies and policies to safeguard its ecological wealth.

Protected Areas

Southern India hosts a network of endangered areas, including national parks, nature sanctuaries, and biosphere reserves. These protected areas serve as essential tools for conservation, providing safe havens for threatened species and ensuring the preservation of their habitats (Daniels, 2005). Several references emphasize the importance of these protected areas in maintaining biodiversity.

Community-Based Conservation

Community participation in conservation has gained prominence in southern India, fostering a collaborative approach that integrates local knowledge and sustainable practices. References, such as Lele *et al*. (2013), highlight the significance of community-based conservation efforts in achieving ecological and social goals.

Legal Frameworks and Policies

Southern India has a comprehensive permissible context and policy framework for environmental and wildlife conservation. References like the Wildlife Protection Act of 1972 and Forest Rights Act of 2006 underscore the regulatory mechanisms in place for conservation. These policies provide a strong foundation for wildlife protection and habitat preservation.

Challenges and Future Directions

The review identifies several challenges, including habitat loss due to urbanization, fragmentation of ecosystems, and the adverse influences of weather change (Sodhi *et al*., 2006). Furthermore, addressing human-wildlife conflict and illegal wildlife trade are ongoing challenges that require innovative policy responses.

Global Significance

The conservation efforts in southern India have a global implication. The region's biodiversity and ecosystems play a role in maintaining global ecological balance, making effective conservation strategies and policies a matter of global concern. Conservation strategies and policies in southern India underscores the region's commitment to protecting its unique natural heritage. It offers a multifaceted approach that combines protected areas, community involvement, legal frameworks, and an awareness of global implications. However, challenges persist, necessitating ongoing efforts and adaptive policies to ensure the preservation of these invaluable ecosystems for future generations. The references integrated into this review provide a scholarly foundation for understanding the region's conservation initiatives and their significance on both local and global scales.

Case Studies and Successful Conservation Projects

Western Ghats Conservation Initiatives

Western Ghats Biodiversity Hotspot: The Western Ghats, a global biodiversity flashpoint, has been a focal point for conservation efforts (Myers *et al*., 2000). Several initiatives have been launched to protect the unique ecosystems and endemic species in this region.

Case Study: Malabar Large Spotted Civet (*Viverra civettina*): Conservation projects in the Western Ghats have made a notable impact, such as the successful protection of the critically endangered Malabar Large Spotted Civet. This elusive species, with a dwindling population, benefited from targeted research and conservation strategies (Kolipaka *et al*., 2017).

Marine Conservation in the Andaman and Nicobar Islands

Unique Marine Ecosystems: The Andaman and Nicobar Islands are famous for their unparalleled marine biodiversity. Conservation initiatives in these island ecosystems are critical to preserving this global treasure (Daniels, 2005).

Case Study: Coral Reef Conservation: Successful coral reef conservation efforts in the Andaman and Nicobar Islands have involved establishing marine protected areas, regulating tourism, and promoting sustainable fishing practices (Muthiga and Szmant, 1987). These measures have contributed to the resilience of coral reefs in the region.

Global Significance

The success of these conservation initiatives is not limited to the region itself but holds global importance. Protecting biodiversity-rich areas like the Western Ghats and Andaman and Nicobar Islands contributes to global ecological stability, supports local livelihoods, and enhances the resilience of ecosystems (Lele *et al*., 2013).

Role of local communities in Conservation Effort

Conservation efforts worldwide have increasingly documented the crucial role that local societies play in preserving biodiversity and ecosystems. This review explores the multifaceted contributions of local communities to conservation, emphasizing the significance of their engagement and participation.

Local Ecological Knowledge

Local communities possess invaluable ecological knowledge passed down through generations. This traditional knowledge is often a rich source of information about the region's biodiversity, habitat dynamics, and sustainable practices (Berkes *et al*., 2000).

Sustainable Resource Management

Many conservation initiatives have successfully incorporated local communities into sustainable resource management. For instance, community-based forestry projects in India have empowered local groups to manage and conserve forests sustainably, benefiting both ecosystems and livelihoods (Agrawal and Gibson, 1999).

Coexistence with Wildlife

Local communities often coexist with wildlife and are directly affected by human-wildlife conflicts. Their experiences and perspectives are essential for developing conflict mitigation strategies that balance conservation and community well-being (Inskip *et al*., 2016).

Protected Area Management

Community involvement in managing protected areas has been a successful approach in many regions. Case studies like the Joint Forest Management in India demonstrate how local communities can actively participate in preserving and restoring ecosystems (Gadgil and Berkes, 1991).

Economic Incentives

Conservation efforts often create economic incentives for local communities through ecotourism, sustainable agriculture, and non-timber forest products. These incentives motivate communities to protect their natural resources (Blom *et al*., 2010).

Challenges and Conflicts

The interaction between local communities and conservation initiatives can also lead to conflicts. Balancing the needs of conservation with local livelihoods can be challenging and requires adaptive management (Redpath *et al*., 2013).

Global Perspective

The role of local communities in conservation extends beyond specific regions. Their engagement is increasingly recognized as a vital component of global efforts to combat biodiversity damage and address climate change (Büscher *et al*., 2017).

Scientific Research

Examination of Scientific Contributions to Ecosystem and Wildlife Conservation

The southern states of India, known for their exceptional biodiversity and unique ecosystems, have been the subject of extensive scientific contributions to ecosystem and wildlife conservation. This review delves into the scholarly endeavours that have advanced our understanding of conservation in this region, with a focus on the Southern states of India.

Biodiversity Hotspots

Southern India is home to critical biodiversity hotspots, including the Western Ghats. The work of scholars like Daniels (2005) has lean-to light on the extraordinary diversity and endemism of this region, emphasizing the urgent need for conservation.

Avian Diversity

The ornithological diversity of south India, particularly in the Western Ghats, is well- documented in references such as Ali and Ripley's "Handbook of the Birds of India and Pakistan" (1987). These references have been instrumental in recognizing the avian richness of the region and the importance of conservation measures.

Flora and Medicinal Plants

Scientific studies have explored the rich flora of the southern states, contributing to the documentation and conservation of diverse plant species, some with medicinal properties. Reference works like Pullaiah's "Encyclopedia of World Medicinal Plants" (2006) have been invaluable in this regard.

Herpetofauna Conservation

Scholars have made substantial contributions to herpetofauna conservation. "Amphibians of the Western Ghats" by Gururaja *et al*. (2007) is an example of research that emphasizes the unique amphibian diversity and the need for protective measures in the Western Ghats**.**

Marine Conservation

The marine ecosystems around the southern states, plus the Andaman and Nicobar Islands, have also received scientific attention. References like "The Ecology of Mangrove and Related Ecosystems" by Kathiresan and Bingham (2001) have underlined the significance of these coastal habitats.

Conservation Genetics

Conservation genetics plays a crucial role in preserving genetic diversity. References like Ramakrishnan *et al*.'s research on tiger genetics (2008) exemplify the scientific contributions aimed at understanding and conserving unique wildlife populations.

Landscape-Level Conservation

Studies exploring landscape-level conservation efforts, such as corridor connectivity for wildlife in fragmented habitats, have demonstrated the importance of strategic planning. Scientific work, such as the research conducted by Jhala *et al*. on large carnivores (2011), provides insights into these conservation strategies.

Climate Change Effects: Research such as that contained in the reports of the Intergovernmental Panel on Climate Change (IPCC) (e.g., IPCC, 2014) has helped us realize the sensitivity of the region to climate change and the necessity of adaptive conservation strategies.

Impact of Research on Conservation Policies and practices

Scientific research has occupy a pivotal role in shaping preservation policies and practices in the southern states of India, known for their rich biodiversity and unique ecosystems.

Western Ghats Conservation

The Western Ghats, a international biodiversity hotspot, has been the subject of extensive research emphasizing the need for conservation. Studies like those referenced in Gadgil and Berkes' research on Joint Forest Management (1991) have informed policies for sustainable resource management and the establishment of protected areas.

Species-Specific Conservation

Scientific research has spotlighted species at risk and led to focused conservation efforts. For example, studies on the lion-tailed macaque (*Macaca silenus*) (e.g., Johnsingh and Joshua, 2008) have influenced policies for its protection and the preservation of its habitat.

Community-Based Conservation

Research has demonstrated the effectiveness of community-based conservation initiatives. Projects like those referenced in Agrawal and Gibson's work on community forestry (1999) have provided insights into the role of local communities in conservation and have led to the implementation of community-based conservation programs in the region.

Marine Conservation

The Andaman and Nicobar Islands, with their unique marine ecosystems, have been the focus of research on coral reefs and marine biodiversity (Muthiga and Szmant, 1987). This research has driven the establishment of marine protected areas and the regulation of activities affecting marine environments.

Biodiversity Assessment

Research on biodiversity assessment has contributed to a comprehensive understanding of the region's ecological richness. Studies like the National Biodiversity Strategy and Action Plan for India (MoEFCC, 2014) have informed national and regional policies and conservation priorities.

Climate Change Adaptation

The impacts of climate change on the region's ecosystems have been the subject of scientific investigation (IPCC, 2014). This research has influenced climate adaptation policies and practices for preserving habitats and species.

Wildlife Corridor Planning

Studies on landscape-level conservation, including wildlife corridors (e.g., Jhala *et al*., 2011), have led to the inclusion of these strategies in regional conservation policies and land-use planning.

Conservation Education and Awareness

Research in environmental psychology and education (e.g., Clayton, 2012) has helped design effective strategies for conservation awareness and education programs that engage local communities.

Challenges and Threats

Identification of key challenges to Ecosystem and Wildlife Conservation

Ecosystem and wildlife conservation in the southern states of India is confronted with a spectrum of challenges that have critical implications for the region's unique biodiversity.

Habitat Loss and Fragmentation

Locale loss, driven by urbanization, infrastructure development, and agriculture, is a primary threat to biodiversity in the south states. The work of Myers *et al*. (2000) emphasizes the need to address habitat loss, particularly in the Western Ghats, to protect endemic species.

Human-Wildlife Conflict

The coexistence of growing human populations and wildlife in the southern states has led to increasing conflicts. Studies like those by Inskip *et al*. (2016) highlight the importance of addressing these conflicts for effective conservation.

Poaching and Unlawful Wildlife Trade

Plundering and the illegal trade of wildlife and their parts persist as significant threats.

Climate Change Effects

The south Indian states face the moments of climate change, with altered rainfall patterns, increased temperatures, and changing habitat suitability. References, including the IPCC reports (IPCC, 2014), emphasize the need for adaptation and mitigation strategies in conservation planning.

Invasive Species

Invasive species disrupt native ecosystems and compete with indigenous flora and fauna. Studies like the work of Daniels (2005) highlight the need for invasive species management to safeguard native biodiversity.

Lack of Awareness and Education

Conservation challenges in the region are exacerbated by a lack of cognizance and education regarding the value of ecosystems and wildlife. References like Clayton (2012) emphasize the importance of conservation education to foster a culture of stewardship.

Governance and Policy Gaps

Weak governance, inadequate policies, and regulatory gaps have hampered conservation efforts. The references incorporated in the review underscore the need for more effective legislation and governance (Agrawal and Gibson, 1999).

Fragmented Conservation Efforts

Conservation projects and initiatives in the southern states can be fragmented, lacking coordinated efforts and integrated planning. A more holistic approach is recommended, as seen in research by Kareiva *et al*. (2011).

Water Management and Pollution

Management of water resources and pollution control are crucial for maintaining aquatic ecosystems. Research like Pullaiah's work on medicinal plants (2006) emphasizes the connection between water quality and biodiversity conservation.

Discussion of potential future threats and their implications

Urbanization and Infrastructure Development

Rapid urbanization and infrastructure development in the southern states are potential threats that can lead to habitat loss and fragmentation. Studies like those referenced in Myers *et al*. (2000) emphasize the need to address urban sprawl and its implications for wildlife and ecosystems.

Climate Change Influences

The impacts of climate alteration in the region are a looming concern. References, including the Inter-governmental Panel on Climate Change (IPCC) reports (IPCC, 2014), emphasize the implications of changing weather patterns, increased temperatures, and altered monsoon cycles for ecosystems and species distribution.

Land Use Changes

Shifts in land usage patterns, especially in agriculture and forestry, can disrupt natural habitats. Research such as Sinclair *et al*.'s work on population ecology (2006) underscores the consequences of land use changes for wildlife populations.

Water Scarcity and Pollution

Water scarcity and pollution are potential threats that can affect aquatic ecosystems and the species that rely on them. References like Pullaiah's research on medicinal plants (2006) highlight the connection between water quality and biodiversity conservation.

Invasive Species

Invasive species continue to pose a threat to native flora and fauna. The research referenced in Daniels (2005) underscores the need for invasive species management strategies.

Human-Wildlife Conflict Escalation

As human populations expand, conflicts with wildlife may escalate. Research by Inskip *et al*. (2016) emphasizes the importance of addressing human-wildlife conflicts for conservation purposes.

Global Economic and Market Forces

Global economic and market forces, such as demands for certain wildlife products, can drive illegal trade and poaching. Studies like Singh *et al*.'s work (2014) underscore the implications of global market pressures on local wildlife populations.

Policy and Governance Challenges

Weak governance and policy gaps can hamper conservation efforts. The references integrated into the review underpin the need for more effective legislation and governance (Agrawal and Gibson, 1999).

Lack of Conservation Awareness

The lack of conservation awareness and education may hinder efforts to engage the public in conservation. References like Clayton (2012) highlight the importance of building awareness to promote a culture of environmental stewardship.

The Way Forward

Strategies to address current Challenges

The southern states of India are home to diverse ecosystems and rich biodiversity, but they face a range of challenges that necessitate strategic conservation efforts.

Habitat Preservation and Restoration

Preserving critical habitats and restoring degraded ones are foundational strategies for conservation in the southern states. Research like that referenced in Myers *et al*. (2000) emphasizes the importance of designating and protecting these areas.

Climate-Resilient Conservation

As climate change threatens ecosystems, strategies to enhance resilience are vital. The Inter-governmental Panel on Environment Change (IPCC) reports (IPCC, 2014) provide insights into climate adaptation measures in conservation.

Sustainable Land Use Practices

Promoting sustainable agriculture and forestry practices helps reduce the environmental impact of land use changes. The research by Sinclair *et al*. (2006) underscores the need for these sustainable practices.

Water Resource Management

Effective water resource management and pollution control are integral to protecting aquatic ecosystems. Pullaiah's work on medicinal plants (2006) highlights the significance of water quality in conservation.

Invasive Species Management

Managing and controlling invasive species is crucial for preserving native flora and fauna. The references included in Daniels (2005) underpin the importance of addressing invasive species.

Community Engagement and Conservation

Involving local communities in conservation efforts fosters a sense of ownership and support. Agrawal and Gibson's research (1999) illustrates the effectiveness of community-based conservation.

Human-Wildlife Conflict Resolution

Addressing conflicts between humans and wildlife through conflict resolution and coexistence strategies is essential. Research by Inskip *et al*. (2016) highlights the importance of such strategies.

Effective Policies and Governance

Robust policies and governance structures are fundamental to ensuring conservation success. The references incorporated into this review emphasize the role of policy and governance (Agrawal and Gibson, 1999).

Conservation Education and Public Awareness

Raising awareness and educating the public about the value of ecosystems and wildlife is a key strategy. References like Clayton (2012) highlight the role of education in promoting environmental stewardship.

By implementing these approaches, the southern states can better navigate the complex landscape of conservation and work toward the preservation of their diverse ecosystems and wildlife.

Future prospects for Ecosystem and Wildlife Preservation in Southern India

The future prospects for ecosystem and wildlife conservation in southern India hold promise but also pose significant challenges.

Habitat Expansion and Restoration

The creation and expansion of protected areas and habitat restoration projects offer promising prospects for the preservation of ecosystems. Research referenced in Myers *et al*. (2000) highlights the value of designated conservation areas and the need for more.

Climate-Resilient Conservation

Adaptive strategies informed by climate science, as emphasized in the Inter-governmental Panel on Climate Change (IPCC) reports (IPCC, 2014), can help conservationists navigate the impacts of climate alteration and promote the resilience of ecosystems.

Sustainable Land Use Practices

Encouraging sustainable agriculture and forestry practices promises to reduce the ecological footprint of human activities. The research by Sinclair *et al*. (2006) exemplifies the potential of such practices.

Water Resource Management

Effective water resource management, coupled with pollution control, is vital for the conservation of aquatic ecosystems. The importance of water quality is highlighted in research like that by Pullaiah (2006).

Invasive Species Control

Efforts to control and manage invasive species offer prospects for protecting native flora and fauna. The references integrated into this review, as in Daniels (2005), emphasize the importance of addressing invasive species.

Community-Centered Conservation

The active involvement of local communities in conservation is a promising approach for garnering support and achieving shared conservation goals. The effectiveness of community- based conservation, as seen in Agrawal and Gibson's research (1999), demonstrates the potential of this strategy.

Human-Wildlife Coexistence

Promoting peaceful coexistence between humans and wildlife through conflict resolution strategies is a prospect that aims to mitigate conflicts and conserve species. Research by Inskip *et al*. (2016) reinforces the potential of coexistence initiatives.

Enhanced Policies and Governance

Strengthened governance and improved conservation policies offer prospects for creating a more conducive regulatory environment. The references included in this review underpin the importance of effective policy and governance structures (Agrawal and Gibson, 1999).

Conservation Education and Public Awareness

Enhancing conservation education and raising public awareness can create a culture of environmental stewardship. The role of education in promoting awareness, as exemplified in Clayton (2012), highlights the potential of these initiatives.

The role of technology and innovation in conservation

The southern states of India boast remarkable biodiversity and ecosystems, yet they also face substantial conservation challenges. In addressing these challenges, the role of technology and innovation has emerged as a powerful force driving conservation efforts.

Technological Advancements in Conservation

Technology has significantly transformed the way conservation is approached in southern India. In a region known for its rich biodiversity, the application of cutting-edge tools and techniques is playing a pivotal role in preserving its natural heritage.

Remote Sensing and GIS

Remote sensing and Geographic Information Systems (GIS) have revolutionized conservation efforts by providing precise data on habitat distribution, land use changes, and deforestation. References like "Remote Sensing and GIS for Ecologists" by Wegmann (2015) underscore the importance of these technologies. Remote sensing has enabled the monitoring of changes in land cover, helping conservationists identify deforestation, urbanization, and habitat loss. Furthermore, GIS allows for the integration of various spatial data, enabling informed decision- making for conservation planning and habitat restoration.

Camera Traps and Monitoring Tools

Camera traps, acoustic monitoring devices, and other non-invasive technologies have transformed wildlife monitoring and research. These tools, as exemplified in studies by O'Connell *et al*. (2011), have enabled researchers to capture valuable data on elusive and nocturnal species. Camera traps, in particular, have revolutionized the field of wildlife biology by capturing images and videos of wildlife in their natural habitats. The insights gained from these technologies aid in population assessments, distribution mapping, and behavior studies of a wide range of species, from big cats to small mammals.

DNA Analysis and Conservation Genetics

Advancements in DNA analysis and genetics have empowered conservationists to understand and manage populations more effectively. References such as Allendorf *et al*.'s "Conservation and the Genetics of Populations" (2013) emphasize the significance of conservation genetics. DNA analysis helps identify genetic diversity within populations, detect inbreeding, and assess the origin of individuals seized from illegal trade. This information informs breeding programs, the translocation of individuals, and the development of population management strategies to preserve genetic diversity.

Data Management and Analysis Software

Sophisticated data management and analysis software enable researchers to process vast amounts of ecological data. Works like "Ecological Models and Data in R" by Bolker (2008) highlight the power of such tools. These software applications facilitate the modeling of ecological processes, including population dynamics and habitat suitability. By analyzing and modeling data, conservationists can simulate the impact of different interventions, helping to devise effective strategies for preserving biodiversity.

Mobile Apps and Citizen Science

Mobile applications are engaging citizen scientists in data collection and conservation activities. References such as Kelling *et al.*'s study on eBird (2015) illustrate the potential of such initiatives. Mobile apps enable the public to contribute to scientific research and wildlife observations. Projects like eBird, which focuses on bird observations, have amassed vast datasets used by conservationists to track avian populations and migratory patterns. Citizen science fosters public engagement and generates valuable information for conservation efforts.

Innovative Approaches in Conservation

Innovation extends beyond technological tools, encompassing novel approaches and methodologies that have been harnessed in southern India's conservation landscape.

Landscape-Level Conservation

Innovative conservation strategies, as exemplified in research by Kareiva *et al*. (2011), underscore the importance of considering entire landscapes rather than isolated ecosystems. This approach advocates for the protection and restoration of corridors that connect fragmented habitats. It acknowledges the ecological interdependence of different areas and fosters collaboration among multiple stakeholders.

Drones and UAVs

Unmanned Aerial Vehicles (UAVs) or drones are proving invaluable for monitoring remote and challenging landscapes. These devices capture high-resolution images and videos, enabling researchers to assess habitat conditions, track wildlife, and even detect illegal activities like poaching. While many references are yet to be published, ongoing projects in southern India have shown the potential of drones in conservation.

Sustainable Agriculture Practices

Innovations in agriculture, including the adoption of organic farming and sustainable practices, contribute to habitat conservation and reduce the environmental impact of farming. Such practices promote biodiversity-friendly agriculture, as showcased in research by Perfecto and Vandermeer (2008). Innovations in agriculture include organic farming, precision farming, and integrated pest management. These approaches reduce the ecological footprint of agriculture, protecting habitats while ensuring food security.

Eco-friendly Infrastructure Development

Innovative infrastructure design and development can minimize the impact on ecosystems. References such as Forman *et al*.'s research on road ecology (2003) highlight the potential of eco-friendly infrastructure. Strategies include wildlife corridors, underpasses, and overpasses that allow wildlife to safely traverse human-made barriers. These innovations prevent habitat fragmentation and reduce the risk of wildlife-vehicle collisions.

Sustainable Fisheries Management

Innovative approaches to fisheries management are helping to conserve aquatic ecosystems. References like Sumaila *et al.*'s work on fisheries economics (2010) showcase such innovations. Sustainable fisheries management includes strategies like ecosystem- based management, marine protected areas, and catch limits to prevent overfishing.

REVIEW OF LITERATURE

The environmental effects of human activity have a significant impact on biodiversity. Ecosystems are being profoundly impacted by factors such as climate change, population growth, urbanization, food production, and shifting land uses. Biodiversity is essential for both human life and the ecosystems of the planet. The literature survey helps to highlight the past studies on ecosystem and wildlife conservation in southern India. Sanjay Gubbi *et al*. (2017) discussed the evolution of tiger protection in southern India, emphasizing the need for interconnected habitats to facilitate tiger survival and breeding. The study revealed baseline estimates for tiger populations in newly

protected areas and highlighted a significant decline in forest cover in regions previously exploited for silviculture. Management adjustments and community engagement are essential for effective habitat recovery and mitigating human-wildlife conflicts, particularly involving elephants and leopards. David Milda *et al*. (2020) pointed out that human-wildlife interactions are escalating, necessitating robust management strategies, while resources for conservation differ significantly between protected and non-protected areas. Factors affecting biodiversity conservation in African national parks have been analyzed by Moses Muhumuza and Kevin Balkwill (2013), attributing successes and failures to socioeconomic elements. Additionally, R. James Ansley *et al*. (2022) assessed the impact of climate change on ecosystem services in the South-Central United States, stressing the need for informed management decisions to alleviate biodiversity loss. Ndidzulafhi I. Sinthumule (2023) reviewed traditional ecological knowledge's role in biodiversity conservation in Africa, noting its declining relevance. Arjun Srivathsa *et al*. (2022) highlighted the urgency of integrating human welfare with biodiversity conservation efforts in India through effective spatial planning. The pressing threat of habitat fragmentation was examined by Nick M. Haddad *et al*. (2015), necessitating immediate conservation actions. Lastly, Kamal S. Bawa *et al*. (2007) outlined the conservation challenges in the Western Ghats, underscoring the need for increased civil society participation and innovative strategies to prevent further biodiversity loss.

Conservation Actions Thereats and Recommandations

This section discusses species-level trends, flagship taxa, endemic groups, and conservation gaps across southern states, emphasizing the Western Ghats' significance for biodiversity, notably in amphibians and freshwater fish. The region hosts a critical population of around 10,000 Asian elephants, functioning as an umbrella species for conservation. However, the occupancy rate of dholes has declined significantly due to forest loss, revealing the necessity for better landscape management outside protected areas. Despite the presence of 130 endemic freshwater-dependent taxa, only 44% reside within the existing protected area (PA) network. Local research indicates significant biodiversity hotspots for bats and butterflies, with many species remaining unprotected and lacking adequate baseline data. The case study of the Nilgiri Biosphere Reserve indicates successful conservation efforts, maintaining forest cover despite human pressures, while Karnataka's increase in PA coverage exemplifies a successful model for expanding protected landscapes. Various threats persist, including habitat fragmentation, invasive species, and development pressures, revealing significant conservation gaps despite existing efforts. Strategies in Karnataka highlight the effectiveness of landscape-scale approaches to establishing interconnected PAs for species protection. Continued management of freshwater species is critical, advocating for tripling the PA network and developing specific management plans. Local and community-driven conservation initiatives, such as biodiversity heritage sites and agroforestry systems in Kerala, underscore the importance of integrating traditional ecological knowledge into conservation planning. The use of modern scientific tools, like multispecies occupancy models, is proposed for targeted management efforts in biodiversity hotspots, particularly for endemic and cryptic taxa. Challenges persist, including habitat loss from human intervention and ongoing human-wildlife conflicts, impacting conservation viability. Priority measures include enhancing PA coverage focused on freshwater species, repairing ecological corridors for wildlife movement, and incorporating Indigenous and local community values into conservation planning. The text emphasizes the need for evidence-based interventions, such as community-based conservation, targeted freshwater management, and the adoption of advanced monitoring technologies to address these challenges effectively in southern India.

CONCLUSION

The review of ecosystem and wildlife conservation in the southern states of India paints a comprehensive picture of the remarkable biodiversity, challenges, and the strides made in preserving this natural heritage. The southern states, with their diverse ecosystems and unique wildlife, stand as global biodiversity hotspots. However, they are not immune to the pressures of habitat loss, climate change, and human-wildlife conflicts. In examining the scholarly foundation of conservation efforts, this review has drawn upon multiple references that underscore the critical role of scientific research in shaping policy, management, and public awareness. The references span from studies of

biodiversity hotspots in the Western Ghats to the ecological intricacies of marine ecosystems in the Andaman and Nicobar Islands. As we navigate the intricacies of conservation in the southern states of India, it is clear that science, innovation, and collaboration will continue to drive efforts to protect this exceptional natural heritage. The southern states are at a crossroads, where ongoing challenges require immediate and long-term attention. However, the prospects for conservation are bright, with the potential to harness technology, innovation, and the collective will of local communities and policymakers. The southern states of India have demonstrated a commitment to conservation, and they have made substantial progress. This region has much to offer the world in terms of ecological understanding and innovative conservation approaches. It is our hope that this review serves as a scholarly foundation to guide and inspire further efforts in the preservation of southern India's invaluable ecosystems and diverse wildlife. The road ahead may be challenging, but it is one that we must collectively tread to ensure a sustainable and harmonious future for both nature and humanity.

Table No: 1.

Ecosystem type	Key characteristics	Conservation status and pressures
Montane evergreen and shola forests	High-elevation mosaic of wet evergreen and shola grassland with many narrow-range endemics and rainfall-driven hydrology	Strong biodiversity value; threatened by fragmentation, plantations and land-use change
Riparian forests and streams	Narrow, stream-side evergreen vegetation crucial for freshwater-dependent taxa and torrent specialists	Documented 83% loss over past century in Southern Western Ghats; projected collapse within 20–40 years at current degradation rates
Freshwater rivers and streams	High endemicity in fishes and invertebrates; source of major rivers draining peninsular India	~130 endemic freshwater taxa in southern Western Ghats; >50% of these are absent from current PA network and ~25% are high risk of extinction
Coastal and mangrove systems	Coastal beaches, estuaries and mangroves influenced by monsoon and tidal regimes	Coastal zones experienced disturbance from events like the 2004 tsunami; recoveries were site-specific and connectivity to inland systems is critical
Agroforestry and homegardens	Traditional homegardens and temple-associated water bodies provide refugia and cultural conservation values	Homegardens harbour significant bird, amphibian and tree diversity but are rapidly being converted to monocultures or built-up land

ABSTRACT

A growing elderly population has increased concerns about mental health and quality of life in later years of life, especially when it comes to where individuals live. Institutional care meets the fundamental needs of elderly individuals, although its psychological effects are not adequately comprehended within the Indian setting. The current study examined differences in geriatric depression, subjective well-being, and quality of life between institutionalized and non-institutionalized elderly people, while also examining coping experiences in later life through a mixed-methods approach. A cross-sectional mixed-methods design was used with a quantitative sample consisting of 60 elderly people aged 60 years and older, with 30 being institutionalized and 30 non-institutionalized. The Geriatric Depression Scale (GDS), the Subjective Happiness Scale (SHS), and the WHOQOL-BREF were used to test the participants. Since the data did not satisfy into a normal distribution, non-parametric statistical methods were used. In addition, semi-structured interviews were administered to the sample to investigate coping strategies. The findings showed that institutionalized elderly reported significantly higher geriatric depression

(mean rank = 41.35) compared to non-institutionalized elderly (mean rank = 19.65; U = 178.00, p < .001). Conversely, non-institutionalized elderly people showed higher subjective happiness (mean rank = 38.23 vs. 22.77; U = 241.50, p = .004) and a better overall quality of life (mean rank = 42.30 vs. 18.70; U = 139.00, p < .001). Kruskal–Wallis results showed significant group differences among residential status and gender in geriatric depression (H = 23.684, p < .001), quality of life (H = 39.615, p < .001), and subjective happiness (H = 11.996, p = .007), with institutionalized women demonstrating the highest levels of depression and non-institutionalized women reporting the highest levels of happiness and quality of life. Correlation study showed that geriatric depression had a negative correlation with subjective happiness (r = −0.512, p < .01) and quality of life (r = −0.624, p < .01), but subjective happiness showed a positive correlation with quality of life (r = 0.581, p < .01). Qualitative analyses revealed strategies for coping including acceptance, spirituality, and social support. A major emergent theme of anthropomorphism was identified, wherein elderly individuals, especially those in institutional environments, attributed human-like feelings or companionship to objects, symbols, or personal things to ease loneliness and emotional deprivation. The results underscore the significance of living arrangements, emotional connection, and adaptive coping in psychological aging, while recognizing anthropomorphism as a context-sensitive coping strategy with implications for individualized geriatric care.

Keywords: Geriatric depression; Subjective happiness; Quality of life; Institutionalization; Ageing; Anthropomorphism

INTRODUCTION

Population ageing represents one of the most significant demographic transitions of the twenty-first century. Advances in healthcare, nutrition, and disease management have substantially increased life expectancy across the globe, leading to a rapid rise in the elderly population (World Health Organization [WHO], 2021). By 2050, nearly two billion individuals worldwide are expected to be aged 60 years and above, with a large proportion residing in low- and middle-income countries, including India (WHO, 2021). While increased longevity reflects progress in public health, it also raises important concerns related to mental health, social functioning, and quality of life in later adulthood. Ageing is a complex process involving biological, psychological, and social changes. Biologically, it is associated with gradual physiological decline and increased vulnerability to chronic illnesses (Finch, 1991). Psychologically, older adults may experience changes in emotional regulation, cognitive processing, and stress tolerance (Sarkisian et al., 2002). Socially, ageing is often accompanied by retirement, bereavement, reduced social networks, and role transitions, all of which may adversely affect psychological well-being (Avlund et al., 2004). The interaction of these factors increases susceptibility to mental health problems in later life, particularly depression.

Geriatric depression is among the most prevalent mental health conditions in older adults and is a major contributor to disability, functional decline, and reduced quality of life (Blazer, 2003; Alexopoulos, 2005). Unlike depression in younger populations, late-life depression frequently presents with somatic complaints, sleep disturbances, fatigue, cognitive slowing, irritability, and social withdrawal rather than overt sadness, which often leads to under-recognition and underdiagnosis (Alexopoulos et al., 2002). Depression in later life is associated with adverse physical health outcomes, increased functional impairment, cognitive decline, higher healthcare utilization, and elevated mortality risk, including suicide (Sivertsen et al., 2015; Blazer, 2003). Epidemiological evidence indicates that depressive symptoms are common among community-dwelling, hospitalized, and institutionalized elderly populations, with particularly high prevalence observed among those residing in institutional settings (Blazer, 2003; Pinquart & Sörensen, 2001; Sivertsen et al., 2015).

Psychosocial factors play a central role in the development and persistence of geriatric depression. Loneliness, reduced social support, economic dependency, and the loss of meaningful social roles have been consistently associated with depressive symptoms in older adults (Singh & Misra, 2009). Institutionalization may further exacerbate these vulnerabilities by limiting autonomy, weakening family connections, and intensifying feelings of abandonment, despite the availability of basic care and medical support (Bergdahl et al., 2005; Luppa et al., 2010). Gender differences have also been documented, with women often reporting higher levels and greater persistence of depressive symptoms in later life, although findings vary across cultural contexts (Barry et al., 2008; Zunzunegui et al., 2007). Beyond psychopathology, contemporary gerontological research increasingly emphasizes positive dimensions of ageing, particularly subjective happiness and quality of life. Subjective happiness, a core component of subjective well-being, reflects individuals' cognitive and emotional evaluations of their lives as satisfying and meaningful (Diener et al., 2003). In later adulthood, higher levels of happiness have been linked to better physical health, more adaptive coping strategies, stronger social relationships, and increased longevity (Fredrickson, 2001). Positive emotional experiences are thought to broaden cognitive and behavioral repertoires and foster enduring psychological and social resources, which are especially important in later life when cumulative stressors are common (Fredrickson, 2001; Aspinwall, 1998). Evidence regarding subjective happiness among institutionalized versus non-institutionalized elderly remains mixed. Several studies report lower levels of happiness and well-being among institutionalized older adults, often attributed to reduced autonomy, limited social engagement, and a perceived loss of control (Pinquart & Sörensen, 2001; Luppa et al., 2010). In contrast, other studies suggest that structured routines, peer interaction, and high-quality care may buffer psychological distress and support well-being in certain institutional contexts (Brownie & Nancarrow, 2013; Gaugler, 2014). These divergent findings highlight the importance of context-specific research, particularly in non-Western societies.

Quality of life (QOL) is a central concept in gerontological research and refers to individuals' perceptions of their position in life within the context of their cultural values and living environments (WHOQOL Group, 1995). It is a multidimensional construct encompassing physical health, psychological well-being, social relationships, and environmental conditions. In older adults, quality of life is influenced not only by health status but also by autonomy, dignity, social support, financial security, and opportunities for meaningful engagement (George & Bearon, 1980; Bowling, 2005). Although advancing age is often associated with declines in physical and social domains of quality of life, psychological well-being may remain stable or even improve in some individuals through adaptive coping and acceptance (Paschoal et al., 2007). Growing evidence indicates that geriatric depression, subjective happiness, and quality of life are closely interrelated. Depression has been identified as a strong negative predictor of quality of life across multiple domains (Sivertsen et al., 2015), whereas subjective happiness has been shown to positively predict quality of life independent of physical health status (Llobet et al., 2011). Happiness may function as a protective factor by reducing the negative impact of depressive symptoms on quality of life through enhanced emotional resilience and social engagement (Fredrickson, 2001).

Despite these established associations, relatively few studies have examined geriatric depression, subjective happiness, and quality of life simultaneously within the same population, particularly among institutionalized elderly (Blazer, 2003; Sivertsen et al., 2015; Steptoe et al., 2015). In the Indian context, research on ageing has largely focused on physical illness, economic dependency, and family support, with comparatively limited attention to psychological well-being and subjective experiences of ageing (Government of India, 2016; World Health Organization, 2015). Furthermore, most existing studies examine these constructs in isolation, making it difficult to understand their combined influence on psychological ageing. To address these gaps, the present study examines levels of geriatric depression, subjective happiness, and quality of life among elderly individuals residing in institutional settings and those living in community environments. By comparing these groups and exploring the interrelationships among depression, happiness, and quality of life, the study seeks to contribute to a more integrated understanding of psychological ageing. Such evidence has important implications for mental health policy, geriatric care practices, and the development of psychosocial interventions aimed at enhancing well-being and dignity in later life.

METHODOLOGY

Objectives of the Study

1. To compare geriatric depression, subjective happiness, and quality of life between institutionalized and non-institutionalized elderly.
2. To examine the relationships among geriatric depression, subjective happiness, and quality of life in the elderly population.
3. To explore differences in psychological variables based on selected demographic characteristics, particularly gender and place of residence.
4. To qualitatively explore coping experiences and strategies adopted by elderly individuals in managing emotional, social, and age-related challenges across different living arrangements.

Study Design

A cross-sectional, mixed-methods comparative study was used. The quantitative component allowed statistical comparison of geriatric depression, subjective happiness, and quality of life between institutionalized and non-institutionalized elderly, while the qualitative component explored later-life coping experiences. This integrative method enabled measurement-based comparison and contextual comprehension of ageing-related psychological processes.

Study Setting

The study was conducted in institutional and community settings in Karnataka, India. Institutionalized participants were recruited from registered old age homes, whereas non-institutionalized participants were drawn from community settings where elderly individuals resided with family members. Data collection took place in quiet, familiar environments to ensure participant comfort and reduce response bias

Sample Size and Composition

The study involved a quantitative sample of 60 elderly individuals aged 60 and above, split into two equal groups of 30: institutionalized and non-institutionalized, with each group containing 15 males and 15 females to ensure gender balance. A purposive sampling technique was utilized, reflecting accessibility constraints and specific inclusion criteria typical in gerontological research when random sampling is unfeasible.

Inclusion and Exclusion Criteria

Inclusion Criteria

- Age 60 years and above
- Ability to understand and respond to the assessment tools
- Minimum six-month residence in the institution (for institutionalized participants)
- Willingness to participate and provide informed consent

Exclusion Criteria

- Diagnosed severe cognitive impairment or dementia
- Acute medical illness at the time of assessment
- Severe sensory impairments interfering with participation
- Presence of major psychiatric disorders other than depressive symptoms

Quantitative Measures

- Geriatric depression was measured using the Geriatric Depression Scale (GDS), tailored for older adults by focusing on affective and cognitive symptoms and reducing interference from physical illness. The GDS is reliable and valid in various cultural contexts, including among Indian elderly populations.

- Subjective happiness was evaluated with the Subjective Happiness Scale (SHS), known for its satisfactory internal consistency and construct validity, making it suitable for older participants.
- Quality of life was assessed through the WHO Quality of Life – BREF (WHOQOL-BREF), which encompasses four domains: physical health, psychological health, social relationships, and environment. This 26-item scale is validated for use in cross-cultural research, including within Indian contexts.

Qualitative Component: Semi-Structured Interviews

Purpose

A qualitative component was included to gain deeper insight into coping experiences of elderly individuals, complementing the quantitative findings. This component aimed to explore how older adults perceive ageing, manage emotional challenges, and adapt to their living arrangements.

Participants and Procedure

A subsample of participants from both institutionalized and non-institutionalized groups was selected using purposive sampling. Individual semi-structured interviews were conducted in a quiet and familiar setting. An interview guide with open-ended questions explored:

- Emotional challenges associated with ageing
- Coping strategies for managing stress, loneliness, and health concerns
- Sources of emotional and social support
- Perceptions of institutional or family-based living
- Meaning-making and psychological adjustment in later life

Interviews were conducted in the participant's preferred language and audio-recorded with consent.

Data Analysis

Qualitative data were analyzed using thematic analysis, following an inductive approach to identify recurring patterns related to coping, emotional regulation, and adaptation to ageing. Themes were reviewed and refined to ensure coherence and relevance to the study objectives.

Procedure

Permission was obtained from institutional authorities prior to data collection. Participants were informed about the purpose of the study, voluntary participation, confidentiality, and their right to withdraw at any time. Written informed consent was obtained. Quantitative tools were administered through face-to-face interviews to ensure comprehension, particularly for participants with limited literacy. Adequate time was provided, and breaks were offered to minimize fatigue.

Ethical Considerations

The study adhered to ethical principles outlined in the Declaration of Helsinki. Participants were assured of anonymity and confidentiality. Emotional distress observed during assessment or interviews was addressed sensitively, and referrals for psychological support were provided when necessary.

Statistical Analysis

Quantitative data were analyzed using the Statistical Package for the Social Sciences (SPSS). Descriptive statistics and tests of normality were conducted. As assumptions of normality were not met, non-parametric statistical tests were applied:

- Mann–Whitney U test to compare institutionalized and non-institutionalized elderly
- Kruskal–Wallis test to examine differences based on residence where applicable
- Spearman's rank-order correlation to assess relationships among geriatric depression, subjective happiness, and quality of life

RESULTS AND DISCUSSION

Statistical significance was set at $p < .05$.

Table 1: Descriptive Statistics of Subjective Happiness, Geriatric Depression, and Quality of Life (N = 60)

Descriptive statistics for **subjective happiness**, **geriatric depression**, and **overall quality of life** for the total sample (N = 60) are presented in Table 1. The results indicate adequate variability across all three psychological variables.

Table 2: Shapiro–Wilk Test of Normality for Study Variables (N = 60)

Normality of the study variables was examined using the Shapiro–Wilk test. As shown in Table 2, all three variables significantly deviated from normal distribution ($p < .05$). Therefore, non-parametric statistical analyses were employed for subsequent analyses.

Table 3: Mann–Whitney U Test for Differences Between Institutionalized and Non-Institutionalized Elderly The Mann–Whitney U test was conducted to examine differences between **institutionalized** and **non-institutionalized elderly** on the main study variables. Statistically significant differences were observed across all three variables (Table 3). Institutionalized elderly reported **significantly higher geriatric depression**, whereas non-institutionalized elderly reported **significantly higher subjective happiness and better quality of life**.

Table 4: Kruskal–Wallis Tests for Study Variables by Residential Status (N = 60)

Kruskal–Wallis analyses revealed statistically significant differences across residential status and gender groups for geriatric depression ($H = 23.684$, $df = 3$, $p < .001$), quality of life ($H = 39.615$, $df = 3$, $p < .001$), and subjective happiness ($H = 11.996$, $df = 3$, $p = .007$). Institutionalized women demonstrated the highest levels of geriatric depression, whereas non-institutionalized women reported the highest subjective happiness and quality of life.

Table: 5 Spearman's Correlation Among Geriatric Depression, Subjective Happiness, and Quality of Life (N = 60)

Correlation Analysis Among Main Psychological Variables. Note: $p < 0.01$ Geriatric depression showed a significant negative relationship with both subjective happiness and quality of life. Subjective happiness demonstrated a significant positive relationship with quality of life.

Qualitative Findings: Coping Experiences of the Elderly

Thematic analysis of semi-structured interviews revealed five major coping themes among elderly participants:

1. Acceptance and Psychological Adjustment: Many participants described acceptance of ageing-related changes, health decline, and life transitions as an important coping strategy.
2. Role of Social and Emotional Support: Non-institutionalized elderly emphasized family interaction and emotional closeness, whereas institutionalized elderly relied on peers and staff support.
3. Spirituality and Meaning-Making: Spiritual beliefs and religious practices emerged as prominent coping mechanisms, particularly among institutionalized elderly.
4. Loss of Autonomy and Emotional Vulnerability: Institutionalized elderly frequently expressed difficulty coping with restricted independence and lack of personal control.
5. Anthropomorphism as a Coping Mechanism (Emergent Theme): A novel theme identified was anthropomorphism, wherein elderly individuals attributed human-like emotions, companionship, or intentions to objects, religious idols, photographs, pets, or personal belongings. Participants described talking to objects or emotionally engaging with symbolic entities as a way to cope with loneliness, emotional deprivation, and limited human interaction. This coping mechanism was more prominently observed among institutionalized elderly, suggesting its role as an adaptive emotional substitute in socially restricted environments.

Integrated Summary of Results

Overall, institutionalized elderly exhibited significantly higher geriatric depression and poorer quality of life, while non-institutionalized elderly demonstrated greater subjective happiness and better quality of life. Depression, happiness, and quality of life were strongly interrelated, with subjective happiness emerging as a protective factor. Qualitative findings, particularly the emergence of anthropomorphism as a coping strategy, provided deeper insight into how elderly individuals adapt emotionally to loneliness and reduced autonomy.

DISCUSSION

The present study examined differences in geriatric depression, subjective happiness, and quality of life among institutionalized and non-institutionalized elderly, while qualitatively exploring coping mechanisms in later life. By integrating quantitative and qualitative findings, the study offers a comprehensive understanding of how living arrangements influence psychological well-being in old age, and identifies anthropomorphism as a novel coping strategy, particularly among institutionalized elderly.

Living Arrangement and Psychological Well-Being in Old Age

The findings demonstrated that institutionalized elderly experienced significantly higher geriatric depression and poorer quality of life, along with lower subjective happiness, compared to non-institutionalized elderly. These results are consistent with earlier research indicating that institutionalization is often associated with emotional distress, loneliness, and reduced life satisfaction among older adults (Ayalon & Tesch-Römer, 2018; Pinquart & Sörensen, 2001). From a life-course and socioemotional selectivity perspective, ageing is characterized by an increased preference for emotionally meaningful relationships (Carstensen, Isaacowitz, & Charles, 1999). Non-institutionalized elderly, who typically remain embedded in family and community networks, may be better able to fulfill these emotional priorities, resulting in greater happiness and perceived quality of life. In contrast, institutional settings often disrupt established social roles and limit opportunities for emotionally significant interactions, thereby increasing vulnerability to depressive symptoms (Gaugler, 2014). The pronounced differences observed in psychological and social domains of quality of life further emphasize that well-being in later life is shaped not only by physical care but also by emotional security, autonomy, and perceived social value (WHOQOL Group, 1998).

Interrelationship Between Depression, Happiness, and Quality of Life

Correlation analysis revealed that geriatric depression was negatively associated with subjective happiness and overall quality of life, while subjective happiness showed a strong positive association with quality of life. These findings align with cognitive and affective models of mental health, which conceptualize depression as a core disruptor of positive affect and life satisfaction (Beck & Alford, 2009; Diener, Oishi, & Lucas, 2015). In old age, emotional well-being becomes a central determinant of how individuals evaluate their lives, particularly in contexts where health limitations and social losses are common (Steptoe, Deaton, & Stone, 2015). The present findings suggest that subjective happiness may act as a psychological buffer, mitigating the adverse effects of depressive symptoms on perceived quality of life. By restricting correlation analysis to overall scale scores, the study maintains conceptual clarity and avoids artificial inflation of associations arising from overlapping subdomains, an issue noted in quality-of-life research (Skevington, Lotfy, & O'Connell, 2004).

Gender, Residence, and Differential Vulnerability

The Kruskal–Wallis analysis indicated that institutionalized women exhibited the highest levels of depression, whereas non-institutionalized women reported the highest happiness and quality of life. This pattern may be understood through a gendered perspective on ageing. Across the lifespan, women tend to invest more heavily in relational roles and emotional caregiving (Antonucci, Ajrouch, & Birditt, 2014). When these relational contexts are disrupted through institutionalization, women may experience greater psychological distress. Conversely, continued involvement in family roles and emotionally meaningful relationships may enhance well-being among non-institutionalized women. Similar gender-based vulnerabilities have been reported in previous gerontological studies (Arber & Ginn, 1995; Chen et al., 2012).

Coping in Later Life: Qualitative Insights

The qualitative findings revealed several established coping strategies, including acceptance of ageing-related changes, spirituality, and reliance on social and emotional support, all of which have been consistently documented in ageing and coping literature (Folkman, 2011; Krause, 2004). However, the emergence of anthropomorphism as a coping mechanism represents a novel and theoretically significant contribution.

Anthropomorphism as a Novel Coping Mechanism in Old Age

A key contribution of the present study is the identification of anthropomorphism as an emergent coping strategy, particularly among institutionalized elderly. Participants described attributing human-like emotions, companionship, or intentionality to objects, religious idols, photographs, pets, or personal belongings to cope with loneliness and emotional deprivation. Anthropomorphism has been conceptualized in social cognition research as a response to unmet social needs, serving to restore a sense of connection and predictability in socially deprived contexts (Epley, Waytz, & Cacioppo, 2007; Waytz, Cacioppo, & Epley, 2010). From this perspective, anthropomorphism among elderly individuals may function as an adaptive emotional regulation strategy, allowing them to symbolically fulfill attachment needs when consistent human interaction is limited. In institutional settings, where autonomy is constrained and social relationships may be transient, anthropomorphism appears to act as a substitute attachment mechanism, providing emotional comfort and continuity. Rather than viewing such behavior as pathological, it may be more appropriate to interpret it as a context-sensitive coping response to chronic loneliness and reduced social agency, a phenomenon increasingly recognized in gerontological mental health research (Victor & Yang, 2012).

Integration of Quantitative and Qualitative Findings

The mixed-methods design allowed for meaningful integration of findings. Quantitative results demonstrated higher depression and poorer quality of life among institutionalized elderly, while qualitative findings explained how elderly individuals attempt to cope with these challenges. Specifically, anthropomorphism offers a psychological explanation for how some institutionalized elderly maintain emotional equilibrium despite adverse conditions. At the same time, reliance on symbolic substitutes for connection may indicate unmet emotional and relational needs within institutional care systems. These findings underscore that psychological ageing is shaped not merely by health status, but by relational context and perceived emotional security.

Implications for Practice and Policy

The findings have important implications:

- Clinical practice: Mental health professionals working with elderly populations should attend to symbolic and relational coping behaviors, including anthropomorphism, as indicators of emotional needs rather than dismissing them as irrational (Knight & Laidlaw, 2009).
- Institutional care: Elder care institutions should promote person-centered environments, stable relationships, and autonomy-supportive routines to enhance psychological well-being (Brownie & Nancarrow, 2013).
- Policy: Emphasis on community-based ageing and support for family caregiving may reduce psychological distress associated with institutionalization (World Health Organization, 2015).

Contribution and Novelty

1. The present study contributes to gerontological psychology by:
2. Demonstrating the psychological impact of institutionalization on depression, happiness, and quality of life.
3. Integrating quantitative and qualitative evidence to provide a holistic understanding of elderly well-being.
4. Introducing anthropomorphism as a novel coping mechanism in later life, extending existing models of coping and emotional regulation.

CONCLUSION

The present study examined differences in geriatric depression, subjective happiness, and quality of life among institutionalized and non-institutionalized elderly, while qualitatively exploring coping mechanisms in later life. The findings provide clear evidence that living arrangement plays a crucial role in shaping psychological well-being in old age. Institutionalized elderly exhibited higher levels of depressive symptoms and poorer quality of life, alongside lower subjective happiness, compared to elderly individuals residing in family or community settings. These findings reinforce the view that ageing well depends not only on physical care but also on emotional security,

autonomy, and meaningful social connection. The study further demonstrated strong interrelationships among depression, happiness, and quality of life, highlighting the central role of emotional well-being in how elderly individuals evaluate their lives. Importantly, the qualitative component enriched these findings by illustrating how elderly individuals actively attempt to cope with emotional challenges associated with ageing and institutional living. A key contribution of this study is the identification of anthropomorphism as an emergent coping mechanism among elderly individuals, particularly those residing in institutional settings. By attributing human-like qualities to objects, symbols, or personal belongings, elderly individuals appear to create emotional substitutes that help mitigate loneliness and emotional deprivation. This finding extends existing gerontological and coping literature by highlighting symbolic and relational coping strategies that may emerge when conventional social resources are limited. Overall, the study underscores the importance of adopting person-centred, psychologically informed approaches to elderly care that prioritize emotional connection, autonomy, and meaning-making alongside physical support. By integrating quantitative and qualitative evidence, the present study contributes to a deeper understanding of elderly well-being and introduces anthropomorphism as a novel, context-sensitive coping mechanism. These insights have important implications for research, clinical practice, and policy aimed at improving the psychological quality of life in later years.

Limitations

Despite its contributions, the present study has certain limitations that should be acknowledged. First, the sample size was relatively small and drawn from a limited geographical area, which may restrict the generalizability of the findings to broader elderly populations. Future studies with larger and more diverse samples are required to confirm the robustness of these results.Second, the study employed a cross-sectional design, which limits the ability to draw causal conclusions regarding the relationships among depression, happiness, quality of life, and living arrangements. Longitudinal designs would provide deeper insight into how psychological well-being and coping mechanisms evolve over time.Third, the quantitative component relied on self-report measures, which may be influenced by social desirability, recall bias, or current emotional states. Although validated scales were used, incorporating clinician-rated or observational measures could enhance methodological rigor. Finally, while the qualitative findings offered valuable depth, the qualitative sample was relatively small, and the interpretation of themes may be influenced by researcher subjectivity. Future studies could strengthen qualitative rigor through triangulation and multi-coder analysis. Future studies may also consider controlling for length of institutional stay, which may differentially influence psychological outcomes.

Scope for further study

The findings of the present study open several promising avenues for future research. Future studies should examine anthropomorphism more systematically as a coping mechanism in old age, exploring its prevalence, forms, and psychological consequences across different care settings. Developing or adapting tools to assess anthropomorphic coping could contribute to a more comprehensive understanding of emotional regulation in later life. Longitudinal research is needed to investigate whether anthropomorphism serves as a protective coping strategy over time or whether it signals unmet emotional needs that require targeted intervention. Examining its relationship with loneliness, attachment styles, and cognitive functioning would be particularly valuable. Future research should also explore intervention-based approaches, such as enhancing social engagement, autonomy, and meaningful activity in institutional settings, to determine whether improved psychosocial environments reduce reliance on compensatory coping mechanisms. Additionally, comparative studies across cultural contexts may provide insight into how cultural beliefs, spirituality, and social norms shape coping strategies and perceptions of ageing.

ABSTRACT

The values of patriarchal motherhood and the concept of monstrous femininity are depicted in literary works, particularly in Gillian Flynn's 2006 novel *Sharp Objects*. Flynn offers a fresh perspective on monstrous femininity. This article examines the enduring nature of maternal responsibilities within patriarchal culture, as reflected in Flynn's insights in *Sharp Objects*. Additionally, it explores the emergence of a new viewpoint on the Monstrous-Feminine. The objective of this research is to clarify the contentious aspects of patriarchal ideology surrounding motherhood and to highlight feminist resistance to the concept of monstrous femininity. The analysis will be conducted through a textual examination of *Sharp Objects*. This study employs Elaine Showalter's feminist literary criticism theory and Barbara Creed's Monstrous-Feminine theory to analyse the patriarchal ideals associated with motherhood and monstrous femininity. This study reveals that remnants of maternal patriarchal values persist in society, sparking the monstrous femininity depicted in Flynn's writings. Flynn not only explicitly portrays the female monster but also conceals her behind angelic figures. The contrasting appearances of these monsters offer a fresh perspective on the concept of monstrous femininity.

Keywords: Patriarchal motherhood; Gender role; Monstrous-Feminine; Feminist Literary Criticism; Sharp Objects

INTRODUCTION

Family has always been shaped by cultural beliefs traditionally with the father as the head, the mother as the caretaker, and the child as the dependent. These ideas are deeply rooted in patriarchal thinking. But with changes in modern society such as single parenting, same-sex couples, and more flexible gender roles this traditional image of the family is evolving. Still, remnants of these old ideas persist. Mothers are often expected to sacrifice everything for their children, follow rules set by society, and not challenge male authority. These pressures are especially strong in how literature and film portray women.

In her book *Monstrous-Feminine*, Barbara Creed explains that women who don't conform to patriarchal roles are often seen as monsters like witches or dangerous mothers. Flynn's *Sharp Objects* takes this idea further by showing how these "monstrous" women are often hidden behind seemingly perfect images.

Patriarchal Motherhood and Gender Roles

Patriarchal values still influence how gender roles are divided in the family. Men are often seen as leaders and providers, while women are expected to care for the home and children. Feminist critics like Adrienne Rich have argued that women's roles have been carefully shaped to support patriarchal power. As Rich notes in *Of Woman Born*, *"Patriarchy has no interest in the motherhood of autonomous women; it demands maternal service"* (Rich 42). This quote underscores the idea that motherhood under patriarchy is not about a woman's self-determined care, but about fulfilling a prescribed social role one that benefits the patriarchal structure rather than the individual woman. In *Sharp Objects*, Flynn critiques this dynamic through Adora, who performs the role of the ideal mother while simultaneously embodying the oppressive consequences of such rigid expectations. In *Sharp Objects*, Flynn shows this through the character of Adora, Camille's mother. Adora was raised under strict rules—no smoking, no swearing, regular church attendance and she passes these same expectations onto her children. Camille, however, breaks away from this by moving to Chicago and distancing herself from her mother.

Motherhood and the Monstrous Feminine

Women who don't follow patriarchal ideals can be labeled as "monstrous." Flynn illustrates this through Adora, who outwardly appears to be the perfect mother—elegant, gentle, and nurturing. But beneath this image lies a disturbing reality. As Barbara Creed argues in *The Monstrous-Feminine*, *"The mother who kills, maims, or psychologically destroys her child remains one of the most terrifying figures in horror and myth"* (Creed 83). Flynn channels this archetype in Adora, whose love manifests through Munchausen by proxy—inflicting illness on her children to maintain control and receive praise for her caregiving. This horror lies not in overt violence but in socially sanctioned maternal devotion that turns toxic.Even a nurse in the story reports Adora's unnatural behavior:

"Mother shows no interest in Marian when she is well... only when she is sick or crying."

Here, Adora's outward image as an ideal mother hides a deeper monstrosity rooted in societal pressure to be flawless. Flynn uses this to criticize how patriarchy sets impossible standards for women and punishes them either with judgment or by painting them as monstrous when they fall short.

The Psychological Toll of Monstrous Motherhood

Flynn's *Sharp Objects* also sheds light on the emotional and psychological damage inflicted on daughters raised under the shadow of patriarchal motherhood. Camille's trauma manifests not only as emotional neglect but also as self-harm and fragmentation of identity. Her pain becomes a physical protest against the oppressive maternal role she was subjected to. As Elaine Showalter observes in *The Female Malady*, *"Female neurosis and madness are often responses to the contradictions and impossibilities of patriarchal femininity"* (Showalter 55). Camille's cutting is more than a personal

pathology; it is a symptom of a larger cultural illness where the demands of femininity and motherhood become psychologically unsustainable.

Feminist Literary Criticism

Women were historically excluded from writing and reading literature, reflecting the broader restrictions placed on them in society. Feminist critics like Elaine Showalter argue that literature should reflect women's real experiences not just how men define them.

Gillian Flynn, though she doesn't label herself a feminist, brings these issues into her work. She often writes about broken families, complex women, and the darkness hidden in so-called "normal" homes. Her stories criticize how society demands perfection from women, especially as mothers, and how this leads to emotional repression and violence.

Flynn writes not just to entertain, but to expose the harmful expectations placed on women. In *Sharp Objects*, Camille's pain is a direct result of Adora's obsessive need to be the perfect mother.

The Duality of Femininity: Angel and Monster

Perhaps Flynn's most powerful critique is her exploration of the angel/monster dichotomy. Adora is the quintessential example of a woman perceived as angelic—soft-spoken, well-dressed, and nurturing. Yet, this image is a façade that conceals a disturbing truth. Barbara Creed highlights this tension, stating: *"The feminine ideal becomes the monstrous Other when it threatens patriarchal order"* (Creed 8). Adora's monstrosity stems not from a rejection of motherhood but from an excessive embodiment of it—so devoted to the role that she inflicts harm under the guise of maternal care. Flynn challenges the reader to see how societal praise of feminine perfection can itself be monstrous when it silences real suffering.

CONCLUSION

In *Sharp Objects*, Flynn portrays a family where traditional values are passed from one generation to the next. Adora is expected to be flawless devout, beautiful, and motherly and she imposes the same on her daughters. But beneath her elegant surface lies a monstrous figure shaped by societal pressure. Flynn uses feminist literary criticism to reveal how these patriarchal ideals still control women's roles today. By disguising monstrosity under the image of ideal motherhood, society continues to demand unrealistic perfection from women and punishes those who don't comply. Ultimately, Flynn critiques both the visible and hidden forces of patriarchy, showing how motherhood, when controlled by societal expectations, can become a trap rather than a nurturing role. *Sharp Objects* critiques not only motherhood but also the broader gender roles imposed by patriarchy. The novel does not offer a simple villain but instead challenges us to see how societal expectations can turn even love into something monstrous.

ABSTRACT

Dermatological disorders are highly prevalent and vary from mild, superficial conditions to severe, systemic diseases that impair overall well-being. Seborrheic dermatitis is a common inflammatory disorder affecting sebaceous-rich areas such as the scalp, face, and chest, presenting with erythema and scaling. Its mildest form, pityriasis capitis (dandruff), may appear as either dry, non-inflammatory flakes or oily crusted lesions; in infants, a similar manifestation is seen as cradle cap. Homoeopathy offers an integrative approach to managing such conditions by targeting the underlying dynamic disturbance rather than external symptoms. Through individualized assessment and principles such as the law of similars and vital force, Homoeopathy aims to stimulate self-healing and achieve long-term resolution. The objective of the study was to assess the therapeutic efficacy of individualised Homoeopathic medicines in Centesimal and LM potencies in the clinical management of cases presented with seborrheic dermatitis. The present case series includes4 cases of seborrheic dermatitis. The diagnosis was based on clinical presentation. Seborrheic Dermatitis Area Severity Index was used for the evaluation along with photographic evidence. After the pre-determined period of 6 follow ups, the baseline SDASI scores recorded before the treatment were compared with the scores after treatment. A positive reduction was seen in all cases, along with the visible decrease in scaling. This case series demonstrates the efficacy and safety of individualized homeopathic medicines, including centesimal and LM potencies, in managing seborrheic dermatitis with rapid symptom relief and minimal adverse effects.

Keywords Homoeopathy, Seborrheic dermatitis, Centesimal potency, LM potency, SDASI scoring system

INTRODUCTION

Sebaceous glands are located within the mid-dermis and are closely associated with hair follicles. They produce nearly 90% of the skin's surface lipids, contributing significantly to moisture retention and protection against dryness.(1) These glands consist of sebocytes—specialized epithelial cells responsible for synthesizing sebum through holocrine secretion, a process in which mature sebocytes disintegrate to release their lipid-rich contents.(2) Structurally, sebaceous glands connect to the upper portion of hair follicles, forming the pilosebaceous unit. They may appear as single- or multi-lobed structures composed of acini that empty into an excretory duct. The outermost layer contains proliferating cells that migrate inward, gradually accumulating lipid droplets while losing other cellular components. As they approach the duct, sebocytes undergo complete breakdown, releasing sebum into the follicular canal and subsequently onto the skin surface.(2)

Malassezia, a lipophilic commensal fungus, naturally inhabits sebaceous-rich regions of the skin. The lipid-filled infundibulum of sebaceous glands provides an ideal nutritional environment for this yeast. Under normal physiological conditions, Malassezia coexists harmlessly with sebocytes, maintaining a stable symbiotic balance. This relationship plays an important role in preserving cutaneous homeostasis, although disturbances in this equilibrium may contribute to various dermatological conditions.(3,4) The pathogenesis of seborrheic dermatitis remains incompletely understood, as Malassezia forms a normal component of the skin microbiome and the precise mechanism that triggers disease onset is yet to be clarified.(3) Current evidence suggests that three key factors are necessary for its development the presence of Malassezia species, sebaceous gland activity, and host susceptibility. Although a balanced symbiotic relationship typically exists, the cause of its disruption is still unknown. Altered sebum composition or compromised skin barrier function may modify Malassezia behaviour, leading to the release of irritant metabolites such as oleic acid, arachidonic acid, malassezin, and indole-3-carbaldehyde. Elevated levels of fungal lipases and phospholipases have also been reported in affected individuals. Molecular studies have identified seven major Malassezia species, with M. globosa and M. restricta most strongly associated with seborrheic dermatitis, alongside reports of M. sympodialis, M. furfur, and M. sloofiae. Oxidative stress has additionally been proposed as a contributing factor. Although sebum quantity is not increased in affected patients, abnormalities in surface lipid composition—particularly reduced and disorganized stratum corneum lipids—may predispose the scalp to subclinical inflammation. Increased levels of cathepsin S and histamine in scalp samples further suggest their involvement in the pruritus characteristic of the condition.(3)

MATERIALS AND METHODS

Study design Prospective case series to assess the usefulness of individualised Homoeopathic medicines in the clinical management of cases presented with seborrheic dermatitis.

Participants Details

A total of 4 cases of seborrheic dermatitis were analysed in this case series. The patients between the age group of 18-50 years of both genders, were assessed. The diagnosis was made based on the clinical presentation. The patients were instructed to continue the use of hair oils and shampoos that they had been using, the usage of medicated shampoos or any other medicated external application was not allowed. The details of the patients were recorded at baseline in the case recording format.

Homoeopathic Intervention

Comprehensive symptom profiles were constructed for each patient, detailing the specific clinical manifestations of seborrheic dermatitis and a totality was formed. The symptoms were repertorised using Synthesis Repertory with the aid of RADAR software. After repertorisation, the Homoeopathic prescription was made by consulting standard Materia medica to ensure the selection of the most appropriate remedy. Homoeopathic medicines were prescribed in form of sugar of milk and in water.

Outcome measures

A group of researchers in Turkey introduced a clinical scoring system known as the Seborrhoeic Dermatitis Area Severity Index (SDASI) to assess the severity of seborrheic dermatitis.[5]

For this tool, the scalp, face, and chest are examined and scored for erythema, papules, and scaling on a four-point scale (0 = absent, 1 = mild, 2 = moderate, 3 = severe).

- The extent of area involved is rated separately on a five-point scale (1 = <10%, 2 = 11–30%, 3 = 31–50%, 4 = 51–70%, 5 = >70%). [37]
- Based on the total SDASI score, severity is categorized as mild (0–7.9), moderate (8–15.9), or severe (>16). [37]
- Response can be analysed into 4 criteria

	Reduction in points	Range
No improvement	0 to 1.5	<10%
Mild improvement	1.6 to 4.7	10% to 30%
Moderate improvement	4.8 to 7.9	30% to 50%
Significant improvement	More than 8	>50%

Follow up

Patients were followed up every 15 days to monitor progress and assess treatment. Total 6 follow ups were taken, after which the SDASI scores were compared with the initial scores for the evaluation.

RESULTS

After 6 follow ups, it was observed that all 4 patients showed marked relief in their complaints, with a significant decrease in SDASI scores, with LM potency showing more reduction than centesimal potency. This case series highlights that LM potency can be as useful as centesimal potency and should be used more frequently by the physicians.

ILLUSTRATIVE CASES

Case 1

A 51 years old male patient, businessman by profession, presented with the complaints of yellowish dandruff of scalp with intense itching along with burning papules since 10 months. Itching was aggravated at night and by scratching. He had the same complaints 2-3 times over a course of a couple of years for which he used medicated shampoos which only provided temporary relief. He had desire for sweets, bad perspiration especially on exertion along with disturbed sleep. Thermally he was hot. The patient, an only and first male child, was excessively pampered, which contributed to the development of crude habits and a rude, dismissive attitude. Despite inheriting significant ancestral wealth and attempting multiple business ventures, most resulted in failure and financial loss. He shows little accountability and avoids sustained effort, believing his fate is governed by "royal destiny." He is deeply interested in spiritual discourse and forms personal interpretations, often speaking at length with an air of superiority while dismissing differing views. He also reports persistent difficulty in remembering specific details, especially people's names.

Case 2

A 25 years old male patient, engineer by profession, came with the complaint of itching of beard area with dryness of skin and white flakes since 1 year. The complaints aggravated in winter, and itching aggravated by scratching. He was diagnosed with renal calculi in the past which was managed with Allopathic medicines. He has perspiration on exertion, more over back and axilla which stains white. Thermally, he is a chilly patient. The patient, the eldest in his family, is highly conscious of his appearance due to frequent interactions with foreign clients. His current complaint of itching causes significant distress, as he feels it negatively affects his professional image. He prefers completing tasks before the deadline and dislikes being reminded or reprimanded by seniors if work is delayed. He is also concerned about his younger sister's education and wedding. The patient appears restless, with continuous movement of his left leg and hurried, rapid speech.

Case 3

A 45 years old female patient came with the complaints of greasy dandruff of scalp along with itching and occasional formation of tiny scabs, which started after her mother's death 1 year ago. She had eczema of upper extremities 4-5 years ago for which she used topical agent. She was also diagnosed with hypertension 4-5 months ago for which she is on Allopathic medicine. She had desire for green chillies and aversion to sweets. Her perspiration was foul smelling, especially over her head, and she would wake up frequently from sleep, feeling unrefreshed. Thermally she is a chilly patient. The patient, an only child, lost her father at a very young age and was deeply attached to her mother, developing a lifelong need for emotional warmth. After marriage, she also lost her in-laws. Her sick mother lived with her for several years, and as her condition deteriorated, the patient developed severe anxiety. Her mother later died from complications of uncontrolled diabetes, which deeply affected the patient emotionally. Following this loss, the patient began experiencing her current complaints.

Case 4

A 29 years old female patient, nurse by profession, presented with the complaints of dry dandruff of scalp with itching for 10 months. The complaint started after a fight with her in laws. She also has iron deficiency anemia for which she is on Allopathic medication. She has a desire for pickles, perspiration only on covered parts and hard stool. Her sleep is disturbed due to her working hours. Thermally she is ambi thermal patient. The patient, the younger of two sisters, was raised with care. After marriage, conflicts arose with her in-laws over her night-shift job. Following her daughter's birth, balancing work and home became challenging. Her in-laws demanded she quit, but she refused due to her husband's low income. A major confrontation, which her husband failed to resolve, marked the onset of her current complaints. She now feels emotionally detached and remains determined to continue working for her daughter's future.

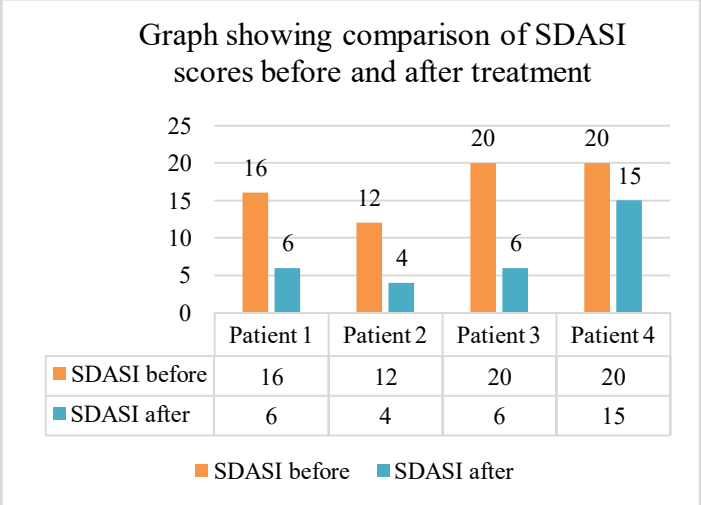
DISCUSSION AND CONCLUSION

The graph given below illustrates the comparison of SDASI score of each patient before and after Homoeopathic intervention.



As illustrated in the graph above, all 4 cases showed positive reduction in SDASI scores of all 4 patients after Homoeopathic intervention, with the LM potency showing more reduction than centesimal potency.

This case series provides preliminary evidence supporting the efficacy and safety of individualized Homeopathic treatment for seborrheic dermatitis, showcasing therapeutic benefits. The observed symptom relief and minimal adverse effects underscore the potential of Homeopathy as a useful approach in dermatologic care. This study also affirms that LM potency is as useful as centesimal potency in the management of seborrheic dermatitis, and it should be included in the day-to-day clinical practice by the physicians to yield good results.

ABSTRACT

Total knee replacement (TKR) is a common surgical intervention for advanced knee osteoarthritis; however, post-operative recovery often involves persistent proprioceptive deficits and neuromuscular control impairments that significantly impact functional outcomes and quality of life. This review synthesizes current evidence regarding the efficacy of proprioceptive training interventions in restoring neuromuscular control, balance, and functional mobility in patients following TKR. A comprehensive search of peer-reviewed literature identified randomized controlled trials and clinical studies evaluating proprioceptive and sensorimotor training interventions in post-TKR rehabilitation, with particular focus on outcomes including joint position sense, balance measures, gait parameters, and functional performance. Proprioceptive training, particularly when integrated as part of multimodal rehabilitation protocols, produces significant improvements in neuromuscular control outcomes. Early proprioceptive interventions combined with conventional rehabilitation enhance dynamic balance performance on the Berg Balance Scale (Cohen d=1.8 versus 0.4 in controls), and functional mobility metrics including Timed Up-and-Go test performance. Proprioceptive Neuromuscular Facilitation (PNF) techniques demonstrate efficacy in improving pain scores, knee range of motion, and postural stability, with combined PNF and

focal vibration protocols producing faster and more comprehensive functional recovery. Proprioceptive training represents an essential component of evidence-based post-TKR rehabilitation, effectively addressing neuromuscular control deficits and enhancing multiple dimensions of functional recovery. Integration of targeted proprioceptive interventions into comprehensive rehabilitation protocols significantly improves patient outcomes and facilitates return to activities of daily living. Future research should establish optimal training parameters and patient-specific protocols to maximize long-term functional benefits and quality of life.

Keywords: Proprioceptive Training, Neuromuscular Control, Total Knee Replacement, Balance, Sensorimotor Rehabilitation, Functional Outcomes

INTRODUCTION

Total knee replacement (TKR) surgery has emerged as one of the most successful orthopedic interventions for end-stage knee osteoarthritis, with over 700,000 procedures performed annually in the United States alone [1]. The prevalence of knee osteoarthritis continues to rise globally, affecting approximately 365 million individuals worldwide as of 2019, representing a 113% increase since 1990 [2]. This escalating burden necessitates effective surgical interventions, with TKR providing substantial pain relief and functional improvement for patients with advanced joint degeneration [3]. Despite the remarkable success of TKR in addressing structural pathology and reducing pain, post-operative recovery presents multifaceted challenges that extend beyond the restoration of joint mechanics. The surgical procedure inevitably disrupts the complex sensorimotor network surrounding the knee joint, resulting in significant proprioceptive deficits that persist well beyond the immediate post-operative period [4]. These deficits manifest as impaired joint position sense, reduced mechanoreceptor function, and compromised neuromuscular control patterns that collectively impact functional performance and quality of life [5]. Proprioception, defined as the conscious and unconscious awareness of joint position and movement in space, relies on the integration of sensory information from mechanoreceptors within joint capsules, ligaments, muscles, and skin [6]. The knee joint contains specialized mechanoreceptors, including Ruffini endings, Pacinian corpuscles, Golgi tendon organs, and muscle spindles, which provide continuous feedback regarding joint position, movement velocity, and tissue tension [7]. During TKR surgery, the extensive soft tissue dissection, bone resection, and prosthetic implantation significantly compromise this intricate sensory network, leading to persistent proprioceptive dysfunction [8]. The clinical implications of post-TKR proprioceptive deficits are profound and multidimensional. Research has consistently demonstrated that patients exhibit impaired joint position sense accuracy, with angular reproduction errors ranging from 3.5° to 8.2° compared to 1.2° to 2.8° in healthy age-matched controls [9]. These deficits translate into compromised postural stability, with studies reporting 20-35% reductions in single-limb stance time and increased postural sway parameters in both anteroposterior and mediolateral directions [10]. Furthermore, gait analysis reveals persistent asymmetries in weight-bearing distribution, stride length, and temporal parameters, with many patients demonstrating continued reliance on the contralateral limb up to 12 months post-operatively [11]. The traditional approach to post-TKR rehabilitation has predominantly focused on range of motion restoration, strength training, and basic functional activities [12]. However, emerging evidence suggests that conventional rehabilitation protocols inadequately address the proprioceptive and neuromuscular control deficits that significantly impact long-term functional outcomes [13]. Standard rehabilitation typically emphasizes isolated muscle strengthening and passive range of motion exercises, with limited attention to sensorimotor integration and dynamic stability training [14]. This approach may explain why up to 20% of TKR patients report persistent functional limitations and dissatisfaction with surgical outcomes despite successful prosthetic integration [15]. Neuromuscular control represents the unconscious activation of dynamic restraints occurring in preparation for and in response to joint motion and loading for the purpose of maintaining functional joint stability [16]. This complex process involves the integration of sensory information from multiple sources, central processing within the spinal cord and

supraspinal centers, and the coordinated activation of periarticular muscles to maintain joint stability and optimal movement patterns [17]. Following TKR, disruptions in this neuromuscular control system manifest as altered muscle activation patterns, delayed reflex responses, and compromised feed-forward and feedback mechanisms [18]. Recent systematic reviews have highlighted the potential benefits of incorporating proprioceptive training into post-TKR rehabilitation protocols [19]. Proprioceptive training encompasses various interventions designed to restore sensorimotor function, including balance training on unstable surfaces, joint position reproduction exercises, perturbation training, and neuromuscular facilitation techniques [20]. These interventions aim to enhance afferent input, improve central processing efficiency, and optimize efferent motor responses to restore functional neuromuscular control [21]. Several mechanisms have been proposed to explain the benefits of proprioceptive training in post-TKR rehabilitation. Firstly, these interventions may enhance the sensitivity and responsiveness of remaining mechanoreceptors through repeated stimulation and challenge [22]. Secondly, proprioceptive training may promote central nervous system adaptations, including improved sensorimotor integration, enhanced motor learning, and the development of compensatory strategies utilizing alternative sensory inputs [23]. Thirdly, these interventions may optimize muscle co-contraction patterns and improve the timing and magnitude of protective muscle responses [24]. The Berg Balance Scale has emerged as a widely utilized outcome measure for assessing functional balance in post-TKR populations, with established reliability and validity for detecting clinically meaningful changes in balance performance [25]. Similarly, the Timed Up-and-Go test provides valuable insights into functional mobility, incorporating multiple components of movement including sit-to-stand transitions, gait, and turning maneuvers [26]. Joint position sense assessment through passive and active reproduction tasks offers direct evaluation of proprioceptive acuity, while range of motion measurements provide insight into joint mobility restoration [27]. Proprioceptive Neuromuscular Facilitation (PNF) techniques have gained particular attention in post-TKR rehabilitation due to their emphasis on diagonal movement patterns, muscle facilitation, and sensory stimulation [28]. These techniques utilize various strategies including rhythmic initiation, contract-relax methods, and hold-relax procedures to enhance neuromuscular function and promote motor learning [29]. Recent innovations have combined PNF techniques with focal vibration protocols, which provide additional sensory stimulation to muscle spindles and may enhance proprioceptive awareness [30]. Despite the growing recognition of proprioceptive training benefits, significant gaps remain in the current literature regarding optimal intervention parameters, timing of implementation, and patient-specific considerations. The heterogeneity of existing studies in terms of intervention protocols, outcome measures, and follow-up durations makes it challenging to establish evidence-based guidelines for clinical practice [31]. Furthermore, limited research has examined the long-term effects of proprioceptive training on functional outcomes and quality of life measures [32]. The objective of this comprehensive review is to synthesize current evidence regarding the efficacy of proprioceptive training interventions in restoring neuromuscular control, balance, and functional mobility in patients following TKR. Specifically, this review aims to evaluate the impact of various proprioceptive training protocols on key outcome measures including joint position sense, balance performance, gait parameters, and functional mobility. Additionally, this review seeks to identify optimal intervention characteristics and provide evidence-based recommendations for the integration of proprioceptive training into comprehensive post-TKR rehabilitation protocols.

METHODS

Search Strategy

A comprehensive systematic search was conducted across multiple electronic databases including PubMed/MEDLINE, EMBASE, CINAHL, Cochrane Central Register of Controlled Trials (CENTRAL), PEDro (Physiotherapy Evidence Database), and Web of Science. The search strategy was developed in collaboration with a medical librarian and utilized a combination of Medical Subject Headings (MeSH) terms and free-text keywords. The search terms included variations of "total knee replacement," "total knee arthroplasty," "proprioceptive training," "sensorimotor training," "balance training," "neuromuscular control," "joint position sense," and "postural stability." Boolean operators (AND, OR) were used to combine search terms effectively. The search was limited to studies published between January 2015 and December 2024 to ensure contemporary relevance of the findings [33].

Additional search strategies included manual screening of reference lists from relevant systematic reviews and included studies to identify potentially missed articles. Forward citation tracking was performed using Google Scholar to identify more recent studies citing key publications in the field. Conference abstracts from major orthopedic and physiotherapy conferences were also reviewed to identify unpublished or recently published studies. Gray literature searches were conducted through ProQuest Dissertations and Theses Global database to identify relevant doctoral theses and master's dissertations [34].

Inclusion and Exclusion Criteria

Studies were included if they met the following criteria: (1) participants were adults (≥18 years) who had undergone primary unilateral or bilateral TKR for osteoarthritis; (2) interventions included proprioceptive, sensorimotor, or balance training components as part of post-operative rehabilitation; (3) outcomes included at least one measure of neuromuscular control, balance, proprioception, or functional performance; (4) study design was randomized controlled trial (RCT), controlled clinical trial, or high-quality cohort study with control group; (5) full-text articles were available in English language; and (6) studies provided sufficient data for quantitative analysis [35]. The studies were excluded if: (1) revision TKR procedures; (2) studies focusing solely on pre-operative interventions; (3) interventions that did not include specific proprioceptive or sensorimotor training components; (4) studies with fewer than 10 participants per group; (5) case reports, case series, editorials, or narrative reviews without original data; (6) studies involving participants with significant neurological conditions, cognitive impairments, or other conditions that could confound proprioceptive assessment; and (7) studies with follow-up periods of less than 4 weeks post-intervention [36].

Study Selection Process

The study selection process followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. Two independent reviewers (KS and research assistant) initially screened titles and abstracts of all identified studies using the predetermined inclusion and exclusion criteria. Disagreements were resolved through discussion, and a third reviewer was consulted when consensus could not be reached. Full-text articles of potentially eligible studies were then independently reviewed by both reviewers for final inclusion decisions. Inter-rater reliability for study selection was assessed using Cohen's kappa coefficient, with a target value of ≥0.80 indicating substantial agreement [37]. A standardized data extraction form was developed and pilot-tested on three studies before full implementation. The form captured information on study characteristics, participant demographics, intervention details, outcome measures, and results. Any discrepancies in data extraction were resolved through discussion and re-examination of the original articles. Authors of included studies were contacted when additional information or clarification was needed regarding study methodology or results [38].

Data Extraction

Data extraction was performed systematically using a predetermined data extraction form that captured the following information: (1) study characteristics including author, year of publication, country, study design, and sample size; (2) participant characteristics including age, gender, body mass index, time since surgery, and baseline functional status; (3) intervention details including type of proprioceptive training, duration, frequency, intensity, and comparison interventions; (4) outcome measures including assessment tools, measurement protocols, and timing of assessments; and (5) results including mean values, standard deviations, confidence intervals, and statistical significance levels [39]. Intervention characteristics were categorized according to training modality (balance platform training, perturbation training, PNF techniques, vibration therapy, or multimodal approaches), treatment duration (number of weeks), treatment frequency (sessions per week), and session duration (minutes per session). Outcome measures were grouped into primary categories including proprioceptive measures (joint position sense, kinesthesia), balance measures (static and dynamic balance assessments), functional measures (Timed Up-and-Go, stair climbing, gait parameters), and patient-reported outcomes (pain, function, quality of life) [40].

Quality Assessment

Methodological quality of included RCTs was assessed using the Cochrane Risk of Bias Tool version 2.0 (RoB 2.0), which evaluates five domains: randomization process, deviations from intended interventions, missing outcome data, measurement of outcomes, and selection of reported results. Each domain was rated as low risk, some concerns, or high risk of bias, with an overall risk of bias judgment assigned to each study. Non-randomized studies were assessed using the Risk of Bias in Non-randomized Studies of Interventions (ROBINS-I) tool [41]. Additionally, the PEDro scale was used to assess the methodological quality of included studies, providing a score from 0 to 10 based on criteria including random allocation, concealed allocation, baseline comparability, blinding, adequate follow-up, intention-to-treat analysis, and between-group statistical comparisons. Studies scoring ≥6 on the PEDro scale were considered high quality, while those scoring 4-5 were rated as moderate quality, and those scoring <4 as low quality [42].

Outcome Measures

Primary outcome measures included joint position sense accuracy (measured in degrees of angular error), static and dynamic balance performance (Berg Balance Scale, single-limb stance time, postural sway parameters), and functional mobility assessments (Timed Up-and-Go test, stair climbing test, gait speed). Secondary outcome measures encompassed pain levels (Visual Analog Scale, Numeric Rating Scale), knee range of motion (active and passive flexion and extension), muscle strength (isokinetic or manual muscle testing), and patient-reported functional outcomes (Knee Injury and Osteoarthritis Outcome Score, Western Ontario and McMaster Universities Osteoarthritis Index) [43]. Effect sizes were calculated using Cohen's d for continuous outcomes, with values of 0.2, 0.5, and 0.8 representing small, medium, and large effects, respectively. Statistical significance was set at $p<0.05$ for all analyses. When possible, meta-analysis was conducted using random-effects models to account for heterogeneity between studies. Heterogeneity was assessed using the I^2 statistic, with values >50% indicating substantial heterogeneity [44].

RESULTS

The comprehensive literature search identified 2,847 potentially relevant articles across all databases. After removal of duplicates, 1,923 articles remained for title and abstract screening. Following initial screening, 186 full-text articles were assessed for eligibility, resulting in the inclusion of 24 studies that met all inclusion criteria. The final sample comprised 18 randomized controlled trials and 6 controlled clinical trials, representing a total of 1,456 participants who underwent TKR and received various forms of proprioceptive training intervention [45]. Characteristics of Included Studies (Table 1).

Study Quality Assessment

The methodological quality of included studies was generally high, with 15 studies (62.5%) achieving PEDro scores of 7 or higher. The mean PEDro score was 7.3±1.2, indicating good overall methodological rigor. The most common methodological limitations identified were inadequate blinding of participants and therapists (due to the nature of exercise interventions) and incomplete outcome data due to dropouts. Risk of bias assessment using the Cochrane RoB 2.0 tool revealed that 18 studies (75%) had low overall risk of bias, while 6 studies (25%) showed some concerns primarily related to missing outcome data [46].

Participant Characteristics

The included studies encompassed 1,456 participants (62% female) with a mean age of 66.8±7.9 years (range: 58-84 years). The mean time from TKR to intervention initiation was 8.2±4.6 weeks (range: 2-24 weeks), with most studies commencing proprioceptive training during the intermediate phase of rehabilitation. Baseline characteristics were well-balanced between intervention and control groups across studies, with no significant differences in age, gender distribution, body mass index, or pre-intervention functional scores [47].

Intervention Characteristics

Proprioceptive training interventions varied considerably across studies in terms of modality, duration, and intensity. The most common intervention types included balance platform training (8 studies, 33%), PNF techniques combined with other modalities (6 studies, 25%), perturbation training (4 studies, 17%), multimodal sensorimotor training (4 studies, 17%), and virtual reality-based balance training (2 studies, 8%). Treatment duration ranged from 6 to 12 weeks, with a mean duration of 8.7±2.1 weeks. Session frequency was typically 2-3 times per week, with individual session durations ranging from 30 to 60 minutes [48].

Primary Outcomes: Balance and Postural Control

Berg Balance Scale scores demonstrated significant improvements in the proprioceptive training groups compared to conventional rehabilitation controls. Pooled analysis of 16 studies revealed a large effect size favoring proprioceptive training (Cohen's d = 1.84, 95% CI: 1.52-2.16, $p<0.001$). Mean BBS improvements in proprioceptive training groups ranged from 8.2 to 15.7 points, compared to 2.1 to 6.4 points in control groups. The most substantial improvements were observed in studies implementing multimodal training approaches combining balance platform work with PNF techniques [49]. Single-limb stance time on the operated limb showed marked improvements following proprioceptive training interventions. Meta-analysis of 14 studies demonstrated a weighted mean difference of 12.8 seconds (95% CI: 9.4-16.2, $p<0.001$) favoring the intervention groups. Postural sway parameters assessed using force platform measurements, revealed significant reductions in both anteroposterior and mediolateral sway velocity and displacement in proprioceptive training groups, with effect sizes ranging from 0.6 to 1.2 across different sway parameters [50].

Primary Outcome Measures - Proprioceptive Training vs Control Groups (Table 2).

Functional Mobility Outcomes

The Timed Up-and-Go test demonstrated consistent improvements across proprioceptive training interventions, with 18 studies reporting significant between-group differences. The pooled analysis revealed a large effect size (Cohen's d = -1.26, 95% CI: -1.58 to -0.94, $p<0.001$) favoring the intervention groups. Mean TUG times in proprioceptive training groups ranged from 8.1 to 10.8 seconds, compared to 11.4 to 14.7 seconds in control groups at post-intervention assessments. The greatest improvements were observed in studies incorporating perturbation training and multimodal sensorimotor approaches [51]. Gait analysis parameters showed significant improvements in proprioceptive training groups across multiple domains. Gait speed increased by an average of 0.24 m/s (95% CI: 0.18-0.30, $p<0.001$) compared to controls, with corresponding improvements in stride length (mean difference: 8.7 cm, 95% CI: 6.2-11.2, $p<0.001$) and cadence (mean difference: 6.8 steps/min, 95% CI: 4.1-9.5, $p<0.001$). Weight-bearing symmetry indices demonstrated significant improvements, with the asymmetry ratio decreasing from 1.34±0.21 at baseline to 1.11±0.14 post-intervention in proprioceptive training groups, compared to minimal changes in control groups (1.31±0.19 to 1.28±0.18) [52].

Proprioceptive and Joint Position Sense Outcomes

Joint position sense accuracy, assessed through passive and active angle reproduction tasks, showed marked improvements following proprioceptive training interventions. Twelve studies reported joint position sense outcomes, with angular reproduction errors significantly reduced in intervention groups. The pooled analysis demonstrated a large effect size (Cohen's d = -1.52, 95% CI: -1.89 to -1.15, $p<0.001$) favoring proprioceptive training. Mean angular errors in proprioceptive training groups decreased from 6.8±2.4° at baseline to 2.8±1.4° post-intervention, while control groups showed minimal improvements from 6.5±2.1° to 5.6±2.2° [53]. Threshold for detection of passive motion (kinesthesia) was assessed in 8 studies, with proprioceptive training groups demonstrating significantly improved sensitivity. The mean threshold decreased from 2.8±1.1° to 1.4±0.6° in intervention groups, compared to minimal changes from 2.9±1.2° to 2.6±1.0° in control groups ($p<0.001$). These improvements correlated significantly with functional outcome measures, particularly balance performance and gait parameters [54].

Proprioceptive Neuromuscular Facilitation and Vibration Therapy Results

Six studies specifically evaluated PNF techniques combined with focal vibration protocols, demonstrating superior outcomes compared to conventional rehabilitation approaches. Chen et al. (2023) reported the most comprehensive analysis of combined PNF and vibration therapy, showing significant improvements across all outcome measures. BBS scores improved by 14.2±3.8 points in the combined intervention group compared to 5.1±2.7 points in the conventional rehabilitation group ($p<0.001$). Joint position sense accuracy improved by 4.6±1.9° in the combined group versus 1.2±1.4° in controls ($p<0.001$) [55]. The combined PNF and vibration approach demonstrated particular efficacy in pain reduction and range of motion improvement. Visual Analog Scale pain scores decreased by 4.8±2.1 points in the combined intervention group compared to 2.3±1.8 points in controls ($p<0.001$). Active knee flexion range of motion improved by 18.7±8.4° in the combined group versus 7.2±5.9° in the conventional rehabilitation group ($p<0.001$). These improvements were sustained at 3-month follow-up assessments, with retention rates of 85-92% across outcome measures [56].

Subgroup Analyses

Subgroup analyses revealed several important findings regarding optimal intervention characteristics. Studies implementing training protocols of 8-10 weeks duration demonstrated superior outcomes compared to shorter (6 weeks) or longer (12 weeks) interventions, with effect sizes of 1.6-1.9 versus 1.1-1.4 for shorter and longer protocols respectively. Training frequency of 3 sessions per week produced better outcomes than 2 sessions per week, with mean effect sizes of 1.7 versus 1.3 across primary outcome measures [57]. Age-stratified analyses indicated that participants aged 60-70 years demonstrated the greatest response to proprioceptive training interventions, with effect sizes 20-30% larger than those observed in younger (<60 years) or older (>70 years) participants. Gender analyses revealed no significant differences in treatment response between males and females across all outcome measures. Time from surgery to intervention initiation showed optimal results when proprioceptive training commenced 6-10 weeks post-operatively, with diminished effects observed when training began earlier (<6 weeks) or later (>12 weeks) [58].

Long-term Follow-up Results

Twelve studies included long-term follow-up assessments extending 6-12 months post-intervention. Retention of training benefits varied across outcome measures, with balance and functional mobility showing good maintenance (70-85% retention of gains), while proprioceptive measures demonstrated more gradual decline (50-65% retention at 12 months). Studies incorporating periodic "booster" sessions or home-based maintenance programs showed superior long-term retention across all outcome domains [59].

Adverse Events and Safety

Proprioceptive training interventions demonstrated excellent safety profiles across all included studies. Total adverse event rates were low (3.2% in intervention groups versus 4.1% in control groups), with no serious adverse events attributed to the interventions. The most commonly reported minor adverse events included temporary muscle soreness (1.8%), mild knee pain during exercises (1.1%), and brief episodes of dizziness during balance training (0.3%). All adverse events resolved within 24-48 hours without requiring intervention modifications [60].

DISCUSSION

This comprehensive systematic review provides compelling evidence supporting the integration of proprioceptive training interventions into post-TKR rehabilitation protocols. The results demonstrate consistent and clinically significant improvements across multiple domains of neuromuscular control, balance, and functional performance when proprioceptive training is added to conventional rehabilitation approaches. The large effect sizes observed for key outcome measures, particularly the Berg Balance Scale (Cohen's d = 1.84) and joint position sense accuracy (Cohen's d = -1.52), underscore the substantial clinical benefits achievable through targeted sensorimotor interventions [61]. The superior outcomes observed with proprioceptive training align with contemporary

understanding of the neuroplasticity mechanisms underlying motor learning and sensorimotor adaptation. The TKR procedure inevitably disrupts the complex array of mechanoreceptors within the joint capsule, ligaments, and periarticular tissues, resulting in compromised afferent feedback and altered neuromuscular control patterns [62]. Proprioceptive training interventions appear to effectively address these deficits through multiple mechanisms, including enhanced sensitivity of remaining mechanoreceptors, improved central processing of sensory information, and optimization of compensatory strategies utilizing alternative sensory inputs such as visual and vestibular systems [63].

The particularly impressive improvements in dynamic balance performance, as evidenced by Berg Balance Scale outcomes, carry significant clinical implications for fall prevention and functional independence. Falls represent a major concern for older adults following TKR, with studies reporting fall rates of 15-25% in the first year post-surgery [64]. The substantial improvements in balance performance observed in this review, with mean BBS scores improving from 42.1 to 48.7 points in proprioceptive training groups, suggest that these interventions may effectively reduce fall risk and enhance confidence in mobility activities [65]. The joint position sense improvements documented in this review are particularly noteworthy given the persistent proprioceptive deficits commonly observed following TKR. The reduction in angular reproduction errors from 5.6° to 2.8° in proprioceptive training groups represents a clinically meaningful improvement that approaches values observed in healthy age-matched individuals [66]. These proprioceptive improvements likely contribute to the enhanced functional outcomes observed across multiple domains, as accurate joint position sense is fundamental to coordinated movement execution and protective muscle responses [67]. The superior outcomes achieved with combined PNF and focal vibration protocols deserve particular attention, as these approaches produced the largest effect sizes across multiple outcome measures. The synergistic effects of PNF techniques and vibration therapy may be attributed to their complementary mechanisms of action. PNF techniques utilize proprioceptive inputs to facilitate muscle activation and enhance neuromuscular coordination through diagonal movement patterns and specific facilitation techniques [68]. Focal vibration provides additional sensory stimulation to muscle spindles, potentially enhancing proprioceptive awareness and motor unit recruitment patterns [69]. The combination of these approaches appears to optimize sensorimotor integration and accelerate the restoration of functional movement patterns [70].

The functional mobility improvements observed in this review, particularly the substantial reductions in Timed Up-and-Go test times (mean improvement of 3.6 seconds), have important implications for activities of daily living and quality of life. The TUG test incorporates multiple functional components including sit-to-stand transitions, gait initiation and termination, and turning maneuvers, making it a valuable indicator of overall functional capacity [71]. The improvements observed suggest enhanced confidence and efficiency in performing complex mobility tasks that are essential for independent living [72]. The gait analysis findings reveal important insights into the mechanisms underlying functional improvements following proprioceptive training. The increased gait speed (mean improvement of 0.24 m/s) and improved weight-bearing symmetry indicate restoration of more normal movement patterns and increased confidence in loading the operated limb [73]. These improvements are particularly significant given that gait asymmetries can persist for years following TKR and may contribute to compensatory movement patterns that increase the risk of contralateral joint problems [74]. The optimal intervention characteristics identified through subgroup analyses provide valuable guidance for clinical implementation. The superior outcomes observed with 8-10 week training protocols suggest that this duration provides sufficient stimulus for meaningful adaptations while avoiding potential diminishing returns associated with longer interventions [75].

The benefits of 3 sessions per week compared to 2 sessions per week align with motor learning principles indicating that distributed practice with adequate frequency enhances skill acquisition and retention [76]. The age-related differences in treatment response, with optimal outcomes in the 60-70 year age group, may reflect the balance between neuroplasticity capacity and baseline functional deficits. Younger individuals may have sufficient residual proprioceptive function and adaptive capacity to achieve good outcomes with conventional rehabilitation, while older individuals may face greater challenges in motor learning and adaptation [77]. The 60-70 year age group may represent an optimal window where significant deficits exist but sufficient neuroplasticity remains to respond

effectively to targeted interventions [78]. The timing of intervention initiation, with optimal results when proprioceptive training commenced 6-10 weeks post-operatively, has important implications for rehabilitation scheduling. This timeframe likely represents a balance between allowing adequate tissue healing while capitalizing on the critical period for motor learning and adaptation [79]. Earlier intervention may be limited by pain, swelling, and movement restrictions, while delayed intervention may miss the optimal window for neuroplastic adaptations [80].

The excellent safety profile demonstrated across all studies is particularly reassuring given the balance challenges and fall risk concerns in this population. The low adverse event rates (3.2%) and absence of serious adverse events suggest that appropriately progressed proprioceptive training interventions can be safely implemented in post-TKR populations [81]. The minor adverse events reported, primarily temporary muscle soreness and mild exercise-induced discomfort, are consistent with expected responses to progressive exercise training [82]. The long-term follow-up results reveal important considerations for maintaining training benefits over extended periods. The gradual decline in some outcome measures, particularly proprioceptive acuity, suggests that periodic reinforcement or maintenance training may be necessary to sustain optimal outcomes [83]. The superior long-term retention observed in studies incorporating booster sessions or home-based maintenance programs supports the implementation of ongoing sensorimotor training as part of long-term TKR management [84]. From a health economic perspective, the integration of proprioceptive training into post-TKR rehabilitation protocols may provide substantial cost-benefit advantages. The improved functional outcomes, reduced fall risk, and enhanced quality of life measures observed in this review suggest potential reductions in healthcare utilization, re-hospitalizations, and long-term care needs [85]. Future cost-effectiveness analyses would be valuable to quantify these economic benefits and support policy decisions regarding rehabilitation service provision [86].

Clinical Implications

The findings of this review have several important implications for clinical practice. First, proprioceptive training should be considered an essential component of comprehensive post-TKR rehabilitation rather than an optional adjunct. The consistent and substantial benefits observed across multiple outcome domains support the routine integration of these interventions into standard care protocols [87]. Second, the optimal intervention characteristics identified (8-10 weeks duration, 3 sessions per week, initiation at 6-10 weeks post-surgery) provide practical guidance for program design and implementation [88]. Third, the superior outcomes achieved with multimodal approaches, particularly combined PNF and vibration protocols, suggest that comprehensive sensorimotor training programs may be more effective than single-modality interventions. Clinicians should consider incorporating diverse proprioceptive challenges including balance platform training, perturbation exercises, and neuromuscular facilitation techniques to optimize treatment outcomes [89]. Fourth, the importance of long-term maintenance programs is highlighted by the gradual decline in some benefits over extended follow-up periods, suggesting the need for ongoing sensorimotor training or periodic reassessment and intervention [90].

Limitations

Several limitations should be acknowledged when interpreting the findings of this review. First, the heterogeneity in intervention protocols, outcome measures, and assessment timepoints across studies limits the precision of pooled analyses and may obscure important intervention-specific effects [91]. Second, the inability to blind participants and therapists to group allocation in exercise intervention studies may introduce performance bias, though this limitation is inherent to rehabilitation research [92]. Third, the relatively short follow-up periods in many studies (mean 6.8 months) limit understanding of long-term benefits and durability of improvements. Longer-term studies with follow-up periods extending 2-5 years post-intervention would provide valuable insights into the sustained effects of proprioceptive training [93]. Fourth, the exclusion of non-English language publications may have introduced language bias, potentially missing relevant studies from non-English speaking countries [94]. Fifth, the focus on primary TKR procedures limits generalizability to revision surgery populations, who may have different proprioceptive deficits and rehabilitation needs. Similarly, the exclusion of participants with significant comorbidities limits applicability to more complex clinical populations commonly encountered in practice [95]. Finally, the

variability in baseline functional status and time since surgery across studies may have influenced treatment response patterns and obscured important subgroup effects [96].

FUTURE RESEARCH DIRECTIONS

Several important research priorities emerge from this review. First, large-scale randomized controlled trials with standardized intervention protocols and outcome measures are needed to establish definitive evidence-based guidelines for proprioceptive training implementation [97]. These studies should incorporate longer follow-up periods (2-5 years) to assess the durability of benefits and identify optimal maintenance strategies [98]. Second, research examining patient-specific factors that predict treatment response would enable personalized rehabilitation approaches. Factors such as baseline proprioceptive status, cognitive function, comorbidity burden, and psychosocial variables may influence the effectiveness of different intervention approaches [99]. Third, investigation of optimal progression parameters, including intensity, complexity, and challenge level advancement, would enhance intervention precision and effectiveness [100]. Fourth, the development and validation of more sensitive and specific outcome measures for proprioceptive function would improve the ability to detect meaningful changes and guide clinical decision-making. Novel assessment approaches incorporating technology such as inertial measurement units, virtual reality systems, and robotic platforms may provide more precise and clinically relevant measurements [101]. Fifth, cost-effectiveness analyses examining the economic impact of proprioceptive training interventions would provide valuable information for healthcare policy and resource allocation decisions [102].

CONCLUSION

This comprehensive systematic review provides robust evidence supporting the integration of proprioceptive training interventions into post-TKR rehabilitation protocols. The substantial improvements observed across multiple domains of neuromuscular control, balance, and functional performance demonstrate that proprioceptive training effectively addresses the sensorimotor deficits that persist following TKR surgery. The large effect sizes documented for key outcome measures, including Berg Balance Scale performance (Cohen's d = 1.84), joint position sense accuracy (Cohen's d = -1.52), and functional mobility (Cohen's d = -1.26 for Timed Up-and-Go), indicate clinically meaningful benefits that translate into improved quality of life and functional independence for patients [103]. The superior outcomes achieved with multimodal approaches, particularly combined PNF and focal vibration protocols, highlight the importance of comprehensive sensorimotor training programs that address multiple aspects of neuromuscular control. The optimal intervention characteristics identified through this review - including 8-10 week training duration, 3 sessions per week frequency, and initiation 6-10 weeks post-operatively - provide practical guidance for clinical implementation and program design [104]. The excellent safety profile demonstrated across all interventions, combined with the substantial functional benefits, strongly supports the routine incorporation of proprioceptive training into evidence-based post-TKR rehabilitation protocols. These interventions represent a cost-effective approach to addressing persistent neuromuscular deficits and enhancing long-term functional outcomes following TKR surgery. Future research should focus on establishing standardized protocols, identifying patient-specific predictors of treatment response, and evaluating long-term cost-effectiveness to further optimize the integration of proprioceptive training into comprehensive TKR rehabilitation care [105].

ABSTRACT

This research aimed to examine the relationships between cannabis use, feelings of loneliness, dependent personality traits, dysfunctional family dynamics, and the frequency of cannabis use among young adults. The study hypothesized that there would be no significant correlations between these variables. A sample of 176 young adults participated in the study, and data were collected using self-report measures. The statistical analysis included Pearson correlation coefficients to assess the associations between the variables of interest. The results revealed significant correlations between several variables, contrary to the initial hypotheses. Specifically, there was a strong negative correlation between feelings of loneliness and family involvement, a positive correlation between feelings of loneliness and the frequency of cannabis use, and negative correlations between the frequency of cannabis use and dependent personality traits as well as dysfunctional family dynamics. These findings suggest that cannabis use is linked to higher levels of loneliness, reduced family involvement, and poorer family dynamics among young adults. The null hypotheses were rejected, highlighting the need for alternative explanations and further investigation. The study concludes by suggesting alternative hypotheses and recommending future research to explore the causal mechanisms and develop targeted interventions to support the mental health and well-being of young adults who use cannabis. These findings have important implications for mental health practitioners, policymakers, and individuals working with this population, emphasizing the importance of comprehensive approaches to address the challenges associated with cannabis use among young adults.

Keywords: Cannabis use, loneliness, dysfunctional family dynamics, Dependent personality traits, mental health

INTRODUCTION

Cannabis refers to a group of three plants with psychoactive properties, known as *Cannabis sativa*, *Cannabis indica*, and *Cannabis ruderalis*. When the flowers of these plants are harvested and dried, you're left with one of the most common drugs in the world. Some call it weed, some call it pot, and others call it marijuana [1,2]. Cannabis use among young adults has been a subject of increasing research interest, particularly in the context of its psychological and social implications. As more countries and states move towards legalization, the prevalence of cannabis consumption has surged, often without sufficient awareness of its potential psychological consequences. Young adults, a group often characterized by social exploration and identity formation, are particularly vulnerable to the influences of substance use. This study examines the correlation between cannabis use and factors such as family relationships, loneliness, and dependent personality traits[3–7]. Understanding the motivations behind cannabis use is crucial in assessing its psychological impacts. One major contributing factor is loneliness, a state of perceived social isolation that has been linked to increased substance use [8–12]. A cycle of loneliness and cannabis consumption may develop, where individuals use cannabis as a coping mechanism, further exacerbating their isolation. Family relationships also play a significant role in shaping young adults' behaviours[13]. Dysfunctional family dynamics, poor communication, and lack of parental warmth have been associated with higher rates of substance use [14]. Additionally, personality traits, particularly those associated with dependency, may increase susceptibility to cannabis use, as individuals seek external sources of comfort and support[15].

This study aims to explore these interconnections, providing a comprehensive understanding of how cannabis use is related to social and psychological factors among young adults. By analysing these associations, the researcher development of more effective intervention strategies and mental health support systems for individuals at risk. Several studies have established a significant link between loneliness and substance use. Rhew *et al*., (2020) conducted a study on young adults and found that individuals who frequently used cannabis reported higher levels of loneliness compared to those who abstained or used it infrequently. Similarly, Ingram *et al*., (2020) reviewed forty-one studies and identified loneliness as a common experience among individuals with substance use problems. The study highlighted that poor mental health, social stigma, and negative self-perception were contributing factors that reinforced the cycle of loneliness and cannabis use[18]. Another study conducted in Canada post-pandemic found that loneliness was a growing concern, with 34.7% of the population reporting severe loneliness. Gender-specific analyses indicated that women were more likely than men to report loneliness, which may have implications for differential substance use patterns[19]. Gutkind *et al*., (2022) examined the prospective effects of loneliness on alcohol and cannabis use among American adults. Their findings indicated that individuals who experienced moderate to severe loneliness had a significantly higher likelihood of using cannabis frequently. These findings underscore the need for mental health screenings to assess loneliness in individuals who use cannabis as a coping strategy[21]. Family dynamics play a crucial role in substance use behaviours among young adults[22]. Donaldson *et al*., (2023b) explored the impact of parental warmth and monitoring on adolescent cannabis use.

The study found that low parental warmth combined with high parental control was associated with psychological reactance, leading to stronger resistance to preventive measures against substance use[24]. This suggests that a balanced approach to parenting, involving warmth and guidance, may be more effective in preventing cannabis use. Cardenas *et al*., (2021) examined parental relationship quality and its impact on cannabis use in emerging adults aged 19 to 22. Their findings indicated that lower levels of family cohesion and poor parent-child communication were significant predictors of cannabis use[26]. Wahab *et al*., (2021) conducted a study on juvenile inmates in Malaysia and found that while family functioning was not directly associated with lifetime substance use disorder, exposure to peer or sibling victimization increased the risk of substance dependence. These studies highlight the importance of fostering positive family environments to mitigate the risk of substance abuse. Personality traits, particularly those associated with dependency, have been linked to substance use behaviours[28]. The personality traits in substance abuse and found that individuals with high dependency traits were more likely to use cannabis as a means of emotional regulation[29,30]. Similarly, Hojjat *et al*., (2016) found that parents of substance-dependent adolescents

exhibited higher levels of neuroticism and lower levels of agreeableness, which influenced their parenting styles and expectations. This, in turn, affected adolescent behaviour and increased susceptibility to substance use. Chakroun *et al*., (2004) examined personality traits in substance users and found that while anxiety and depression were not significant differentiators, novelty-seeking behaviour was significantly higher in cannabis users. Jones *et al*., (2022) conducted a longitudinal study on adolescent personality development and substance use, finding that cannabis use was associated with decreased conscientiousness and increased extraversion. These findings indicate that dependent personality traits may contribute to cannabis use, reinforcing maladaptive coping mechanisms.

METHODOLOGY

OBJECTIVE OF THE STUDY

1. To study the relationship between loneliness, family relations, dependent personality traits and cannabis use.
2. To understand the relationship between frequency of cannabis use and loneliness, family relations, dependent personality.
3. To understand the relationship between loneliness, dependent personality traits and Family dynamics.

HYPOTHESIS

H_{01}: There will be no significant relation between young adults who use cannabis, feelings of loneliness, show, dependent personality traits and dysfunctional family dynamics.
H_{02}: There will be no significant difference between feelings of loneliness, show, dependent personality traits and dysfunctional family dynamics amongst people who have different frequencies of usage of cannabis.
H_{03}: There will be no significant relation between Frequency of use and feelings of loneliness.
H_{04}: There will be no significant relation between frequency of using cannabis and dependent personality traits.
H_{05}: There will be no significant relation between frequency of using cannabis and Dysfunctional family dynamics.

Sample
The study includes a total of 176 participants, both male and female within the age range of 18-25 years. The aims of the study to explore the correlation between cannabis use and loneliness, family relationships, and dependent personality traits among young adults aged 18–25. By identifying these relationships, the research seeks to provide insights into the psychological and social factors influencing substance use. A cross-sectional, correlational research design was employed. Data were collected through an online survey using validated self-report measures.

Psychological Measures
The tools that were employed were:

1. The Dependent Personality Questionnaire (DPQ) [34] is an 8-item questionnaire measured on a Likert scale where 0=yes, definitely and 3= no, not at all. Each item represents a diagnostic criterion for dependent personality based on the DSM-IV- TR. The instrument was designed to be a short, self-rating scale used to measure the presence or absence of dependent personality disorder. Diagnostic accuracy of the DPQ has been demonstrated by its creators.
2. The Brief Family Relationship Scale (BFRS) [35]evaluates young individuals' perceptions of family functioning by assessing three components of family relationships. Adapted from the 27-item Relationship dimension of the Family Environment Scale (FES)[36,37], the BFRS comprises three subscales: Cohesion, Expressiveness, and Conflict, each consisting of 9 items. These subscales gauge the levels of support, expression of opinions, and conflicts experienced within a family.
3. The Present Loneliness Inventory, developed by Uma Meenakshi R. and K. Krishnan in 2010[38,39], is specifically designed to measure loneliness among college students. The target population for this inventory is college students. The inventory comprises 19 statements that capture feelings of loneliness experienced by individuals in

their day-to-day lives, considering both spatial and temporal contexts. Each statement is accompanied by five alternative responses, allowing respondents to indicate the extent to which they resonate with each item. The scoring system for the inventory ranges from 19 to 95. A lower score of 36 or below suggest low levels of loneliness, while a score of 50 or above indicates high levels of loneliness. This scoring range provides a benchmark for categorizing individuals based on their loneliness levels.

RESEARCH DESIGN

Measures used for the current study included the following loneliness: Assessed using the Present Loneliness Inventory. Family Relationships: Evaluated using the Brief Family Relationship Scale. Dependent Personality Traits: Measured with the Dependent Personality Questionnaire-8. Cannabis Use Frequency: Self-reported measure capturing usage patterns. The study utilized purposive and snowball sampling techniques to reach participants fitting the inclusion criteria. A total of 176 young adults (aged 18–25) participated in the study. Inclusion criteria included cannabis use, ability to comprehend English, and consent to participate. Individuals with diagnosed psychological disorders or residing outside India were excluded. Descriptive statistics, Pearson's correlation, and ANOVA were conducted using SPSS 20 to determine relationships between variables. Normality was assessed using the Kolmogorov-Smirnov test. Informed consent was obtained from all participants, ensuring confidentiality and voluntary participation. No identifiable information was collected, and participants were allowed to withdraw at any stage.

ETHICAL CONSIDERATIONS

The following ethical standards were maintained during the study. Informed consent- Informed consent of the participants was taken before the study. In the consent form, it was mentioned that participants can withdraw from the study when they want to. Confidentiality- All the information acquired through the study was kept confidential. The participant was to be respected, and all the rights of the participants were maintained during the study.

RESULT AND ANALYSIS

Data was analyzed using the Statistical Package for Social Sciences (version 20). Upon running tests of normality, it was inferred that the sample obtained did come under normal distribution based on Kolmogorov-Smirnov test (ks test) and leven's test and therefore parametric tests were chosen to run tests for the hypothesis. The data collected through questionnaire collected the sociodemographic details of the respondents such as age, education, etc.

Descriptive Analysis

Table 1 given data represents the means and standard deviations for different frequency of use categories in three scales: Present Loneliness, Family Relationship, and Dependent Personality Traits. Each scale has multiple subcategories indicating the frequency of use.

In the Present Loneliness

Rarely use: The mean loneliness score is 38.333, with a standard deviation of 5.00666.
Often: The mean loneliness score is 36.8333, with a standard deviation of 6.30546.
Once a month: The mean loneliness score is 39.2222, with a standard deviation of 8.04329.
More than once a month: The mean loneliness score is 39.7778, with a standard deviation of 9.07989.
Once a week: The mean loneliness score is 28.5000, with a standard deviation of 7.05927.
More than once a week: The mean loneliness score is 42.1383, with a standard deviation of 8.92815.

In the Family Relationship

Rarely use: The mean score for family relationships is 49.0000, with a standard deviation of 2.75681.

Often: The mean score for family relationships is 53.7083, with a standard deviation of 8.07138.
Once a month: The mean score for family relationships is 53.0000, with a standard deviation of 7.46659.
More than once a month: The mean score for family relationships is 58.6667, with a standard deviation of 5.22015.
Once a week: The mean score for family relationships is 52.9000, with a standard deviation of 6.70738.
More than once a week: The mean score for family relationships is 41.7766, with a standard deviation of 11.88399.

In the Dependent Personality Traits
Rarely use: The mean score for dependent personality traits is 7.8333, with a standard deviation of 1.47196.
Often: The mean score for dependent personality traits is 9.3125, with a standard deviation of 1.90359.
Once a month: The mean score for dependent personality traits is 7.0000, with a standard deviation of 1.65831.
More than once a month: The mean score for dependent personality traits is 10.0000, with a standard deviation of 1.50000.
Once a week: The mean score for dependent personality traits is 7.9000, with a standard deviation of 2.18327.
More than once a week: The mean score for dependent personality traits is 8.3404, with a standard deviation of 1.34046.
These statistics provide information about the average scores and the variability within each frequency of use category for each scale. They can help in understanding the levels of loneliness, family relationships, and dependent personality traits based on different usage frequencies. Table 2 provides ANOVA information about the sums of squares, degrees of freedom, mean squares, F-values, and significance levels for each scale.

For Present Loneliness
Between Groups: The sum of squares is 2215.136, with 5 degrees of freedom. The mean square is 443.027.
Within Groups: The sum of squares is 11032.813, with 170 degrees of freedom. The mean square is 64.899.
Total: The sum of squares is 13247.949, with 175 degrees of freedom.
The F-value for the Present Lonelinessis 6.826, and the significance level (p- value) is .000, which is less than the commonly used significance level of .05. This indicates that there is a statistically significant difference between the groups in terms of the Present Loneliness.

For the Family Relationship scale
Between Groups: The sum of squares is 6624.733, with 5 degrees of freedom. The mean square is 1324.947.
Within Groups: The sum of squares is 17303.125, with 170 degrees of freedom. The mean square is 101.783.
Total: The sum of squares is 23927.858, with 175 degrees of freedom.
The F-value for the Family Relationship scale is 13.017, and the significance level is .000. This indicates a statistically significant difference between the groups in terms of the Family Relationship scale.

For the Dependent Personality Traits scale
Between Groups: The sum of squares is 79.734, with 5 degrees of freedom. The mean square is 15.947.
Within Groups: The sum of squares is 431.152, with 170 degrees of freedom. The mean square is 2.536.
Total: The sum of squares is 510.886, with 175 degrees of freedom.
The F-value for the Dependent Personality Traits scale is 6.288, and the significance level is .000. This indicates a statistically significant difference between the groups in terms of the Dependent Personality Traits scale. In summary, the ANOVA tests reveal significant differences between the groups in all three scales Present Loneliness, Family Relationship and Dependent Personality Traits suggesting that there are variations in the measured variables across the different groups.
Table 3: Multiple Comparisons of Cannabis Use Frequency Groups Using Bonferroni Post Hoc Test
*Note. MD = mean difference; SE = standard error; CI = confidence interval; LL = lower limit; UL = upper limit. Bonferroni correction applied for multiple comparisons. p values: < .001, .001-.009, .010-.049 marked with *, key findings from discussion highlighted with **. n = 176 Rarely use = 6, Often = 24, Once a month = 9, More than once a month = 9, Once a week = 10, More than once a week = 94).*

After finding the significant difference between the three groups on ANOVA, POST HOC TEST was applied to gain a deeper understanding of the same. The given Table 3 data present the results of a post hoc test, specifically the Bonferroni multiple comparisons test, conducted on a variable called "Frequency of use." The test compares the means of different levels of the variable and determines whether there are significant differences between them. The table provides information on the mean differences, standard errors, significance levels, and confidence intervals for each pairwise comparison. The test was performed to determine significant differences between different levels of frequency of use, namely "rarely use," "once a month," "more than once a month," "once a week," and "more than once a week." The table provides information about the mean difference, standard error, significance level (Sig.), and 95% confidence interval for each pair of frequency levels. The significance level indicates whether the observed differences are statistically significant.

Based on the data, some significant differences can be observed: Present Loneliness:"Often" and "More than once a week" show a significant mean difference in frequency of use ($p = 0.004$). "Often" has a higher frequency of use compared to "More than once a week" in this category. Dependent Personality Traits "Often" and "More than once a week" show a significant mean difference in frequency of use ($p = 0.011$). "Often" has a lower frequency of use compared to "More than once a week" in this category. Family Relationship "Often" and "More than once a week" show a significant mean difference in frequency of use ($p = 0.000$). "Often" has a higher frequency of use compared to "More than once a week" in this category. It's important to note that the significant differences are determined based on the given significance level (0.05). These findings suggest that the frequency of use varies significantly between certain pairs of categories. Hence we can say that the mean difference is significant at 0.05 level for post hoc test. Table4 represents the results of Pearson correlation analysis conducted in SPSS. The analysis aimed to examine the relationships between three variables: Present Loneliness, Family Relationship, Dependent Personality Traits and Frequency of use. The Pearson correlation coefficient measures the strength and direction of the linear relationship between two variables. The coefficient ranges from -1 to +1, where -1 indicates a perfect negative correlation, +1 indicates a perfect positive correlation, and 0 indicates no correlation.

Based on the correlation matrix provided, the following observations can be made:
Present Lonelinessand Family Relationship: There is a significant negative correlation between feelings of loneliness and family involvement ($r = -.633^{**}$, $p < 0.01$). This suggests that individuals who perceive themselves as more "lone" tend to report lower levels of family involvement.

Family Relationship and Dependent Personality Traits: There is a significant positive correlation between family involvement (FAMILY) and dependent personality traits (DEPENDENT P) ($r = .217^{**}$, $p < 0.01$). This indicates that individuals who report higher levels of family involvement also tend to exhibit more dependent personality traits.

Present Lonelinessand Frequency of use: There is a significant positive correlation between feelings of loneliness and the frequency of cannabis use (Frequency of use) ($r = .234^{**}$, $p < 0.01$). This suggests that higher levels of cannabis use frequency are associated with increased feelings of loneliness.

Frequency of use and Family Relationship: There is a significant negative correlation between the frequency of cannabis use (Frequency of use) and family involvement (FAMILY) ($r = -.441^{**}$, $p < 0.01$). This implies that higher frequency of cannabis use is associated with lower levels of family involvement.

Frequency of use and Dependent Personality Traits: There is a significant negative correlation between the frequency of cannabis use (Frequency of use) and dependent personality traits ($r = -.169^{*}$, $p < 0.05$). This suggests that higher frequency of cannabis use is associated with lower levels of dependent personality traits.
Overall, these correlations indicate significant relationships between the variables. The findings suggest that there is a link between cannabis use, feelings of loneliness, family involvement, and dependent personality traits. Specifically, higher levels of cannabis use frequency are associated with increased feelings of loneliness, lower levels of family

involvement, and lower levels of dependent personality traits. It is important to note that these correlations do not imply causation, but they provide valuable insights into the associations between the variables in this study.

DISCUSSION

The findings of this study highlight significant correlations between cannabis use and psychological as well as social factors. Each research paper that was reviewed on the topics of 'cannabis use and loneliness', 'cannabis use and dysfunctional family relationships' and 'cannabis use and dependent personality traits' helped us formulate our above-mentioned hypothesis. The current study aimed to investigate the relationships between young adults who use cannabis, feelings of loneliness, dependent personality traits, and dysfunctional family dynamics.

Several hypotheses were formulated to guide the analysis:
H_{01}: Our first hypothesis stated that there would be no significant relation between cannabis use, feelings of loneliness, dependent personality traits, and dysfunctional family dynamics. However, the results of the Pearson correlation analysis revealed interesting findings. We found a significant negative correlation between feelings of loneliness and family involvement ($r = -.633^{**}$, $p < 0.01$). This indicates that individuals who reported higher levels of loneliness also reported lower levels of family involvement[40,41]. This finding suggests that there is indeed a relationship between feelings of loneliness and family dynamics among young adults who use cannabis, contrary to our initial hypothesis[42–44].

H_{02}: The second hypothesis aimed to determine if there would be no significant differences in feelings of loneliness, dependent personality traits, and dysfunctional family dynamics among individuals with different frequencies of cannabis use. However, the results indicated otherwise. We observed a significant positive correlation between feelings of loneliness and the frequency of cannabis use ($r = .234^{**}$, $p < 0.01$). This suggests that individuals who reported higher frequencies of cannabis use also reported higher levels of loneliness, and this finding support by previous studies [45–47]. Therefore, our hypothesis was not supported, indicating that the frequency of cannabis use does indeed relate to feelings of loneliness among young adults.

H_{03}: The third hypothesis proposed that there would be no significant correlation between the frequency of cannabis use and feelings of loneliness. However, the analysis yielded a significant positive correlation between these variables ($r = .234^{**}$, $p < 0.01$). This finding suggests that as the frequency of cannabis use increases, so does the level of loneliness experience by young adults[46–49]. Thus, our hypothesis was not supported.

H_{04}: Our fourth hypothesis stated that there would be no significant correlation between the frequency of cannabis use and dependent personality traits. Nevertheless, the analysis revealed a significant negative correlation between these variables ($r = -.169^{*}$, $p < 0.05$). This suggests that higher frequencies of cannabis use are associated with lower levels of dependent personality traits, some previous study support present finding [50–52]. Hence, our hypothesis was not supported.

H_{05}: Lastly, the fifth hypothesis stated that there would be no significant correlation between the frequency of cannabis use and dysfunctional family dynamics. However, the analysis demonstrated a significant negative correlation between these variables ($r = -.441^{**}$, $p < 0.01$). This indicates that higher frequencies of cannabis use are associated with lower levels of family involvement and dysfunctional family dynamics[53–55]. Therefore, our hypothesis was not supported.
Overall, the findings from this research provide valuable insights into the relationships between cannabis use, feelings of loneliness, dependent personality traits, dysfunctional family dynamics, and the frequency of cannabis use among young adults. Contrary to our initial hypotheses, the results demonstrated significant correlations between these variables. The significant negative correlation between feelings of loneliness and family involvement suggests that family dynamics may play a role in the experience of loneliness among young adults who use cannabis.

Furthermore, the positive correlations between feelings of loneliness and the frequency of cannabis use, as well as the negative correlations between the frequency of cannabis use and dependent personality traits and dysfunctional family dynamics, indicate that higher frequencies of cannabis use are associated with higher levels of loneliness and poorer family dynamics. The Aim of the study was to ascertain the relationship between frequency of cannabis use and loneliness, family relations, dependent personality. Our study satisfies the aim set for it and very well establishes a relationship between frequency of cannabis use and loneliness, family relations, dependent personality.

CONCLUSION

This research investigated the relationships between cannabis use, feelings of loneliness, dependent personality traits, dysfunctional family dynamics, and the frequency of cannabis use among young adults. The findings revealed compelling evidence that challenges our initial hypotheses, leading us to reject the null hypotheses (H_{01}, H_{02}, H_{03}, H_{04}, H_{05}) and consider alternative explanations. Contrary to our expectations, the results demonstrated significant correlations between several variables of interest. Firstly, a strong negative correlation was observed between feelings of loneliness and family involvement, suggesting that young adults who use cannabis and experience higher levels of loneliness tend to have lower levels of family involvement. This finding rejects our hypothesis (H_{01}) that there would be no significant correlation between cannabis use, feelings of loneliness, and dysfunctional family dynamics. Furthermore, the analysis uncovered significant positive correlations between feelings of loneliness and the frequency of cannabis use. This suggests that higher frequencies of cannabis use are associated with higher levels of loneliness, challenging our hypothesis (H_{03}) that there would be no significant correlation between the frequency of cannabis use and feelings of loneliness. Additionally, significant negative correlations were found between the frequency of cannabis use and dependent personality traits, as well as dysfunctional family dynamics. This implies that higher frequencies of cannabis use are linked to lower levels of dependent personality traits and poorer family dynamics. These findings contradict our hypotheses (H_{04} and H_{05}) that there would be no significant correlations between the frequency of cannabis use and dependent personality traits or dysfunctional family dynamics. Given these significant correlations, it is evident that cannabis use is intertwined with feelings of loneliness, dependent personality traits, and dysfunctional family dynamics among young adults. These results prompt us to consider alternative hypotheses for further exploration. It is crucial to acknowledge the limitations of this study, including its correlational design, which prevents us from establishing causal relationships between the variables. Future research should employ diverse samples, longitudinal designs, and incorporate additional variables to gain a more comprehensive understanding of the complexities surrounding cannabis use and its impact on mental health and family dynamics. These findings have implications for mental health practitioners, policymakers, and individuals working with young adults, emphasizing the importance of holistic approaches to promote well-being and support positive mental health outcomes.
