within this time frame, or whether baseline microbiome or other characteristics alter the response to this type of intervention [17]. Prebiotics are the substances that trigger the proliferation of the desirable microorganisms in the gut. When obtained in the form of raw oats and honey, they benefit human health by helping to balance the intestinal microbiome. In the fermentation process by intestinal bacteria, they generate SCFA, including propionate, butyrate, and acetate, which enhance intestinal membrane health, mineral absorption, reduce glycaemic levels and body mass, and boost immunity and regulate metabolic and cardiovascular biomarkers.[18].

Recent researches have suggested that preclinical tests are being conducted on both garlic and its compounds, but little is known about how it affects human beings. It is important to note that the daily intake of black garlic has been reported to reduce the total and LDL cholesterol by a significant margin in patients with hypercholesterolemia. Moreover, studies are being conducted to assess the therapeutic value of a standard preparation of onion extract and garlic powder as a treatment of hypercholesterolemia [19]. In randomized, double-blind, and crossover trials, the healthy females were given two weeks of onion peel extract, then a 1-week washout period, and another two weeks of the other treatment. Two weeks of onion peel extract supplementation resulted in a significant reduction in the level of cholesterol, low-density lipoprotein cholesterol level, and the erythrocyte antioxidant enzyme activity showed no changes [20]. Fructans are natural storage polysaccharides in plants, which are important in the food, nutraceutical and pharmaceutical industries. They are made up of fructose molecules connected to a moiety of sucrose glucose, which is usually obtained using inulin and oligofructose oligomers of chicory and Jerusalem artichoke. Research by Weerasingha et al. showed that using asparagus officinalis fructans did not affect the quality of the nutritional content and improved the sensory and physiochemical properties of the yogurt in comparison to plain yogurt[21]. In addition to the intriguing nutritional and health characteristics, fructans are also utilized in food formulations due to their techno-functional characteristics, such as low-calorie foods substituting sugar. Their gelling property allows them to be a substitute for fat when making foods. In fact, the product that has been made using fructans rather than fat possesses the same mouthfeel, as it is creamy and homogenous.

They are also counted as dietary fiber and have a low value of calories 1-1.5 kcal/g.[22]. Oats [*Avena sativa L.]* is regarded as a functional food because of their fiber, lipid and phenolic compounds, including β-glucan, which has been shown to have prebiotic properties. The studies draw emphasis on the links between β-glucan and hypoglycemic and cholesterol-lowering, β-glucan being fermented by human gut microbiota, and resulting in changes in microbial composition and the generation of short-chain fatty acids, including acetate, propionate, and butyrate. [23]. The Institute of Medicine recommends a minimum of 14g total fiber /1000 kcal. The recommended intake in adult women and men is 25g per day and 38g per day, respectively [24]. The recommended volume of intake fiber is determined by considering the intake of populations in which the lowest risk of developing coronary heart disease is realized. Oats consumption can be used to meet the recommended fibre consumption. Oats do possess certain amount of nutrition in terms of carbohydrates, soluble fiber, proteins, lipids, vitamins, and mineral as well as phenolic compounds. The liquid fiber in oats could have an effect on the gut microbiota. Oats also have a lot of protein content compared to other cereals. According to some recent studies, oats are capable of modifying the structure of microbiota of the gut, as well as stimulating the generation of SCFA.[25].**Table 1** summerises various natural sources of prebiotics.

Comparison of prebiotic content in raw vs. cooked foods

Prebiotics are found in large quantities in fermented food, and they have been part of the human diet since time immemorial. The glutinous/ bora rice is simply consumed as a beverage, which is derived as a result of filtration[26]. Beer consumption plays the role of rituals/ceremonies through practices. This specific drink has been made using various herbs. Quinoa grain contains nutritional factors such as proteins, lipids and fiber in great content. The chemical composition and bioavailability of nutrients in quinoa change after processing and cooking. Extracts have been investigated, but very little is known about the impact that quinoa food products might exert on human gut microbiota. In such a way, the capacity of one of the chosen lines of quinoa to regulate the faecal microbiota of 10 healthy donors was tested in the form of raw, boiled, extruded, and baked[cookie]. After in vitro digestion, samples were fecally fermented and measured at different intervals [0, 6, 12, 24 and 48 h]. The total polyphenol content in

boiled and extruded quinoa was considerably greater than the content in raw quinoa. Most commonly, quinoa is cooked in one form or another, and it is then eaten. The most popular method of quinoa processing is boiling, though milling is increasingly getting used in a variety of baked or extruded food products, especially those which are gluten- free. All the various ways of processing quinoa change the texture as well as the nutritional value depending on the heat, pressure, and time used. Banking can cause the loss of vitamins and other nutrients, and extrusion can avoid this loss, but in this case, only by wasting less time. Food processing is crucial in order to modify the texture profile, nutrient availability, digestion and in shaping the gut microbiota [27]. Quinoa has both carbohydrates and amino acids in high concentration, and processing methods can thus result in the production of both melanoidins and resistant starches. Polyphenols can react with dietary fibre, and melanoidins and in the resultant reaction can regulate the bioavailability of the food bioactives, particularly to the gut microbiota. It can therefore be anticipated that quinoa cooked or prepared in various ways will lead to different effects on the gut microbiota because of such interactions between those compounds that are usually less digestible. There was an increase in the TPC [Total Polyphenol Content] of boiled and extruded quinoa samples, and no change was observed in baked quinoa samples. Interestingly, the Total Polyphenol Content concentration was affected by the digestion that took place in vitro, with boiled and extruded samples showing higher retention and lower retention than the digested raw sample in the case of the baked sample [28].

Inadequate consumption of fruits, vegetables and other foods rich in prebiotics and excessive consumption of refined grains and alcohol are linked with a shift in gut intestinal flora content and activity, i.e., dysbiosis, which in turn induces systemic inflammation in a chronic form. Cardoon is an Asteraceae Mediterranean plant, which is grown predominantly in Spain, Italy, Greece, France and southern Portugal. Cardoon stalks are either eaten raw in salads or boiled. Although it is less familiar, the edible stalks, which are the red cardoon type, are a more promising source of polyphenols than the white ones. Moreover, the heat treatments that were done on the cardoon stalks, including frying and griddling, had a positive stalks effect on the polyphenols bioaccessibility such that the polyphenol bioaccessibility of digested cooked cardoons were higher than it was of the raw cardoons after GI digestion. Although the total content of polyphenols [13.15 and 13.14 mg/g dm] of raw and sous-vide-cooked red cardoon was similar, they differed in the content of individual polyphenol profiles [29]. Also, the Yams [*Dioscorea oppositifolia L.*] is a very important ingredient in the diets of most nations in Asia and Africa. The intake of the Chinese yam has been linked to the diminished risk of chronic disease like cardiovascular diseases, diabetes, inflammation, high blood pressure. It is believed that yam polysaccharides are the hotspot in yam nutrition given their multiple bioactivity such as anti-hypoglycemic, antioxidant, immune-regulatory and anti-tumor effects. The recent finding of the non-starch polysaccharides of yam established its possible microbiota modulatory properties. Recently gut microbiota has been indicated to have a role to play in pathogenesis, progression and management of various chronic illnesses like cardiovascular diseases, diabetes, cancers etc[30]. The climate change is already disturbing the semi-arid food production systems, in which livestock forms a significant part of food security and livelihoods in Southern Africa. The literature on the implications of climate change to livestock nutrition and thermal welfare was examined in a regional agroecological environment[31].

This led to the systematic synthesis of the outcome information into a tabular summary of the principles of climate-smart bioenergetics, thermoregulation, heat stress defence systems of livestock, the thermo-bioactive feed components, and possibly climate-smart feed sources in the area. The keystone alternative feedstuffs that possess climate-smart potentials are known as cereal grains, such as pearl and sorghum as energy, local beans, such as cowpea, marama bean as protein sources, browse Fabaceae species, such as *Vachellia and C. mopane*, as source that provide dry season and drought supplementation with protein, minerals, and antioxidants, and as directly sought-after feed. Other tree species that are not fabricaceae are *S. Birrea* or the marula tree which produces energy and electrolyte rich foods as food fed as pulp. The livelihood of the Southern Africa is varied and includes the large farms, pastoralist production systems which are supported by livestock production and sustain the livelihood of millions of people. The agricultural practice of livestock production in the South African region plays a key role in food security[32]. The current situation is the critical crossroad of mankind in the solution of environmental and sustainable food problems. Agricultural industry produces lignocellulosic waste in 182 billion tons annually on the

global geography, and only 4.4% is being transformed into reusable material. The Lignocellulosic waste materials are lignin [10-20%], hemicellulose [15-35%], and cellulose [30-50 percent] and can be originally used as a raw material in the value addition in the concept of a circular economy e.g. food production. The second one is the spirit drink to be used after tequila that, according to its region, is prepared in an artisanal way. To produce mezcal, the agave requires 7-10 years to bloom. The leaves of the plant, popularly referred to in Mexico as pencas, are cut so that the sugar focus can be drawn out of the middle of the plant, the leaf base, can be pulled out of the ground and boiled over several days using an earthen oven constructed of wood and agave leaves. It is later broken up physically or mashed by hand and fermented over a period of 6-10 days, through the action of drinking water and agave yeasts. The process of fermentation is dependent on the weather of the area. The liquid should then be distilled later using wooden alembics. In some cases, it requires a twofold process/distillation in order to increase its alcoholic content. The pace, through which the consumption of mezcal has become global, has exceptionally quickened over the last few years. By the year 2020, 66 percent of cumulative percentage value relating to mezcal exportation was to be directed to other countries. The US is leading in this respect as the largest importer of meskal. The 73 percent of cumulative meskal importation occurs only in the United States itself [33]. In Table 2 various prebiotic compounds and their mechanisms are given.

Prebiotic Supplements

It has been scientifically proven that the prebiotic substances found in food and dietary supplements have the potential to bring about a state of health in a human. More than thirty years have elapsed since the framework of the concept of prebiotics was established [27]. It is proven that the area of prebiotic-induced microbiota disturbances is very complex and that it has a direct connection to the health benefit link [28]. Its efficacy has been proved for a very long time now to determine the beneficial aspect of the supplementation of probiotics together with prebiotics in diet towards the beneficial role in intestinal and intrinsic physiology of a person. But it may get hampered due to lack of vigor throughout the whole process of intake in the body, thus resulting in a meager delivery of probiotics' active compounds by the intestines. Very recently, nanotechnology has also been introduced with passion in this field to enhance the bioavailability of active compounds to a level of being completely extra-ordinary. Variations of highly effective adaptable nanoparticles have been designed to be developed for use along with probiotics and prebiotics. These demanded nanoparticles are composed of oxides of silver, titanium/magnesium, and a few other inorganics, along with some special individualized organic compounds like carbohydrates, proteins, and lipids, among others [29]. The defecations [$p< 0.001$] and the betterment of stool texture [$p< 0.01$] had a significant increase in the groups of subjects who used prebiotic powder formulation compared with the groups who used the capsule formulation. Accordingly, the gastrointestinal symptoms in general [$p< 0.001$], the abdominal ones [$p = 0.001$], rectal ones [$p = 0.004$] and the stool ones [$p = 0.002$] were significantly reduced, and the Quality of Life was also significantly improved [$p = 0.001$]. The mean score of depression/anxiety/stress also reduced to show a decrease in symptoms of mood change in the study groups of the subjects of both categories. [30]. Studies about gut-brain interactive functions discovered that the condition of gut microbiota may affect the condition of cognition. Well-functioning gut microbiota can weaken the impact of inflammation on cognition, which are connected to neurodegenerative disease. Prebiotics, probiotics, and synbiotics are dietary supplements and functional food ingredients; these are connected to the health of the gastrointestinal system. Two-way communication between these two organs should occur to achieve balance and health owing to the significance of homeostasis. These prebiotics, probiotics, and synbiotics may interact with the process of cognition through attention, perception, and memory. There were many studies to verify the favourable impacts on the condition of cognition from the combination and administration of these dietary supplements in addition to healthy eating [31].

The healthy status of gut microbiota may enhance the best possible process of cognition, which is important within the contemporary life we are experiencing today. In our study, results demonstrated the administration of probiotics having a favourable impact on healthy older people's cognition. There are no impacts if the target subjects are healthy older people and those who conducted optimal physical activities regularly [32]. Prebiotics exhibit high variability in terms of preparation type, dosage, administration duration, and treatment timing. Due to insufficient evidence, no general conclusions can be drawn about their clinical efficacy or safety for preterm infants or conditions

like infantile colic, acute infectious diarrhea, H. pylori infection, functional constipation, inflammatory bowel disease, celiac disease, and allergies, making recommendations impossible [33]. One could say that the use of psyllium supplements could be suggested to pediatric patients with IBS, specifically for patients with referred cases for abdominal pain. There definitely should be trials involving children and adolescents. They should be randomized, prospective, controlled, with an identical form and dose of prebiotic administration for dealing with defined diseases [34]. Children who have been treated with enteral nutrition may present with intestinal symptoms. However, there is an increasing demand for formulas that not only provide nutrition but can also help the intestinal flora and function. Formulae supplemented with fiber would result in improved intestinal function, an increase in the intestinal flora of normal composition, and an enhanced immune status. Some studies involving patients on enteral support with normal intestinal function have been identified to have benefited from the incorporation of fibers with respect to decreased episodes of diarrhoea, lower values of fecal pH, bowel movements, and intestinal microflora, among others[35].Concerning the foregoing mentioned digestion systems, meta-analysis found a significant reduction in the risk of Diabetes by 6% [$p = 0.001$], Rectal Cancer by 9% [$p = 0.007$], Colorectal Cancer by 8% [$p = 0.02$], Ischemic & Hemorrhagic Stroke by 7% [$p = 0.002$], & CHD by 9% [$p < 0.001$] per 7g/day of fiber intake.According to the meta-analysis conducted in 2019, there is a significant relationship between the daily intake of 25-29 grams of fiber and the reduction of all-cause mortality by 15% based on the RR.International community's recommendation is not the same for kids over 2 years and depends upon the energy need or the consumption of fibers in 1000 Kcal, in grams/day or grams/Kg body weight/day. The international community's recommendation about the guidelines is supported and advocated by scientific data, such as the consumption of fiber, and the correlation between the two in adults[36].

This was further defined by Williams et al. in 1995 that for age two years & above, at least an intake equivalent to the same amount in grams of their required intake of fiber & 5g/day is a must & it should not at all cross 10g/day.Institute of Medicine [IOM], the recommended daily intake of 14g of Fiber for every 1,000 calories of dietary intake will be applicable for an adult. Moreover, despite the presence of clinical evidences regarding the utilization of certain fibers such as PHGG, FOS, or Inulin, and so forth, there is a need for more research in the forthcoming future regarding the matching of the choice of fibers as per the requirements of the patients. Further, primary researches are required to be conducted regarding the matching of the choice of various fibers along with their effects, as till date, the recommendations are only based upon the judgments of the professionals. Furthermore, it will also be able to formulate customized diets; besides, it will also avail itself of the literature regarding microbes and their relation to the constitution of diets[37] [38]. The regulatory process of the prebiotics and postbiotics, along with the market of these products, is going to transform the Indian market. The requirement of these products has been stated by the Food Safety and Standards Authority of India. This has been done in order to ensure that these products remain safe and effective. Some demands need to be met in this regard, along with the labeling of these products, health benefits, and the inclusion of some strains within the probiotics and prebiotic products. These health benefits of these products have been guaranteed by FSSAI to be science-driven. Therefore, health benefits and stability/viability of the strains within the probiotics have been included in this case. They have to be safe, and the strains have to be safe too, along with the process of its manufacturing, which will have to ensure the absence of any contaminations within them. These requirements of the stability/viability of the microorganisms within the probiotics and postbiotics will have to be included within the lifecycle of the probiotics and prebiotics. It is mandatory that these companies have to register themselves in an elaborate process to obtain permission to sell these products. This will be activated in the elaborate process of formulation, safety, and effectiveness of these products. Finally, the prebiotic and postbiotic market of Indian marketplaces will ultimately be subjected to undergo an exponential process of growth in the coming years. This will happen because of an increased awareness process of consumers about the health along with the overall benefit of these products. For instance, the Indian market of prebiotics is projected to grow in an 18.52% CAGR from 2024 to 2032[39]. The categories are based on whether they are drugs or are in the form of supplements/foods. It is surprising to note that the classification/status of these prebiotics is still vague and not even defined in already existing categories in the international marketing world. The situation from this perspective is analyzed based on R&D activities in various companies in terms of new developments in products related to probiotics involving gut-skin interface and/or gut-brain axis [40].

Functional foods and beverages

Functional foods and drinks can, therefore, briefly be defined as raw, heat-processed, or processed food and drink products that are rich in a mixture of health-benefying ingredients, due to the nature of their high content levels of bioactive compounds, functional foods and beverages play a significant role in the prevention and treatment of health disorders, as well as in improving and promoting health functions and capabilities within their biological systems[41]. The increasing concern and demand for the global requirements of functional food products, such as beverages containing nutrient factors with possible beneficial health properties, are broadening their concern and demands rapidly. The functional beverage with possible beneficial properties regarding the improvement of health, such as reducing the blood cholesterol content, less sucrose content, high fibers, ability to improve the immune system, support in digestion processes, and several other properties, has lately been focused upon by everyone. Probiotic dairy as well as non-dairy probiotic products have been focused upon largely because of their lower cost, along with several promising health benefits. At present, the possible value of probiotic fermented milk, along with probiotic yogurt for consumption, was estimated to be €46 billion, along with the present global market reported to comprise 77% in the European, North American, and Asian markets [42].

Liquids have been playing a major part in the fulfilment of the nutritional needs of human beings. The health properties of these liquids have been receiving considerable interest lately. The liquids have the ability to satisfy their consumers in terms of their demands regarding size, shape, and storage. Moreover, they also have possible beneficial properties regarding the presence of valuable nutrients as well as bioactive compounds [43]. The factors that affected fermentation beverages were also clearly identified to determine the type, starter culture, or use of cereal paste, or use of both, that is required in making a fermentation beverage. The application of fermentation beverages combining Weissella confusa 2LABPT05 and *Lactiplantibacillus plantarum* 299v to finger millet helped improve fermentation rates. The levels of concentration, however, exceeded 10^8 CFU/mL counts among both bacteria. Apart from that, it also meets all physical, physicochemical, and viscoelastic parameters that entail 25% more Threonine, Arginine, GABA, and Glutamine, 25% more protein digestibility rather than 64% protein digestibility, 16% more substantial dextran production rather than 0% substantial dextran production, and 12 mPa.s viscoelastic rather than 35 mPa.s viscoelasticity [44]. The functional prototype design form and shape of a new product, that is, fermentation beverage, is new, desirable, and has immense possibilities even among global populations that vary from kids to aged persons [45]. Cow milk has had an important place within the general human food functions of sustenance for a fairly long period of time. However, because of allergies and/or lactose intolerances, as well as environment-related factors and other considerations strongly linked to the above-stated reasons, there has also been the development of an ever-demanding need within the general population these days for the development of the substitute of the above-stated type of milk from plants. Lifestyle, which is being grown to a remarkable extent because of the ever-advancing affinity of individuals towards healthier and vegetable-based foodstuffs and because of the ever-developing manner of living that favourably supports the chosen lifestyle of being a vegetarian or vegan" food habit, because of environment-related considerations and controversies linked to the ever-consumed demand of the above-stated type of the unethical demand of the ever-consumed milk of the cow type that overall satisfies the appetitive craving of the ever-advancing customer of the modern world because of the advancement of their ever-developing lifestyle that supports the ever-new and healthy vegetarian food habits of the modern world, is one of the factors that leads to the high rate of adoption of the ever-developing plant-based type of the milk substitute. People are of the belief that this type of milk will help them remain healthier and that this type of milk will also help them attain all of their health-related ambitions [46].

With the case of the need to substitute their consumption of the above-mentioned type of milk of the cow type, to start off, there already existed within the last two decades of the modern history of humanity an important range of vegetable-based alternatives of the above-stated type of milk. But of these general milk substitutes of the vegetable type already existing within the general marketplace are soy milk and almond milk substitutes. These vegetable-based foodstuffs are the water suspensions of pulverized vegetable material that is mostly cereals, legumes, pseudo-cereals, oilseed crops and nuts dissolved to a definite boiling strength, which are then homogenized to generate particles measuring between 5 and 20 μm that are remarkably close to that of the above-stated type of milk of the

cow type. Finally, therefore is the conclusion that cereals are emerging as important contributors to the preparation of functional milk substitutes that can render numerous health benefits [47]. Owing to the limitations of the effectiveness of the chemical preservatives, the demand for preservative-free food systems by the industries and consumers has been rising relentlessly; hence, an emerging need exists to develop novel and safe antimicrobial parts of food systems for enhancing the shelf life of the food system. The microorganisms that harbor numerous thriving attributes have been quoted to be probiotics and their metabolites and are being explored increasingly as novel bioprotection parts of the food system. The microorganisms have potential promises to help enhance the shelf life of the food parts as well as offer substantial boosts to human and immune system health. During the processing part, they will help decrease the growth of unwanted microorganisms in the food system and hence help enhance food safety and quality concomitantly [48].

Furthermore, the probiotics might have the ability to survive the stringent demands of the gastrointestinal tract [bowel wall and fluid] environment of the low pH levels, bile salts, microbial enzyme action, and microbial competition, among others. These probiotics might harbor numerous biological activities in their hosts. The probiotics might be ingested as food parts or as health supplements and might be packaged using EP [edible packaging]. The EP parts might be diverse considering the bioprotections of the food parts. The parts might decrease the development of numerous unwanted parts during food bioprotections and enhance the preservative life of the food parts as well as provide protection and therapeutics to human and immune system health parts [49]. However, it needs to be made clear that the most vital difference in prebiotics and dietary fibers, like selectivity in the fermentation that is occurring in the latter, will be done by only one microorganism. This will be so because it has to be of benefit by facilitating such fermentation by one microorganism, so that it will be able to raise the growth rate of one specific bacterium that will be needed in the human colon [50].

Prebiotic bacteria are also known as lactic acid bacteria. They have become a prime focus of study due to the immense application in the health sector because of their health-promoting element in food products. Their biosafe properties and qualities constitute the major valuable element within the bacteria of prebiotic [51]. Functional food can thus be said to be the food that contains an addition of nutrient compounds, which are essential in the prevention of chronic diseases such as cancer, high blood pressure, and neurodegenerative diseases. Functional food can be categorized into three types of food: food in its natural form/conventional food, modified food, as well as synthesis food/synthetic food. The primary useful nutritional supplements in the food include: various species of microalgae or macroulga in marine ecosystems; dairy products; plant materials; in addition to dairy products, botanicals; botanicals active bio-compounds; phyto bioactive compounds; microphyto bioactive compounds present in plants expressed in food materials in the form of sterols and other plant-derived substances such as phenolics; Carotenoids in the substance; in addition to fatty acids such as Unsaturated fatty acids alias Omega fatty acids[52]. The new nanotechnology instruments/technologies used in manufacturing nutritional supplements contained in functional food include: Metallic nano particles of silver, copper, gold nano particles; Polymer nano particles of Biodegradable polymers in Chitosans Cyclodextrin, in addition to lipid nano particles based on solid-liquid lipids[53].

With regard to securing a sustainable and innovative nutraceutical sector which behaves in a way that is ethical for the realization of potential, there exists a possibility of fulfillment with regard to all the above-listed stakeholders to emphasize the objective of coming together in the sense that there will be guaranteed the influence of the general transition of the engagement of consumers to relate to their attitude about the role of the for-profit sector to the role of the key actor with regard to the general well-being of the community. Requires a segment development by all concerned individuals being involved in scientific research and the medicinal field to develop a segment that not only satisfies the need that is present within the marketplace but also multiplies the lives of all classes of people. The most efficiently proven evidence-based, transparent nutraceutical segment will also be an important part of all those factors that will be helpful to ensure a success related to a better life for all global people [54]. This will mandate a success related to all those above stages concerning the influence of the impact of activity of public health as it is concerned to markets or development activity of products as it is concerned to development activity of all that potential that is offered by nutraceuticals, as it is concerned to all those above stages that mandate problem-solving

or planning as is done within a short term, utilizing an approach and factors related to the data and intelligence by a new adopted approach that is called data and analytics[55].

Dietary integration strategies

Food literacy can also be believed to be an individual skill that could be relevant in the context of change in the food system as well as sustainable consumption. The establishment of eating habits has its roots in the major events of one's youth. This is for consideration that the youth, during the stages of growth and development, would be at the stages of understanding various skills of thinking that would enable them to be empowered in the context of copying strategies in the context of a complicated food system. Thus, there is the realization that an outline in the context of the implementation plan for food literacy has to be developed from the youth[56].A probiotic is a live microbial agent, which, when given in adequate dosage, shows a beneficial effect upon the microorganisms. The prebiotics are the foods of the probiotics. They also produce beneficial physiological effects upon the hosts. The syn-biotics are the modern versions of probiotics. They consist of different formulations of probiotics and pre-biotics. They act synergistically to produce a healthy biological environment into the gut [57].

In summary, probiotics, prebiotics, and synbiotics are some of the most reliable and non-toxic substitutes for antibiotics because probiotics and synbiotics act by managing the growth of antibiotic-resistant bacteria, while prebiotics act by impacting bacteria directly. The probiotic bacteria Lactobacillus, Bifidobacterium, and other probiotic bacteria are documented to produce different types of bacteriocins capable of attacking antibiotic-resistant bacteria; as a result, their growth can be managed. The prebiotics, which impact bacteria directly, include inulin/oligosaccharides, which act by stimulating beneficial bacteria. The synbiotics, which are a combination of probiotics and prebiotics, act by stimulating the growth of beneficial bacteria. Furthermore, these compounds possess other immunomodulatory abilities, which are of more value to human health [58]. Yogurt is one of the dairy products that are well-known around the world because of their nutritional components and the presence of probiotics. Since it is a functional foods source, it has promising factors that could remedy Health. The study was intended to find out if the green banana peel polyphenol extract could be added as an ingredient in yogurts to help enhance the efficiency and vitality of the probiotics, besides having the capacity to enhance the quality of the yogurt. Extraction technique was used to facilitate the supplementation of the Green Banana Peel Polyphenol Extract in yogurts at 0.0%, 0.5%, 1%, and 2% concentration [59]. Some of the physical, bio-chemical, and physical-chemical properties of Green Banana Peel Polyphenol Extract, besides analysis of the samples taken from the processed yogurts, were used. As what was seen in relation to the utilization, it tended to show an increase in the function capacity attributed to the increase in antioxidant capacity, therefore not harmful to physical and chemical properties. As what was seen concerning physical-chemical properties, it demonstrated an astonishing increase in all samples that were supplemented with an amazingly significantly [$p<0.05$] higher total phenolic, flavonoid contents, besides antioxidant capacity than other samples. However, supplementation with Green Banana Peel Polyphenol Extract tended to significantly show [$p < 0.05$] a higher pH, titratable acidity, viscosity, water-binding capacity, syneresis, and total soluble solids. However, colour properties tended not to be affected and decreased in lumen and brightness besides augmentation in red parts of samples. Viability counts of all samples tended to show the same amount, whereas highest and lowest loss in maximum and minimum viabilities of Probiotics tended to prove that it belonged to control and 2% Green Banana Peel Polyphenol Extract supplemented samples, respectively. These peels, which are in the form of unripened bananas, are also found to contain more starch, fiber, and bioactive compounds than ripe bananas [60].

However, as justified in the above-mentioned health benefits, green banana peels are also found to be highly beneficial in the processing of health-associated functional foods in relation to health benefits associated with the gut, blood, and weight management. Green banana peels are also found to be associated with unutilized resources, which usually get wasted during the processing and consumption stages. About 826,200 metric tons of bananas were produced in the period from 2020 to 2021 in Bangladesh. Indeed, bananas are also found to be in the most preferred fruits among all other fruits in Bangladesh. The peels of healthy bananas are also found to be disposed of before the processing and preparation of foods in Bangladesh. This might be due to a lack of awareness about the benefits

associated with banana peels by consumers [61]. Yogurts supplemented with fruit peel powders proved efficiency as matrices in terms of stability of the possible LAB viability for 28 days of storage of fresh yogurt. *S. thermophillus* and all probiotics proved maximum stability and viability of bacteria at initial values and 28 days of storage of fresh synbiotic samples. Freeze-drying indicated a decrease in the metabolic functions of LAB and the prebiotic function of Fruit Peel Powder. Yogurt materials supplemented with Mango Peel Powder and Banana Peel Powder could be a highly efficient food matrix which contains beneficial properties of pure probiotic cultures, existing nutritional values, and additional polyphenol compounds. Currently, the present study in our laboratory focuses on determining the possible benefits of the integration of the proposed yogurt and Fruit Peel Powder with a shortlist of the foregoing probiotics in terms of bio-accessibility of existing nutritional values [62]. Efficiently having a well-balanced diet and making good use of the ingredients available has slowly become a chore in the fast-moving contemporary world. This is because most people feel burdened by meal planning, taking into consideration their special dietary needs due to certain health conditions, such as diabetes, heart-related disorders, or food allergies. Besides this, food wastage has become a big concern and developed into a big problem, since most people buy food ingredients with the intention of consuming them but later discard them when they approach their expiration dates. Challenges apart, the project intends to develop a smart recipe recommendation system website that shall be used to offer users personalized recipe recommendations based on two key considerations: 1] at-home ingredient use for the users, serving the dual purpose of efficient use and minimization of wastage, and 2] users' health conditions and needs in nutritional meal recommendations which would best suit their conditions, whether it be diabetes, high blood pressure, or certain kinds of food allergies[63].

Personalized nutrition in the context of meal planning using ingredients will enable the consumer to pursue proper eating habits, avoid the complications that may arise due to food wastage, and make choices that will be less stressful while preparing the food. Eating habits are considered to be among the top causes of health hazards due to various studies conducted in different fields. An estimation made by the World Health Organization reports that 30% of the world's population suffer from health problems caused by eating habits, and further adds that 60% of children die due to active malnutrition [64]. The existence of these chronic health issues remains a challenge that has always been associated with an increase in the rates of morbidity as well as rates of mortality. The use or reduction of the number of possible cases or factors that may also be associated as a consequence of bad dietary practices remains a relevant consideration to associate with good dietary practices. The search for recipes associated with preferences, especially those associated with considerations associated with health concerns, also remain a challenge associated with wasting precious time searching for these recipes, especially those associated with an individual coming from a health concern perspective[65].On the other hand, should these prebiotics be ingested, regardless of whether they are food additives or supplements, the colon flora would try to break them down to produce the short chain fatty acids that would then be excreted through the blood circulatory system. Fructo-oligosaccharides [FOS] and Galacto-oligosaccharides [GOS] are two forms of prebiotics that have attracted significant concern over the effects that they would generate to the human health. The effectiveness of the prebiotic as a prebiotic is, however, dependent on the amounts of fibrous components that the two are made of. These fibrous components are actually found within the seeds that are obtained from date palm trees. The growing need among people to eat fruits and seeds owing to the need for food, coupled with the lack of appropriate systems to store these seeds, has resulted in the above-stated large waste that is emanating from these seeds, which are actually disposed of by the residents to the landfill or incinerator bin [66]. The behaviours of the residents are environmentally destructive because of the large amount that is actually generated mostly from these seeds that end up being disposed of to the environment to decompose and produce gas emissions that are dangerous. Due to the decreased amounts of prebiotics in the nutritional products that are currently in vogue in the contemporary diet, there arises a need for an increased production of these prebiotics for consumption. There also arises a need for searching and discovering novel sources of prebiotics in order to ensure an increased amount of their usage [67].

Various studies and researches have been conducted by various different researchers in the past, which have revealed and unveiled the usage and extraction of prebiotics from various different sources, and our own quest and search therefore would be the first one to unveil and reveal the usage potential of seed waste generated from various

different products like fruits, cereals, legumes, pulses, oily seeds, and so on, as prebiotics. The purpose and scope of our own project and research, therefore would be to unveil and reveal the usage potential of seed waste generated from various products like fruits, cereals, legumes, pulses, oily seeds [68].

Prebiotics Across life stages

The gut microbiota, which is made up of the trillions of microorganisms that live in the stomach. These are vital partners in our health rather than observers. These Microbes affect every aspect of our lives, from our neurological health to the immune system. The main use of prebiotics is not a static intervention but rather than the dynamic requirement to meet the unique health needs of each life stage [69]. They help in the process of digestion. Prebiotics are a special type of dietary fibres. Gut Microbiota influence the growth and differentiation of gut Epithelial cells [70]. The establishment of gut microbiota starts right from birth itself and represents a crucial phase that is influenced by the delivery type and childhood dieting practices, creating a foundation for the establishment of gut microbiota itself [71]. The established gut microbiota defines childhood and adolescence in periods driven by increasing richness of gut microbiota itself, influenced through antimicrobials and environmental exposure during childhood, and creates a phase within the adult life of an individual which itself establishes its own gut microbiota effectively influenced by environmental factors such as dieting practice based on genetic makeup[72].Prebiotics are special types of dietary fiber that we can't digest ourselves, but they serve as food for these good gut bacteria. By feeding them, prebiotics help our gut stay healthy at every stage of life [73]. This primitive microbial community precurs the further changes in that period of childhood and adolescence that are characterized by a progressive rise in microbial diversity, which is disrupted by antimicrobials and influenced by environmental exposures. [74]. For babies, especially those who don't drink breast milk they drink formula. Prebiotics can help develop a healthy gut environment similar to that of breastfed babies.Research has shown that adding specific prebiotics like galacto oligosaccharides [GOS] and fructo oligosaccharides [FOS] to baby formula helps increase the number of good bacteria such as Bifidobacterium. This also helps in lowering the pH [makes the gut more acidic], which prevents from the harmful bacteria which is growing [75]. In adult prebiotic help in keeping the gut of adult strong and balanced. As we grow older, our gut bacteria become most stable, but factors like stress, poor diet, and medication can disturb this balance. For adults, prebiotics help us in maintaining healthy gut function and overall well-being [76].

Whenever these prebiotics become unavailable to undergo fermentation by good bacteria in the intestine, they generate short-chain fatty acids. These short-chain fatty acids are extremely significant in that they aid in feeding the cells in the colon, It helps to repair the intestinal wall and strengthen the gut barrier.[77]. Prebiotics help by supporting good bacteria, which produce helpful substances like short-chain fatty acids. These substances reduce inflammation, protect the gut wall, and support overall health [78]. When adults consume prebiotics regularly, helpful bacteria like Bifidobacterium increase in the gut. These bacteria produce substances that protect the gut lining and reduce harmful bacteria growth. This balance is very important to prevent weakness and health problems in later life[79]. Studies from 2022 show that prebiotics can help older adults by improving gut health, reducing inflammation, and strengthening the immune system. They also relieve common problems like constipation. By doing this, prebiotics help older adults stay healthier and improve their quality of life[80-81].

Culinary Applications

In addition to their biochemical importance, prebiotics have a practical use in the border of nutrition science and culinary aspects. Prebiotics may be added to diets in the form of smoothies and breakfast bowls, with plant foods such as bananas, oats, apples, flaxseeds, onions and garlic. They are beneficial to the intestinal bacteria and may be complemented with different fruits, nuts, seeds, and yogurt in breakfast bowls[82]. Such foods as chia seeds, almonds, or dates can be softened and put in as chunks to add flavor and boost the fiber intake. These bowls are good for constipation and poor[83]. The other excellent method of adding foods that are rich in prebiotics is through soups and salads. Vegetables such as onions, leeks, garlic, cabbage, beans, lentils, and carrots are naturally high in dietary fiber and, therefore, help maintain the health of the gut on top of being comforting to eat. [84]. Whole grains such as barley or oats are added to soups to make them even more satisfying and healthier. Salads can be made better with chickpeas, kidney beans, boiled potatoes or even raw vegetables such as onions and cabbage.[85]. Whole grains

such as brown rice, millets are also eaten instead of refined grains in main meals, thus increasing the amount of fiber intake[86]. Baked goods can also be helpful to the gut because they include such substances as resistant starch and inulin. Inulin is a natural fiber present in foods like bananas, onions, garlic, and chicory root. It can be added to baked goods like bread and muffins to improve texture and add sweetness, while also serving as a prebiotic. [87]. Beverages often get overlooked, but they can also be of great importance to the health of the gut, like herbal teas, which are recommended [such as chicory or ginger, fennel or cinnamon], to facilitate digestion and act as gentle prebiotics. [88]. As an example, natural inulin is reported to be contained in chicory root tea. When taken after meals, it may assist in enhancing bowel movements and reducing bloating. Similarly, ginger tea relieves stomach pains and improves digestion. [89]. Traditional fermented probiotic drinks are butter milk, fermented rice water, and homemade lassi. Prebiotics and probiotics can be balanced by adding a little fruit pulp or other ingredients high in fiber into these beverages. These beverages are cheap, easy to prepare at home, and do not contain artificial components[90-91].

Monitoring and Personalised Nutrition

Nutrition science is slowly evolving into personalized nutrition. The customized strategy is intended to enhance the health condition by considering the nutritional requirements of an individual [92]. Following the advent of digital health aids, diet and gut monitoring have never been easy. A lot of individuals are currently utilizing mobile applications to track the food they consume, the post-meal feeling, and the digestive process. Other contemporary nutrition apps integrate microbiome testing with food tracking, as part of which users can find out how the microbes of the stomach respond to different foods. [93]. People who pay enough attention to documenting this data may know which prebiotic-rich foods will benefit them and which ones will cause discomfort. Such monitoring enables individuals to make more knowledgeable food decisions in their everyday lives as opposed to making guesses. [94]. It has also been made clear by scientific research that individuals react differently to the same prebiotic food. One individual, though, might have improved digestion and vitality, whereas other individuals might not have the same food benefiting them immensely. Such differences are due to the fact that gut bacteria differ in each individual. [95]. As a result, by monitoring the data of microbiomes, nutritionists will be able to create individual dietary plans that incorporate certain prebiotics in accordance with the gut profile, which will minimize trial and error and contribute to improving gut health. [96]. In particular, individualized strategies are particularly advantageous in individuals with a digestive issue since it is possible to control the symptoms more closely [97]. Numerous nutrition sites invite users to leave responses regarding their feelings following the consumption of specific foods. Such feedback can be used to make meal recommendations better and diet plans more realistic and enjoyable. [98-99]. The ability to individualize prebiotic consumption is provided by the modern technologies of mobile applications, microbiome testing, and AI-based nutrition systems. Personalized nutrition will provide a viable and efficient means to enhance the health and well-being of the gut and human body in general by combining both scientific data with consumer feedback. [100].

Future Trends and Sustainability

Plant-based foods that are enriched with prebiotic, greener production methods, and preventive healthcare are some of the elements of the nutrition of the future. The green extraction development, bioprocessing, and functional foods design contribute to a sustainable approach and reduce the threat of chronic diseases. These trends, in totality, are healthy and promote healthier planet and healthy population[101] New generation prebiotics such as xylo-oligosaccharides [XOS] and polyphenol-derived glycans have been shown to have a particular bifidogenic effect and may target Akkermansia. These new oligosaccharides require additional mechanistic knowledge and safety tests [102]. Meta-analyses imply significant anti-inflammatory or metabolic effects of synbiotics compared to prebiotics alone. Nevertheless, systematic head to head randomized controlled trials [RCTs] are needed to determine the best probiotic-prebiotic combination and stability needs[103].The production of resistance starch [RS] can be increased by selecting special food-processing conditions, including cooking and cooling. There is considerable evidence that translational studies are required to assess dietary RS approaches in the populations of metabolic diseases with emphasis on the involved microbial taxa and metabolites [104]. Microencapsulation, coacervation and nanotechnology are advanced delivery systems that are used to improve the stability of prebiotics and target colonic

delivery. With the safety, bioavailability, and scale-up studies, the viability of these platforms in food applications as opposed to supplements will be determined [105]. Collectively, these priorities help develop a roadmap of mechanistic discovery to sustainable solutions that are consumer-ready. The next step will require the interdisciplinary consortia, standardized procedures and trials, which will integrate real-world food matrices and acceptable culinary practices into study designs [106].

CONCLUSION

The article is significant in presenting detailed highlighted significance of the role played by prebiotics in guaranteeing gut health, immune health and overall health and well being at different levels of life. The significance of prebiotics, which predominantly consist of nondigestible food fibers, such as inulin, fructo-oligosaccharides, galacto-oligosaccharides, resistant starch, and beta-glucans, was supported by the positive selection of the gut bacteria and thereby enhanced human metabolic, immune, and gastrointestinal functions. The scientific literature used throughout the article indicates that proper intake of food fibers prevents various deadly diseases, including diabetes, cancer, heart-related illnesses and stroke. Another example that can be discussed in this paper is functional foods and personalized nutrition; this paper also mentions innovations in the field of food processing technologies, green extraction methods, and bioprocessing technologies to make the manufacturing of prebiotic ingredients more sustainable. Positive changes in regulations and awareness creation will surely see the market of prebiotics improve all around the world. This paper, thus, affirms that intake of prebiotics in our diets either in their natural forms, or fortified or as supplements is a safe, effective and sustainable methodology of prevention and promotion against diseases. Prebiotics are not food ingredients only- they are an investment to the sustainability of the human health.

Table 1. Natural Dietary Sources of Prebiotics and Their Principal Bioactive Components

Food source	Major prebiotic components	Components	Health benefits	References
Chicory root [*Cichorium intybus*]	Inulin	15–20 g/100 g fresh weight; richest natural source	Promotes *Bifidobacterium*, increases SCFA production, improves gut barrier	[26]
Jerusalem artichoke [*Helianthus tuberosus*]	Inulin, FOS	16–20% fructans [dry weight]	Lipid metabolism regulation, improved gut microbiota	[27]
Garlic [*Allium sativum*]	Inulin, FOS	9–16% of dry matter	Cholesterol lowering, immunomodulation, prebiotic effect	[28]
Onion [*Allium cepa*]	Inulin, FOS	5–8% prebiotic carbohydrates	Improved gut microbial balance, metabolic health	[28]
Green banana	Resistant starch [RS2]	Major carbohydrate fraction in unripe bananas	Glycemic control, SCFA production	[29]
Oats [*Avena sativa*]	β-glucan	3–7 g/100 g depending on variety	Cholesterol-lowering, gut microbiota modulation	[30]

Table 2. Common Prebiotic Compounds and Mechanisms of Health Benefit

Prebiotic Compound	Category	Mechanism of action	Key Reference
Inulin	Fructan oligosaccharide	Fermented by gut microbiota → increases beneficial bacteria & SCFAs	[39]
FOS [Fructo-oligosaccharides]	Linear short-chain fructans	Promotes Bifidobacterium & Lactobacillus growth	[40]
GOS [Galacto-oligosaccharides]	Galactan oligosaccharide	Promotes growth of Bifidobacteria	[41]
Resistant Starches	Starch resistant to digestion	Fermented into SCFAs in colon	[42]
Pectin-derived oligosaccharides	Fruit polysaccharide fragments	Serve as prebiotic substrates	[43]

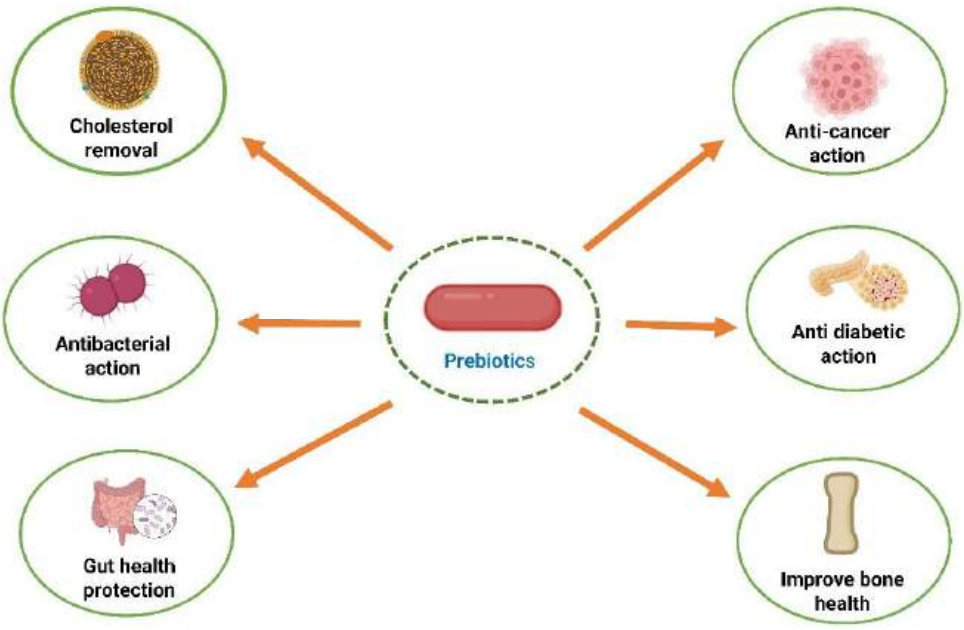

Figure 1 is a schematic summary of the systemic advantages of fucoidan driven by prebiases.

ABSTRACT

Women in business are increasingly becoming significant in economic development, creation of jobs, and household wellbeing. It is therefore important to know the variables that shape their decision making process in making investments to enhance sustainable entrepreneurial growth and financial inclusion. This paper examines the factors that affect investment decision making by women entrepreneurs based on a qualitative secondary research of the available literature. Incorporating the insights of the classical economic theory, behavioural finance and the literature on entrepreneurship, the study summarizes the results of the peer-reviewed journal articles, academic publications, and institutional reports. The discussion points out that investment behaviour of women entrepreneurs is influenced by several factors that are interdependent such as financial literacy, behavioural biases, the socio economic attributes of women entrepreneurship, institutional access to finance, digital financial inclusion, and social capital networks. The results indicate that the choice of women to make an investment is, in most cases, influenced by more than profit motive; they are also motivated to make such investment decisions guided by more complex goals. Risk perception, trust in financial decision-making, and past experiences in finance are other psychological considerations that determine the evaluation of investment opportunities. Also, institutional constraints like lack of access to credit and structural differences in the financial systems have been impacting the capacities of women to invest and grow their businesses. The paper highlights that it is crucial to enhance financial capability, institutional access to credit, digital financial inclusion, and entrepreneurial enabling ecosystems. The study incorporates both the economic and behavioural approach to entrepreneurship and thus adds value to the existing body of literature on

women entrepreneurship and offers policy implications on enhancing financial participation and investment efficiency of women entrepreneurs in the emerging economies.

Keywords: Women Entrepreneurship, Investment Decision-Making, Financial Literacy, Behavioural Finance, Financial Behaviour

INTRODUCTION

Women entrepreneurship is becoming one of the major driving forces of economic growth, job creation and social change both in the developed and the developing economies. The involvement of women in the world of entrepreneurship has increased significantly over the last few decades because of the increased access to education, policy encouragement, and an increased appreciation of financial security. With women opening up and operating businesses in various directions, their financial decision-making processes especially their investment behaviour has attracted a major position of interest in academia and policy. Investment choices are essential in making the entrepreneurial endeavors sustainable, grow as well as competitive. In the case of women entrepreneurs, economic rationality, behavioural factors, social factors, and institutional conditions have a complicated combination of factors that influence them when it comes to making such decisions. The standard assumptions in the traditional economic theory, are that the choice of investment is informed by rational analysis of risk and returns. Nevertheless, new views on financial decision-making have been brought by the behavioural economics and the research on entrepreneurship indicating that interaction of psychological factors, personal experiences, and socio-cultural situations also contribute to the process of financial decision-making. The female entrepreneurs often work in a dynamic environment that is defined by the differences in the financial knowledge, scarce access to formal credit organizations, as well as high family demands. These environmental aspects affect the processes of analysis of financial opportunities, perception of risks, and determination of investment priorities.

Moreover, the accelerating interdependence of digital financial services, micro-finance programs and entrepreneurship support systems has opened new chances to women to have access to financial resources and investment platforms. In spite of these new trends, studies have shown that the investment behavior of women does not always follow the traditional market behavioral models since they are likely to have other considerations, which are associated with welfare of the household, long-term security and social responsibility as well. These multidimensional implications must be understood in order to come up with inclusive financial policies and empower women-led businesses. It is on this background that studying the determinants of investment decision-making by women entrepreneurs is of importance to academic research and the policy-making process. Through a combination of knowledge acquired on the literature, the study aims of addressing the economic, behavioural and institutional determinants that influence how women entrepreneurs make and take investment decisions in changing financial conditions.

BEHAVIOURAL FINANCE THEORY

Behavioral finance is also an important theoretical framework that should help in understanding the role of psychological factors in financial decision-making. In contrast to traditional economic theories, which presume that individuals act rationally and that they will always endeavor to maximize their expected utility, behavioral finance acknowledges the fact that financial decision making largely depends on cognitive biases, emotions and social pressures. The discipline looks at the way in which the psychology of investors and financial practitioners influence the behaviour of markets and the results of decisions, thus providing the reason why financial markets are not always efficient. Daniel Kahneman and Amos Tversky were the pioneers of behavioral finance as they developed the Prospect Theory in 1979. Their study indicated that people do not make financial decisions with pure objective probabilities and anticipated returns. Rather, individuals are likely to apply cognitive shortcuts and perceptions to assess risks and benefits. Among the key lessons of this theory is that people tend to give more emphasis on the

recent events in coming up with financial predictions, as typically known as memory bias or recency bias. This kind of tendency can make entrepreneurs make investment decisions based on the immediate business performance as opposed to the long term analysis of the financial performance. Behavioral finance has also led to the realization that people harbor overconfidence bias, which refers to the tendency of overestimating the correctness of their knowledge and judgments. The past success of the entrepreneurs in the business could result in high confidence in the financial judgments they make, and in some cases it may result in either overestimating the expected returns or underestimating the risks that are likely to occur. In the same manner, the idea of conservatism bias implies that people tend to be very slow to change their opinions when the new information appears, and they would rather use the already formed assumptions. The tendency can influence the way in which entrepreneurs perceive new possibilities of investing or react to the alterations of the markets.

Mental accounting is the other significant concept of the field of behavioral finance that was introduced by Richard Thaler. Mental accounting is the habit of people to divide financial resources and choices on different mental accounts instead of considering them together. In the case of female entrepreneurs, this mental categorization can affect the management of business profit and household money and the decision to reinvest. Financial decisions could in most instances be influenced by larger factors like family stability, long term family wellness and risk aversion. Behavioral finance is also aware of the use of regret avoidance where people avoid making decisions that may bring regrets in the future. Entrepreneurs might thus want to use safer business methods that reduce the chances of losses. This type of cautiousness with regard to investment is usually common with small-scale entrepreneurship who operate in unpredictable financial conditions.

Generally, behavioral finance remains an important source of information on the complicated interplay of the psychology and financial decision-making. Using these dimensions of behavior, the theory can be used to understand why women entrepreneurs can be cautious, experience-based, and socially-influenced investment approaches, instead of using only rational economic calculations.

RESEARCH METHODOLOGY

The research design in this study is qualitative secondary research that aims at investigating the influences on investment decision-making by women entrepreneurs. The sources of secondary data covered a diverse variety of academic and institutional access such as peer-reviewed journal articles, books, dissertations, research reports, and policy publications on the topics of women entrepreneurship, behavioural finance, financial literacy, and entrepreneurial investment behaviour. The literature choice used certain inclusion criteria in order to make it relevant and scholarly. The process of selecting the sources was focused on the publications issued over the past ten years, though some works on the seminal theoretical background were also taken to establish conceptual background. Some of the areas of concern in the reviewed literature include financial capability, behavioural determinants of financial decision-making, institutional finance access, digital financial inclusion, entrepreneurial orientation, and the impact of social capital on investment behaviour. The thematic analysis methodology was taken to integrate the results of the chosen literature. The studies reviewed were systematically classified into major thematic issues that have impact on investment decision among women entrepreneurs. These themes are the financial literacy and investment awareness, psychological and behavioural factors, institutional and financial access limitation, and technological and digital financial systems. Recurrent patterns, similarities of concepts and gaps concerning the literature were detected through comparative analysis in various research works and settings.

The secondary analytical methodology allows uniting the multidisciplinary views of economics, sociology, the study of entrepreneurship and behavioural finance. The study does not imply primary data collection, but methodological rigor was ensured by the critical analysis of sources, cross-validation of the results of the empirical research, and the synthesis of the evidence based on the existing academic sources. This would enable the research to generate a

holistic conceptual knowledge of the determinants affecting investment decision-making decisions among female entrepreneurs.

Financial Competence and Investment Perception

One of the most essential factors that determine investment decisions by women in the world of business is financial capability. It does not only involve the rudimentary Understanding of financial aspects like savings, interest rates, diversification of risks and management of credits, but the capability to take the knowledge to practical entrepreneurial scenarios. Female entrepreneurs with a greater degree of financial awareness tend to be more effective in determining investment possibilities, estimating the possible risks, and using the resources strategically to facilitate sustainability of the business in the long run. Monetary competence thus is crucial in enhancing enterprise development as well as financial sovereignty. In most business environments, women tend to start their own businesses with little formal education in the field of financial management. This can affect their initial investment choices in that they will base more on unofficial knowledge sources like family, peer network or even localized financial culture. Although these informal systems could offer meaningful aid, they could also confine one to diversified investment opportunities that exist in formal financial markets. Therefore, the enhancement of financial ability is vital in order to empower women entrepreneurs to operate in financial conditions that are becoming more sophisticated and in order to make better investment decisions.

The financial capability equally influences the way in which entrepreneurs perceive the financial information and rate the success of their investments. Strong knowledge in finance will help the entrepreneurs in taking part in budgeting, financial forecasting and cost-benefit analysis prior to they commit their resources in new ventures or in expansion activities. These practices increase their capacity to recognize lucrative opportunities and reducing the possible financial risks. Also, entrepreneurs fully informed financially can be more aware of credit terms, interest rates, and repayment plans, which can contribute to responsible lending and use of funds even more. Capacity building programs and creation of educational programs have been seen as an effective weapon in empowering women entrepreneurs financially. Women can gain financial literacy through financial literacy training programs, gain entrepreneurship development skills through entrepreneurship development training programs and gain confidence in investment management through mentorship networks. These programs tend to expose entrepreneurs to the latest financial instruments, online banking, and systematic investment planning techniques which can otherwise be unknown.

Besides, financial capability is one of the factors that contribute to long-term financial resilience. Those entrepreneurs who are aware of the diversification of risks and financial plans can be more inclined to invest in various areas of investment, thus securing their businesses in case of changes in the market and the unpredictability of financial offsets. Such strength is especially relevant to small and medium enterprises where financial stability can be the only difference between survival and extinction in times of economic uncertainty. All in all, financial capability is not just a technical capability but is an essential resource that enables the female entrepreneurs to make informed investment choices. Policymakers and institutional stakeholders can assist in improving the efficiency of women-led enterprises in terms of investment and sustainability and improve their contribution to the economy by boosting financial awareness and access to financial education.

Psychological Impact on Entrepreneurial Investment Choice

Economic calculations are not the only criteria used by the women entrepreneurs when it comes to the investment decision making, but it also heavily depends on the psychological and behavioural factors as well. Behavioural economics emphasizes the fact that human beings tend to take mental shortcuts, emotional reactions and personal experiences in making their financial choices. These behavioural patterns determine the ways entrepreneurs view risk, assess opportunities and eventually make a decision on whether to invest or not in a given venture or financial asset. Risk perception is one of the psychological factors that play an important role in investment decisions. Depending on previous experiences, financial responsibility as well as level of entrepreneurial confidence, women entrepreneurs can analyze financial risks differently. Risk aversion can also in most instances make entrepreneurs

choose lower-risk investment opportunities that are more stable rather than making risky investments. This type of cautious behaviour can be viewed as an indication of a need to preserve what is there and to secure both the economic sustainability of the business and the family. Although, aggressive expansion strategies are at times constrained by risk aversion, cautionary financial planning and sustainable expansion of a business can be promoted. The other behavioural factor is self-confidence regarding financial judgement. To a greater extent, entrepreneurs with high self-efficacy in their decision-making skills are more prepared to venture into new investment opportunities and have a proactive business strategy. Confidence would encourage people to invest in new technologies, diversify their business activities or venture into new markets. Nevertheless, too much confidence can also result in overestimation of the returns or miscalculation of the risks that can culminate in inefficient financial decisions. As such, a balance in the level of confidence is relevant in good investment behaviour.

The aspect of emotions is also a contributing factor to investment decisions. Past positive or negative financial returns can change the future investment behaviour through the development of risk and uncertainty attitudes. Businesspersons who have already had a negative experience of being financially set-back might be cautious in their further investment activities, but on the other hand a successful businessperson might be more open to trying something new. The emotional reactions towards financial performance can then be used to entrench certain behavioural trends in the long term. Financial decision-making can also have social and cultural pressures affecting the psychological dimensions of the problem. Gender enterprises tend to be socialized, and the burden of family and social norms influences finances. Investment decisions can thus be based on more encompassing factors of house welfare, education of kids, or stability of the family in the long run. Such social incentives can make businessmen focus on safe and sustainable investments, instead of just profit-oriented ones. Learning of the psychological aspects of investment behaviour is important since it can help in understanding why we can occasionally find ourselves making some irrational financial decisions that are not necessarily based on the model of rational economic actions. If the contribution of behavioural aspects can be acknowledged, it can assist policymakers and financial institutions to develop the support systems like mentorship, financial counselling, and behavioural training programs. These interventions have the potential to help women entrepreneurs to learn balanced risks evaluation and confidence in financial decision-making.

Institutional Surroundings And Access To Financial Resource

The environment of an institution is one of the key factors that influence the investment behaviour of women entrepreneurs. The institutions and banking systems, credit markets, government policies, and financial regulation systems affect the access to financial resources and the allocation of capital by entrepreneurs in business development. Proper working support systems in institutions create the possibilities of entrepreneurs to attract funds, invest in productive resources, and develop their businesses. On the other hand, the small number of financial institutions can hinder the investment prospects and limit the growth of a business.

Lack of access to formal credit is one of the greatest institutional challenges encountered by a number of women entrepreneurs. Before a loan is approved, the financial institutions usually demand collateral, documentation of financial history and credit histories. To small-scale women entrepreneurs running an informal or newly-established businesses, they may find it challenging to fulfill these requirements. This has led most women to use personal savings, family or unpaid lending circles to fund their investments. Although these sources may offer instant financial solutions, they do not necessarily have enough capital to support bigger business projects or long-term growth. Structural inequalities of financial systems may also become institutional barriers. In other settings, female entrepreneurs can face gender-based restrictions to financial services such as reduced rates on credit approvals or reduced size of loans. Such restrictions are capable of affecting the investment processes by constraining the opportunities that women-owned businesses have. To counter this kind of barriers, it is necessary to consider inclusive financial policies that can acknowledge the specific difficulties encountered by women entrepreneur and introduce equity in access to financial resources.

Government programs and development projects have been turning more to support entrepreneurship of women by providing specific financial schemes. Microfinance services, small business credits and entrepreneurship development services are geared towards enhancing the accessibility of capital by women entrepreneurs. The programmes usually offer liberal credit terms, reduced collaterals, and capacity building to stimulate business investment and creation. Entrepreneurial participation and economic empowerment can be greatly increased when these initiatives are properly employed. The financial institutions also contribute significantly to the advisory services and financial advice to the entrepreneurs. Professional financial advice can be availed to enable the women in the business to learn about the investment opportunities, analyzing the financial risks, and set long-term business plans. The knowledge sharing and development of skills in entrepreneurial communities is also facilitated by institutional mentorship and support networks.

The institutional environment in general defines the financial environment that women entrepreneurs are doing business. The enabling environment that will ensure more women invest their money in their enterprises with great confidence can be achieved through reinforcement of mechanisms that support institutions, making access to credit more readily available, and through gender sensitive financial policies. These advances do not only favor personal entrepreneurship, but they also lead to economic growth and inclusive growth in general.

Technological Advancement And Digital Financial Opportunities

The financial ecosystem has evolved greatly through technological developments, which have provided new avenues to the business people to use financial services and investment platforms. Financial transactions have been made to be more convenient, more convenient, and more visible as a result of the rapid growth of digital financial technologies such as mobile banking, online payment systems, and digital investment applications. Among women entrepreneurs, these technological advances can break numerous conventional barriers in the physical banking expertise and institutional accessibility. Internet-based financial services assure entrepreneurs to perform financial operations without the need to be physically present at a specific location, which makes the process of online banking cheaper and less time-consuming. With mobile banking applications and other digital payment systems, women entrepreneurs are now able to maintain business accounts, transfer funds, track financial documents and settle payments at a more convenient point. These services facilitate efficient functioning and enable business people to keep a better financial record that often has to be provided to obtain the help of the institutions to get credit and other investment facilities.

The other critical benefit of digital financial technologies is the accessibility to financial information. The internet gives business people the real-time information on the market and investments opportunities, as well as financial products. Women entrepreneurs will be able to compare the various financial opportunities and make sound investment decisions when they have access to such information. Moreover, digital financial solutions usually come along with budgeting software, financial planning tools, and performance monitoring tools that help entrepreneurs to manage business finances better. E-financial inclusion is also important in increasing inclusion of people in formal financial systems. Most women entrepreneurs that used to depend on informal financial practices are now able to access banking services offered in digital platforms even where physical banking facilities are scarce. This addition enhances financial transparency and assists entrepreneurs to establish credit histories, which could be used to obtain institutional loans and investment funds. Moreover, the digital technologies have stimulated the development of online entrepreneurial communities in which business owners can meet customers, suppliers and financial services providers. Online platforms and online marketplaces give business owners a chance to increase their customer base and earn more revenue. Enhanced business revenue, in their turn, generates more possibilities of reinvestment and expansion of the enterprise.

Even with these benefits, such issues as low digital literacy, insufficient internet connectivity, and cybersecurity concerns can affect the use of digital financial technologies by women entrepreneurs. The only way to deal with these challenges is to have the governments, financial institutions, and the technology providers work together to encourage digital education and make technology more accessible. To sum it up, the role of women entrepreneurs in

the investment environment is transformed by the technological aspect and the opportunity of digital financial markets. Digital technologies have the potential to empower women entrepreneurs to follow better investment decisions and support the sustainability of their businesses in the long term by enhancing access to financial services, improving transparency, and improving market connectivity.

DISCUSSION

The results of the current study suggest that choices that women entrepreneurs make regarding the investment decision-making process are determined by a multifaceted interdependence between economic, behavioural, social, and institutional factors. The financial literacy becomes a core factor to enhance the capacity of the women entrepreneurs to comprehend financial market, assess investment opportunities and make knowledgeable financial choices. More financially savvy entrepreneurs can better perform cost-benefit analysis, financial risk management, and diversification in order to secure the business sustainability in the long term. Nevertheless, the analysis also demonstrates that the rational economic models cannot be used to explain investment behaviour fully. The behavioural finance approaches reveal that risk perception, loss aversion, self-confidence, and previous financial experiences are psychological factors that affect the decision to invest by an entrepreneur to a large extent. Female entrepreneurs tend to be cautious of their financial behaviour because of the family welfare and financial stability issues, which could influence their choice of safe and stable investment. The institutional conditions also affect the decision-making of investment. Few access to formal credit provisions, collateralization and institutional barriers in financial institutions limit access to sufficient financial resources by women entrepreneurs to expand their business. Social capital networks such as family, peer entrepreneurs, and community support systems, are also relevant in such cases in terms of the provision of financial information, informal credit, and entrepreneurial advice.

The paper, also, marks the increasing relevance of digital financial technologies in changing the way women access financial services. Mobile banking, online payments, and internet based financial systems have increased the horizons on which entrepreneurs can transact financial transactions, view financial information, as well as being part of formal financial systems. Digital financial inclusion is thus a very important process of improving the financial inclusion of women, as well as increasing their investment decision-making capacity. In general, the interplay between the individual behavioural determinants and larger institutional features indicates that the policy should be holistic to increase the investment performance of women. Enhancing financial literacy, encouraging gender-balanced financial systems, enhancing digital technology accessibility as well as supporting entrepreneurial ecosystems are crucial measures towards empowering women entrepreneurs and increasing their investment potential.

CONCLUSION

Multidimensional interaction between financial knowledge, behavioural characteristics, socio-economic conditions, institutional conditions and technological developments determines investment decision-making among women entrepreneurs. The paper indicates that women in business are likely to consider economic goals alongside other Social and domestic factors when deciding to invest their resources. This leads to their financial behaviour being more about maximizing profits but also financial security, family, and long-term sustainability of an enterprise. The results indicate that there should be a stronger focus on financial literacy and entrepreneurial skills development among women entrepreneurs to enhance opportunities to assess investment opportunities and to adequately address financial risks. This also requires expansion of access to institutional finance, and structural barriers of the credit systems and encouraging gender-sensitive financial policies to improve women's involvement in the activities of entrepreneurial investment. Moreover, the quick development of digital financial technologies opens the new possibilities to enhance financial inclusion and diversify investment participation into the domain of women entrepreneurs. Financial transactions can be made easier, market information can be accessed better and financial transparency can be enhanced via the use of digital platforms. Nonetheless, these advantages are achievable only

under the conditions that there should be some effort to raise the level of digital literacy and technological availability. Altogether, policy interventions, including financial education, institutional reforms, progress of digital infrastructure, and entrepreneurship support programs, should be combined to support women in their entrepreneurship. The additional contribution to this field can be made in the future through carrying out the empirical studies that would examine the region-specified socio-cultural situations and behavioural patterns that affect the investment practice of women.

ABSTRACT

Cloud computing has transitioned from a technical convenience to a foundational requirement for modern enterprises, offering the scalability and cost-efficiency needed to remain competitive. As organizations prioritize operational resilience, the migration of legacy, on-premises applications to Amazon Web Services (AWS) has become a primary strategic goal. This study proposes a next-generation framework for cloud migration that emphasizes a structured, performance-driven approach to transitioning legacy environments.The research systematically explores the migration lifecycle, beginning with readiness assessments and deep-dive application discovery to map complex dependencies. By evaluating specific migration strategiessuch as rehosting, replatforming, and refactoringthe framework aligns technical execution with overarching business objectives to mitigate downtime and operational risk.A significant contribution of this work is its focus on performance engineering and cost-optimization. By integrating cloud-native practicesincluding resource right-sizing, auto-scaling, storage tiering, and reserved capacity planningthe proposed model ensures that resource utilization remains lean and budgets remain under control. Furthermore, the study incorporates essential governance, security compliance, and disaster recovery protocols to ensure long-term architectural sustainability.Ultimately, through analytical modeling and practical insights, this paper

demonstrates how a well-orchestrated AWS strategy can lower the Total Cost of Ownership (TCO) while enhancing workload performance. This framework serves as a practical roadmap for enterprises and practitioners aiming for a secure, efficient, and economically viable cloud transformation.

INTRODUCTION

This paper presents a comprehensive roadmap for developing a migration strategy tailored to your organization's unique requirements. It outlines the key steps, techniques, and methodologies essential for successfully transitioning enterprise applications to the AWS Cloud. A basic understanding of Amazon Web Services (AWS) products and features will help readers fully leverage the insights provided.We explore a range of migration strategies to help enterprises maximize the advantages of cloud computing, including:

- R-Lane Approach
- Hybrid Approach
- Containerization
- Orchestration Approach
- Big Bang Migration
- Phased Migration
- Data-First Migration

Particular emphasis is placed on a phase-driven, step-by-step **R-Lane Approach**, designed to streamline migration and ensure smooth cloud adoption.

OBJECTIVES

The primary objective of this implementation is to transition on-premise applications to the AWS Cloud through a container-based deployment model. This approach moves applications, data, and operating systems into a cloud-hosted Docker environment, enabling scalability, portability, and operational efficiency.

The migration journey is organized into the following key phases:

- **Discovery Phase**
- **Planning Phase**
- **Design Phase**
- **Build & Migration Phase**
- **Production and Stabilization (Validation) Phase**
- **Hypercare Phase**
- **Handover Phase**

Cloud Migration Benifits

Cloud migration is a multifaceted process that involves extensive research, comparison, and decision-making before relocating data and processes. It offers numerous benefits across various scenarios, including:

- **Resource Scaling:** On-demand allocation to meet fluctuating requirements.
- **Cost Efficiency:** Reduction in operational costs.
- **IT Performance:** Improved efficiency and streamlined processes.
- **Application Management**: Simplified tracking, versioning, and upgrading of applications.
- **Automation:** Automated database backups, software updates, and routine maintenance.

- **Deployment Speed**: Faster application deployment and operational workflows.
- Development Focus: Reduced infrastructure overhead, enabling better focus on development tasks.
- Global Accessibility: Seamless business access worldwide without the need for multi-region infrastructure.
- Sustainable Storage: Cost-effective, resilient storage solutions.
- Team Collaboration: Enhanced productivity for distributed teams, including remote workers.
- Disaster Recovery: Superior disaster recovery systems compared to on-site data centers, providing quick and reliable resource control

LITERATURE SURVEY

A literature survey serves as a critical analysis of existing research on a specific topic, enabling a deeper understanding of the current state of knowledge, identifying gaps, and laying the groundwork for future studies. This collection of research papers provides an in-depth perspective on AWS cloud computing solutions.

- **AWS Cloud Computing:** "**A Case in South Korea**" – This study explores the use of AWS in South Korea, with a particular emphasis on big data processing and analytics. It examines how AWS supports large-scale dataset management, machine learning implementations, and the development of regional business intelligence strategies.
- "**A Review on AWS Security Issues: Review of Amazon Web Services**" – This paper focuses on AWS security, discussing encryption techniques, network security protocols, compliance frameworks, and potential vulnerabilities in the AWS infrastructure. It underscores the shared responsibility model and outlines best practices for safeguarding cloud-based data and applications.
- "**Review on AWS – Cloud Technology**" – This review highlights AWS as a cost-effective and secure cloud model, emphasizing its scalable storage capabilities, pay-as-you-go pricing structure, and integrated security features. Key topics include Amazon S3 storage solutions, Identity and Access Management (IAM), and advanced encryption mechanisms.

Cloud Migration Strategy

Application migration refers to the process of relocating an application from one environment to another, which can include:

On-Premises Data Centers: Migration within a local infrastructure.

On-Premises to Cloud: Transitioning applications from traditional on-premises environments to a cloud-based platform.

Cloud-to-Cloud: Transferring applications between different cloud service providers

The R-Lane Approach is a structured methodology for cloud migration, aimed at ensuring a seamless transition from on premise systems to the cloud. It emphasizes several critical components to facilitate a successful migration process.

Rehost(Lift and shift)- This is for lift and shift operation. Simple migration without significant optimization or rationalization or transformation

Re-Platform (Lift , thinker, Shift):This process will help Optimize for cloud services without rewriting the entire application.

Repurchase (Drop and shop): To Replace existing system with commercial off-the-shelf (COTS) or SaaS solution

Re-Factor(Re- Architect): To Make significant changes to architecture, design, and code for cloud optimization

Relocate: Move workloads to different cloud regions or providers

Retire (Decommission):Decommission unnecessary or unsuitable workloads

Retain :Do the changes later

Application Migration Process:
Application migration involves the following tasks, organized into key phases:

Planning Tasks:
- Map application dependencies.
- Finalize the target environment.
- Determine the application migration method.
- Define pre- and post-migration task lists.
- Collaborate with the application team to prepare the test plan.

Design and Development Tasks:
- Ensure environment readiness.
- Finalize test cases.
- Perform application remediation.
- Set up the project repository.
- Validate dependencies, libraries, and the migration strategy.
- Package the application in a deployable format.
- Validate scripts.
- Load the application.

Migration and Testing Tasks:
- Transfer deployment files from the repository to the VM.
- Verify deployment file execution, identifying and resolving errors.
- Fix issues and establish required connections.
- Execute test cases.
- Address any errors identified during testing.
- Conduct acceptance testing.

Data Migration process:
Database migration involves multiple phases, each with a defined set of activities:

Analysis Phase:
- Understand the existing "As-Is" landscape.
- Develop a detailed migration plan.
- Analyze the source data structure.
- Complete a detailed migration inventory.
- Perform data analysis and profiling.
- Prepare data query reports.

Design Phase:
- Define the migration strategy.
- Map the source to the target.
- Create the data conversion framework.
- Design migration components.

Build Phase:
- Build database migration components.
- Perform unit testing.
- Conduct reviews.
- Fix identified bugs.

- ❖ Retest and rerun processes as needed.

4. Mock Run Phase:

- ❖ Execute mock screens for testing.
- ❖ Conduct performance testing.
- ❖ Perform functional testing.
- ❖ Complete User Acceptance Testing (UAT).
- ❖ Finalize the cutover process.

5. Go-Live Phase:

- ❖ Prepare for deployment.
- ❖ Execute incremental deployment and data loading.
- ❖ Generate reports.
- ❖ Obtain final sign-off

Container Automation Deployment Using Docker

Deployment Workflow Overview

1. **Developer Commit**
   Developers push changes to the GIT repository, generating a new change set ID.
2. **Jenkins – Build Trigger**
   Jenkins continuously monitors the GIT repository for changes. When a change is detected, it triggers the build process using **ANT**, **Maven**, or **Gradle**.
3. **Build Completion**
4. After the build completes, Jenkins validates the packaged artifacts (WAR/JAR files).
5. **Artifact Deployment to Repository**
   The validated build artifacts are pushed to a designated repository such as **ECS**, **EKS**, **JFrog**, **Docker Hub**, or another central repository.
6. **Ansible Deployment Trigger**
   Jenkins triggers the Ansible deployment process in parallel.
7. **Ansible – Artifact Retrieval**
   Ansible downloads the latest WAR/JAR artifacts from the repository.
8. **Ansible – Application Deployment**
   Ansible automatically deploys the application to the target environment—such as **AWS EKS**, **VMs**, or other cloud infrastructure.
9. **Ansible Playbook Structure**
   - **Playbook**: YAML configuration containing server details, start/stop commands, artifact paths, and updated WAR file information.
   - **Rules**: Stores standardized and non-variable deployment details for consistency.

Containerization Steps

- Build the Docker image.
- Push the image to a Docker registry.
- Pull the image onto the production host.
- Run the application in production as a container.

Experimental Design

The above transformation can be implemented using:

- Sample Java Spring Boot Application
- MySQL Database

- Deploy:
  - On-Prem VM
  - AWS EC2
  - AWS EKS (Containerized)

Implementation Comparison Table

This table 1. compares the performance of **On-Prem VM, AWS EC2, and AWS EKS container infrastructure**. On-Prem virtual machines require more deployment time (3 hours), higher cost (₹85,000), and experience downtime during updates. AWS EC2 reduces deployment time and cost while providing better disaster recovery through snapshots. AWS EKS offers the best performance with faster deployment (15 minutes), automatic scaling, lower CPU utilization, minimal response time, zero downtime during updates, and the lowest monthly cost. Thus, EKS provides more efficient and reliable cloud infrastructure. This table 2. explains different **cloud migration strategies**. Rehost involves moving applications to the cloud without major modifications and is the cheapest option. Replatform makes minor optimizations during migration. Refactor redesigns the application to become fully cloud-native but involves higher cost and risk. Repurchase replaces existing software with SaaS solutions. Retire means removing obsolete or unused applications. Each strategy is chosen based on cost, risk, and optimization needs.

This table 3 compares **traditional virtual machine deployment** with **container-based deployment using Docker and EKS**. Traditional VMs have slower startup times (3–5 minutes), lower resource efficiency, and complex rollback processes. Containers start very quickly (10–15 seconds), use resources more efficiently, provide high portability, support automated CI/CD integration, and allow easy rollback. Therefore, container-based deployment is more flexible and efficient.

This table shows the performance improvement when moving from **On-Prem infrastructure to EC2 and EKS**. Latency decreases significantly from 480 ms to 165 ms. Throughput increases from 110 requests per second to 260 requests per second. Monthly infrastructure cost is reduced from ₹85K to ₹47K, and downtime during updates is completely eliminated. This demonstrates that cloud-based container infrastructure improves performance, scalability, and cost efficiency.

CONCLUSION

Migrating critical, distributed industrial systems to Amazon Web Services (AWS) is as much a business evolution as it is a technical project. Because these environments are defined by strict security requirements, real-time operational needs, and complex legacy dependencies, the migration process cannot be rushed. As this study demonstrates, with a well-orchestrated, phased approach, enterprises can transition even the most sensitive workloads to the cloud without sacrificing performance or operational continuity. The proposed migration blueprint emphasizes a "measure twice, cut once" philosophy. By prioritizing thorough workload assessment and precise dependency mapping, organizations can execute transitions that significantly reduce downtime and mitigate risk. Central to this framework is the adoption of Infrastructure as Code (IaC) principles. Utilizing tools like Terraform to automate containerized deployments ensures that the entire infrastructure is consistent, repeatable, and easily audited. This level of automation is transformative: it not only speeds up deployment cycles but also bakes governance and compliance directly into the environment.

Furthermore, the research underscores that moving to the cloud is only the first step. True value is realized through cloud-native optimization—using dynamic scaling, right-sizing resources, and active performance tuning to balance budgetary goals with high availability. By integrating these practices, organizations can achieve a measurable reduction in Total Cost of Ownership (TCO) while gaining the elasticity and responsiveness that legacy, on-premises systems simply cannot provide. In short, a structured, automation-driven migration path is the most reliable way to future-proof industrial workloads. By combining a phased deployment strategy with robust security design and

infrastructure automation, enterprises can move beyond the limitations of their legacy systems and fully leverage the agility and resilience inherent in the AWS ecosystem.

ABSTRACT

Protein-protein interactions (PPIs) play a crucial role in cell communication, signal transduction, and regulation of complicated biological processes. Human interactome contains over 650,000 disease related PPIs, most of which are involved in oncogenic signaling. Abnormal PPIs caused by genetic mutations promote the development, growth, and resistance to therapy. PPIs have also historically been regarded as undruggable since they have large, flat interfaces (1,0004,000 Å^2), no deep-lying binding pockets, and diffuse interaction hot spots, which restrict small-molecule binding. Peptidomimetics have also become a promising approach to selective control of PPI interfaces through structural replication of main recognition motifs of native peptides with enhanced metabolic stability, membrane permeability, and pharmacokinetic properties. The classification, rational design concepts, structural optimization and translational developments of peptidomimetics in cancer therapy have been thoroughly discussed in this review. Key therapeutic targets are MDM2 -p53 axis, BCL-2 family proteins and integrin-mediated signaling pathways. The overall response rate of BCL-2 inhibitor venetoclax in chronic lymphocytic leukemia BCL-2 targeting has shown a response rate of about 79% clinically, reflecting the success of PPI targeting in the translational model. Besides, new MDM2 inhibitors are promising in acute myeloid leukemia in terms of combination regimens. Moreover, we discuss the mode of action by which peptidomimetics cause apoptosis, prevent angiogenesis, prevent metastasis, and circumvent resistance to drugs. In combination, structural biology and rational drug design are turning PPI targets that were once believed to be difficult into a therapeutic possibility in oncology.

Keywords: peptidomimetics, protein-protein interactions, cancer therapy, MDM2 inhibitors, stapled peptides, venetoclax.

INTRODUCTION

Protein-protein interactions (PPIs) constitute the molecular language through which cells communicate, coordinate, and execute complex biological processes. With over 650,000 disease-relevant PPIs identified in the human interactome, these interactions represent an extraordinarily rich yet historically challenging therapeutic target space [1]. In cancer, aberrant PPIs drive oncogenic signaling, suppress apoptosis, promote angiogenesis, and facilitate metastatic dissemination. The traditional view of PPIs as 'undruggable' stemmed from their distinctive structural characteristics: interface areas spanning 1000-4000 Å², the absence of deep binding pockets, and surfaces that are often flat and featureless [2].Small molecule inhibitors, typically effective against targets with well-defined pockets of 300-1000 Å², were ill-suited to disrupt these extensive contacts. However, the identification of 'hot spots' within PPI interfaces has transformed this landscape. Systematic alanine scanning mutagenesis has revealed that substitution of hot spot residues reduces binding free energy by at least 2 kcal/mol [3]. These regions are enriched in aromatic and hydrophobic amino acids (Tyr, Trp, Leu, Ile, Phe, Arg) and frequently associate with secondary structural motifs, particularly α-helices, which comprise more than 50% of all secondary structures in protein complexes. Peptidomimetics have emerged as a powerful strategy to target PPI hot spots by mimicking the key recognition elements of native peptides while overcoming their pharmacological limitations. Unlike natural peptides, which suffer from proteolytic instability, poor membrane permeability, and rapid clearance, peptidomimetics can be engineered for enhanced stability, bioavailability, and target specificity [4]. This review provides a comprehensive examination of peptidomimetic development for cancer therapy, from fundamental design principles to clinical translation, with emphasis on recent advances and emerging therapeutic opportunities.

Classification and Design of Peptidomimetics

Figure 1 representpeptidomimetic classification with clinical examples. Class A (stapled peptides) includes ALRN-6924 in Phase II trials. Class D small molecules include FDA-approved venetoclax for CLL/AML treatment.The efficient mimicking of peptides in their bioactive conformation represents a longstanding goal in medicinal chemistry. Peptidomimetics are defined as compounds whose essential pharmacophoric elements mimic natural peptide or protein in three-dimensional space, retaining the ability to interact with the iological target and produce the same biological effect Figure.1 Over the past two decades, classification systems have evolved to capture the spectrum of peptidomimetic designs [5]

Class A Mimetics: Stapled Peptides

Class A peptidomimetics are peptides with minimal alterations to the side chains and backbone. They consist primarily of the antecedent peptide amino acid sequence with a limited number of modified amino acids incorporated to stabilize the bioactive conformation. Stabilization strategies include the incorporation of unnatural amino acids, lactam bridges, and hydrocarbon staples [6]. The stapled peptide ALRN-6924, developed by Aileron Therapeutics, represents a leading example in this class. This dual MDM2/MDMX inhibitor binds MDM4 and MDM2 with Ki values of 24.7 nM and 7.7 nM, respectively, and has demonstrated more potent antitumor activity than small-molecule MDM2 inhibitors in AML cell lines [7].

Class B Mimetics: Foldamers

Class B mimetics represent modified Class A structures incorporating unnatural amino acids, isolated small-molecule building blocks, or major backbone alterations. Prominent examples include peptoids (N-substituted glycine oligomers), β-peptides, and α/β-mixed peptides [8]. Foldamers with side chains aligning topologically identical to the antecedent peptide form a significant subset of this class. These modifications enhance proteolytic stability while maintaining the ability to engage PPI targets.

Class C Mimetics: Helix Mimetics

Class C mimetics consist of highly modified structures that completely replace the peptide backbone with small molecule character. The central scaffold displays substituents in comparison to the orientation of key residues (Hot

spots) in the bioactive conformation of the parent peptide. Representative scaffolds include terphenyls, terephthalamides, benzoylureas, and oligooxopiperazines[9]. This replacement results in molecules with improved oral bioavailability and pharmacokinetic properties, more likely to comply with Lipinski's rule of five.

Class D Mimetics: Small Molecule PPI Inhibitors

Class D mimetics are small molecule drugs from classical medicinal chemistry that mimic the mode of action of a bioactive peptide without direct link to its side chain functionalities. The Nutlin family of MDM2 inhibitors, discovered by Vassilev et al. [10], represents the pioneering achievement in this class. These compounds bind to the hydrophobic cleft at the N-terminus of MDM2, mimicking the p53 residues Trp23, Leu26, and Phe19. Venetoclax (ABT-199), a selective BCL-2 inhibitor, has achieved FDA approval for chronic lymphocytic leukemia and acute myeloid leukemia, demonstrating the clinical viability of targeting BCL-2 family PPIs with small molecules [11].

Targeting Specific PPIs in Cancer

The MDM2/p53 Axis

The tumor suppressor p53, often termed the 'guardian of the genome,' is negatively regulated by MDM2 (murine double minute 2) and its homolog MDMX (also known as MDM4). In response to cellular stress, p53 mediates the expression of genes involved in DNA repair, cell cycle arrest, and apoptosis[12]. MDM2 and MDMX bind to the N-terminal transactivation domain of p53, blocking its function and mediating ubiquitin-dependent proteasomal degradation. Crystal structures of the p53-MDM2 complex reveal an α-helical conformation of the p53 interaction domain, with hot spot residues Phe19, Trp23, and Leu26 projecting into a deep hydrophobic cleft on MDM2 [10]. This structural information has enabled rational design of peptidomimetics that competitively displace p53 from MDM2, restoring its tumor suppressor function. Stapled α-helical p53-derived peptides (SAHp53) with i and i+7 cross-linking positions have shown increased α-helicity and improved binding affinity for MDM2 [13]. The incorporation of hydrocarbon staples enhances proteolytic stability and cellular uptake, addressing key limitations of native peptides.

BCL-2 Family Proteins

The BCL-2 family proteins regulate apoptosis through a complex network of PPIs. Anti-apoptotic members (BCL-2, BCL-xL, BCL-w, MCL-1) contain four BCL-2 homology domains (BH1-BH4) that create a hydrophobic groove (BC groove) binding to the BH3 α-helical motif of pro-apoptotic proteins [14]. Disruption of these interactions can restore apoptotic signaling in cancer cells. Stabilized α-helices of BCL-2 domains (SAHBs) have been developed using peptide stapling. The SAHB from the BH3 domain of BID induces apoptosis in leukemia cells in vitro and in vivo [15]. Despite the success of venetoclax, resistance mechanisms have emerged in clinical practice. The Gly101Val mutation in BCL-2, located within the drug-binding pocket, directly impairs drug-target affinity [16]. Additionally, compensatory upregulation of MCL-1 and BCL-xL enables tumor cells to maintain survival when BCL-2 is inhibited [17]. Understanding these resistance mechanisms is crucial for developing next-generation therapeutics.

Integrin-Mediated Signaling

Integrins are heterodimeric cell surface receptors that mediate cell-cell and cell-extracellular matrix adhesion. The $\alpha v\beta 3$, $\alpha v\beta 5$, $\alpha 5\beta 1$, and $\alpha v\beta 6$ integrins recognize the Arg-Gly-Asp (RGD) sequence in ECM proteins. These integrins are upregulated in various cancers and promote tumor angiogenesis, invasion, and metastasis [18]. Cilengitide (cyclo[RGDf(N-Me)V]), a cyclic pentapeptide αv integrin antagonist, demonstrated significant inhibition of tumor angiogenesis in preclinical studies (Figure 2).

Unfortunately, the Phase III CENTRIC trial for glioblastoma failed to demonstrate significant efficacy, with median overall survival of 26.3 months in both treatment and control arms [19]. This outcome highlighted the challenges of translating preclinical promise into clinical benefit and underscored the need for improved patient selection strategies. Nevertheless, integrin ligands continue to show promise as targeting moieties for drug delivery. RGD-drug conjugates with cleavable linkers enable selective accumulation of cytotoxic agents in tumors while sparing normal tissues.

Clinical Development and Translation

The translation of peptidomimetic PPI inhibitors from bench to bedside has accelerated dramatically over the past decade. Multiple compounds targeting the MDM2/p53 interaction have entered clinical trials, providing valuable insights into both therapeutic potential and challenges (Figure 3).

RG7112: First-in-Class MDM2 Inhibitor

RG7112 (RO5045337), developed by Hoffmann-La Roche, was the first MDM2 inhibitor advanced into human clinical trials. With a binding affinity of IC50 = 18 nM to MDM2, RG7112 effectively inhibits cell growth in cancer cell lines with wild-type p53 [21]. In Phase I trials involving liposarcoma patients, clear activation of p53, increased p21 protein, and apoptosis induction were observed. Evidence of antitumor activity included stable disease in 14 of 20 patients and one confirmed partial response. However, dose-limiting toxicities emerged, particularly hematological adverse events including neutropenia and thrombocytopenia [20].

RG7388 and Second-Generation Inhibitors

RG7388 (idasanutlin) represents a second-generation MDM2 inhibitor with superior potency (IC50 = 6 nM) and selectivity (>100-fold over p53-mutant cell lines) [22]. Phase I data established maximum tolerated doses and demonstrated p53 activation measured by MIC-1 concentration in plasma. The combination of venetoclax and idasanutlin has been evaluated in relapsed/refractory AML, showing a composite complete remission rate of 26% and morphologic leukemia-free state rate of 12% [23]. Despite not demonstrating improved overall survival compared to cytarabine alone, the combination showed promising efficacy and acceptable safety in unfit patients with limited treatment options.

Emerging Challenges: Resistance Mechanisms

A significant challenge identified during clinical development is the emergence of resistance mechanisms (Figure 4). Analysis of circulating cell-free DNA from patients treated with SAR405838 revealed p53 mutations in the DNA-binding domain, with variant allele frequency increasing during treatment [24]. In venetoclax-treated patients, mutations in BAX were identified in up to 17% of relapsed patients, with all identified mutations resulting in loss of BAX function [17]. These observations suggest that combination strategies incorporating agents effective against resistant clones may be necessary for durable responses.

Induction of Apoptosis

Peptidomimetics trigger apoptosis through both intrinsic and extrinsic pathways. MDM2 inhibitors restore p53-mediated transcription of pro-apoptotic genes including BAX, PUMA, and NOXA [25]. BH3 mimetics such as venetoclax displace pro-apoptotic proteins from anti-apoptotic BCL-2 family members, enabling mitochondrial outer membrane permeabilization and cytochrome c release. In chronic lymphocytic leukemia, venetoclax achieves an overall response rate of 79%, with complete remission in 20% of patients [26].

Inhibition of Angiogenesis

Angiogenesis is essential for tumor growth and metastasis. Peptidomimetics targeting the VEGF pathway effectively bind neuropilin-1 and VEGFR-1, reducing pathological angiogenesis. The Src kinase inhibitor KX2-391, a first-in-class peptidomimetic that binds the peptide substrate pocket, significantly reduces microvessel density in breast cancer xenografts [27]. Cyclic RGD peptidomimetics with diketopiperazine scaffolds effectively inhibit angiogenesis induced by VEGF, EGF, IGF-I, and FGF2.

Overcoming Drug Resistance

Multidrug resistance (MDR) mediated by ATP-binding cassette transporters, particularly P-glycoprotein (P-gp/ABCB1), limits chemotherapy efficacy. The lysine-peptidomimetic (Lys-P) reverses P-gp-mediated MDR through non-competitive suppression of P-gp ATPase activity [28]. TTT-28, a thiazole-valine peptidomimetic, selectively blocks ABCB1 efflux, increasing intratumoral paclitaxel concentrations and promoting apoptosis in resistant tumors[29]. These findings highlight the potential of peptidomimetics as adjuncts to conventional chemotherapy.

Targeted Protein Degradation

The emergence of PROTACs (proteolysis targeting chimeras) and molecular glues has opened new avenues for PPI modulation. PROTACs are heterobifunctional molecules consisting of a ligand for the target protein, a linker, and a ligand for an E3 ubiquitin ligase [30,31]. This design recruits the E3 ligase to the target protein, leading to ubiquitination and subsequent proteasomal degradation. Stapled peptide PROTACs (SP-PROTACs) combine the PPI-blocking capabilities of stapled peptides with the protein degradation machinery, potentially achieving more durable target suppression [30].

Computational Design and AI

Advances in computational chemistry and artificial intelligence are accelerating peptidomimetic discovery. AlphaFold-Multimer and related structure prediction tools enable accurate modeling of PPI interfaces, facilitating rational design of inhibitors [32]. Machine learning algorithms can predict binding affinity, pharmacokinetic properties, and off-target effects, streamlining the optimization process. These computational approaches are increasingly integrated with experimental validation to identify promising lead compounds more efficiently. In conclusion, peptidomimetics have emerged as a transformative therapeutic modality for targeting protein-protein interactions in cancer. From the pioneering Nutlin compounds to the latest stapled peptides and PROTACs, this field continues to mature with multiple compounds advancing through clinical development. The clinical success of venetoclax, achieving 79% response rates in CLL, demonstrates that PPI targets are indeed druggable. While challenges remain, including resistance mechanisms and hematological toxicities, the combination of innovative chemistry, rational design, and clinical validation positions peptidomimetics at the forefront of precision oncology. As our understanding of PPI networks deepens and delivery technologies advance, peptidomimetics are poised to address previously 'undruggable' targets and expand the therapeutic arsenal against cancer.

CONCLUSION

The use of peptidomimetics has becoming a paradigm shift in the therapeutic approach of protein–protein interaction (PPI) targeting in cancer diseases, defeating the old notion that PPIs are undruggable. Peptidomimetics disrupt oncogenic signaling through structural replication of important recognition signals of native peptides and the inclusion of chemical modifications that improve metabolic stability, selectivity, and pharmacokinetic properties. Inhibition of the critical axes like MDM2 -p53, BCL-2 family proteins and integrin-mediated pathways have both provided mechanistic specificity and significant clinical results, as the translational success of BCL-2 inhibition in hematological malignancies has illustrated. The progress in structural biology, computational modeling and rational drug design have facilitated a perfect mapping of the interaction hot spots and the formation of optimized scaffold able to induce apoptosis, inhibit angiogenesis, suppress metastasis and overcome therapeutic resistance. In addition, combination regimens that include peptidomimetics are becoming increasingly relevant to clinical use especially in cancers that are resistant or have relapsed.

ABSTRACT

Cancer has been one of the biggest causes of death in the world with traditional allopathic cancer therapies of chemotherapy, radiotherapy and surgery frequently constrained by debilitating side effects of the treatment including immunosuppression, organ toxicity and secondary carcinogenesis. Although chemotherapeutic agents are useful in treating malignant cells, they often cause chromosomal damage, oxidative stress, and gene multi-drug resistance, which makes patients more morbid and less responsive to therapy. To counter this, bioactive compounds of plants, which are known as phytochemicals, have been proposed as substitute products: polyphenols (e.g., curcumin, resveratrol, quercetin), alkaloids, terpenoids. These natural agents demonstrate strong anticancer effects, such as induction of apoptosis, arrest of cell cycle, anti-angiogenesis and inhibition of metastasis but much fewer side effects are observed because they are biocompatible and selective in targeting tumor pathways. The clinical application of phytochemicals is impeded, however, by poor solubility in aqueous solution, low bioavailability, rapid metabolism, and instability in physiological conditions. To overcome these obstacles, nanotechnology-based delivery systems have been employed wherein phytochemicals have been entrapped in nanoparticles, be it liposomes, polymeric nanoparticles, solid lipid nanoparticles and dendrimers. These systems improve solubility, extend circulation/circulation times, allow site-specific targeting through passive (EPR effect) or active (ligand conjugation) processes, and controlled release in response to tumor microenvironment (e.g., pH, enzymes) stimuli. The new developments, such as hybrid

nanocomposites and biomimetic nanovectors, have shown to have better pharmacokinetic and antitumor effect in preclinical models of breast, colorectal, lung, and prostate cancer.

INTRODUCTION

Cancer has been one of the most critical health issues globally with millions of deaths being recorded every year all over the world. Although there has been massive investment in the conventional cancer treatment methods which include chemotherapy, radiotherapy, and surgical operation, the outcome of treatment is not optimal because of multifactorial constraints, which include systemic toxicity, emergence of drug resistance, unfavorable pharmacokinetics, and uncertainty of specificity to tumor tissues [1]. The traditional chemotherapeutic paradigm has been crippled persistently by the lack of selective targeting processes that destroy both neoplastic and normal tissue resulting in extreme adverse effects that undermine the quality of life of patients [2]. The natural product-based drug discovery field has undergone an impressive revival in recent decades, where phytochemicals bioactive compounds of medicinal plants have emerged as promising therapeutic agents as a result of their multi-targeting abilities, wide array of biological activity, and naturally favourable safety profiles [3]. Some of the main phytochemicals which are currently being actively studied are curcumin, resveratrol, quercetin, epigallocatechin gallate (EGCG), berberine, and various polyphenolic compounds that have shown strong anticancer effects with different molecular mechanisms [4]. Nonetheless, basic pharmacological issues have posed great difficulties to the clinical translation of these naturally occurring compounds. The majority of phytochemicals lack water solubility, exhibit high hepatic levels of metabolism, low oral bioavailability, and cellular uptake. The effects of these bioavailability limits are poor drug concentrations at the target tumor locations thereby undermining therapeutic efficacy in spite of the anticancer property inherent in these compounds. Nanotechnology has come forth as a governative solution to these historical constraints and present some novel methods of encapsulating, stabilizing, and delivering phytochemicals with improved specificity to cancer cells and an overall reduced systemic toxicity [5].

Significant phytochemical classes and their anticancer properties &mechanisms

The phytochemicals have an impressive anticancer diversity of structurally varied molecules. One of the most intensively researched classes is comprised of polyphenolic compounds such as flavonoids, phenolic acids, and stilbenes [6]. The main bioactive constituent of turmeric is curcumin, which has shown the capacity of regulating numerous signaling pathways such as NF-κBbinding cascades, MAPK cascades, and ultimately cell cycle arrest and induction of apoptosis. Resveratrol is a naturally occurring stilbene, which predominantly exists in grape skins and berries, which possesses strong antioxidant as well as anti-inflammatory effects at the same time inducing apoptosis through the upregulation of pro-apoptotic proteins [7]. Another significant group of phytochemicals that have been recorded to have antitumor effects is quercetin and its analogous flavonoids. The compounds exhibit versatile effect such as tyrosine kinases inhibition, angiogenic inhibition and control of estrogen receptor signaling. Epigallocatechin-3-gallate (EGCG) which is the most common catechin content in the green tea extract induces its anticancer action by inhibiting telomerase, growth factor signaling, and by inducing mitochondrial-mediated apoptosis [8]. Alkaloids like berberine, which are present in medicinal herbs like Berberis species and Coptis chinensis, appear to have some of the strongest anticancer effects, acting upon DNA repair machinery and non-coding RNA regulation [9].

Signaling Pathways Targeted by Phytochemicals

The mechanistic basis of cancer cell death caused by phytochemicals is the regulation of interrelated signaling pathways that control cell survival, growth, and apoptosis. The phosphatidylinositol 3-kinase/protein kinase B/mechanistic target of rapamycin (PI3K/AKT/mTOR) pathway is one of the main targets because the disruption of

this pathway is part of the oncogenic transformation, as well as, therapeutic resistance in various cancers [10]. Phytochemicals like mangiferin and curcumin exhibit significant binding affinities to important nodes in this pathway, where computational studies have shown binding energies of 11.20 kcal/mol to PI3K, 15.16 kcal/mol to AKT, and 10.24 kcal/mol to mTOR [11]. Another important target system is the mitogen-activated protein kinase (MAPK) family, which includes extracellular signal-regulated kinases (ERK1/2), p38 MAPK, and c-Jun N-terminal kinase (JNK) [12]. The inhibition of MAPK signaling by phytochemicals also suppresses proliferative responses and at the same time induces pro-apoptotic gene transcription. Also, the Wnt/ 2 -catenin pathway, which controls the differentiation and stemness of cellular functions, is significantly suppressed by some phytochemicals by inhibiting the stabilization of 2 -catenin and the expression of genes by transcription factors.

The Notch and Hedgehog signaling pathways that control the maintenance and differentiation of the cancer stem cells are also becoming the major targets. Recent studies show that natural compounds that affect such pathways exhibit improved effectiveness in destroying cancer stem cell populaces that are resistant to therapy. The phytochemical interventions also regulate tumor suppressor pathways, such as p53-mediated responses and PARP-dependent DNA repair, which in turn cause greater genomic instability in cancer cells with comparative sparing of normal cell function [12].

Nanocarrier systems for phytochemical delivery

Figure 1 represent different nanocarrier systems for drug delivery system.

Polymeric Nanoparticles

Nanoparticles made of poly(lactic-co-glycolic acid) (PLGA) and poly(lactic acid) (PLA) have been used as the gold standard in phytochemical encapsulation because of their biodegradability, biocompatibility and FDA approved status [13]. The PLGA-based systems exhibit exceptional flexibility when it comes to being able to accommodate a wide range of phytochemicals such as curcumin, resveratrol, and EGCG. The extent of encapsulation of these compounds into PLGA nanoparticles is generally 80-95% and the release profile of these compounds is long-lasting that expands the therapeutic efficacy. The polymer skeleton offers intrinsic resistance to enzymatic degradation preserving phytochemical integrity in circulation and facilitating localization at tumor sites through increased permeability and retention (EPR) effects.

It is important to note that, the release kinetics of the PLGA nanoparticles can be tuned by adjusting the molecular weight of the polymer, copolymer ratio, as well as by adding plasticizers or surfactants. The use of triple phytochemical formulation of resveratrol, acetyl-11-keto-β-boswellic acid (AKBA), and quercetin within the PLGA nanoparticles showed the ability of multiplex phytochemical delivery with a particle size of 198.5 nm polydispersity index of 0.492 and encapsulation efficiencies of 90, 80, and 75 % respectively [14]. Enhanced therapeutic efficacy mechanisms are protection against first-pass metabolism, increased cellular uptake through endocytosis, crosses biological barriers such as blood-brain barrier.

Lipid-Based Nanocarriers

Liposomes, which are vesicles in the shape of a sphere and are made up of lipid bilayers, have also experienced an amazing use as a way of encapsulating both phytochemicals that are hydrophilic and hydrophobic [15]. Amphipathic liposomal architecture also allows the lipophilic molecules like curcumin to be accommodated in the lipid membrane with hydrophilic agents partitioning in the aqueous interior compartment. Solid lipid nanoparticles (SLNs) and nanostructured lipid carriers (NLCs) are further developments of the liposomal technology, with better stability, and lower burst release kinetics than traditional liposomes [16]. Another paradigm of lipid delivery using salts and proteins over the lipid is the use of albumin-based nanoparticles that take advantage of the great biocompatibility and transport capabilities of endogenous serum albumin. It is demonstrated that the nanoparticles stimulated apoptosis in several signaling pathways and demonstrates the synergistic advantage of targeted delivery with intrinsic phytochemical bioactivity. Niosomes are non-ionic vesicles that are an affordable, biodegradable solution to liposomes, having an equivalent encapsulation effect and biocompatibility [17]. These vesicular systems have

demonstrated specific potential in transferring polyphenolic substances and evading certain aspects of stability and batch dispersion as associated with traditional liposomes, therefore, simplifying manufacturing scalability and regulatory endorsement strategies.

Metal and Metal Oxide Nanoparticles

Green chemistry synthesized gold nanoparticles (AuNPs) that use plant extracts have risen to fame as biocompatible phytochemical carriers with inherent photothermal and photodynamic characteristics [18]. Plant mediated AuNP synthesis is a more sustainable substrate to chemical reduction approaches, which exploits phytochemicals in their own capacity as reducing agents, and at the same time loads therapeutic cargo. These green-synthesized AuNPs exhibit selective cytotoxicity on cancer cells, but not healthy counterparts and highlights the higher level of safety profile as compared to counterparts made using chemicals. Silver nanoparticle (AgNPs) was synthesized by using environmentally friendly synthesis that uses herbal extracts and exhibit strong anticancer effects by various mechanisms such as the production of reactive oxygen species (ROS), mitochondrial dysfunction, and regulation of apoptosis [19]. Green-synthesized AgNPs against colon cancer demonstrated selective cytotoxicity with IC_{50} values that were much lower than those of chemically synthesized counterparts, which was attributed to retained bioactive compounds of plant extracts that gave it better biocompatibility and bioactivity.

Zinc oxide nanoparticles (ZnO NPs) are a new platform based on the potential of the biological targeting of the novel nanoparticles that ties together the biological properties of zinc as an essential micronutrient and the rate of targeting. The encapsulation efficiency of znO nanoparticles conjugated with metformin and folic acid was 95-98 %, and the IC_{50} was much lower than controls of the free drugs, showing better cytotoxic effects with melanoma and bladder cancer cells [20]. The physiological functions of zinc as a trace element make the ZnO NPs less toxic with respect to other inorganic nanoplatforms.

Stimuli-Responsive and Multifunctional Nanoarchitectures

Stimuli-responsive nanocarriers are the paradigm shift in targeted phytochemical delivery, by creating site-specific delivery of cargo in response to endogenous or exogenous stimuli, making it possible to deliver drugs selectively to malignant sites due to the acidic microenvironment occurring in the solid tumor (versus physiological pH) [21]. functionalized ZnO nanoparticles with phenylboronic acid functional groups to make them pH-responsible in curcumin delivery showed selective release of the particle in tumor tissue followed by apoptotic cell death of MCF-7 breast cancer cells using oxidative stress and mitochondrial damage pathways. By taking advantage of the increased glutathione (GSH) levels in the cancer cells compared to the extracellular surroundings, Redox-responsive systems initiate the cleavage of disulfide bonds and cargo release. Similar nanocarrier nanomaterials based on matrix metalloproteinase (MMP)-responsiveness can also utilize the tumor microenvironment-specific proteolytic enzyme activity to enable spatial and temporal control of phytochemical bioavailability. Light-responsible systems use photosensitizing reagents allowing either near-infrared (NIR) or ultraviolet activation, which sets free therapeutic cargo with photothermal ablation implications.

Molecular Mechanisms of Nano-Phytochemical-Induced Cancer Cell Death

Apoptosis Induction Mechanisms

Apoptosis is the most common cell death mechanism (Figure 2) activated by nano-delivered phytochemicals on different cancer models. Dysregulation of Bcl-2 protein family with increased expression of pro-apoptotic ones (Bax, Bak, Bad) and decreased expression of anti-apoptotic ones (Bcl-2, Bcl-xL) causes the intrinsic apoptotic pathway and is triggered by mitochondrial outer membrane permeabilization (MOMP). Compounds delivered through nanotechnology are found to exhibit increased apoptosis in cancerous cells of the breast which have high expression of p53 and Bax with suppression of Bcl-2 [22]. The release of cytochrome c through damaged mitochondria leads to the initiation of apoptosome formation Apaf-1 (apoptotic protease activating factor-1), pro-caspase-9 and cytochrome c [23]. The activation of caspase-9 then triggers the executioner caspase cascade, which includes caspase-3 and caspase-7 that catalyze substrate degradation and typical apoptotic morphological alterations such as chromatin condensation, nuclear fragmentation, and membrane blebbing. Aggregates of phytochemical-functionalized

nanoparticles showed significant induction of apoptosis by targeting caspase pathways, which were mechanistically supported by the rise in caspase-8 and ROS levels [24]. The extrinsic apoptotic pathway which is triggered by the engagement of death receptors (Fas, TNF receptor family members) also leads to the convergence into caspase activation by death-inducing signaling complex (DISC) formation [23]. Natural phytochemical combinations are found to have the greater ability to activate the two apoptotic pathways in a synergistic manner. Functionalized gold nanoparticles loaded with doxorubicin and resveratrol exhibited increased anticancer cell cytotoxicity which can be explained by the effect of synergetic apoptosis via the combined pathways [25].

Reactive Oxygen Species Generation and Oxidative Stress

One of the key mechanistic nodes by which the nano-phytochemicals have cytotoxic effects on cancer cells is the ROS generation. Nanoparticle-controlled ROS formation takes place in various ways such as electron transfer reaction induced by metal nanoparticles, activation of a photosensitizing agent, and mitochondrial destabilization of electron transfer chain by phytochemicals [26]. Green-synthesized silver nanoparticles exhibited dose-dependent ROS formation of colon cancer cells with a corresponding reduction in the activity of antioxidant enzymes such as superoxide dismutase (SOD) and catalase, which collectively caused the shift of the cellular redox balance to favor pro-death signaling.

The massive build-up of ROS triggers mitochondrial dysfunction by lipid peroxidation of inner mitochondrial membrane, uncoupling of oxidative phosphorylation, and membrane potential loss. On the other hand, the use of nanoparticles as a method of administration of antioxidants gives a paradoxical therapeutic perspective as too much antioxidant activity will paradoxically reduce the effectiveness of chemotherapy in ROS scavenging [26]. This two-fold nature of oxidative stress requires complex nanoformulation methods that could allow maximum ROS control that preserves pro-apoptotic signaling and minimizes normal tissue collateral damage. DNA damage is a pathological effect of over-accumulation of ROS, which occurs in the form of single-strand breaks, double-strand breaks, and base modifications. The Berberine loaded nano-delivery systems showed a higher DNA damage response of upregulating the ATM-mediated. checkpoint signaling and the p53-dependent transcriptional activation of the apoptotic target genes. The ROS-contingent lipid peroxidation also triggers the lipid-based reactive intermediates capable of the covalent alteration of cellular proteins, which promotes a cascade of pro-death signaling.

Cell Cycle Arrest and Proliferation Inhibition

Nano-phytochemical interventions exhibit a stunning ability to block cell cycle progression at various points, most of them at G0/G1 and G2/M stages [24]. Inhibition of the cyclin-dependent kinase (CDK) is one of the major mechanisms with quercetin and baicalin as examples of phytochemicals showing significant inhibition of CDK2, CDK4, and CDK6 activities alongside hypophosphorylation of the retinoblastoma protein and decreased transcription of E2F. G1 arrest was observed with mesoporous silica nanoparticles loaded with chrysin which interacts with the CDK and downregulates cyclin D1 in breast cancer cells [27]. Another key mechanism is the activation of cell cycle checkpoints mediated by p53, which is essential especially in tumors that still express wild-type p53. The detection of DNA damage by ATM/ATR kinases leads to p53 stabilization and progressive protein levels and transcription of CDK inhibitors such as p21 (CDKN1A) and p27 (CDKN1B). In these inhibitory proteins, the assembly of cyclin-CDK complex is inhibited, which inhibits progression to the S-phase and allows DNA repair prior to lesion replication. Nanoparticles made with polyphenols exhibited cell cycle arrest of colorectal cancer cells with accumulation of G0/G1 and corresponding proliferation inhibitory proteins such as Ki-67 and cycline E [14].

Angiogenesis Inhibition and Anti-Metastatic Effects

One confirmed therapeutic target that can be utilized by various phytochemicals is tumor angiogenesis, the process of developing vasculature that is necessary to deliver nutrients to the body and eliminate waste products. Phytochemicals in nano-delivery inhibit angiogenesis by blocking vascular endothelial growth factor (VEGF) signaling, inhibiting transcription of pro-angiogenic genes and inducing endothelial cell cytotoxicity. Nanoparticles with quercetin and resveratrol showed inhibitory effects of tube formations and cellular migration of human umbilical vein endothelial cells (HUVECs), indicating direct anti-angiogenic effects. A cellular program that is

necessary to promote metastatic diffusion is epi-thelial-mesenchymal transition (EMT) which is significantly prevented by nano-phytochemical delivery. Nano-particles of berberine showed significant inhibition of EMT transcription factors (Snail, Slug, Twist) along with the recovery of E-cadherin and inhibition of N-cadherin and vimentin. The associated phenotypic reversion into epithelial phenotypes with lower migratory ability decreases the metastatic ability. Similarly, nano-delivered phytochemicals inhibit the expression of metalloproteinase (MMP) which inhibits extracellular matrix degradation and basement membrane breaching that is essential in invasion [24]. The simultaneous anti-migratory signaling, EMT inhibition, and direct cytotoxicity make nano-phytochemical platforms very useful in the prevention of the local invasion and distant dissemination metastases.

Preclinical and Clinical Evidence

***In Vitro* Efficacy Studies**

In vitro studies have shown that nano-phytochemical preparations have better anticancer activity compared to free phytochemical controls in a wide variety of cancer cell lines. PLGA nanoparticles containing curcumin exhibited an IC_{50} that was about 3-5 times less than free curcumin with respect to various breast cancer models, which is believed to be due to the increased uptake into cells and longer maintenance of intracellular drug concentration [13]. Likewise, HPV-related cervical cancer was targeted by quercetin-loaded chitosan nanoparticles and was found to have a better IC_{50} value as compared to unbound quercetin [28]. The nanoparticles made of polyphenols showed greater cytotoxicity of colorectal cancer cells and low IC_{50} values and high populations of annexin V-positive populations. Nano-formulated berberine was found to be more effective against cancer cells with high levels of response to ROS generation and DNA damage [9]. The triple phytochemical nanoformulation had good in vitro properties as the formulation had a cytotoxicity assay IC_{50} of 365 µg [14].

***In Vivo* Tumor Xenograft Studies**

The use of nano-phytochemical platforms has proven to be the best delivery system to achieve better therapeutic effects in vivo as studied in immunocompromised mouse models that have human tumor xenografts. Mesoporous silica nanoparticles with chrysin and folic acid conjugates exhibited considerable tumor regression in breast cancer-bearing mice with improved and higher accumulation at tumors and restored folic acid-conjugated folic acid-chrysin nanoparticles. Nanoparticles charged with chrysin led to significant growth retardation of tumors relative to chrysin controls administered orally, and no severe systemic toxicity occurred. Nano-delivered baicalin showed deep antitumor activity in breast tumor-bearing mice where tumor growth inhibition was associated with an increase in caspase and ROS intratumor tissues that were excised. Nanoparticles carrying berberine also demonstrated increased anti-cancer activities in cancer models where there was increase in survival rates compared with control of berberine administration.

Nanoformulations containing herbal bioactive compounds that are novel and loaded showed improved antitumor activity in different xenograft models bearing different genes expression profiles indicative of activation of apoptotic pathways and cell cycle stasis. Remarkably, nanoparticle treated animals retained their body weight and showed enhanced health conditions than traditional chemotherapy treated ones indicating a lesser systemic toxicity.

Clinical Trial Landscape

There is a deficit of clinical translation of nano-phytochemical platforms with most of the therapeutics in preclinical developmental phases. Nevertheless, certain formulations have progressed to human clinical trial giving some early indications of clinical usefulness. Formulations of green tea extracts in nanocarrier systems, which have been under evaluation in clinical trials against several types of malignancies, have shown an initial positive safety profile with limited benefit efficacy. A number of nano-phytochemical preparations have made their way into early-phase clinical testing as part of investigator-initiated trials, but there is only a limited amount of Phase II/III efficacy information on these preparations. Regulatory environment keeps on changing with a growing understanding of nanoparticle platforms as a distinct regulatory body that needs systematic safety, efficacy, and manufacturing quality assessments. Without any doubt, the most significant clinical progress issues are the complications of scale-up manufacturing, the cost-effectiveness aspect, and the uniformity of phytochemical source material [29].

Challenges in Clinical Translation and Future Perspectives

Manufacturing and Scale-Up Challenges

This is a daunting aspect when trying to scale the laboratory-scale nano-phytochemical formulations to clinically relevant amounts [29]. Both polymeric and lipid-based, and metal-derived nanoparticles. The synthesis methodologies of nanoparticles exhibit intrinsic batch-to-batch variability due to subtle process parameter dependencies such as temperature, pH, mixing rates, solvent evaporation behavior, and the distribution of polymer molecular weights. Reproducible production of nanoparticles with uniform size distributions, zeta potential, encapsulation efficiencies, and drug release characteristics across scale of manufacturing are a key requirement to regulatory approval (Figure 3). Although green synthesis methods have the benefits of sustainability and biocompatibility, they also add to the complexity due to the variability of plant extracts that can be ascribed to the heterogeneity of botanical source materials, seasonality and inconsistency in the extraction methods [18]. Standardization procedures that define botanical source material botanical variety, growth, harvesting and extraction parameters are not fully developed. The change in liquid-phase chemistry-based on small-scale production to a solid-state and spray-drying-based manufacturing process is a major area of concern that requires a large-scale development of the process and optimization of scale transfer [29].

The cost-effectiveness factor also imposes considerable limitation on the opportunities of translation, especially on the case of phytochemical-based nanoparticles that need a lot of purification and characterization. Even with the ability of the cost of manufacturing PLGA nanoparticles to decrease due to economies of scale, the cost is still large compared to small-molecule therapeutics, and this hinders the competitiveness in the market unless the therapeutic benefits are considerable and the prices are high to reflect the superior therapeutic benefits.

Regulatory and Safety Considerations

The regulations governing nano-phytochemical preparations are yet to be established and therefore there is a lot of doubt about the requirements to be met in terms of approval. Regulatory bodies are now appreciating the fact that nanoparticles are different regulatory entities, and that they must be documented as to their safety in a thorough way as compared to that required of conventional formulations. Of particular concern are the biodistribution patterns, organ localization, and the long-term retention of nanoparticles, possible toxicity of nanocarrier materials, and immunogenicity. The variability in phytochemicals as obtained by botanical origin requires standardization procedures that determine the quantitative parameters of the active constituent composition, hence guaranteeing consistency of batches and reproducible therapeutic responses. Also, metabolic characterization of the metabolites formed by hepatic metabolism of phytochemicals and the degradation products of nanocarrier requires an extensive evaluation of toxicity. The safety of most nano-phytochemicals platforms in long-term safety studies on the potential of delayed adverse effects, malignant transformation, or organ toxicity are limited [29].

Bioavailability Enhancement and Overcoming Biological Barriers

Although nanotechnology enhances phytochemical solubility and uptake by cells significantly, the residual bioavailability constraints remain, especially in case of oral administration [29]. Blood-brain barrier (BBB) permeability is an essential factor in neurological malignancies, and, in general, the majority of nanoparticles exhibit low BBB penetration without the inclusion of special targeting ligands or size engineering [21]. Functionalization of the surface with BBB-penetrating peptides or transcytosis-stimulating ligands is a promising approach but is not feasible in clinical practice due to their cost-effectiveness and lack of clinical feasibility. Permeation barriers in the intestine also limit oral bioavailability of encapsulated phytochemicals, requiring formulation strategies that use permeation enhancers or use nanoemulsion technologies that allow a better absorption by the intestines. The intestinal and hepatic enzyme metabolism of phytochemicals is counterintuitive and works as fast as it can be under nanoparticle-enhanced bioavailability, decreasing the overall drug exposure to the system unless prevented by chemical modification or encapsulation in enzyme-resistant carriers.

Strategies to Overcome Current Limitations

To cope with the challenges stated, the multifaceted strategies will involve the enhancement of formulation technologies, standardization methods, the combination therapies, and long-term safety studies. The high-pressure homogenization, microfluidic synthesis, and supercritical fluid processing are also advanced formulation methods that provide a prospect of increased manufacturing consistency and scalability [30]. Nanoarchitectures based on stimuli-responsible release of cargo at the required site are dynamic approaches to minimizing off-target toxicity and maximizing tumor-specific therapeutic efficacy [21]. Synergistic anticancer effects are evidenced by co-delivery of complementary therapy agents using conventional chemotherapeutic agents and phytochemicals, which are synergists. Simultaneously, engineered multifunctional nanoparticles derived by introducing radiotherapy sensitizers, chemotherapeutic agents as well as phytochemicals permit the use of combinatorial therapeutic modalities in individual nanosystems. Liposomal-polymeric hybrid nanoparticles with co-loading phytochemicals and chemotherapeutics are found to be more cytotoxic to various cancerous cell lines [31].

Individual medicine strategies based on genomic profiling and phytochemical pharmacogenomics are new paradigms, which allow selecting therapy according to strata of patients. Rational design of nanocarrier systems that promote optimal combinations of phytochemicals and targets is achieved with the help of computational techniques such as molecular docking, molecular dynamics simulations, and machine learning algorithms. The use of waste plant-based materials and the use of solvents that are environmentally friendly in green chemistry practices allow the production of nanoparticles on a sustainable basis in line with the modern environmental sustainability demands.

Future Directions and Emerging Technologies

New nanotechnologies such as quantum dots, carbon nanotubes, and graphene-based nanocarriers present new platforms to deliver phytochemicals with unique physicochemical characteristics of multimodal therapeutic and diagnostic applications. Graphene oxide systems are characterized by superior biocompatibility, high surface area to load drugs and inherent photothermal characteristics to provide combinatorial chemotherapy and photothermal ablation capabilities within a single nanosystem. Exosome-based drug delivery platforms are a paradigm shift, which takes advantage of endogenous cellular nanovesicles which inherently enjoy targeting properties and immunotolerance attributes [32]. Exosomes made of plants and synthetic exosomes allow the delivery of phytochemicals or genetic material target cells with greater biocompatibility as compared to synthetic nanoparticles. Nano-phytosomes technologies based on phospholipid-phytochemical interactions allow the generation of bioactive complexes that are more stable and can be eaten by the cell than the individual compounds [33]. New technologies of artificial intelligence and machine learning considerations increasingly dictate rational design of nanocarrier systems, estimating the ideal formulation parameters, potential adverse effects, and patient groups that have the highest likelihood of responding positively to a particular nano-phytochemical platform. With high-throughput screening technologies, it is now possible to quickly investigate nanoparticle physicochemical properties and biological activity, speeding up the process of translation.

CONCLUSION

The delivery of phytochemicals using nanotechnology creates a paradigm shift in the oncologic therapies in response to long-term bioavailability and targeting of the naturally occurring compounds. Extensive preclinical studies have proven that nano-encapsulation of various phytochemical classes increase anticancer effects significantly by a variety of molecular mechanisms including ROS generation, induction of apoptosis, arresting cell cycles, and inhibiting key survival signaling pathways. Multifaceted nanocarrier frameworks based on biodegradable polymeric vehicles to biocompatible lipid-based and metal-derived nanoparticles provide different benefits in realizing different phytochemical cargoes as well as targeting and controlled-release approaches.By blending the wisdom of traditional herbal medicine with the new nanotechnological advances, novel possibilities of developing the next generation of anticancer drugs with higher efficacy and safety profiles are created. Nonetheless, there are still significant obstacles concerning the scalability of the manufacturing process, clarification of the regulatory route and extensive safety

documentation and the issue of cost-efficiency. These encouraging preclinical results would require the strategic investment in process development, standardization methodology and long-term clinical investigation to translate such promising results into the development of clinical therapies that have potential impact on patient populations all over the world. Nano-engineered phytochemical platforms are becoming an integral element in the future of cancer therapies as adjunctive or alternative therapies to traditional chemotherapy, especially in those patient groups that prove to be chemotherapy intolerant or drug-resistant cancers.

ABSTRACT

Trametes versicolor, also called "turkey tail" mushroom, is a well-known medicinal fungus recognized for its wide-range of pharmacological potential and diverse phytochemicals. This review compiles and evaluates current literature on the morphological, microscopic, chemical and biological properties of T. versicolor to provide a thorough understanding of its therapeutic significance. Morphologically, the species has a fan-shaped, multi-coloured fruiting body with concentric rings of various colours and a velvety surface. Microscopic analysis shows a hyphal structure that includes both generative and skeletal hyphae, along with cylindrical and smooth basidiospores. Phytochemical studies have discovered several bioactive components, such as PSP and PSK, β-glucans, phenolic compounds, triterpenoids, flavonoids, sterols, and glycoproteins. These substances have been recognized through chromatographic and spectroscopic methods, including FTIR, HPLC, GC-MS, and NMR. Notably, protein-bound polysaccharides like PSK and PSP have been linked to immunomodulatory, antioxidant, anticancer, antimicrobial, and liver-protective effects. Biological assessments show that extracts of *Trametes versicolor* have significant radical scavenging, anti-inflammatory, cytotoxic, and antimicrobial effects. These effects occur through the modulation of immune pathways and oxidative stress mechanisms. Additionally, the mushroom's components may work together to boost the host's immune defence and slows down tumour growth. Despite extensive research, standardizing extraction methods, isolating compounds, and conducting bioactivity tests remain challenging. This evaluation emphasizes the significance of T. versicolor as an important resource of natural therapeutic agents and stresses the need for better phytochemical profiling, detailed biological studies, and clinical validation to fully utilize its pharmacological potential.

Keywords: Medicinal mushrooms, Trametes versicolor, Polysaccharopeptide (PSP), PSK, Immunomodulatory activity, Anticancer properties, Antioxidant activity, antimicrobial activity

INTRODUCTION

In recent decades, mushrooms have attracted considerable interest as functional foods and sources of biologically active substances. Various Trametes Various species have been utilized for centuries in traditional medicine, especially in East Asia, but T. versicolor is the most extensively researched. [1] Trametes, a type of agaric mushroom in the order Polyporales, is a saprophytic fungus that thrives on decaying logs or wood.[2] It is characterized by thin-walled basidiospores, a pore-like hymenophore, three types of hyphae, and features both a cap and a basidioma.[3] As noted by Species Fungorum, a total of 195 species of Trametes are documented worldwide.[4] T. versicolor is a medicinal fungus acknowledged for its various biological impacts, including boosting the immune system,[5] fighting tumours,[6] and showing antiviral properties.[7] A preventive compound known as PSK has been proven effective in slowing cancer development.[8] PSK, or Krestin, is a protein-bound polysaccharide derived from *Trametes versicolor* mycelia.[9] It received authorization for cancer treatment from the Japanese Ministry of Health and Welfare in 1977, signifying the first time this organization approved a polysaccharide-based antitumor medication. The majority of research conducted thus far has concentrated on the polysaccharide fraction, which contains β-glucans. These are polymers of D-glucose, frequently associated with components such as glucuronic acids, arabinose, mannose, fucose, galactose, and xylose. In addition to polysaccharides, scientists have discovered 18 distinct amino acids, such as aspartic acid, threonine, serine, glutamic acid, glycine, alanine, valine, and leucine.[10] This investigation analyzed the overall phenolic compounds, total flavonoid content, and antioxidant properties of three different extracts from Trametes versicolor. Phenolic compounds were detected through UV-Vis and FTIR spectroscopy, in addition to liquid chromatography paired with mass spectrometry (LC-MS).[11]

Cultivation

Because of its medicinal significance, an initiative to cultivate *Trametes versicolor* has been started at ICAR-DMR in Solan. The culture was developed on malt extract agar by incubating inoculated Petri dishes in darkness at 25±2°C for two weeks. For spawn creation, fresh mycelium was grown on boiled wheat seeds treated with 2% calcium carbonate and 0.5% calcium sulphate.[12] Mycelial colonization of the wheat grains was achieved after 15 days at 25±1°C. For fruiting, the substrate included wheat straw enriched with 5-15% wheat bran. Additionally, 1% calcium carbonate and 1% calcium sulphate (based on dry weight) were added to manage pH levels. The prepared substrate was soaked in water for 24 hours. After draining excess water to reach a moisture content of 65%, 1 kg of substrate was placed into polypropylene bags, then autoclaved at 126°C and 22 psi for one hour. Once prepared and sterilized, the substrate was introduced to Trametes versicolor spawn at 3-5% of the fresh weight of the substrate within a laminar flow chamber.[13] It was then moved to a dark growth room at 25 ± 1°C to complete the spawn run. After finishing the spawn run, the bags were transferred to the fruiting phase, where the temperature was lowered to 20±1°C. The relative humidity was increased to 85±5%, and light was provided for 8-12 hours daily. The fruiting bodies can be harvested 35-40 days after the spawning stage. [14,15,16]

Morphology

Trametes versicolor primarily grows as a saprobic polypore and sometimes shows weak parasitic traits, commonly on dead or dying deciduous hardwood trees, with rare occurrences on conifers. It produces basidiocarps that can cluster, overlap, or arrange in a rosette shape, visible for most of the year.[17] The caps are thin, measuring 1–3 mm thick and 2.5–8 cm wide, displaying the species' distinctive multi-coloured concentric bands—some velvety and others nearly smooth—in white, grey, brown, cinnamon, orange, blue, and red, often with a pale edge. The pore surface appears whitish to pale yellow-brown, contains small pores (3–6 per mm), and has tubular extensions that can reach up to 1.5 mm. [18] The flesh is tough, white, and not very substantial, featuring a unique thin black line in cross-section beneath the cap. The odour and taste are not distinctive, and the reaction to KOH ranges from negative to weakly yellowish. A whitish spore print is produced.[19]

On a microscopic level, T. versicolor has a trimitic hyphal structure featuring clamped generative hyphae and is devoid of cystidia.[20] The basidiospores are hyaline, smooth, and cylindrical, measuring 4.5–5.5 × 1.5–2 μm, while the basidia are 18–20 × 3–4.5 μm and contain four spores.[21]

Chemical Constituents

Medicinal mushrooms, particularly wood-dwelling varieties like polypore species, provide abundant source of biologically active substances that significantly affect human health and help prevent various diseases. They offer pharmacological benefits such as antidiabetic, antitumor, immunomodulatory, cardiovascular, antimicrobial, liver-protective, and antioxidative properties.[22] Nonetheless, the bioactive characteristics of these mushrooms can differ considerably among various strains, and their chemical makeup is primarily influenced by the environmental factors in which mycelia develop. [23].

Trametes versicolor is high in polysaccharides, including heteroglycan macromolecules that show substantial potential for structural diversity. Glucans have been extracted from *Trametes versicolor* and its mycelium, making them noteworthy therapeutic agents.[24] Moreover, *Trametes versicolor* contains bioactive secondary metabolites, confirmed by various techniques like liquid chromatography-mass spectrometry (LCMS) and nuclear magnetic resonance (NMR) spectroscopy.[25] Numerous studies have reported the bioactive components of T. versicolor, with researchers extracting diverse phenolic acids, flavanols, flavones, coumarins, isoflavonoids, and bioflavonoids from its aqueous, methanolic, and acetone extracts using LCMS.[16] Jin et al. successfully isolated 27 compounds from the fruiting body of T. versicolor, identified through NMR spectroscopy.[26,27,28] These include nine triterpenoids, eight sterols, two ribonucleotides, four phenolic compounds, three glycosides, and one feron. Another study by Habibi et al. investigated the chemical properties of mushroom extracts made in three different solvents: n-hexane, chloroform, and ethyl acetate. They isolated various compounds for the first time, including five sterols, derivatives of two triterpenoids, one hydroquinone derivative, one cerebroside, and one triglyceride derivative. Other isolated compounds included ergosterols, ergosterol peroxide, and betulin. All of these compounds were acquired through thin-layer chromatography and identified via NMR spectroscopic analysis. [29]

T. versicolor contains minerals, vitamins, and carbohydrates. Polysaccharopeptide Krestin (PSK) and polysaccharopeptides (PSP) are two well-known polysaccharopeptides extracted from the mushroom's mycelial culture. Both PSK and PSP are proteoglycans with a molecular mass of 100 kDa and variations in sugar compositions like glucose, fructose, mannose, galactose, and xylose.[30] They are obtained from the COV-1 and CM-101 strains of the mushroom. PSP features glucans without the peptide, consisting of a main chain and branches of β1–3 and β1–6 when extracted extracellularly from the fermentation broth of T. versicolor. PSP extracted intracellularly from the mycelium forms a glycopeptide with covalently linked peptides.[20] PSP has a backbone of β1–4/β1–3 or β1–4/β1–6-linked glucose with branches of β1–3 or β1–6-linked glucose. PSK mainly consists of D-glucose as the key monosaccharide.[31] These proteoglycans from mushrooms are valuable for medicine and are considered promising compounds. Among them, PSP is recognized as a broad-spectrum response modifier.[32] Additionally, PSP has low toxicity and acts as an immunomodulating and anticancer agent. It has been used to boost the immune health of cancer patients undergoing treatments like radiotherapy and chemotherapy, and it also shows analgesic and antiviral effects.[33,34]

Pharmacological Action

Immunomodulating properties: Trametes versicolor is full of various bioactive substances, including antioxidants, polyphenols, terpenes, and protein-bound polysaccharides.[35] These components strengthen both the innate and adaptive immune systems. Many clinical and preclinical research has shown its significant anticancer effects, especially against breast, lung, gastric, and colorectal tumours, mainly through immunomodulatory actions.[36] Its polysaccharide ingredients, such as polysaccharide krestin (PSK) and polysaccharopeptide (PSP), activate monocytes, dendritic cells, and natural killer cells, which leads to increased cytokine production and better elimination of tumour cells.[37] These polysaccharide-peptides act as biological response modifiers, restoring immune balance without

targeting a specific immune pathway. [38,39] Moreover, extracts from T. versicolor act as mitogens, encouraging the growth of T and B lymphocytes and promoting overall immune activation.[40]

Antimicrobial properties

Trametes versicolor demonstrates a broad spectrum of antimicrobial activity. Methanolic extracts show bactericidal effects against both Gram-positive and Gram-negative bacteria, such as Staphylococcus aureus, Escherichia coli, methicillin-resistant Staphylococcus aureus, Pseudomonas aeruginosa, Klebsiella pneumoniae, Listeria monocytogenes, Streptococcus pneumoniae, and Candida albicans.[41] These antimicrobial effects partly result from immune system activation, which involves stimulating polymorphonuclear cells and increasing the release of Cytokines such as tumor necrosis factor and interleukin-1.[42,43] Additionally, T. versicolor has antiparasitic and antifungal properties, showing inhibitory effects against Leishmania amazonensis and Fusarium langsethiae. Protein-bound polysaccharides, particularly PSK, have strong antiviral effects by blocking HIV-1, HIV-2, HTLV-1, and herpes simplex viruses while boosting interferon production and the activity of natural killer cells.[44] PSP further reduces HIV-1 replication by blocking the gp120–CD4 interaction, inhibiting reverse transcriptase, and promoting antiviral chemokines in monocytes and peripheral blood mononuclear cells.[45] Furthermore, preclinical and early clinical research suggests antiviral effectiveness against influenza viruses, herpes viruses, and human papillomavirus, emphasizing the healing possibilities of compounds from *Trametes versicolor*.[46]

Anticancer properties:

Trametes versicolor extracts are widely used as adjuvants in cancer therapy and prevention, with additional applications in anti-aging and antiviral support, and may reduce the risk of secondary malignancies associated with radiotherapy and chemotherapy.[47] In Japan and China, polysaccharide peptides such as polysaccharide krestin (PSK) are clinically employed alongside surgery, chemotherapy, and radiation, where they inhibit tumor growth and enhance therapeutic outcomes, particularly in colorectal and intestinal cancers.[48,49] PSK exerts anti-invasive effects by downregulating key metastasis-related factors, including TGF-β1, uPA, and matrix metalloproteinases, without adversely affecting cell viability.[50] Furthermore, *T. versicolor* mycelial extracts and enzymes demonstrate anti-melanoma, anti-tyrosinase, and melanin-decolorizing activities, supporting their potential application in managing skin pigmentary disorders.[51]

CONCLUSION

Trametes versicolor is a medically important mushroom with a rich variety of phytochemicals and extensive pharmacological significance. Studies indicate that it has restorative properties properties mainly come from protein-bound polysaccharides like PSK and PSP, along with β-glucans, phenolic compounds, triterpenoids, sterols, and glycoproteins. In combination, these elements provide robust immunomodulatory, antioxidant, antimicrobial, antiviral, and anticancer effects, supported by substantial in vitro, in vivo, and clinical findings. The roles of PSK and PSP as biological response modifiers in enhancing immune functions, inhibiting tumour growth, and increasing the success of conventional cancer treatments highlight their clinical value, particularly for colorectal and other solid tumours. Besides its cancer-fighting properties, *Trametes versicolor* also shows promising antibacterial and antiviral effects against multidrug-resistant bacteria, harmful fungi, and various important viruses, expanding its therapeutic applications. Advances in analytical methods like LC-MS, NMR, FTIR, and chromatographic profiling have improved our understanding of its complex chemical structure. However, variations in strain, growing conditions, and extraction methods still create challenges for standardization and reproducibility. In summary, *Trametes versicolor* is an important source of bioactive substances with great potential for practical use. Future studies should concentrate on developing standardized cultivation and extraction methods, studying mechanisms in depth, and conducting well-structured clinical trials to fully realize its therapeutic potential and support its integration into evidence-based medicine and pharmacy.

ABSTRACT

Graham and Sloane [2] initiated the harmonious graphs. Singh and Varkey [3] developed the odd sequential graphs. Gayatri and Muthuramakrishnan ([4], [1]) instigated the $k-$odd sequential harmonious labeling of graphs. In this slog, we bequest the pattern and restrict the constraints for the $k-$ odd sequential harmonious labeling.

Keywords: Odd Harmonious Labeling, Degree, Consecutive Numbers.

INTRODUCTION

In this exertion we deliberate connected , finite simple and undirected graphs. A graphs $G = (V, E)$ with 'p' vertices and 'q' edges is called a (p, q) graphs. The graph labeling is an assignment of integers to the set of vertices or edges or both subject to certain condition. A graph is said to be harmonious if there exist an injection $f: V(G) \to \{0,1,2,\ldots.2q-1\}$ such that the induced function$f^+: E(G) \to \{0,1,2,..2q-1\}$ defined by $f^+(uv) = (f(u) + f(v)(q-1)$ is a bijection and $f$is said to be harmonious labeling of G. In [4] Gayatri and Muthuramakrishnan say that a labeling is a k-odd sequential harmonious labeling for any integer $k \geq 1$. A labeling is a k-odd sequential harmonious labeling if there exists an injection f from the vertex set V to $\{k-1,\ k, k+1.\ldots k+2q-1\}$ such that the induced mapping $f^+$from the edge set E to $\{2k-1,2k+1,\ldots..2k+2q-3\}$ defined by.

$f^+(uv) = \{f(u) + f(v) \quad if\ f(u) + f(v)\ is\ \ odd\, f(u) + f(u) + 1 \quad if\ \ f(u) + f(v)\ is\ even$ are distinct

A Graph G is said to be *k*-odd sequential harmonious graphs if it admits a *k*-odd sequential harmonious labeling. This effort, is based on the restrictions for the *k*-odd sequential harmonious labeling on degree of the vertices – odd and even values to a vertex label – consecutive four natural numbers. Throughout this paper, *k* denotes any positive integer ≥ 1. for brevity, we use $k - OSHL$for k-odd sequential harmonious labeling.

MAIN RESULTS

Definition 2.1 [8]

The number of edges incident on a vertex v with self-loops counted twice is called the degree of the vertex v. *H*is denoted by $d(v)$.

Definition 2.2 [8]

A Graph in which any two distinct vertices are adjacent is called a complete graph and it in denoted by k_p

Theorem (1)

Let G be a k-odd sequential harmonious labeling graph and $G^1 = p_3$ say $v_1e_1v_2e_2v_3$ be an subgraph of G and $P_3$is labeled with three consecutive integers in any order (as in fig.1)

(i) $if\ \ f(v_1) < f(v_3),\ \ f(v_1)\ is\ odd\ and\ f(v_3)$ is even then $f(v_2)$ cannot be odd

(ii) $if\ \ f(v_1) < f(v_3),\ \ f(v_1)\ is\ even\ and\ f(v_3)$ is odd then $f(v_2)$ cannot be even.

Proof

Case (i)

Consider $if\ \ f(v_1) < f(v_3),\ \ f(v_1)\ is\ odd\ and\ f(v_3)$ is even

Let $x, x+1, x+2$ be 3 consecutive integers.

Case 1.1

Let x be odd then

$f(v_1) = x,\ f(v_2) = x + 2\ , f(v_3) = x + 1$

$f^+(v_1v_2) = x + x + 2 = 2x + 2 = 2x + 3$ → (1) [By definition of *k-OSHL*]

$f^+(v_2v_3) = x + 2 + x + 1 = 2x + 3$ → (2)

$\Rightarrow \quad \Leftarrow$

$\therefore\ f(v_2)$ should be even.

Case 1.2

Let x be even then $f(v_1) = x + 1\ ,\ \ f(v_2) = x\ \ ,$ f(v3) = x + 2

$f^+(v_1v_2) = x + 1 + x = 2x + 1$ → (3)

$f^+(v_2v_3) = x + x + 2 = 2x + 2 = 2x + 3$ → (4) [By definition of *k-OSHL*]

From (3) & (4)

It is possible that $f(v_2)$ is even.

$\therefore\ f(v_2)$ cannot be odd.

Case (ii)

Consider $f(v_1) < f(v_3),\ \ f(v_1)\ is\ even\ and\ f(v_3)$ is odd.

Case 2.1

Let x be odd then $f(v_1) = x + 1,\ f(v_2) = x,\ f(v_3) = x + 2$

$f^+(v_1v_2) = x + x + 1 = 2x + 1$ → (5)

$f^+(v_2v_3) = x + x + 2 = 2x + 2 = 2x + 3$ → (6) [By definition of *k-OSHL*]

From (5) & (6)
$f(v_2)$ is odd
$\therefore$ $f(v_2)$ cannot be even.

Case 2.2
Let x be even then $f(v_1) = x$, $f(v_2) = x + 2$, $f(v_3) = x + 1$
$f^+(v_1v_2) = x + x + 2 = 2x + 2 = 2x + 3$ → (7) [By definition of *k-OSHL*]
$f^+(v_2v_3) = x + 2 + x + 1 = 2x + 3$ → (8)
⇒ ⇐
$\therefore$ $f(v_2)$ is not even.
Hence the theorem.

Theorem 2
Let G be a odd sequential harmonious labeling of graphs. If 'a' is the vertex label then the adjacent vertex cannot have the vertex label greater than or equal to $2q - a$.

Proof
Let v be a vertex in $G$with $f(v) = a, v_1$be a vertex adjacent to v then there exist an edge $e_1 = (v, v_1)$

Claim: $f(v_1) = b \leq 2q - a - 1$ or if not then $f(v_1) = b > 2q - a - 1 \geq 2q - a$ w.l.o.g let $f(v_1) = 2q - a$.
$\because$ G is a odd sequential harmonious labeling and

$$f^*(e) = \begin{cases} f(v) + f(v_1) & if\ f(v) + f(v_1)\ is\ \ odd \\ f(v) + f(v_1) + 1 & if\ \ f(v) + f(v_1)\ is\ even \end{cases}$$

$\therefore$ $f^*(e) = 2q$ which is greater than $2q - a - 1$
⇒ which is out of range.
⇒ ⇐ to a is odd sequential harmonious labeling.
∴ It is evident from the proof that the adjacent vertex cannot have the vertex label greater than or equal to $2q - a$.
Hence the theorem.

Theorem 3
Let G be a *k*- odd sequential harmonious labeling and $G' = F_3$ be a subgraph of G. then G' cannot have consecutive vertex labeling.

Proof
Given $G$is a *k*-odd sequential harmonious labeling with $G' = F_3$ as a subgraph. Then the labeling of $G' = F_3$ is shown in figure 2. It is clear that F_3has 4 vertices. Let $x, x + 1, x + 2, x + 3$ be four consecutive integers.

Case (1)
Let x be vertex label of the vertex with degree 2.
w.l.o.g let the vertex label of a be x.
w.l.o.g Let x be odd.

Sub case 1.1
Let the vertex of *c* be $x + 1$
w.l.o.g Let $f(d) = x + 3$, $f(b) = x + 2$ then the graph is
(Fig 3)

Here there is a subgraph P_3 such that $f(b) = x + 2$, $f(d) = x + 3$, f(c)=x+1
(Fig 4).

then the resultant edge labels are
$f^+(bd) = x + 2 + x + 3 = 2x + 5$
$f^+(dc) = x + 3 + x + 1 = 2x + 4 = 2x + 5$ [By definition of *k-OSHL*]
$\Rightarrow \Leftarrow$ to both edge labels are same.

The same argument can be applied on inter changing the vertex label of b and d.
(Here the $P_3 = dbc$)

Sub case 1.2

Let the vertex label of c be $x + 2$
w.l.o.g Let $f(d) = x + 3$, $f(b) = x + 1$ then the graph is
(Fig 5).
Here there is a subgraph P_3 such that $f(b) = x + 1$, $f(d) = x + 3$, $f(c) = x + 2$
(Fig 6).
then the resultant edge labels are
$f^+(bd) = x + 1 + x + 3 = 2x + 4 + 1 = 2x + 5$
$f^+(dc) = x + 3 + x + 2 = 2x + 5$
$\Rightarrow \Leftarrow$ to both edge labels are same.
The same argument can be applied on interchanging the vertex label of b and d.
(Here the $P_3 = dbc$).

Sub case 1.3

Let the vertex label of c be $x + 3$
w.l.o.g let $f(d) = x + 2$, $f(b) = x + 1$ then the graph is.
(Fig 7).
Here there is a subgraph P_3such that $f(a) = x$; $f(d) = x + 2$, $f(b) = x + 1$
(Fig 8).
then the resultant edge labels are
$f^+(ad) = x + x + 2 = 2x + 2 = 2x + 3$
$f^+(db) = x + 2 + x + 1 = 2x + 3$
$\Rightarrow \Leftarrow$ to both edge labels are same.
The same argument can be applied on interchanging the vertex label of b and d.
(Here the $P_3 = dab$).

Case 2

Let x be the vertex label of the vertex with degree 2.
w.l.o.g let the vertex label of 'a' be x.
Let x be an even number.

Sub case 2.1

Let the vertex label of 'c' be $x + 1$
w.l.o.g let $f(d) = x + 3$, $f(b) = x + 2$
(Fig 9)
Here there is a subgraph P_3 such that $f(b) = x + 2$, $f(d) = x + 3$, $f(c) = x + 1$
(Fig 10).
then the resultant edge labels are
$f^+(bd) = x + 2 + x + 3 = 2x + 5$
$f^+(dc) = x + 3 + x + 1 = 2x + 4 + 1 = 2x + 5$

$\Rightarrow \Leftarrow$ to both edge labels are same.
The same argument can be applied on interchanging the vertex label of *d* and *c*.
(Here the $P_3 = bcd$).

Sub case 2.2

Let the vertex label of c be $x + 2$
w.l.o.g let $f(d) = x + 3$, $f(b) = x + 1$ then the graph is.
(Fig 11).
Here there is a subgraph
(Fig 12).
then the resultant edge labels are
$f^+(bd) = x + 1 + x + 3 = 2x + 4 + 1 = 2x + 5$
$f^+(dc) = x + 3 + x + 2 = 2x + 5$
$\Rightarrow \Leftarrow$ to both edge labels are same.
Similar argument can be applied on interchanging the vertex label of *b* and *d*
(Here the $P_3 = dbc$).

Sub case 2.3
Let the vertex label of *c* be $x + 3$
w.l.o.g let $f(d) = x + 2$ then the graph is.
(Fig 13).

Here there is a subgraph P_3 such that $f(a) = x$, $f(d) = x + 2$, $f(b) = x + 1$
(Fig 14).
Then the resultant edge labels are
$f^+(ad) = x + x + 2 = 2x + 2 = 2x + 3$
$f^+(db) = x + 2 + x + 1 = 2x + 3$
$\Rightarrow \Leftarrow$ to both edge labels are same.
The same argument can be applied on interchanging the vertex label of *a* and *d*
(Here the $P_3 = dab$).

Case 3
Let *x* (odd / even) be the vertex label of the vertex with degree 3.
w.l.o.g let x be the vertex label of the vertex d. that is $f(d) = x$
$\because$ *d* is adjacent to all other vertices w.l.o.g we can give the remaining vertex label as
$x + 1$, $x + 2$, $x + 3$ randomly to other vertices.
Here we have a subgraph $k_1, 3$ with root vertex as *d*.
(Fig 15).
w.l.o.g let $f(a) = x + 1$, $f(b) = x + 2$, $f(c) = x + 3$
then the resultant edge labels are
$f^+(bd) = x + 2 + x = 2x + 2 = 2x + 3$
$f^+(cd) = x + 3 + x = 2x + 3$
$\Rightarrow \Leftarrow$ to both edge labels are same.
Similar argument can be given for the vertex *b* with label *x*.
Hence we conclude from the above proof that the case 1 is for odd and case 2 is for even , x cannot be the vertex label of the vertex with degree 2 for F_3 graph.
In **case 3,** x cannot be a vertex label of the vertex with degree 3.
Thus, from the above three cases x cannot be the vertex label for the vertices with degree 2 and 3.
Thus, we have found a starting value for any consecutive 4 numbers which cannot be labeled with x, which is a vertex label for F_3 .

Hence the theorem.

Theorem 4

If G is a *k*-odd sequential harmonious labeling graph and let $G' = K_5$ be the subgraph of G, then G cannot have 4 consecutive vertex label.

Proof

Given G is a *k*-odd sequential harmonious labeling.

Let $G' = K_5$ be the subgraph of G.(Fig 16).

To prove: G cannot have 4 consecutive vertex label.

If not $G' = K_5$ can be labeled with 4 consecutive vertex label.

Let G'' be the star (K_1, n) subgraph of G'.

Let the root vertex be $v_1 and\ v_2, v_3, v_4\ and\ v_5$ be the leaf of the ((K1, n) subgraph (as in fig. 17).

Let the labeling of the leaf vertex be from these 4 consecutive numbers of any order. Clearly there will be two odd vertex labelling and two even vertex labeling.

Since we consider 4 consecutive integer there exist 2 pair of vertices with the following two conditions.

One pair must be odd < even → (1)

and

One pair must be even < odd → (2)

Now consider the equation (1)

we have leaf vertex label with condition odd < even by the theorem 1

∴ the root vertex cannot have odd labeling

∴ $f(v_1)$ is not odd → (3)

Consider the equation (2)

we have leaf vertex label with condition even < odd.

∴ the root vertex cannot have even labeling

∴ $f(v_1)$ is not even → (4)

From (3) & (4) the root will have neither even nor odd vertex labeling.

⇒ ⇐ G is a *k*-odd sequential harmonious labeling.

Hence the theorem

CONCLUSION

In this exertion we mainly focus on investigating the labelling schemes of *k*-odd sequential harmonious graphs and manifested theorems based on degree with some restrictions of *k*-odd sequential harmonious graphs.

ABSTRACT

This study examines the causal impact of higher educational attainment on income, employment outcomes, and socio-economic empowerment among tribal women in West Garo Hills District, Meghalaya. Drawing on Human Capital Theory and the Capability Approach, the research employs a quantitative and explanatory design using cross-sectional primary data collected from 200 tribal women aged 18–30 during 2024–2025. To address potential endogeneity in education, the study applies Ordinary Least Squares (OLS), Instrumental Variable (IV) estimation using Two-Stage Least Squares (2SLS), and logistic regression techniques. The findings reveal that higher educational attainment significantly increases monthly income, enhances employment probability, and strengthens socio-economic empowerment. IV estimates indicate that conventional OLS underestimates the true causal effect of education, confirming the presence of endogeneity bias. Structural constraints such as distance to higher education institutions and limited credit access continue to impede mobility. Notably, within the district's matrilineal context, inheritance norms alone do not guarantee economic advancement; rather, higher education emerges as the primary determinant of socio-economic transformation. The study contributes district-level empirical evidence to the literature on gender, tribal development, and education economics, offering policy-relevant insights for inclusive growth in marginalized regions.

Keywords: Higher Educational Attainment, Socio-Economic Status, Tribal Women, Income Mobility, Employment Outcomes, Empowerment, Instrumental Variable (2SLS), Human Capital Theory, Meghalaya, West Garo Hills.

INTRODUCTION

Higher educational attainment is widely recognized as a critical driver of socio-economic mobility, particularly for marginalized populations. Rooted in Human Capital Theory, education enhances productivity, skills, and earnings potential, thereby improving labor market outcomes (Becker, 1964). Empirical evidence consistently shows that additional years of schooling are associated with higher wages, better employment stability, and improved occupational mobility (Psacharopoulos & Patrinos, 2018). Beyond income effects, education also expands individual agency and decision-making capacity, aligning with the Capability Approach, which views education as a means of enhancing substantive freedoms (Sen, 1999). For women, especially those from socially disadvantaged communities, higher education can transform intra-household bargaining power, social participation, and long-term well-being (Kabeer, 1999).

In the context of India's tribal populations, educational attainment remains uneven despite policy interventions aimed at inclusion. Tribal women face compounded disadvantages due to geographic isolation, socio-cultural constraints, and limited access to higher education infrastructure (Desai & Kulkarni, 2008). Meghalaya, particularly the West Garo Hills District, presents a distinctive socio-cultural setting characterized by a predominantly tribal and matrilineal society. While matriliny may provide certain inheritance rights to women, it does not automatically translate into improved economic outcomes or labor market integration. Understanding whether higher educational attainment causally improves income, employment, and socio-economic empowerment among tribal women is therefore a crucial empirical question.

However, estimating the impact of education is methodologically challenging due to potential endogeneity arising from unobserved ability, family background, and reverse causality (Card, 1999). Failure to address these biases may overstate or understate the true effect of education. Hence, this study employs multivariate regression and instrumental variable techniques to identify and quantify the causal effect of higher education on income levels, employment outcomes, and socio-economic empowerment among tribal women in West Garo Hills District, Meghalaya. By generating district-level empirical evidence, the study contributes to the literature on gender, tribal development, and human capital formation in India.

Need for the Study

Recent research underscores the critical need to study higher education's impact on tribal women's socio-economic outcomes. Empirical evidence from Mayurbhanj, India, demonstrates that women's education is pivotal in enabling tribal women to overcome socio-economic constraints and break cycles of poverty through enhanced access to opportunities and empowerment (Das & Bhoi, 2025). Despite policy efforts, significant barriers to education persist for tribal women, including socio-cultural norms, limited access to schooling, and inadequate educational infrastructure, which hinder their socio-economic mobility (Sukhija & Mishra, 2024). Understanding the causal effects of higher educational attainment in specific contexts like West Garo Hills is therefore essential to inform targeted interventions and promote inclusive development among tribal women.

Rationale of the study

The rationale for this study stems from recent empirical evidence highlighting persistent educational deprivation and its linkage with socio-economic marginalization among tribal women in India. Studies reveal that despite policy initiatives, tribal women face significant barriers to acquiring education and skills, due to socio-cultural constraints, limited institutional access, and economic pressures, which restrict their income and empowerment opportunities (Sukhija & Mishra, 2024). Further, research in Mayurbhanj demonstrates that education significantly influences tribal women's economic status and empowerment, underscoring the need to understand causal effects in specific tribal contexts (Tudu et al., 2025). Therefore, investigating the causal impact of higher educational attainment on socio-economic outcomes among tribal women in West Garo Hills is essential for effective policy design and tribal development interventions.

Scope and significance of the study

The scope and significance of the study lie in its focus on generating context-specific empirical evidence on how higher educational attainment affects socio-economic status among tribal women—a group often overlooked in broader education and development research. Recent studies show that educational empowerment of tribal women is crucial for inclusive socio-economic development, as education enhances agency, participation, and opportunities in marginalized communities (Tudu et al., 2025; *empowerment of tribal women*). Despite existing government schemes, persistent educational barriers limit access and retention among tribal women, highlighting the need for localized causal evidence to inform policy (education and economic dimension).

Statements of the problem

Despite sustained policy efforts to promote inclusive growth and educational expansion in India, significant socio-economic disparities persist among tribal communities, particularly among women. In Meghalaya's West Garo Hills District, tribal women continue to experience limited access to stable employment opportunities, lower income levels, and restricted participation in formal economic activities. Although higher educational attainment is theoretically associated with improved earnings, occupational mobility, and empowerment, empirical evidence on its causal impact in tribal and geographically isolated contexts remains limited.

Existing studies largely rely on simple correlations between education and income, often overlooking the problem of endogeneity arising from unobserved ability, household background, and socio-economic privilege. Consequently, the true magnitude of education's impact on income, employment outcomes, and socio-economic empowerment among tribal women remains uncertain. Moreover, in a matrilineal society such as West Garo Hills, inheritance rights do not necessarily guarantee economic independence or labor market integration, creating further ambiguity regarding the role of higher education in enhancing women's socio-economic status.

Therefore, the central problem of this study is to determine whether higher educational attainment causally improves income, employment, and socio-economic empowerment among tribal women in West Garo Hills District, while rigorously addressing potential endogeneity bias through appropriate econometric techniques.

Research Question

Does higher educational attainment causally improve income, employment outcomes, and socio-economic empowerment among tribal women in West Garo Hills District, when accounting for potential endogeneity in education?

Objectives

This study aims to identify and quantify the causal effect of higher educational attainment on income levels, employment outcomes, and socio-economic empowerment among tribal women in the West Garo Hills District of Meghalaya, employing multivariate regression analysis and instrumental variable techniques to address potential endogeneity.

Overview of Reviewed Literature And Research Gap

Several comparative studies from Northeastern India examine whether matrilineal social structures translate into tangible economic empowerment for women. (Mal & Saikia, 2024) finds that although matriliny may grant inheritance rights and social recognition, it does not automatically ensure higher labour force participation or economic autonomy. Instead, higher educational attainment emerges as a decisive factor influencing women's agency, employment access, and income outcomes in Meghalaya and neighbouring states. This suggests that education, rather than customary norms alone, plays a transformative economic role (Mal & Saikia, 2024). A systematic review of vocational education and skill development among tribal youth highlights persistent gaps between program availability and effective participation. (Biswal et al., 2025) observe that structural barriers, limited awareness, and socio-cultural constraints reduce the uptake of training initiatives. The authors argue that higher education combined with context-sensitive skilling strategies is essential for improving employability and income prospects in tribal regions (Biswal et al., 2025). Microeconometric research on education and earnings in India

consistently reports positive returns to schooling across demographic groups. However, (Hussain & Mukhopadhyay 2023) cautions that conventional OLS estimates may suffer from selection bias and unobserved heterogeneity, potentially overstating the true effect of education. The study emphasizes the importance of instrumental variable approaches to establish causal relationships, particularly for marginalized communities (Hussain & Mukhopadhyay 2023). District-level analyses indicate that tribal-dominated districts, including those in the Northeast, experience weak learning outcomes and limited access to higher education infrastructure. Such structural disadvantages constrain long-term income mobility and perpetuate socio-economic exclusion among tribal women (IndiaSpend, 2024). Empirical research in West Bengal and adjacent tribal regions demonstrates that education significantly enhances women's decision-making power, asset ownership, and participation in economic activities. However, (Pal et al. 2024) note that the magnitude of impact varies by locality and institutional access, underscoring the need for district-specific analysis (Pal, & Priya, 2024). Regionally focused research in Mayurbhanj, Odisha, finds a strong association between higher education and improvements in household income and empowerment indicators among tribal women. Tudu, Khatua, and Panda (2025) recommend rigorous causal estimation techniques to guide targeted scholarship and infrastructure policies (Tudu et al., 2025). Finally, policy reviews on tribal education emphasize both supply-side barriers—such as distance to colleges, hostel shortages, and language constraints—and demand-side challenges like poverty and cultural norms. These factors introduce endogeneity concerns in estimating education's impact, justifying the use of instruments such as college proximity or policy shocks in 2SLS frameworks (OAJI, 2023).
Existing studies largely establish correlations between education and empowerment among tribal women but rarely employ rigorous econometric techniques to identify the causal impact of higher educational attainment. Moreover, there is a lack of district-level empirical evidence specifically focusing on tribal women in West Garo Hills, Meghalaya, accounting for endogeneity in education.

MATERIALS AND METHODS

Research Design

The present study adopts a quantitative, analytical, and causal research design to examine the impact of higher educational attainment on income, employment outcomes, and socio-economic empowerment among tribal women in West Garo Hills District, Meghalaya. The study is explanatory in nature, aiming to establish the magnitude and direction of the causal relationship between education and socio-economic outcomes. A cross-sectional survey method is used for primary data collection. To address potential endogeneity bias in education, the study employs Ordinary Least Squares (OLS) regression and Instrumental Variable (IV) estimation using the Two-Stage Least Squares (2SLS) method.

Area of Study and Period of Study

The study is conducted in West Garo Hills District of Meghalaya, a predominantly tribal district characterized by a matrilineal social structure. The target population consists of tribal women aged 18–30 years residing in both rural and semi-urban areas of the district. The data collection is proposed for the period 2024–2025.

Sampling Design and Sampling Technique

A multi-stage sampling design is adopted for the study. In the first stage, Community and Rural Development (C&RD) blocks in West Garo Hills District are selected using simple random sampling. In the second stage, villages and urban wards are randomly selected from the chosen blocks. In the third stage, respondents are selected through stratified random sampling based on educational attainment levels (Below Higher Secondary, Graduate, and Postgraduate) to ensure adequate representation of different education categories.
The sample size is determined using Cochran's (1977) formula:

$$n_0 = (Z^2\, p\, (1 - p)) / e^2$$

Where:

n_0 = initial sample size
Z = 1.96 (at 95% confidence level)
p = estimated population proportion (assumed as 0.50 for maximum variability)
e = margin of error

Assuming a margin of error of 7% (0.07), the sample size is calculated as follows:
$n_0 = (1.96^2 \times 0.50 \times 0.50) / (0.07^2)$
$n_0 = (3.8416 \times 0.25) / 0.0049$
$n_0 = 0.9604 / 0.0049$
$n_0 = 196$
Thus, the minimum required sample size is 196 respondents. For better representation and to ensure robustness of statistical analysis, the sample size is rounded off to 200 respondents.
Therefore, the final sample size for the study is fixed at 200 tribal women respondents.

Variables of the Study

Independent Variable:
Higher Educational Attainment
- Years of schooling
- Dummy variable (1 = Graduate and above, 0 = otherwise)

Dependent Variables:
1. Monthly Income
2. Employment Status (1 = employed, 0 = unemployed)
3. Socio-Economic Empowerment Index

Control Variables:
- Age
- Marital status
- Household size
- Parental education
- Distance to nearest college
- Access to credit
- Rural/Urban dummy

Instrumental Variable (Proposed):
- Distance to nearest college
- Availability of girls' hostel
- Scholarship eligibility

Sources of Data
Primary Data: Primary data are collected through a structured questionnaire and household interviews.
Secondary Data: Secondary data are collected from Census of India reports, NSSO publications, Ministry of Tribal Affairs reports, Meghalaya Statistical Handbook, and District Statistical Office records.

Tools for Analysis

Descriptive Statistics:
Mean: The mean represents the average value of a variable and is calculated by dividing the total sum of all observations by the number of observations.

$\bar{X} = \Sigma X / n$

Standard Deviation: Standard deviation measures the extent to which individual observations deviate from the mean, indicating the degree of dispersion or variability in the data.

$$SD = \sqrt{[\ \Sigma\ (X - X)^2 / (n - 1)\ ]}$$

Ordinary Least Squares (OLS) Model

$$Yi = \beta 0 + \beta 1Edui + \beta 2Xi + \varepsilon i$$

The OLS model estimates the linear effect of education on socio-economic outcomes while controlling for other variables.

Where:

Yi = Income / Employment / Empowerment

Edui = Education level

Xi = Vector of control variables

εi = Error term

Instrumental Variable (Two-Stage Least Squares – 2SLS)

First Stage:

$$Edui = \pi 0 + \pi 1Zi + \pi 2Xi + vi$$

The first stage predicts education using an instrumental variable to remove endogeneity bias.

Second Stage:

$$Yi = \beta 0 + \beta 1\hat{E}dui + \beta 2Xi + ui$$

The second stage estimates the causal effect of predicted education on the outcome variable.

Where:

Zi = Instrumental variable

Logistic Regression Model (for Employment Status)

$$P(Y = 1) = 1 / [1 + e^{-(\beta 0 + \beta 1Edu + \beta 2X)}]$$

The logistic regression model estimates the probability of being employed based on education and control variables.

Empowerment Index (PCA Method)

$$Index = w1X1 + w2X2 + ... + wnXn$$

The empowerment index is constructed by assigning weights derived from principal component analysis to multiple indicators.

Cronbach's Alpha (Reliability Test)

$$\alpha = [k / (k - 1)] \times [1 - (\Sigma\sigma^2 i / \sigma^2 T)]$$

Cronbach's Alpha measures the internal consistency and reliability of the empowerment scale items.

Data Analysis Tools

Data will be analyzed using SPSS, STATA, or R software. STATA is preferred for conducting IV regression using the IVREG command. MS Excel will be used for data coding and cleaning. Reliability and validity tests will also be performed to ensure robustness of results.

Hypotheses of the Study

H1: Higher educational attainment has a positive and significant impact on income among tribal women.

H2: Higher educational attainment increases the probability of employment among tribal women.

H3: Higher educational attainment significantly improves socio-economic empowerment among tribal women.

H4: There is a significant difference between OLS and IV estimates, indicating the presence of endogeneity in education.

Analytical flow chart.
Fig. 1: Analytical Workflow from Data Collection to Model Interpretation

RESULTS AND DISCUSSIONS

Table.1 presents the socio-demographic profile of the respondents. The majority of tribal women fall within the 22–25 age group (36%), indicating that most participants are in their prime working and education-completion years. A larger proportion is unmarried (59%), which may positively influence educational continuation and labour force participation. Most households consist of 4–6 members (54%), suggesting moderate family dependency. Parental education remains low, with 32% having no formal education, reflecting intergenerational educational constraints. A significant share resides 5–10 km from a college (42%), highlighting accessibility challenges. Furthermore, 67% live in rural areas and 52% lack credit access, indicating structural barriers affecting socio-economic mobility.

Table 2 clearly demonstrates a strong positive relationship between educational attainment and employment status among tribal women. Only 35% of women below higher secondary education are employed, while 65% remain unemployed. Employment rates increase substantially with higher education, reaching 54.5% among higher secondary graduates, 76.9% among graduates, and 85% among postgraduates. Correspondingly, unemployment declines sharply as education levels rise. This trend indicates that higher educational attainment significantly enhances labour market participation and employability. The pattern supports human capital theory, suggesting that advanced education equips women with better skills and opportunities, thereby increasing their probability of securing employment in the formal or semi-formal sectors.

Table 3 reveals a clear and progressive increase in mean monthly income with higher educational attainment among tribal women. Respondents below higher secondary education earn an average income of ₹8,500, whereas higher secondary graduates earn ₹11,200. The income rises substantially to ₹17,500 for graduates and ₹24,800 for postgraduates. This steady upward trend indicates strong economic returns to higher education. Although the standard deviation increases at higher education levels, suggesting income variability within advanced qualifications, the overall pattern confirms that greater educational attainment significantly enhances earning capacity. These findings provide descriptive evidence that education plays a crucial role in improving economic status and reducing income disparities.

Table 4 presents the descriptive statistics of major study variables. The average years of schooling is 12.4 years, indicating that most respondents have completed at least secondary education. The mean monthly income of ₹14,650 reflects moderate earning levels, though the relatively high standard deviation suggests income disparities among respondents. The average empowerment index score of 0.62 indicates a moderate level of socio-economic empowerment. The mean age is 24.1 years, representing a young and economically active population. Additionally, the average distance to the nearest college is 8.2 km, highlighting accessibility constraints that may influence educational attainment and subsequent socio-economic outcomes.

Table 5 presents the OLS regression results examining the impact of education and control variables on monthly income. Years of schooling has a positive and highly significant effect on income (β = 1,240, $p < 0.01$), indicating strong economic returns to education. Parental education and access to credit also positively and significantly influence income, suggesting intergenerational and financial support mechanisms enhance earning capacity. Distance to college and rural residence negatively affect income, reflecting infrastructural disadvantages. Household size shows a marginal negative impact, implying economic pressure from larger families. Overall, the model confirms that higher educational attainment significantly improves income among tribal women in the district.

Table 6 presents the OLS regression results for both income and empowerment models. Years of schooling and graduate status show positive and highly significant effects on monthly income and empowerment index scores,

confirming the dual economic and social returns to higher education. Access to credit and parental education positively influence both outcomes, indicating the importance of financial inclusion and family background. Distance to college negatively affects income and empowerment, highlighting infrastructural constraints. Rural residence also shows a negative association. Overall, the findings demonstrate that higher educational attainment substantially enhances both economic earnings and socio-economic empowerment among tribal women.

Table.7 presents the first-stage regression results of the Two-Stage Least Squares estimation, where years of schooling is regressed on the instrumental variables and controls. Distance to the nearest college shows a negative and highly significant effect on education, indicating that greater distance reduces educational attainment. Scholarship eligibility and availability of girls' hostel facilities have positive and significant impacts, confirming their role in promoting higher education. Parental education also positively influences schooling, reflecting intergenerational effects. The statistical significance of the instruments demonstrates their strong relevance, satisfying the necessary condition for valid instrumental variable estimation in the subsequent stage analysis.

Table 8. presents the logistic regression results estimating the probability of employment among tribal women. Years of schooling has a positive and statistically significant effect on employment ($p < 0.01$), indicating that additional education increases the likelihood of securing a job. The graduate dummy variable shows a strong positive impact, with graduates being significantly more likely to be employed compared to non-graduates. Parental education and access to credit also positively influence employment probability, while greater distance to college reduces employment chances. Rural residence shows a marginal negative effect. Overall, the findings confirm that higher education substantially enhances labour market participation.

Table 9 presents the results of the Principal Component Analysis used to construct the socio-economic empowerment index. The first principal component (PC1) has an eigenvalue of 2.86 and explains 47.6% of the total variance, indicating strong explanatory power. The second component adds 20.7%, bringing the cumulative variance explained by the first two components to 68.3%. This substantial proportion confirms that the selected indicators effectively capture the underlying dimensions of empowerment. The declining eigenvalues for subsequent components suggest diminishing explanatory contribution. Overall, the PCA results validate the statistical adequacy and dimensional reliability of the constructed empowerment index.

Table 10 provides a macro-level contextual understanding of educational and socio-economic conditions in West Garo Hills District. The female literacy rate stands at 62.7%, which is lower than the overall literacy rate of 67.6%, indicating a gender gap in educational attainment. The district reports 255,693 workers, while the state-level female worker population ratio of 44.1% suggests moderate female labour participation. The presence of 63 higher secondary institutions and approximately six degree colleges indicates limited higher education infrastructure relative to population needs. The national Gross Enrolment Ratio (GER) in higher education, ranging between 27.1–28.4%, reflects gradual expansion but highlights scope for improvement. These indicators underscore structural constraints and justify targeted educational interventions to enhance socio-economic mobility among tribal women.

Table No 4.12 summarizes the outcomes of hypothesis testing based on OLS, IV, logistic regression, and Hausman test results. Hypothesis H1 is accepted as higher educational attainment shows a positive and statistically significant impact on income in both OLS and IV estimations. Hypothesis H2 is also accepted, as logistic regression results indicate that graduates are significantly more likely to be employed. Hypothesis H3 is supported by the empowerment model, where education positively influences socio-economic empowerment at the 1% significance level. Finally, Hypothesis H4 is confirmed through the significant Hausman test result ($p = 0.008$), indicating the presence of endogeneity and validating the use of instrumental variable estimation. Overall, the findings establish education as a strong causal determinant of socio-economic status among tribal women.

DISCUSSION

The findings of this study provide strong empirical support for Human Capital Theory, confirming that higher educational attainment significantly enhances income, employment, and socio-economic empowerment among tribal women in West Garo Hills District. The positive and significant OLS and IV estimates indicate that education yields substantial economic returns, while the logistic regression results demonstrate that graduates are considerably more likely to be employed. Importantly, the IV results reveal that conventional OLS underestimates the true causal effect, highlighting the presence of endogeneity. The empowerment index analysis further shows that education strengthens women's agency and decision-making capacity. Despite the district's matrilineal structure, education—not customary norms—emerges as the decisive factor influencing socio-economic mobility, reinforcing the need for targeted higher education policies for tribal women.

MAJOR FINDING

1. **Positive impact of education on income:** Higher educational attainment has a strong and statistically significant positive effect on monthly income among tribal women. both ols and iv results confirm that education substantially increases earning capacity.
2. **Returns to additional years of schooling:** Each additional year of schooling significantly raises income levels, demonstrating measurable economic returns to investment in education.
3. Income advantage of graduates and postgraduates: Women with graduate and postgraduate qualifications earn considerably higher incomes compared to those with lower educational attainment, indicating a clear income gradient.
4. **Education increases employment probability:** Logistic regression results reveal that higher education significantly increases the likelihood of employment among tribal women.
5. **Higher Employability of Graduates:** Graduates are nearly three times more likely to be employed compared to non-graduates, reflecting enhanced labour market competitiveness.
6. **Education enhances socio-economic empowerment:** Higher education significantly improves empowerment indicators such as decision-making ability, social participation, and financial independence.
7. **OLS underestimates true effect:** The IV (2sls) coefficient is larger than the ols estimate, suggesting that ordinary regression underestimates the true causal impact of education.
8. **Presence of Endogeneity in education:** The significant Hausman test confirms Endogeneity bias, justifying the use of instrumental variable techniques.
9. **Distance to college reduces educational attainment:** Greater distance to higher education institutions negatively affects schooling levels and income outcomes.
10. **Access to credit improves outcomes:** Women with access to credit show higher income and employment probability, highlighting the role of financial inclusion.
11. **Influence of parental education:** Parental education positively influences respondents' schooling and socio-economic status, indicating intergenerational effects.
12. **Education as the primary determinant of mobility:** Despite the matrilineal social structure of west garo hills, higher education—not inheritance norms—emerges as the most significant determinant of socio-economic mobility among tribal women.

POLICY SUGGESTION

1. **Expansion of Higher Education Infrastructure:** The government should establish more degree colleges, satellite campuses, and distance-learning centres in West Garo Hills to reduce geographic barriers. Improving physical access to higher education will directly enhance enrolment and completion rates among tribal women.
2. **Strengthening Scholarship and Financial Support Schemes:** Targeted scholarships, fee waivers, and stipends for tribal women should be expanded. Timely disbursement of financial assistance can reduce dropout rates and encourage continuation into graduate and postgraduate studies.

3. **Development of Girls' Hostels and Safe Transport Facilities:** Provision of well-equipped girls' hostels and subsidized transport facilities is essential to address distance-related constraints. Safe residential and mobility support can significantly increase higher education participation.
4. **Integration of Skill Development with Higher Education:** Higher education programs should be linked with employability-oriented skill training, internships, and entrepreneurship support to ensure smooth transition into the labour market.
5. **Promotion of Financial Inclusion and Credit Access:** Strengthening self-help groups (SHGs), microfinance access, and women-specific credit schemes can complement educational attainment by enabling income-generating activities and economic independence.

CONCLUSION

This study provides robust empirical evidence that higher educational attainment is a decisive and causal determinant of socio-economic status among tribal women in West Garo Hills District, Meghalaya. Drawing upon Human Capital Theory and the Capability Approach, the findings demonstrate that education significantly enhances income levels, employment probability, and socio-economic empowerment. Both OLS and Instrumental Variable (2SLS) estimations confirm strong and statistically significant returns to education, while the Hausman test validates the presence of endogeneity and the necessity of causal estimation techniques. Notably, the IV estimates reveal that conventional models may underestimate the true impact of education, thereby strengthening the causal interpretation of results. The study further establishes that graduates are substantially more likely to be employed and earn higher incomes compared to women with lower educational attainment. Education also contributes meaningfully to empowerment outcomes, including improved agency and decision-making capacity. Structural constraints such as distance to college and limited access to credit continue to impede educational and economic advancement. Importantly, within the matrilineal context of West Garo Hills, inheritance norms alone do not guarantee economic mobility; rather, higher education emerges as the primary transformative mechanism. Overall, the findings underscore the centrality of higher education in advancing inclusive development and gender-equitable growth in tribal regions.

Limitations of the Study

This study is subject to certain limitations. First, the analysis is based on cross-sectional data, which restricts the ability to observe long-term dynamic effects of education over time. Second, although instrumental variable techniques were employed to address endogeneity, the validity of instruments depends on underlying assumptions that cannot be fully tested. Third, the sample is limited to tribal women aged 18–30 in West Garo Hills, which may constrain generalizability to other age groups or regions. Finally, self-reported income and empowerment measures may involve reporting bias, potentially affecting precision of estimates.

Scope For Further Research

Future research may employ longitudinal or panel data to examine the long-term impact of higher education on income mobility and intergenerational outcomes among tribal women. Comparative studies across different tribal districts or Northeastern states could provide broader generalizability and contextual insights. Further research may also explore qualitative dimensions of empowerment, including leadership participation and social norms. Additionally, evaluating the effectiveness of specific policy interventions—such as scholarships, hostel facilities, and skill-linked education programs—through experimental or quasi-experimental designs would strengthen evidence-based policymaking in tribal education and development.

Author contributions

Jayashree Hajong, Ph.d. Research Scholar, conceptualized the study, formulated the Research Problem, Designed the Research Methodology, Collected Primary and Secondary data, performed the econometric analysis, interpreted the results, and prepared the original draft of the manuscript. Dr. R. Baby Bowna, Research Supervisor, provided overall

academic guidance in framing and refining the research objectives, strengthening the methodological and econometric framework, critically reviewing the empirical analysis, validating the findings, and enhancing the theoretical coherence and scholarly quality of the manuscript. Both authors read and approved the final version of the study and jointly assume responsibility for its academic integrity and intellectual content.

FUNDING

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

ACKNOWLEDGEMENT

The author expresses sincere gratitude to the Department of Economics, Annamalai University, for providing a supportive academic environment and essential facilities to undertake the present research work. I am profoundly grateful to my Research Supervisor, Dr. R. Baby Bowna, for her continuous guidance, insightful suggestions, and academic mentorship throughout the study. Her constructive feedback and critical observations significantly enhanced the quality and rigor of this research. I also extend my heartfelt appreciation to the respondents—tribal women of West Garo Hills District—who generously shared their time and valuable information during the field survey. Their cooperation made this empirical investigation possible. I acknowledge the support and encouragement received from faculty members, non-teaching staff, and fellow research scholars of the Department of Economics. Finally, I sincerely thank all individuals and institutions who directly or indirectly contributed to the successful completion of this study.

Conflict of Interest

The authors affirm that there are no conflicts of interest associated with the publication of this study. The research was carried out independently, and no financial, institutional, or personal affiliations influenced the design, analysis, interpretation, or reporting of the findings.

ABSTRACT

Lung cancer, the leading cause of cancer death worldwide, presents significant treatment challenges due to the limitations of conventional therapies, including severe toxicity, suboptimal efficacy, and the development of multidrug resistance. This challenge has driven increased research into natural products and integrative oncology as vital complementary strategies. This paper reviews the anti-cancer properties and molecular mechanisms of various promising natural compounds against non-small cell lung cancer (NSCLC). Key bioactive agents, such as Curcumin (Turmeric), (–)-Epigallocatechin-3-gallate (Green Tea), Ginsenosides (Ginseng), and Berberine, demonstrate potent anti-proliferative and pro-apoptotic effects. Their mechanisms often involve the complex modulation of fundamental cancer signaling pathways, including PI3K/AKT, MAPK, and NF-κB. Crucially, the review also highlights the essential role of integrative oncology, where natural products are employed to mitigate the debilitating side effects of chemotherapy and radiation. Specific examples, including Ginger for nausea/vomiting and Ashwagandha for hepatotoxicity, are documented, illustrating how these agents enhance patient tolerance, support immune function, and ultimately improve the quality of life for individuals undergoing standard lung cancer treatment.

Keywords: Cancer, Curcumin, Nausea, Vomiting, Hepatotoxicity

INTRODUCTION

Lung cancer, also known as lung carcinoma, is a malignant tumor that starts in the lungs and is the leading cause of cancer death. According to WHO data, lung cancer counts for 2.09 million cases worldwide, making it the leading cause of cancer-related deaths in both men and women [1]. Lung cancer is the second largest cause of the death in men and women globally [2]. One of the most prevalent malignancies in our country is lung cancer, which claims

many lives each year [3]. Traditionally, lung malignancies are classified as either small cell carcinoma (small cell lung carcinoma, or SCLC) and non-small cell carcinoma (NSCC), with the latter making up 20% of cases and the former 80% of cases [4]. Smoking is the primary risk factor for lung cancer and is responsible for 75–80% of fatalities from the disease. Today, people with cancer properly relies on treatment with surgical intervention, chemotherapy, radiation therapy, hormonal therapy, and immunotherapy. Complementary and alternative therapies, such as herbal medicine, are frequently used in conjunction with these conventional approaches. Despite its widespread use, chemotherapy is associated with several limitations, including suboptimal efficacy, significant toxicity, and the emergence of multidrug resistance [5]. Surgery is vital for treating non-small-cell lung cancer in stages I and II but patients in stage III have a worse chance of survival because of the presence of mediastinal lymph nodes [6].

Natural products are used from ancient times for the treatment of number of diseases with very less sides effects. Natural products and their derivatives continue to play a significant role in cancer research and treatment [7]. Their diverse chemical structures and biological activities offer promising avenues for developing novel therapies. Many natural compounds and their synthetic derivatives continue to be essential in cancer treatment [8,9]. Furthermore, numerous compounds from plants and other organisms are being investigated in vitro to understand their potential mechanisms of action against lung cancer cells [10]. The conventional treatments like chemotherapy, radiation, surgery, and targeted therapy are the primary pillars of cancer care, a growing body of research is exploring the potential of natural products as complementary agents to improve efficacy and manage side effects [11]. It is crucial to understand that natural products are not a substitute for standard cancer treatment and should always be discussed with an oncologist as part of an integrated treatment plants.

Promising natural compounds and their mechanism

Many natural compounds, primarily derived from plants and fungi, have demonstrated anti-cancer properties in preclinical (laboratory and animal) studies. These compounds often target the same molecular pathways involved in cancer growth and inflammation as pharmaceutical drugs.

Curcumin (Turmeric)

Curcumin (Figure 1) is a powerful anti-inflammatory and antioxidant properties. It may inhibit tumour growth and metastasis. It can enhance the effectiveness of chemotherapy drugs. Curcumin inhibited non-small cell lung cancer growth through downregulating circ-PRKCA, which regulated ITGB1 expression by adsorbing miR-384[12,13].

(–)-Epigallocatechin-3-gallate (Green Tea)

In green tea and in white tea (–)-Epigallocatechin-3-gallate (EGCG) is most abundant polyphenol (Figure 2) It is rich in antioxidants, anti-inflammatory, a antifibrotic, anti-remodelation, and it has tissue-protective properties. It may inhibit tumour growth and induce cancer cell death. Studies suggest potential protective effects against lung cancer [14]. (–)-Epigallocatechin-3-gallate regulates cell molecular pathways of apoptosis, angiogenesis, proliferation, differentiation, and self-renewal ability of cancer stem cells. It regulates the development of cancer by changing the molecules involved in in multiple signal transduction pathways like Ras-GTPase, ERK, COX2, VEGF, and protein kinases [15].

Ginsenosides (Ginseng)

Ginsenosides has anti-tumor, immunomodulatory, and anti-inflammatory effects. One compound, Ginsenoside Rg3, is approved in China as an anti-cancer drug for non-small cell lung cancer (NSCLC). Ginsenosides Rh2 and Rg3 induce autophagic cell death in Non-Small Cell Lung Cancer (NSCLC) cells, a mechanism inextricably linked to their modulation of cell metabolomics. Specifically, the regulatory effect of these ginsenosides on autophagy appears to be coupled with their control over choline metabolism. This crucial metabolic-autophagy crosstalk provides a more comprehensive understanding of the anticancer mechanism of Rh2 and Rg3, suggesting their potential as therapeutic agents that target both cellular survival pathways and metabolic plasticity in NSCLC[16].

Ginsenosides ([Figure 3) exert their anti-cancer effects by comprehensively regulating key enzymatic and signaling pathways critical to tumor growth and migration. They modulate the activities of major cellular signaling cascades, including NF-kappa$B, the MAPK family (specifically p38 MAPK, JNK, and ERK1/2), the transcription factor AP-1, and the gelatinase network involving MMP-2/9. Furthermore, ginsenosides demonstrate significant anti-inflammatory properties by inhibiting the generation of pro-inflammatory cytokines, notably TNF-alpha$ and IL-1beta$, and simultaneously suppressing the activities of inflammatory signaling pathways such as NF-kappa$B and the Jak2/Stat3 axis[17].

Berberine (Barberry)

A potential effective of Berberine as anti-cancer agent against lung cancer is demonstrated. Berberine's (Figure 4) ability to inhibit the growth of lung cancer cells, induce apoptosis, and slow down tumor growth in both laboratory and animal studies. It has direct anti-proliferative and pro-apoptotic effects, while also modulating critical signaling pathways, including PI3K/AKT, MAPK, STAT3, and NF- κB[18,19].

Medicinal Mushrooms (Reishi, Cordyceps)

Both mushrooms (Reishi and Cordyceps) exhibit anti-proliferative and pro-apoptotic effects in non-small cell lung cancer (NSCLC) cell lines, with Cordyceps' active component, cordycepin (Figure 5), inducing apoptosis and inhibiting cell growth. The bioactive compounds from these mushrooms enhance immune function, by increasing the percentages and activity of lymphocytes (CD3+) (CD4+),(CD8) and Natural Killer (NK) cells, often driving a T-helper response which is critical for patients undergoing chemotherapy or radiation[20].

Phloretin (Pears and Apples)

Phloretin (Figure 6) induces programmed cell death (apoptosis) in non-small cell lung cancer (NSCLC) cells and has shown potential to enhance the effect of chemotherapy like cisplatin. Phloretin employing a multi-mechanistic approach to regulate the cell cycle and induce programmed cell death. Its efficacy includes the arrest of tumor cell proliferation achieved by inhibiting cell cycle regulatory proteins, specifically cyclins and cyclin-dependent kinases. Phloretin induces apoptosis through the activation of the intrinsic, mitochondria-mediated cell death pathway. Complementing these effects, phloretin exhibits anti-metabolic properties by downregulating the expression of GLUT2 which inhibiting tumor cell migration, collectively validating its profound anti-cancer effects[21,22,23].

Resveratrol (Grapes)

Resveratrol (RV) (Figure 7) has potential to reduce the risk of lung cancer. Resveratrol (RV) exhibits significant promise as a nanomedicine candidate for lung cancer treatment through diverse molecular actions. RV modulates the apoptotic machinery by promoting intrinsic cell death, evidenced by the upregulation of pro-apoptotic proteins (Bax and Bak) and the downregulation of anti-apoptotic protein Bcl-2.[24.] RV suppresses cell proliferation by interfering with critical signalling cascades that drive cancer progression, including the MAPK, mTOR, PI3K/Akt, and Wnt beta-catenin pathways [25].

Organosulfur compounds (Garlic*)*

Garlic has organosulfur compounds (OSCs) like diallyl trisulfide (DATS), diallyl disulfide (DADS), and allicin (Figure 8). These compounds exert an anti-proliferative effect on non-small cell lung cancer (NSCLC) cells by inducing apoptosis via the mitochondria-mediated pathway, increasing the Bax/Bcl-2 ratio,[26] and causing cell cycle arrest (e.g., G2/M arrest in A549 cells). OSCs demonstrate anti-metastatic properties by inhibiting cell motility, adhesion, and aggregation, and by modulating signalling pathways [27].

Fucoidan (Undaria pinnatifida)

Fucoidan is a sulfated polysaccharide (Figure 9), shows potent anticancer activity against A549 human lung carcinoma cells. It induces apoptosis by causing chromatin condensation and increasing sub-G1 cells. Mechanistically, fucoidan shifts the Bax/Bcl-2 ratio, activates caspase-9, cleaves PARP, and reduces procaspase-3. The effect is mediated by down-regulation of p38 and PI3K/Akt while activating the ERK1/2 MAPK pathway [28].

Semecarpus anacardium (Bhallataka*)*
Metabolites from Bhalla taka taila interact with 180 human target proteins, as identified by Binding DB. These proteins modulate key pathways, including TRAIL signaling, PAR1-mediated thrombin signaling, Syndecan-1/Glypican pathways, and VEGFR1/2. *In vitro* studies in A549 cells showed the oil significantly induced apoptosis (57%) and ROS production (56%). The findings suggest Bhallataka taila regulates cancer by modulating these specific signaling pathways [29].

Melittins (Apis florea and Apis mellifera)
Both Mel-AF (Melittins,Apis florea) and Mel-AM(Melittins, *Apis mellifera)* peptides induce apoptosis via the intrinsic mitochondrial pathway and inhibit cell migration/invasion in NSCLC cells. Mel-AF showed a more pronounced effect on apoptosis induction and better enhanced the gefitinib's inhibitory effects than Mel-AM. Combining these peptides with the chemotherapeutic drug gefitinib resulted in synergistic effects against A549 and NCI-H460 lung cancer cells. This highlights Mel-AF's superior therapeutic potential for use in combination lung cancer treatments [30].

Role of Integrative Oncology
Integrative Oncology is combining helpful complementary therapies with mainstream cancer care to reduce symptoms and improve quality of life. The most widely supported role for natural products is within integrative oncology, which combines evidence-based complementary therapies with conventional medicine.to reduce oral mucositis, hepatotoxicity, neurotoxicity, nephrotoxicity, gastrointestinal toxicity, cardiotoxicity, bone marrow hematopoietic.

- *Mitigating side-* Herbs are commonly used to manage side effect induced by chemotherapy in lung cancer patients Table 1.
- *Immune support-* Some plants give immune support for potentially helping patient fpr better tolerance and recover from chemotherapy or radiation. eg. Tinospora cordifolia (Wild) Miers has Choline, tinosporin, columbin, isocolumbin, palmatine, tetrahydropalmatine and magnoflorine reduce the skin diseases, vomiting, anemia, piles and increase the immunity [46,47]. Bioactive constituents of Astragalus (*Huang Qi*) are used in traditional Chinese medicine to boost the immune system, potentially helping patients better tolerate and recover from chemotherapy or radiation [48].
- *Nutritional support-* A diet rich in natural, antioxidant-rich whole foods—such as **fruits,** vegetables (especially cruciferous varieties), whole grains, and lean proteins—is essential for fighting oxidative stress, supporting the immune system, and maintaining strength during treatment.

Lung Cancer Prevention
In addition to exploring natural products, adopting healthy lifestyle habits is crucial for lung cancer prevention:
- Quit smoking: Smoking is the leading cause of lung cancer. Quitting smoking is the most effective way to reduce your risk.
- Avoid second hand smoke: Exposure to second hand smoke can also increase your risk of lung cancer
- Eat a healthy diet A diet rich in fruits, vegetables, and whole grains can help protect against cancer.
- Regular exercise: Regular physical activity can help reduce your risk of cancer.
- Maintain a healthy weight: Obesity is linked to an increased risk of lung cancer.

CONCLUSION

The unescapable limitations of conventional non-small cell lung cancer (NSCLC) treatments, such as toxicity and resistance, underscore the necessity of moving toward integrative strategies. This review establishes that promising natural compounds like Curcumin, EGCG, Ginsenosides, and Berberine offer robust anti-cancer efficacy through complex modulation of key oncogenic pathways (PI3K/AKT, MAPK, NF-κB). Beyond direct tumor suppression, the

strategic integration of these natural products, including Ginger and Ashwagandha, is crucial for mitigating debilitating treatment side effects, thereby enhancing patient adherence and overall quality of life. Future research must now focus on advancing these synergistic approaches through rigorous clinical trials to firmly establish natural products as standardized, complementary components of lung cancer care.

ABSTRACT

The primary goal of this research work is to be introduced two new domination numbers namely odd and even sum eccentricity domination numbers from the existing odd and even sum eccentricity dominating sets of a graph H. In this paper an algorithm for finding an odd and even sum eccentricity domination number of graph H is presented and explained with an example. Odd and evensum eccentricity dominating sets are distinguished and the limitations of their numbers are obtained in terms of graph terminologies for some special graphs. Finally, odd and even sum eccentricity domination numbers are determinate for operation on graphs.

Keywords: Oddsumeccentricity dominating set, Odd sum eccentricity domination number, Even sum eccentricity dominating set, Evensumeccentricity domination number.

INTRODUCTION

Let H = (V,E) be a simple, undirected and connected graph. All the basic graph terminologies are used in the sense of V.R. kulli[7].The maximum and minimum degree of graph H is denoted by $\Delta(H)$ and $\delta(H)$ respectively. The eccentricity $e(v)$ of v is the distance to a vertex farthest from v. Thus, $e(v) = \max\{d(u, v): u \in V\}$, where $d(u,v)$ is the distance between u an v. The radius and diameter of the graph $H$are respectively the minimum and maximum

eccentricity of all the vertices, and they are denoted by *rad(H)* and *diam(H).* A vertex *w* is said to be an eccentric vertex of a vertex *v* if *d(v, w) =e(v).* The set of all eccentric vertex of *v* is said to be an eccentric set of $E(v) = \{u \in V(G) / d(u, v) = e(v)\}$. A set $R \subseteq V(H)$ is an eccentric dominating set if *R* is a dominating set of *H* and for every $v \in V–R$, if there exist at least one eccentric vertex of *v* in *R*. The minimum cardinality of all eccentric dominating sets of H is called the eccentric domination number and its denoted by $\gamma_{ed}(H)$[5]. The domination in graph is one of the most rapidly growing fields within and outside of graph theory. Many researchers have been attracted to work on it due to its diversified applications in the various fields like linear algebra and optimization, design and analysis of communication networks as well as surveillance[10]. The concept of distance in graphs plays a dominant role in the study of structural properties of a graph in various angles using related concept of eccentricity of vertices in graphs. The study of structural properties of graphs using distance and eccentricity started with the study of centre of tree and propagated in different directions. All the graphs used in this paper are referred from Joshep A. Gallian[6]. There are many domination models available in the literature Total domination[2], Odd and even domination[3,11], Odd and Co-odd sum degree domination[4], Co-even domination[8], Even sum domination[9], Eccentric domination[1] are among worth to mention. Motivated by the notion of all the above parameters and their applicability in this article, the odd and even sum eccentricity dominations are introduced and studied for some standard classes of graphs like cycle, wheel, comb, star, complete, crown, book, friendship, fan, helm, bistar and ladder graphs. Further, the bounds of the above parameters are determined and the relationships between some of the existing domination parameters are found. Additionally, in this paper an algorithm for finding an odd and even sum eccentricity domination number of graph *H* is presented and explained with an example.

MATERIALS AND METHODS

Definition 2.1 A dominating set $R \subseteq V(H)$of a graph $H=(V,E)$ is said to be an odd(even) sum eccentricity dominating set(osed(esed)-set) $R^e_{os}\left(R^e_{es}\right)$ of *H*, if the sum of eccentricity values of vertices of $R^e_{os}\ \left(R^e_{es}\right)$ is on odd(even) number. The odd(even) sum eccentricity domination number $\gamma^e_{os}\left(\gamma^e_{es}\right)$ is the minimum cardinality taken over all osed(esed)-setof *H*and is defined as zero, if no such set exist in *H*. The osed(esed)-set with cardinality $\gamma^e_{os}\left(\gamma^e_{es}\right)$ is denoted as $\gamma^e_{os}\left(\gamma^e_{es}\right)$ - set of H.

Definition 2.2 A vertex of a graph H is said to be an odd or even eccentricity vertex, if its eccentricity value is odd or even.

Definition 2.3 The sum of the eccentricity values of vertices of $\gamma^e_{os}\ \left(\gamma^e_{es}\right)$ -set of H is said to be the odd(even) sum eccentricity domination value and its denoted by $S^e_{os}\left(S^e_{es}\right)(H)$.

Definition 2.4 An eccentric dominating set $R \subseteq V(H)$ is said to be an odd(even) sum eccentric dominating set, if the sum of eccentricity values of vertices of $R^E_{os}\left(R^E_{es}\right)$ is an odd(even) number. The odd(even) sum eccentric domination number $\gamma^E_{os}\ (\gamma^E_{es})(H)$is the minimum cardinality taken over all odd(even) sum eccentricity dominating set of H.

Example 2.5 From the graph *H*, in Figure 1, odd sum eccentricity dominating set $R^e_{os} = \{r_1, r_4, r_8\}$ it gives the number $\gamma^e_{os}(H) = 3$, it is also a and the corresponding value is $S^e_{os}(H) = \sum_{r \in R^e_{os}} e(r) = 15$. Even sum eccentricity dominating set

R^e_{es} = {r_2, r_4, r_8} it gives the number $\gamma^e_{es}(H)$ =3 and the corresponding value is $S_{es}{}^e(H) = \sum_{r \in R^e_{es}} e(r)$ =14. Odd sum eccentric dominating set R^E_{os} = {r_1, r_4, r_8} it gives the number $\gamma_{os}{}^E(H)$ = 3. Even sum eccentric dominating set R^E_{es} = {r_2, r_4, r_8, r_9}it gives $\gamma_{es}{}^E(H)$ = 4. The odd eccentricity vertices of *H*are r_2, r_3,r_5,r_6,$r_8$and the even eccentricity vertices of H are r_1, r_4, r_7,r_9.

Remark 2.6 Since the double fan graph Df_n,$n \geq 3$ has no osed-set, gives in general osed-set need not exist for all graphs. But every graph contains an even sum eccentricity dominating set, gives esed-set exists for all graph.

Algorithm for finding an odd sum eccentricity domination number and value

Input: Given a graph *H=(V,E)*,with vertex set *V* = {r_1, r_2, …, r_n} and edge set *E* = {e_1, e_2, …, e_n}

Step 1: Initially, set the vertex set *R*is empty

Step 2: Find the eccentricity of every vertex r in H and hence find the diameter of H by using Breadth-First Search algorithm. Let a path $P(r_1,r_n)$, be corresponded to the *diam(H)*.

Step 3: If *diam(H)=1*, from the path $P(r_1,r_n)$ choose an eccentricity vertex $e(r_i) \in R$. Then go to step (7).

Step 4: If *diam(H)* $\geq$ 2, then from the path $P(r_1,r_n)$, choose an eccentricity vertices $e(r_i/\ i=2,3,\ldots,n-1)$ which are adjacent to r_1 and r_n. Then include those vertices with *R*. If twice the eccentricity vertices occur in the above selection, choose the vertices in the selected path as r_2 and r_{n-1}.

Step 5: Let $M = N(r_2) \cup N(r_{n-1})$. Delete all the edges having either one end at r_2 or r_{n-1}. Also, delete all the edges having both ends in *M*. In this process, if any vertex become isolated, delete it from the graph. Delete the pendent edge in *M* from the graph.

Step 6: Repeat the steps *3-6*, until the graph becomes empty. If R is a dominating set of *H* and for every $r_i \in V\text{-}R$, there exists at least one eccentricity vertex r_i in R.

Step 7: The resulting set *R* is the required eccentricity dominating set R^e_{os}. The required eccentricity domination number is $|R^e_{os}| = \gamma^e_{os}$ of H. If the sum of eccentricity vertices of R^e_{os} is odd then R^e_{os} is the required odd sum eccentricity domination value of *H*, else add one odd eccentricity vertex in R^e_{os} of *H*.

Output: Oddsum eccentricity domination number $\gamma^e_{os}(H)$, and odd sum eccentricity domination value $S_{os}{}^e(H) = \sum_{r \in R^e_{os}} e(r)$.

By the similar way one can find the even sum eccentricity domination number and value.□

Example 2.8 The above algorithm is explaining with the help of graph *H*. From the graph *H*, in Figure 2.

Input: The vertex set *V(H)* = {r_1, r_2, …, r_9} and edge set *E(H)* ={e_1, e_2, …, e_{10}}

Step 1: Initially, set the vertex set R is empty.

Step 2: Using the BFS algorithm for finding the eccentricity and diameter of the graph. It gives *diam(H)* = *6* and the corresponding path is $P(r_1, r_6) = r_1 - r_2 - r_4 - r_5 - r_7 - r_8 - r_9$. Since *diam(H)* = 6, go to step 4.

Step 4: Inspecting the adjacent eccentricity value of vertices of r_1 and r_9, it is easy to find that r_2 and r_8, so to get *R* ={r_2, r_8}.

Step 5: Now $M = N(r_2) \cup N(r_8)$ = {r_1, r_3, r_4, r_6, r_7, r_9}. Delete all the edges having either one end at r_2 *or* r_8. Also delete the edges {e_1, e_2, e_3, e_8, e_9, e_{10}} which having both ends in M. The resulting graph $H_1$is shown in Figure 3. Now delete the isolated vertices r_1, r_2, r_8 and r_9 from the modified *H* graph and we get a new graph H_2 in Figure 4.

Step 6: Repeat the step 4 since $diam(H_2) = 2$. Inspecting the adjacent eccentricity value of vertices of r_5, it is easy to find the vertex set $R = \{r_2, r_5, r_8\}$until the graph become empty. If R is a dominating set of H and for every $r_i \in V\text{-}R$, there exists atleast one eccentricity vertex r_i in R.

Step 7: The resulting set R is the required odd sum eccentricity dominating set $R^e_{os} = \{r_2, r_5, r_8\}$. The odd sum eccentricity domination number is $| R^e_{os} | = \gamma^e_{os}(H) = 3$. If the sum of eccentricity vertices of R^e_{os} is odd, then R^e_{os} is the odd sum eccentricity domination value of H $\sum_{r \in R^e_{os}} \{5 + 5 + 3\} = 13 = S^e_{os}(H)$.

Output: The oddsum degree domination number $\gamma^e_{os}(H) = 3$ andThe odd sum eccentricity domination value $S^e_{os}(H)=13$.□

3. RESULTS AND DISCUSSIONS

Without loss of Generality to study the odd sum eccentricity domination number, we assume that all the graphs consider here are having atleast one odd sum eccentricity dominating set

Theorem3.1 For any graph H, then

(a) $\gamma(H) \le \gamma^e_{os}(H)$,(b) $\gamma(H) \le \gamma^e_{es}(H)$ and this bound is sharp.

Proof: This is follows from the fact that every oddsumeccentricity dominating set of H is a dominating set of H. The graph P_2 and W_3achieve this bound.
By the Similar arguments one can prove for even case.□

The exact bounds of the odd(even) sum eccentricity and the accompanying sum value for several classes of graphs are provided below.

Theorem3.2 For cycle C_n, $n \ge 3$

$$(i)\ \gamma^e_{os}(C_n) = \begin{cases} 0, & n \equiv 0,1,4,5,8,9 \pmod{12} \\ \frac{n+1}{3}, & n \equiv 2 \pmod{12} \\ \frac{n}{3}, & n \equiv 3 \pmod{12} \\ \frac{n}{3}+1, & n \equiv 6 \pmod{12} \\ \frac{n+2}{3}, & n \equiv 7 \pmod{12} \\ \frac{n+5}{3}, & n \equiv 10 \pmod{12} \\ \frac{n+4}{3}, & n \equiv 11 \pmod{12} \end{cases} ; S^e_{os}(C_n) = \begin{cases} 0, & n \equiv 0,1,4,5,8,9 \pmod{12} \\ n\left(\frac{n}{6}\right) + 2\left(\frac{n}{6}\right) + 3, & n \equiv 2,3,6,7,10,11 \pmod{12} \end{cases}$$

$$(ii)\ \gamma^e_{es}(C_n) = 2+2\left\lfloor \frac{n-1}{6} \right\rfloor ; S^e_{es}(C_n) = \begin{cases} n\left\lceil \frac{n}{6} \right\rceil, & n \equiv 0,2,4 \pmod 3 \\ (n-1)\left\lceil \frac{n}{6} \right\rceil, & n \equiv 1,3,5 \pmod 3 \end{cases}$$

Proof: Let H be the cycle$C_n$with atleast three vertices and the vertex set$V(H) = \{r_1, r_2, \ldots, r_n\}$, $n \ge 3$.

Claim 1: Odd sum eccentricity domination number

The eccentricity value of every vertex $r_i \in V(H)(i = 1 \text{ to } n)$ is

$$e(ri) = \begin{cases} \frac{n}{2}, n \equiv 0,2,4,6,8,10(\text{mod } 12) \\ \frac{n-1}{2}, n \equiv 1,3,5,7,9,11(\text{mod } 12) \end{cases}$$

Case (i): $n \equiv 0,1,4,5,8,9(\text{modl}2)$

In this case, $e(r_i)$ is an odd number for every i, and hence the osed-set does not exist it gives odd sum eccentricity domination number $\gamma_{os}^{e}(H)=0$. Thereis no $\gamma_{os}^{e}(H)=0$ and the corresponding $S_{os}^{\ e}(H)=0$.

Case (ii): $n \equiv 2(\text{mod}12)$

In this case, the vertex set R = {r_{3i-2}/ i = 1, 2, …, $\frac{n+1}{3}$ }is an γ_{os}^{e} - set of H and hence $\gamma_{os}^{e}(H) = \frac{n+1}{3}$.

Case (iii): $n \equiv 3(\text{mod}12)$

In this case, the vertex set R = {r_{3i-2}/ i = 1, 2, …, $\frac{n}{3}$ }is an γ_{os}^{e} - set of H and hence $\gamma_{os}^{e}(H) = \frac{n}{3}$.

Case (iv): $n \equiv 6(\text{mod}12)$

In this case, the vertex set R = {r_{3i-2}/ i = 1, 2, …, $\frac{n}{3}$ } $\cup$ {r_n}is an γ_{os}^{e} - set of H andhence $\gamma_{os}^{e}(H) = \frac{n}{3}$ +1.

Case (v): $n \equiv 7(\text{mod}12)$

In this case, the vertex set R = {r_{3i-2}/ i = 1, 2, …, $\frac{n+2}{3}$ } $\cup$ {r_n}is an γ_{os}^{e} - set of H and hence $\gamma_{os}^{e}(H) = \frac{n+2}{3}$.

Case (vi): $n \equiv 10(\text{mod}12)$

In this case, the vertex set R = {r_{3i-2}/ i = 1, 2, …, $\frac{n+2}{3}$ } $\cup$ {r_{n-1}}is an γ_{os}^{e} - set of H and hence $\gamma_{os}^{e}(H) = \frac{n+5}{3}$.

Case (vii): $n \equiv 11(\text{mod}12)$

In this case, the vertex set R = {r_{3i-2}/ i = 1, 2, …, $\frac{n+1}{3}$ } $\cup$ {r_n}is an γ_{os}^{e} - set of H and hence $\gamma_{os}^{e}(H) = \frac{n+4}{3}$.

Claim 2: Odd sum eccentricity domination value.

Further, from the above γ_{os}^{e} - set of H, one can get the odd sum eccentricity domination value of G as, S_{os}^{e}

$$(C_n) = \begin{cases} 0 & , n \equiv 0,1,4,5,8,9(\text{mod } 12) \\ n\left(\frac{n}{6}\right) + 2\left(\frac{n}{6}\right) + 3, n \equiv 2,3,6,7,10,11(\text{mod } 12) \end{cases}$$ .It completes. Similar way one can prove an even sum eccentricity domination number and its sum value in *(ii)*.□

Theorem3.3 For ladder graph L_n, $n \geq 3$

$$(i)\ \gamma^e_{os}(L_n) = \begin{cases} \frac{n}{2}+2 & , n \equiv 1 (\text{mod } 2) \\ \frac{n}{2}+1 & , n \equiv 0 (\text{mod } 2) \end{cases} ; S^e_{os}(L_n) = \left\lfloor \frac{n^2+2n-1}{2} \right\rfloor$$

$$(ii)\ \gamma^e_{es}(L_n) = \left\lceil \frac{n}{2} \right\rceil + 1 \ ; S^e_{es}(L_n) = \begin{cases} \frac{n^2}{2}+2, & n \equiv 0 (\text{mod } 2) \\ \left\lceil \frac{n^2}{2} \right\rceil + 4, & n \equiv 1 (\text{mod } 2) \end{cases}$$

Proof: Let H be a ladder L_n with atleast three vertices and the vertex set$V(H) = \{r_1, r_2, \ldots, r_{2n}\}$. The eccentricity value of every vertex $r_i \in V(H)$and$e(r_i) = n, (i = 1 \text{ to } n)$. The radius and diameter of the graph is, $R(H) = \begin{cases} \frac{n}{2}+1 & , n \equiv 0 (\text{mod } 2) \\ \frac{(n+1)}{2} & , n \equiv 1 (\text{mod } 2) \end{cases}$ and $diam(H)=n$.If $n \equiv 1 (\text{mod } 2)$ then $R = \{r_{3i+1} / i = 1,2,\ldots, \frac{n-2}{6}\} \cup \{r_{2i-3} / i = 1, 2, \ldots, n\} \cup \{r_{2i} / i = 1, 2, \ldots, n\}$ is an odd sum eccentricity dominating set of H. therefore, $\gamma^e_{os}(H) = |R| = \frac{n}{2}+2$ .If $n \equiv 0 (\text{mod } 2)$ then $R = \{r_{3i+1} / i = 1, 2, \ldots, \frac{n-2}{6}\} \cup \{r_{2i} / i = 1, 2, \ldots, n\}$ is an odd sum eccentricity dominating set of H. therefore, $\gamma^e_{os}(H) = |R| = \frac{n}{2}+1$.

Further, from the above γ^e_{os} - set of H, one can get the odd sum eccentricity domination value of H as, $S^e_{os}(H) = \left\lfloor \frac{n^2+2n-1}{2} \right\rfloor$.

Similar way one can prove an even sum eccentricity domination number and its sum value in *(ii)*.□

Theorem 3.4 For complete graphK_n, $n \geq 3$

(i) $\gamma^e_{os}(K_n) = 1 \quad ; S^e_{os}(K_n) = 1$

(ii) $\gamma^e_{es}(K_n) = 2; S^e_{es}(K_n) = 2$

Proof: Let H be a complete$K_n$with atleast three vertices with$V(H) = \{r_1, r_2, \ldots, r_n\}$be a vertex set of H. Herethe $R(H) = diam(H) = 1$.

Since each vertex $r \in V(H)$ is adjacent to remaining vertices of $V(H)$gives $r$is an odd sum eccentric vertex of remaining vertices of H.

Since H is complete graph gives each vertex of H is an eccentric vertex of remaining vertices of H. Itgives $R^e_{os} = \{r_1\}$ is a minimum odd sum eccentric dominating set of H and hence $\gamma^e_{os}(H) = 1$. Since $e(r_i) = 1$for i = 1 to n, gives the corresponding odd sum eccentric domination value is $S^e_{os}(H) = 1$.It completes the proof. By the similar arguments, one can prove the results an even sum eccentricity domination number and its sum value in *(ii)*.□

The following proposition gives the exact values of odd(even) sum eccentricity domination number and value for some standard graphs.

Proposition 3.5

*(i)*For wheel graph$W_n, n \geq 3$

(a) $\gamma_{os}^{e}(W_n) = 1 \quad ; S_{os}^{e}(W_n) = 1$

(b) $\gamma_{es}^{e}(W_n) = 2; S_{es}^{e}(W_n) = 2$

(ii) For helm graph$W_{n^+}, n \geq 3$

(a) $\gamma_{os}^{e}(W_{n^+}) = n; S_{os}^{e}(W_{n^+}) = \begin{cases} 3n, n \equiv 1(\text{mod } 2) \\ 3n+1, n \equiv 0(\text{mod } 2) \end{cases}$

(b) $\gamma_{es}^{e}(W_{n^+}) = n; S_{es}^{e}(W_{n^+}) = \begin{cases} 3n, n \equiv 0(\text{mod } 2) \\ 3n+1, n \equiv 1(\text{mod } 2) \end{cases}$

(iii) For star graph $S_n, n \geq 3$

(a) $\gamma_{os}^{e}(S_n) = 1 \quad ; S_{os}^{e}(S_n) = 1$

(b) $\gamma_{es}^{e}(S_n) = n-1; S_{es}^{e}(S_n) = \begin{cases} 2n-4, n = 3 \\ 2n-2, n \geq 4 \end{cases}$

(iv) For friendship graph $F_n, n \geq 2$

(a) $\gamma_{os}^{e}(F_n) = 1 \quad ; S_{os}^{e}(F_n) = 1$

(b) $\gamma_{es}^{e}(F_n) = n; S_{es}^{e}(F_n) = 2n$

(v) For comb graph$P_{n^+}, n \geq 2$

(a) $\gamma_{os}^{e}(P_{n^+}) = n \quad ; S_{os}^{e}(P_{n^+}) = n^2 - n + 3$

(b) $\gamma_{es}^{e}(P_{n^+}) = n; S_{es}^{e}(P_{n^+}) = n^2 - n + 2$

(vi) For crown graph$C_{n^+}, n \geq 3$

(a) $\gamma_{os}^{e}(C_{n^+}) = n \quad ; S_{os}^{e}(C_{n^+}) = \begin{cases} 7, n = 3 \\ \frac{n^2}{2} + n + 1, n \equiv 0(\text{mod } 2) \\ \frac{n^2}{2} + n - 3, n \equiv 1(\text{mod } 2) \end{cases}$

(b) $\gamma_{es}^{e}(C_{n^+}) = n; S_{es}^{e}(C_{n^+}) = \begin{cases} \frac{n^2}{2} + n, n \equiv 0(\text{mod } 2) \\ \frac{n^2}{2} + n - 2, n \equiv 1(\text{mod } 2) \end{cases}$

(vii) For fan graph$f_n, n \geq 3$

(a) $\gamma_{os}^{e}(f_n) = 1 \quad ; S_{os}^{e}(f_n) = 1$

(b) $\gamma_{es}^{e}(f_n) = \begin{cases} \left\lceil \frac{n}{4} \right\rceil + 1, n \equiv 0,3 (\mathrm{mod}\ 4) \\ \left\lfloor \frac{n}{4} \right\rfloor + 1, n \equiv 1,2 (\mathrm{mod}\ 4) \end{cases}$; $S_{es}^{e}(f_n) = \begin{cases} 2\left\lceil \frac{n}{4} \right\rceil + 2, n \equiv 0,3 (\mathrm{mod}\ 4) \\ 2\left\lceil \frac{n}{4} \right\rceil \quad , n \equiv 1,2 (\mathrm{mod}\ 4) \end{cases}$

(viii) For book graphB_n, $n \geq 2$

(a) $\gamma_{os}^{e}(B_n) = 3$; $S_{os}^{e}(B_n) = 7$

(b) $\gamma_{es}^{e}(B_n) = 2$; $S_{es}^{e}(B_n) = 4$

(ix) For bistar graph$B_{n,n}$, $n \geq 2$

(a) $\gamma_{os}^{e}(B_{n,n}) = 3$; $S_{os}^{e}(B_{n,n}) = 7$

(b) $\gamma_{es}^{e}(B_{n,n}) = 2$; $S_{es}^{e}(B_{n,n}) = 4$

Now we present the necessary and sufficient condition for the existence of minimal odd sum eccentricity dominating set of a graph H.

Theorem 3.6[7]A dominating set *R*is minimal if and only if for each $r \in R$, oneof the following two conditions holds

(i) $N(r) \cap R = \phi$

(ii) There exists a vertex $r_1 \in V \setminus R$such that $N(r_1) \cap R = \{r\}$. □

Based on the above theorem we have the following necessary and sufficient condition for existing the minimal odd sum eccentricity dominating set

Theorem 3.7 An odd sum eccentricity dominating set R_{os}^{e} of a graph H is a minimal odd sum eccentricity dominating set if and only if for each vertex $r \in R_{os}^{e}$, one of the following two conditions holds.

*(i) r*is an isolated vertex in$< R_{os}^{e} >$

*(ii)*there exists some vertexs $\in V - R_{os}^{e}$ such that $N(s) \cap R_{os}^{e} = \{r\}$.

(iii) r is an odd eccentricity vertex in R_{os}^{e}.

Proof: The first two conditions are for the existence of the minimal dominating set of *H*. R_{os}^{e} is a minimal odd sum eccentricity dominating set iff *r* must be an odd eccentricity.

□

Theorem 3.8 For any graph *H*with diameter *diam(H)= 2*, $\gamma_{os}^{e}(H) \leq 1 + rad(H)$.

Proof: Since *diam(H)* = 2, gives the eccentricity dominating set of *H* must have contained atleast one element, say *r*. If the eccentricity *e(r)* is an odd then R = {r} is an odd sum eccentricity dominating set of H. It gives $\gamma_{os}^{e}(H) \leq |R| = 1$. Since for every vertex $r \in V(H)$ we have $1 \leq rad(H) \leq e(r)$. Therefore, $\gamma_{os}^{e}(H) \leq rad(H)$. Suppose *e(r)* is an even number then take one odd eccentricity vertex for γ_{os}^{e} - set. In this case $\gamma_{os}^{e}(H) \leq 1 + rad(H)$.By the similar arguments, one can prove the results an even sum eccentricity domination number.□

Theorem 3.9 For the path corona$P_n \circ K_1$, then $\gamma_{os}^{e}(P_n \circ K_1) = n$, and $S_{os}^{e}(P_n \circ K_1) = n^2 - n + 3$.

Proof: Let H be a path coronagraph$P_n \circ K_1$with order 2n. Let $\{r_1, r_2, \ldots, r_n\}$ and $\{s_1, s_2, \ldots, s_n\}$respectively be the set of vertices of P_n and set of pendent vertices attached with $\{r_1, r_2, \ldots, r_n\}$. Here $e(r_i) = n+1 (i=1 \text{ to } n)$, $R(H) = \left\lceil \frac{n+1}{2} \right\rceil$ and $diam(H) = n+1$.Now the set of vertices$\{s_1, r_2, r_3, \ldots, r_n\}$ is the minimum odd sum eccentricity dominating set of H.It gives, $\gamma_{os}^{e}(P_n \circ K_1) = n$, and the corresponding sum value is $S_{os}^{e}(P_n \circ K_1) = n^2 - n + 3$.

In Figure 5. In particular n=3, $\gamma_{os}^{e}(P_3 \circ K_1) = |\{s_1, r_2, r_3\}| = 3$, $S_{os}^{e}(P_3 \circ K_1) = 9$. □

Theorem 3.10 For the cycle corona$C_n \circ K_1$, then $\gamma_{es}^{e}(C_n \circ K_1) = n$, and

$$S_{es}^{e}(C_n \circ K_1) = \begin{cases} \frac{n^2}{2} + n & , n \equiv 0 (\text{mod } 2) \\ \frac{n^2}{2} + n - 2 & , n \equiv 1 (\text{mod } 2) \end{cases}.$$

Proof: Let H be a cycle coronagraph$C_n \circ K_1$ with order 2n. Let $\{s_1, s_2, \ldots, s_n\}$and $\{r_1, r_2, \ldots, r_n\}$ respectively be the set of vertices of C_n andset of pendent vertices attached with$\{s_1, s_2, \ldots, s_n\}$. Here $e(r_i) = \frac{n}{2} + 1$ $(i=1 \text{ to } n)$, R(H) =diam(H) = 2.

Now the vertex set $\{r_1, r_2, \ldots, r_n\}$is the minimum even sum eccentricity dominating set of H.Therefore, $\gamma_{es}^{e}(C_n \circ K_1) = n$,

and the corresponding sum value is $S_{es}^{e}(C_n \circ K_1) = \begin{cases} \frac{n^2}{2} + n & , n \equiv 0 (\text{mod } 2) \\ \frac{n^2}{2} + n - 2 & , n \equiv 1 (\text{mod } 2) \end{cases}$, when $2n = p$.

In Figure 6. In particular $n = 6$, $\gamma_{es}^{e}(C_6 \circ K_1) = |\{r_1, r_2, r_3, r_4, r_5, r_6\}| = 6$, $S_{es}^{e}(C_n \circ K_1) = 24$.

□

CONCLUSION

This study introduced two new domination parameters used in the eccentricitytool. Which is highly applied in designing the fault-tolerant networks. An algorithm for finding those domination number are presented and illustrated with an example.The associative dominating sets are characterised. The bounds arethe exact values of that parameters are computed for some special graphs. Further, we found the upper bound for odd and even sum eccentricity domination number.

ABSTRACT

Intuitionistic fuzzy labelling graphs (ILFG) and a number of new connectivity notions. It presents the ideas of block, bridge, partial cut node, and strong arc. It also defines the intuitionistic fuzzy labelling tree and examines a number of intriguing characteristics related to it. Lastly, it defines the notion of the partial intuitionistic fuzzy labelling tree and explores a number of intriguing characteristics associated with it, which are important in many scientific and technological domains. We provide two types of fuzzy graphs (IFGs): intuitionistic and completely constant. Examined are the sufficient and necessary conditions for their equivalency. Constant IFGs on a cycle are characterized. A few characteristics of constant IFGs are also covered, along with relevant examples.

Keywords: IFG, IFLG, PIFLT

INTRODUCTION

Krassimir T. Atanassov presented "intuitionistic fuzzy graph theory" in [1]. Intuitionistic fuzzy graphs were introduced by Karunambigai M. G. and Parvathi R. in [4] as a particular instance of Atanassov's IFG. These ideas were used in [6] to use a Dynamic Programming Problem technique to find the shortest path in networks. Furthermore, certain significant operations on IFGs are defined and their characteristics are analyzed in [6]. A. NagoorKani and K. Radha introduced regular fuzzy graphs and entirely regular fuzzy graphs, as well as the degree, size, and order of FGs [10]. Constant and absolutely constant IFGs are introduced in this study along with relevant examples. Here, necessary and sufficient conditions for their equivalency are examined.A few basic ideas required for our research. The definitions of completely constant IFG and constant IFG are given in Section 3. A description of a constant. IFG in a cycle. Several significant characteristics of continuous IFG. A summary is included at the end of the paper. Krassimir T. Atanassov presented intuitionistic fuzzy graph theory in [1]. Intuitionistic fuzzy graphs were introduced by Karunambigai M G and Parvathi R in [4] as a particular instance of Atanassov's IFG. These ideas were used in [6] to use the Dynamic Programming Problem technique to identify the shortest path in networks. Some significant operations on IFGs are defined and their characteristics are examined further in [6]."This study examines the necessary and sufficient conditions for their equivalency." The structure of the paper is as follows: Some basic principles that are necessary for our research are given in Section 2. "The definitions of constant IFG and totally constant IFG" are provided in Section 3. It is described how to characterize constant IFG on a cycle. A few significant characteristics of constant IFG are discussed. Fuzzy tolerance graphs [28], fuzzy threshold graphs [27], bipolar fuzzy graphs [18, 19, 33], balanced interval-valued fuzzy graphs [12, 16], fuzzy k-competition and p-competition fuzzy graphs [31], fuzzy planar graphs [26, 34], bipolar fuzzy hypergraphs [29, 30], m−step fuzzy competition graphs [25], and so on. Telecommunication uses fuzzy graphs system [32]. A novel idea for fuzzy graph coloring is presented [35]. Novel ideas of bipolar fuzzy competition graphs were discussed by Sarwar and Akram [36]. Strong intuitionistic fuzzy graphs were defined by Akram and Davvaz [1]. Additionally, intuitionistic fuzzy hypergraphs with applications are discussed [3]. Akram et al. provide a novel use of intuitionistic fuzzy digraphs [2]. Additionally, intuitionistic fuzzy cycles, intuitionistic fuzzy trees, and intuitionistic fuzzy planar graphs were defined by Akram and Al-Shehrie [4] [7]. Karunambigai et al. describe "balanced intuitionistic fuzzy graphs" [10]. Additionally, intuitionistic fuzzy graphs were defined by Parvathi and Karunambigai [13]. The idea of an intuitionistic fuzzy competition graph was covered by Sahoo and Pal [22]. Additionally, they talked about various kinds of products on intuitionistic fuzzy graphs [21] and intuitionistic fuzzy tolerance graphs with applications [23].

Basic Fuzzy Graph

A graph is defined as an ordered pair (G = (V, E) , where (V) represents the set of all vertices of (G), which is non-empty, and (E) denotes the set of all edges of (G). Two vertices (x) and (y) in a graph (G) are considered adjacent if G((x, y)) is an edge of (G). A simple graph is one that contains neither loops nor multiple edges.The complete graph with (n) vertices contains (frac{n(n−1)}{2} \) edges. An isomorphism between graphs (G ,1) and (G , 2) is a bijection between their vertex sets such that two vertices (v , 1) and (v , 2) of (G , 1) are adjacent in (G ,1) if and only if (f(v,1)) and (f(v,2)) are adjacent in (G,2 \). Isomorphic graphs are denoted as (G , 1 sim= G ,2).

Intuitionistic Fuzzy Graphs

An intuitionistic fuzzy set A on the set X is characterized by a mapping m: X→ [0, 1], known as the membership function, and (n: X → [0, 1]), referred to as the non-membership function. An intuitionistic fuzzy set is represented as (A = (Xm_a,n_a). The membership function for the intersection of two intuitionistic fuzzy sets (A = (Xm_a,n_a)and (B = (= (Xm_b,n_b) is defined as (m{A ,cap B} = min{m_A,n_B} , while the non-membership function is defined as $mA \cap B\}$ = max{n A∩ $B\}$ \). We denote that (A = (Xm_a,n_a) \subset B = (X,m_b, $_b$)) (indicating an intuitionistic fuzzy subset) if $M\ A(x) \leq MB(x)$ and$nA(x) \geq nA(x) forall\ x \in X$.

Definition .1 [13] An intuitionistic fuzzy graph is represented as G = (V, σ, μ), where σ = (σ_1, σ_2) and μ = (μ_1, μ_2). (i) The set V = {v_0,v_1, ...,v_n } is such that σ_1: V → [0, 1] and σ_2: V → [0, 1], which denote the degree of membership and non-membership of the vertex vi ∈ V, respectively. It holds that $0 \le \sigma_1(v_1) + \sigma_2(v_1)) \le 1$ for every v_1) ∈ V (i = 1, 2, ..., n). (ii) The functions μ_1: V × V → [0, 1] and μ_2: V × V → [0, 1] are defined, where$\mu_1(v_i, v_j)$ and $\mu_2(v_i, v_j)$ represent the degree of membership and non-membership values of the edge (v_i, v_j), respectively. It is required that $\mu_1(v_i, v_j) \le$ min{σ1(vi), σ1(vj)} and $\mu_2(v_i, v_j) \le \max\{\sigma_2(v_i), \sigma_2(v_j)\}$, and that $0 \le \mu_1(v_i, v_j) + \mu_2(v_i, v_j) \le 1$ for every pair (v_i, v_j).

Example 1. Let G = (V, σ, μ) be an intuitionistic fuzzy graph, where σ(v) = (σ_1(v), σ_2(v)) and μ(u, v) = (μ_1(u, v), μ_2(u, v)). The vertex set is V = {v_1, v_2, v_3, v_4}, with σ(v_1) = (0.3, 0.6), σ(v_2) = (0.8, 0.2), σ(v_3) = (0.2, 0.8), and σ(v_4) = (0.5, 0.4). Additionally, μ(v_1, v_2) = (0.25, 0.45), μ(v_2, v_3) = (0.18, 0.75), μ(v_3, v_4) = (0.15, 0.52), μ(v_4, v_1) = (0.3, 0.25), μ(v_1, v_3) = (0.2, 0.8), and μ(v_1, v_4) = (0.4, 0.35). The corresponding intuitionistic fuzzy graph is illustrated. (0.3, 0.6) v_4(0.5, 0.4) (0.3, 0.25) (0.15, 0.52) (0.25, 0.45) (0.18, 0.75) (0.2, 0.8) (0.4, 0.35) v_2(0.8, 0.2) v_3(0.2, 0.8)

Intuitionistic Fuzzy Labelling Tree

Definition.2A graph (G = (V, sigma, mu)) is referred to as an intuitionistic fuzzy labelling tree if it possesses an intuitionistic fuzzy labelling and an intuitionistic fuzzy spanning subgraph (F = (V, sigma, rho)) that is a tree. For all arcs ((u, v)) not included in (F), it is required that (mu1(u, v) < rhonifty$_1$(u, v)) and (mu2(u, v) > rhoinfty$_2$((u, v)).

Theorem 1 Every intuitionistic fuzzy labelling graph is an intuitionistic fuzzy labelling tree.

Proof. Let G = (V, σ, μ) be an intuitionistic fuzzy labelling graph. Since μ is bijective, each and every vertex of G will have at least one arc as intuitionistic fuzzy bridge. Therefore, the spanning subgraph F will exist, such that whose arcs are intuitionistic fuzzy bridges. Hence, every intuitionistic fuzzy labelling graph is an intuitionistic fuzzy labelling tree.

Definition.3 A graph (G = (V, sigma,mu)) is called an intuitionistic fuzzy labelling tree if it has an intuitionistic fuzzy labelling and an intuitionistic fuzzy spanning subgraph (F = (V, sigma, rho)) that is a tree. For all arcs ((u, v)) not included in (F), it is required that (mu1(u, v) < rhoinfty1(u, v)) and (mu2(u, v) >rhoinfty2(u, v)).

Theorem 2.A connected intuitionistic fuzzy labelling graph (G) is a partial tree if and only if, for any cycle (C) in (G), there exists an arc (e = (u, v)) such that (mu1(e) < text{CONN}1(G-e)(u, v)) and (mu2(e) > text{CONN}2(G-e)(u, v)), where (G-e) is the subgraph of (G) obtained by removing the arc (e) from (G).

Proof: Let (G) be a connected intuitionistic fuzzy labelling graph. If there are no cycles, it is clearly a tree and therefore a partial tree. If cycles exist in (G), let ((u, v)) be an arc belonging to the cycle (C) with the minimum membership weight and maximum non-membership weight in (G). Then, remove the arc ((u, v)) from (G). If there are still cycles in the graph, we can repeat the process. At each stage, no previously deleted arc is stronger than the arc currently being deleted. When no cycles remain, the resulting subgraph is a tree F. Let (u, v) be an arc not present in F. Then (u, v) is one of the arcs deleted during the construction of F. Since F is a tree and the arc (u, v) has the minimum membership value and maximum non-membership value among the arcs in a cycle in G, it follows that there exists a path from u to v with a membership value greater than μ_1(u, v) and a non-membership value less than μ2(u, v) that does not involve (u, v) or any arcs deleted prior to it. If this path includes arcs that were deleted later, the path can be further diverted, and so on. This process stabilizes with a path consisting entirely of the arcs in F. Thus, G is a partial intuitionistic fuzzy labelling tree.

Conversely, if G is a partial intuitionistic fuzzy labelling tree and P is a cycle, then some arc e = (u, v) of P does not belong to F. Thus, by definition, we have μ1(e) < CONN1(G−e)(u, v) < CONN1G(u, v) and μ2(e) > CONN2(G−e)(u, v) > CONN2G(u, v).

Theorem 3. If there exists at most one strongest path between any two nodes in G, then G must be a partial forest.
Proof. Assume G is not a partial forest. This implies there is a cycle C in G such that (mu1(u, v) geqtext{CONN}1^G(u, v)) and (mu2(u, v) leq text{CONN}2^G(u, v)) for all arcs (u, v) in the cycle C. Therefore, (u, v) represents the strongest path from u to v. If we select (u, v) as a weakest arc of C, it follows that the remainder of the cycle C is also a strongest path from u to v, leading to a contradiction. Consequently, G must be a partial forest.

Theorem 4. If G is a partial tree and not a tree, then there exists at least one arc (u, v) for which (mu1(u, v) < text{CONN}1^G(u, v)) and (mu2(u, v) > text{CONN}2^G(u, v)).
Proof: If G is a partial tree, then by definition, there exists a spanning tree F such that (mu_1(u, v) < text{CONN}1^G(u, v)) and (mu2(u, v) >text{CONN}2^G(u, v)) for all arcs (u, v) not in F. By hypothesis, there is at least one such arc (since G is not a tree), and thus the result follows.

Theorem 5sIf G is a partial tree and F is the spanning tree, then the arcs of F are the partial bridges of G.
Proof Let (u, v) be an arc in F. This arc is the unique path between u and v in F. If there are no other paths in G connecting u and v, then clearly (u, v) is a bridge of G and therefore a partial bridge of G. If there exists a path, say P, from u to v in G, then P will certainly contain an arc (x, y) that is not in F such that (mu1(u, v) < text{CONN}1^G(u, v)) and (mu2(u, v) > text{CONN}2^G(u, v)). Thus, (u, v) is not the weakest arc of any cycle in G, confirming that (u, v) is a partial bridge.

CONCLUSION

Connectivity concepts are a key aspect of intuitionistic fuzzy graph problems. In this work, we have introduced new connectivity concepts in intuitionistic fuzzy labelling graphs. We also defined terms such as strong arc, partial cut node, bridge, and block based on the connectivity concepts of intuitionistic fuzzy graphs. Furthermore, we defined intuitionistic fuzzy labelling trees and partial intuitionistic fuzzy labelling trees, establishing many interesting properties related to them, which play a significant role in various fields of science and technology. We are expanding our research to include (1) the covering problem on intuitionistic fuzzy graphs, (2) the chromatic number in intuitionistic fuzzy graphs, and (3) the colouring of intuitionistic fuzzy graphs.

ABSTRACT

Starch is unique in that it's the primary storage polysaccharide in plants and an important biopolymer in food, pharmaceutical, and industrial applications. It consists of two parts: amylose and amylopectin, and its properties are influenced by a hierarchical structure, from the number of glucose residues per chain to the semi-crystalline lamellae. The interactions between plastid enzymes influence the process of granule initiation, development, structure, and thus digestibility, gelatinization, pasting, and retrogradation. Such specific information as the extent of branching, crystallinity, and amylose to amylopectin ratios has a direct effect on glycemic index and metabolism, emphasizing the importance of starch structure in nutrition. New tools have improved our understanding of the multi-scale structure of starch, and this has opened the door for precise modifications to improve performance in biodegradable materials, pharmaceutical additives, and food preservation. A mechanistic understanding of starch biosynthesis and structure-function relationships is essential for developing tailored starch systems.

Keywords: Starch biosynthesis, Amylose, Amylopectin, Gelatinization, Retrogradation.

INTRODUCTION

Starch is a significant polysaccharide that is found in many plants and algae. Starch is mostly made up of numerous units of D-glucopyranosyl, which are mostly connected via 1,4-linkage and -1,6 branch score towards the structure, which is paired with complementary polymers, mainly the linear amylose and highly ramified amylopectin. These macromolecules combine to form a distinct semi-crystalline granule containing an amorphous and ordered lamella, which acts as a substitute, thereby providing a hierarchical structure that is based on the physicochemical properties of starch and serves both plant and human applications of various kinds. The granular structure, which affects water

intake, crystallinity, and enzyme accessibility, is determined at the molecular level via the distribution of chain lengths, the degree of branching, and the relative proportion of amylose to amylopectin.[1,2]

The phenomenon of biosynthesis of starch takes place inside the plastid of cells, and it is coordinated by a group of enzymes, namely ADP-glucose pyrophosphorylase, multiple starch synthases, branching enzymes, and also debranching hydrolases, together with numerous accessory proteins which control the granule's initiation, growth, and expansion, which are all responsible for the biosynthesis of the plastid inside starch molecules [3]. The aforementioned isoform composition, function of protein, and interactions of the protein dictate the size, shape, and internal blocklet structure of the granules. The minor alterations in things like enzymatic control and protein-protein interactions can result in major changes in the large, granular structure of the starch molecule, which can range from chain-length distributions up to lamellar packing and morphology.[2,3] From a nutritional point of view, starch makes up a large proportion of the caloric intake of the world. This is because of the physiological characteristics of starch, which are closely linked to the structural characteristics of the starch molecule, which governs its digestibility as a major component of our diet. The Glycaemic response and post-prandial metabolism are affected by the pace and degree of enzymatic hydrolysis in our small intestine, which is strictly regulated by chain length distributions, amylose concentrations, and the crystalline shape of the starch molecule [1]. Additionally, the interaction of starch with the gut microbiota impacts our downstream metabolic and health outcomes, making structural characterization of starch vital for both food science and nutritional epidemiology.[1,2]

The subsequent molecular and supramolecular structures of starch correspondingly establish the functional properties that are exploited in industries for various uses. These include gelatinization, pasting, retrogradation, solubility, and film-forming capacity of starch molecules. The gelatinization process occurs as a result of the turbulence of the crystalline lamellae and the hydration of polymer chains; the pasting and viscosity evolution properties reflect polymer disentanglement and swelling; retrogradation, as a phenomenon, occurs due to the reassociation of linear and short branched chains during the cooling and storage of starch [4]. The above mentioned properties of starch have allowed for its extensive adaptation to various non-food applications as a renewable biopolymer, which can be used in various applications like biodegradable packaging, pharmaceutical excipients, and adhesive matrix, where changes in molecular weight, branching, and chemical functionalities control the mechanical and thermal properties of starch [4,5] . Although recent advances in analytical testing have improved our understanding of the starch molecule across length scales- from detailed chain-length profiling and helix packaging to lamellar and blocklet organization, significant questions remain about the mechanistic properties of starch, which need to be answered. In particular, little is known about the molecular factors that influence granule initiation, the various functions of post-translational modifications, and the non-enzymatic scaffold proteins which are in the control enzymes. Much is yet unknown as to how biosynthetic systems of starch react to environmental stress. Addressing these aforementioned gaps is critical to engineer and build starch molecules that are stable and easy to handle [2–5]

Starch and Its Sources

Molecular identity, granular architecture, and the cellular biosynthetic framework

Starch is a major plant storage carbohydrate and a semicrystalline, insoluble farinaceous glucan produced mainly from a pair of very different glucan polymers, mainly linear amylose and highly ramified amylopectin.[6] Starch granules change greatly in size, outline, and internal structure in the middle of the botanical roots, changing from sub-micron pieces to larger granules with spherical, biconvex, polyhedral, and ribbon-like morphology.[7] The two major starch polymers, amylose and amylopectin, are chemically comparable in the sense that their glucose residues are connected principally by a -1,4 glycosidic linkage and interrupted by a -1,6 branch score, which differs greatly from one another in branch frequency, polymerization rate, and granule organization; however, they differ greatly from one another in branch frequency, polymerization rate, and function.[6] Amylose can, by and large, be imagined as a very largely linear polymer with infrequent -1,6 sidechains arising from extended irons capable of containing a thousand glucose units and occupying the excess amorphous regions of the granule, hence controlling gelatinization, retrogradation, and resistance to enzymatic hydrolysis. Amylopectin, which usually constitutes a major component

of the starch grain (typically 70–85 % ww in the majority of storage starches), is a highly ramified macromolecule whose compact irons assemble in a double-helical array inside the nanocrystalline gill and hence determine the semi-crystalline lamellar architecture of the starch granule.[8] The nanoscopic agreement of amylopectin double helix gives rise to characteristic crystalline polymorphs (typically called A-, B-, and C-types) which are diagnostic for the beginning of the plant and exert significant restraint on thermal characteristics and enzymatic properties.[7] X-ray scattering and microscopy experiments show that semi-crystalline development rings and alternate crystalline and amorphous gills (9–10 nm repeat) are a widespread feature in the natural granule and show the ordered conformity of the double helix punctured by amorphous interlamellar segments.[8] In the crystalline gill, limited amylopectin irons (also known as A and B type limited irons) are packed in double helixes which stabilize the nanocrystals. During the extended irons and amorphous block parts structure, a flexible backbone or interblock localities allow granule expansion and malleability. [9].

At the molecular level, the circulation of the chain length within the bounds of amylopectin — compact, intermediate, and long irons in relative abundance — is a fingerprint that is highly correlated with the crystallinity, gelatinization temperature, adhesive properties, and digestibility, and therefore the CLD is a central shape for the structure–function relationship in all parts of the starches of assorted plants.[10]Existing analytical approaches, such as debranching and subsequent size-exclusion chromatography, superior anion exchange chromatography with pulsed amperometric detection, and asymmetrical flow field-flow fractionation, promptly allow CLD measurements with high resolution and identify that the S L sequence ratio and frequency of individual degree-of-polymerization windows are predictors of functional performance. [10] Two academic models have extended the predominate systematic notion related to amylopectin: the traditional bunch " model where truncated irons aggregate as discrete crystalline bunches joined by long inter-cluster irons, and the new building-block/backbone " model where modular structure blocks that are related united within a longer foundation; recent signs from enzymology, debranching mutant, and dextrin profiling possesses result in polish and fragmentary reconciliation of those models. [8,9] In particular, the building block and backbone models explain whether debranching enzymes (isoamylases and pullulanases) are needed during biosynthesis to remove excessive branching and arrange semi-crystalline lamellae as an alternative to the development of soluble phytoglycogen. [9].

Starch biosynthesis takes place in the plastid (amyloplasts for storage starch, alternatively chloroplasts for impermanent starch) and is guided by an enzyme that constructs linear irons (starch synthases), produces a branch (starch ramify enzyme), removes unsuitable branches (debranching enzymes), constructs and restricts ADP-glucose substrate ADP-glucose pyrophosphorylase; AGPase), and uses accessory proteins that position the enzyme else primer for the new shaping of glucans.[6] The canonic model defines several isoforms of soluble starch synthases (SSI–SSIV and different individuals), starch ramify enzyme (SBEI–III), and debranching enzyme, while granule-bound starch synthase (GBSS) specifically elongates amylose polymer and requires a precise target protein for appropriate localization toward the evolving granule. [6,11]The use of heritable and biochemical approaches, especially in model and crop systems, confirms that isoforms fulfill and their spatial-temporal form of expression restricts chain-length distribution and, consequently, significantly restricts granule size, morphology, and starch functionalities. [12] For example, loss or decline of GBSS task may lead to waxy starches (essentially amylose-free), together with characteristic pasting, retrogradation, and digestibility during ramify or debranching enzyme disturbances, possibly resulting in hyper-branched, soluble glucans or modified crystalline system. [10,11] Advances have perfected our knowledge of the initial stage of granule formation, which involves a participating plastidial carbohydrate-binding protein, an admiral member of the protein targeting to facilitate the transport of maltooligosaccharide primer and regulate granule size and shape, thus connecting protein–polysaccharide communication with the macroscopic granule framework. [3,11].

Transcriptional relationships, posttranslational control (similar to protein phosphorylation and redox regulation), creation of a multiprotein complex, and substrate provide a complete function in modulating starch biosynthesis in response to metabolic and ecological signals, and the aforementioned governing layer is increasingly present in cereal endosperm and vegetative tissues.[6,12] In cereals, the endosperm-specific complement of enzyme isoforms,

ADP-glucose conveyance frameworks geared towards the sink, and determinant of the sink strength, together form a huge, agriculturally important starch militia which is the cornerstone of the worldwide human diet.[12] The last decade of work using mutant genetics, proteomics, and high-tech biochemical fractionation has confirmed that starch biosynthetic enzymes form in dynamic macromolecular complexes whose composition changes with evolution and which seem to be able to manage the correct arrangement of glucans.[3,9] More, the recent genomic and molecular challenges in major crops (rice, corn, wheat, cassava, potato) have defined the inherent and induced variation in starch biosynthesis to improve capacity, retrogradation behavior, and digestibility, thus demonstrating how enzyme genotype starch scaffolding functional property correlation can be leveraged for engendering. [12].

The corporeal chemistry of starch, gelatinization, glue profile, retrogradation dynamics, and enzyme digestibility is an emerging property of the polymeric composition and the hierarchical consistency of the crystalline and amorphous spheres in the granule. [13] Gelatinization is equivalent to the interruption of the double helix and thawing of crystalline gill at a temperature when heat enters the water; the temperature and initial temperature of the same procedure correlate with amylopectin crystallinity, string length distribution, and the presence of lipid, alternatively phosphate monoesters attached to glucans.[7,10] The retrogradation, the reassociation of amylose and amylopectin irons beyond the period of cooling, is essentially caused by linear amylose irons and small amylopectin irons and is crucial for the texture change during storage, stale bread, and development of immune starch type 3 (retrograde starch). [13,14] On the other hand, autochthonous obstacles have a restricted surface area of the skin, decreased water resistance, and tightly packed crystalline lattices, which may produce starch parts less prone to -amylase and -glucosidase attack, resulting in slow digestible starch (SDS) and immune starch (RS) fraction with significant nutritional outcomes. [14,15].

The plant foundation thus acts as a first order factor determining the starch properties of tuber (e.g., potato) usually has large granules, increased swell capacity, and B-type crystallinity with evident cold gelatinization behavior, while starches from cereals (e.g., maize, rice, and wheat) frequently show A-type crystallinity with smaller granule and higher gelatinization temperature; root/tuber starches admire cassava and tapioca tend to reveal intermediate fictional characters, but wide cultivar variation. [7,16,17] Within the limits of the family, cultivar variation, increased conditions, and postharvest treatment more adjust starch composition and functionality, thus causing cultivar choice and agronomy use to modify starch performance for food, feed, and industrial objectives. [12,17] united, the combination of polymer composition (amylose/amylopectin ratio), ultrafine molecular architecture (CLD), granule ultrastructure (lamellar stacking, crystallinity), and macromolecular association (protein and lipid residues) establishes the fingerprint of the order in which the individual starch behaves during management, digestion, and in non-food use (appreciate adhesive material, bioplastics, and pharmacy). [13,18].

Botanical sources, extraction technologies, variability, and analytical characterization

Starch in the structure of a botanical commodity has been discovered beyond a broad phylogenetic scope and is stored mainly in amyloplasts of kernels, endosperm, tubers, roots, and a few fruits. Corn, wheat, rice, potato, and cassava supply the vast majority of the commercial supply chain around the world[19] . The macromolecular arrangement of starch — amylose to amylopectin ratio and dispersion under conditions of sequence length, organization of amylopectin gang, and allocation of crystalline and amorphous gill varies between species and tissues and is controlled by the native functional fingerprint of the starch cause below consideration [20]. Endosperm of cereals produces a starch granule with a bimodal or otherwise polymodal size distribution and amylopectin content, which contributes to glue viscosity and gelation demeanor in food systems [19].

Compared to potato starches, tuber starches produce highly large, high-molecular-weight granules with increased swelling ability and decreased retrogradation inclination, which are related to their loosely aggregated amorphous sphere and unique amylopectin group architecture [19]. Cassava (Manihot esculenta) starches are characterized by their reduced gelatinization temperature, high-quality paste transparency, and function in film and adhesive formulations; these properties are due to a typical amylopectin branching structure and a relatively low lipid content

relative to cereal starches [16]. Root starches (e.g. , sweet potato and arrowroot), which can be attributed to a genotypic difference in biosynthetic enzyme and the tissue environment during granule development [21].

In addition to the conventional five, otherwise six industrially dominant starch crops, a growing number of researchers report 'non-conventional '' and underexploited botanical origins whose starches are likely to have a single amylose content, unexpected crystalline polymorph, or reduced granule size, which makes them of curiosity for specialized use [22]. Starch isolation has been a longstanding and important method of starch isolation, primarily simple mechanical interference of the tissue followed by differential separation, washing, and drying. Nevertheless, the actual choice of press, mechanical regime, and chemical aid radically adjusts the yield, purity, and elusive architectural features of the isolated starch [20]. As long as they are scalable and as long as they have proven downstream management for protein denudation, all right sieving, and drying, although they largely require extensive water and energy inputs and are sensitive to cultivation and harvest conditions [19]. Alkaline washing, sulfite bleaching, and oxidative treatment are usually used industrially to remove pigment, lipids, and residual cell debris from tuber and root starches. However, skin chemistry and light scattering properties can be modified to prevent molecular hydrolysis, otherwise known as depolymerization[21] . Enzymatic pretreatment — usually cellulases, otherwise pectinases for interrupting plant tissues and protease for better protein isolation — is likely to increase starch recovery together with molecular ethics and provide a nerve pathway for a less harsh, more selective extractant that is food and pharmaceutically compatible[20] . Modern' guided '' extraction systems, especially ultrasonic, microwave, and enzyme-assisted extraction methods, have been developed in comparative studies with a view to increasing extraction productivity, short processing times, and occasionally providing starches that modify granule veneer morphology or modify molecular weight[23,24] . The recent advances in green solvents, especially organic deep eutectic solvents (NADES), and supercritical fluids guided fractionation open up the prospect of small molecule extractions associated with starch, else fractionate co-extracted lipids and protein with reduced ecological impacts, even though these approaches are, however, pilot-to-bench next to the best for the large starch industry[24,25]. Small variations in the composition of the isolation medium, such as the occurrence, mild NaOH compared with pure water, or the addition of sulfite for color enhancement, do not significantly change the crystallographic shape or amylose content, although they modify the melting temperature, swelling, and whiteness, which are essential standard variables for two uses [21].

Comparative studies across innumerable root and tuber crops show that extraction medium and mechanical shear interact with the inherent granule size allocation toward the regulation of the apparent amylose content and gelatinization heat content measure, suggesting that several measurements of origin difference '' are processing artifacts unless extraction is controlled [21]. Near the molecular degree, the precise chain length allocation of amylopectin and the presence of long extra-chains in the amylose fraction restrict lamellar stacking and hence the X-ray diffraction shape and relative crystallinity on which the analyst bases the classification of starch as A-, B-, or otherwise C-type [8,26]. A recent architectural review combines enzymatic debranching with fluorophore-aided carbohydrate electrophoresis, HPAEC-PAD, and multi-detector SEC to define string distribution everywhere diminished and high polymerization, a methodological feature facilitating mechanistic linkage for biosynthetic enzyme tasks [26]. Microscopy, ranging from SEM and TEM to more sophisticated nonlinear optical methods such as second-harmonic covalent bonds and coherent anti-Stokes Raman disperse, shows granule topography, interior channels, and crystallinity heterogeneity, and these spatially determined conclusions are essential for the interpretation of bulk thermomechanical data [27]. The thermal analysis of the DSC approach gelatinization endotherms and heat content, when correlated with the RVA glue profile, outputs forecasting parameters for food and material handling operations, despite the fact that such macroscopical parameters should exist translate alongside the mention of granule size circulation and polymer CLD to prevent unbalanced equality through breed [26]. X-ray diffraction is a standard method for determining crystallographic polymorphism and determining relative crystallinity, but the measurement must involve sample preparation and hydration declared delicate and must therefore be complemented by a spectroscopic probe [26,27]. Because granule size has a first-order influence on top swell dynamics, water absorption, and enzyme efficiency, granule size dispersion is a serious form of analysis beginning for specific technological purposes, i.e., Texturants, encapsulants, or film-forming polymer [28]. Genotypic

divergence of starch synthases, the ramify enzyme, and the debranching enzyme produces quantifiable differences in amylose content, sequence allocation of amylopectin, and granule size, and plant breeders habitually prefer plant starch for target industrial use[29]. The green conditions throughout crop development — temperature close to grain filling, earth nitrogen, water, and agronomic practices — regulate endosperm enzyme activities and thus alter granule size dispersion, amylose/amylopectin ratio, and even elusive compositional properties such as phosphate mono degree in potato starch [19,29]. Hence, multi-location and multi-season tests frequently record useful genotype ecosystem exchanges for starch functional parameters, which obliges starch processors to pass simultaneous cultivation and supply chain controls where uniform performance is essential [29]. The analytic fractionation of starch by sieving, deposit, or field-flow fractionation enables the purification of a narrow granule size fraction whose distinctive physicochemical signature can be correlated experimentally with precise application, e.g. The small granules possess the ability to form a solid paste and to resist enzymatic hydrolysis in the individual objective [26,28]. The combination of molecular testing with multi-scale imagination and rheological measurement provides a structure-function relationship that explains the possibility of duo starches together with the same amylose remaining dramatically different in gelatinization, retrogradation, and film formation [26,27].

In order to ensure minimal damage to starch and preservation of granule morphology for high-value functions, recent industrial practices continuously incorporate carafe centrifuge, hydrocyclones, and belt dryer to ensure minimal starch damage and preservation of granule integrity [19,20]. The resilience index is becoming a more powerful root and approach choice: cassava and potato can produce high starch output per hectare in a couple ecology despite that water footprint, nitrogen utilization efficiency, and risk of post-harvest degeneration must remain balanced against cereal starting implant in an enormous, simplified milling plant [16,19]. Valorization of innovative starch starting and agroprocessing co-products may be appealing within the framework of the circular economy; however, the scale-up requirements need to be reviewed carefully in light of the fact that a large number of such starting starches supply starch with unusual characteristics and reduced extraction efficiency relative to the commodity crop [22]. Starch granules with a large surface area and high swelling capacity are preferred in certain adhesive materials and fabrics with a view to improving the adhesion and film formation properties, while small, round granules are usually selected for instantaneous food powder and encapsulation material [19,28]. Forecasting breeding for starch qualities, such as mutant or otherwise choice of starch synthase isoforms, has already resulted in altered granule size dispersion and high immune starch satisfied line, proving that plant genetics extends an extraneous avenue to alter natural material properties in addition to post-harvest processing [8,29]. Analytic reproducibility is a widespread issue in starch science; comparisons among laboratories show that changing debranching methods, detector calibration, and hydration history of the sample can alter CLD and apparent amylose beliefs, implying the need for standard protocols at that time for critically analyzing botanic origins [26]. The presence of a non-starch component — residual protein, phospholipid, and phenolic resin — is usually co-extracted to influence functional behavior in elusive tactics in various ways, for instance by complexing together with amylose to reduce apparent swell, or by moving paste clarity, and such interactions must be measured when initiating a correlation [16,21]. Recent analytic coupling, such as uniting small-angle X-ray scattering alongside deconvolution of CLD and rheologic mastercurves, allows mechanistic separation of which method lamellar repeat distance and bunch size measurement alongside macroscopic gel potency, and thus establishes a nerve pathway toward rational root choice for targeted mechanics[26,27]. Lastly, the genetic fingerprint, the botanical root, the context, and the extraction method collectively order the multi-level organization of starch from the molecular CLD via lamellar architecture to the granule morphology, and only a multi-modal analytic technique can reliably superimpose this organizational fingerprint on the functional endpoint demand of the food and non-food industries [19,20,26,27].

Fundamental Chemical Architecture And Biosynthesis Of Starch

Starch is the main storage glucan in the larger plant; the existing composition consists mainly of a d-glucose polymer, a fundamentally linear amylose, and a highly ramified amylopectin, whose relative proportion and architectural details determine the physicochemical behavior of the granule.[6] . Amylose has, by and large, been described as a fundamentally α-(1→4)-linked glucan with a few α-(1→6) branch marks and a molecular pressure circulation, which changes with the botanical root, despite that commonly ranges between a couple of hundred and several thousands

of DP dependent on the breed and the method of examination (Fig. 1.)[30] . Amylopectin is a highly bifurcated macromolecule whose hierarchical organization consists of brief external irons, long interblock irons, and branching point clusters in a semicrystalline gill that regulates the Farinaceous crystallography. [8]. While considerable occupation possesses concentrated concentrations above the aforementioned latter features, chain-length allocation of amylopectin, usually obtained by enzymatic debranching followed by chromatographic size, is the molecular form primarily directly connected to the crystalline lamellar space, gelatinization temperature, and glue behaviour.[6] .

In the present study, a mathematical and mechanistic model has shown that the association of the rates of chain propagation, branching, and debranching to the adjacent CLD can explain the most certain features of the CLD derived from the distinct botanical origins and the engineered genotype established on a relatively few biosynthetic parameters. [31]. The biosynthesis returns to the plastid from the ADP-glucose substrate and is orchestrated by soluble starch synthases (SSs), granule-bound starch synthase (GBSS), starch ramify enzyme (SBEs), and debranching enzyme (DBEs) working together; perturbation of any of the above enzyme sessions produces predictable changes in CLD and granule properties. [11]. GBSS is primarily responsible for the preparation of long linear irons that are operationally called amylose, but it is granule-bound and highly processive; its product strongly influences the dynamics of retrogradation and the formation of an integration complex with lipid. [11] To establish branch density and branch spacing in amylopectin, the composition of the SBE isoform must be known, while the transition of the SBE project shifts the mass between small and elongated irons within the amylopectin CLD, with different results in gelatinization and paste. [31]. The degranulation enzyme, similar to isoamylases, behaves throughout the biosynthesis as a corrective trimming organization that removes erroneous branch topologies, enabling the ordered composition of iron inside the double helix; a loss-of-function DBE mutant typically consists of soluble phytoglycogen rather than insoluble, semicrystalline granule. [11]. Towards the monosaccharide degree, the glucose residues in starch supply three hydroxyl groups and individual anomeric centers; the placements (C-2, C-3, and C-6) and stereochemistry of these functional groups create a large hydrogen bonding web that regulates the movement of the ropes and the packing material. [32].

In addition, double helix formations in short amylopectin irons (approximately DP 6–12) are particularly powerful near stabilized crystalline gills, and their frequency and dispersion are almost uniform regardless of whether a starch adopts an A-, B-, or another C-type crystalline pack motif. [8]. Amylose, although less ordered in the native granule, can grasp a single or double-helical motif in the thermal mediation and complicate it with a hydrophobic guest, akin to fatty acid or monoglycerides, toward the arrangement V-type inclusion complex, which has a simultaneous high-tech behavior and digestion. [33]. The result of the periodic branching and regular rotation of double-helical and amorphous layers in amylopectin is a lamellar architecture of the natural granule'lamellar architecture, a concentrated alternate crystalline and amorphous layer with a repeat distance of 9–12 nm. [8]. The state-of-the-art analytic workflow combines enzymatic debranching with size-exclusion chromatography, HPAEC-PAD, or fluorophore-assisted capillary electrophoresis to determine the CLD, and these data are combined with small-angle scattering, X-ray diffraction, and solid-state NMR to connect the molecular architecture for lamellar and crystalline systematics [26]. The lamellar repeat, hence, matches so that it approximates the electron-density transition, so long as solid-state 13C NMR and SAXS confirm the alternation between the dumbly packed double helix and hydrate amorphous regions, together with the CLD variations systematically alter the lamellar disparity and peak situation. [8]. The size-exclusion analysis of debranched starch suits with a biosynthetic model provides parameters that are directly related to enzyme projects and hence useful in linking inherited variation to molecular organization in a plant breeding program. [31].

The botanical origins of cereal endosperm starches are, by and large, A-type starches, with a large amount of limited amylopectin irons and a moderate amylose content of 20-30 %, whereas tuber starches are often B- or C-type and have a very distinct hydration and swelling conductivity. [30]Natural variation and a targeted mutant of a biosynthetic gene within the range of variety allow breeders to adjust amylose stages and CLD characteristics. GBSS, SBE, and DBE are demonstrations. It enables custom thermal and adhesive properties for precise food and industry use, far removed from dispersal.[11] . The minor components of the granules, lipids, phosphate monoesters,

particularly tuber starches, covalently or otherwise non-covalently bound protein, and phenolic residues influence the nearby packing material, intricate formation, and veneer density, and thus influence the water consumption, swell, and enzyme availability in source-specific techniques. [33]. The phosphate monoesters introduced to the plant by glucan dikinases have an adverse charge on starch and increased hydration and swelling, which is exploited by the native starches to produce better cold expansion and paste transparency. [34]. In the end, given that amylose and amylopectin are functional definitions dependent on the analytical method, rigorous chemical analysis requires that CLD, molecular weight distribution, and degree of branching be reported together with amylose fraction beliefs. [26].

Supramolecular Organisation, Physical Chemistry And Analytical Probing

Starch granules are nanocomposite atoms in which double helix semicrystalline regions coexist with amorphous, hydrate interlamellar zones, which contain branch tips and minor components in those. [8]. The classical lamellar repeat, approximately 9–12 nanometers, which can be detected by small-angle scattering, is therefore produced by periodic alternation between electron-dense crystalline gills composed of ordered double helix and less dense amorphous gills with high ramification and water content. [8]. The three primary crystalline polymorphs that can be detected by X-ray diffraction are A-type, B-type, and C-type, which develop mainly in roots and legumes.[7] . The molecular mold, together with the X-ray evaluation of the double-helical inner packing material and cell geometry of the A and B type crystals, and also the method of determining the water content and packing material of the helix in the two polymorphs. [33]. The single or double coiling of amylose by a suitable-sized hydrophobic guest molecule forms a V-type inclusion complex upon gelatinization in a lipid, which is characterized by a characteristic V-type XRD reflection and a Specific FTIR/NMR signature. [35]. Amylose-lipid involvement alters gelatinization endotherms, decreases amylose leach, and influences the dynamics of retrogradation, as the involved entraps linear irons and reduces their capacity to re-associate with the native double helix. [36]. The DSC provides an estimate of gelatinization endotherms and retrogradation energies, although the DSC signal is usually a combination of long-range crystalline thaw and biased molecular disorder and must remain interpretable alongside the organizational probe in order to provide mechanistic intelligence. [37].

FTIR, Raman spectroscopy, and solid-state NMR analysis of a short-range conformational system and hydrogen bonding activity active in thermal passages, complementing the verification of a multistage, water-mediated gelatinization system with consecutive hydrogen chemical bonding and helix thaw. [37]. The solution-state 1H NMR in a solvent such as DMSO, together with a dissolution dynamics experiment, ensures the quantification of the genuinely soluble fraction, and the chain movement during extraction and chemical derivatisation may also be followed supplementary. [26]. Debranching attaching to by chromatographic size (SEC, HPAEC-PAD else face) yields the CLD, which, when analyzed by applying a biosynthetic model, assigns a certain CLD characteristic to SS, SBE, and DBE isoforms. [31]. Electron microscopy and small-angle scattering reveal mesoscopic heterogeneities-blocklets, covering pores, and inner channels whose formation depends on biosynthetic history and postharvest processing, and have a significant effect on water absorption and enzymatic penetration. [8]. As A-type crystals are thicker and less hydrated than B-type crystals, together with more water per unit of measurement cell, this inherent difference provides a minimal difference to the typically higher gelatinization temperature of cereal starches than tuber.[33]. Lamellar SAXS profiles are associated with CLD, as the more restricted irons, the greater the electron-density distinction, and the more acute the lamellar extremum, typically promoting gelatinization initiation and temperature content[8]. Gelatinization is accompanied by a rise in granule size, phosphate and lipid content, as well as an outer layer protein, and material barriers to water ingress [34]. The retrogradation process is biphasic in the surroundings: fast amylose re-association inside the period for producing delicate crystallite, and very slow amylopectin recrystallization over days or weeks for producing more solid gel and bread staining [38]. The supramolecular arrangement manages the dynamics of enzymatic hydrolysis; crystalline domains decrease the enzyme binding and processivity as amylopectin with dense compact outer irons is hydrolyzed more rapidly due to the incorporation of an additional end for -amylase to attack. [39].

Recent enzymatic and architectural surveys have shown that retrograded starches are capable of adhering directly to and suppressing amylase via a mechanism in which mechanistic constraints are revealed through systematic changes

in both substrate accessibility and catalytic deceleration from segregation. [40]. Slowly digestible starch and immune starch forms in the course of cooling, or alternatively retrogradation, as a result of mechanical resistance. In order to achieve a glycaemic response and substrate for colonic agitation, nutritional importance must be accompanied by admiration. [39]. For the first time, the new time-resolved synchrotron scattering and neutron processes allowed the observation of crystallite dissolution and re-formation in the heat treatment and cooling rotations, thus allowing the mechanistic model of gelatinization and retrogradation towards the existence test alongside the high transient resolution. [8]. From a substance point of view, supramolecular administration could be controlled by adjusting thermal parameters, shear, and humidity during management to produce paste, gel, and film with unchanging rheology and mechanical properties.[26] .

Chemical Reactivity, Derivatisation Strategies, Functional Consequences And Applications

The many primary and secondary hydroxyls present in starch, at positions C-6, C-2, and C-3, provide a chemical framework for esterification, etherification, oxidation, cross-linking, and grafting while adjusting solubility, hydrophobicity, and mechanical properties. [18]. By esterification, e.g., acetylation, succinylation, or octenyl succinic anhydride modification, the hydroxyl groups are transformed to ester groups, forming gelatinization properties, paste transparency, and interfacial activity with the intention of emulsification and encapsulation. [41]. OSA-modified starches are used to stabilize oil in water frameworks and improve microencapsulation efficiency among food-grade amphiphiles. The addition of a project, together with the intensification of the replacement and the plant base used. [41]. Only a few etherifications that improve solubility, low retrogradation, and optimize. Durability during freezing and subsequent use in food and drug compositions. [18]. Cross-linking, via bifunctional reagents Epichlorohydrin or phosphorus oxychloride, produces intra- and inter-molecular Bridges that limit the expansion and cracking of the paste beneath the shear, which is used in the manufacture of canned food, stabilized starches, and several industrial applications. [18]. Oxidative chemistry (periodate, hypochlorite, or TEMPO-mediated oxidation) oxidizes vicinal diol to produce carbonyls and carboxyls, changing the molecular pressure and gelation conductivity and providing a fresh reactive site for the extra junction. [18].

In planta glucan dikinases or chemically induced identical phosphorylation, an anionic phosphate monoester is introduced, which enhances hydration, thickens, and clarifies the paste and is thus particularly useful for use in potato starch. [34]. The formation of an amylose–lipid complex (Amylose–Fatty Acid/Monoglyceride) can be achieved during heat treatment and can be detected by V-type XRD contemplation and by typical thermal and spectroscopy signatures; the complex decreases apparent digestibility and enhances the immune starch fraction [35]. The formation of retrograded and chemically deduced immune starches (RS type II-IV) is a systematic manipulation of mainly nutritional function through the reduction of small intestinal amylolytic hydrolysis together with increased colonic agitation and subsequent production of short-chain fatty acids.[39] . Pregelatinized and physically treated starches (anneal, heat–moisture therapy, hard hitting management) alter the supramolecular system free of covalent replacement and are potential 'clean label' courses for adjusting gelatinization, glue, and retrogradation properties in food compositions. [18]. The chemoenzymatic and enzymatic modification of transglycosylation, lipase-catalysed acylation, or ramify enzymes facilitates regioselective substitution and less severe chemical modification compatible with food and Drug Administration [18].

Skin oxidation or grafting of starch nanoparticles enhances the outer layer and the interfacial project hence forming a composition suitable for use in Pickering emulsion, nanoparticle encapsulation, and biocomposite reinforcement.[26]. A number of examples of biodegradable thermoplastics whose performance varies greatly with phase morphology, as well as with graft density and interfacial bonding, are a starch-graft copolymer and an aliphatic polyester blend. [26]. In the manufacture of medicines, modified starches are used as disintegrants, binders, and by film producers. Pregelatinized and co-processed starch excipients enhance guide compaction and are used to modify the dynamics of tablet dissolution and release.[7] . The majority of supervisory habitat sanctions for several starch modifications, such as OSA-, acetyl-, and hydroxypropyl-starches used in food, with a given degree of substitution, must be individual safety measures for the stay reagent and by-product [41]. Modern green chemistry, including enzymatic catalysis, deep-eutectic solvents, or reactive bulges, produces far fewer harmful reagents and lower energy requirements,

driving recent large-scale starch transformation. [18]. Life Cycle and Technoeconomic analysis also show that relic carbon input signals are reduced by starch rather than mainly petroplastics, but nevertheless, land use, cultivation inputs, and end-of-life waste are well dominated by net ecological benefits. [26]. The biodegradation test confirmed that starch-based substances, particularly blends with compostable polyester, can readily mineralize under industrial conditions and thus provide a measurable method of diminishing polymer continuity.[26] . Finally, starch's chemical adaptability, together with its organic properties and biodegradability, anchors its position as a fundamental renewable polymer used in applications such as renewable packaging, controlled release excipients, and personalized food products, and the upcoming advances in regioselective chemistry and biosynthetic technology will contribute to its value in the circular bioeconomy.[18].

Problems of Starch-Related Drug Delivery

Starch has been intensively analysed as a renewable, biodegradable platform for drug distribution, ranging from granule-derived excipients to engine nanoparticles and chemically modified matrix. However, the translation of starch chemistry into a resilient, clinically useful carrier is hindered by several interlinked physicochemical, living, and regulatory problems that confuse formulation design and scale-up. [18]. The main obstacle for human being material heterogeneity is the starch exists nay a monodisperse polymer, although a botanical mixture whose amylose: amylopectin ratio, amylopectin train length dispersion (CLD), granule size, and crystalline polymorphism vary efficiently together with family, cultivar, addition ecosystem, extraction tools, and identical variation causes vast, frequently non-linear variations in swell, gelation, and drug release demeanor exceeding a suppose comparable batch. [18,42]. It must be closely associated with common industrial isolation and dry rung (mechanical shear, alkaline wash, enzymatic pretreatments, and garment cleaning), which alter external chemistry, granule porosity, imperfect molecular degeneration, and produce batch-to-batch differences in molecular force, peak charge, and porosity, which are difficult to suit without thorough technique standardisation and in-line information assessment. [42]. Despite the correct architecture of the polymer branch and the dispersion of the sequence, the everyday excellence of business normally relies on coarse prosody (iodine binding, apparent amylose %), which does not function in the same way as nanoparticle formation, matrix wear away motion, or API release profile, and thus complicates the reproducibility and trustworthiness. [18,43].

The hydrophilic, polyhydroxylated environment of native starch has individual advantages (biocompatibility, biodegradability), and liabilities to increase water affinity and increase the degree of hydration, mechanical weakening, and premature release of a drug in an aqueous environment unless the starch is chemically crosslinked, hydrophobically modified, or mixed with complementary polymers, which add new organisational complexity and safety options. [18]. A chemical modification scheme that reduces water sensitivity, e.g., acetylation, hydroxypropylation, octenyl succinylation, cross-linking) are very familiar together, although their handling intensity of substitution (DS) and regiochemistry by extent can retain difficult, residual reagent and by-product must be thoroughly snuff out to obtain a pharmaceutical safety gauge, and the acclimate normally does not modify entirely hydration although that in addition to enzymatic degradability and downstream biodegradation nerve nerve pathway in systems which are not always predictable from small-scale surveys. [18,41]. When mixed with an incorporation complex (Amylose–Lipid V-type complex) and an amphiphilic compound (e.g., OSA-starches), improved lipophilic warhead incorporation; the above-mentioned tactic requires a precise assessment of lipid content, organisation thermodynamics, and substitution appraisal, which is likely to alter gastrointestinal management and bioavailability in a plan involving careful in vivo research. [41,43].

The manufacture of nanoparticles by strategies identical to nanoprecipitation, acerb hydrolysis, enzymatic atomization, and spray drying produces starch nanoparticles with significant variations in crystallinity, skin chemistry, residual oligomer content, and the overarching architectural features restrict colloidal firmness, protein adsorption, opsonisation, and biodistribution, parameters which are frequently undervalued in preclinical reviews. [42,43]. Enzymatic and microbiome variations in the intended organic milieu constitute useful physiological uncertainty for starch-based carrier targets in vivo due to the host's amylase activity, luminal microbiota composition, and secondary agitation tasks. Consequently, a significant difference between the deterioration and the

release of medicine in the human body could be demonstrated by an identical starch matrix, thus affecting the dose and the pharmacokinetics. [18,40]. Retrogradation and recrystallization. Current excessive time-dependent problems with starch matrix: retrogradation (re-association of linear irons atop cooler, more storage) increases crystallinity and minimises enzymatic properties, possibly capable of floating in release interaction. Above shelf life elsewhere following thermal management ascent; on the additional hold, retrograde aspects sometimes increase the resistant-starch fraction and can retain the drug molecule, reducing bioavailability. [18,40].

Sterilisation and finishing work over excessive starch constraint utility of common sterilisation techniques for pharmaceuticals—gamma irradiation, electron irradiated beam, steam autoclave, ethylene oxide—can fragment starch irons, introduce oxidation, and alternately fluctuating crystalline phases, hence changing rheology, compressibility, and release properties; validation of sterilisation method that continues functional performance is hence non-trivial. [41–43] The mechanical properties and compactibility of the various starches in a buoyant oral dose of native starches are not the binding capacity that may be necessary to manage compaction, nor are the starch excipients co-processed or alternatively chemically modified to restore tabletability, but are likely to change the decomposition process erratically under physiological conditions. [42]. Another recurring problem, together with hydroxyl local and residual impurities (protein, lipid, phenolic material), is the development of hydrogen bonding sites, hydrophobic association, or Maillard-type chemical reactions, which could destabilise labile APIs, encourage gathering, or catalyse an unnecessary decrease in storage. [18,42]. Nevertheless, these decisive obstacles, the various sophisticated metamorphosis pathways—regioselective enzymatic acylation, deep eutectic solvent operation, reactive extrusion—prove that near the laboratory dimension, capital-intensive equipment, solvent recovery organizations, otherwise enzyme equipment irons to exist economically feasible near the industrial majority, and the life cycle examination must show apparent stamina support relative to the incumbent excipients to justify adoption. [42,43]. The fact that the technical obstacles to modify starches can exist embroil between the oversight group (food additive, pharmaceutical excipient volt fresh material) and the administration requirements for complete impurity, toxicology, and degradability of fresh material, which increases the cost and timetable of the system, particularly when the modification introduces a chemical moiety nay previously approved for parenteral alternatively oral pharmaceutical use. [18,41].

Analytical challenges impede growth and excellence in leadership. CLD, complex architecture, nanoparticle outer layer chemistry, and low-level residual reagent require a combination of complementary tactics (HPAEC-PAD, SEC-MALLS, solid-state NMR, SAXS/WAXS, DSC), and are associated with multi-modal computational assessments that are resource-intensive and normally convenient in a batch of formulation laboratories, creating a stop in the middle of the intellectual presentation and pulling out an idea. [42] Finally, the immunological and biodistribution profile of modified starch nanoparticles is incompletely analysed, although starch is enormously biocompatible. Oinnacle chemistry and nanoscale morphology likely disrupt complement activation, otherwise ineluctable bioaccumulation, and rigorous immunotoxicology and ADME probes are indispensable before clinical use, a study that is expensive and hence slow to translate. [42,43]. United, the higher physicochemical, physiological, analytic, and supervisory problems execute nay is not used in academic writing to invalidate the assurance of starch-based drug conveyance journalism but rather to explain the demand course of action via botanically informed organic material management, tightly standardized control, green and well-characterized transform chemistry, outlook in vitro-in vivo connection model based on enzymatic and microbiome variability, various analytic apparatus, and in a while interaction together with direction model to guarantee safety, reproducibility, and scalability. [18,42].

Modifications of Starch

Physical modifications — manipulating supramolecular order without covalent chemistry

The corporeal changes are caused by a total of thermal, hydrothermal, mechanical, and radiation agents, which alter the granule morphology, crystallinity, and water-polymer bonding without the scent of the recent covalent substitute. [44] Heat–Moisture Medicine (HMT) — slow heating of starch near restrict moisture (by and widely ranging 35 % w/w) and increased temperature — encourage the reorganization of amylopectin branch pack material and expanded short-range harmony to decrease the bang-up coerce and paste dislocation, produce starches together

with a precise gelatinization passage and improved thermal durability for operating over. [44]. Annealing, a mild thermal equilibrium of starch in excess, increases the molecular flexibility sufficient to allow the reorganisation of the amorphous sphere and crystalline perfection, thus narrowing the gelatinization endotherms and a uniform increase in the thickness of the paste and freeze-thaw toughness. [44]. Pregelatinization by beating, spray drying, or bulged conclusion item, soluble alternately partially gelatinized powder, which hydrates immediately and is used for direct mixture composition; however, the corporeal upheaval introduces amorphous regions and disrupts iron, which alters the rheology and retrogradation interaction relative to the native starch.[44] . Hard-hitting supervision and shear (for example, jet cooking and bulge) (Table 1) physically disrupt the granule, break down the molecular solubilization, and can form a fresh supramolecular organization at the cool pinnacle; regulate the shear record remains therefore exploited to create reproducible paste viscosity otherwise toward predigest starch for a particular nutritional outcome.[44] .

In a structure to avoid excessive series scission, supersonic and microwave-assisted medication addition, inner heat, and facilitation of microfisuring and external porosity of the granule, which might increase enzyme productivity and supply extra strong nanoparticle formation for encapsulation, although more arrangements must exist calibrated to avoid excessive series scission.[42]. Corporal changes normally alter the lamellar differentiation (measured by SAXS), narrow or broaden the DSC gelatinization extreme apex, and modify the X-ray diffraction intensity without the presence of fresh chemical substances that appeal to food and a few medicines.[44]. As the material normally follows the monosaccharide chemistry, it normally retains the beneficial biodegradation nerve pathway, but the fact that the emerging supramolecular rearrangement can significantly affect the enzymatic susceptibilities and the storage durability of the method, which requires careful shelf life and in vitro digestion.[44]. A hybrid physical/chemical framework, e.g., Anneal followed by mild acetylation or HMT prior to enzymatic transglycosylation use management state to increase readiness, e.g., to get the arranger to the desired place, e.g. To show how material care is normally applied as a precondition for a multi-step transformation structure. [42].

Hence, in order to associate macroscopic functional ends (gel stamina, paste, solubility) with the fundamentals of lamellar and molecular reorganization which are alike in terms of non-covalent therapy, enhancing body change requires multi-scale detailed inspection (DSC, SAXS/WAXS, SEM/TEM, CLD probe) in sequence so that they may associate macroscopic functional ends (gel stamina, paste, solubility) alongside the fundamentals of lamellar and molecular reorganization which are alike in terms of non-covalent therapy.[37] .

Chemical modifications — creating new covalent functionality to tune performance

Chemical modification of the hydroxyl group of the ester, quintessence, oxidize group, phosphate ester, cross-linking otherwise grafted polymer side chains to restrict hydrophobicity, charge, cross-link density, and degradability. [18]. Hydrophobic alkyl division and, in the case of OSA, amphiphilicity, which enhances the arrangement of the outer layer and enhances the lipophilic active agent's encapsulation together with substitution (DS) and allocation of substituents. [41]. Hydrogen propylation and carboxymethylation produce a water-soluble deduced function that reduces retrogradation, increases freeze–thaw stamina, and increases the compressibility of the guide compaction tablet, despite the fact that excessive substitution may compromise biodegradability or alter the enzymatic nerve pathway. [18]. Cross-linking together with bifunctional reagents (epichlorohydrin, phosphorus oxychloride) produces intra- and inter-molecular Bridges which reduce shrinkage and increase paste toughness compared to shear and thermal rotation used in food starches and many industrial adhesives; nevertheless, cross-linking density is necessary to maintain handling and administration acceptability.[18] The oxidative nerve pathway (duration, hypochlorite, TEMPO) selectively introduces carbonyl or carboxyl functionality, otherwise cleaves vicinal diol, facilitates subsequent counterpart chemistry, or ionic exchange, regardless that oxidation inevitably shortens the train length dispersion and must exist calibrated to prevent the loss of mechanical performance or excessive depolymerization. [18]. The grafting of a manufactured polymer or zwitterionic moiety towards a starch core termination of a hybrid material having a mechanical, blockade, alternatively antifouling, and reactive bulge has emerged as an industrially promising uninterrupted platform for grafting chemical reaction units together with improved energy and solvent efficiency.[42].

Regiochemistry: substitution with C-6 disrupts crystallinity less compared to C-2/C-3 when primary hydroxyl is excessively convenient, and as a result, selective chemical reactions, alternatively enzymatically directed approaches that discriminate C-6 adapt frequently produce a derived function with better retention of starchlike structure. [18]. The Analytical evaluation of DS, the dispersion of the molecular stress, residual reagents, and the substitution shape (NMR, SEC-MALS, titration, and mass spectroscopy) are of great importance for the supervisory dossier and for the forecast of the chemical variations which will alter the hydration, the enzymatic decline, and the mechanical performance of the test sample (Table 2)[18].

The development of amphiphilic excipients for nanoparticle stabilization, the evolution of mucoadhesive different ion exchangeable matrix for controlled release, and the marketing of RS4 (chemically modified) resistant starches for nutrition transport are key functional ends achieved by chemical modification. [18,41]. The green chemical advances enzymatic acylation, use of deep eutectic solvents, solvent-free reactive bulge, and reclaimable catalysts reduce the green burden of chemical modification and refinery scaleability, but the uninterrupted active area of exploration in the fields of innovation and administration, as well as the steady industrial contribution. [42].

Biological modifications — enzymatic tailoring and in-planta engineering

Life adaptations involve two complementary approaches: ex-plant enzymatic progress, which selectively alters starch composition, and in-plant organically modified involvement, which reprogrammes the biosynthetic pathway to produce starches compatible with the desired intrinsic chemistry.[3] . Enzymatic modifications in the ex-plant use glycosyltransferases, complexifying enzymes, debranching isoamylases, amylomaltases, and glycoside hydrolases to produce regio- and chain-length selective metamorphosis in accordance with the mild habitat, allowing precise branching density, series length, and molecular strain free of annoy reagent.[3]. Transglycosylation and enzymatic series extension approaches may be used in order to extend the elongated linear division of the cinema for better video stamina, or to stimulate control short-chain enrichment to stimulate prompt digestion or precise paste expulsion; enzyme system parameters (pH, water treatment, acceptor concentration) provide individual appropriate restriction. Respecting the allocation of primary rates. [3].

The lipase alternatively acyltransferase-mediated acylation has an enzymatic nerve pathway to amphiphilic decoding function, together with increased regiochemical properties and decreased chemical residues compared to the classic chemical acylation, which is associated with food and pharmaceutical safety (Table 3) [42]. The in-planta technique manipulates the gene encoding GBSS, a measure of soluble starch synthase, complex enzyme, and glucan dikinases in order to reconfigure the in vivo CLD, amylose fraction, phosphate saturation, and granule morphology, thus delivering interior designer starches near a crop that is not used in academic writing undergo post-harvest chemical handling.[3] .

The illustration shows the coevals of waxen line (approximately zero amylose) by suppressing GBSS, tall amylose line by downregulating ramify enzyme different overexpressing GBSS, and evolving phosphate agreement by manipulating dikinase undertake — every support produces starch and basically alters gelatinization, retrogradation, and digestibility. [3]. Genome editing devices such as CRISPR/Cas currently allow multiplexed, precise changes to the biosynthetic environment, allowing the combinative tuning of the branch architecture, which was previously impossible with conventional breeding, and related to these edits, can reduce the downstream modification requirements for the target industrial goal. [3].

The physiological nerve pathway has the advantage of producing inherently homogeneous starches, so the evolution occupies space during the biosynthesis, simplifies the downstream processing, and assumes that the change mimics a naturally occurring allelic variation. It needs massive growth rotation, agronomic validation, and attention to intellectual property and reliability problems. [3]. The compact plan, which combines the in-planta design with minimal enzymatic covering, similar to a genetically increased amylose crop followed by a mild enzymatic skin acylation, represents a simplified value iron that maximizes working productivity while minimizing chemical load and procedural complexity. [42]. In collaboration, organic modifications extend the design space for starch far

beyond what can still be achieved by post-harvest chemistry, although their realization depends on the harmonization of plant genetics, agronomy, downstream work, and finally use specification in a coordinated, multidisciplinary scheme. [3].

Advantages Of Modifications Of Starch

Starch change, whether induced by corporeal conditioning, covalent chemistry, enzymatics, or alternatively by plant organic support, expands the intrinsic functional repertoire of the native glucan by fluctuating supramolecular sequence, skin chemistry, and receptiveness, a technique that is simultaneously predictable and exploitable for food, pharmaceuticals, and material purposes-[3].In close proximity to the principally immediate level, body adaptations such as annealing, heat–moisture therapy (HMT), pregelatinization and control bulge license adjustment of gelatinization temperature, glue viscosity, and retrogradation project free from opening fresh covalent moiety supply formulators with fortified custom thermal and rheologic demeanor as well as maintaining a perfectly clean label mention for foods and nutraceuticals [3]. Moreover, a minimal energy method to improve the body's supply is to precondition the body. Processability, for instance, drum-dried or spray-dried pregelatinized starches hydrate immediately and extinguish the demand for wet cooking stages in an instantaneous formulation, thus reducing the organization's complexity and improving the consistency of the product in the management mix purpose [3].

The substitution calibration (DS) and the substitution structure are quantitatively controlled when the hydroxyl populations are converted to ester, quintessence, phosphate ester; otherwise, cross-link variation, hydrophilicity, charge density, steric profile, and Web connectivity. [18]. The coevals of amphiphilic starch reveal their functions, for instance. Octenyl succinic anhydride (OSA) starch, which provides external ventures, colloidal stabilization, and improved encapsulation performance of lipophilic active agent, a function that natural starch can provide together with comparable productivity. [41]. Similarly, hydroxypropylation and carboxymethylation have significantly improved cold water solubility, minimal gelatinization temperature achieved, and decreased retrogradation, which is desirable for frozen foods, pharmaceutical syrups, and instantaneous powders where clarity and freeze-thaw stability are essential. [18]. Cross-linking chemistry produces an intrinsically excessively flexible granule and paste, together with decreased swelling, decreased dislocation beneath shear, and increased dimensional solidity during thermal cycling, properties exploited in canned foods, adhesive slurry, and industrial applications, which otherwise would never have been used in scholastic authoring functions together with built-in starches. [18].

Chemical phosphorylation enhances anionic functionalities and water consumption, thus increasing cold water swelling, paste clarity, and the ability to form a solid gel alongside a decreased operating temperature, which underpins the premium location of a few native potato starches in durable formulation. [6]. The ability, by systematic variations, to produce an immune starch difference (e.g. This transforms starch from a quickly digested carbohydrate into a functional dietary fiber with a demonstrable prebiotic and glycaemic benefit.[40]. Enzymatic transglycosylation and complex transformation, or lipase-mediated acylation, facilitate selective changes of regio and chain length to obtain an aqueous assertion that maintains molecular stresses and lowers chemical residues, thus delivering a functionally precise deduce function that complies with a tight safety profile.[3]. In-planta tribal machinery and conventional breeding supplies a systemic advantage by producing interior designer starches directly within the limits of the harvested crop; by reprogramming GBSS, SBE, or DBE enterprises, the animal can acquire high amylose, waxen (approximately amylose-free), or alternatively modify CLD starches, which save downstream modification stairs and reduce origin costs in addition to dimension. [6]. The interior designer crop thus enables vertical integration of functions: a human breeding or gene editing move can produce built-in factors tailored to demand thermal characteristics, enzymatic degradability, alternatively motion likeness formation capacity, eliminate the need for post-harvest chemical modification in countless uses, and simplify the supervisory nerve pathway, at the same time the adjustment mimics an organic allelic variation.[6]. From the material science peak of interpretation, the modification motivates starch to bridge commodity and high-value stocks with graft fabricated polymer irons or nanoparticles deposited in the starch matrix, which produce biodegradable thermoplastic and complex mechanical properties in a systematic manner to produce oil-derived polymer during stimulation of compostability. [42]. Reactive bulge and twin-screw actives continuously produce modified starches together with a marked increase in

energy efficiency and solvent economy in comparison with batch chemical systems, thus enhancing the scalability and reducing organizational footprint in industry. [42]. This change is also intended to produce excipients with controlled pharmaceutical qualities, identical to binder, disintegrants, mucoadhesives, or alternatively matrix ideas with predictable swelling, degradation, and drug release profile necessary for straight compaction, widening release, and oral administration. [18].

In addition, amphiphilic and facade modify starch nanoparticles agreement shield Pickering emulsion and microcapsules, which enhance solubility, longevity, and bioavailability of the ailment water-soluble drugs and nutraceuticals, provide dose-sparing, and target cargo approach may not be used in academic writing, applied in intellectual writing, and easily achievable alongside conventional excipients. [41]. Nutrient-wise, modified starches provide a toolkit for modulating postprandial glycaemia and colonic disturbances through heat and moisture therapy, retrogradation promotion, and precise chemical cross-linking, which may increase immune starch fraction and hence colonic short-chain fatty acid production together with the capacity to support metabolic health and migration of microorganisms. [40]. Modification of starches, addition of carbon intensity from cradle to form, and increased end-of-life compostability compared to various petroleum-based polymers, and chemical compositions using green solvents, enzyme catalysts, and solventless bulge improve the prevailing longevity advantage. [42]. Importantly, the alteration extends the functional subsistence and storage performance of the many alterations by reducing the susceptibilities of retrogradation, regulating moisture-induced recrystallization, and enhancing mechanical properties, allowing the alteration of starch products to have an extended shelf life and excessive firmness during circulation and use. [3].

Analytically, chemically, and organically modified starches are capable of quantifying regiochemistry, SEC-MALLS completing a good molecular mass allocation, DSC, and XRD equip tips for thermal and crystalline variations, thus facilitating the ability to accurately and reproducibly specify functional characteristics for the administration of the application.[37] . From the point of view of the production sequence, the ability to match the inherent material performance by means of a modification makes it possible to exploit heterogeneous agricultural evaluation signals and standard modification procedures in order to produce systematically functional ingredients, thus reducing agricultural dependency. [3]. Moreover, the translational advantage is, in addition to the economic value of high-value, performance-differentiated starch, which can justify the acquisition of assets for downstream processing, the development of a new extraction stream of agricultural value irons, and the quick industrialization through the processing of municipal starches. [42].Finally, the supervisory atmosphere systematically approves an increasing amount of modified starch plants (e.g., acetylate, hydroxypropylated, OSA-modified) as food or pharmaceutical excipients within a confirmed substitution limit, which reduces retail barriers for producers using recognised chemistry rather than a fresh mixture requiring complete toxicology tasks. [18].

Starch alteration has a great advantage: it imposes a precise change in thermal, rheologic, mechanical, and built-in functionality; it contributes to better nutrition and bioavailability; it facilitates the development of biodegradable superior acting variables; and it extends the nerve nerve pathway to a scalable, green operating, and augmented fiscal value within the limits of agro-industrial compositions, an advantage that produces the starch change necessary for contemporary foods, pharmaceuticals, and components. [3,18,42].

CONCLUSION

Starch can better be understood as a hierarchically structured, biosynthesised glucan platform whose functional identity emerges from the interaction of polymer chemistry (amylose versus amylopectin), chain length circulation (CLD), granule ultrastructure, and minor components such as boundary lipids and phosphate ester [6]. Apart from the molecular scope, the two operationally defined fractions — largely linear amylose and highly ramified amylopectin — present distinct physicochemical behavior: amylose helps to gel energy, retrogradation, and V-type

engagement involved formation, whereas amylopectin's consequent structural branching underpins the semi-crystalline lamellar architecture, which determines gelatinization and glue quality [30].

The biosynthetic machinery that assembles starch in plastid — ADP-glucose pyrophosphorylase, many soluble starch synthases, granule-bound starch synthase, branching, and debranching enzymes — can remain modular and tunable, and the innate alternative engineering change to the complementary function of those enzymes translates directly within the predicted transition in CLD, granule size, and morphology, and accordingly macroscopic function [8]. Thus, assuming applied for corn, rice, potato, cassava, alternatively palpitation starches, which create a fundamental design variable for both food and non-food objectives [3], the same nominal handling otherwise alteration procedure can produce significantly divergent functional findings when applied for corn, rice, potato, cassava, alternatively palpitation starches, which create a fundamental design variable for both food and non-food intentions [6]. The handling record, including wet milling, alkaline wash, enzymatic pretreatments, dry grinding, and mechanical shear, may also produce processing-induced heterogeneity that confuses scale-up and reproducibility unless the tactics and strict material specification are used [6]. Analytically, current starch science requires a multi-modal toolkit — enzymatic debranching integrated with HPAEC-PAD or SEC for CLD, DSC, and RVA to qualify thermal and glue behaviour, X-ray scattering/diffraction and SAXS for lamellar/crystalline systematic, and solid-state NMR for short-range conformational details — because individual assays like apparent amylose %, otherwise iodine binding are insufficient to visualize performance in involved formulations[6].

Material, chemical, and organic alteration strategies joined develop a flexible design space to modify starch features: corporeal path (anneal, HMT, pregelatinisation, bulge) reorganise supramolecular structures free of recent covalent chemical bonding and are invaluable pure label instruments; chemical derivatisation (acetylation, hydroxypropylation, OSA, cross-linking, oxidation) delivers quantitative tune through substitution and regiochemistry; and the innate strategy (enzymatic coating, alternatively in-planta familial tailoring) licenses regioselective alternatively intrinsic property alteration that can lower downstream managing necessities [18]. Despite the need for careful handling of residual reagents, regiochemistry, and supervisory adherence, chemical substitutions can provide amphiphilicity, freeze-thaw durability, and, alternatively, shear resistance. Material care continues, however, chemical peculiarities likely induce an unchanging supramolecular rearrangement which changes digestibility and shelf mannerisms; population tactics produce homogeneous, application-tailored starches near get down although needed longer growth circle and agronomic validation [18].

From a nutritional and physiological point of view, architectural assert terrors fast digestible starch fraction correlates with highly complexified, short-chain amylopectin and disrupted granule structure, whereas elongate linear irons and retrograde crystalline sphere defy small-intestinal amylase and function as immune starch together with documented impacts on colonic agitation and metabolic termination apex – hence change can exist utilized toward engineer health-oriented ingredients although must report for inter-individual microbiome and amylase variability [40]. Starch is a clear attraction for drug delivery and pharmaceutical excipient design, although there are likely challenges for botanical and process variation, limited native affinity for lipophilic APIs, sensitivity to aqueous expansion and retrogradation, sterilization-induced degeneration, and the need for a rigorous explanation of nanoparticle outer layer chemistry and immunological exchange entangle translation in order to manage therapeutics [6]. The past size, cost, and natural challenges to chemical transformation have been solved by sophisticated advances such as reactive bulge, enzyme-catalyzed regioselective acylation, and green solvent using a deep eutectic technique, thus improving the viability of producing application-specific starch function alongside industrial size [18].

Nevertheless, computational investigation and standardization remain narrow associate CLD and lamellar prosody to routine quality control needs, simplifying proxy, alternatively fast assays that accurately forecast performance, and an administration dossier for fresh chemically modified starch excipients requiring thorough impurity profiling, toxicology, and degradability facts that increase development costs and timeline [6]. Cultivar degree and train repair — for instance, engender uniform, designer starch trait, otherwise implementing upstream specification to stipulate

CLD windows — equip courses to mitigate downstream alteration demand and increase batch reproducibility, despite that such a strategy involves form plant breeding, agronomy, and supervision of grapevines to stay profitable near the trade dimension [45]. In objective examples where starch can be consolidated with sophisticated factors, graft compatibility, together with biodegradable polyester and nanoparticle support, may provide thermoplastic or composite properties of petrochemical polymers below trace carbon reduction, although topography and end-of-life supervision must remain holistically monitored [42].

Unite in-vitro–in-vivo connection research explicitly describes enzyme activity, retrogradation project, and host microbiome engagement likely to remain useful for clinically oriented starch channels for controlled release, a nanoparticulate carrier otherwise mucoadhesive matrix, as release detection in simplified buffer frameworks may mispredict mannerisms in the gastrointestinal tract, or near the tissue interface [40]. Convergent improves through a wide range of predictive multiscale models that translate the interaction of enzymes and CLD in macroscopic release and rheology, powerful, scalable green chemistry for selective alteration, quick QC statistical analysis that correlates with the functional end point, and an agricultural plan that delivers unchanging, high-performing natural starches to the processing line [8]. The administration and exchange of certificates may be sped up by ordering changes to standard foods and medicines (e.g. Minimal DS acetylation, hydroxypropylation, and OSA within the permitted limits), progress standard analytical and reporting frameworks for CLD and lamellar prosody, and early interaction with the competent authorities on impurity threshold and biodegradation testing [30].

Starch in synthesis has a unique fertile design space close to the interface in the midst of carbohydrate chemistry, enzymology, component science, and nutrition, although that very complexity demands rigorous, multimodal statement portrait and unite upstream-downstream contemplation to transform laboratory progress among robust, safe, and scalable products in all parts of the food, pharmaceutical, and substance sectors [6,18]. In the end, the starch discovery will be that it treats starch nay as an individual commodity polymer despite that it is a tribe of genetically and process-defined components whose intrinsic chemistry corresponds to the conditions of use in combination with a compound of plant genetics, restraint, selective change, and high-resolution inspection — a combination of a vantage peak that transforms starch from an agricultural bystander into an intentionally designed, renewable polymer platform of the twenty-first century. [8,45].

Table 1: Functionality of Physical modification of starch

Modification Type	Specific Modification	Structural Change Introduced	Mechanistic Effect in DDS	Drug Delivery Function	Representative Applications
Physical Modifications	**Pregelatinization**	Disruption of crystalline lamellae; increased amorphous regions	Enhanced water uptake and rapid swelling	Superdisintegrant; fast drug release	Immediate-release tablets
	Annealing (ANN)	Reorganization of crystalline domains without granule rupture	Increased crystallinity and thermal stability	Controlled swelling; sustained release	Matrix tablets
	Heat–Moisture Treatment (HMT)	Altered hydrogen bonding; reduced granule swelling	Reduced solubility and permeability	Extended drug release	Hydrophilic matrices
	Micronization/Nanoparticulation	Reduced particle size; increased surface area	Enhanced dissolution rate	Solubility enhancement of BCS II drugs	Solid dispersions
	Spray-drying	Formation of porous spherical particles	Improved compressibility and dispersibility	Carrier for inhalation/oral DDS	Pulmonary delivery
	Freeze-drying (Lyophilization)	Highly porous sponge-like matrix	Rapid hydration and disintegration	Fast dissolving systems	ODTs, buccal films
	Extrusion processing	Partial gelatinization and chain alignment	Formation of thermoplastic starch matrices	Controlled release scaffolds	Implantable systems
	Cross-linking (physical radiation)	Intermolecular bonding without chemical reagents	Increased gel strength and reduced erosion	Sustained drug release	Hydrogel matrices

Table 2: Functionality of Chemical modification of starch

Chemical Modifications	Specific Modification	Structural Change Introduced	Mechanistic Effect in DDS	Drug Delivery Function	Representative Applications
Esterification (e.g., acetate, succinate)	Introduction of ester groups	Reduced hydrogen bonding; increased hydrophobicity (depending on DS)	Modulated solubility and permeability	Controlled release; colon targeting	Enteric coatings
Etherification (e.g., hydroxypropyl starch)	Introduction of ether substituents	Increased flexibility and solubility	Enhanced swelling and gel formation	Sustained release matrix	Oral CR tablets
Carboxymethylation (CMS)	$-CH_2COO^-$ groups added	Increased anionic charge and water solubility	pH-responsive swelling	Colon-targeted delivery	Polyelectrolyte complexes
Oxidation	Formation of carbonyl/carboxyl groups	Reduced molecular weight; increased reactivity	Faster hydration and erosion	Rapid drug release	Immediate release
Chemical Cross-linking (e.g., STMP, epichlorohydrin)	Covalent interchain bridges	Reduced swelling; enhanced mechanical strength	Slower diffusion and erosion	Sustained release hydrogels	Injectable depots
Graft Copolymerization (e.g., polyacrylic acid, PEG)	Side-chain polymer grafting	Stimuli responsiveness (pH, temperature)	Controlled drug diffusion	Smart drug delivery systems	Targeted DDS
Hydrophobic modification (octenyl succinic anhydride, OSA)	Amphiphilic substitution	Self-assembly into micelles/nanoparticles	Encapsulation of hydrophobic drugs	Nanocarriers	Oral bioavailability enhancement
Cationization	Quaternary ammonium groups	Positive surface charge	Mucoadhesion; enhanced epithelial uptake	Buccal/nasal delivery	Mucosal systems

Table 3: Functionality of Biological modification of starch

Biological Modifications	Specific Modification	Structural Change Introduced	Mechanistic Effect in DDS	Drug Delivery Function	Representative Applications
Enzymatic Debranching (Pullulanase/Isoamylase)	Reduction of $\alpha(1\rightarrow6)$ linkages	Increased linear chains; altered crystallinity	Modified gelation behavior	Sustained release matrices	Oral matrices
Enzymatic Hydrolysis (α-amylase)	Cleavage of $\alpha(1\rightarrow4)$ bonds	Reduced molecular weight	Increased biodegradability	Biodegradable carriers	Injectable microspheres
Fermentation modification	Partial depolymerization; altered granule morphology	Increased porosity	Enhanced drug loading capacity	Porous carriers	Encapsulation systems
Resistant starch	Retrograded	Reduced	Colon-specific	Colon	Anti-

formation (RS type III)	crystalline domains	digestibility in small intestine	biodegradation	targeting	inflammatory drugs
Genetic modification (high-amylose starch)	Increased amylose content	Higher gel strength and retrogradation tendency	Slower enzymatic degradation	Sustained/colon delivery	Matrix tablets
Enzyme-responsive starch derivatives	Specific enzymatic cleavage sites	Targeted biodegradation	Site-specific drug release	Microbiota-activated DDS	Colon-specific delivery

ABSTRACT

Digital acquisition and automated transactions are becoming more prevalent in retail and supply chain processes; however, their financial consequences are hardly considered into analytical inventory models. This study proposes a sustainable inventory model based on partial prepayment strategy by employing paper-free and automated transactions. The proposed framework considers an instantaneously deteriorating products, price-sensitive demand, preservation investment, shortages with full backlogging and digital ordering systems. Mathematical expressions for the ideal replenishment process are obtained by minimizing the overall cost. A numerical instance, solved using python is provided to illustrate the effectiveness of the model and to assess the financial advantages of automated electronic payments. Comparative findings reveal that adopting paper-free and digital transaction handling results in a noticeable drop in overall costs from 48, 435, 273.00 to 47, 817, 609.95 confirming its significance as an efficient and sustainable cost-savings tool. The suggested methodology offers valuable managerial perspectives for retailers seeking for cost-effective and sustainable inventory practices under prepayment agreements.

Keywords: Inventory model, Partial Prepayment, Installment, Automated Transaction, Price-dependent demand, Sustainability.

INTRODUCTION

Inventory management has become a significant component of operations research because of its importance in managing financial efficiency with customer satisfaction in supply chains. Traditional inventory models, which began with the Economic Order Quantity (EOQ) structure, have been further expanded to include realistic aspects like deterioration, limited availability, preservation investment, and demand variability. In recent times, economic coordination processes, especially prepayment and trade credit regulations, have received more attention since they have a major effect on ordering decisions and supplier-retailer interactions. Sarker *et al*. (2024) developed an inventory model for instantly degrading items with numerous trade options under demand that is reliant on price and stock as well as complete backlog. They also conducted an analytical evaluation of the efficacy of various payment methods [10]. Khan *et al*. (2024) suggested a quantitative decision-making approach emphasising the significance of advance payment approaches in enhancing cost effectiveness in inventory systems [7]. Duary *et al*. (2022) established an inventory framework with nonlinear price-sensitive demand for non-instantaneous deteriorating items, illustrating how advanced payment systems interact with pricing strategies for optimum ordering decisions [3]. Concurrently, an extensive study has been conducted on inventory management strategies for perishable or degrading products with shortfalls and preservation investment. Kumar *et al*. (2025) created an inventory approach with price and trade credit dependent demand for degrading commodities, using preservation technologies and entire backlog to maximize overall profit under inflationary scenarios [8]. Ali *et al*. (2025) introduced a sustainable inventory structure for deteriorating products with price and inventory-based customer demand, employing sophisticated metaheuristic optimization to combine preservation investment and environmentally friendly criteria [2]. Patra *et al*. (2024) constructed an inventory model that includes energy supply demand, trade loan, and preservation investment, with shortages permitted and fully backlogged [9]. Although the aforementioned research areas have greatly advanced inventory concept, they implicitly depend on conventional, manual transaction methods by assuming that ordering-related expenses are constant and exogenously provided. Nevertheless, automation and technological advancements are rapidly influencing modern supply chains. Ali *et al*. (2024) investigated the impact of the online supply chain abilities, discovering that technological versatility and adaptability vastly enhance inventory performance by increasing transparency and lowering operational inefficiencies [1]. Fang *et al*. (2024) demonstrated that incorporating digital innovation into inventory processes boosts effectiveness via automated procedures and improved data flow [4]. Grutzner *et al*. (2025) found that digitalization along with robotics improve inventory decisions through advanced workflow coordination [5]. Khan *et al*. (2023) stressed the essential role of digital platforms and provenance to promote inventory management through visibility [6]. Despite these advancements, analytical application of online ordering efficiencies into inventory models with partial prepayment is still limited. In specific, even though placing orders, records, and managerial handling of transactions make up a major portion of acquisition-related costs in massive retail systems, current inventory models fail to consider the cost-saving benefits of digital transaction processes.

This observation raises lots of crucial research questions:

1. How can digital ordering efficiency be analytically integrated into an inventory model with partial prepayment scheme?
2. Does the use of paper-free and automated transaction processing result in a quantifiable decrease in the overall cost of inventory when demand is price-dependent and shortages are totally backlogged?
3. How does the ideal replenishment period and the stock depletion time react to internet-based ordering cost savings?

To answer these queries, this study creates a sustainable inventory model with a partial prepayment mechanism that includes price-dependent demand and completely backlogged shortages. This approach considers digital transaction processing as a reasonable reduction in ordering costs, thereby maintaining analytical feasibility. Mathematical formulations are developed and a numerical example is provided to demonstrate the financial advantages of the suggested technique. To the best of our knowledge, no prior work has integrated digital ordering efficiency as a sustainability-focused cost saving strategy within a partial prepayment inventory model for instantaneously

deteriorating items. The results are helpful for practitioners as well as researchers looking to employ digital technology for long-term cost reduction in inventory management systems.

METHODOLOGY

This study considers a single deteriorating item where degradation starts as soon as it is received. Instantaneous replacement takes place, and shortfalls are allowed and fully backlogged. Demand is predictable and price-sensitive, exhibiting a linear demand pattern. The replenishment process of time t comprises two stages: a positive inventory time $[0, d]$ when inventory shrinks owing to demand and degradation, and a shortage time $[d, t]$ when demand is entirely backlogged. In this context, the retailer can't afford to pay the entire purchase amount in advance. To handle this, the supplier provides a partial prepayment scheme in which a portion of the purchase price is paid beforehand and the balance is settled in installments. Preservation investment is used to lessen degradation impacts during the positive stock period. Then, the overall cost of the system includes ordering, purchasing, holding, deterioration, shortage and preservation costs. The model is described into two circumstances: (i) Inventory model under partial prepayment strategy and (ii) Inventory model with digital transaction handling.

Notations

O_c : Cost of ordering per order

P_c : Cost of purchasing per unit

H_c :Cost of holding per unit per unit time

S_c :Cost of shortage per unit

D_c :Cost of deterioration per unit

M_c : Cost of preservation per unit time

μ : Constant rate of deterioration

γ : Discount percentage on the purchasing cost

I :Maximum quantity in stock (units)

P : Maximum level of permitted shortages (units)

Q_O : Order quantity per cycle (units)

S :Inventory level at time t_0 , where $0 \le t_0 \le t$

k : Initial demand, $k \succ 0$

l : Demand-based price scale, $l \succ 0$

P_s : Selling price per unit

q : Stock reliant usage

ε : Prepayment proportion

ρ : Digital transaction's efficiency, where $0 \le \rho \prec 1$

i : Number of installments for payment

d : Inventory depletion time

t :The length of each replenishment period (units)

OC : Overall expense per unit time

Assumptions

1. The inventory framework handles a single instantaneous item.
2. In one batch, the entire quantity is delivered.
3. Demand rate depends on price, and is predictable.
4. There is a complete backlog of shortages.
5. During the inventory process, the decaying items are neither rectified nor replaced.
6. The supplier provides a partial prepayment policy along with an installment payment option.
7. Holding costs are charged only to good items.
8. Investments in preservation are made to lower the pace of degradation.
9. Digital ordering process is solely applicable to ordering-based administrative tasks and does not influence the payment scheme of the model.

Model I: Inventory Model Under Partial Prepayment Strategy

The inventory systems are

$$\frac{dS}{dt_0} + \mu S = -[k - lP_s + qS] \quad \text{for } 0 \prec t_0 \le d \quad (1)$$

$$\frac{dS}{dt_0} = -[k - lP_s] \quad \text{for } d \prec t_0 \le t \quad (2)$$

From equation (1), $$S = \frac{k - lP_s}{\mu + q}\left\{e^{(\mu+q)(d-t_0)} - 1\right\} \quad \text{for } 0 \prec t_0 \le d \quad (3)$$

Considering $S = 0$ at $t_0 = d$ and $S = I$ at $t_0 = 0$, we get

$$I = \frac{k - lP_s}{\mu + q}\left\{e^{(\mu+q)d} - 1\right\} = k - lP_s\left[d + \frac{(\mu+q)d^2}{2}\right] \quad (4)$$

From equation (2), $S = k - lP_s(d - t_0)$ for $d \prec t_0 \le t$ (5)

Considering $S = 0$ at $t_0 = d$ and at $t_0 = t$, we get

$$P = -(k - lP_s)(d - t) \quad (6)$$

Therefore, the entire ordering quantity is $Q_0 = I + P$

$$Q_0 = (k - lP_s)\left[d + \frac{(\mu+q)d^2}{2} + (t - d)\right] \quad (7)$$

Then, the cost elements of this model are outlined below.

Ordering Cost

The ordering cost is a fixed operational fee paid when an order is submitted.

The ordering cost per cycle is

Ordering Cost = O_c (8)

Purchasing Cost:

The purchase cost describes the payment method in which a part of the purchasing cost is paid upfront and the remainder is handled through installments.

Purchasing cost is paid beforehand = $$(1-\gamma)P_c\varepsilon(k-lP_s)\left[d+\frac{(\mu+q)d^2}{2}+(t-d)\right]$$

Remaining purchase cost paid in installments = $$\frac{S_i(1-\varepsilon)P_c(k-lP_s)\left[d+\frac{(\mu+q)d^2}{2}+(t-d)\right]}{\left[1-(1+S_i)^{-i}\right]}$$

The effective total purchase cost for each cycle is stated as

Total purchasing cost = $$(k-lP_s)\left[(1-\gamma)\varepsilon+\frac{S_i(1-\varepsilon)}{1-(1+S_i)^{-i}}\right]P_c\left[t+\frac{(\mu+q)d^2}{2}\right] \quad (9)$$

Holding Cost

The cost of holding is spent for keeping fresh items within on-hand inventory phase.

The holding cost per cycle is given as

Holding cost = $$\frac{1}{2}H_c(k-lP_s)d^2 \quad (10)$$

Deterioration Cost

Deterioration charge is incurred when items degrade during in-stock period.

Therefore, the deterioration cost is

Deterioration cost = $$\frac{1}{2}\mu D_c(k-lP_s)d^2 \quad (11)$$

Shortage Cost

During the shortfall phase, demand is completely delayed, resulting in a shortage cost.

The shortage cost per cycle is calculated as

Shortage cost = $$\frac{1}{2}S_c(k-lP_s)(t-d)^2 \quad (12)$$

Preservation Cost

Preservation investment is employed to reduce the impact of deterioration during the cycle.

The preservation cost for each cycle is expressed as

Preservation cost = $$M_c t \quad (13)$$

Therefore, the overall cost per unit time is determined as

$$OC=\frac{1}{t}\left[O_c+(k-lP_s)\left\{\begin{aligned}&\left[(1-\gamma)\varepsilon+\frac{S_i(1-\varepsilon)}{1-(1+S_i)^{-i}}\right]P_c\left[t+\frac{(\mu+q)d^2}{2}\right]\\&+\frac{1}{2}(H_c+\mu D_c)d^2+\frac{1}{2}S_c(t-d)^2\end{aligned}\right\}+M_c t\right] \quad (14)$$

By differentiating the overall cost with respect to d and t, we obtain

$$d = \sqrt{\frac{2O_c S_c}{(k-lP_s)\left\{\left[(1-\gamma)\varepsilon + \frac{S_i(1-\varepsilon)}{1-(1+S_i)^{-i}}\right](\mu+q)P_c + (H_c+\mu D_c+S_c)\right\}\left\{\left[(1-\gamma)\varepsilon + \frac{S_i(1-\varepsilon)}{1-(1+S_i)^{-i}}\right](\mu+q)P_c + (H_c+\mu D_c)\right\}}} \tag{15}$$

$$t = \sqrt{\frac{2O_c\left\{\left[(1-\gamma)\varepsilon + \frac{S_i(1-\varepsilon)}{1-(1+S_i)^{-i}}\right](\mu+q)P_c + (H_c+\mu D_c+S_c)\right\}}{(k-lP_s)\left\{\left[(1-\gamma)\varepsilon + \frac{S_i(1-\varepsilon)}{1-(1+S_i)^{-i}}\right](\mu+q)P_c + (H_c+\mu D_c)\right\}S_c}} \tag{16}$$

Model II: Inventory Model with Digital Transaction Handling

The higher priority on sustainable and economical supply chain management has inspired enterprises to adopt digital tools that enhance procurement and inventory decision processes. Digital ordering tools make it easier to place orders and share information, which leads to better operational efficiency. These technological enhancements are reflected as a corresponding drop in the practical ordering fee, whereas the payment mechanism and stock fluctuations remain constant. By replacing traditional records and standard administrative processes with automated systems, the ordering procedure becomes a greater resource saver as well as less waste-intensive, thus promoting sustainable practices. Therefore, this study considers paper-free and digital transaction processing within partial prepayment-based inventory model and evaluating its effects on ordering-based administrative expenditures.

To reflect the impact of internet-based ordering performance, the optimum ordering cost per cycle is given as

$$\text{Ordering cost per cycle} = O_c(1-\rho) \tag{17}$$

Apart from the ordering cost, the remaining costs are exactly the same as in Model 1.

Therefore, the overall cost per unit time is

$$OC = \frac{1}{t}\left[O_c(1-\rho) + (k-lP_s)\left\{\begin{array}{l}\left[(1-\gamma)\varepsilon + \frac{S_i(1-\varepsilon)}{1-(1+S_i)^{-i}}\right]P_c\left[t + \frac{(\mu+q)d^2}{2}\right] \\ +\frac{1}{2}(H_c+\mu D_c)d^2 + \frac{1}{2}S_c(t-d)^2\end{array}\right\} + M_c t\right] \tag{18}$$

By differentiating the overall cost with respect to d and t, we obtain

$$d = \sqrt{\frac{2O_c(1-\rho)S_c}{(k-lP_s)\left\{\left[(1-\gamma)\varepsilon + \frac{S_i(1-\varepsilon)}{1-(1+S_i)^{-i}}\right](\mu+q)P_c + (H_c+\mu D_c+S_c)\right\}\left\{\left[(1-\gamma)\varepsilon + \frac{S_i(1-\varepsilon)}{1-(1+S_i)^{-i}}\right](\mu+q)P_c + (H_c+\mu D_c)\right\}}} \tag{19}$$

$$t=\sqrt{\frac{2O_c(1-\rho)\left\{\left[(1-\gamma)\varepsilon+\frac{S_i(1-\varepsilon)}{1-(1+S_i)^{-i}}\right](\mu+q)P_c+(H_c+\mu D_c+S_c)\right\}}{(k-lP_s)\left\{\left[(1-\gamma)\varepsilon+\frac{S_i(1-\varepsilon)}{1-(1+S_i)^{-i}}\right](\mu+q)P_c+(H_c+\mu D_c)\right\}S_c}} \quad (20)$$

RESULT

In order to show the applicability of the suggested approach and the impact of paper-free and automated transaction processing, Python-driven computation is employed to assess the model. The parameter values are taken from Sarker *et al*. [10] and related industrial studies.

$O_c = 1,000,000\ IR/order, k = 250,600\ L/unit\ time, l = 1.5, P_s$=400 IR/L,

P_c= 300 $IR/L/unit\ time, H_c$=30 $IR/L/unit\ time, S_c$=50 $IR/L/unit\ time$,

D_c=40 $IR/L/unit\ time, q = 0.2, \mu = 0.005, \varepsilon = 0.5, S_c$= 100 $IR/unit\ time$,

S_i=0.4, γ=35%, i=4, ρ=30%

The optimal replenishment period, inventory depletion time, and the total cost with and without digital ordering efficiency are provided in Table 1. The numerical findings indicate that digital ordering methods significantly lowers the overall cost, validating its purpose as an economical and sustainable operational upgrade in analytically feasible inventory systems.

DISCUSSION

The majority of the inventory models under partial prepayment scheme focus on analytical modifications regarding payment schedules, deterioration and shortage frameworks, while implicitly presuming traditional manual ordering procedures [7, 10]. These assumptions restrict the capability of conventional models to reflect the practical reality of today's retail and supply chain operations, where transaction handling is becoming more and more automated. In reality, industries have increasingly implemented online ordering applications, automated billing systems to reduce administrative work, prevent human error, and expedite procurement processes. According to recent research, the online transaction systems improve inventory management as well as profitability by accelerating ordering methods [1]. Nevertheless, despite their increasing practical applications, the cost impact of digital ordering is rarely included in inventory models with partial prepayment agreements. This gap separates academic inventory formulations from contemporary procurement approaches. In order to overcome this constraint, this research models the effect of digital ordering efficiency via effective ordering cost and incorporates it into a partial prepayment inventory model.

CONCLUSION

This study established an inventory model for instantly deteriorating items under a price-sensitive demand, complete backlogging of shortages, investment on preservation, and partial prepayment strategy by employing digital procurement efficiency. The optimum replenishing duration and the period when inventory reaches zero were determined by reducing the overall costs. A numerical illustration shows that advances in digital ordering efficiency resulted in a significant drop in the entire system cost, proving that even minor savings in ordering costs can yield major financial benefits. Aside from its analytical development, this research emphasize that sustainable inventory management can be accomplished by process-focused digital upgrades without relying on multifaceted sustainability limitations or enormous technical changes. From a managerial standpoint, the results indicate that

retailers can improve cost efficiency and operational effectiveness while investing in digitally enabled ordering processes. Future studies could expand the suggested framework by considering different upfront payment arrangements, various kinds of digital investment or uncertainty in demand or degradation rates.

ABSTRACT

A key component of contemporary cooling systems, the Vapour Compression Refrigeration (VCR) system is mostly utilised in commercial, residential, and industrial settings. However, the demand to enhance its performance is developing in order to lessen the environmental effect, increase energy efficiencyand minimise costs. The current study explores several strategies to enhance the efficiency of the VCR system. It offers a thorough examination of cutting-edge approaches, such as the application of advanced refrigerants, system optimization, and the use of cutting-edge technology like ejectors, phase-change materials, and nanofluids. This paper provides a clear roadmap towards creating more sustainable and high-performing VCR systems that meet changing energy and environmental needs by emphasizing recent developments and outlining future research priorities.

Keywords: Vapor Compression Refrigeration (VCR), Coefficient of Performance (COP), Global Warming Potential (GWP), Design rectification, Nano refrigerant and Nano lubricant

INTRODUCTION

VCR systems are most popular in both industrial and domestic applications. Though they are most popular in refrigeration technology, they are always in focus of researchers due to their higher energy consumption, environmental impact, and limited efficiency. As the modern era demands energy-efficient and environmentally friendly technologies, performance improvement of the VCR system has attracted the researchers[1]. Many approaches have been investigated over time to increase the effectiveness of VCR systems. These strategies include advancements in system components, modifications to the working fluid, and the implementation of novel cycle configurations. Furthermore, combining digital technologies, such as intelligent control algorithms and real-time monitoring systems, has also shown promise in optimizing system performance. Despite these attempts, complications still exist in achieving the desired balance between energy savings, cost-effectiveness, and environmental sustainability[2]. This review aims to provide a comprehensive overview of the current pathways to enhance the efficiency of VCRsystems. By examining the latest developments in refrigerants, system designs, cycle modifications, and control strategies, this paper will highlight the major advancements and identify the most exciting areas for further study and advancement. The objective is to offer insights into how VCRsystem can evolve to meet the growing need for sustainable, effective and cost-effective refrigeration technologies.

Performance Enhancement of VCR System

Over the years, numerous strategies have been investigated to improve the performance of VCR systems, focusing on refrigerant and lubricant optimization, component design enhancements, and the adoption of advanced control methods.

Design rectification over conventional system:

The performance of a VCR system is heavily influenced by its design and operational parameters. Conventional VCR systems, while widely utilized, often suffer from inherent inefficiencies like pressure drop, throttling loss, compressor loss due to outdated design elements and suboptimal configurations. Addressing these limitations through design rectifications has emerged as a key pathway to enhancing system efficiency[1]. Evaporative condensers have been extensively studied for enhancing performance of VCRsystems. Harby *et al*. reviewed potential of evaporative condenser, showing power savings up to 58% and a 113.4% coefficient of performance (COP) improvement over air-cooled condensers, especially in hot and dry climates[3]. Islam *et al*. validated a theoretical model for an evaporatively-cooled R134a air-conditioning unit with experimental result, demonstrating a 28% COP boost due to increased cooling capacity and reduced compressor work.[4]Liu *et al*. experimentally analyzed a dual independent evaporative condenser, finding COP gains of 13.1% with higher air velocity and 6.1% with increased water spray rate[5]. These studies highlighted evaporative condensers as effective design improvements for energy-efficient refrigeration systems. Cao *et al*. studied heat transfer and pressure drop of R600a in a mini-channel condenser with multi-louvered fins. They found heat transfer coefficient and pressure drop increase with mass flux but decrease with saturation pressure, while inclination significantly affects them. The authors proposed improved correlations for heat transfer and friction factor, with 90% of data points within ±15% and ±12%, respectively. The authors also modified the calculation of logarithmic mean temperature difference, which reduced deviations by 15%[6]. Several researchers have investigated ejector-expansion technologies to enhance VCR efficiency. Zhang *et al*. reviewed standard and advanced ejector-expansion systems, with a particular focus on R744. Their theoretical and experimental analyses reported COP improvements ranging from 5% to 40%.[7]Bilir and Ersoy experimentally studied a two-phase ejector as a replacement for the expansion valve in an R134a system and achieved a 10.1% to 22.34% increase in COP, with greater gains observed at lower evaporator and higher condenser temperatures[8]. Both the studies highlighted ejector optimization as a key strategy for improving refrigeration system performance. VCR system of 100 kW using R134a as refrigerant for the water chiller application have been analyzed by Solanki *et al*. using EES software. The study found that the dedicated mechanical subcooled vapor compression refrigeration (DMS-VCR) system reduced electricity consumption by 15.52% and achieved a COP of 3.92, a 9.5% increase compared to a standard vapor compression refrigeration system with a COP of 3.58. This resulted in a 15.55%

reduction in CO2 emissions[9]. Babu and Basha experimentally investigated a VCR system using R134a.Experiment was carried out with the diffusers at the condenser inlet having divergence angles of 10°, 15°, and 20°.Results showed that, system provides best performance at 15° divergence angle. Increase in COP was 35.10% with the use of divergence angle of diffuser as 15° as compared to the system without diffuser.The refrigerating effect and its rate both increased by 27.89%, and overall refrigeration efficiency improved by 38.60%, according to the study[10]. Using a shell and coil heat exchanger at the compressor outlet and R12 as the refrigerant, Prasanna *et al*. conducted an experimental analysis of a VCR system. At various evaporation temperatures, the study assessed compressor power consumption, COP, and the refrigerating impact. The results indicated that as a result of the usage of a heat exchanger, compressor power decreased by 14%, and COP as well as the refrigerating impact improved by 16%.[11]
R134a and R600a refrigerants were used in an experimental study by Shakir *et al*. to examine the performance of a VCR system. In order to lower power usage, the authors assessed the effects of adding capacitors (5μF, 8μF, 10μF, and 12μF) to the electrical circuit of the system. According to their results, R600a had a greater COP than R134a. The maximum COP (3.43) and a 62.5% decrease in energy usage were obtained by combining the use of R600a with a 10μF capacitor. According to findings of the study, R600a is a more energy-efficient and environmentally friendly option than R134a, and adding a 10μF capacitor improves system efficiency even more[12]. The performance of a 165-liter household refrigerator utilising R-134a refrigerant was experimentally examined by Vali *et al*., who compared a conventional condenser with a helical condenser. The authors replaced the existing condenser with a helical design and tested different helical coil diameters (187 mm, 225 mm, 262 mm, and 300 mm). Their results showed that the helical condenser improves COP of the system. A helical coil diameter of 262 mm yielded the best performance with a COP of 4.33, a significant improvement compared to the existing condenser's COP of 3.56[13]. Key findings by design rectification (Table 0).

Application of magnetic field

The application of a magnetic field has gained significant attention as an innovative approach to enhance the efficiency of VCRsystems. Magnetic fieldshaveinfluence on thermodynamic and fluid flow properties of the refrigerants, which leads to enhance heat transfer and reduce energy losses. Studies on magnetic fields and nano-lubricants in VCR system shows significant performance improvements. Gudlavalleti *et al*. found a 41.528% COP increase using four magnet pairs at 11,800 Gauss[24], while Tipole *et al*. observed an 8.94% COP boost in an R404a system with 3000 Gauss magnets[25]. Deshmukh *et al*. highlighted magnetic fields as more effective than tube inclination for heat transfer[26], and Shinde *et al*. reported a 40.158% COP rise for R134a, identifying three magnet pairs as optimal[27].

Hybrid refrigeration system

Hybrid refrigeration systems represent a promising direction for improving the performance and sustainability of VCR systems. By combining, conventional VCR technology with alternative cooling methods such as thermoelectric, absorption, or evaporative cooling, provides higher performance and reduces energy consumption as well as environmental impact. Fu *et al*. studied a hybrid vapor compression-thermoelectric refrigeration system using R600a. A three-dimensional numerical model was used to optimize the finned heat sink of the TER. The numerical results demonstrated that increasing fin height decreased thermal resistance, while increasing fin pitch increased thermal resistance. An optimized fin height of 50 mm was determined, resulting in a thermal resistance of 0.05 °C/W and a cooling capacity of 53.6 W higher than the original 30 mm fin height. The study achieved a temperature of -38.1 °C in the freezer compartment, a 29.3 °C improvement compared to the VCR system alone. This improvement came at the cost of an additional 99.5 W of power consumption[28]. Söylemez *et al*. constructed and tested two hybrid refrigerators combining vapor compression and thermoelectric cooling technologies. The study involved energy consumption, cooling capacity, and noise tests according to EN 62552:2013, IEC 62552:2015, IC 15068, and IEC 60704-2-14 standards. The hybrid refrigerators exhibited at least three times higher energy consumption than conventional refrigerators due to the lower efficiency of thermoelectric coolers. However, the hybrid systems demonstrated a 40% reduction in cooling time, highlighted their potential for achieving rapid cooling. Noise levels were significantly higher in the hybrid systems due to the fans used for heat dissipation in the thermoelectric coolers[29]. Soylemez *et al*. tested two hybrid refrigerators combining vapor compression and thermoelectric cooling. They consumed three

times more energy than conventional system but cooled 40% faster. Noise levels were due to thermoelectric cooler fans[30].

Substitute Refrigerants with Low Global Warming Potential (GWP)

The transition to low GWP refrigerants is a crucial strategy for enhancing sustainability and performance of VCR systems. Conventional refrigerants, though effective, produce adverse effect to greenhouse gas emissions and environment. Low GWP refrigerants offer an eco-friendly alternative, reducing environmental impact while maintaining or even improving system performance. Sanchez *et al*. tested six different lowGWP refrigerants in a beverage cooler. Energy consumption and pull-down tests were conducted at a controlled ambient temperature of 30°C and 55% relative humidity. With the use of R290 and R1270 reduced energy consumption by 27.5% and 26.3%respectively, while R152a cut energy consumption by 13.7%[31]. ODP and GWP were highlighted in Mahmood *et al*.'s review of the environmental effects of refrigerants. The study highlighted natural alternatives like water (R-718), CO_2, and hydrocarbons as eco-friendly solutions. The study recommended more research on water as a sustainable working fluid in mechanical refrigeration systems and highlighted the relevance of the Montreal Protocol in the elimination of harmful refrigerants[32]. In their study of natural and synthetic refrigerants, Abas *et al*. highlighted the necessity of eliminating the use of HFCs and HCFCs in accordance with international accords. To evaluate refrigerants across 25 parameters in six categories, they proposed the Refrigerant Parametric Quantification (RPQ) methodology. The model determined that the best natural options were CO_2 (R-744), ammonia (R-717), and ethane (R-170) when applied to a vapor compression cycle (-15°C to 30°C). Although there are still issues with hydrocarbon safety, R-152a, R-1234yf, and R-1234ze performed well among synthetics[33]. Mota-Babiloni *et al*. reviewed the replacement of high GWP Hydrofluorocarbons (HFCs) with lower GWP synthetic alternatives, emphasizing the European Union's F-Gas Regulation. They analyzed Hydrofluoroolefins (HFOs) and HFO/HFC mixtures across various cooling applications, highlighting trade-offs between GWP reduction and efficiency[34]. Mota-Babiloni *et al*. reviewed ultralow-temperature (ULT) refrigeration systems, focused to reduce environmental impact. The study highlighted the lack of GWP limits for ULT systems under EU F-Gas regulations, which does not impose GWP limits for ULT systems despite the high GWP of commonly used refrigerants like R23 and R508B.Two main system types namely two-stage cascade and auto-cascade were analyzed for better performance. Low-GWP alternatives like R170, R1150, R1132a, and R41 were examined. R170 showed high COP but raised flammability concerns, while R1132a/R170 blends outperformed R508b at -85°C[35]. Table 0: Key findings by substitute refrainment's with low GWP.

Application of Nano refrigerant and Nano lubricant

The application of nano refrigerants and nano lubricants has emerged as a cutting-edge approach to enhance the performance of VCR systems. By incorporating nanoparticles into traditional refrigerants and lubricants, these nanofluids exhibit superior thermal conductivity, heat transfer efficiency, and lubrication properties. The application of TiO_2-based Nano refrigerants and lubricants in VCR systems has shown remarkable potential to enhance performance and reduce energy consumption. Gill *et al*. demonstrated that using LPG with TiO_2 nanoparticles in mineral oil as a replacement for R134a reduced irreversibility by 2.21 to 48.10% across various components, with optimal performance achieved at 40g LPG and 0.4 g/L TiO_2.[50]Adelekan *et al*. found that a TiO_2-R600a Nano refrigerant mixture (0.1g TiO_2 in 40g R600a) achieved the highest COP (4.99) with minimal compressor work, showcasing energy savings and environmental benefits[51]. Similarly, Babarinde *et al*. tested an R600a/TiO_2 mineral oil blend, obtained a COP of 3.20, offering lower power consumption and superior cooling performance compared to R134a.[52]Adelekan *et al*. also explored TiO_2 Nano lubricants in R600a, finding COP improvements of up to 16.32%, with the highest COP (4.20) achieved under optimal conditions at 60g R600a and 0.2 g/L TiO_2[53]. Several studies have investigated the use of graphene and graphene-oxide nano lubricants in VCRsystems using R600a refrigerant, aiming to enhance performance. Babarinde *et al*. explored the impact of graphene nano lubricant at different concentrations (0.2, 0.4, 0.6 g/L)obtained60 g of R600a with 0.2 g/L graphene achieved the highest performance. Results showed that at lowest power consumption (0.0651 kW) and fastest cooling rate COP found as 3.2[54] Similarly, Adelekan *et al*. examined varying concentrations of graphene nano lubricants in R600a, The lowest compressor power consumption of 65 W and cabinet temperature of -12°C occurred with 40g and 0 g/L or 60g and

0.2 g/L mixtures. The highest COP of 0.76 was achieved with 70 g and 0 g/L.[55] Patil *et al*. tested graphene-oxide nano lubricants in Polyolester (POE) oil with R600a, found that a concentration of 0.3 g/L with a 40 g mass charge of R600a achieved the highest COP (1.72), along with a maximum refrigeration effect of 0.1977 kW and the lowest power consumption of 0.115 kW[56]. Several studies have examined the use of Al_2O_3 nanoparticles in R134a to improve the performance of VCR systems. Bondre *et al*. tested various Al_2O_3 concentrations in POE oil and found that 0.1% Al_2O_3 achieved the best performance, improving COP by 17.2% and reducing energy consumption by 32.48%.[57] Similarly, Ajayi *et al*. investigated Al_2O_3 nanoparticles prepared by a wet chemical reduction method in R134a, observing faster cooling, better performance, and improved energy efficiency. The nano refrigerant also exhibited better thermal conductivity and reduced viscosity compared to the base oil, with a slight COP increase after 180 minutes of operation.[58] Hussain *et al*. used a two-step method to prepare Al_2O_3 nanofluids at varying concentrations and found that a 0.01% concentration led to a COP increase of up to 25.7% at 28°C. However, they noted that the refrigerating effect decreased as the ambient temperature increased[59]. Several studies have explored the use of ZrO_2 nanoparticles in R134a to enhance the performance of VCRsystems. Baskaran *et al*. investigated an R134a-ZrO_2 nano refrigerant (0.2 g/L) in a domestic refrigerator and found significant improvements in system performance. The nano refrigerant resulted in a 38.7% increase in refrigeration capacity and 6.25% reduction in energy consumption for better-improved COP.[60] Similarly, Barza *et al*. tested R134a with ZrO_2 nanoparticles prepared via a two-step method using a magnetic stirrer and ultrasonic homogenizer. Their results showed a 7.68% reduction in compressor energy consumption with increase in cooling capacity and thermal performance. The system also achieved a COP of up to 3.5[61]. Ghorbani *et al*. studied the impact of CuO nanoparticles on R600a. Adding CuO at 0.5%, 1%, and 1.5% increased the heat transfer coefficient by 4.1%, 8.11%, and 13.7% respectively, with the highest gain at 1.5% concentration. Results showed that CuO has potential to enhance condensing system performance through improved thermal conductivity and mixing effects[62]. Several review articles have highlighted the potential of nano refrigerants and nano lubricants in enhancing the performance of refrigeration, air conditioning, and heat pump systems. Alawi *et al*. reviewed various nanoparticles, including Al_2O_3, CuO, and TiO_2, which improves thermal conductivity, leading to reduced energy consumption and enhanced COP.[63] Sawant *et al*. focused on the preparation and applications of nano fluids in refrigeration. These suspensions of nanoparticles in base fluids improved thermal conductivity and heat transfer, thus enhancing COP and reducing compression work.[64] Sharif *et al*. reviewed the mechanisms of nano refrigerants and nano lubricants in VCRsystems. Their findings showed that nanofluids increases heat transfer coefficients by 12 to 101%, thermal conductivity by up to 4%, and reduce compressor work by 11%, while enhancing COP by 24%[65].

Application of phase change material

The integration of phase change materials (PCMs) into VCR systems offers a novel approach to enhancing energy efficiency and thermal performance. PCMs, with their high latent heat storage capacity, can effectively manage temperature fluctuations, reduce compressor workload, and improve overall system efficiency. Varvagiannis *et al*. developed a semi-dynamic model of a photovoltaic driven vapor compression chiller with a refrigerant-PCM-water heat exchanger (RPW-HEX) for domestic cooling. They used TRNSYS dynamic simulation software to evaluate the system performance of low-temperature energy storage using paraffin-based PCM with a melting point of 4°C.Compared to conventional PV cooling with only battery storage, the hybrid system reduced cooling peaks and improved the solar fraction. The study concludes that integrating thermal storage with PV chillers enhances energy efficiency, especially in retrofitted buildings[66]. Karthikeyan *et al*. studied the impact of PCM (OM32, OM29, OM03 and HS3N) on a 185L household refrigerator using R134a. They tested different locations for placing the PCMinside the freezer, fridge, and near the condenser and measured temperatures at important points to see how each placement affected performance. Results showed that placing PCM in the freezer, fridge, and near the condenser reduced temperature fluctuations, lowered condenser coil temperatures dropping from 46°C to 40°C at the inlet (top) and from 43.8°C to 39°C at the outlet (bottom)and improved overall system efficiency. The study concluded that PCM integration enhances food preservation and reduces energy consumption[67]. Khaire *et al*. reviewed methods to enhance the COP of domestic refrigerators using PCM. They examined PCM placement in the freezer, fridge, and condenser, highlighting its role in reducing temperature fluctuations, extending compressor off-cycle time, and

improving energy efficiency. The study emphasized PCM's benefits for food preservation and energy savings, stressing the need for proper PCM selection based on temperature requirements[68].

Application of combine cycle

Using combined cycles in VCR systems is a new way to improve energy efficiency. By adding other cooling methods like absorption or ejector cycles to the regular VCR system, the system can use energy more effectively. Bao *et al*. investigated the performance of single-fluid and dual-fluid organic Rankine cycle and vapor compression cycle (ORC-VCC)systems for heat-activated cooling using geothermal water at 140 °C as a heat source. The researchers compared four systems: single-fluid ORC-VCC (ORC-VCC-S), dual-fluid ORC-VCC (ORC-VCC-D), single-fluid ORC with flash tank vapor injection cycle (ORC-FTVIC-S), and dual-fluid ORC-FTVIC (ORC-FTVIC-D). They used Aspen HYSYS software to model the systems and a genetic algorithm to optimize key parameters, including turbine inlet pressure and temperature, and intermediate vapor injection temperature, for six working fluids (R1270, R290, R161, R152a, R1234yf, and R1234ze). Results showed that the dual-fluid ORC-FTVIC system achieved the highest cooling capacity (2282.0 kW) using R1234yf-R152a as the working fluid pair. The single-fluid ORC-FTVIC system, using R1234yf, attained a cooling capacity of 2177.5 kW. The study found that ORC-FTVIC systems generally outperformed ORC-VCC systems due to reduced throttling losses. The optimum working fluids varied depending on the system and heat source temperature. The authors concluded that dual-fluid ORC-FTVIC systems offer the best performance for heat-activated cooling applications[69]. Javanshir *et al*. proposed and analyzed a novel combined cycle using R134a, R22, and R143a refrigerants for simultaneous power and cooling generation. This cycle integrated a VCC with an ORC powered by geothermal water. The methodology involved thermodynamic and thermo-economic modelling using EES software. The system achieved a thermal efficiency of 27.2% and an exergy efficiency of 57.9% with R143a, resulting in a total product unit cost of 60.7 $/GJ. The study revealed that R143a yielded the highest energy and exergy efficiencies, while R22 exhibited the highest exergy destruction rate, leading to the highest production cost. Parametric analysis demonstrated that higher turbine inlet pressure and lower condenser pressure, as well as lower pinch-point temperature difference, improved both thermodynamic and economic performance[70].

Waste heat recovery

Waste heat recovery is a transformative approach to improving the performance of VCR systems. By capturing and utilizing the heat generated during the refrigeration process, waste heat recovery systems can reduce energy waste and provide additional utility, such as water heating or power generation. Mahesh *et al*. investigated the performance enhancement of a VCRsystem using a water-cooled condenser to recover waste heat. The researchers compared the performance of R134a and a hydrocarbon mixture of R290 (50%) and R600a (50%) under no-load and 6-litre load conditions. Comparing the compressor work, condenser heat rejection rate, refrigeration effect, and COP for air-cooled and water-cooled condenser configurations was part of the experimental technique. According to the study, the COP for both refrigerants increased when a water-cooled condenser was used. The COP of R134a increased by 10.86% when there was no load and 13.4% when there was a 6-liter load.For the hydrocarbon mixture, the COP increased by 9.9% under no load and 13.5% under 6-litre load. The hydrocarbon combination had a much better refrigeration effect, indicating improved cooling capacity, whereas R134a had a slightly higher COP. The authors recommended the hydrocarbon mixture because of its lower GWP and found that a water-cooled condenser effectively improves VCR system performance[71].

Regenerative expansion

Regenerative expansion is an innovative technique designed to enhance the efficiency of VCR systems by recovering the energy that is typically lost during the expansion process. By employing a regenerative heat exchanger, the energy from the high-pressure refrigerant can be partially recovered to pre-cool the refrigerant before it undergoes expansion, thereby reducing the compressor's energy demand. Kadam *et al*. investigated enhancing the performance of a simple VCR system using R-12 refrigerant by implementing a regenerative expansion device. The experimental methodology involved designing and analyzing a regenerative expansion device comprised of a capillary tube, flash chamber, and heat exchanger. The researchers compared the COP of a conventional VCR system with a capillary tube with the modified system with the regenerative expansion device under various condenser and evaporator

temperatures. The results showed that the modified VCR system consistently achieved a higher COP than the conventional system. Specifically, with a condenser temperature of 42°C and an evaporator temperature of -8°C, the conventional system achieved a COP of 4.03, while the modified system achieved a COP of 4.32[72]

Hot gas bypass method

The hot gas bypass method is a widely used technique to enhance the performance and stability of VCR systems, particularly under variable load conditions. This technique avoids compressor overload and maintains the ideal evaporator temperature by redirecting a part of the hot refrigerant gas from the compressor's discharge side back into the suction side. Kirar and Agrawal used R-134a refrigerant with a cooling capacity of 134 TR to analyse the performance of an air-cooled compact screw chiller system.A specially designed setup with Resistance Temperature Detectors (RTDs) and a data logger was used to detect the temperature in addition to gathering data from the Human Machine Interface (HMI) panel.The researchers manually created a pressure-enthalpy (p-h) diagram for the system and verified the thermodynamic characteristics of R-134a. Calculations revealed a refrigeration capacity of 132.31 TR, closely matching the chiller's rated capacity, and a COP of 3.71. This study examined an R-134a VCRS industrial chiller and found that it operated exceptionally well at full heat load. But a significant problem was noted when there was either no heat demand or a partial one, which resulted in "cut-off cycles". To maintain temperature throughout these cycles, the chiller turned on and off frequently, which over time may lead to component malfunctions and misbehaviour. The study came to the conclusion that the "hot gas bypass system" was the only practical way to improve performance and guarantee safe operation under these varying circumstances. In the chiller, it was specifically advised to model and implement a hot gas bypass system. This technique was also shown to be essential for future VCRS chiller capacity control.[73]

CONCLUSION

The VCRS is most prominent technology in cooling applications, yet improving its efficiency is critical in addressing growing energy and environmental concerns. This review has explored various performance enhancement strategies. Enhancements such as ejector-expansion systems, evaporative condensers, and vortex tube cooling significantly improve VCR system performance.

- Studies showed magnetic fields improve COP and energy efficiency, with optimal performance achieved using specific magnet configurations.
- Combining VCR with thermoelectric or absorption systems enhances cooling efficiency and energy savings.
- Transitioning to eco-friendly refrigerants like R290, R1270, and R1234yf reduces environmental impact while maintaining performance.
- Incorporating nanoparticles like TiO_2, Al_2O_3, and CuO improves thermal conductivity, COP, and energy efficiency.
- PCM reduces temperature fluctuations, extends compressor off-cycle time, and enhances energy efficiency.
- Utilizing waste heat through water-cooled condensers improves COP and refrigeration effect while reducing overall energy consumption.
- Regenerative expansion and hot gas bypass methods optimize energy use by recovering lost energy and improving system stability under varying loads.

Future research should focus on refining these advancements through experimental validation, system integration, and real-world applications to achieve cost-effective and scalable solutions. By leveraging these innovative strategies, VCRsystem can evolve to meet performance standards and sustainability goals, ensuring long-term energy savings and reduced environmental footprint.

Table 1: Key findings by design rectification

Reference	Author	Modification	Findings
[14]	Papade *et al*.	Matrix heat exchangers	The matrix heat exchanger led to reduced power consumption and improves overall system efficiency.
[15]	Aranguren *et al*.	Thermoelectric sub-cooler	Optimizing voltageto thermoelectric modules led to ~~an~~ 11.3% increase in COP and a 15.3% rise in cooling capacity.
[16]	Nebot-Andres *et al*.	Mechanical sub-cooling	An experimental trans critical CO_2 refrigeration plant with integrated mechanical subcooling system was optimized and achieved COP of 1.40–2.48.
[17]	Puangcharoenchai *et al*.	Vortex tube cooling	With air as the working fluid, COP was 5.16% higher, and power use 4.36% lower than conventional systems at 25%

			cold mass fraction and 100% load.
[18]	Al-Obaidi *et al*.	Liquid suction line heat exchanger (LSLHX)	The study tested various water flow rates, subcooling, and full LSLHX, using R22 as a refrigerant. The best basic VCC achieved a COP of 3.23. Subcooling improved COP by 10%, while full LSLHX decreased it by 47.5%.
[19]	Jeon *et al*.	Two phase ejectors	The study varied ejector geometries and operating conditions to assess the Coefficient of Performance (COP). The maximum COP improvement of the condenser outlet split(COS) ejector cycle with the optimum mixing section diameter over a baseline cycle was 6.8%.
[20]	Mahmood *et al*.	Vapor Injection	Vapor injection with a vertical flash tank boosted COP and lowered discharge temperature, with R290, R1234ze, R1234yf, and R507 as alternatives to R22.
[21]	Llopis *et al*.	Sub-cooling with accumulation receiver	COP improvements reached up to 37.8%. The review synthesized the current state-of-the-art and highlighted new research opportunities.
[22]	Ansari *et al*.	Mechanical sub-cooling	A thermodynamic analysis of a VCRsystem with mechanical sub-cooling found R1233zd(E) had a higher COP than R134a, while R1243zf was slightly lower.
[23]	Rajendran *et al*.	Suction line heat exchanger (SLHX)	An R134a mobile AC study with SLHX and retuned Thermostatic ExpansionValve (TXV) improved COP by 16.2% and cooling capacity by 6.7%.

Table 0: Key findings by substitute refrainment's with low GWP

Reference.	Author	Refrigerants	Findings
[36]	Kulkarni *et al*.	R134a, R290, R600a, R1234yf	The study analyzed COP, GWP, and ODP of various refrigerants like R134a, R290, R600a, R1234yf, along with nanofluids such as Al2O3 and TiO2and found that hydrocarbon mixtures and nanofluids can enhance performance while reducing environmental impact.
[37]	Hamza *et al*.	R134a, R152a, R1234yf,R1234ze(E)	Researchers have analyzed R152a, R1234yf,R1234ze(E) as low GWP R134a alternatives in a VCRsystem with a plate heat exchanger. R152a achieved 6.3–11% higher COP.
[38]	Yu *et al*.	LowGWP mixtures	A study modeled low GWP R410A alternatives for HVAC, identifying 34 mildly flammable blends. Some matched R410A's vapor pressure, while others had -4% to +17% capacity changes and 5–10% lower COP.
[39]	K. Harby	HC, HC mixtures, HC/HFC blends	A review carried out on hydrocarbons, highlighting zero ODP, low GWP, higher efficiency, and lower mass as compared toCFCs, HCFCs, and HFCs. Flammability is a drawback, but safety measures mitigate risks.
[40]	Gimenez-Prades *et al*.	R-1336mzz(Z), R-1233zd(E), R-1224yd(Z)	R-1233zd(E) and R-1224yd(Z) suitable for high-temperature heat pumps (HTHP) and Organic Rankine Cycles (ORC). R-1336mzz(Z) also showed potential for these applications.
[41]	Korshetti *et al*.	R290, R22	The study found R290 had a higher cooling capacity than R22, but as condenser temperature increased, power consumption also increased. COP was higher for R22 than R290 under some conditions.
[42]	Savitha *et*	HFOs, HFCs	The review covered HFOs, HFCs, and natural refrigerants,

	al.		noting that HFOs have low GWP but reduced system efficiency. Natural refrigerants have zero ODP and GWP, while blends offer a trade-off between flammability and GWP.
[43]	Uddin *et al*.	R32, R1123, R1234yf, R1234ze(E), R744	Researchers assessed R32, R1123, R1234yf, R1234ze(E), and R744 blends for GWP, temperature glide, volumetric capacity, and COP. Some blends with GWP of 200 and 300 showed potential as R410A replacements.
[44]	N Austin	R152a, R32, R290, R1270, R600a, and RE170	An analysis using Cycle_D4.0 software of R152a, R32, R290, R1270, R600a, and RE170 as alternatives to R134a, R22, and R12has been carried out. It was found that R152a, RE170, and R600a had better COP, with RE170 showing a 5.96% lower compression ratio than R134a.
[45]	Fatouh *et al*.	Mixtureof R290:R600:R600a (60:26.6:13.4%)	A ternary hydrocarbon mixture (60% propane, 26.6% isobutane, 13.4% n-butane) was tested in a domestic refrigerator. The study concluded that THM refrigerants can achieve better energy and exergy characteristics than R134a while offering an environmentally friendly alternative.
[46]	De Paula *et al*.	R290, R1234yf,R744	R290 achieved the highest COP (2.32), lowest Total Equivalent Warming Impact(1891 kgCO_2), and highest exergy efficiency, making it a top eco-friendly, energy-efficient R134a alternative.
[47]	R.S. Mishra	R1234yf, R1234ze, R141b, R125, R245fa, R236fa, R227ea, R143a, R152a, R410a, R404A, R407c	Highest COP of 2.769 and lowest of 1.99 obtained for R141b and R125 refrigerants respectively.R1234ze matched with R134a in second law efficiency. Author concluded that HFO-1234ze(Z) and R1233zd(E) enhance both first and second law efficiencies in VCR system.
[48]	Kasera *et al*.	R407c	The review concluded that although R407c offers slightly lower performance, it remains a viable option for retrofitting, while R410a is preferred for new designs.
[49]	R.S. Mishra	R134a, R1234ze, R1234yf	An energy-exergy analysis of R1234ze and R1234yf as eco-friendly R134a alternatives found R1234ze 5–10% better than R1234yf, though R134a performed slightly better.

ABSTRACT

Brain tumours are a widespread serious neurological phenomenon that can be life-threatening, which is effectively managed by the most versatile and abruptly developing field known as Artificial Intelligence (AI) by mimicking the neural network of the human brain. This technology has act as a great support system for the researchers by capturing hidden, high-dimensional images of brain tumours. These images provide new insights into the nature of brain tumours and help to improve treatment options. AI and precision medicine (PM) are converging to revolutionize healthcare. AI has the potential to improve cancer imaging interpretation in several ways, including more accurate tumour genotyping, more precise delineation of tumour volume, and better prediction of clinical outcomes. AI-assisted brain surgery can be an effective and safe option for treating brain tumours. This review focuses on various AI and PM techniques that can be used in the treatment of brain tumours. This review discusses various AI and PM techniques that can be used in brain tumour treatment. These new techniques for the treatment of brain tumours, i.e., genomic profiling, microRNA panels, quantitative imaging, and radiomics, hold great promise for the future advancement. However, several challenges need to be addressed to facilitate these technologies to improve healthcare management.

Keywords: Precision medicine, brain tumours; artificial intelligence; imaging technology; gene targeting; patient care.

INTRODUCTION

The rising global incidence of cancer and multidrug-resistant infectious diseases has intensified the demand for innovative therapeutic interventions and advanced research methodologies within these expanding health burden central nervous system CNS tumors remain among the most clinically challenging malignancies due to their biological complexity and critical anatomical location [1]. These tumors harbor distinct molecular and epigenetic alterations that govern tumor initiation progression therapeutic responsiveness and clinical outcome a comprehensive understanding of these alterations is fundamental to improving patient survival and optimizing individualized treatment strategies. Brain tumors originate from abnormal cellular proliferation occurring within the brain parenchyma or in surrounding anatomical structures including cranial nerves the meninges and endocrine-associated regions such as the pituitary and pineal glands [2,3]. The progressive expansion of these lesions disrupts essential neurological functions as the brain regulates cognition motor coordination sensory integration and vital physiological processes depending on their site of origin. Brain tumors are categorized as primary neoplasms arising directly within the CNS or secondary tumors that metastasize from systemic malignancies from a pathological standpoint [4]. Tumors are classified as benign or malignant based on their proliferative capacity invasiveness and potential for recurrence despite limited extra cranial spread even histologically benign tumors can cause significant morbidity due to mass effect and intracranial pressure. Within the confined cranial cavity among malignant primary brain tumors glioblastoma represents the most aggressive and therapeutically resistant subtype in elders [5]. It is defined by a high-speed cellular increased diffuse penetration of surrounding neural tissue and a strong likelihood of recurrence following treatment prognosis remains poor despite multimodal management approaches including surgery radiotherapy and chemotherapy. The World Health Organization grading framework stratifies brain tumors into four grades according to histological and molecular criteria with higher grades reflecting increased malignancy accelerated growth and worse clinical outcomes accurate classification and molecular characterization are therefore essential components of precision-based therapeutic decision-making the incorporation of AI [6]. AI into neuro-oncology has developed into a transformative advancement in recent years, AI encompasses computational algorithms capable of learning from extensive datasets to perform complex feature extraction predictive model and decision support. Within the framework of brain tumor management AI-driven systems enhance multiple stages of clinical care including early detection tumor segmentation volumetric assessment prognostic prediction and treatment planning. Advanced AI applications in magnetic resonance imaging MRI enable automated identification of tumor margins quantitative feature extraction and longitudinal monitoring of therapeutic response by leveraging large-scale imaging and clinical datasets. AI facilitates the discovery of subtle patterns beyond human visual perception thereby strengthening precision medicine approaches in CNS oncology [7,8].

AI-Enhanced Multidisciplinary Brain Tumor Management: -

Artificial intelligence enhances neuro-oncology and radiation oncology practice by facilitating integrated, data-driven diagnosis, refining disease characterization, improving prognostic accuracy, and enabling patient stratification for personalized treatment planning. AI facilitates neurodiological practice by refining MRI data to enable automated tumor identification, accurate delineation and molecular profiling, and generating quantitative imaging biomarkers to enhance diagnostic precision. It also supports differentiation between viable tumor and necrotic tissue while enabling automated quality assurance to ensure consistency and reliability in imaging interpretation. Artificial intelligence technologies are increasingly integrated into neurosurgical practice to support intraoperative diagnosis, enhance surgical margin assessment, and provide real-time decision support during surgical procedures. Artificial intelligence facilitates neuropathological analysis of fresh and FFPE specimens by enabling automated feature quantification, enhancing tumor detection, and supporting tumor classification and grading through integrated histo-molecular assessment of cellular and tissue architecture. Furthermore, AI augments molecular pathology by identifying biomarkers, molecular pathways, and genetic variants, as well as assisting in diagnosis and prediction of treatment response [9,10].

Imaging Innovations in Neuro-Oncology

Computed Tomography (CT)-

In 1972, CT scan was first introduced which is most widely used neuro diagnosis techniques. Compared with MRI, CT is less expensive and more widely available, relatively brief acquisition time enhances patient comfort and overall tolerability [11,12]. It demonstrates greater sensitivity than MRI in identifying bone destruction, ventricular size alterations, acute hemorrhage, and subarachnoid hemorrhage however; it demonstrates lower sensitivity for visualizing brain anatomy and for detecting intracranial pathology. This imaging tool offers practical advantages due to rapid acquisition time and widespread availability, because the data obtain quickly and also less susceptible to motion related artifacts than MRI [13,55,65].

Magnetic Resonance Imaging (MRI)-

Magnetic resonance imaging (MRI) has become integral to the evaluation of brain tumors due to its ability to produce highly detailed anatomical images with remarkable soft-tissue differentiation. Its advanced spatial resolution allows clinicians to accurately identify, localize, and characterize intracranial lesions. In neuro-oncology practice, MRI is generally preferred over computed tomography (CT) because it provides superior anatomical detail without exposing patients to ionizing radiation or requiring iodinated contrast agents. The imaging technique is based on the interaction between strong magnetic fields and radiofrequency energy, which influence hydrogen nuclei within biological tissues. By detecting the signals emitted as these nuclei return to equilibrium, MRI generates images that reflect the structural and biochemical characteristics of tissues [14]. The exceptional contrast resolution achieved through this mechanism makes MRI particularly valuable for visualizing central nervous system structures. Beyond tumor detection, MRI is widely used in assessing a broad spectrum of neurological conditions, including intracranial malignancies, infectious processes such as brain abscesses and encephalitis, inflammatory demyelinating disorders like multiple sclerosis, along with various intraspinal disorder, such as intramedullary masses and intervertebral disc pathology. In the context of brain tumor diagnosis, conventional MRI sequences provide essential information regarding lesion size, anatomical boundaries, and spatial relationship to adjacent structures. This includes evaluation of peritumoral edema, mass effect on surrounding brain tissue, involvement of the ventricular system, and proximity to major vascular structures [15, 30]. Furthermore, MRI facilitates multiplanar visualization—typically in axial, coronal, and sagittal orientations—allowing comprehensive assessment of both the brain and spinal cord. By reflecting tissue composition, molecular environment, and structural organization, MRI serves not only as a structural imaging modality but also as a foundation for advanced functional and quantitative imaging techniques that assist in diagnostic refinement and therapeutic planning [16,17,39]

Functional MRI (fMRI)-

Functional magnetic resonance imaging (fMRI) evaluates regional brain activity by detecting variations in blood oxygen level dependent (BOLD) signals that are temporally and spatially associated with neuronal activation. fMRI is employed to evaluate cerebral activity using vdetecting alterations in the molecular structure of specific brain regions, which occur over time intervals ranging from seconds to minutes. (fMRI) detects regional alterations in cerebral blood flow, which serve as an indirect indicator of underlying neuronal activity. Resting state fMRI (rs-fMRI) monitors baseline neural dynamics while the patient is during rest which study how tumors disrupt functional networks, which can help predict patient survival. Thus fMRI plays a pivotal role in preoperative planning by enabling neurosurgeons to accurately localize and consequently, it contributes significantly to the protection of essential neurological functions and improves postoperative outcomes, particularly in the management of neuro-oncological conditions and epilepsy [18,19].

Positron Emission Tomography Imaging (PET)-

The integration of positron emission tomography with magnetic resonance imaging (PET/MRI) represents a notable technological progress in hybrid neuroimaging. These combined systems enable the simultaneous acquisition of high-resolution anatomical MR images alongside metabolic and functional information derived from PET, thereby bridging structural and molecular imaging within a single examination [20]. This multimodal approach has gained increasing importance in both clinical practice and translational neuroscience research. Among PET radiotracers,

fluorine-18 labeled fluorodeoxyglucose (^{18}F-FDG) remains the most extensively utilized agent in oncologic imaging. As a glucose analog, FDG reflects cellular metabolic activity, which is typically elevated in malignant tissues. PET imaging operates through the detection of gamma photons produced during positron-electron annihilation events, captured by a ring-shaped array of detectors within the scanner. The resulting data provide quantitative insights into regional metabolic processes [57]. In neuro-oncology, PET techniques have been applied not only to assess tumor glucose metabolism but also to investigate cerebral oxygen consumption and disruptions of the blood–brain barrier associated with neoplastic growth. In addition to FDG, radiolabeled amino acid tracers have emerged as valuable tools for brain tumor imaging. These tracers demonstrate preferential uptake in tumor cells while exhibiting reduced to accumulation in healthy brain tissue, thereby generating improvedlesion to parenchyma contrast ratio. This enhanced contrast facilitates more accurate tumor localization, margin delineation, and overall diagnostic confidence. Clinically, PET imaging plays an increasingly important role in therapeutic decision-making. It contributes to radiotherapy planning by defining metabolically active tumor regions, assists in selecting optimal biopsy targets, and enables longitudinal assessment of treatment response. When combined with MRI in integrated PET/MRI platforms, metabolic information can be precisely correlated with anatomical structures, further strengthening its utility in personalized neuro-oncologic management [21,26].

Perfusion Imaging-

Perfusion imaging is an essential approach in neuroradiology and neuro-oncology, providing comprehensive characterization cerebral hemodynamic through the quantitative assessment of cerebral blood flow, cerebral blood volume, and mean transit time within brain tissues. It acts as a pivotal fuction in the identification, classification and therapeutic planning of brain tumors, specifically in the context of gliomas, by identifying aberrant perfusion patterns that frequently correlate with tumor progression rate and the extent of angiogenesis [22]. Computed tomography perfusion, dynamic susceptibility contrast MRI, and arterial spin labelling. MRI are widely utilized perfusion imaging techniques in neuro-oncology. These modalities facilitate the differentiation of high-grade from low-grade tumors, enable the distinction between tumor recurrence and post-treatment changes, and contribute to the evaluation of therapeutic response. When combined with anatomical imaging and molecular methodologies, perfusion imaging significantly enhances diagnostic accuracy in neuro-oncologic practice. It plays a critical role in guiding targeted biopsy and optimizing surgical planning. Furthermore, the integration of perfusion parameters with structural and molecular data facilitates the development of personalized treatment strategies, thereby improving overall clinical management in neuro-oncology [23,56].

SPECT in Brain Imaging

Single-Positron Emission Computed Tomography (SPECT) provides comprehensive morphological and physiological assessment through 3D evaluation of cerebral perfusion and receptor binding activity. SPECT imaging is frequently valuable in the clinical management of patients, as it provides novel and complementary information that may not be obtained through other diagnostic modalities. In particular, brain perfusion SPECT plays a significant role in the diagnosis, therapeutic planning, and longitudinal follow-up of patients [24,57]. Radiotracers such as Technetium-99m HMPAO and Technetium-99m Tetrofosmin are employed to detect perfusion abnormalities. SPECT imaging facilitates the diagnosis and grading of brain tumors, particularly gliomas, by neuro-oncologists. Moreover, it enables differentiation between high-grade and low-grade neoplasm according to the relative extent of tracer uptake and perfusion. Through integrating anatomical imaging modalities such as MRI, CT, SPECT enhances diagnostic accuracy and facilitates comprehensive, multidisciplinary decision-making in patient management [25,26].

Diffusion-Weighted Imaging (DWI) and Diffusion Tensor Imaging (DTI)-

Diffusion-weighted imaging (DWI) and diffusion tensor imaging (DTI) are modernized magnetic resonance imaging (MRI) approaches that offer critical insights into the microstructural organization related to the brain. Diffusion-weighted imaging is a form of molecular imaging that provides quantitative information regarding the mobility of water molecules within biological tissues, including normal brain parenchyma, tumor tissue, purulent collections, and cystic lesions [27,66]. Diffusion tensor imaging (DTI) assesses the brain's microstructural architecture by measuring anisotropic water diffusion. It detects subtle abnormalities in disorders such as stroke, multiple sclerosis,

amyotrophic lateral sclerosis, dyslexia and is increasingly integrated into clinical practice. DTI also supports neurosurgical planning and radiation therapy dose optimization. As an extension of DWI, DTI visualizes white matter fiber tracts through tractography and quantifies directional diffusion. [18,56].

MR Spectroscopy-

Magnetic resonance spectroscopy (MRS) delivers valuable understanding of the metabolic composition of evaluated brain tissue. On proton (^{1}H) MRS, the principal metabolites assessed in brain tumors comprise N-acetylaspartate (NAA) at approximately 2.0 ppm, creatine (Cr) at around 3.0 ppm, and choline (Cho) at about 3.2 ppm. NAA serves as a neuronal integrity marker, Cr reflects cellular energy metabolism, and Choline indicates membrane turnover and cellular proliferation [28]. Additional relevant metabolites include lipid and lactate peaks near 1.3 ppm—often associated with necrosis and anaerobic metabolism—and myo-inositol at approximately 3.5 ppm, which is considered a glial marker. Lipids and lactate are regarded as metabolic indicators of necrosis and tissue hypoxia, respectively, whereas myo-inositol is associated with astrocytic integrity and plays a role in osmotic regulation within the brain [29,56].

AI in brain tumor prognosis: -

Prognosis in neuro-oncology encompasses the systematic assessment of anticipated disease progression and clinical outcome in an individual patient, integrating variables such as therapeutic strategy, tumor stage, molecular and histopathological characteristics, and overall clinical condition. In brain tumor management, artificial intelligence significantly enhances prognostic assessment. Machine learning (ML) and deep learning (DL) approaches are increasingly utilized to predict overall survival (OS) and progression-free survival (PFS) by analysing features derived from pre-treatment imaging data [31]. Notable studies demonstrate that radiomic features obtained from T1, T2, and FLAIR MRI scans—particularly in treatment-naïve glioblastoma patients—hold substantial potential for predicting progression-free survival (PFS) and overall survival (OS). Among patients with glioblastoma, AI models overcome conventional clinical variables and achieve superior performance when integrated with clinical features. This DL framework predicted spatial transcriptional profiles and prognosis from histology images, highlighting the potential of AI to elucidate complex tumor behaviour [32]. AI can predict specific genetic mutations (e.g. IDH mutation, MGMT promoter methylation) from non-invasive imaging, which are critical for determining prognosis. AI rapidly and accurately distinguishes between high-grade (HGG) and low-grade (LGG) gliomas, with some models achieving over 96-98% accuracy [60,61].

AI in brain tumor therapeutic management:-

Beyond enhancing both diagnostic and prognostic capabilities, artificial intelligence has been increasingly applied to optimize brain tumor treatment planning and to improve the assessment of therapeutic response. It revolutionizes therapeutic strategies and improves precision by facilitating the accurate detection and detailed evaluation of brain tumors. It assists clinicians in selecting the most appropriate, patient-specific treatment strategies [33,59]. AI-driven approaches demonstrate strong capability in predicting therapeutic responses, thereby facilitating more effective and individualized treatment planning across diverse cancer types. Innovative strategies—for example predicting treatment response to Gamma Knife radiosurgery for metastatic brain tumors using radiomic features derived based on contrast-enhanced T1-weighted and FLASH sequences, as well as employing predictive models based on pre-treatment apparent diffusion coefficient (ADC) maps to forecast radiotherapy outcomes—highlight the growing efficacy of AI-driven methodologies in neuro-oncology. Although identifying the key biomarker MGMT associated with temozolomide resistance in glioblastoma remains challenging, AI-based radiomic approaches can predict both MGMT status and treatment response, thereby supporting more informed therapeutic decision-making [34,35].

Molecular Diagnosis Approaches:-

Molecular diagnosis has revolutionized neuro-oncology by transitioning tumor classification from a purely histopathological approach to an integrated histomolecular framework. While traditional diagnosis of central nervous system tumors relied mainly on microscopic features, advances in genomic and epigenetic profiling have revealed that morphologically similar tumors can differ significantly in their molecular signatures, biological

behaviour, and treatment response. Consequently, molecular characterization is now central to precise diagnosis, prognostic assessment, and personalized therapeutic planning in neuro-oncology.

MGMT Promoter Methylation and Temozolomide Response-

Epigenetic silencing of the MGMT (*O6-methylguanine–DNA methyltransferase*) gene through promoter methylation is associated with improved overall survival in patients with glioblastoma treated with radiotherapy combined with alkylating agents such as ***Carmustine*** or ***Temozolomide*** [36]. Located on chromosome 10q26, the MGMT gene encodes a DNA repair protein that excises alkyl groups from guanine's O6 position. This repair process consumes the MGMT protein, requiring continuous replenishment. If unrepaired, chemotherapy-induced lesions—particularly O6-methylguanine—lead to cytotoxicity and apoptosis [37,38].

IDH-Mutant Gliomas-

Gliomas constitute the most common malignant primary brain tumors in adults and are categorized by the World Health Organization (WHO) into distinct subtypes and grades based on combined Tissue-based and molecular features. Mutations in the metabolic enzyme genes *IDH1* and *IDH2* are found in nearly all adult grade 2 diffuse gliomas [40]. ***Ivosidenib*** targets and blocks mutated IDH1 enzymes that abnormally convert α-ketoglutarate to D-2-hydroxyglutarate (2-HG). ***Vorasidenib*** inhibits mutant IDH1/2, reducing 2-HG levels, restoring normal cell metabolism and epigenetic regulation, and slowing glioma growth. Combined radiotherapy and chemotherapy has become the standard postoperative treatment for patients with IDH-mutant grade 3 gliomas and for those with high-risk IDH-mutant grade 2 gliomas who are at increased risk of early disease progression[41,42]

Targeted Chemotherapy in BRAF-Altered Tumors-

BRAF is a proto-oncogene that encodes the serine/threonine-protein kinase B-Raf, a key component of the mitogen-activated protein kinase (MAPK) signalling pathway, where it regulates cellular proliferation, differentiation, and survival. BRAF V600 mutations are identified in approximately 50% of cutaneous melanomas and lead to constitutive activation of the downstream mitogen-activated protein kinase (MAPK) signalling pathway [43]. ***Vemurafenib*** is a selective oral inhibitor targeting the BRAF V600 kinase and has demonstrated an overall response rate of around 50%, along with improved survival outcomes in patients with BRAF V600E–mutant metastatic melanoma [44]. ***Dabrafenib*** is selectively blocks mutated forms of the BRAF kinase, a protein involved in cell growth signalling.

Blood–Brain Barrier Dynamics-

The blood–brain barrier (BBB) is a specialized, significantly selective boundary composed consisting of tightly joined endothelial cells, together with astrocytic end-feet and pericytes. It tightly controls the exchange of ions, molecules, and cellular elements linking the systemic circulation and the central nervous system (CNS), thereby preserving neural homeostasis and protecting the brain microenvironment. n malignant brain tumors, the blood–brain barrier (BBB) is often disrupted due to abnormal angiogenesis mediated by factors such as VEGF[45]. The resulting tumor vasculature is structurally and functionally aberrant, with disorganized architecture, impaired tight junctions, reduced pericyte support, and increased permeability, forming the so-called blood–tumor barrier (BTB). However, this disruption is heterogeneous. Infiltrative margins and microscopic tumor foci may retain an intact BBB, leading to uneven drug distribution, subtherapeutic exposure in certain regions, and subsequent therapeutic resistance [46,47]. This variability poses a significant obstacle to effective drug delivery in malignant brain tumors such as Glioblastoma. ***Lomustine*** (CCNU) is an alkylating chemotherapy drug that penetrates the blood–brain barrier to target tumor DNA, commonly used for treating gliomas and other brain tumors. ***Temozolomide*** also penetrate BBB [53,54].

ATRX Mutations-

The alpha-thalassemia/mental retardation syndrome X-linked (ATRX**)** gene encodes a chromatin-remodeling protein that plays a critical role in telomere maintenance through the alternative lengthening of telomeres (ALT) pathway, a telomerase-independent mechanism [48]. ATRX mutations are frequently observed in astrocytic tumors and commonly co-occur with TP53 and IDH1 mutations. In contrast, they are typically absent in tumors harboring 1p/19q

co-deletions, making ATRX status a valuable molecular marker for distinguishing astrocytic neoplasms from oligodendroglial tumors. Furthermore, loss of ATRX expression has been associated with a more favorable prognosis, particularly Within patients whose neoplasms also carry IDH1 mutations [49,50].

Histone H3 Mutations-

Histones are structural proteins essential for DNA packaging and chromatin organization. Recent studies have identified mutations in the H3F3A gene, which encodes histone H3.3, in pediatric patients with high-grade gliomas, including Glioblastoma and diffuse pontine gliomas [51]. These mutations occur at specific residues within histone variants H3.1 and H3.3, most notably lysine 27 (K27) in both H3.1 and H3.3, and glycine 34 (G34) in H3.3.Among these, the H3 K27 mutation is associated with a particularly poor prognosis. Importantly, H3F3A mutations are typically mutually exclusive with IDH1 mutations, defining a distinct molecular subgroup of gliomas characterized by unique epigenetic and biological alterations [52].

Personalized Chemotherapeutic Agents :-

Biosimulation-Guided Precision Chemotherapy in MGMT-Methylated Glioblastoma

This 2021 study by Castro et al. applied computational biological modeling (biosimulation) to TCGA genomic data from 274 newly diagnosed methylated-MGMT glioblastoma patients (207 successfully modeled) to personalize chemotherapy. Temozolomide (TMZ) alkylates guanine, inducing futile mismatch repair (MMR), replication fork arrest, and cell death in MGMT-silenced tumors, yet MMR deficiency (MMRD) paradoxically causes hypermutation and deleterious effects in some cases. Lomustine, a chloroethylating agent, exploits defects in base excision repair (BER), homologous recombination repair (HRD), DNA checkpoints, IDH1 mutations, and epigenetic regulators (e.g., KMT2, EP300, HOXA10) for superior single-agent efficacy in subsets. Biosimulation generated efficacy scores (T_eff) revealing marked heterogeneity: the TMZ-lomustine combination [58] produced synergy (>33% ΔT_eff, up to 99% efficacy) in 47.8% of patients versus TMZ alone, modest benefit in 33.8%, negligible gain in 18.4%, and harm (lomustine alone superior) in 15.9%. By integrating NF-κB, Hedgehog, and multiple DNA repair pathways, the model identifies individuals poised for major survival gains from combination therapy (as in NOA-09) while sparing others unnecessary toxicity, demonstrating biosimulation's role in precision oncology beyond one-size-fits-all approaches [64,67]

Targeted IDH Inhibition with Vorasidenib in Grade 2 Glioma

The phase 3 INDIGO trial, published in The New England Journal of Medicine, represents a significant step in precision therapy for IDH-mutant grade 2 glioma [63]. Diffuse low-grade gliomas are defined by mutations in IDH1 or IDH2, which produce the oncometabolite 2-hydroxyglutarate and promote tumorigenesis. In this double-blind study, patients with residual or recurrent tumors after surgery were randomized to vorasidenib or placebo. Vorasidenib Markedly enhanced progression-free survival (27.7 vs. 11.1 months; HR 0.39) and delayed the need for additional therapy (HR 0.26). By selectively inhibiting mutant IDH enzymes, it lowers 2-hydroxyglutarate, mitigates epigenetic dysregulation, and slows tumor progression with manageable toxicity, redefining early targeted management of IDH-mutant gliomas [68-71].

Evaluation of vemurafenib in children and young adults with BRAF V600–mutant tumors-

In the framework of precision oncology, the NCI-COG Pediatric MATCH trial (APEC1621 Arm G) demonstrates personalized medicine by molecularly matching children and young adults with relapsed/refractory solid tumors harbouring BRAF V600 mutations to vemurafenib, a selective oral BRAF V600 kinase inhibitor. Patients received maximum 960 mg twice daily in 28-day cycles. Of 22 patients identified through tumor sequencing, only 4 (18%) enrolled—primarily due to exclusions for low-grade glioma or prior BRAF-inhibitor exposure—underscoring accrual barriers when targeted agents are commercially available. Enrolled cases (one each of high-grade glioma, histiocytosis, ameloblastoma, and Ewing sarcoma, all BRAF V600E-positive) showed overall tolerability, with mostly grade 1–2 adverse events and rare grade 3 toxicities. Strikingly, the high-grade glioma patient achieved a confirmed partial response sustained for 15 cycles, yielding 12.9 months progression-free survival. These findings affirm

vemurafenib's role as a biomarker-driven option in BRAF V600-mutated pediatric cancers, particularly aggressive gliomas, while highlighting the need for innovative trial designs in the personalized medicine era [43,72].

CONCLUSION

We examined the transformative applications of artificial intelligence (AI), including computer vision, deep learning (DL), in the management of brain tumors. AI demonstrates substantial potential in enhancing diagnosis, prognostic assessment, and treatment planning by accurately detecting. In therapeutic management, AI contributes significantly to personalized treatment planning, protocol therapeutic planning and outcome forecasting, thereby facilitating individualized therapeutic guidance and continuous monitoring of disease progression. Implementation of AI-based methodologies strongly corresponds to the principles of precision medicine and promotes a patient-centred approach to neuro-oncologic care. Nevertheless, the integration of AI in Neuro-oncological care necessitates rigorous evaluation of ethical, regulatory, and community related implications. Particular attention must be directed toward safeguarding data privacy, ensuring transparency and accountability, and mitigating potential healthcare disparities to promote equitable and responsible implementation. The integration of anatomical imaging modalities (MRI, CT) with functional and molecular techniques (fMRI, DTI, MR spectroscopy, and PET) enhances precise disease localization, reduces radiation exposure, and better preserves eloquent cortical regions.

Future efforts should focus on addressing existing research gaps, integrating multimodal data, exploring large language models, and improving continuous monitoring systems. Artificial intelligence models developed using diverse, high-quality datasets show strong potential to predict therapeutic response response and enhancing clinical impact. Continued refinement and validation are crucial to fully realize AI's role in the clinical management of brain tumors and its translation into routine practice.

ACKNOWLEDGEMENT

We are grateful for the technical support provided by Brainware University, Department of Pharmaceutical Technology, in carrying out the review process.

ABSTRACT

Sciatica is a common neuromuscular disorder characterized by radiating pain along the distribution of the sciatic nerve. In Ayurveda, this condition is described as *Gridhrasi*, a *Vata-pradhana Vatavyadhi*[1]. Conventional management often provides symptomatic relief and may be associated with recurrence or adverse effects. *Agnikarma*, a para-surgical procedure described in classical Ayurvedic texts, is considered an effective intervention for pain-dominant Vata disorders. The present case report aims to evaluate the role of Agnikarma in the management of sciatica (Gridhrasi)[2]. A single patient diagnosed with sciatica (Gridhrasi) was treated with Agnikarma as the primary intervention. The procedure was performed under aseptic conditions using a *Panchadhatu Shalaka* at selected anatomical points over the lumbosacral region and along the affected lower limb. Assessment was carried out using subjective parameters such as pain intensity, stiffness, and numbness, along with objective parameters including the Straight Leg

Raising (SLR) test. Observations were recorded before treatment and during follow-up. The patient showed marked improvement following Agnikarma therapy. Significant reduction in pain intensity was observed along with improvement in functional parameters. The Straight Leg Raising test showed notable improvement, and associated symptoms such as stiffness and numbness were markedly reduced. No adverse events or complications were reported during or after the procedure. This case report suggests that Agnikarma can be an effective and safe para-surgical intervention in the management of sciatica (Gridhrasi). Further well-designed clinical studies with larger sample sizes are recommended to validate these findings.

Keywords: *Agnikarma; Gridhrasi;* Sciatica; Para-surgical procedure; *Ayurveda*

INTRODUCTION

Sciatica is a common clinical condition characterized by radiating pain along the distribution of the sciatic nerve, frequently associated with low back pain, restricted mobility, and sensory disturbances in the lower limb. Epidemiological data suggest that the lifetime incidence of low back pain ranges from 50–70%, with sciatica affecting up to 40% of individuals during their lifetime. Degenerative spinal changes and lumbar disc pathology are among the most common etiologies contributing to this condition [3,4]. In Ayurveda, sciatica closely correlates with *Gridhrasi*, which is classified as a *VatajaNanatmaja Vyadhi*. Classical texts describe Gridhrasi as a condition marked by radiating pain (*Ruk*), pricking sensation (*Toda*), stiffness (*Stambha*), numbness (*Suptata*), and restricted lifting of the affected limb (*Sakthikshepa Nigraha*). When associated with *Kapha Dosha*, additional features such as heaviness (*Gaurava*) and lethargy (*Tandra*) may be present[1,2]. Conventional medical management of sciatica primarily involves non-steroidal anti-inflammatory drugs, muscle relaxants, physiotherapy, and, in refractory cases, surgical interventions. These approaches may provide symptomatic relief but are often associated with recurrence, adverse effects, and economic burden. In contrast, Ayurveda describes multiple therapeutic modalities for Gridhrasi, including *Bheshaja*, *Snehana*, *Swedana*, *Siravedha*, *Basti*, and *Agnikarma*[3]. Among these, Agnikarma is regarded as a superior para-surgical intervention, particularly for pain-dominant conditions, due to its rapid and sustained analgesic effect[5]. Previous clinical and case-based studies have demonstrated the efficacy of Agnikarma in reducing pain intensity and improving functional outcomes in patients with Gridhrasi. However, despite available clinical studies, detailed documentation of individual patient outcomes following Agnikarma remains limited. This case report aims to contribute to existing evidence by presenting a systematically documented single-patient outcome.

Case Presentation

A 50-year-old male patient presented to the Department of Shalya Tantra with complaints of radiating pain in the lumbosacral region extending to the right lower limb for the past 3 months. The pain was described as continuous in nature, aggravated by prolonged standing, walking, and forward bending, and partially relieved by rest. The patient also reported associated symptoms of stiffness and intermittent numbness in the affected limb. There was no history of trauma, spinal surgery, bowel or bladder involvement, or systemic illness such as diabetes mellitus or inflammatory arthritis. The patient had previously received conventional analgesic medications, which provided only temporary symptomatic relief. No significant personal or family medical history relevant to the present illness was reported. Ayurvedic evaluation was carried out using *Ashtavidha Pariksha* and *Dashavidha Pariksha* to assess the *Dosha*, *Dushya*, and *Samprapti* involved in the disease process.

Ashtavidha Pariksha

Nadi (Pulse): Vata-predominant
Mutra (Urine): Samyak (normal)
Mala (Stool): Samyak
Jihva (Tongue): Nirama

Shabda (Speech): Prakruta
Sparsha (Touch): Anushna-sheeta
Drik (Eyes): Prakruta
Akruti (Build): Madhyama

Dashavidha Pariksha
Prakriti: Vata-Kapha
Vikriti: Vata-Kapha vriddhi
Sara: Madhyama
Samhanana: Madhyama
Pramana: Madhyama
Satmya: Madhyama
Satva: Madhyama
Ahara Shakti: Madhyama
Vyayama Shakti: Avara
Vaya: Madhyama

Samprapti Ghataka
Dosha: Vata (predominant), Kapha (anubandhi)
Dushya: Rasa, Rakta, Asthi, Majja, Snayu
Srotas: Rasa Vaha, Rakta Vaha, Asthi Vaha, Majja Vaha
Srotodushti: Sanga
Agni: Vishama Agni
Udbhava Sthana: Pakwashaya
Adhisthana: Kati, Prishta, Uru, Janu, Jangha, Pada
Roga Marga: Madhyama
On Ayurvedic evaluation, the condition was diagnosed as Gridhrasi, based on classical features such as *Ruk (pain)*, *Toda (pricking sensation)*, *Stambha (stiffness)*, *Suptata (numbness)*, and *Sakthikshepa Nigraha (restricted lifting of the affected limb)*.

Clinical Examination
General Examination
The patient was conscious, cooperative, and well oriented to time, place, and person. Vital parameters were within normal limits. No pallor, icterus, cyanosis, clubbing, or lymphadenopathy was observed. Gait assessment revealed difficulty during ambulation due to pain.

Locomotor Examination
Inspection
- Antalgic posture observed
- Difficulty in standing and walking for prolonged duration
- Restricted movements of the lumbosacral region

Palpation
- Localized tenderness present over the lumbosacral region
- Increased stiffness of paraspinal muscles on the affected side

Range of Motion of Lumbar Spine
Forward flexion: Restricted and painful
Extension: Restricted with discomfort
Lateral flexion: Restricted on the affected side

Special Tests
Straight Leg Raising (SLR) test: Positive on the right side
Contra lateral SLR: Negative
Gait: Antalgic
Based on clinical examination findings and Ayurvedic assessment, the diagnosis of Gridhrasi (sciatica) was confirmed.

Timeline of Clinical Events (Table 1).

Clinical Assessment
Subjective parameters: Pain intensity, stiffness, numbness
Objective parameters: Straight Leg Raising (SLR) test, gait assessment
Baseline findings indicated significant functional impairment with a positive SLR test on the affected side.
Based on clinical presentation and examination findings, alternative causes such as peripheral neuropathy and vascular claudication were considered less likely.

Therapeutic Intervention
Agnikarma was selected as the primary therapeutic modality based on classical indications and previous clinical evidence.

PROCEDURE

The procedure was performed under strict aseptic precautions using a *Panchadhatu Shalaka*. Controlled thermal cauterization (*Bindu Dahana*) was carried out at selected points over the lumbosacral region and along the course of the affected lower limb. The procedure was performed in a single sitting, and the patient was followed up periodically to assess clinical response. Post-procedure care included application of *JatyadiGhrita*to promote wound healing. The patient was advised on appropriate dietary and lifestyle measures to support recovery.

Outcome and Follow-Up
Post-intervention assessment revealed a marked reduction in pain intensity and improvement in associated symptoms such as stiffness and numbness. The Straight Leg Raising test demonstrated significant improvement compared to baseline. Functional mobility improved, and the patient reported enhanced quality of life. No complications or adverse effects were observed during the treatment or follow-up period. Assessment of Subjective Parameters Before and After Treatment (Table 2). Assessment of Objective Parameters Before and After Treatment (Table 3). Pain intensity showed marked reduction from baseline, and the Straight Leg Raising angle on the affected side improved considerably during follow-up.

Patient Perspective
The patient reported significant relief from pain and improvement in daily activities without the need for continued analgesic medications.

DISCUSSION

The observed clinical improvement following Agnikarma may be attributed to its multifaceted mechanism of action. From an Ayurvedic perspective, Agnikarma pacifies aggravated *Vata Dosha* through its *Ushna*, *Tikshna*, and *Sukshma* properties, thereby relieving *SrotasAvarodha* and restoring normal physiological function[6]. From a modern scientific viewpoint, the therapeutic heat generated during Agnikarma may modulate nociceptive pathways through mechanisms analogous to thermotherapy and gate control theory of pain[7,8,11]. Increased local blood circulation, muscle relaxation, and neuromodulation may collectively contribute to pain relief and functional recovery. Similar

findings have been reported in earlier case studies and clinical trials, where Agnikarma demonstrated significant improvement in pain scores and functional parameters in patients with Gridhrasi[9,10].

CONCLUSION

This single case report highlights the potential role of Agnikarma as an effective and safe para-surgical intervention in the management of sciatica (Gridhrasi). The favorable clinical outcome observed in this case supports classical Ayurvedic references and contemporary clinical evidence. Further well-designed randomized controlled trials with larger sample sizes are necessary to establish definitive clinical guidelines.

INFORMED CONSENT

Written informed consent was obtained from the patient for publication of this case report and accompanying clinical information.

ETHICAL CONSIDERATION

Ethical approval was not required for this single case report as per institutional policy.

ABSTRACT

Quality sleep significantly influences cognitive function, emotional well-being, and overall health, yet allied health science students often face sleep disruptions due to demanding curricula. This cross-sectional study examined the relationship between sleep quality, academic performance, and quality of life (QoL) among 200 students. Sleep quality was assessed using the Pittsburgh Sleep Quality Index (PSQI), academic performance via self-reported Cumulative Grade Point Average (CGPA), and QoL with the WHOQOL-BREF. Results showed 68% of students had poor sleep (PSQI >5), with mean PSQI score of 6.8 ± 2.1. Poor sleepers exhibited lower CGPA (3.1 ± 0.5 vs. 3.6 ± 0.4, $p<0.001$) and reduced QoL scores across physical (52 ± 12 vs. 68 ± 10), psychological (55 ± 14 vs. 72 ± 11), social (58 ± 13 vs. 75 ± 9), and environmental domains (50 ± 15 vs. 65 ± 12, all $p<0.01$). Multiple regression indicated PSQI independently predicted 28% variance in CGPA and 32% in overall QoL.

Interventions targeting sleep hygiene are recommended for enhancing student outcomes in allied health programs.

Keywords: Sleep quality, Academic performance, Pittsburgh Sleep Quality Index (PSQI), Quality of Life (QoL), Allied health science students

INTRODUCTION

Allied health science students in India, particularly in rigorous programs endure high academic pressures leading to sleep deficits. The recent generation under integrated multidisciplinary training, frequently report of amplifying stress from clinical rotations and exams.[6]Poor sleep impairs memory consolidation, attention, and executive function, directly affecting academic performance measured by CGPA[1,7]. Additionally, sleep influences QoL, encompassing physical health, psychological state, social relations, and environment[8]. Studies from Kerala report 65% poor sleep prevalence among medical postgraduates, correlating with stress and inactivity[9]. These deficits impair neuroplasticity essential for mastering complex topics like musculoskeletal physiology and nutritional biochemistry, setting the stage for suboptimal academic outcomes. Poor sleep compromises memory consolidation during slow-wave sleep, attention via prefrontal cortex dysregulation, and executive functions critical for clinical simulations and examinations. Evidence from college cohorts shows consistent sleep patterns predict up to 25% of grade variance, with each lost hour correlating to a 0.07 GPA decline, directly relevant to self-reported Cumulative Grade Point Average (CGPA) metrics in Indian 4-point scales. In North Kerala's humid climate and high-stakes training, fragmented sleep exacerbates fatigue, reducing procedural skill acquisition vital for allied health professionals. Beyond academics, sleep influences WHOQOL-BREF domains—physical health, psychological state, social relationships, and environmental factors—fostering resilience against burnout prevalent in rehabilitation-focused programs. Poor sleepers report 15–20-point deficits across domains, amplifying stress from clinical workloads and peer competition, which undermines empathy and interdisciplinary collaboration essential for future practice. Regional studies highlight inactivity and caffeine reliance as contributors, underscoring the need for culturally tailored sleep hygiene in Kerala's allied health ecosystem. Despite global evidence, allied health-specific data from North Kerala remains scarce, with most research centered on medical students in urban South Kerala hubs. This study hypothesizes that better sleep quality associates with higher CGPA and QoL in these students, addressing a gap in allied health-specific data from North Kerala. This study intends to investigate the interplay between sleep quality, academic performance, and quality of life (QoL) among these students, addressing a regional evidence gap amid rising academic pressures.

METHODS

A cross-sectional survey was conducted from September to November 2025 at an integrated Allied Health Science in North Kerala, targeting undergraduate students [10] Sample size of 200 was calculated for 50% prevalence, 5% error, 95% CI with 92% response rate (n=184)[11]. Full-time students aged 18-25 years were included, while those unwilling to participate and with any known illness were excluded.

Outcome Measures

Sleep Quality: Pittsburgh Sleep Quality Index (PSQI), a 19-item validated tool (α=0.83)[12]. Seven components (subjective quality, latency, duration, efficiency, disturbances, medication, dysfunction) scored 0-3; global >5 indicates poor sleep[13].

Academic Performance: Self-reported CGPA (0-4 scale), reliable (r=0.84 with official records)[14].

Categories: Excellent (3.75-4.0), Good (3.25-3.74), Average (2.75-3.24), Poor (<2.75)[15].

Quality of Life: WHOQOL-BREF (26 items, 4 domains: physical, psychological, social, environmental; 0-100 transformed scores, α=0.80-0.89)[16]. Higher scores denote better QoL[17].
Data collected via Google Forms after informed consent. Analysis used SPSS v26: descriptives, t-tests, ANOVA, Pearson correlations, multiple linear regression ($p<0.05$)[18].

RESULTS

Participants (n=184) were 58% female, mean age 20.4 ± 1.6 years, 42% first-year. Mean PSQI was 6.8 ± 2.1; 125 (68%) had poor sleep.[19] Poor sleepers had shorter duration (5.9 ± 1.2 vs. 7.2 ± 0.9 hrs, $p<0.001$), higher latency (28 ± 15 vs. 12 ± 8 min), and more disturbances[20].

Academic Performance: Mean CGPA 3.3 ± 0.6. Good sleepers (PSQI ≤5, n=59) had higher CGPA (3.6 ± 0.4) than poor (3.1 ± 0.5, t=5.2, $p<0.001$)[21]. Correlation: r=-0.52 ($p<0.001$)[22] (Table 1).

Quality of Life: Overall WHOQOL-BREF 60 ± 14. Good sleepers scored higher across domains (Table below)[23]. Correlation PSQI-QoL: r=-0.58 ($p<0.001$)[24] (Table 2).

Regression: PSQI predicted CGPA (β=-0.42, R^2=0.28, $p<0.001$) and QoL (β=-0.49, R^2=0.32, $p<0.001$), controlling age/year[25].

DISCUSSION

Quality sleep profoundly influences cognitive processes essential for academic success and holistic well-being among allied health science students facing intense multidisciplinary training. This study integrates on PSQI, CGPA, and WHOQOL-BREF with broader evidence on mechanisms, contextual factors, and implications. Further, confirms a poor sleep prevalence (68%) among North Kerala allied health students, exceeding general college rates (50-60%) but aligning with Kerala medical students (65%)[9,26]. PSQI >5 linked to 0.5-point CGPA drop, consistent with findings of Okano,K. *et al*.,(2019) where sleep explained 25% grade variance via chronic effects, not single nights[1]. Mechanisms include impaired hippocampal neurogenesis and prefrontal cortex function from fragmented sleep[27]. Poor sleep disrupts hippocampal memory consolidation and prefrontal executive function, critical for allied health curricula explaining the 0.5-point CGPA drop observed. Short duration (5.9 vs. 7.2 hours), prolonged latency (28 vs. 12 minutes), and disturbances compound this, aligning with where consistent sleep patterns-not just duration-account for 25% grade variance. For QoL, sleep deprivation elevates cortisol, impairing emotional regulation and social engagement, with psychological domain hits most pronounced in this Kerala cohort amid clinical rotation stress. QoL deficits in poor sleepers span domains, with psychological/social impacts largest, mirroring WHOQOL validations (r=0.55-0.64 with SF-36)[17]. In rehabilitation-focused curricula, sleep deprivation exacerbates fatigue, reducing clinical skill acquisition and empathy[28]. Kerala context: cultural night studying, hostel noise, caffeine contributes, unlike Western chronotype mismatches[29]. Integrated programs amplify sleep deficits through late-night studying, hostel noise, caffeine culture, and humid climates-factors mirroring 65% poor sleep in Kerala postgraduates. Unlike Western chronotype issues, Indian cultural norms favor evening vigilance, exacerbating allied health demands like musculoskeletal simulations requiring sustained focus. Females, overrepresented, often maintain consistency yet face higher latency, paralleling gender patterns in medical student studies

LIMITATIONS

Self-reports (though validated), cross-sectional causality unproven, single college generalizability limited (vs. South Kerala)[30]. Strengths: allied health specificity, multi-tool integration.

IMPLICATIONS AND RECOMMENDATIONS

Longitudinal, actigraphy, interventions like CBT-I[31]. Colleges should enforce sleep education, screen via PSQI, align schedules with circadian rhythms for better outcomes[32]. Reduced screen mandates could enhance clinical empathy and retention in rehabilitation tracks. Longitudinal follow-ups with actigraphy would strengthen future allied health research in Kerala.

CONCLUSION

Quality sleep significantly enhances academic performance and quality of life with poor sleep predicting lower CGPA and WHOQOL scores. Institutions should prioritize the importance of quality sleep and sleep hygiene programs to optimize student success, holistic impact on overall health.

ABSTRACT

Super disintegrating tea tablets can disintegrate rapidly in hot water and/or milk within a few seconds and can manage tea-making within a short period. On the contrary, this particular formulation has been formulated by the direct compression. This formulation provides optimum quantity of tea in a tea tablet which can manage making of tea appropriately and to overcome the unnecessary wastage of tea, proper dispersion of tea leaves to make tea liquor, and overcomes the consumer's complications with conventional tea consumption. During the evaluation tests, it was found that the tablet which contains small amount of tea can manage concocting tea with two times more liquor release compared to the conventional tea leaves (results obtained from UV spectrogram that the absorbance at 272 nm of formulated tea was 1.025 whereas the absorbance of commercially procured tea was 0.513), longer shelf life (results obtained from FTIR spectrogram that no microbial contamination or degradation observed), and more caffeine content (results obtained from HPLC chromatogram that the Rf value of caffeine in the formulated tea tablet was 3.580 whereas, standard Rf value of caffeine in tea is 3.569). Interestingly, this formulation can reduce the wastage of money compared to the conventional tea drawing up.

Keywords: Super disintegrating agent, Tea powder, Tea tablet, Caffeine release, Oligomerization, Noyes-Whitney equation

INTRODUCTION

Tea (*Camellia sinensis*) which is one of the most substantially consumed liquid refreshments in the world was derived from Southeast China. Then slowly expanded to India, Sri Lanka and further into many tropical and sub-tropical regions of the world, respectively. There are fundamentally two varieties of tea. *Camellia sinensis* var. sinensis (known as China tea) which is grown vividly in China, Japan, and Taiwan, while *C. assamica* var. assamica (Assam tea) found in south and south East Asia, and nowadays in Australia [1]. Starting from the 19th century more than forty types of inorganic compound have been found in tea [2]. Tea predominantly contains polyphenols of thirty types among which the content of polyphenols is large uttermostly in green tea [3]. Tea also includes catechin, epicatechin, epicatechin gallate, and epigalocatechin gallate which have various therapeutic properties for different diseases [4, 5, and 6]. Green tea comprised of numerous flavonoids among which myricetin glycosides, quercetin glycosides, and behenyl glycosides are significantly remarkable [7, 8]. Anthocianin which is soluble in water is a flavonoid found in tea. Even though the content of anthocyanins is not in huge amount in tea but is responsible for the bitter taste [9, 10]. Gallic acid, Chlorogenic acid, Caffeic acid, p-Coumaric acid, Ellagic acid, Quinic acid, and tea gallate are the phenolic acids respectively are non-identical acids or acidic compounds which can be found in tea [13]. Among the discrete alkaloids the caffeine content is found to be more in tea. Apart from that a small amount of theophylline and theobromine can also be found [14]. The alkaloids are responsible for the revitalizing effect of tea [15]. Tea comprises of 1% to 4% of amino acids. So far, 26 amino acids have been found in tea, including 20 essential amino acids and 6 non-essential amino acids. The highest content is theanine, glutamic acid, arginine, serine, and aspartic acid [16]. Theanine and Aminobutyric acid are two significant active amino acids identified in tea. They have exceptional protective effects on the human nervous system [17, 18]. Most carbohydrates found in tea are polysaccharides in nature, such as cellulose, starch, and pectin, which are insoluble in water and are also responsible for a bit of sweetness in tea [4]. Among the chemical constituents of green tea, the aromatic components are not found much quantity. However, 0.005% to 0.020% has been found which is responsible for the impression of tea [20]. As of now more than 40 organic acids have been isolated and got identified from tea, including unbound organic acids and more than 30 have been found in aromatic components [21, 22, and 23]. The striking mineral elements are Phosphorus and Potassium, including Calcium, Magnesium, Iron, Manganese, Aluminum, Sulpher, Silicon, and also some trace elements such as Zinc, and Copper [24, 25, and 26] have been found in tea. Green tea also comprised of certain number of vitamins, such as vitamin B, vitamin C, and vitamin E, enzymes such as glucosidases and lipoxidases, and also chlorophyll, which is recognized as a safe natural edible pigment [27, 28, 29] have been detected and identified.

Disintegrants or disintegrating agents are those substances or combinations of ingredients added to different medicinal and/or nutraceutical formulations to enhance the disemination or foundering of tablets and capsule contents into very small fragments or minute particles resulting faster dissolving. When they encounter with watery substance in the GI tract or perhaps outside of GI tract of the human body they may work by gulping water into the tablet, causing it to expand and break into minute diminutive fragments. The most common disintegrating agents are starch USP, numerous starch derivatives, and many natural disintegrants. Numerous pre gelatinized starches are also employed as disintegrants during different formulations, with 5 % concentration [30, 31, 32, 33, and 34]. The API powders with compressibility of 12% to 16% are considered as good flowing powders. In contrast to other superdisintegrants, crospovidone are remarkabely compressible and established [35, 36, and 37].

MATERIALS AND METHODS

Materials and Chemicals: Tea Powder: Tea Powder is a powdered form of tea leaves prepared in the experimental laboratory from the tea leaves (TATA Tea Gold, FSSAI Lic No: 10014031001025) obtained from the local market in Barasat, West Bengal, India.

Compressible Agent (Microcrystalline cellulose): Microcrystalline cellulose $(C_6H_{10}O_5)_n$ is meliorated pulp made up of wood. It's white, free flowing greasepaint. Chemically, it's an inert substance. It was supplied from Sigma-Aldrich, CAS No: 9004-34-6.

Diluent (Lactose): Lactose is a disaccharide type sugar which gets synthesized by galactose and glucose subunits with the molecular formula $C_{12}H_{22}O_{11}$. Lactose was purchased from Sigma-Aldrich, CAS No: 63-42-3.

Lubricant (Talc): Talc is a naturally being mineral that's generally used in a wide range of diligence, as well as a lubricant; including the pharmaceutical assiduity. Talc used in this formulation was from Loba Chemie, CAS No: 14807-96-6.

Super Disintegrant (Sodium Starch Glycolate): A disintegrant is a cumulative that promotes decomposition, which is the breakage of a tablet into small fractions when in contact with a liquid medium. It was collected from Sigma-Aldrich, CAS No: 9063-38-1. .

Glidants (Magnesium Stearate): Glidants are blended with the expression to enhance the tablet- core mix- material inflow property. In this formulation it was collected from Loba Chemie, CAS No: 557-04-0.

Equipment: - Weighing balance (Danwer High Precision Weighing Scale 220 g, DWAI-223**),**

HPLC (Waters, Quaternary or Binary gradient pump with manual injector, PDA Detector, Model 2489 UV/Visible [UV/Vis] Detector),

IR spectrophotometer (Bruker, Alpha ii Compact FTIR Spectrometer),

UV spectrophotometer (Shimadzu, UV-1900 UV-VIS Spectrophotometer)

Method: -The present invention relates to a process for making a Biconvex Shaped Super Disintegrating Tea Tablet with the composition comprising of Tea Powder: Microcrystalline Cellulose: Talc: Magnesium Stearate: Sodium Starch Glycolate = 25: 2: 2: 2: 6; whereas to get faster disintegration the ratio should be 25: 2: 2: 2: 9 by which better result can be obtained.

Commercially procured tea powder in granular form (50 gms). This was taken in a mortar and subjected for drying at 50 to 60 ℃ in hot air oven (Remi). It should be considered that temperature in between 40 to 45 ℃ is enough to remove moisture from the tea leaves. Time should be approximately two to five minutes. It is highly recommended to do dry heating in a closed system in order to keep the tea flavour intact. As there was the usage of large particle tea of CTC (Crush Tear Curl), the temperature was adjusted up to 60 ℃. It is highly recommended to keep the temperature between 40 to 45 ℃ in order to get better result (flavour and infusion).

The dried tea powder was crushed with the help of a pestle and finely powdered. Here in this case crushing of dried tea leaves by using machine is recommended. The obtained tea powder was passed through sieve no 85 (As sieve 120 was not available during the experiment) to get uniform size particles (up to sieve no 120 can be used to get more fine particles) with which remaining ingredients, such as, microcrystalline cellulose (5%), "Sigma –Aldrich", sodium starch glycolate, "Sigma –Aldrich" (5%, 10%, and 15%) was added and mixed uniformly. Lactose was added in required quantity. Talc, "Loba Chemie", and magnesium stearate, "Loba Chemie" was incorporated in required quantity and mixed uniformly.

The obtained mixture was subjected to tablet compression using 8 stationed (Kambert Tablet Press) tablet compression machine. Tablets of 400 mg were prepared which was evaluated for various parameters like solubility, disintegration time, hardness etc. Now, it should be considered that tea is a naturally occurring substance. Therefore, according to the quality of tea leaves the flavour and taste will differ but the basic pattern to prepare tea tablet is same in every case. Here according to the requirement and/or choice different colour and different flavour can also be added in order to gain its different appearance and flavours. It is highly recommended that there should be pure form of dried tea powder. Additions of less adulterant or no adulterants can enhance the quality of tea tablet.

Therefore, it can easily be considered that small particles of tea tablet/tablets can easily disperse into the boiled water and/or boiled milk in order to release flavour very quickly. Here the comparatively small particles of tea leaves dust are highly recommended.

As it is described earlier that Lactose is not required to prepare the whole formulation but here in this case during the experiment Lactose was added to fill up the total quantity. Instead of not using Lactose here the similar amount of dried tea powder or ginger powder, elichi powder, tulsi powder etc. can be added to get some unique flavor. Similarly other flavoring agents can also be added like peppermint oil rose oil, jasmine oil etc. According to the requirement FDC (Food, Drugs, and Cosmetics) approved colour can also be added to get colour and texture. On the other hand, for different tea formulations the main ingredient will change whereas, the rest of the elements i.e. compressible agent, lubricant, glidant, and super disintegrating agent will remain same.

In this present invention the amount of tea powder required will be less 200 to 250 mg of tea powder for making 100 ml of tea. Fine powder (Sieve 120 can be used which can produce 0.125 mm of particle size) can be obtained. Therefore, after disintegration, the effective surface area will be more resulting in the rapid solubilization of the active ingredient. Extraction of tea liquor will be obtained instantly. In this present formulation the amount of tea powder required will be less. 200 mg to 250 mg of tea powder is required for making 100 ml of tea. Fine powder (Sieve 120 can be used which can produce 0.125 mm of particle size) can be obtained. Therefore, after disintegration, the effective surface area will be more resulting in the rapid solubilization of the active ingredient. Extraction of tea liquor will be obtained instantly. Caffeine in tea dissolves in hot water because it has significant intermolecular forces, specifically hydrogen bonds and dipole-dipole interactions. Caffeine is polar in nature molecule with more than one hydrogen bond, which allows it to interact with polar water molecules. In hot water, the kinetic energy of the water molecule increases, which helps break the intermolecular forces between the caffeine molecules and allows more dissolution in the hot water.

As the tea granules were crushed in a powder form therefore, the effective surface area becomes greater. The less amount of particle size can give more effective surface area by which the tablet can release its colour and flavour rapidly. It is highly recommended to keep the particle size lesser as far as possible. During the research work initially Sieve 85 was used where the particle size was 0.177 mm approximately. Then Sieve 120 was used where the particle size was 0.125 mm approximately which was responsible for more effective surface area. It is recommended to use Sieve 170 or more in order to gain better outcome i.e. less than 0.100 mm of particle size to get highly effective result. (Ref: Noyes and Whitney Equation). The tea tablet also reflected a disintegration time of 38 sec, while maintaining the water temperature of 60-65 degree Celsius. Later on the temperature was raised up to 70 degree Celsius or more by which it showed the time of disintegration of 28 sec. This indicates the disintegration time is dependent on temperature of the medium which may be suitably maintained above 70 degree Celsius. Therefore, considering the conventional tea powder or tea bag, the tea tablet would be a better choice as it can disintegrate very fast (less than half minute) and consume lesser time.

DISCUSSION

The release of soluble active ingredients was studied by taking tea tablets containing 250 mg finely divided tea powder and the same amount of marketed tea granules. 100 ml distilled water was heated around 65 degree Celsius in which one tea tablet was placed and occasionally stirred with a glass rod providing gentle agitation. After 60 seconds, the resultant solution was filtered. In fig: 5 and fig: 6 respectively the filtrate was taken after 10 times dilution using distilled water and the obtained samples were analyzed using UV Visible Spectrophotometer. The absorbance was found at 1.025 at 272 nm. Similar procedure was followed for marketed tea granules which reflected an absorbance of 0.513 at 272 nm. Caffeine in tea dissolves in hot water because it has significant intermolecular forces, between the hydrogen bonds and dipole interactions. Caffeine molecule is polar in nature with more than one hydrogen bond, which allows it to interact with polar water molecules. In hot water, the kinetic energy of the water molecule increases, which helps break the intermolecular forces between the caffeine molecules and allows more dissolution in the hot water.

Initially, the tea granules were roasted at 45 to 50 degree Celsius and crushed into fine particles to get a better taste and smoky flavour. Therefore, during the making of the infusion, it produced fully induced flavour. It is applicable to any type of tea. On the other hand, dry roasting of tea leaves results an oligomerization in tea catechins which is responsible for the reduction of the astringency of tea and never effect on sleep. In fig: 7, the stability was determined by using FTIR Spectroscopy whether any biochemical changes were occurring or not. Initially the spectrogram was taken for the tea tablet which was prepared approximately six months earlier and the data was recorded. Then after having kept them in stability chamber the spectrogram was taken. The results of accelerated stability proved that there is no significant changes have been found, also there is no decay or degradation of the tea tablet for last six months and no any microbial contamination found. Therefore, it can be concluded that the shelf life of the tea tablet is approximately 24 months. In Fig 7A to Fig 7E, Caffeine shows its efficacy due to the presence of the Carbon-Nitrogen bond, Carbon-Hydrogen bond, and amide carboxyl group. In the spectrogram, FTIR (Fourier Transform Infrared Spectroscopy) was determined. In pure caffeine the Carbon-Hydrogen bond vibration showed the peak at 1357.02 cm^{-1}, the Carbon-Nitrogen bond vibration showed the peak at 1546.50 cm^{-1}, and the amide carboxyl group vibration showed the peak at 1645.96 cm^{-1}, respectively. On the other hand, in caffeine obtained from conventional tea leaves the Carbon-Hydrogen bond vibration showed the peak at 1320.06 cm^{-1}, the Carbon-Nitrogen bond vibration showed the peak at 1549.19 cm^{-1}, and the amide carboxyl group vibration showed the peak at 1690.56 cm^{-1}.

On the contrary, in the case of the formulated tea tablet (CTC), the caffeine has shown the Carbon-Hydrogen bond vibration with the peak at 1326.16 cm^{-1}, the Carbon-Nitrogen bond vibration has shown the peak at 1540.21 cm^{-1}, and the amide carboxyl group vibration has shown the peak at 1632.90 cm^{-1}. Similarly, in the case of the formulated tea tablet (tea leaves), the caffeine has shown the Carbon-Hydrogen bond vibration with a peak at 1327.80 cm^{-1}, the Carbon-Nitrogen bond vibration has shown a peak at 1539.27 cm^{-1}, and the amide carboxyl group vibration has shown the peak at 1634.87 cm^{-1} , respectively.

Now, from the obtained results it can clearly be stated that despite treatment with some other excipients the end product (tea tablet prepared from CTC tea granules and/or tea leaves) is showing similar or almost similar caffeine content as the conventional tea leaves and CTC tea granules have. On the contrary, the amount of tea is less in the tea tablet compared to the conventional usage of tea that is it can manage to make one cup of tea with only one tablet consisting of 200 mg to 250 mg of tea. It can also be concluded that the other chemical constituents present in the tea tablet will remain the same or almost the same as compared to conventional tea leaves and CTC tea granules.

In case of the formulated tea tablet the release of caffeine is higher than the conventional tea leaves whether it may be caffeine release from black tea or green tea. The given chromatogram data clearly proves that the standard caffeine release which is denoted as Rf value is 3.569. Whereas, in black tea leaves the caffeine release is 3.551 and in green tea leaves the caffeine release is 3.544. That is also observed in the representation of the chromatogram. Now, in the formulated and developed tea tablet the release of caffeine is more superior that is 3.580. Therefore, it can be clearly concluded that the release of flavonoids, theine, and other chemical constituents will be higher compared to the conventional tea leaves. On the other hand, in order to gain similar amount of active ingredient release from the tea leaves there is a requirement of more amount of tea leaves. Whereas, the caffeine/active ingredient release is almost two times in tea tablet in spite of using less amount of tea powder. The UV-Vis spectrogram already denoted that earlier.

CONCLUSION

In conclusion it can be clearly stated that no requirement to isolate the active ingredient separately. The formulated biconvex super disintegrating tea tablet itself can release the active ingredient (caffeine) very fast while putting into hot water and/or milk. There is no requirement of any type of chemical treatment. There is no requirement of any type of granulation. Fine tea powder can show its efficacy in a better way. There is no requirement of freeze drying, spray drying and/or any lyophilization. Similarly, there is no requirement to produce effervescence as during effervescence in case of the preparation of milk-tea it can produce casein or curd due to the presence of citric or tartaric acid. There is no requirement of any diluents or fillers (completely optional).There is no requirement of any type of adulterants as adulterants can reduce the quality of tea. Whereas particular in that case it can be confirmed that the tea tablet can be the most preferable option for the consumers and the tea makers compared to conventional tea leaves. Definitely it is possible to prepare four to five cups of tea by using same amount of tea leaves conventionally used to prepare only one cup of tea. There is no requirement of any combinational drug/drugs. There is no requirement of centrifugation to separate the fine particles as at the initial stage during the formulation already fine particles were obtained. There is no requirement of any purification and concentration of the end product. Already all the ingredients used in this formulation was in pure form. During the quality control tests it showed greater hardness (4 kg approx and it can be adjusted according to the requirement). Finally the prepared tea can be consumed directly. On the other hand, the unique ratio of the chemical compositions makes it exceptional compared to other ways of conventional tea consumption. The amount of tea powder will be less by which only a few amount of tea powder can prepare more number of super disintegrating tea tablets. Fine powder can be obtained. Therefore, after disintegration, the effective surface area will be more resulting in the rapid solubilization of the active ingredient which is already found in the experiment. Extraction of tea liquor will be obtained instantly by which the prepared tea can be consumed instantly. Total time of disintegration will be less (max 30 seconds) which clearly denotes the pioneering in this formulation. The number of ingredients will be lesser (no requirement of any kind of

diluents). It has less astringency by which those who are suffering from insomnia or any other ambiguities regarding sleeping can use the tea tablet undoubtedly. Better shelf life (experimentally proved) can prevent any further degradation and/or any microbial contamination.

Patent: We acknowledge to Mr. Gaurav Singhal and Mrs. Sanchita Singhal of Singhwal Techlaw OPC Private Limited, No.33/1, 4th Floor, Krishna Complex, Near Mahatma Gandhi Statue, Horamavu Main Rd, Horamavu, Bengaluru, Karnataka 560043, India for going further to file the patent application regarding this formulation vide Patent Application Number: 202341074315; Reference Number: TEMP/E-1/87416/2023-CHE.

Approval: We acknowledge to the honorable member secretary, Dr. B. Balaji (IFS) of National Biodiversity Authority, Government of India (NBA), 5th Floor, TICEL Biopark, CSIR Road, Taramani, Chennai-600113, Tamil Nadu, India, for issuing the Form-8 approval vide Application Number: NBA/IPR Appl/INBA/8202500920/26/25-26/2879.

Table 1: Ingredients used during the formulation of biconconvex shaped super disintegrating tea tablet.

Formulation batch	Main Ingredient (Tea Powder) mg	Compressible Agent (Microcrystalline Cellulose) mg	Lubricant (Talc) mg	Glidant (Magnesium Stearate) mg	Super Disintegrating Agent (Sodium Starch Glycolate) mg
1	250	20	20	20	20
2	250	20	20	20	40
3	250	20	20	20	60

Table 2: Comparison of conventional tea granules and super disintegrating tea tablet

Parameter	Conventional Tea Granules	Super Disintegrating Tea Tablet
Particle Size	Larger (CTC granules)	Fine powder (<0.125 mm)
Surface Area	Lower	Significantly higher
Disintegration	Time consuming	Very fast (<30 s)

Extraction Efficiency	Moderate	Nearly 2× (UV data)
Dose Uniformity	Variable	Standardized
Shelf Stability	Moisture-sensitive	Improved stability
Processing	Simple drying	Direct compression

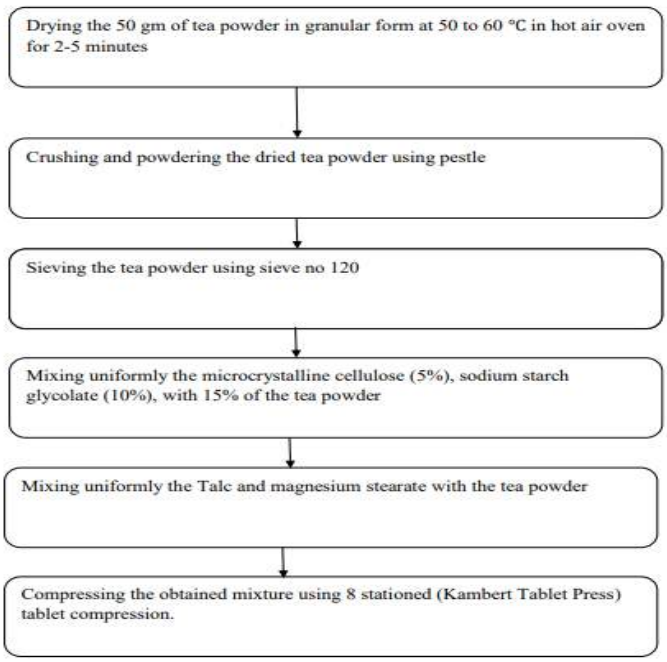

Fig 1: Flowchart describes the processing steps of biconvex shaped super disintegrating tea tablet

Fig 2: Shows the mixture of the required ingredients to formulate biconvex shaped super disintegrating tea tablet

ABSTRACT

The increasing complexity of global pharmaceutical regulations has made Regulatory Information Management Systems (RIMS) critical to ensuring compliance and efficient regulatory operations. This study highlights the importance of cloud-based RIMS in the pharmaceutical industry, focusing on key factors such as regulatory compliance, data integrity and operational efficiency. Key regulatory requirements, including 21 CFR Part 11, GXP guidelines, ALCOA+ data integrity principles and data security provisions such as GDPR, have been highlighted as key drivers of cloud RIMS adoption. The study shows that cloud-based RIMS offers significant advantages over traditional on-premise systems, including improved scalability, real-time global collaboration, standardized regulatory data management and reduced total cost of ownership. Industry case studies show that properly implemented cloud RIMS can support critical compliance controls such as audit trails, electronic signatures, secure access management and validated workflows. However, the findings also identify key challenges, including data security issues, cross-border data transfer limitations, vendor dependency and the need to manage frequent SaaS updates. The study concludes that the successful use of cloud-based RIMS depends not only on technology, but primarily on a strong governance framework, rigorous supplier qualification, risk-based verification and continuous monitoring of compliance, making cloud-based RIMS a reliable and strategic solution for modern pharmaceutical regulatory management.

Keywords: Cloud Computing, Regulatory Information Management System, Pharmaceutical Compliance, 21 CFR Part 11, Data Integrity, ALCOA+.

INTRODUCTION

Overview of the Regulatory Information Management System (RIMS)

Regulatory Information Management Systems (RIMS) are specialized software solutions used in the pharmaceutical industry to help centrally manage, store and submit regulatory documentation throughout the product lifecycle [12]. Over time, these systems have evolved from basic document management tools to comprehensive platforms that enable global regulatory operations and ensure compliance across multiple health authorities [10]. Their main functions include managing the document lifecycle, preparing submissions in eCTD-like formats, tracking regulatory intelligence, and supporting collaborative workflows between cross-functional teams [14]. As regulatory requirements become increasingly complex and pharmaceutical companies are required to submit to various global agencies simultaneously, the role of robust and efficient RIMS has become more important than ever [11].

Evolution of RIMS towards cloud-enabled platforms

The shift from traditional on-premise RIMS to cloud-enabled platforms marks a marked change in pharmaceutical regulatory operations [1, 21]. Previous RIMS systems hosted on internal servers were limited in scalability, availability and integration. With the rise of cloud computing – especially SaaS models – the management of regulatory information has become more flexible and efficient [8, 21]. Cloud-based RIMS now offer significant benefits such as real-time global collaboration, automatic updates, robust disaster recovery, and lower IT infrastructure costs [6, 9]. Many leading pharmaceutical companies have adopted cloud solutions such as Veeva RIM, Ennov and Regulatory One to keep pace with rapidly changing regulatory requirements [15, 16]. This change has been supported by improved cloud security measures, validated frameworks for cloud-based GXP systems, and increased regulatory acceptance of cloud-based applications [17, 25]. The regulatory landscape for pharmaceutical information systems is diverse globally, with the US FDA's 21 CFR Part 11 requiring validation, audit trails, secure access and data integrity for electronic records, including cloud systems [23, 24]. EMA's GxP and ALCOA+ principles reinforce strict requirements for data integrity in Europe [26]. GDPR adds strict requirements for privacy and cross-border data transfer that largely shape cloud RIMS architectures [2, 5]. Although ICH promotes harmonization, significant regional differences remain, making adaptable cloud-based RIMS essential for multinational pharmaceutical operations [3, 4].

Research problem, objectives

Despite the obvious benefits of cloud-based RIMS, pharmaceutical organizations face significant challenges in adoption and implementation. These challenges include technical concerns (data security, system validation), organizational factors (change management, skills development) and regulatory uncertainties (jurisdictional data restrictions, evolving compliance requirements) [2, 5].

Goals

1. Understand the key compliance requirements for using cloud-based RIMS in the pharmaceutical industry.
2. To identify the main challenges and risks that companies face when adopting cloud RIMS.
3. Review of real industry case studies to see how Cloud RIMS is implemented in practice.
4. To propose clear best practices and recommendations for the successful implementation of Cloud RIMS.

Regulatory Compliance Requirements for Cloud Rims

Ensure data integrity according to ALCOA+ principles

Data integrity represents the cornerstone of pharmaceutical quality systems and regulatory compliance. The ALCOA+ principles provide a comprehensive framework for assessing data reliability and trustworthiness in electronic systems [26]. For cloud-based RIMS, implementing these principles requires systematic controls throughout the data lifecycle.

Attributable: Data should clearly show who created or modified it.

Legible: Data must be readable, permanent, and understandable.

Contemporaneous: Data should be recorded at the time the activity is performed.
Original: Data should be the first recorded information or a verified true copy.
Accurate: Data must be correct, complete, and free from errors.

Audit trail, audit tracking and change control

Audit trails in GXP-compliant cloud-based RIMS are essential for regulatory compliance, as they must capture details of all user changes and system-level events, including software updates and security activities [17, 23, 24, 25]. These records should be immutable to prevent tampering, with full version history maintained to support regulatory oversight and audits [7, 11, 14]. Due to frequent SaaS updates, robust change control processes are required to ensure vendor changes are properly tested, approved and documented prior to deployment to maintain ongoing compliance – typically in a sandbox environment.

Electronic signature, identity management and authentication protocols

Electronic signatures in cloud-based RIMS must comply with 21 CFR Part 11 by clearly capturing the signer's identity, timestamp, and intent using appropriate signature methods based on regulatory actions [23,24]. Cloud GxP systems require strong authentication controls, including multi-factor and risk-based authentication, often integrated with enterprise identity platforms such as SAML 2.0 or O Auth 2.0 for centralized access management [5]. In addition, cloud RIMS must display signature information on records correctly and enforce role-based access controls to ensure secure approval, authorized submission and controlled document editing within regulated workflows [2,17].

Validation requirements for cloud-based systems

Validation of cloud-based RIMS is challenging due to limited control over the underlying infrastructure, making risk-based approaches such as GAMP 5 necessary to assess system configuration and vendor reliability [25]. Validation activities should verify correct system configuration, integration with other regulated systems, and continued validity after vendor-driven SaaS updates through planned testing and continuous monitoring. Under the shared responsibility model, suppliers manage the security and availability of the infrastructure, while pharmaceutical companies remain responsible for data integrity, configuration and regulatory compliance, which require clearly defined responsibilities, SLAs and audit documentation to maintain inspection readiness [18].

Integration of regulatory requirements into cloud RIMS functional design

Successful implementation of cloud-based RIMS depends on a compliance-by-design approach, where regulatory requirements are built into the system architecture, workflow, and user interface from the beginning [9, 20]. Important regulatory principles such as ALCOA+ should be translated into functional features, including user identification, electronic signatures, access logging and strong data integrity controls [1, 2]. Ongoing validation is supported by robust configuration management, controlled changes and verified integration with related systems, while the use of structured content and standardized data models increases compliance, consistency and operational efficiency [11, 13, 14, 20].

Challenges and risks of adopting cloud-based RIMS

Data protection, security vulnerabilities and consideration of multiple tenancies

Risks of multiple tenancies and data isolation

Cloud-based RIMS use shared infrastructure, which introduces risks related to tenant isolation and potential data leakage, requiring careful evaluation of access controls, network segmentation, and encryption mechanisms before implementation [2, 18, 25].

Encryption and cryptographic controls

Strong encryption standards such as AES-256 and the use of customer-managed encryption keys are essential to protect sensitive regulatory data and prevent unauthorized vendor access [17].

Vulnerability management and update dependencies

Since security updates are controlled by cloud providers, clear SLAs are required to ensure timely remediation of vulnerabilities, transparency and compliance, supported by independent security audits such as SOC 2 Type II and ISO 27001 [25].

Mitigation strategies

Effective security management includes verifying tenant isolation controls, implementing customer-managed encryption keys, enforcing strict patch response SLAs, and ensuring vendors maintain accredited security certifications.

Data movements across national borders and regulatory uncertainty

GDPR and international data transfer restrictions

The GDPR imposes strict controls on the transfer of personal data outside the EEA, requiring mechanisms such as SCC, BCR and TIA, which complicates global cloud RIMS operations, especially after the invalidation of the EU-US Privacy Shield [2,5].

Data localization requirements in all jurisdictions

Many countries, including Russia, China, and India, require local storage of certain personal or regulatory data, leading organizations to deploy region-specific or locally hosted cloud RIMS environments to meet residency requirements [5].

Regulatory ambiguity in cloud-based systems

While agencies such as the FDA and EMA accept cloud systems for GXP use, limited guidance on oversight, system architecture, and long-term data retention creates uncertainty in validation and regulatory risk assessment, especially under multi-agency oversight [3, 17, 18].

Mitigation strategies

Compliance risk can be mitigated through region-specific deployments, use of SCC/BCR/TIA for legitimate data transfers, use of hybrid cloud models, and implementation of regulatory mapping tools to support global cloud RIMS operations.

Supplier qualification and shared responsibility in cloud environments

Eligibility challenges due to limited infrastructure control

Pharmaceutical companies remain responsible for compliance, although cloud providers manage most of the underlying infrastructure, making vendor qualification essential [17, 18]. Organizations must assess the supplier's technical capabilities, quality systems, financial stability and regulatory maturity before approval.

Understand the shared responsibility model

Cloud platforms divide responsibilities into infrastructure, platform and application layers, requiring companies to document which security, validation and compliance functions belong to the provider versus the customer [17, 25]. Clear contract terms – such as audit rights, breach reporting and secured data access – are critical to compliance.

Requirements for business continuity and disaster recovery

Cloud RIMS providers must demonstrate strong continuity capabilities, including redundant sites, automated backups, and tested recovery processes, supported by SLAs that define uptime, RTO, and RPO that comply with regulatory requirements [18]. Companies often require proof of regular recovery testing before production approval.

Mitigation strategies

Vendor audits, a defined shared responsibility matrix, strong contract security and verified disaster recovery capabilities with strict SLAs reduce overall qualifications and operational risk in cloud-based RIMS.

Manage (and reduce) rapid SaaS release cycles and change management barriers

SaaS cloud platforms release frequent updates, creating challenges in maintaining a valid system state in pharmaceutical environments [9, 17]. Each update should be assessed for impact, tested as needed and documented without delaying necessary security fixes.

The risk-based approach ensures efficient efforts: Low-impact infrastructure or security updates require minimal validation, while changes affecting GxP workflows require full testing [25]. Close coordination with suppliers – advance notices, release notes and confirmation support – is essential. Organizations should use effective regression testing to verify that updates are bug-free. Automated test tools can help, but these must be verified and supported with documented test evidence [9].

Case Studies and Industry Insight

Case Study-1 Cloud RIMS migration in a mid-sized pharmaceutical company

Example: Sobi (Swedish Orphan BioVitrum) – Viva Vault RIM [15]

Background

Swedish Orphan Biovitrum (Sobi) is a medium-sized biopharmaceutical company with a focus on rare diseases and operates in several global markets. Rapid international expansion and projected revenues of over $371 million created a need for a scalable, enterprise-quality regulatory information management system. Legacy, disjointed regulatory systems have limited global submission support and operational efficiency.

Challenges

- Existing RIM systems could not support global growth
- Regulation data spread over several platforms
- Limited cooperation between the regulator and other teams
- Manual and complex submission preparation processes

RESULT

- Viva Vault RIM and Vault Submission Publishing implemented in 2023
- Created a single centralized source for regulatory data
- Improved scalability and global regulatory operations
- Streamlined presentation preparation and publishing
- Achieved higher user adoption and improved operational efficiency

Case study 2: Case study: Astellas Pharma – cloud-based RIM transformation

Background

Astellas Pharma, a global biopharmaceutical company, began a cloud-based regulatory information management (RIM) transformation in 2020 by implementing ErisGlobal's Life Sphere platform. The move was intended to modernize regulatory operations, support standardized data exchange, and free up staff time previously spent maintaining the old system[16].

Challenges

- Existing RIM systems could not support global growth
- Regulation data spread over several platforms
- Limited cooperation between the regulator and other teams
- Manual and complex submission preparation processes
- Poor integration with other company systems

RESULT

- Viva Vault RIM and Vault Submission Publishing implemented in 2023
- Created a single centralized source for regulatory data
- Improved scalability and global regulatory operations
- Better collaboration between teams
- Streamlined presentation preparation and publishing
- Achieved higher user adoption and improved operational efficiency

Case Study 3: Adopting a cloud-based RIM for e CTD submission (US Biotech, 2023)

Background

In 2023, mid-sized US biotechnology company making regulatory submissions to the FDA relied heavily on manual processes to compile and manage Electronic Common Technical Document (ECTD) documents. Preparation for the submission involved multiple tools, manual document compilation and extensive quality checks, which increased timelines and regulatory risks. To improve efficiency and submission quality, the organization decided to adopt a cloud-based Regulatory Information Management (RIM) system[18].

Challenges

- Frequent manual errors in dossier assembly
- Incorrect document placement and broken hyperlinks
- Inconsistent tagging of metadata
- Delays in preparations for submission and repeated internal reviews
- Limited visibility into regulatory, publishing and quality teams

RESULT

- Preparation time for submission reduced by 30%
- Better dossier quality with fewer validation errors
- Reduction in post-work and manual effort
- Better coordination and visibility across teams
- Reduced dependence on old equipment and manual processes

Compliance Strategies and Best Practices

Supplier evaluation and qualification

- Pharmaceutical companies must thoroughly qualify cloud RIMS providers by evaluating contract terms such as infrastructure security, quality management maturity (eg ISO 9001, ISO 27001), regulatory experience, financial stability, and audit rights and data ownership [17,18].
- Key activities include reviewing supplier documentation, conducting audits (virtual or physical), checking references and validating technical capabilities. Qualification scorecards help rank suppliers based on risk and organizational priorities.
- After implementation, continuous monitoring is required through periodic audits, review of SOC 2/ISO 27001 reports, tracking of supplier performance and ensuring contract compliance for regulatory support and data retention [17, 25].

Risk-based verification method

- Risk-based validation focuses on actions with the greatest impact on patient safety, data integrity and regulatory compliance [25]. For cloud resources, this includes electronic signatures, audit trails, data migration accuracy and disaster recovery capability.
- Low-risk features (such as reporting tools) may undergo less testing.

- Vendor validation documentation can reduce customer workload, but organizations must still verify vendor content and test configuration, integration, and customer-specific workflows [9, 17].

Competence development and data quality assurance

- Success depends on the user's abilities. Role-based training should include regulatory basics (21 CFR Part 11, GXP), data integrity principles, system navigation, workflow, electronic signatures, and data quality expectations [9, 12].
- Training effectiveness should be measured through competency testing rather than attendance.
- Ongoing data quality processes should track error trends, conduct periodic audits, implement automated validation rules, and collect user feedback to maintain accuracy and consistency [13, 26].

Security Monitoring, Incident Response and Performance Monitoring

- Cloud GxP systems require continuous monitoring. Organizations should use SIEM tools, conduct vulnerability testing, regularly review access rights, and provide security awareness training [17, 18].
- Incident response plans should clearly define roles, notification timelines, CAPA procedures and documentation requirements, with periodic simulation exercises to test preparedness.
- Performance monitoring should track uptime, response time, backup success, help desk metrics and user satisfaction. SLAs must establish clear performance expectations and consequences for supplier non-compliance [18].

Unified Compliance Model for Cloud RIMS

- A unified compliance model integrates cloud RIMS into enterprise quality systems by standardizing validation templates, aligning SOPs, and including cloud computing in quality assessments [9,12].
- Governance should define system ownership, establish cross-functional oversight committees and provide escalation paths for compliance issues. Documentation must maintain end-to-end traceability from guidelines to validation records [12, 14].
- Organizations using multiple cloud systems (eg, cloud RIMS, cloud QMS, cloud ERP) must harmonize vendor qualifications, validation strategies, security standards, and training programs to achieve consistency and efficiency [1, 9].

RESULTS

The results of this study indicate a clear and steady shift towards cloud-based regulatory information management systems in the pharmaceutical industry. Comparative analysis shows that cloud rims outperform local and hybrid models in terms of scalability, global reach and maintenance efficiency, while offering a lower total cost of ownership through a subscription-based model. Adoption data shows a strong upward trend, with cloud RIMS usage increasing from approximately 15% in 2017 to approximately 88% by 2025, reflecting the industry's growing confidence in cloud solutions. The case study findings confirm that organizations that implemented Cloud RIMS achieved better regulatory data centralization, faster submission preparation, better cross-functional collaboration and less manual effort. Compliance results indicate that Cloud RIMS can meet key regulatory requirements, including 21 CFR Part 11, GXP and ALCOA+ principles when supported by appropriate validation, audit trails and governance controls. Overall, the results highlight cloud-based RIMS as a more efficient, scalable and sustainable solution for modern pharmaceutical regulatory operations compared to traditional systems.

RIMS Deployed Model Comparison (Fig. 1).

The figure compares on-premise, hybrid, and cloud RIMS based on scalability, maintenance effort, and global accessibility. On-premise RIMS show high maintenance effort with limited scalability and global reach, while hybrid RIMS demonstrate moderate performance across all parameters. Cloud RIMS perform best overall, offering high

scalability and global accessibility with lower maintenance effort, highlighting their suitability for modern regulatory operations.

Percentage of Companies Using Cloud RIMS (%)(Fig. 2)

The figure shows a steady increase in the adoption of cloud-based RIMS in the pharmaceutical industry over time. Usage rose from about 15% in 2017 to nearly 88% by 2025, indicating strong and consistent growth. This trend reflects increasing industry confidence in cloud RIMS for scalable, compliant, and globally accessible regulatory operations.

Cloud RIMS Adoption Strategy (Fig. 3).

DISCUSSION

Strategic Considerations for Successful Cloud RIMS Adoption

The synthesis of regulatory requirements, implementation experiences and industry best a practice indicates that the successful use of cloud RIMS in pharmaceutical organizations depends more on organizational readiness than technology choice alone. Strong management sponsorship and continuous change management are essential, as Cloud RIMS implementation requires process alignment, role realignment and cultural adaptation to the cloud operating model supported by visible leadership commitment [9, 15, 16]. The phased implementation approach helps reduce risk by enabling incremental capacity development, rapid vendor validation, and controlled resolution of challenges, although long-term parallel system operation can reduce efficiency if not carefully managed. Equally important is investment in internal capabilities, including cloud-specific validation expertise, shared responsibility management, vendor oversight and user adoption management, with external consultants playing a supportive but non-dependent role [9]. Strategic supplier partnerships increase long-term value by enabling innovation adaptation, shared learning, and sustained regulatory and operational performance [15, 16].

Future Directions: AI Integration, Automation, and Predictive Analytics

- Artificial intelligence and automation can enhance cloud-based RIMS by improving regulatory change tracking, document analysis, and submission timeline prediction [19].
- Automated workflows, such as eCTD compilation and regulatory updates, help reduce manual effort and errors [13].
- Transparency and human oversight are essential to ensure continued compliance with regulations when using AI-based systems [6].

In conclusion, the study shows that cloud-based regulatory information management systems have the potential to fundamentally improve pharmaceutical regulatory operations by enabling improved global collaboration, scalability, operational efficiency and cost optimization. When implemented with a strong governance framework, including rigorous vendor qualification, risk-based validation, and continuous compliance monitoring, cloud RIMS platforms can fully meet regulatory expectations such as 21 CFR Part 11, GXP requirements, and data integrity principles. Comparative evaluations show that cloud-RIMS generally offer advantages over on-premises systems in terms of flexibility and total cost of ownership, while compliance and security results are determined primarily by the quality of implementation rather than the deployment model. Realizing these benefits requires sustained executive sponsorship, strong change management, and continued development of organizational capabilities. Looking ahead, advances in automation, artificial intelligence and analytics are expected to further expand the value of cloud RIMS, underscoring the importance of continued regulatory guidance and global harmonization to support effective multinational regulatory activities.

ACKNOWLEDGEMENTS

I express my gratitude to the Chalapathi institute of pharmaceutical sciences for the support.

ABSTRACT

This study investigates the potential of new isatin derivatives as treatments for diabetes using a combination of lab techniques and computer-based methods. Diabetes, particularly Type 2, is a major global health issue, often linked to insulin resistance and high blood sugar levels after eating. Current medications have limitations, highlighting the need for more effective options. In this research, isatin derivatives were created and tested to determine their effects on enzymes involved in carbohydrate metabolism, such as α-amylase and α-glucosidase. The compounds were also evaluated for antioxidant and anti-inflammatory properties. Using network pharmacology, multiple targets were identified within critical pathways related to insulin signaling and blood sugar regulation, suggesting a broad, multi-target effect. Virtual screening and molecular docking revealed that these derivatives bind strongly to key proteins associated with diabetes. The study offers a solid computational foundation to support future experiments and the development of isatin-based treatments for diabetes.

Keywords: Isatin derivatives, Antidiabetic agents, Network pharmacology, Molecular docking, Glucose metabolism

INTRODUCTION

Diabetes mellitus is a chronic condition marked by high blood glucose levels due to insulin production or action defects. The two main types are Type-1 (T1DM), an autoimmune disease that destroys insulin-producing cells, and Type-2 (T2DM), primarily caused by insulin resistance and linked to lifestyle factors like poor diet and obesity. T1DM requires lifelong insulin therapy, while T2DM is increasingly affecting adults and children due to rising obesity rates[1–4]. With over 422 million people affected globally, diabetes leads to serious complications such as

cardiovascular disease, kidney failure, and nerve damage. The growing prevalence, especially in developing countries, has become a major public health concern[5,6]. Several classes of antidiabetic medications have been developed over the years to help manage blood glucose levels in people with diabetes. These drugs target different aspects of glucose metabolism and insulin regulation. Some of the most commonly used classes include: Biguanides (e.g., Metformin)[7,8], Sulfonylureas (e.g., Glibenclamide, Glipizide)[9,10], Dipeptidyl Peptidase-4 (DPP-4) Inhibitors (e.g., Sitagliptin, Saxagliptin)[11,12], Sodium-Glucose Co-Transporter 2 (SGLT-2) Inhibitors (e.g., Canagliflozin, Empagliflozin)[13,14]. While these drugs have proven effective in managing diabetes, their use often comes with limitations, such as side effects, contraindications in specific populations, and suboptimal control of blood glucose, especially postprandial (after meal) glucose spikes. For instance, even though metformin is widely used, it does not address postprandial hyperglycemia, which is a critical factor in the progression of diabetes-related complications[15,16]. Despite the availability of current treatments, there is an increasing need for novel antidiabetic agents that can: Target Postprandial Hyperglycemia, in recent studies it has highlighted the importance of controlling post-meal glucose spikes, which contribute significantly to cardiovascular complications.[17] Improve Insulin Sensitivity, while existing agents like metformin and thiazolidinediones, their efficacy can be improved by developing drugs that better target insulin signaling pathways. [18]

Minimize Side Effects as newer agents should aim to minimize common side effects like gastrointestinal issues, hypoglycaemia, and weight gain, seen with many older treatments. [19] The development of drugs targeting mechanisms like glucagon-like peptide-1 (GLP-1) agonists, SGLT-2 inhibitors, and DPP-4 inhibitors represent promising avenues for managing both glucose levels and associated comorbidities more effectively.[20] Isatin (1H-indole-2,3-dione) is a heterocyclic compound with a distinct molecular structure that plays a crucial role in its medicinal chemistry. The structure consists of an indole ring fused with a carbonyl group at positions 2 and 3, giving isatin its aromatic and reactive characteristics. The compound exists predominantly in its lactam form, though a lactim form also exists, which can participate in different chemical reactions depending on the reaction conditions[21]. The chemistry of isatin allows for a variety of functional modifications at key positions, primarily at the nitrogen atom (N-1), the carbonyl groups (C-2 and C-3), and the aromatic ring (C-5 and C-7)[22,23]. These reactive sites enable isatin to undergo a broad range of reactions, including nucleophilic substitutions, acylation, alkylation, and electrophilic substitution, such as halogenation and nitration[24,25]. These properties make isatin and its derivatives valuable precursors in drug design, as they can be modified to create compounds with diverse biological activities. For example, N-substituted isatins have been shown to possess potent activity against carbonic anhydrase, a therapeutic target in cancer and other diseases. The structural flexibility of isatin allows it to be used as a scaffold for creating a wide array of bioactive compounds[26]. By modifying different positions on the molecule, researchers can tailor its biological properties, enhancing its effectiveness in treating various conditions. These modifications have led to the development of isatin derivatives used in a range of therapeutic applications, from anticancer to antimicrobial treatments[27].

Recent research has increasingly focused on the potential of isatin derivatives as antidiabetic agents, with promising results in both in vitro and in vivo studies. The growing prevalence of type 2 diabetes has made it essential to develop new therapeutic approaches, particularly those targeting the regulation of blood sugar levels and prevention of complications like diabetic neuropathy and retinopathy. Many isatin derivatives exert their antidiabetic effects by inhibiting key enzymes involved in glucose metabolism, particularly α-amylase and α-glucosidase, which are responsible for the breakdown of starch and sugar in the digestive tract. By inhibiting these enzymes, isatin derivatives slow the absorption of glucose, thus reducing postprandial blood sugar levels. For instance, isatin-thiazole hybrids have shown significant inhibition of these enzymes, with IC50 values comparable to the established antidiabetic drug acarbose. [28,29] Isatin derivatives also exhibit antioxidant and anti-inflammatory properties, which are essential for managing diabetic complications. Oxidative stress and inflammation play a significant role in the progression of diabetes and its complications. By reducing oxidative damage and inflammation, isatin derivatives can help prevent the long-term damage associated with diabetes [30,31]. Some studies have also suggested that certain isatin derivatives may act as insulin sensitizers, enhancing the body's response to insulin and improving glucose uptake in peripheral tissues. This is especially beneficial for individuals with insulin resistance, a hallmark of

type 2 diabetes. Research into these compounds is still ongoing, but early results indicate that isatin derivatives could play a role in developing therapies that address both the symptoms and root causes of diabetes.[32,33]

MATERIALS AND METHODS

Network Pharmacology Analysis

The chemical structures of isatin derivatives were retrieved from databases like PubChem or drawn using ChemBioDraw software. The SMILES format of each compound was input into SwissADME and Swiss Target Prediction tools to predict potential protein targets based on molecular similarity and pharmacokinetic properties. The UniProt IDs of the predicted drug-related targets were uploaded into the STRING database to generate PPI networks. Disease-related genes associated with diabetes were obtained from resources like GeneCards. Common targets between the drug-related genes and diabetes-associated genes were identified, and their interactions were visualized using Cytoscape software.

Molecular docking:

Molecular docking was performed in PyRx to evaluate the binding affinities of synthesized ligands against several diabetes-related protein targets (PDB IDs: 3W0L, 1DPG, 1K3A, 1KNU, 1RE1, 1XB7, 2AXN, 2G01, 3G33, and 3WE4). Docking scores (in kcal/mol) were calculated to assess the stability and binding strength of each ligand-protein complex. Compounds with strong docking scores were selected for further analysis based on favourable protein-ligand interactions.

Adme study:

The absorption, distribution, metabolism, and excretion (ADME) properties of synthesized compounds were predicted using the ADME tools like SwissADME. Parameters such as solubility, gastrointestinal (GI) absorption, and blood-brain barrier (BBB) permeability were assessed. Lipinski's Rule of Five was used to evaluate the drug-likeness of the compounds and their potential oral bioavailability.

Toxicity prediction:

Toxicity prediction was carried out using computational models like ProTox 3.0 to estimate the LD50 values and classify the compounds into toxicity classes. Compounds with low to moderate toxicity profiles were identified as safer candidates for further pharmacological testing.

Synthesis of isatin derivatives:

Synthesis of 1-[6-(Substituted Phenyl)-2-oxo-1,2,5,6-tetrahydropyrimidin-4-yl]-3-(substituted phenylimino)indolin-2-ones (5a1–5a3, 5b1–5b3): A mixture of chalconized Schiff base (0.01 mol), urea (0.01 mol), and KOH (1 g) in ethanol (30 mL) was refluxed for 3 hours. The reaction mixture was cooled overnight at room temperature, filtered, washed, dried, and recrystallized from 95% ethanol.

Synthesis of 1-[6-(Substituted Phenyl)-2-thioxo-1,2,5,6-tetrahydropyrimidin-4-yl]-3-(substituted phenylimino)indolin-2-ones (6a1–6a3, 6b1–6b3): A mixture of chalconized Schiff base (0.01 mol), thiourea (0.01 mol), and KOH (1 g) in ethanol (30 mL) was refluxed for 3 hours. The reaction mixture was cooled overnight, filtered, washed, dried, and recrystallized from 95% ethanol.

Characterization of compounds:

The synthesized compounds were characterized by infrared (IR) spectroscopy, proton nuclear magnetic resonance (^1H NMR), and mass spectrometry (MS). Thin-layer chromatography (TLC) was used to monitor the purity of the compounds throughout the synthesis process.

Network pharmacology approach:

Introduction to network pharmacology:

Network pharmacology is a systems biology-based approach that integrates bioinformatics, computational biology, and pharmacology to understand drug actions at a holistic level rather than a single target. It focuses on the interaction between drugs, targets, and diseases through biological networks[34,35]. This approach helps in identifying multiple targets and pathways involved in disease mechanisms and provides a scientific basis for multi-component therapeutics. It is widely used in drug discovery to explore complex diseases like diabetes by analysing how compounds interact with biological systems at molecular and network levels[36,37].

Drug–target interactions:

The first step involves identifying potential targets of isatin derivatives using cheminformatics tools. Initially, the chemical structure of compounds is obtained from databases like PubChem or drawn using ChemBioDraw, and their SMILES format is generated. These SMILES are then input into SwissADME and Swiss Target Prediction to predict potential protein targets based on molecular similarity and pharmacokinetic properties. The predicted targets are downloaded in CSV format along with UniProt IDs. These targets typically include enzymes, receptors, and proteins involved in glucose metabolism, insulin signaling, and diabetes-related pathways, forming the basis for further analysis [38,39].

Network construction:

After obtaining drug-related targets, network construction is performed to understand molecular interactions. The UniProt IDs are uploaded into the STRING database to generate protein–protein interaction (PPI) networks by selecting Homo sapiens as the organism. The resulting interaction data is downloaded and processed in Excel to obtain preferred gene names. Disease-related genes (e.g., diabetes-associated genes) are collected from databases such as GeneCards. These datasets are compared using tools like Venny to identify common targets between drug and disease[40,41]. A total of 69 compound related target were predicted for and a total of 4761 diabetes related targets were obtained. The 25 shared targets are again analysed in STRING to construct a refined PPI network. Finally, Cytoscape software is used to visualize and analyse the network, and plugins like CytoHubba help identify key hub genes based on topological parameters such as degree centrality.

Multi-target action:

Network pharmacology emphasizes that compounds such as isatin derivatives act on multiple targets and pathways simultaneously. These compounds may influence various biological processes involved in diabetes, including insulin resistance, pancreatic β-cell function, glucose uptake, and overall glucose homeostasis [42]. By interacting with multiple proteins such as Glucokinase Regulatory Protein complex (PDB ID: 3W0L), Glucose 6-Phosphate Dehydrogenase (PDB ID: 1DPG), Insulin-like Growth Factor 1 (PDB ID: 1K3A), Human Peroxisome Proliferator Activated Receptor Gamma (PDB ID: 1KNU), Peroxisome Proliferator-Activated Receptor Alpha (PDB ID: 1XB7), Nicotinic Acid Aldehyde Inhibitor (PDB ID: 1RE1), 6-Phosphofructo-2-Kinase/Fructose-2,6-Bisphosphatase (PDB ID: 2AXN), Ribosomal protein S6 kinase 1 (PDB ID: 3WE4), C-Jun N-Terminal Kinase 1 (PDB ID: 2G01), and Cyclin-Dependent Kinase 4 (PDB ID: 3G33), along with key signaling pathways (such as PI3K-Akt, inflammatory pathways, and metabolic pathways), isatin derivatives can exert synergistic therapeutic effects. This multi-target mechanism provides better efficacy compared to single-target drugs and helps in managing complex diseases like diabetes more effectively.

RESULTS

The results of the network pharmacology analysis include identification of common drug–disease targets, construction of PPI networks, and detection of hub genes that play critical roles in disease regulation. Enrichment analysis such as Gene Ontology (GO) and KEGG pathway analysis helps identify biological processes and pathways involved. The final output includes key targets, major signaling pathways, and network visualization, which together

explain the mechanism of action of isatin derivatives. These findings can further be validated using molecular docking and experimental studies, providing a strong foundation for drug development and therapeutic exploration.

Virtual screening and molecular docking

Molecular docking is a computational method used to predict the preferred orientation of a small molecule (ligand) when it binds to a target macromolecule, typically a protein, to form a stable complex[43,44]. It helps estimate the strength of binding and identify key interactions such as hydrogen bonds, hydrophobic contacts, and electrostatic forces that stabilize the complex. This technique is widely applied in drug discovery and structural biology to screen potential drug candidates, understand protein–ligand interactions, and guide experimental studies[45-48]. Here molecular docking analysis was carried out to evaluate the binding affinity of the synthesized ligands against multiple protein targets (PDB IDs: 3W0L, 1DPG, 1K3A, 1KNU, 1RE1, 1XB7, 2AXN, 2G01, 3G33, and 3WE4). The docking scores (kcal/mol) indicated favourable interactions for most of the tested compounds, suggesting their potential as bioactive molecules. Among all ligands, compounds of the 5a and 6a series demonstrated the most significant binding affinities across nearly all protein targets. In particular:

Ligand 5a1 exhibited the strongest overall binding performance, showing highly negative docking scores with several targets, including −12.4 kcal/mol (3W0L), −11.3 kcal/mol (1DPG), −12.8 kcal/mol (2G01), and −12.4 kcal/mol (3WE4). Ligand 6a1 also showed consistently strong affinities, with docking scores reaching −12.7 kcal/mol (2G01), −11.9 kcal/mol (2AXN), and −12.5 kcal/mol (3WE4).

Adme study

The ADME analysis of the synthesized compounds revealed generally favourable drug-likeness properties. Most molecules showed good solubility, with several classified as soluble and a few as moderately soluble. Gastrointestinal absorption was predicted to be high for the majority of compounds, indicating good oral bioavailability potential, while only a limited number displayed low absorption. Blood–brain barrier permeability was predicted for some derivatives, suggesting possible central nervous system activity, whereas others were non-permeant. All compounds largely complied with Lipinski's rule of five, with very few violations observed, and most exhibited a consistent bioavailability score of 0.55. Overall, the ADME profile suggests that many of the designed molecules possess acceptable pharmacokinetic characteristics suitable for further drug development studies.

Toxicity study

The toxicity prediction results indicated that most of the compounds fall within toxicity classes 4 and 5, suggesting relatively low to moderate acute toxicity. Many derivatives showed high predicted LD_{50} values around 5000 mg/kg, indicating low toxicity and a favourable safety margin. However, a few compounds demonstrated lower LD_{50} values and belonged to higher toxicity classes, implying comparatively greater toxicity that may require structural optimization. Overall, the majority of the compounds appear to be safe candidates with acceptable toxicity profiles, supporting their consideration for further pharmacological investigation.

Synthetic approach:

METHODOLOGY

General Procedure for the Synthesis of 1-[6-(Substituted Phenyl)-2-oxo-1,2,5,6-tetrahydropyrimidin-4-yl]-3-(substituted phenylimino)indolin-2-ones (5a1–5a3, 5b1–5b3):

A mixture of chalconized Schiff base (0.01 mol), urea (0.01 mol), and KOH (1 g) in ethanol (30 mL) was refluxed for 3 h. The reaction mixture was allowed to stand overnight at room temperature. The resulting solid was filtered, washed, dried, and recrystallized from 95% ethanol to afford the corresponding pyrimidinone derivatives. Purity was confirmed by TLC.

General Procedure for the Synthesis of 1-[6-(Substituted Phenyl)-2-thioxo-1,2,5,6-tetrahydropyrimidin-4-yl]-3-(substituted phenylimino)indolin-2-ones (6a1–6a3, 6b1–6b3):

A mixture of chalconized Schiff base (0.01 mol), thiourea (0.01 mol), and KOH (1 g) in ethanol (30 mL) was refluxed for 3 h. The reaction mixture was left overnight at room temperature. The precipitated solid was filtered, dried, and recrystallized from 95% ethanol to yield the corresponding thioxopyrimidine derivatives. Purity was verified by TLC.

Characterization data of the compounds:

5a1: 1-[6-(2-Nitrophenyl)-2-oxo-1,2,5,6-tetrahydropyrimidin-4-yl]-3-(nitrophenylimino) indolin-2-one: IR (KBr, νmax, cm^{-1}): 3403 (N–H), 1730 (C=O), 1630 (C=N), 1330 (Ar–NO_2), 1245 (C–N), 896 (Ar–CH). ^{1}H NMR (400 MHz, DMSO-d_6) δ: 10.80 (s, 1H, NH), 6.80–8.00 (m, Ar–H), 4.70–5.20 (dd, pyrimidine-H), 3.40–3.60 (m), 2.30–2.50 (m). MS (EI) m/z: 486 (M^+), 267, 219, 145, 123.

5a2: 1-[6-(2-Hydroxyphenyl)-2-oxo-1,2,5,6-tetrahydropyrimidin-4-yl]-3-(nitrophenylimino) indolin-2-one: IR (KBr, νmax, cm^{-1}): 3581 (Ar–OH), 3403 (N–H), 1704 (C=O), 1636 (C=N), 1330 (Ar–NO_2), 1245 (C–N), 890 (Ar–CH). ^{1}H NMR (400 MHz, DMSO-d_6) δ: 10.80 (s, 1H, NH), 10.30 (s, 1H, OH), 6.80–7.40 (m, Ar–H), 4.70–5.20 (dd), 3.40–3.60 (m), 2.30–2.50 (m). MS (EI) m/z: 455 (M^+), 334, 266, 121.

5b2:3-(2-Chlorophenylimino)-1-[6-(2-hydroxyphenyl)-2-oxo-1,2,5,6-tetrahydropyrimidin-4-yl] indolin-2-one: IR (KBr, νmax, cm^{-1}): 3396 (O–H), 3048 (N–H), 1740 (C=O), 1636 (C=N), 645 (C–Cl), 1245 (C–N), 890 (Ar–CH). ^{1}H NMR (400 MHz, DMSO-d_6) δ: 11.04 (s, 1H, NH), 10.30 (s, 1H, OH), 6.89–7.60 (m, 8H, Ar–H), 4.50–5.00 (dd), 3.40–3.60 (m), 2.40–2.50 (m). MS (EI) m/z: 442 (M^+), 309, 255, 135, 76, 56.

5b3:3-(2-Chlorophenylimino)-1-[6-(4-methoxyphenyl)-2-oxo-1,2,5,6-tetrahydropyrimidin-4-yl] indolin-2-one: IR (KBr, νmax, cm^{-1}): 3034 (N–H), 1734 (C=O), 1630 (C=N), 2808 (Ar–OCH_3), 648 (C–Cl), 1245 (C–N), 880 (Ar–CH). ^{1}H NMR (400 MHz, DMSO-d_6) δ: 11.04 (s, 1H, NH), 3.80 (s, 3H, OCH_3), 6.89–7.60 (m, 8H, Ar–H), 4.40–4.90 (dd), 3.20–3.40 (m), 2.00–2.40 (m). MS (EI) m/z: 456 (M^+), 309, 255, 149, 144, 56.

6a1: 1-[6-(2-Nitrophenyl)-2-thioxo-1,2,5,6-tetrahydropyrimidin-4-yl]-3-(nitrophenylimino) indolin-2-one: IR (KBr, νmax, cm^{-1}): 3403 (N–H), 1730 (C=O), 1620 (C=N), 1330 (Ar–NO_2), 1245 (C–N), 1096 (C=S), 898 (Ar–CH). ^{1}H NMR (400 MHz, DMSO-d_6) δ: 10.80 (s, 1H, NH), 6.80–8.00 (m, Ar–H), 4.80–5.20 (dd), 3.40–3.70 (m), 2.40–2.60 (m). Future Prospects for Isatin Derivatives

Future research on isatin derivatives as potential treatments for diabetes offers great promise for improving diabetes care. With their ability to target multiple pathways like insulin signaling, glucose metabolism, and inflammation, these compounds could provide a new way to tackle the disease. Moving forward, studies should focus on validating these findings through experiments, including in vivo research to evaluate how the compounds are absorbed, processed, and their long-term safety. Additionally, modifying the molecular structures of the derivatives could boost their effectiveness, precision, and reduce possible side effects. More research into how these compounds might help with diabetic complications like neuropathy and retinopathy could expand their uses. Clinical trials will also be crucial to verify their effectiveness in humans. In the end, a combination of computational, lab-based, and clinical research could lead to the development of safe and effective isatin-based therapies for managing diabetes.

CONCLUSION

This study successfully synthesized a series of novel isatin derivatives and evaluated their potential antidiabetic activity using network pharmacology, molecular docking, ADME analysis, and toxicity prediction. The results demonstrated that several compounds, particularly those belonging to the 5a and 6a series, showed strong binding affinity toward multiple diabetes-related protein targets. Network pharmacology analysis revealed that these

compounds act through multi-target mechanisms, influencing insulin signaling, glucose metabolism, inflammatory pathways, and cellular survival pathways. Additionally, most compounds displayed favourable drug-likeness, acceptable oral bioavailability predictions, and low to moderate toxicity profiles. Overall, this study provides a strong computational and theoretical foundation for the development of isatin-based antidiabetic drugs. While the results are promising, further experimental validation, pharmacological evaluation, and clinical investigation are necessary to confirm their therapeutic applicability. Continued research in this direction may contribute significantly to the discovery of safer, more effective, and mechanistically advanced treatments for diabetes mellitus.

ACKNOWLEDGMENTS

The authors are thankful to the Department of Pharmaceutical Technology, Brainware University, for the service and support for this article.

Conflict of Interests

The authors state that they do not have any conflicts of interest.

Author Contributions

The present work which is related to Isatin Derivatives as Multifunctional Antidiabetic Agents. All the authors contributed substantially to its conception, development and refinement of manuscript. All are participated in review and filannly approved for the publication ready.

ABSTRACT

Globally, ischemic heart disease continues to place a heavy strain on both people and medical resources. A decrease in circulation, which results in a shortage of oxygen for essential cardiomyocytes, is known as myocardial ischemia. The amount of expertise regarding the etiology of cardiovascular illnesses is expected to undergo further change in the current generation of genomic medicine. Here, we examine the progress made in this area across the last decade or so and talk about the many variations in genes that have been linked to a number of cardiovascular illnesses. Often mistaken for atherosclerotic plaque, it results in flow-limiting occlusion in large to medium-sized arteries of the heart. A thorough assessment of the pathogenesis of ischemic heart disease that considers all available information is still lacking, and the root cause of frequent ischemic heart disease in ward individuals is sometimes misleading. It is essential to comprehend and research the pathophysiological mechanisms underlying this complicated disorder in order to better assess it and provide future perspectives, as atherosclerotic plaque issues may not always signify ischemic heart disease. Treatment options for ICM include revascularization, device therapy, mechanical circulatory support, heart transplantation, changes in behavior, and the right

medication. Consequently, in order to have a deeper comprehension of ischemic heart disease, we suggest a summary of the material that is currently accessible.

Keywords: Genomics, mutation, precision medicine, polypharmacy, ischemia

INTRODUCTION

According to recent clinical and imaging research, the plaque burden across the coronary tree has been linked to major adverse cardiac events (MACE) outcomes rather than just severe coronary obstructions (ischemia hypothesis or stenosis hypothesis). Congenital heart disease is typically brought on by chromosomal abnormalities. Ischemic cardiomyopathies are usually linked with atherosclerosis and its consequences, namely myocardial infarction (MI) and stroke in the elderly[1,2]. Numerous investigations, specifically sophisticated Genome Wide Association Studies(GWAS), have identified numerous general types of genetics involved atherogenesis, including those implicated in immunology, inflammation, and cholesterol metabolism. Notably, coronary artery disease CAD was linked to a locus on chromosome 9 (9p21) in 2005 [3].

Precision medicine's impact

Why is precision medicine relevant? Precision medicine offers a tailored approach by focusing on early detection and targeted therapy based on an every single separate genes, nature, lifestyle, other health reasons that effect disease phenotype (Figure 1). Rather than applying generalized treatment strategies, precision medicine seeks to determine the most effective course of action for each individual. Its strength lies in integrating diverse datasets—by standardised medical, images, and diagnostic assessments to coming advancement DNA metabolics and sequencing, proteomics, past medical records. Advanced network and system biology analysis can discover novel relationships between health determinants and disease. Ideally, precision medicine systems should learn and adapt continuously, offering efficient prevent, detect, and cure across a huge range of heart illness and risk factors [4].

Importance of phenotyping

Accurate phenotyping of any condition is a cornerstone of precision medicine (Figure 2). For the precised treatment to effectively increase outputs at every single person and huge populated levels, it's that important to know and identify relationships among components which define phenotypes of health and disease [5,6].

Significance of Genomic Study

Advances in genes studies enhanced understanding in cardiovascular pathophysiology, disovering new ways for treatment strategies, risk mitigation, and prognostic tools (Figure 3). Although genetic risk prediction is still in its early stages, current evidence is insufficient to justify clinical use of genetic risk scores derived from single nucleotide polymorphisms (SNP) determined by genetic ways. [7,8]More studies are required for retrospectively evaluate use by familial amount of risks in predicting cardiovascular diseases, particularly myocardial infarction. Some estimates suggest that predictive accuracy may require data from few numbers of genetics [9]. Future genetic risk score studies will likely require the integration of thousands of linked snp discovered through genome-wide associated study (GWAS) and less frequent risk factors identified via full body genes sequence. Research is ongoing for applying next-generation DNA sequencing to detect all genetic variants and screen for rare forms of cardiovascular disease [10,11]. Despite the falling cost of whole-genome sequencing, clinical adoption remains limited due to the high cost of data interpretation and storage.

Role of Genome-Wide Association Research

Many cardiac conditions are polymorphic, meaning that both environmental and genetic factors contribute to disease [12]. Common heart related risks and their medical conditions, have polygenic heritable components [13]. Prior to the completion of the human genome draft, efforts to determine the genes of complex cardiovascular diseases were largely unsuccessful. Over the past decade, multiple loci associated with arterial traits and disorders have been

discovered through GWAS, which analyze numerous gene alleles in case-control populations to identify disease-associated variants [14]. Most common disease and common variants suggests that usual diagnostics were influenced from gene species that were common in at least 5% of the world people. GWAS testing is based on this principle, linking widespread genetic variants to disease. Utilizing genetic changes, various tools, researchers have created databases of cardiovascular genetic variations. Open-access genomic databases and multinational collaborations, often involving thousands of investigators, have further accelerated discoveries.

Opportunities for the Future

Cardiovascular genomics aims to (1) study physiological pathways and (2) use that knowledge to guide tailored therapies. Understanding molecular pathways can inform both general treatments and genotype-specific interventions. Identification of multiple cardiovascular loci in recent years is only the beginning. Large-scale studies involving tens of thousands of cardiovascular patients, integrating sequencing and genome-wide analyses of rare and common variants, will be crucial. Working studies were required to elucidate biochemical and cell level mechanisms for updating precisely tailored therapies. This involves preclinical proof-of-principle studies, first-in-human trials, clinical trials, regulatory approval, and ongoing basic and functional research [16]. Building on a century of progress in cardiovascular physiology, molecular biology, and epidemiology, genomic medicine is now poised to contribute substantially to the field of cardiology.

AI in conjunction with Precision Cardiology

Advances in artificial intelligence (AI) and machine learning enable the integration of multimodal and multidimensional omics data, offering potential improvements in diagnosis and treatment. AI can enhance precision healthcare by classifying patients according to phenotypic traits and guiding clinical decisions. Integration of AI in diagnostics and laboratory workflows improves efficiency in screening and validating tests. By combining high-performance computing with analytical capabilities, AI can learn, reason, and assist in clinical decision-making [17]. AI has automated several typical evaluating tasks in clinics, involving various risk analysis, evaluation, reducing burden on clinicians and minimizing errors. Cardiology is particularly suited for AI adoption due to its reliance on pattern recognition and interpretation. Applications include improving diagnosis, imaging analysis, diagnostics, précised treatment, and treatment planning. Neural networks and machine learning have enhanced diagnostic accuracy, particularly in pediatric cardiac conditions. AI has improved the clinical utility of imaging modalities such as electrocardiograms, CT scans, echocardiograms, and cardiac MRI. AI-based predictive algorithms significantly enhance outcomes in pediatric cardiac surgery, enabling accurate risk assessment and treatment outcome prediction.
Despite these advances, challenges remain, including limited physician training, concerns about losing the "human touch," early-stage technological limitations, and potential over-reliance on AI. Ensuring algorithm generalizability using high-quality, diverse datasets is essential. Risks include data biases, overfitting, inadequate validation, and lack of transparency in deep learning models ("black box" systems) [18,19]. Nevertheless, AI is expected to serve as a valuable tool for clinicians, particularly in guiding cardiac interventions in elderly and pediatric populations.

CONCLUSION

Precision medication represents advancements healthcare along with significant ensurity by thorough management of heart related diseases, which often develop gradually and exhibit hetergenous, and long way characteristics. The diseased state of this conditions can start hundreds of years for clinical belives. So the utility of specific diagnostic methods and individual diagnostic strategies has the potential to advancements and individualized therapy. Precision medication is still a upcoming discovery phase, various supporting advancements remain in early stages. Additionally, ethical, social, legal, and economic challenges limit research and data availability, potentially introducing bias into reviews such as this one. Cardiac, summarizing clinically relevant developments in the field. As our population and structures for exploring genomics, metabolics in heart related disease expand, a future in which therapy is precisely for requirements of each individual is within reach. The future of cardiology is here; it is essential

to educate healthcare providers on these advances and to make infrastructure more accessible and equitable for the public [20].

ABSTRACT

Poor trunk control, weight shifting, and equilibrium reaction are all significantly impacted by stroke. (TIS 2.0) or The Trunk Impairment Scale 2.0 is available in , Chinese, Italian, Thai, and Spanish for assessing dynamic seated balance and coordination in stroke patients. However, because there isn't a trustworthy and valid Hindi translation, its use among stroke victims who only speak Hindi is restricted. The objective of this study is to translate TIS 2.0 into Hindi and to evaluate reliability and validity of this Hindi version. The Hindi translation was carried out following the guidelines provided by Beaton's instructions with consent from the original author of the TIS 2.0 scale. Experts in both medical and non-medical domains participated in the translation process, which followed all eight processes. The study aims to examine the reliability and content validity of the Hindi version of the Trunk Impairment Scale 2.0 among individuals with stroke. Content validity will be assessed through item-level (I-CVI) and scale-level (S-CVI) indices, using both the averaging method (S-CVI/Ave) and the universal agreement approach (S-CVI/UA). Reliability analysis will include Pearson's and Spearman's correlation coefficients, intra-class correlation coefficients (ICC), Bland–Altman agreement analysis, and Cronbach's alpha to

measure internal consistency. This study will evaluate the reliability and content validity of the Hindi adaptation of the Trunk Impairment Scale 2.0 in individuals with stroke.

Keywords: Stroke, Cross-Sectional Studies, Hindi, validity and reliability.

INTRODUCTION

Stroke is characterized as a sudden, localized loss of neurological function arising from vascular pathology within the central nervous system, such as hemorrhagic or ischemic injury[1]. The circle of Willis manages cerebral blood supply through the paired internal carotid arteries anteriorly and the vertebral arteries posteriorly. An ischemic stroke occurs when the brain is deprived of adequate blood flow and oxygen, while a hemorrhagic stroke results from bleeding caused by ruptured blood vessels[2]. Neurological injuries often lead to sensory and motor disturbances, including paralysis, spasticity, and balance dysfunction, which form the primary basis of subsequent physical disability. These impairments not only involve the face and limbs but also significantly impact trunk function[3]. Stroke is one of the main reason of impaired trunk control, weight shifting, and balance[4]. Reports from 2013 indicate that around 25.7 million people were living with the effects of stroke, 6.5 million deaths were attributed to stroke, 113 million DALYs were lost, and 10.3 million new stroke cases occurred globally[5]. Effective trunk control is essential for maintaining postural balance and coordinating movements during daily functional tasks[6]. Generally speaking, the trunk muscles of a healthy individual control initial posture and are engaged prior to upper and lower limb movement. However, as the reaching muscles usually respond before the trunk muscles, it has been demonstrated that stroke patients have delayed trunk muscular activation[7]. Trunk function has been identified as a significant independent predictor of activities of daily living (ADL) outcomes after stroke[8]. Trunk rehabilitation following a stroke is still not given enough attention. The primary source of trunk postural control issues after stroke is thought to be loss of trunk selective activity[9]. Individuals who have had a stroke often describe problems with their trunk. These deficiencies are marked by reduced seated stability, trunk coordination, and muscular strength. Unlike the extremities, the trunk is damaged on both sides. Consequently, individuals exhibit decreased activity levels, delayed initiation of movement, and impaired coordination of trunk muscles on both the affected and unaffected sides[10]. Deficits in trunk and postural control, along with poor balance, are linked to an increased likelihood of falls and decreased mobility[11]. This affects posture, stability, and balance.

The overall extent of functional independence and ambulation capability are intrinsically associated with trunk stability and control. Stabilization of the trunk is important to maintain both static and dynamic balance of the body[12]. However, trunk motion is often ignored as a crucial part of the rehabilitation process for mobility and balance. Trunk control refers to the ability of the muscles to maintain an upright posture and coordinate movements so that the center of gravity remains over the base of support[13]. Sitting balance is required for executing functional activities, including dressing and eating in a seated posture. Moreover, seated balance is an essential indication of post stroke mobility and functional outcomes [14]. Sitting balance has consistently been shown to be a strong indicator of motor and functional recovery following a stroke. Therefore, assessing trunk performance is essential and plays a crucial role in the clinical evaluation of stroke patients[15]. The Trunk Impairment Scale was created to evaluate trunk movement quality and helpful in physiotherapy treatment planning[2]. The Trunk Impairment Scale (TIS) was introduced by Verheyden in 2004 to evaluate trunk control in a seated posture. It assesses static and dynamic balance as well as trunk coordination. Later, in 2010, Verheyden and Kersten revised the scale to create TIS 2.0, removing the static sitting balance item from the original version because this component did not show sufficient internal validity[8]. As a result, it has two subscales: one for coordination and one for dynamic sitting balance, which increases its predictive potential and use[12]. Using the English version of this tool because of a language barrier may result in evaluation errors and misunderstandings in clinical practice. According to the 2011 National Census of India, approximately 0.322 billion out of the global 1.3 billion Indian population identify Hindi as their primary language. Language differences significantly influence healthcare quality, particularly when patients and healthcare

professionals do not share a common language[16]. Any translation errors could induce bias because the TIS 2.0 is a tool that is administered by a therapist, and only the therapist records the responses. The reliability and validity of the tool in clinical and research settings may be impacted by this reliance on therapist interpretation, which could result in subjective scoring variations. This is because minor linguistic variations may change the meaning of some items when translating the scale into Hindi, which could affect the assessment's accuracy. Although Hindi has not yet been translated, the TIS 2.0 tool has been translated into Spanish, Italian, Chinese, and Thai. The goal of this study was to translate the TIS-2.0 into Hindi in order to foster a deeper comprehension.

METHODOLOGY

The study received approval from the Institutional Ethical Committee (IEC-3444) and was registered with the Clinical Trials Registry of India (CTRI/2025/08/092622). The Delphi method will be used for validation after the translation is complete. After receiving approval from the Institutional Ethical Committee (IEC-3444), the study will be registered on the open-access platform ClinicalTrials.gov. The research will be conducted in full compliance with the World Medical Association's Declaration of Helsinki, the National Ethical Guidelines for Biomedical and Health Research Involving Human Participants issued by the Indian Council of Medical Research, and the 2017 revised International Ethical Guidelines for Health-Related Research involving Humans by CIOMS. Reliability assessment of the translated scale will commence once the CTRI registration number is obtained. Written informed consent will be collected from all participants prior to enrollment, and confidentiality will be strictly maintained.

Study Design
A cross-sectional translational study.

Study Participants and setting of the study
51 patients[17] with subacute and chronic strokes, both male and female, aged more or equal to 18 years, will be chosen from a tertiary care super specialized hospital in compliance with Beaton requirements. Additionally, they must to speak Hindi well. The trial will not include any patients who have cognitive problems.

Study Location - Maharishi Markandeshwar tertiary care super speciality hospital, Mullana-Ambala, Haryana, India.

Selection of sample
Inclusion criteria
1. Stroke patients with sub-acute (>7 days and ≤3 months) and chronic (>3months) suffering from ischemic or hemorrhagic stroke were recruited.
2. Individuals with a basic understanding of Hindi.
3. Able to sit independently for 10 seconds.
4. Both males and females will be included.

Exclusion criteria
1. Musculoskeletal disorders.
2. Non-native Hindi speakers.
3. Patients with poor general health (including neurological conditions).
4. Uncontrolled comorbidities dementia, anymental deficit, which may affect cognition.
5. Functional impairment from moderate–severe pain and inability to follow verbal instructions.

Outcome measure and scoring
The Trunk Impairment Scale (TIS) was originally created by Verheyden in 2004 to evaluate trunk control in a seated position. The scale comprises assessments of static balance, dynamic balance, and trunk coordination. In 2010, Verheyden and Kersten revised the tool and developed TIS 2.0 (TIS-2.0), removing the static sitting balance item

because it failed to demonstrate adequate internal validity. The updated version enhanced precision and clinical applicability by incorporating two primary subscales: dynamic sitting balance and coordination. The Dynamic Sitting Balance subscale consists of seven tasks that examine selective lateral flexion initiated from both the shoulder and pelvic girdles. Each of the ten elements within this subscale is scored on a two-point ordinal scale, producing a total possible score ranging from 0 to 10. The Coordination subscale evaluates the time-dependent selective rotation of the upper and lower trunk. It contains four items scored on 2- and 3-point ordinal scales, with total scores spanning from 0 to 6[8,16].

Translation procedure

The scale was translated according to Beaton's guidelines. Eight steps are involved in this process[18].

Forward translation stage

In the initial phase, the scale should undergo at least two independent forward translations from the original language to the target language. Two translators will be chosen: TIS 2.0 FT1 with a medical background who understands the principles and TIS 2.0 FT2 without a medical background. Translations with non-medical backgrounds are referred regarded as "naive," and they are more likely to understand the original scale's true meaning than the first translator. This translator, who will often identify ambiguous terms in the original questionnaire, will create a translation that is less impacted by an academic objective and more closely reflects the vocabulary used by the intended. Both translators must possess solid knowledge and comprehension of both English and the intended Hindi language in order to proceed with this step. Any discrepancies that might point to ambiguous language in the original text or mistakes in the translation process will be noted after the translations are compared. Finding and fixing phrasing errors will be aided by a conversation between the translators.

Stages of synthesis

This stage of the translation process is regarded as essential since it gives priority to the content and removes any particular components that depart from the original scale. Translations gathered from the initial phase were put together in this step. In order to make every item on the newly created scale (TIS 2.0 FT1-2) an accessible scale for the Indian population, the principal investigator and the other two translators (TIS 2.0 FT1 and TIS 2.0 FT2) communicated with one another about all the changes, understand language editing, and correction of all differences from the actual scale.

Backward translation stage

Backward translation is done to ensure that the translated document conveys the same meaning as the source. The authors needed two translators, TIS 2.0 BT1 and BT2, who had a degree in English and were fluent in Hindi, to convert TIS 2.0 FT1-2 back into its original language. To lower the chance of bias the translators were blindfolded. This phase checks to see if the translated tool is correct by comparing it to the original version(Figure 1).

Expert committee

The review committee members input is requested for the translation of the Trunk Impairment Scale 2.0 Form into Hindi. A Delphi technique will be utilized to carry out this procedure online. Experts taking part in the Delphi survey will interact with individuals from diverse parts of India and must have at least 10 years of medical expertise. The expert panel that took part in the first round of the Delphi poll will not take part in any additional rounds if necessary. The experts will receive the translated questionnaire through Google Form. Each question will offer three response options: "neutral," "agree," and "disagree." A three-point rating system was previously created by the authors as the norm for evaluating item-level content. Since the entire written documentation will rely on the experts' rationale for the Hindi scale, their judgment is vital in the Delphi approach. In preparation for validation analysis, responses to the Delphi survey were entered into an Excel spreadsheet.

Content validation procedure

This final phase of the scale translation process involves assessing item-level content validity (I-CVI) for each individual item and scale-level content validity (S-CVI) for the overall instrument. The S-CVI is computed using both the universal agreement method and the averaging method. For acceptance, each item should achieve an I-CVI greater than 0.80, while the entire scale should obtain an S-CVI exceeding 0.90. If these criteria are not satisfied in the initial evaluation, a second review round will be conducted, incorporating necessary textual revisions[19].

Statistical analysis

Content validity of the translated scale will be examined using the Item-level Content Validity Index (I-CVI) and the Scale-level Content Validity Index calculated by the average method (S-CVI/Ave).Following the Delphi survey involving six to ten experts, strong to excellent content validity is anticipated when the S-CVI/Ave approaches 0.90 and each item attains an I-CVI of at least 0.78.

Reliability - There are several ways to assess a measurement scale's reliability:

Relative reliability - used to describe how consistent a measuring scale is across several observations of the same, either an intra-class correlation coefficient (ICC) or a correlation coefficient. Depending on normality, one can use the Pearson product correlation or Spearman Rank rho.

In accordance with the classification of Shrout and Fleiss (1979):

Poor: ICC < 0.5

Moderate: ICC < 0.75 ≤ 0.5

Good: ICC < 0.90 ≤ 0.75

Outstanding: ICC ≥ 0.90[20, 21].

Absolute Reliability: Shows how variable the measurement is. Evaluated using an analysis of Bland-Altman agreement[22].

Test-Retest Reliability: This method looks at how stable a measurement is over time by giving the same test to the same group twice in identical circumstances. A high test-retest correlation (ICC or Pearson r, for example) indicates that the scale yields reliable findings over time.

Cronbach's alpha will be used as the statistical indicator of reliability. Varies between 0.00 (no consistent variance) and 1.00 (variance that is fully consistent)[23,24,25].

DISCUSSION

In stroke patient's rehabilitation, a precise and culturally relevant evaluation of trunk control is essential because trunk stability has a direct impact on movement, balance, and functional independence. However, a major obstacle to consistent and efficient care in Hindi-speaking communities is the lack of a validated Hindi translation of existing trunk evaluation instruments. In addition to filling a language gap, translating the TIS 2.0 into Hindi improves the quality and accessibility of stroke rehabilitation services. This procedure describes a thorough process for creating a Hindi version that is both linguistically accurate and culturally appropriate, including forward and reverse translation, expert committee evaluation, and pilot testing. In order ensure conceptual equivalency and practical applicability, as well as to reduce the possibility of misinterpretation and measurement bias, multilingual specialists, physicians, and target users are included in pretesting.

CONCLUSION

As millions of people worldwide suffer from stroke, and many of them speak Hindi as their first language, this translation is a crucial first step in resolving healthcare inequalities in India and other Hindi-speaking countries. The scale's successful translation and validation will give medical personnel in Hindi-speaking areas a trustworthy instrument for evaluating stroke, enhancing patient care, results, and diagnostic precision. In the end, it is anticipated that this work will support research initiatives, allow for consistent data collecting, and advance equity in stroke care for India's various language communities.

ABSTRACT

The objective of this study was to formulate and optimize an antifungal cream using citronella oil and clove oil, with the Box-Behnken design (BBD) used to examine the independent and combined effect of various concentrations of liquid paraffin, borax, and beeswax on the cream's viscosity, spreadability, and pH, while maintaining optimally effective antifungal activity. For the study, the BBD was used to change the concentrations of liquid paraffin, borax, and beeswax in the cream base with active antifungal agents being the incorporated citronella and clove oils. The primary objective was to establish a formulation with a combination of all ingredients in order to achieve a stable formulation with good spreadability, appropriate pH, and sufficient effective antifungal activity for common fungal pathogens. It was established that the three independent variables and their interactions of liquid paraffin, borax, and beeswax had a significant impact on the cream's physical properties (i.e. viscosity, spreadability, pH). Lastly, the optimized formulation with the best physical properties resulted in the highest antifungal activity, thus being considered as a natural and effective topical treatment. This work illustrates the use of natural antifungal therapies that utilize the properties of citronella oil and clove oil added to adapted optimized cream bases.

Keywords: Anti-Fungal, Citronella Oil, Clove Oil, Box-Behnken Design, Spreadability, Optimization, Bees Wax, Borax.

INTRODUCTION

Design of Experiments (DOE) is a statistical technique employed to investigate the interaction between input factors and output responses. DOE is a systematic, data-driven method better than the conventional trial-and-error method, particularly applied in the cosmetic and pharmaceutical industries. DOE enables one to determine significant factors, individual and interaction effects, and construct predictive models to optimize the formulation for efficacy, consistency, and robustness. While preparing an antifungal cream using citronella and clove oils, DOE makes maximum quantities of active ingredients available in such a way that they confer maximum antifungal effect and still have such physical attributes. A special DOE method referred to as the Box-Behnken Design (BBD) is highly effective in such products when quadratic response surfaces are anticipated. BBD is a three-level response surface design for every factor—high (+1), low (−1), and center (0)—to produce nonlinear responses with fewer experiments than other designs, e.g., Central Composite Design (CCD). BBD places experimental points at center and edges of the design space and not at extreme or impossible combinations, thereby making it efficient and safe. The design is rotatable or quasi-rotatable, thus the prediction accuracy is consistent throughout the experimental space. The capability is essential in trying to examine synergistic or inhibitory effect between clove and citronella oils, and assist in establishing suitable levels of concentration for optimal inhibition of fungal growth, as measured by zone of inhibition and minimum inhibitory concentration (MIC) reactions.

MATERIALS AND METHOD

Ingredients used in the anti-fungal cream (Table.1).

METHODOLOGY

Antifungal cream was optimized via the Box-Behnken Design (BBD) to achieve maximum active ingredient percentage. The ingredients were accurately measured and noted based on the experimental matrix. Oil phase was achieved when ceto-stearyl alcohol and beeswax were melted by the water bath temperature of 70–75°C in a heat-resistant beaker, completely melting and being mixed uniformly. After mild liquefaction and homogenization, the oil phase was loaded with the volumes of citronella and clove oils while stirring evenly using slow, continuous agitation. At the same time, aqueous phase was prepared by dissolving methyl paraben and propyl paraben in double-distilled water. The same was maintained at 70–75°C to synchronize oil phase so that heat shock can be prevented on emulsification. Borax stabilizer used as a buffer was introduced after thorough dissolution for the improvement of pH stabilization of final cream end-product. At the time when both phases were target temperature and homogeneity, oil phase was incorporated with aqueous phase in a high-shear homogenizer with high intensity stirring. Emulsification was required to produce a smooth and homogenous cream without inducing phase separation. Homogenization was continued until a smooth and homogenous emulsion was obtained. After emulsification, the cream was cooled to room temperature by gentle agitation so that it would be made uniform and not become too hard too early. Viscocontrol was attained here, and makeup as required was controlled as required to provide a satisfactory texture and spreadability. The resulting cream was then filled under aseptic conditions under sterile, air-tight containers to avoid microbial contamination and stability on storage. For controlling product quality and safety control, pH measurement, viscosity, and microbial sterility were used as samples. The tests are such that the cream would be of best pharma quality, safe, and effective to apply as an antifungal agent.

Evaluation Parameters

pH Determination

Take 1 gm of antifungal cream and prepare the suspension of cream and detect the pH of the cream by using the digital pH meter and record the values mentioned in the table. 5.

Viscosity Measurement
Take small amount of sample and place it in a Spindel of available number of Brook field viscometer and record the values mentioned in table.5.

Spreadability test
Spreadability is determined by taking a small amount of the cream and placing it between two glass slides, whereupon diameter of spread under fixed weight is measured. A greater value for spreadability means easier application and absorption into the skin results were mentioned in table.6.

Stability Test
The stability of the formulation was tested under accelerated storage conditions involving room temperatures, refrigeration (4°C), and elevated temperatures (40°C) for a specific period. Some of the changes studied included pH, texture, color, and phase separation to establish the shelf-life and stability of the product results were mentioned in table.6.

Microbial Studies
For microbiological research, we tested cream antifungal activity using the plate method. By focusing on *Candida aulbicans* the most common pathogen by using marketed product, standard clotrimazole and optimized batch product. The antifungal activity was assessed using nutrient agar medium. Prepare the agar media, put it in a conical flask, and add a loopful of fungi to the mixture before transferring it to a Petri plate to harden. After solidification, make cups or leave empty spaces in the medium to introduce the sample solution. Now, add the cream solution and let it diffuse in an incubator for 2-5 days. The antifungal activity of cream was assessed by measuring the zone of inhibition in mm. The results were mentioned in table.6.

RESULTS AND DISCUSSION

Optimization of antifungal cream (Table 2).

Fit Summary
Response 1: Spreadability (Table.3).

Sequential Model Sum of Squares [Type I]
Response 1: Spreadability (Table.4).
Relationship between beeswax and liquid paraffin at a fixed borax (Fig.1). Effect of beeswax and borax at constant liquid paraffin (Fig.2). Interaction between liquid paraffin and borax at constant beeswax (Fig.3). Fig.4, 5, 6 demonstrates that response surface and 3D plots show the interactive impact of beeswax, liquid paraffin, and borax on spreadability. Beeswax improves structural quality; however, too much beeswax could result in reduced spreadability due to increased viscosity. Liquid paraffin promotes spreadability through resistance reduction, and borax stabilizes the formulation but can negatively impact spreadability at greater than necessary levels. The quadratic model was determined to be statistically significant, showing that the response was well-fitted with little lack of fit. Overall, achieving optimized proportions of these excipients is crucial to developing ideal spreadability to achieve ease of application and performance of the formulation. The optimization of the formulation based on desirability and spreadability is shown in figures 7 and 8. Figure 7 shows a desirability plot (left side) that is entirely red, indicating a desirability amount of 1.000, indicating that the selected formulation met all the goals established. The right side of figure 7 is a contour plot of spreadability indicating the spreadability was different based on the concentration of beeswax and liquid paraffin. An optimal spreadability region was identified with dashed black lines. Figure 8 is an overlay plot indicating the yellow region where all formulation constraints were met. The desired space in the center provides the optimal amounts of beeswax and liquid paraffin while providing desirable

spreadability and product stability as functional to the entire formulation. The optimization process here leads us to a formulation that can now be developed further.

Final Equation in Terms of Coded Factors

Spreadability = 4.20 + 1.32 A + 0.2375 B + 0.3125 C – 0.1500 AB + 0.4000 AC - 0.0250 BC + 1.29 A^2 – 0.2875 B^2 – 0.0875 C^2

The last equation signifying spreadability indicates that A-beeswax has the greatest positive effect with a decreasing effect from C-borax and B-liquid paraffin suggesting that the higher concentration of A-beeswax improves score for spreadability. Of the interaction terms, the combination of AC-beeswax-borax has the greatest effect while interactions AB-beeswax-paraffin and BC-borax-paraffin reveal almost no effect. A^2-beeswax has a strong quadratic effect indicating a higher level of significance regarding nonlinearity, as optimal concentration is needed to uncover the highest spreadability. For B^2 and C^2-liquid paraffin and borax respectively have negative quadratic effects meaning that spreadability potentially decreases as concentration levels rise. In addition to the predictive roles this equation provides for determining the parameters of the formulation, the inclusion of the degree of Y2-spreadability of A-beeswax and the interaction with C-borax specifically indicates its vital contribution to achieving adequate spreadability

Fit Summary

Response 2: Viscosity (Table.5).

Factor coding is coded. Sum of squares is Type III - Partial

The Model F-value of 8.82 implies the model is significant. There is only a 1.37% chance that an F-value this large could occur due to noise. P-values less than 0.0500 indicate model terms are significant. In this case A, C, A^2, B^2 are significant model terms. Values greater than 0.1000 indicate the model terms are not significant. If there are many insignificant model terms (not counting those required to support hierarchy), model reduction may improve your model. The Lack of Fit F-value of 597.56 implies the Lack of Fit is significant. There is only a 0.17% chance that a Lack of Fit F-value this large could occur due to noise. Significant lack of fit is bad -- we want the model to fit. The fig.9, 10 describes that viscosity contour plots show the effects of beeswax (A), liquid paraffin (B), and borax (C) on the viscosity of the formulation. Increasing the level of beeswax raises the viscosity considerably, shown by the color change from green to red, while borax has an insignificant effect on viscosity. A good viscosity range is around the central point in the design. This can be useful for adjusting amounts of formulation components to provide the desired product characteristics. Figures 12, 13, and 14 include 3D surface plots illustrating the effects of beeswax, liquid paraffin, and borax on the viscosity of the formulation. The surface plots are curved, showing a strong interaction between these three factors; as beeswax and borax increased, viscosity increased, while liquid paraffin had an unpredictable nonlinear effect on viscosity. It also indicated an optimal range for maximum viscosity since high/low viscosity affects both spreadability (non-invasive application) and stability of a formulation. The 3D surface plots validated the model's predictions and/or necessity of balance of proportions in a formulation with these three ingredients.

Final Equation in Terms of Coded Factors

pH = +5.27 +0.9125A +0.2125B +0.4250C -0.3500 AB +0.3750 AC +0.1750 BC +0.9417 A^2 -0.8083 B^2 -0.0333 C^2

The equation in terms of coded factors can be used to make predictions about the response for given levels of each factor. By default, the high levels of the factors are coded as +1 and the low levels are coded as -1. The coded equation is useful for identifying the relative impact of the factors by comparing the factor coefficients**.** Figures 15, 16, and 17 illustrate contour plots for pH responses in relation to the various components comprising the formulations. Figure 15 shows the pH response from combinations of beeswax and liquid paraffin. It is evident there is a shift to lower pH when using higher concentrations of liquid paraffin. Figure 16 shows pH response from the interaction of beeswax and borax, which shows that increased beeswax caused an increase in pH level. Figure 17 illustrates the interaction between borax and liquid paraffin. In this contour plot, the pH response is stable in each interaction. Altogether, contour plots of pH will help identify formulation conditions that allow for optimal and stable formulations.

Figures 18, 19, and 20 include 3D surface plots illustrating the effects of beeswax, liquid paraffin, and borax on the pH of the formulation. The surface plots are curved, showing a strong interaction between these three factors; as beeswax and borax increased, pH increased, while liquid paraffin had an unpredictable nonlinear effect on pH. It also indicated an optimal range for maximum pH. The 3D surface plots validated the model's predictions and/or necessity of balance of proportions in a formulation with these three ingredients. Evaluation test results for optimized anti-fungal cream (Table.6). Fig.21. antifungal activity of optimized batch product of cream by using cup plate method The table.5. describes the findings from the evaluation of the developed antifungal cream preparation suggest that the preparation can be used topically. The pH value of 6.5 is within the acceptable range, indicating that it will not cause irritation and is safe to use on skin. The spreadability of 6.9 cm indicates the cream can be applied uniformly to the skin, leading to less variability of cream residence in the application area, which will increase patient compliance. The viscosity of 28,000 cP shows that the cream has the right consistency to stay placed on the skin surface but is also easy to spread and rub into the skin. The zone of inhibition observing 5.5 mm, shows an antifungal effect of the cream, indicating the ability to inhibit fungus growth. In conclusion, the developed cream's formulation has met some of the general quality control aspects of effective antifungal activity and general user acceptability.

CONCLUSION

This study successfully utilized the Box-Behnken Design (BBD) to optimize a topical antifungal cream containing citronella and clove essential oils, systematically assessing the impact of liquid paraffin, borax, and beeswax upon relevant aspect of the formulation. The BBD accurately determined an optimized formulation that had a favorable pH of 6.5 for skin compatibility, a highly favorable 6.9 cm for spreadability, improving patient adherence, and a viscosity of 28,000cps, which is consistent with products formulated for topical intended use. The cream expressed antifungal efficacy, achieving a 5.5 mm zone of inhibition. Overall, this study illustrates the efficacy of utilizing the BBD to optimize a complex cream formulation for targeted physicochemical properties and antifungal efficacy so that topical products may result in improved treatment for fungal infections.

ACKNOWLEDGEMENT

The authors are thankful to principal, management, department head and colleagues for their support and guidance.

CONFLICT OF INTREST

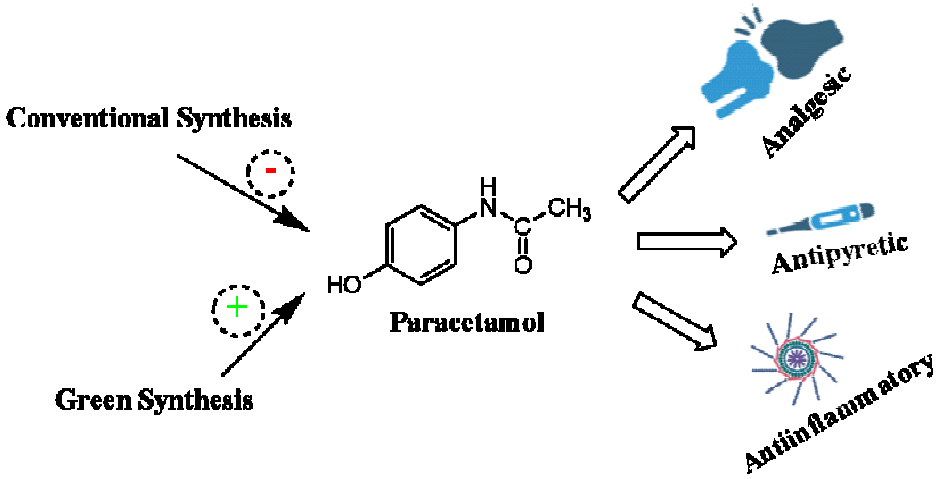
ABSTRACT

Acetaminophen is commonly known as paracetamol, a very famous drug into NSAIDs family. It has several therapeutic activities like analgesic, antipyretic and anti-inflammatory. It contains more than one functional group that create a very interesting structural scaffold, any change of this functional moiety the therapeutic activity of this scaffold will alter. In this review work we highlighted the chemistry, synthetic way and diverse therapeutic activities of paracetamol that reveal the mystery of paracetamol into pharmaceutical field. Hence also explain the how green synthetic approach has been more popular and beneficial than conventional synthetic approach.

Keywords: Acetaminophen, conventional synthesis, green synthesis, pharmacological activity

Graphical Abstract:



INTRODUCTION

N-acetyl para–amino phenol scaffold is promising chemical moiety into NSAIDS drug discovery field. paracetamol or acetaminophen is the widely renowned drug which has antipyretic and analgesic activity[1–3]. The history of paracetamol discovery starts with error and continues by several false assumption[2]. During late 1800s, researchers were actively exploring coal tar derivatives to develop safer alternatives to opioids and salicylates for pain fever. In 1886 Arnold Cahn and Paul Hepp accidentally discovered that acetanilide reduced fever in patients, but it caused some side effects like- cyanosis, methemoglobinemia[3,4]. In 1887 paracetamol was first synthesized by Harmon Northrop Morse at Johns Hopkins university by reducing p-nitrophenol with tin in acetic acid. In 1940s David Lester and Leon Greenberg discovered that paracetamol was the active analgesic metabolite of acetanilide and it did not cause methemoglobinemia[5]. In 1955 paracetamol introduced as Tylenol by McNeil laboratories in USA, basically made for children because it did not cause gastric irritation like aspirin[6,7]. By the 1960s, paracetamol introduced in pharmacopoeias and in 1977 it was approved as OTC drug. Paracetamol is a NSAIDs group of drugs which acts central part of the brain and inhibit the action of COX enzyme and the production of prostaglandin, it is responsible for pain signals[3]. Paracetamol uses as globally but its mode of action is not clear till now. Generally, it is used in the treatment of flu syndrome, headache, relief in joints and muscle pain and inflammatory effects[8]. Paracetamol or acetaminophen widely used for children and adults for fever and pain and comes out in pill, liquid, injectable, tablet, suppository etc. forms. Acetaminophen is the main chemical moiety which is present in paracetamol. The chemical structure of paracetamol is $C_8H_9NO_2$, looks like white odorless crystalline powder with 151.16 molecular weight[8]. The melting point is 160-170^{0}c. It is stable in dry form at 45^{0}c. p-Hydroxy acetanilide is soluble into polar media like water, ethanol and other alkali hydroxides[9] and insoluble in diethyl ether. The recommended dosage of acetaminophen is very controversial. For children, dosing for most medication is based on the child's weight. The recommended dose of paracetamol in adults is 650-1000mg in every 4-6 hours as needed not to exceed 4000mg in 24 hours. For children the recommended dose of acetaminophen is 10-15mg/kg in every 4 to 6 hours[3,10,11]. Various concentration of liquid dosage forms is present for infants and children, so it is strongly recommended to read the instructions carefully and call the doctor for any help regarding dosing[3,10,12]. It does not cause Reye's syndrome and has no gastrointestinal toxicity and does not cause thrombocyte aggregation[13,14]. The side effects of paracetamol are cause by the long-term uses of it. Less than 15% of PCM is absorbed in the body and less is excreted out of the body[3,15]. PCM or p- Hydroxy acetanilide undergoes lots of chemical reactions such as oxidation, acetylation etc. Paracetamol synthesis leads a three-step process, nitration of phenol followed by reduction and acetylation process. The green synthesis methods are attracting to the researchers for it reduce the toxicity level and

eco-friendly in nature. [16]Therefore, the use of green synthesis method is very popular topic now a days[17]. The green synthesis of paracetamol has important applications in pharmaceutical manufacturing, education and environmental protection.

CHEMISTRY

Structure and SAR

Paracetamol **(Fig.1)** is generally a derivative of p-aminophenol that consists a core benzene ring which is substituted in a para orientation (1,4) with two functional groups[18]. The other names of N-acetyl-p-aminophenol are acetaminophen, N-(4-hydroxyphenyl) acetamide, 4-hydroxyacetanilide, p- hydroxy acetanilide, acetophenum, p-acetylamino phenol.[19] The molecular formula and molecular weight of paracetamol is $C_8H_9NO_2$ and 151.16 g/mol respectively. In general, the physical appearance of paracetamol looks like white, odourless crystalline powder and it forms large monoclinic prisms while crystallized from water[20] Its melting point is 169-170.5^0 C and density is 1.293 g/cm^3 [20]The pH range of paracetamol is 5.3-6.5 (at 25^{0}C).

Paracetamol scaffold contains an aromatic core where the benzene ring act as a lipophilic component that helps paracetamol to cross through the blood-brain barrier (BBB) and also helps in the interaction with the cyclooxygenase (COX) enzyme in the hydrophobic pockets.[21,22] A hydroxyl group (-OH) is present as functional group that formed hydrogen bonding with phenyl ring and it also increase the electron density of the benzene ring which makes it more reactive for the electrophilic aromatic substitution reactions[23,24]. This phenolic group is the primary and crucial part for phase II conjugation because it reacts with the glucuronide and sulphate present in the liver and forms water soluble polar metabolites that can be easily flushed out through kidneys[25–28] amide group (-$NHCOCH_3$) also present into paracetamol scaffold. The acetamide group resists the hydrolysis of paracetamol at the acidic environment of stomach and ultimately increase the oral bioavailability of paracetamol[22,29]. It contains both carbonyl group(C=O) and an amine group (-NH_2) that allows it in the participation of strong intermolecular hydrogen bonding[30,31]**.** The 1,4 orientation is crucial for the pharmacological activity. However, several research shows that the ortho and meta substitution may reduce the analgesic activity and increase the toxicity[32–34]. The 1,4-orientation brings the compound to a slim and elongated shape which is helpful in the binding with COX enzymes as it has long and hydrophobic binding site[18,35].

Metabolism

The metabolism of paracetamol **(Fig.2)** generally occurs in the liver and helps in converting the lipophilic compound into water soluble metabolites that will be excreted easily through urine[36,37]. It generally follows 2 pathways, a)Phase II metabolism, that is major for paracetamol metabolism process. Almost 85-90 % of given paracetamol is generally metabolized through phase II metabolism where it attaches a large polar compound in its structure that makes it more water soluble that can be easily get excreted through urine[36–38]. It is generally done by Glucuronidation process that forms paracetamol-glucuronide, an active non-toxic metabolite catalysed by UDP-glucuronosyltransferases (UGT1A1 and UGT1A6) and Sulfation process that catalysed by enzyme sulfotransferase (SULT1A1 and SULT1E1.[36,39] b)Phase I metabolism, that is minor pathway where very little portion of paracetamol undergoes through biological oxidation process with help of cytochrome P450(mostly CYP2E1 and minorly CYP1A2 & CYP3A2)[36,39,40]. It produces N-acetyl-p-benzoquinone imine (NAPQI) that is generally an unstable, toxic and highly electrophilic intermediate that may leads to hepatocyte necrosis[39,40]. It is generally neutralized by glutathione conjugation (GSH) that form non-toxic cystine and mercapturic acid derivatives[25,36,39]

Synthetic strategies of paracetamol

Conventional Methods

Synthesis of paracetamol in conventional ways include **Scheme 1** is the most popular synthesis of paracetamol from phenol. In this process phenols are reacted with conc. nitric acid and sulfuric acid that produces 4-nitrophenol. 4-nitrophenol undergoes catalytic hydrogenation using metal catalyst such as palladium-carbon or raney-nickle to produce 4-aminophenol[41–44]. Reducing agents like tin or iron may be used as an alteration step. 4-aminophenol is reacted with acetic anhydride that synthesize paracetamol[44,45]. This procedure contains several drawbacks as

H_2SO_4 and HNO_3 are hazardous, corrosive and generates acidic waste causes a negative environmental impact. Besides, nitration of phenol results in a mixture of p-nitrophenol and significant portion of o-nitrophenol, separation of the desired p-nitrophenol is difficult from the unwanted o-nitrophenol, reduces overall yield[41,43,45,46]. **Scheme 2** Synthesis of paracetamol by nitrobenzene is another common way where nitrobenzene is reduced to phenylhydroxylamine. In presence of H_2SO_4, the phenylhydroxylamine undergoes Bamberger rearrangement that forms p-aminophenol. Electrolysis method may be used to alter the use of acid for reduction[47–49]. Next, acetylation with using acetic anhydride is done to produce paracetamol. This step partially eliminates the drawbacks such low selectivity and isomer separation of o-nitrophenol and p-nitrophenol because Bamberger rearrangement is more selectively directed to the para position comparing than scheme1[50–52]. However, this step also has several drawbacks like the intermediate phenylhydroxylamine is unstable in nature and H_2SO_4 used for Bamberger rearrangement (in most industries) produces significant amount of hazardous chemical waste (including ammonium sulphate)[45,52,53]. **Scheme 3** It is the less popular and comparatively newer conventional method of preparation of paracetamol. In this process phenol is reacted with acetic anhydride in the presence of hydrogen fluoride (HF) as catalyst and produces 4-hydroxyacetaphenone through Friedel-Craft acylation[41,54–56]. The 4-hydroxyacetaphenone is then reacted with hydroxylamine hydrochloride that converts the ketone into 4-hydroxyacetaphenone oxime. Oxime then undergoes an acid-catalysed Beckmann rearrangement (catalysts used $SOCl_2$ or CF_3COOH or TFA) that forms paracetamol[54,57,58]. It is cost effective than scheme 1 and 2 because of using relatively cheap materials including acetic anhydride, hydrogen fluoride, phenol. This route is highly selective for the para isomers during the initial acylation of phenol and eliminates the use of H_2SO_4 that is highly hazardous and corrosive[45,59–61]. This process also has backwards such as HF required for acylation is exceptionally dangerous that may cause fluoride poisoning[54,62,63]. Besides, 4-hydroxyacetophenone oxime intermediate is chemically unstable and prone to explosive decomposition when heated and produces stoichiometric salt waste that must be disposed of or treated[45,54,64,65].

Green synthetic Methods

Green synthesis is a modern environment friendly approach for the synthesis pf chemicals and nanomaterials by replacing toxic substances with natural, sustainable and safer products[41,66–68]**.** Scheme 4 Synthesis of paracetamol by using microwave irradiation is the modern green approach in modern chemistry. In this process 1:1 or slightly excess molar ratio of 4-aminophenol and acetic anhydride is mixed directly in 2-4 ml of distilled water and few drops of acid catalyst may be added (optional)[69–71]. The mixture is sealed in a vial or Erlenmeyer flask and keep in microwave reactor (power: 600-850W) for 3-5 minutes[72,73]. Cool, filter and recrystallize the crude paracetamol (50% methanol/ethanol-water mixture) to get final product[72,73]. Analysis such as melting point (168^oC – 170^oC), FTIR spectroscopy, TLC should be checked to confirm identity and purity[45,74]. This process has various advantages over conventional method such as reaction typically completes within 3-5 minutes where conventional requires 45 mins to 60 minutes for the same process[41,45,74,75] . This process produces comparatively higher yield products (often 91-92.4%) than conventional (70-72%%) under similar conditions, often many microwave-assisted synthesis is solvent free that eliminates toxic organic wastes[45,74,76]. The drawbacks of this process are maintaining transition in large batches and high initial cost[74,77,78]. **Scheme 5** In this process hydroquinone is directly converted to paracetamol. Hydroquinone is directly with ammonium acetate at an optimum temperature (~220-230^OC) for a specific time (~15 hrs.) to synthesize paracetamol[41,54,79]. The main benefit of this process is it generates water as the only byproduct, avoids metal catalyst and provides high yield (exceeding 95%)[41,54,80]. Often 85% of the acetic acid can be recovered and reused further[41,54,74]. The drawback involves the need of high temperature (220-230 ^oC) for up to 15 hours[41,54,79]. Scheme 6 In this process the synthesis of paracetamol is done by inducing ultrasound. This method is used to overcome the drawback of Scheme 5 i.e. lowering the temperature from 220^0C to 60^0C and also reduced the time to 150 minutes[41,74,81]. In this method, hydroquinone, ammonium acetate and glacial acetic acid (1:6:5) is taken and 22 kHz ultrasound frequency is provided (temperature 60^o C) that produce paracetamol within 2.5 hours[54,74,79,81].

Pharmacological actions of paracetamol

Despite being the first line treatment of pain and fever the pharmacological action of paracetamol were debated for decades. As a multimodal drug, it bridges the gap between the prostaglandin, cannabinoid and serotonergic systems[82,83]. Novel prize winner researcher Sir john vane showed the mechanism of action of aspirin and other NSAID's group of drugs that inhibits the cyclooxygenase (COX) enzyme and reduce the synthesis of prostaglandin or PGE2[84]. PCM is a lipid soluble drug that easily crosses the blood brain barrier and reaches to cerebrospinal fluid. It reaches plasma peak concentration around 120 min of post administration and in CSF the Cmax is 8.8 mg/ml at about 240 minutes.[85]

Analgesic action

Acetaminophen of paracetamol acts on the central nervous system and relief the pain. It has three main pathways. They are COX inhibition, serotonergic modulation and endocannabinoid system.

a) COX inhibition: paracetamol inhibits the action of COX enzymes (COX-1, COX-2, COX-3) within the central nervous system. By reducing prostaglandin synthesis in brain and spinal cord it reduces the pain signals. (**Fig.4a**)[86]

b) serotonergic modulation: serotonin acts on some basic receptors like 5HT3 and 5HT1A that are located in dorsal site of the spinal cord. Increasing the level of serotonin decreases the pian signals from rest of the body. By blocking the serotonin, paracetamol loses pain killing power. This is also known as muffling effect. [87] c) endocannabinoid system: Some reviews shows that paracetamol act as a pro drug for its active metabolite like AM404. Paracetamol deacetylated to p- aminophenol and converted into AM404 with the help of fatty acid amide hydrolase enzyme (FAAH). The conversion occurs in brain and spinal cord. Probably AM404 inhibits the reuptake of anandamide, is an endogenous cannabinoid by increasing its level in synapse. It activates the TRPV1 receptor and inhibits nociceptive sodium channel in CNS and peripheral nervous system and providing a prolonged analgesic effect. (**Fig.4a**)[88]

Antipyretic activity

Paracetamol inhibits the synthesis of prostaglandin (PGE2), triggered by the pyrogens (like- cytokines)[86,87]. Generally, fever-reducing effect is localized in hypothalamus center, which controls the secretion of prostaglandin. When the immune system gets infected by the pyrogens like cytokines, it triggers the production of prostaglandin or PGE_2 enzyme in the brain. This PGE_2 enzyme helps to heat up the body which results fever.[89,90]Paracetamol easily crosses the blood brain barrier thus it inhibits the production of COX enzymes in central nervous system. Basically, it prevents the synthesis of PGE_2 enzyme at the peroxide site by blocking the cox enzymes secretion.[91,92] By suppressing the PGE_2, paracetamol resets the body "thermostat" to normal, by increasing the blood flow to the skin and sweat. (Fig.4b)[93,94]

Anti-inflammatory activity

Paracetamol shows weak anti-inflammatory activity. It acts as reducing agent at the peroxide site of COX enzyme. It inhibits the 80% of COX-2 enzyme in blood which is comparable to some selective NSAIDs. It lacks the ability to function in high-peroxide environments, this inhibition helps to reduce the physical swelling in peripheral tissues. [95]

CONCLUSION

N-acetyl para–amino phenol is very common chemical scaffold into NSAIDs family. It contains several functional moieties that reveals the potency and versatile therapeutic activity like analgesic, antipyretic and anti-inflammatory action. This drug easily penetrates blood brain barrier as it contains hydrophobic phenyl core. Instead of exhibit some side effects this drug show quick action in our body as $t_{1/2}$ is low. In this review we discussed various strategies regarding the synthesis of paracetamol. Conventional synthesis has much more drawbacks, such as it's not ecofriendly in nature, have negative impact into environment, produce hazardous materials. Green synthesis overcomes these types of problems, as in this procedure no toxic materials will produce. The most effecting things is that green synthetic approach is time saver procedure and no metal catalyst used that has non-biodegradable in

nature. This review provides the structure elucidation, synthetic pathway and mechanistic pathway of paracetamol that may be help to researchers into NSAIDs drug discovery field.

ACKNOWLEDGEMENT

The authors would like to thank Brainware University for providing the facilities and support to carry out the review work.

Conflict Of Interest

The authors declare that no conflict of interest.

ABSTRACT

Senna auriculata (L.) Roxb., commonly known as Avaram or Tanner's Cassia, is a medicinal plant widely used in traditional Ayurvedic and Siddha medicine practices. The present study focuses on analyzing the phytochemical and antibacterial activity of *Senna auriculata* leaf extracts prepared using acetone, ethanol, petroleum ether, and aqueous. The qualitative phytochemical screening revealed the presence of multiple bioactive compounds responsible for therapeutic activity. The antibacterial activity of *Senna auriculata* leaf was investigated against the bacterial pathogens *Staphylococcus aureus* (MTCC 3160), *Klebsiella pneumoniae* (MTCC 7162), and *Escherichia coli* (MTCC 1652) using the disc diffusion method. *Senna auriculata* leaf was observed to have antibacterial activity and can be used for pharmaceutical purposes.

Keywords: *Senna auriculata,* phytochemical analysis, antibacterial activity, disc diffusion.

INTRODUCTION

Medicinal plants have served as a primary source of therapeutic agents for centuries, forming the foundation of traditional medicine in many countries around the world [1]. Natural products derived from plants play a significant role in modern drug development [2]. *Senna auriculata* is a traditional Asian nutritional and beverage plant widely used in Indian traditional medicine [3]. The phytochemical components of the plants determine their therapeutic effects. Some of the important phytochemicals include flavonoids, alkaloids, tannins, phenolics, steroids, saponins, terpenes, glycosides, etc., which are distributed in various parts of the plants. Plant secondary metabolites have therapeutic properties, such as anticancer, anti-inflammatory, antibacterial, and antioxidant activities [4]. Worldwide, infectious diseases emanating from microorganisms such as bacteria, fungi, viruses, and parasites are hazardous to public health due to the growing resistance of many microorganisms to currently accessible antibiotics [5].Therefore, this study aimed to evaluate the phytochemical constituents and antibacterial activity of leaf extracts of *Senna auriculata* using different solvents.

MATERIALS AND METHODS

Preparation of Extract

Fresh leaves of *Senna auriculata* were collected from Nanguneri, Tirunelveli District, Tamil Nadu, India. Leaves were washed thoroughly, shade-dried for one month, and pulverized into powder. Extracts were prepared using acetone, ethanol, petroleum ether, and aqueous.

Qualitative phytochemical analysis

The phytochemicals like alkaloids (Mayer's test), carbohydrates (Fehling's test), glycosides (Keller-Kiliani test), proteins (Biuret test), flavonoids (Alkaline reagent test), terpenoids (Salkowski's test), phenolic compounds (Ferric chloride test), tannins (Lead acetate test), saponins (Froth test), and anthraquinones (Borntranger's test) were analyzed [6].

Antibacterial Activity

For antibacterial study, three strains of clinical isolates, *Escherichia coli* (MTCC 1652), *Staphylococcus aureus* (MTCC 3160), and *Klebsiella pneumoniae* (MTCC 7162), were selected and obtained from MTCC, Chandigarh. The disc diffusion method was used on Mueller-Hinton Agar(MHA-Media) [7]. An amikacin 10 μg concentration disc was used for positive control, and an empty sterile disc was used for negative control. Zones of inhibition were measured after 24 h incubation at 37°C [8].

RESULTS AND DISCUSSION

Phytochemical Analysis

The phytochemical analysis of *Senna auriculata* leaves using different solvent extracts were summarized in Table 1.

The present study carried out in the plant sample *Senna auriculata* leaves revealed the presence of various phytochemicals. Alkaloids, phenols, proteins, and tannins were found to be present in all four solvent extracts. Carbohydrates were present only in the acetone extract, while glycosides were present in both acetone and petroleumether extracts but absent in ethanol and aqueous extracts. Flavonoids were detected in acetone, ethanol, and petroleum ether extracts but were absent in the aqueous extract. Terpenoids were present in petroleum ether. Saponins were present in acetone, ethanol, and aqueous extracts but were also absent in petroleum ether. Anthraquinones were completely absent in all four solvent extracts. The pharmacological properties of therapeutic plants are mainly attributed to their secondary metabolites. These include alkaloids, phenols, essential oils, steroids, lignins, and tannins, have been successful sources of potential drugs [9].The leaves of the *Senna auriculata* plant have

been documented to contain a rich array of major phytochemical constituents, including alkaloids, flavonoids, phenols, saponins, tannins, terpenoids, and glycosides [10].

Antibacterial Activity

The antibacterial activity of *Senna auriculata* leaf extracts against selected clinical isolates was evaluated, and the results were presented in Table 2, Figure 1, and Plate 1.

Among the tested isolates, *Staphylococcus aureus* showed the highest zone of inhibition with the acetone extract (30.33±0.39). Ethanol and petroleum ether extracts showed moderate activity (12.33±0.47) and (13.66±0.53). The aqueous extract demonstrated the minimum inhibition (12.00±0.55). *Klebsiella pneumoniae* showed significant susceptibility to the acetone extract (16.00±0.35) and moderate activity with ethanol (13.00±0.64) and petroleum ether (12.33±0.47), while aqueous extract exhibited the lowest inhibition (9.33±0.31). In *Escherichia coli*, the acetone extract showed the maximum inhibitory activity (17.66±0.49), ethanol (13.66±0.53), and petroleum ether (14.33±0.49) respectively, with the aqueous extract showing the minimum inhibition (9.00±0.29). In the four solvents, *Senna auriculata* leaf extract showed the maximum zone of inhibition against *Staphylococcus aureus* with acetone extract (30.33 ± 0.39), while the minimum zone of inhibition was observed against *Escherichia coli* (9.00±0.29) in aqueous extract. Medicinal plants represent a rich source of antibacterial activities. The use of medicinal herbs has become an important part of daily life [11]. Ethanol and aqueous extracts of *Senna auriculata* flowers exhibited significant antibacterial activity, with the highest inhibition zone against *Staphylococcus aureus* [12]. They report that the disc diffusion assay indicates that the ZnONPs synthesized using an aqueous extract of *Senna auriculata* leaves exhibited superior antibacterial activity, particularly against *Klebsiella pneumoniae,* compared to both the standard drug ampicillin and commercially available ZnONPs [13].

CONCLUSION

This study proved that *Senna auriculata* leaf extract revealed the presence of phytochemicals and antibacterial activity against selected clinical isolates, with the acetone extract showing the highest efficacy. These findings can be used for pharmaceutical purposes.

ABSTRACT

Glyphosate is a widely used herbicide for weed management; however, its misuse and limited awareness of safety practices pose serious risks to human health and the environment. In Karnataka, India, glyphosate is frequently applied without adequate training or regulatory oversight. This study assessed farmers' demographics, glyphosate use patterns, awareness of health and environmental impacts, safety behaviour, self-reported health issues, and attitudes toward alternative weed management practices. A cross-sectional survey was conducted among 135 farmers across Karnataka using a structured questionnaire covering demographic information, glyphosate handling, safety behaviour, and perceptions of health and environmental effects. Data were analyzed using IBM SPSS Statistics 26.0. Descriptive statistics summarized responses, and Chi-square tests examined associations between exposure and self-reported health outcomes. Participation was voluntary, and confidentiality was maintained. The majority of participants were aged 36 -50 years (34%), with 64% identifying farming as their main occupation. Awareness of glyphosate regulations was low (22%), and 47% had never tested soil for residues. Unsafe handling was prevalent 69% did not use personal protective equipment (PPE), and 72% ignored safety label instructions. Frequently reported symptoms included skin irritation, headaches, dizziness, and respiratory problems. Chi-square analysis revealed a significant association between glyphosate exposure and adverse health outcomes (χ^2 (35, N = 135) = 125.85, p< 0.001).The findings indicate poor awareness, inadequate safety practices, and frequent health complaints among

farmers in Karnataka. Targeted training programs, stricter enforcement of pesticide regulations, and the promotion of sustainable weed management alternatives are essential to reduce health and environmental risks linked to glyphosate use.

Keywords: Glyphosate, herbicide, farmers' awareness, occupational health, environmental impact, Karnataka

INTRODUCTION

Herbicides play a pivotal role in modern agriculture by controlling weeds that compete with crops for nutrients, water, and sunlight, thereby contributing to enhanced crop yield and productivity (Parven *et al*., 2025). Among these, glyphosate (N-(phosphonomethyl) glycine) is one of the most widely used non-selective herbicides globally due to its broad-spectrum activity, cost-effectiveness, and ease of application (Duke and Powles, 2008). In India, glyphosate is extensively employed in the cultivation of ginger, vegetables, and other high-value crops, particularly in regions where manual weeding is labour-intensive and economically unfeasible (Pal, and Bhutia, 2022; Pandey *et al*., 2023). Despite its agricultural benefits, glyphosate has raised significant environmental and health concerns. Several studies have reported its persistence in soil and water, potential effects on non-target organisms, and disruption of soil microbial communities (Castrejón-Godínez *et al*., 2021; Singh *et al*., 2020). Human exposure, particularly among farmworkers, has been linked to dermatological, respiratory, and neurological symptoms, as well as other adverse health outcomes, depending on exposure intensity, duration, and protective measures used (Duke, 2021; Zabaloy *et al*., 2022). Proper handling of glyphosate, including adherence to label instructions, use of personal protective equipment (PPE), safe storage, and disposal, is critical to mitigate these risks. However, studies in developing countries have highlighted widespread unsafe practices due to limited awareness, lack of training, and insufficient regulatory enforcement (Kudsk, and Mathiassen, 2020; Klingelhöfer, *et al*., 2021). Furthermore, knowledge gaps regarding the environmental impacts of glyphosate, alternative weed management strategies, and the long-term consequences on soil health remain prevalent among smallholder farmers. In the context of Karnataka, glyphosate use is common among ginger and mixed-crop farmers, yet there is limited empirical evidence documenting farmers' awareness, application practices, occupational exposure, and perceived health and environmental impacts. Understanding these factors is essential for developing targeted interventions that enhance safety, promote sustainable herbicide use, and reduce health and ecological risks. Accordingly, this study was designed with the following objectives: to assess farmers' demographic characteristics, agricultural experience, and glyphosate usage patterns; to evaluate awareness, perceptions, and knowledge regarding the health and environmental impacts of glyphosate; to examine adherence to safety guidelines including the use of PPE, handling, storage, and disposal practices; to investigate self-reported health problems associated with glyphosate exposure and their distribution among users; and to explore attitudes toward alternative weed control methods and training programs for safe herbicide handling. By addressing these objectives, the study aims to provide critical insights into occupational safety, environmental sustainability, and policy-relevant interventions for herbicide management in smallholder farming systems in India.

MATERIALS AND METHODS

Study Area

The study was conducted in the selected agricultural regions of Karnataka, India, (Mysore district selected Taluk) (Figure. 1) known for extensive ginger and mixed-crop cultivation. The area experiences a tropical monsoon climate with average annual rainfall between 2500 – 3000 mm and temperatures ranging from 18°C to 33°C. Agriculture forms the primary occupation, with glyphosate being widely used as a post-emergence herbicide for weed control in ginger, vegetable, and mixed cropping systems.

Research Design

A descriptive cross-sectional survey design was adopted to assess farmers' demographic characteristics, glyphosate usage patterns, awareness levels, handling practices, and perceived health and environmental impacts. Data were collected through questionnaires administered to local farmers. This approach aimed to capture existing practices and perceptions without influencing respondents' behaviours.

Sampling Procedure and Sample Size

A total of 135 respondents were selected using a random sampling method from different villages within the study area. The inclusion criteria consisted of individuals actively engaged in farming or herbicide application for at least one year. Respondents were selected to ensure adequate representation across age, gender, and occupational categories. Participation was voluntary, and informed consent was obtained prior to data collection.

Data Collection Instrument

Primary data were collected using a structured questionnaire, which was developed following a thorough literature review on glyphosate use and environmental health studies. The questionnaire consisted of five major sections

(**Suppl. Table 1**)

Demographic information(Age, occupation, family structure, and size)

Agricultural experience and glyphosate use practices.

Awareness and perceptions regarding glyphosate impact on soil, health, and the environment.

Handling and safety practices, including PPE use, storage, and disposal behaviours

Health and environmental effects experienced or observed after glyphosate application

The questionnaire included both closed-ended (multiple-choice) and semi-structured questions to capture qualitative insights.

Validation and Reliability

The questionnaire was reviewed by agricultural scientists, environmental health experts, and statisticians to ensure content validity and clarity of items. A pilot study was conducted with 15 participants outside the main sample to test the instrument's reliability. Based on feedback, minor revisions were made for clarity and cultural relevance.

Data Collection Procedure

Data were collected through face-to-face interviews conducted in the local language (Kannada) to ensure clear understanding. Interviews were held at respondents' farms or residences, lasting approximately 25 - 30 minutes each. Trained field investigators recorded responses manually and verified data for completeness at the end of each day.

Ethical Considerations

Ethical approval for the study was obtained from the institutional ethics review committee. Participants were informed of the study's objectives, assured of confidentiality, and allowed to withdraw at any stage. No identifying information was collected, ensuring anonymity and compliance with ethical research standards.

Statistical Analysis

Data were entered into IBM SPSS Statistics 26.0 and analyzed using descriptive statistics to summarize demographic characteristics, glyphosate usage patterns, awareness, and safety practices. To examine whether self-reported health problems were evenly distributed across different categories, a Chi-square goodness-of-fit test was conducted. The null hypothesis assumed that all categories of reported health problems were equally likely, while the alternative hypothesis stated that some symptoms were disproportionately reported. A significance level of $p < 0.05$ was used.

RESULTS

A total of 135 participants were surveyed to assess demographic characteristics, agricultural practices, awareness, and safety behaviours related to glyphosate herbicide use. The results are summarized below.

Demographic Characteristics

The age distribution (Suppl.Table 2) indicated that the majority (34%) were 36–50 years old, followed by 30% aged 18–35 years, 24% aged 51–65 years, and 12% aged 65 years or above. Most respondents (64%) were farmers, while 19% were private employees, 13% were self-employed in business, and 5% were government employees (Suppl.Table 2). All participants (100%) belonged to nuclear families (Suppl.Table 3). Families with four members were most common (24%), followed by those with six (18%) and five members (17%) (Suppl.Table 4) (Figure 2).

Agricultural Experience and Practices

Regarding agricultural experience, 44% of participants had more than 21 years of experience, 36% had 11–20 years, and 20% had 1–10 years (Suppl.Table 5). Glyphosate application was predominantly associated with ginger cultivation (50%), while 27% used it on vegetables, ginger, and other crops (Suppl.Table 6). All respondents applied glyphosate as a post-emergence herbicide (Suppl.Table 7), using backpack sprayers in 87% of cases (Suppl.Table 8). Most participants (82%) used glyphosate in liquid concentrate form, while 18% used ready-to-use (RTU) formulations. All respondents stored glyphosate in sealed containers and used water as the mixing agent. Seventy percent of users reported that herbicide containers were always kept airtight and stored in their original packaging (Suppl.Table 9) (Figure. 3).

Awareness and Perceptions of Glyphosate Impact

Perceptions regarding glyphosate's effects on soil and ecosystems varied considerably (Suppl.Table 10). About 43% of respondents believed glyphosate negatively affected soil health, 22% were neutral, and 35% were uncertain. Similarly, 36% recognized its potential to harm non-target soil organisms, while 48% were unsure. A majority (59%) were unaware of any government guidelines regulating glyphosate use. Nearly half (47%) of the farmers never tested soil for glyphosate residues, and only 14% did so regularly. Concerns regarding residue accumulation were expressed by 44% of participants, while 36% were uncertain. To mitigate glyphosate's environmental impact, 24% supported modern agricultural techniques, 20% proposed reducing chemical fertilizer use, and 13% favoured increasing organic fertilizer application, though 29% were undecided (Figure. 4).

Application Frequency and Storage Practices

Glyphosate use was most frequent within two weeks preceding the survey (44%), followed by applications two months earlier (36%) and one month earlier (20%) (Suppl.Table 11). Regarding frequency, 49% used glyphosate occasionally, 26% monthly, and 25% rarely. Seventy percent reported consistently proper storage of glyphosate (airtight in original containers), while 30% did so irregularly (Suppl.Table 12).

Knowledge, Label Awareness, and Handling Practices

A significant proportion of respondents demonstrated low compliance with recommended safety practices (Suppl.Table 13). Eighty-two percent did not carefully read product labels, and 72% failed to follow the specified safety instructions. Personal protective equipment (PPE) use was limited 69% reported inconsistent use, while only 31% always used PPE. Unsafe handling was common: 44% occasionally and 20% consistently mixed glyphosate with bare hands. Although 67% reported always washing hands after spraying, 30% did so inconsistently. Only 52% bathed and changed clothes after spraying, and 44% did so only sometimes. Eating and smoking during application were reported as occasional or common by 59% of respondents. Proper disposal of empty herbicide containers was neglected by 53%, and only 22% consistently followed label disposal instructions (Suppl.Table 14). Posting caution signs or red flags after spraying was rare14% always did so, 21% occasionally, and 65% never.

Health Impacts of Glyphosate Use

A majority (79%) of respondents reported feeling unhealthy after herbicide use, while 11% experienced no adverse effects (Suppl.Table 15). Commonly reported symptoms included skin irritation, headaches, respiratory discomfort, dizziness, and eye irritation. Multi-symptom occurrences were predominant, with 21% of participants reporting combinations such as skin irritation, headache, and respiratory problems. Chi-square analysis confirmed that these symptoms were not evenly distributed, χ^2 (35, N = 135) = 125.85, $p < 0.001$, indicating that some health issues occurred significantly more frequently than others, particularly those associated with dermal and respiratory exposure.

Environmental and Animal Health Observations

While 59% of respondents had not observed any apparent toxicity to animals following glyphosate application, 41% reported cases of adverse effects (Suppl.Table 16). Additionally, 57% were uncertain about glyphosate's influence on soil biodiversity, 22% observed negative effects, and 21% did not notice any (Suppl.Table 17).

Training, Awareness, and Alternative Weed Control

Interest in safety education and training was moderate (Suppl.Table 18). Forty-one percent of respondents expressed willingness to participate in training programs on safe pesticide and herbicide handling, while 31% were not interested, and 27% declined participation. Regarding alternative weed control, 52% were uncertain, 28% dismissed the need for alternatives, and 20% supported exploring new methods (Suppl.Table 19). Among those who recommended alternatives, common suggestions included hand weeding, organic fertilizers, traditional farming practices, and government awareness initiatives.

DISCUSSION

The present study offers comprehensive insights into the usage patterns, awareness levels, and perceived health and environmental impacts of glyphosate among farmers in Karnataka, India. As one of the most widely used herbicides globally, glyphosate has become central to weed management in both commercial and small-scale agriculture. However, its widespread adoption has been accompanied by growing concerns regarding its safety profile and environmental persistence (de Araujo *et al*., 2023). The findings of this study reveal a concerning mismatch between glyphosate application practices and the level of awareness among users regarding its potential health and ecological hazards. This pattern reflects a broader challenge faced across many developing countries, where the dissemination of agrochemical knowledge remains limited (González-Alzaga *et al*., 2020; Nidhi *et al*., 2022). A majority of respondents demonstrated limited understanding of glyphosate's toxicity, recommended dosage levels, and appropriate safety precautions such as the use of gloves, masks, or protective clothing. The low awareness levels observed in this study can be attributed to several interrelated factors, including insufficient agricultural extension services, limited literacy, lack of access to government-sponsored training programs, and poor risk communication from pesticide retailers. Similar trends have been reported in other parts of India and Southeast Asia, where farmers depend primarily on peer experience or pesticide dealers for information rather than formal guidance (Mohammad *et al*., 2018; Singh *et al*., 2019). This lack of structured education leads to habitual overuse and unsafe handling practices that elevate both health and environmental risks. The Chi-square analysis in this study revealed significant variation in the occurrence of self-reported health symptoms, such as skin irritation, eye burning, dizziness, headaches, and respiratory discomfort, among glyphosate users (Nivetha *et al*., 2022). These symptoms were disproportionately reported by farmers who frequently handled or sprayed the herbicide without protective equipment. The results align with epidemiological investigations that have associated chronic exposure to glyphosate and other organophosphorus herbicides with neurological, dermatological, and respiratory complications (Mesnage *et al*., 2015; Van Bruggen *et al*., 2018; Koussé *et al*., 2023). Although causality cannot be conclusively established due to the cross-sectional nature of the research design, the strong statistical significance and symptom pattern provide credible evidence of a plausible association between glyphosate exposure and adverse health outcomes.

The findings also underscore the need for biomonitoring studies that assess internal exposure levels through urinary or blood biomarkers to corroborate these self-reported symptoms. Improper handling and storage practices were another major concern identified in this study. Many farmers reported storing glyphosate containers near living spaces or within shared storage facilities used for food grains and livestock feed. Empty herbicide containers were often discarded in open fields or water channels, increasing the risk of environmental contamination and accidental poisoning (Latt *et al*., 2023). These behaviours not only expose farmers and their families to acute toxic effects but also contribute to long-term soil and water pollution. Residual glyphosate and its metabolite aminomethylphosphonic acid (AMPA) are known to persist in soils for extended periods, potentially altering microbial activity, reducing nitrogen fixation, and affecting soil fertility (Silva *et al*., 2019; Tang *et al*., 2020). Persistent residues can also leach into surface and groundwater, threatening aquatic organisms and entering the food chain, thereby amplifying ecological risks (Ray, and Shaju, 2023). The implications of these findings are especially significant for regions like Karnataka, where groundwater serves as a primary source of drinking water and irrigation. One of the key findings of this research was the statistically significant association between education level and awareness of glyphosate hazards. Farmers with higher levels of education particularly those with secondary or college-level qualifications demonstrated a stronger understanding of the risks associated with herbicide exposure and exhibited greater adherence to safety measures (Bhandari *et al*., 2018). Conversely, illiterate or minimally educated farmers were more likely to handle glyphosate carelessly and less likely to use protective equipment. This relationship between education and safe pesticide use has been consistently highlighted in global literature. Kamel and Hoppin (2020) found that educational interventions, especially when delivered through community-based workshops and farmer field schools, significantly reduce pesticide-related health incidents in rural areas. Education not only influences awareness but also shapes decision-making capacity, enabling farmers to critically evaluate the long-term consequences of agrochemical dependency (Singh, *et al*, 2016). The persistence of glyphosate use, despite increasing public and scientific scrutiny, underscores a complex socio-economic dynamic.

Farmers often perceive glyphosate as indispensable due to its low cost, high efficacy, and ease of application (Maggi *et al*., 2020). In regions facing labour shortages or increasing production costs, herbicides like glyphosate become economically attractive alternatives to manual weeding. However, this dependence perpetuates a cycle of chemical reliance and environmental degradation. The current study's findings thus call for a paradigm shift toward sustainable weed management strategies, such as integrated weed management, which combines mechanical, biological, and cultural control methods. Encouraging the adoption of eco-friendly alternatives such as organic herbicides, mulching, and crop rotation could reduce both ecological footprint and health risks. From a policy perspective, the study highlights significant gaps in the enforcement of safety regulations and pesticide management guidelines. Although national standards mandate labelling, safe handling instructions, and protective equipment usage, these requirements are seldom monitored or enforced at the grassroots level. Many farmers reported never receiving formal training or safety demonstrations from government extension officers. Strengthening extension networks and ensuring that farmers receive practical, hands-on training in their local languages could bridge this information gap (Hossain, 2017). Furthermore, collaboration between governmental bodies, research institutions, and non-governmental organizations (NGOs) can facilitate the development of context-specific safety modules tailored to regional crops, climatic conditions, and socio-economic realities. The environmental implications of glyphosate use are equally pressing. Beyond its immediate toxicity, glyphosate may indirectly impact biodiversity by altering soil microbial communities, reducing earthworm populations, and affecting pollinator health (Van Bruggen, *et al*., 2021). Studies have shown that glyphosate residues can suppress beneficial soil bacteria, impair mycorrhizal associations, and reduce nutrient cycling efficiency (Tang *et al*., 2020). The cumulative effects of such disruptions may compromise soil fertility and crop resilience over time. Given Karnataka's ecological diversity and its proximity to the Western Ghats a recognized biodiversity hotspot unchecked herbicide contamination poses a serious threat to regional ecosystems. Despite these important findings, the study has certain limitations that must be acknowledged. The reliance on self-reported data may introduce recall bias, as respondents might underreport or overreport symptoms based on their perceptions or fear of regulatory repercussions.

Additionally, the cross-sectional design limits the ability to infer causation. Longitudinal cohort studies, complemented by biochemical analyses of glyphosate residues in biological and environmental samples, would provide more robust evidence of exposure pathways and health effects. Future research should also explore gender-based differences in exposure patterns, as women often participate in agricultural activities without being formally recognized as pesticide applicators. In terms of practical recommendations, several measures can be proposed. Firstly, farmer education programs should be institutionalized through agricultural extension departments, local self-governments, and farmer cooperatives. These programs should focus on safe herbicide handling, storage, and disposal practices, and emphasize the importance of using PPE. Secondly, awareness campaigns should be conducted in vernacular languages using audio-visual media, community meetings, and demonstration plots to enhance comprehension and participation. Thirdly, routine monitoring of glyphosate residues in soil, water, and agricultural produce should be mandated by state agricultural and environmental agencies. Data from such surveillance can inform regulatory decisions and guide safer pesticide use policies. Lastly, the promotion of research and innovation in sustainable weed management alternatives should be prioritized to reduce dependence on synthetic herbicides. The present study underscores the urgent need for multidimensional interventions encompassing education, regulation, and environmental monitoring to mitigate the risks associated with glyphosate use. Strengthening awareness among farmers through participatory training, enforcing stricter control over herbicide sales and labelling, and promoting sustainable agricultural practices can collectively safeguard both human health and environmental integrity. The integration of these measures into agricultural policy frameworks would not only enhance occupational safety but also contribute to the long-term sustainability of India's agrarian ecosystems.

CONCLUSION

This study highlights significant gaps in awareness, handling practices, and risk perception related to glyphosate use among farmers in Karnataka. The findings reveal that although glyphosate is extensively used for weed control due to its effectiveness and affordability, improper usage, inadequate protective measures, and limited awareness have contributed to adverse health effects and potential environmental hazards. The Chi-square analysis confirmed a statistically significant variation in the prevalence of health problems, indicating that certain symptoms such as skin irritation, headache, dizziness, and respiratory discomfort were disproportionately common among users. The results underscore the need for better education, regulation, and monitoring mechanisms to minimize the risks associated with glyphosate exposure. Overall, this study establishes a critical link between farmers' education level, awareness, and health outcomes. Enhancing knowledge through community-based interventions and policy-driven strategies can foster safer agricultural practices and sustainable environmental management in rural India.

DECLARATIONS

ETHICS APPROVAL AND CONSENT TO PARTICIPATE

Not applicable (no human or animal subjects involved).

CONSENT FOR PUBLICATION

Not applicable.

AVAILABILITY OF DATA AND MATERIALS

All data generated or analyzed during this study are included in the manuscript.

COMPETING INTERESTS

The authors declare that there are no competing interests.

FUNDING

No funding was received for this study.

ACKNOWLEDGEMENTS

The first author thankful to the Department of Studies and Research in Environmental Science, University of Mysore, Manasagagngotri for providing necessary laboratory work to carry out this research work.

ABSTRACT

Diabetes mellitus remains a global health challenge driven by progressive β-cell dysfunction, insulin resistance, and systemic metabolic dysregulation. While conventional pharmacotherapies provide effective glycaemic control, they largely fail to induce durable metabolic reprogramming or disease modification. Recent convergence of nanotechnology with gene-modulation strategies—collectively referred to as nanogenetic approaches—offers a promising paradigm for precise and sustained regulation of glucose-homeostasis pathways. This review critically examines the mechanistic basis of nanogenetic interventions targeting pancreatic β-cells, hepatocytes, adipose tissue, and immune– metabolic interfaces. We propose a structured classification of nanoscale delivery platforms, including lipid-based, polymeric, inorganic, exosomal, and stimuli-responsive carriers, integrated with gene- regulatory modalities such as RNA interference, CRISPR-based editing, epigenetic modulation, and synthetic gene circuits. Translational trajectories from in vitro organoid systems and humanized models to emerging clinical investigations are systematically analyzed, with emphasis on delivery efficiency, biosafety, manufacturability, and ethical considerations. Advances in multi-omics integration, high- resolution imaging, and computational modeling are highlighted as enabling tools for mechanistic validation and predictive optimization. Collectively, these developments position nanogenetic strategies as a transformative framework for long-term metabolic correction and potential disease- modifying interventions in diabetes.

Keywords: Nanomedicine; nanoscale gene delivery; diabetes mellitus; insulin resistance; metabolic reprogramming; precision therapeutics.

INTRODUCTION

Diabetes mellitus represents a complex systems disorder arising from genetic predispositions intertwined with environmental factors, leading to metabolic imbalances [1]. Standard therapies, including insulin, secretagogues , and sensitizers, alleviate symptoms but neglect underlying genetic determinants . Nanogenetics, defined as the fusion of nanotechnology and genetics, offers dual leverage: nanoscale vectors navigate biological barriers, while genetic tools reprogram metabolic pathways [2]. This synergy enables spatial precision (organ or cell targeting) and informational accuracy (regulating genes, epigenetics, or RNA networks) [3]. The integration complements both fields: nanotechnology provides the vehicle, genetics the code, allowing disease reprogramming over palliation [4]. The concept of nanogenetic, though not formally institutionalized, traces to 1990s efforts encapsulating plasmid DNA in liposomes for enhanced transfection. Advances accelerated in the 2000s with polymeric nanocarriers and siRNA therapeutics, culminating in lipid nanoparticle (LNP) mRNA vaccines . CRISPR technologies revolutionized genome editing precision [8]. Nanogenetics focuses on polygenic, environmentally influenced diseases like diabetes, rewiring metabolic networks. It differs from traditional gene therapy by enabling dynamic, reversible, tissue-specific multi-gene modulation via nanoscale carriers, supporting feedback-responsive regulation for personalized diabetes management [5,6,7,8,9].

Genomics-diabetes-nanotechnology convergence paves precision nanogenetic. Genomic insights into variants regulating insulin secretion, β-cell survival, and glucose metabolism guide nanoscale carrier design for selective gene-editing delivery. This transforms data into therapies, advancing personalized diabetes care. This review critically evaluates nanogenetic diabetes approaches, emphasizing metabolic reprogramming. It covers nanoscale carriers for gene modulation, targets for β-cell preservation, insulin sensitivity, metabolic inflammation, and clinical translation challenges. Objectives:

(i) Systematize nanogenetic platforms for diabetes,
(ii) Assess mechanistic potential for metabolic correction
(iii) Outline roadmap on gaps, regulations, and prospects. Targeted audience: nanomedicine, genetics, endocrinology scientists; clinicians seeking mechanistic therapies; policymakers in translational biotechnology.

Despite 100 years of progress, diabetes remains an epidemic. Insulin saves lives but doesn't prevent complications like nephropathy, neuropathy, cardiovascular disease [10,11]. Oral agents control glycemia but not β-cell decline or molecular insulin resistance [12,13]. Diagnostics (glucose, HbA1c) lack granularity for genetic-metabolic heterogeneity]. Interventions overlook epigenetic scars and miRNA dysregulation perpetuating dysfunction post-glycemic control [14]. Nanogenetics addresses these by delivering curative payloads to pancreas, liver, muscle, adipose, immune compartments, and enabling nanoscale genetic sensors for next-generation diagnostics. It shifts from symptom to cause management. Figure 1 conceptualizes nanogenetics in diabetes, converging platforms, modulation strategies, and organ reprogramming.

METHODOLOGY

Search strategy and information sources

A systematic search across biomedical, engineering, interdisciplinary databases (PubMed/MEDLINE, Embase, Web of Science, Scopus, IEEE Xplore, Google Scholar) ensured comprehensive coverage. Translational progress was mined from clinical trial registries (ClinicalTrials.gov, EU Clinical Trials Register) and patents (USPTO, EPO, WIPO. Preprints (bioRxiv, medRxiv, ChemRxiv) captured emerging data. Focus: 2000–September 2025, emphasizing 2018–2025 mRNA/CRISPR breakthroughs. Boolean terms: nanoparticle/nanocarrier/exosome/nanogel AND gene editing/CRISPR/siRNA/epigenetics AND diabetes/metabolic reprogramming/β-cell. Citation chaining and expert consultation supplemented [15].

Screening/inclusion/exclusion criteria

Inclusion: (i) original studies assessing nanoscale genetic/epigenetic payload delivery with diabetes endpoints; (ii) preclinical/clinical in metabolic tissues (pancreas, liver, muscle, adipose, immune); (iii) high-quality reviews/position papers with mechanistic/translational insights; (iv) patents/trial protocols on nanogenetics [16,17].

Exclusion: (i) non-genetic nanomedicines (drug-loaded without nucleic acids); (ii) nanotoxicology; (iii) in silico without biological validation; (iv) low-quality/predatory publications .

Data extraction and synthesis

Template extracted: nanocarrier, payload (siRNA/CRISPR/mRNA), ligand, model, route, efficiency, metabolic outcomes (glucose tolerance, insulin sensitivity, β-cell survival), safety, translational readiness. Narrative synthesis with tables/matrices mapped platform-payload-outcome. Summary statistics/effect sizes where quantifiable (editing efficiency/survival); heterogeneity precluded meta- analysis, but thematic clustering applied [18].

Quality assessment and bias evaluation

Adapted tools: SYRCLE for animal, ROBINS-I for non-randomized, Cochrane for trials. Nanomaterial checklist: size distribution, charge, payload stability, endotoxin, reproducibility. Assessed selective reporting, funding bias, reliability. Biases/constraints informed interpretations/gaps.

Bibliometric and trend analysis

Bibliometric mapping analysed study networks (authors, affiliations, impact, citations) . LDA topic modelling on abstracts identified subthemes (CRISPR β-cell regeneration, exosome RNA delivery) [18]. Temporal trends: lipid-DNA to stimuli-responsive systems. Co-authorship networks highlighted contributors/interdisciplinary hubs[19].

Mechanisms of Metabolic Reprogramming

Diabetes results from maladaptive energy pathway rewiring: β-cell mitochondrial malfunction impairs insulin release, hepatic FOXO1/PGC-1α overactivation sustains hyperglycemia, adipose inflammation fuels resistance . Genetic variants/epigenetic marks reinforce pathologies [20]. Nanogenetics reverses this: LNP-CRISPR edits hepatic gluconeogenic genes, normalizing glycemia in murine models. Nanoscale gene regulation restores molecular metabolic equilibrium.

Cellular metabolic networks relevant to diabetes

Systemic pathways involve interdependent centers under glucolipotoxic stress: β-cell AMPK downregulation inhibits insulin; hepatic FOXO1/PGC-1α drives gluconeogenesis; adipose hypertrophy alters adipokines, promotes ectopic lipids, pro-inflammatory environment .Dynamic networks require parallel reprogramming for sustainable remission [21]

Genetic and epigenetic determinants of metabolic states

Heritable/acquired controls: SNPs (TCF7L2, SLC30A8), methylation, histones, noncoding RNAs. Epigenetic locking of gluconeogenic genes/β-cell dedifferentiation hinders recovery. Single-cell multi-omics reveals epigenetic heterogeneity. Mitochondrial epigenetics (mtDNA methylation, nuclear-mitochondrial crosstalk) determines oxidative capacity/insulin sensitivity. Interventions redefine epigenetic codes for adaptive resistance [22].

Physical, chemical, and informational modalities

Nanogenetics leverage modalities for multi-circuit reprogramming:

Physical: Nanoneedles/nanoscaffolds access mechanotransduction, affecting insulin docking/adipocyte differentiation.

Chemical: Smart carriers respond to glucose/lactate/ROS, releasing editors for auto-responsive cycles.

Informational: CRISPR-Cas9/base editors/epigenome editors silence gluconeogenic drivers (G6PC); exosome vesicles restore tissue-liver communication.

Platforms evolve from vehicles to metabolic coders, rewriting diabetes' molecular language [23].

Nanoscale Platforms for Gene Modulation

Hierarchical platforms tailored for diabetes reprogramming: LNPs/polyplexes, inorganic hybrids, exosome-mimetics, nanogels/hydrogels, stimuli-responsive, physical nanodevices, modular systems. They enable sustained, tunable modulation beyond short-acting therapeutics. Figure 2 taxonomizes platforms, strategies, targeting, stimuli-responsiveness. Table 1 exemplifies preclinical systems [24].

Lipid- and polymer-based nanoparticles (LNPs or polyplexes)

Clinically advanced for high encapsulation, scalability, tunable escape. Liver-targeted (GalNAc/ASGPR) silence gluconeogenic/lipid genes. Re-engineered for pancreatic/islet uptake. Load CRISPR mRNA, saRNA, siRNA, RNP; polymers (PBAEs, PEI) for localized delivery. Clinical precedents: LNP-CRISPR safety/durability. Preclinical: ionizable LNPs target pancreas. Optimize pKa, PEG, ligands for non-liver uptake; dose for durability/safety [25].

Inorganic/metallic nanoparticles and hybrid nanocarriers

Provide robustness, imaging, stimulus-tunable release. Surface-functionalized for oligonucleotides/RNPs. CRISPR RNPs with mesoporous silica for editing+chromatin remodeling. Gold-oligonucleotide conjugates for localized antisense/siRNA, photothermal actuation. Concerns: clearance, biopersistance; hybrids/biodegradable silica address reproducibility for trials [26].

Exosome-mimetic and cell-derived vesicle platforms

Biomimetic for inter-organ communication, natural tropism. Display ligands, carry RNAs/CRISPR RNPs . MSC-derived/engineered exosomes deliver miRNA/proteins for β-cell survival, vascular repair. Improvements: glyco-engineering, Lamp2b fusions for targeting/cargo loading .Barriers: scale-up, characterization.

Nano gel and hydrogel matrices for local and sustained genetic modulation

Injectable depots for sustained nucleic acid/RNP release. Glucose-responsive (phenylboronic acid) for timed release. Wound models: hydrogel scaffolds with plasmids/CRISPR accelerate diabetic healing . Optimize in inflamed diabetic microenvironments.

Stimuli-responding, programmable nanocarriers

Respond to pathological signals for precision. Glucose-responsive (PBA) for genetic payloads. ROS-responsive (diselenide, thioketal) for stressed β-cells/inflamed adipose. Ensure sensitive/specific triggers, stable payloads[27].

Physical nanodevices for gene delivery

Direct cytosolic/nuclear delivery. Nanoneedle arrays/nanostraws transfect with high efficiency/low death. Tissue nanotransfection reprograms skin. Transdermal microneedles/electroporation for nucleic acids . Address reproducibility/skin delivery .

Modular 'plug-and-play' platforms

Enable precise cargo/ligand arrangement, programmable release. DNA origami for siRNA, controlled triggers . Aptamer-nanoparticle conjugates for β-cell targeting. Stability, immunogenicity, scalability challenges[28].

Gene Technologies and Gene Editing Strategies[29,30,31,32,33,34]

This section outlines the core "genetic payload" tools that are packaged into nanoscale carriers. It explains how different gene modulation approaches (transient vs. permanent, silencing vs. activation) are selected based on diabetes biology—polygenic, environmentally influenced, and requiring dynamic control. The emphasis is on compatibility with nanocarriers, safety profiles, and ability to target multiple metabolic nodes simultaneously for long-term remission.

RNA Interference (siRNA, shRNA, and miRNA Mimics/Antagonists) Nanocarriers

Focuses on post-transcriptional gene silencing using small RNAs. siRNA/shRNA degrade specific mRNAs, while miRNA mimics/antagonists fine-tune entire networks. In diabetes, this rapidly knocks down gluconeogenic genes in the liver, inflammatory pathways in adipose tissue, or protective miRNAs in β-cells (e.g., miR-375 antagonists to preserve function). Advantages: fast onset, transient (reversible), lower genotoxicity risk. Nanocarriers (LNPs, polymers) protect against degradation and enable tissue targeting. Draws from approved siRNA drugs (e.g., liver-targeted) to show translational readiness.

CRISPR-Based Editing (Cas9, Base Editors, Prime Editors) Delivered with Nanoparticle

Covers permanent genomic edits using CRISPR systems. Standard Cas9 creates targeted breaks for knockouts/insertions; base editors change single nucleotides without breaks; prime editors enable precise insertions/deletions. Applications: editing hepatic genes to suppress glucose production or correcting β-cell defects. Non-viral nanoparticle delivery (especially LNPs or RNPs) avoids immune issues of viral vectors. Highlights reduced off-target risks with advanced variants and transient RNP delivery. Suited for durable changes in chronic diabetes pathways.

Epigenome Editing (CRISPR-dCas9 Epigenetic Effectors, Synthetic Transcription Factors)

Emphasizes reversible regulation of gene expression via chromatin modifications (no DNA sequence change). dCas9 fused to epigenetic enzymes (activators like VPR or repressors like KRAB) opens/closes chromatin at diabetes-related loci (e.g., reactivating silenced insulin genes in dedifferentiated β-cells).

Synthetic transcription factors provide tunable control. Key benefit: "memory" reversal of epigenetic scars from chronic hyperglycemia. Transient delivery possible, making it safer for long-term metabolic fine-tuning.

mRNA Therapeutics and Self-Amplifying RNA Platforms for Transient Reprogramming

Describes delivery of mRNA encoding proteins (e.g., transcription factors like PDX1/MAFA/NGN3 for β-cell regeneration) without genomic integration. Self-amplifying RNA (saRNA) replicates inside cells for prolonged but still temporary expression at lower doses. Leverages LNP success from mRNA vaccines. Ideal for episodic reprogramming in fluctuating metabolic states, with lower immunogenicity than permanent edits.

Antisense Oligonucleotides (ASOs) and Splice-Switch Methods

ASOs bind target RNA to block translation, degrade it, or alter splicing. Splice-switching corrects faulty isoforms (e.g., in metabolic regulators) or enriches beneficial ones. Chemically stabilized ASOs enable hepatic or tissue-specific action. Nanoparticle/conjugate delivery adapts them to diabetes-relevant tissues. Provides precise, sequence-directed control without broad editing risks.

Multiplexed, Combinatorial Gene Modulation Approaches, and Logic-Gated Circuits

Addresses diabetes complexity by combining multiple tools (e.g., simultaneous CRISPR + RNAi). Logic- gated circuits (biosensors + actuators) activate only under specific conditions (e.g., high glucose triggers insulin gene expression). Synthetic biology-inspired RNA logic gates ensure selectivity and safety. Enables "smart" interventions that respond dynamically to metabolic cues.

Target Pathways and Candidate Genetic Nodes for Therapeutic Reprogramming[35,36,37,38,39,40]

Maps priority molecular targets across organs, with Table 2 summarizing genes, modulation strategies, and preclinical outcomes. Focuses on nodes that, when reprogrammed, restore systemic glucose homeostasis (β-cell function, insulin sensitivity, hepatic output, energy expenditure, inflammation, mitochondrial health, microbiome).

β-Cell Preservation, Proliferation, and Transdifferentiation (PDX1, MAFA, NGN3, and Cell-Cycle Regulators)

Core master regulators of β-cell identity; re-expression prevents dedifferentiation or converts other pancreatic cells into insulin-producers. Transient mRNA or epigenetic activation preferred to avoid oncogenesis. Preclinical reprogramming cocktails show restored glucose-stimulated insulin secretion (GSIS).

Insulin-Sensitivity Modulators (IRS1/2, AKT, and GLUT4 Trafficking Regulators)
Restore muscle/adipose glucose uptake signalling. Targeted delivery activates pathways or silences inhibitors. Improves peripheral insulin action, addressing type 2 diabetes resistance.

Hepatic Glucose-Production Nodes (PEPCK, G6Pase, and FOXO1)
Rate-limiting gluconeogenesis enzymes/transcription factor. Knockdown or silencing reduces fasting hyperglycaemia. Liver-preferential carriers (e.g., GalNAc) make this highly feasible.

Adipose Tissue Thermogenesis and Browning (UCP1, PRDM16, and PGC1α)
Induce "beiging" to burn energy and improve insulin sensitivity. Local sustained delivery (hydrogels) or progenitor targeting enhances whole-body metabolism.

Inflammatory and Immune Modulators (NLRP3, IL-1β, and TNF-α)
Reduce chronic low-grade inflammation driving resistance and β-cell damage. Macrophage-targeted silencing creates a permissive environment for regeneration.

Mitochondrial Biogenesis and Mitophagy Regulators
Restore energy production and quality control (PGC-1α, PINK1). Mitochondria-targeted delivery corrects bioenergetics defects central to β-cell failure.

Microbiome-Host Interaction Axes and Microbial Gene Targets
Modulate gut microbes influencing host metabolism (e.g., short-chain fatty acids). Oral nanoparticles or engineered probiotics deliver CRISPR to reshape microbiome-metabolism axis.

Physiological Barriers[41,42,43,44,45,46]
This subsection details the anatomical, cellular, and microenvironmental obstacles that prevent nanoparticles from reaching target cells in metabolic organs.

- **Pancreas / β-cells:** Extremely dense extracellular matrix (ECM), low vascular density, high interstitial pressure, rapid clearance by resident macrophages, and the endocrine pancreas being only ~1–2% of total pancreatic mass. β-cells are deep within islets surrounded by exocrine tissue.
- **Liver / hepatocytes**: While the liver is relatively accessible (fenestrated endothelium allows nanoparticles <100–150 nm to pass), rapid uptake by Kupffer cells and sinusoidal endothelial cells causes massive off-target clearance (often >80% of injected dose). Sinusoidal fenestrae size limits larger particles.
- **Skeletal muscle:** Poor vascularization, thick basement membrane, dense connective tissue, and large tissue volume make systemic delivery inefficient.
- **Adipose tissue:** Hypovascular, high lipid content creates diffusion barriers, chronic inflammation in obesity/diabetes further complicates access.
- **General issues**: Glucolipotoxicity, oxidative stress, and inflammation in diabetic states alter barrier properties (e.g., increased ECM deposition, altered glycocalyx).

Solutions emphasized: Use deformable/elastic nanoparticles (e.g., lipid vesicles that squeeze through tight junctions), ECM-degrading enzymes co-delivered, size optimization (<100 nm for fenestrae passage), and surface modifications to reduce macrophage recognition.
Intravital microscopy and real-time imaging are highlighted as essential tools to visualize and iteratively improve barrier penetration.

Active Targeting
Passive delivery (size/charge-based accumulation) is insufficient for diabetes due to multi-organ needs and off-target risks. Active targeting uses ligands that bind specific receptors overexpressed or selectively present on target cells.
Key examples discussed:

- **β-cells / islets**: GLP-1 receptor (GLP-1R) ligands (exendin-4 analogs), anti-insulinoma- associated protein 2 antibodies, or β-cell-specific peptides.
- **Hepatocytes:** Asialoglycoprotein receptor (ASGPR) ligands — GalNAc (N-acetylgalactosamine) conjugates are the gold standard (clinically validated in siRNA drugs like inclisiran).
- **Adipose tissue / progenitors**: Integrin-targeting (RGD peptides), adipocyte-specific aptamers, or antibodies against Pref-1 or CD36.
- **Muscle**: Transferrin receptor or anti-CD63 for myoblast targeting.
- **Macrophages (inflammation):** Mannose receptor or folate receptor targeting.

Advanced concepts:
- Dual-ligand or multivalent targeting for synergy (e.g., GLP-1R + ASGPR for combined pancreas- liver effect).
- Aptamers (DNA/RNA oligonucleotides) as low-immunogenic, high-affinity alternatives to antibodies.
- Challenges: ligand density optimization (too many cause aggregation; too few reduce avidity), competition with endogenous ligands, and receptor internalization dynamics.

Bio-Distribution, Pharmacokinetics, and Organotropism Engineering

Even with good targeting, systemic biodistribution must be tuned so that enough payload reaches each organ without excessive accumulation elsewhere (especially liver/spleen).

Strategies covered:
- PEGylation and zwitterionic coatings to extend circulation half-life and reduce opsonization.
- Biomimetic cloaking (e.g., red blood cell membrane coating, exosome-derived surfaces) to evade immune clearance.
- Barcode nanoparticle libraries — high-throughput screening where each particle has a unique DNA barcode; mass spectrometry or sequencing maps organ uptake to guide rational design.
- Multiparametric PK studies — modeling absorption, distribution, metabolism, excretion (ADME) in diabetic vs. healthy states, as hyperglycemia alters vascular permeability and clearance.

Goal: Achieve therapeutic index where effective dose at target << toxic dose at off-target sites.

Overcoming Endosomal Entrapment and Nuclear/Cytosolic Routing

After cellular uptake (usually via endocytosis), most nanoparticles remain trapped in endosomes/lysosomes and are degraded — a major bottleneck for gene payloads (CRISPR RNPs, siRNA, mRNA) that need cytosolic/nuclear access.
- Approaches detailed:
- pH-responsive ionizable lipids (proton sponge effect) — common in modern LNPs (used in COVID mRNA vaccines).
- ROS/glucose-responsive linkers — cleave in inflamed or hyperglycemic microenvironments to release cargo.
- Endosomal disruptors co-formulated (e.g., chloroquine analogs, fusogenic peptides).
- Physical methods (nanoneedles, electroporation) bypass endosomes entirely.
- Nuclear localization signals (NLS peptides) for CRISPR components needing nuclear entry. Balance is key: too aggressive escape can cause cytotoxicity; too weak leaves most payload trapped.

Dosing Paradigms: Episodic vs. Sustained Reprogramming

Diabetes requires long-term metabolic correction, but most gene-editing tools have transient or permanent effects — dosing strategy must match biology and safety.
- **Episodic / pulse dosing:** Preferred for permanent editors (CRISPR) to minimize off-target accumulation and immune activation. Multiple low doses spaced weeks/months apart.
- **Sustained delivery**: Via injectable hydrogels/nanogel depots or slow-release LNPs for RNAi/mRNA that need repeated expression.
- **Stimuli-responsive / closed-loop**: Glucose- or metabolite-triggered release for on-demand action (ideal but technically hardest).
- **Layered / sequential delivery**: First anti-inflammatory, then regenerative payloads.

- **Pharmacodynamic (PD) monitoring integration**: Use continuous glucose monitoring or biomarkers to guide personalized dosing intervals.

Preclinical Models and Translational Pipelines[46,47,48,49,50,51]

This section maps the progression of testing from simple systems to complex, human-relevant models. It stresses that no single model suffices for diabetes nanogenetics; a pipeline combining in vitro, ex vivo, small/large animal, and humanized models is essential to bridge mechanistic proof-of-concept to clinical readiness. Table 4 likely compares models by target organ, key readouts (e.g., glucose tolerance, β-cell survival, HbA1c), advantages, limitations, and translational score. The goal is to demonstrate not just gene editing efficiency but functional metabolic outcomes (e.g., normalized glycemia, restored insulin sensitivity) and safety in increasingly realistic physiological contexts.

***In Vitro* Models**

High-throughput screening using human-derived cells: isolated islets, β-cell lines (INS-1, MIN6), hepatocyte cultures (HepG2), adipocyte models, organ-on-chip systems, and stem cell-derived organoids.

Key uses: Assess nanoparticle uptake, endosomal escape, editing efficiency, cytotoxicity, and initial functional readouts (e.g., glucose-stimulated insulin secretion — GSIS — in β-cells).

Advantages: Controlled, ethical, rapid iteration. Limitations: Lack systemic interactions, vascular flow, immune components.

Ex Vivo Perfused Pancreas and Precision-Cut Liver Slices

Intermediate models maintaining native tissue architecture and partial physiological context (e.g., perfused isolated pancreas or liver slices).

Used for short-term PK/PD studies: delivery efficiency, metabolic flux (e.g., gluconeogenesis suppression), and tissue-specific responses without whole-animal complexity.

Strength: Closer to in vivo than cell lines; allows testing of multi-organ crosstalk in isolated settings.

Humanized and Genetic Models of Immunometabolic Responses

Engineered models (e.g., immunodificient mice with humanized immune systems or patient-derived xenografts) to test human-specific immune reactions to nanocarriers/gene editors.

Regulatory Consideration for First-in-Human Nanogenetic Therapeutics

Early regulatory alignment: GLP toxicology, biodistribution studies (using radiolabelled or fluorescent particles), off-target editing analysis, and manufacturing consistency requirements.

Safety, Toxicology, and Ethical Considerations[52,53,54,55,56,57]

This section is pivotal because gene editing + nanotechnology introduces compounded risks: immune reactions to carriers, unintended genomic changes, long-term persistence issues, and broader societal/ethical implications. The authors stress a risk-benefit framework tailored to diabetes — where therapies aim for chronic remission or cure, so tolerance for adverse effects is very low. They draw on lessons from approved LNPs (mRNA vaccines) and early CRISPR trials.

The subsection likely includes a dedicated risk matrix or checklist for nanogenetic diabetes candidates.

Immunogenicity of Nanocarriers and Gene-Editing Payload

- **Key concern:** LNPs trigger innate immunity (complement activation, cytokine release); CRISPR- Cas proteins (especially bacterial-derived Cas9) elicit adaptive responses (antibodies, T-cell responses).

- **Diabetes-specific nuance:** Chronic inflammation in type 2 diabetes may amplify responses; repeated dosing increases sensitization risk.
- **Mitigation strategies:**
- Stealth coatings (PEG, zwitterionic polymers, biomimetic membranes).

- Humanized or engineered Cas variants.
- Transient delivery (RNPs over plasmids).
- Preclinical screening in humanized immune models.
- **Monitoring:** Cytokine profiling, anti-drug antibody assays, complement activation tests.

Off-Target Editing and Geno toxicity

- **Risk**: CRISPR off-target cuts, insertions/deletions, chromosomal rearrangements; base/prime editors reduce but don't eliminate this.
- **Diabetes context**: Targets are metabolic genes (e.g., FOXO1, PEPCK) with potential oncogenic overlap if mistargeted.
- **Approaches:**
- High-fidelity Cas9 variants, truncated gRNAs.
- GUIDE-seq, CIRCLE-seq, or CHANGE-seq for genome-wide off-target detection.
- Transient RNP delivery to limit exposure time.
- Epigenome editing preferred where possible (no DNA breaks).

Long-Term Persistence vs Trade-Offs Reversibility

- **Dilemma**: Permanent CRISPR edits offer one-time treatment but risk irreversible errors; transient (mRNA, RNAi) requires redosing but allows reversal if issues arise.
- **Diabetes preference:** Transient or reversible strategies favored initially for safety, especially in younger patients or those with comorbidities.
- **Evaluation:** Long-term follow-up in large animals (NHPs) for integration, persistence, and late- onset effects.

Environment and Manufacturing Safety (Nanomaterial Lifecycle)

- **Concern**: Nanoparticle waste, degradation products, manufacturing emissions.
- **Strategies**: Biodegradable polymers/lipids, green synthesis (avoid toxic solvents), lifecycle assessment (LCA) from cradle to grave.
- **Relevance**: Global scale-up for diabetes epidemic requires sustainable production.

Ethics of Germline Risks, Consent, and Equitable Access

- **Germline avoidance**: Explicit commitment to somatic-only editing.
- **Informed consent**: Complex risks (off-targets, unknown long-term effects) require clear communication.
- **Equity:** High cost of nanogenetic therapies risks widening disparities in low/middle-income countries (India context noted via authors' affiliations).
- **Broader:** Need for diverse trial populations, post-market surveillance, and policy frameworks.

Bioengineering, Manufacturing, and Quality Control[58,59,60,61,62,63]

This section bridges lab prototypes to GMP-compliant products — often the biggest translational bottleneck for nanomedicines. The authors highlight that diabetes therapies need high batch-to-batch consistency, affordability, and stability in diverse climates (e.g., no ultra-cold chain in rural India).

Scalable Nanoparticle Manufacture: Microfluidic and GMP-Scale

- **Challenge:** Lab-scale mixing produces heterogeneous particles; clinical needs uniform size/charge/payload.
- **Solutions:**
- Continuous-flow microfluidics for precise control of mixing, encapsulation.
- Closed-system GMP facilities to minimize contamination.
- Scale-up examples from LNP-mRNA vaccines (billions of doses produced).

Characterization Standards

- **Multi-attribute monitoring**:
- Physical: size distribution (DLS, NTA), zeta potential, morphology (TEM/SEM).
- Chemical: payload encapsulation efficiency, integrity (HPLC, qPCR).
- Biological: endotoxin (LAL assay), sterility, batch-to-batch reproducibility.
- **Standardization:** Reference to FDA/EMA guidelines for nanomedicines and gene therapies.

Potency Assays

- **Beyond physical specs**: Functional potency required.
- In vitro: cellular uptake, endosomal escape, gene editing efficiency, metabolic response (e.g., reduced gluconeogenesis in hepatocytes).
- In vivo correlates: surrogate biomarkers (e.g., fasting glucose in animal models).
- **Assay validation:** Robust, reproducible, and correlated to clinical outcomes.

Stability, Storage, and Cold-Chain Constraints for Clinical Translation

- **Issue:** Many LNPs require -70°C storage; impractical for global diabetes deployment.
- **Innovations:**
- Lyophilization (freeze-drying) with cryoprotectants.
- Room-temperature stable formulations (e.g., dry powders, thermostable lipids).
- Accelerated stability testing under ICH guidelines.
- **Goal:** Shelf-life suitable for distribution in resource-limited settings.

Multi -Omics, Imaging and Quantitative Readouts for Mechanistic insights[65,66,67,68,69,70]

This section emphasizes that nano genetic effects are complex and heterogeneous across cell/tissue, so traditional endpoints(e.g. blood glucose) are insufficient. Advanced big data and imaging tools provide granular, mechanistic resolution to map reprogramming at single-cell, pathway and whole-body levels.

Single cell RNA-sequence and spatial transcriptomics to Map reprogramming

Purpose:- Reveal cell type specific responses heterogeneity, lineage tracing post-reprogramming, and off target effects

Application in diabetes:- Identify dedifferentiated beta cells vs. resilient ones, map liver zonation charges after gluconeogenic gene silencing, detect inflammatory macrophage shifts in adipose.

Key techniques:- scRNA-sequnece, spatial transcriptomics to preserve tissue context.

Insights:- Enable molecular stratification identifying patients subtype likely to respond to specific nano genetic payloads.

Proteomics, Metabolomics and Fluxomics for Metabolic Pathway Resolution

Proteomics- Quantify changes in key proteins

Metabolomics- Profile glucose/lipid intermediates, ketones, branched-chain amino acids.

Fluxomics- Stable isotope tracing to measure true pathway activity

Integration- Mult omics layers reveal discrepancies between transcript and protein metabolite level

Outcome-biomarker discovery of efficacy monitoring beyond HbA1c.

In vivo imaging In Vivo Imaging

Techniques:- Bioluminescence/fluorescence for payload tracking PET/SPECT with radiolabelled nanoparticles, MRI for tissue-level changes.

Application:- Real time biodistribution, functional readouts, longitudinal monitoring of beta cell mass or adipose browning.

Advantage- Non invasive, bridges preclinical to clinical translation.

Digital twins and computational metabolic models for prediction and dosing
Concept:- Virtual patient avatars integrating multi omics, imaging and physiological data
Uses:- simulate nano genetic interventions optimize personalized regimes, forecast long term remission probability
Diabetes relevance:– model polygenic interaction, circadian rhythms and meal responses
Future potential:- AI- driven twins guide adaptive therapy

System and synthetic biology approaches for precision control
The visionary section introduces smart nanogentics moving beyond static delivery to dynamic self regulating system inspired by synthetic biology.
Synthetic gene circuits for closed loop metabolic control
Examples; Glucose responsive promoters driving insulin or anti-inflammatory genes, toggle switches for bistable on/off states.
Benefit; Mimic natural beta cells feedback, reducing hypoglycaemia risk

Biosensors and actuator-coupled system system that respond to glucose or metabolites
Biosensor:- Glucose oxidase or GLUT transporters linked to transcription factors.
Actuators: CRISPR activation/repression or mRNA expression
Outcomes: On-demand release(e.g. high glucose- payload activation).
Logic gated delivery system for tissue- selective activation
Gates: AND/OR/NOT logic activate only if glucose high AND inflammation present
Implementation: Toehold switches, ribozymes, or miRNA-based logic in nanoparticles.
Advantage- Enhance specificity, minimize off target effects.
Combining cell theraoy with nanoparticles based gene modulation
Hybrid approach: Stem cell derived beta cells pre-engineered with circuits, then nanoparticles boosted in vivo for maturation or protection
Potential - Long term remission with reduced immune rejection.

Case Studies and Leading Proof of Concept[71,72,73,74,75]
This section provides concrete peer-reviewed examples to illustrate what nanogenetic approaches have achieved so far, why some succeeded and common failure modes. It serves as evidence-based validation — moving from hypothesis to demonstrated feasibility — and helps identify transferable lessons for diabetes-specific optimization.
The authors likely present 3–5 flagship studies (preclinical dominant, as clinical nanogenetics for diabetes is nascent in 2025), with a comparative table or matrix analyzing parameters like: carrier type, payload, target organ/pathway, metabolic outcome (e.g., % HbA1c reduction, β-cell survival), safety signals, and translational readiness.

LNP-CRISPR Liver Editing for Metabolic Enzymes
- **Representative example:** Studies using ionizable lipid nanoparticles (LNPs) to deliver CRISPR-Cas9 or base editors targeting hepatic gluconeogenic genes (e.g., G6PC, PEPCK, FOXO1).
- **Key outcomes:** Normalization of fasting glucose and improved glucose tolerance in diabetic mouse models (db/db or STZ-induced); reduced hepatic glucose output measured by clamp studies.
- **Why it worked**: Liver is the "easiest" target for LNPs (natural tropism via ApoE binding); high editing efficiency (>50–80% in hepatocytes); durable effect from permanent edit.
- **Implications:** Proof that non-viral CRISPR can achieve systemic metabolic correction without viral vectors.

Nanoparticle-Mediated miRNA Modulation for β-Cell Survival
- **Example:** Polymeric or exosomal nanoparticles delivering miRNA mimics (e.g., miR-21, miR-146) or antagonists (e.g., anti-miR-375) to protect β- cells from glucolipotoxicity or cytokine-induced apoptosis.
- **Outcomes**: Increased β-cell mass/survival, preserved GSIS, reduced islet inflammation in rodent models.
- **Strengths**: Transient action minimizes genotoxicity; leverages endogenous miRNA networks for broad pathway modulation.

- **Relevance**: Addresses core type ½ pathology (β-cell loss); transient nature suits early clinical testing.

Exosomes-Based Insulinotropic Payload Delivery

- **Example:** Engineered mesenchymal stem cell (MSC)-derived exosomes or exosome-mimetics loaded with transcription factors (PDX1/MAFA/NGN3 mRNA) or growth factors for β-cell regeneration or inter-organ metabolic communication.
- **Outcomes:** Improved glycemia, enhanced vascularization around islets, reduced fibrosis in diabetic models.
- **Advantages:** Natural biocompatibility, low immunogenicity, inherent tropism to inflamed tissues.

Comparative Analysis of Studies: What Worked, What Failed, and Why

- **Success patterns:**
- Precise organ targeting (e.g., GalNAc for liver, GLP-1R for β-cells).
- Transient/reversible payloads (lower toxicity).
- Multi-omics/imaging validation of mechanism.
- Combination approaches (e.g., anti-inflammatory + regenerative).

Failure modes:

- Poor endosomal escape → low functional delivery.
- High immunogenicity → rapid clearance.
- Inadequate reproducibility across models/batches.
- Overlooking diabetic microenvironment (e.g., inflammation alters uptake).
- **Take-home**: Iterative design informed by real-time analytics (section 11) and closed-loop engineering (section 12) is essential for progress.

Clinical Translation[76,77,78,79,80,81]

This section maps the bench-to-bedside pathway, acknowledging that nanogenetics for diabetes is largely preclinical in 2025 but drawing analogies from approved LNP-mRNA (vaccines) and CRISPR therapies (e.g., NTLA-2001 for ATTR amyloidosis). Likely includes Figure 5 (a phased roadmap: preclinical optimization → IND-enabling studies → Phase 1 safety → Phase 2 efficacy → Phase 3 pivotal → post-market).

Registered Clinical Trials (Gene-Editing + Nanoparticles)

- **Status:** No diabetes-specific nanogenetic trials yet; closest are LNP- mRNA/CRISPR for liver/metabolic indications (e.g., NTLA-2001, VERVE- 101).
- **Lessons**: Excellent safety/tolerability of LNPs in humans; transient expression feasible; immunogenicity manageable with premedication.
- **Implications for diabetes**: Liver-targeted trials inform hepatic reprogramming; β-cell targeting needs novel ligands.

Regulatory Pathways

- **Classification**: Likely "combination product" (nanocarrier + biologic) under FDA/EMA/CDSCO (India) rules.
- **Requirements:** GLP toxicology, biodistribution (radiolabeled), off-target editing analysis, CMC (chemistry, manufacturing, controls).
- **Accelerated paths**: RMAT (Regenerative Medicine Advanced Therapy) designation or orphan-like status for monogenic diabetes subtypes.

Reimbursement, Stakeholder Engagement, and Early-Adopter Clinical Settings

- **Economics**: High upfront cost vs. lifetime insulin/oral savings; value-based pricing or subscription models.
- **Engagement:** Endocrinologists, patient advocacy groups (e.g., Diabetes India), payers.
- **Early adopters**: Monogenic diabetes, brittle type 1, or post-transplant diabetes — smaller cohorts, clearer endpoints.

Future Directions and Grand Challenges[82,73,84,85,86,87]

This forward-looking section outlines a prioritized agenda, convergent technologies, and socioeconomic considerations — recognizing diabetes as a global public health crisis requiring inclusive innovation.

Prioritized Research Agenda

- **Short-term (1–3 years)**: Improve multi-organ delivery, reduce immunogenicity, validate in NHPs
- **Medium-term(3–7 years):** First-in-human trials for liver/pancreas targeting, closed-loop circuits.
- **Long-term (7+ years):** Curative multi-gene reprogramming, personalized nanogenetics via AI/omics.

Convergent Technologies to Watch

- **AI/ML**: For nanoparticle design (inverse design), digital twins for dosing, predictive off-target modeling.
- **Wearables/closed-loop**: Integrate CGM data to trigger responsive nanoparticles.
- **Organoids-on-chip + 3D bioprinting:** High-fidelity testing platforms.

Socioeconomic, Policies, and Global Health Perspectives

- **Equity**: Address cost/access in LMICs (e.g., India, where diabetes prevalence is exploding).
- **Policy**: Harmonized regulations, public-private partnerships, ethical frameworks for gene editing.
- **Global health**: Capacity building in nanomanufacturing, diverse trial inclusion.

CONCLUSION

Nanogenetics represents a paradigm-shifting convergence of nanoscale delivery systems and precise gene-modulation technologies, offering—for the first time—a realistic pathway toward durable metabolic reprogramming and potential curative intervention in diabetes. By simultaneously addressing β-cell failure, insulin resistance, hepatic glucose overproduction, adipose dysfunction, chronic inflammation, mitochondrial impairment, and even microbiome-host crosstalk, these approaches transcend the limitations of lifelong symptomatic management. The field has matured rapidly: clinically validated LNP platforms, high-fidelity CRISPR variants, stimuli-responsive carriers, exosome-mimetic, and sophisticated synthetic gene circuits now stand poised for first-in-human evaluation. Landmark preclinical successes—such as LNP-CRISPR normalisation of glycaemia, exosome-mediated β-cell regeneration, and glucose-responsive nanogel therapies—demonstrate both feasibility and functional metabolic benefit. Yet substantial challenges remain: achieving efficient multi-organ targeting in the diabetic microenvironment, ensuring long-term safety, developing scalable and thermostable manufacturing processes, and guaranteeing equitable global access, particularly in high-burden countries like India. Integration of artificial intelligence for nanoparticle inverse design, real-time multi-omics monitoring, patient-specific digital twins, and fully closed-loop glucose-responsive systems will be game-changing accelerators. With continued interdisciplinary collaboration among nanotechnologists, geneticists, endocrinologists, bioengineers, regulatory experts, and policymakers, nanogenetics holds the genuine promise of transforming diabetes from a chronic, progressive condition into a manageable—or even curable— disease. The next decade will be decisive. Rigorous, ethically grounded, and inclusive preclinical-to-clinical pipelines must be prioritised so that the full potential of nanogenetics can be realised for millions of patients worldwide, ultimately delivering precision, durable, and truly patient-centered metabolic health restoration.

ACKNOWLEDGEMENT

We express our sincere gratitude to our respected guide Mr. Kanha Garg for their continuous support and help throughout the work.

ABSTRACT

This research paper examines the intersection of digital financial inclusion (DFI) and the growth of Micro, Small, and Medium Enterprises (MSMEs) in India, with a specific focus on technology-enabled sustainability and inclusive economic transformation. As India accelerates toward a digital economy, understanding how FinTech platforms, digital payment systems, and technology-driven financial services impact MSME performance becomes crucial for sustainable development. This study employs a mixed-methods approach, combining quantitative analysis of primary data collected from 385 MSMEs across five Indian states with qualitative insights from industry stakeholders. Using regression analysis and correlation studies, this research investigates the relationship between digital financial inclusion indicators (access to digital banking, FinTech adoption, digital payment usage, and online credit accessibility) and MSME growth metrics (revenue growth, employment generation, market expansion, and operational efficiency). The findings reveal a significant positive correlation ($r = 0.742$, $p < 0.001$) between digital financial inclusion and MSME growth. Regression analysis shows that digital financial inclusion accounts for 55.1% of the variance in MSME performance indicators. The study identifies critical enablers, including mobile banking penetration, UPI adoption, digital lending platforms, and government initiatives such as the Jan DhanYojana and MUDRA schemes. However, significant barriers persist, including digital literacy gaps, infrastructure challenges in rural areas, cybersecurity concerns, and regulatory complexities. This research contributes to the literature by providing empirical evidence on the impact of technology-driven financial inclusion on sustainable MSME growth and by offering policy recommendations to enhance inclusive business models. The study suggests that targeted interventions, including digital literacy programs, infrastructure development, simplified regulatory

frameworks, and customisedFinTech solutions for rural MSMEs, can accelerate inclusive economic transformation and help achieve the Sustainable Development Goals.

Keywords: Digital Financial Inclusion, MSME Growth, FinTech, Sustainable Development, Technology Convergence

INTRODUCTION

Background and Context

Technology, business innovation, and sustainability have become a common feature of economic development in the 21 st century, due to their convergence. This social intersection nexus in India occurs through digital financial inclusion (DFI) and its disruptive effect on Micro, Small, and Medium Enterprises (MSMEs). MSMEs are the foundations of the Indian economy, as the sector represents about 30 per cent of the GDP, 45 per cent of the production in the manufacturing industry, and provides over 110 million workers in various sectors (Ministry of MSME, 2023). Although MSMEs are relatively important economically, they traditionally have a difficult experience in using formal financial services, which restricts them in terms of growth and viability. The digital revolution, which has emerged with different initiatives like Digital India, Jan DhanYojana, and the development of FinTech platforms, has offered unprecedented opportunities towards financial inclusion. Digital financial inclusion can be described as the universal access and use of formal financial services provided over digital platforms at reasonable prices. These include digital banking, mobile wallet, UPI-sourced payments, internet banking, blockchain-based financial services and lending sites. The pandemic of COVID-19 also contributed to the increased pace of digital adoption that compelled businesses to turn to technology-based financial solutions to stay afloat and develop.

Research Problem

Although massive advancements have been made in digital infrastructure and FinTech innovation, the correlation between digital financial inclusion and MSME growth has not been properly conceptualised, especially in the Indian situation. Although there is anecdotal evidence that it is beneficial, there are relatively weak empirical studies that quantify this relationship and the exact mechanisms through which DFI can affect the performance of MSMEs. Besides, the sustainability aspects of the technology-related financial inclusion, which are economic resilience, social equity, and environmental responsibility, need additional research. There are a number of critical issues that arise: What is the effect of digital financial inclusion on different aspects of MSME growth? Which particular digital financial services make the most significant contribution to the performance of MSMEs? What is stopping the full exploitation of digital financial services by MSMEs? But how can the convergence of technology bring about an inclusive, sustainable business model of MSMEs?

Research Objectives

The research will fill these gaps using the following objectives:

- To explore existing digital financial inclusion rates of MSMEs in India.
- To study the connection between digital financial inclusion and the indicators of MSME growth based on empirical data.
- To determine the important enablers and obstacles to MSME-driven technology-based financial inclusion.
- To determine the sustainability potential of digital financial inclusion to inclusive economic transformation.
- To present policy recommendations and business strategy to be used to improve the growth of MSMEs driven by DFI.

LITERATURE REVIEW

According to the World Bank (2021), digital financial inclusion (DFI) combines financial inclusion objectives with digital technologies, access to formal financial services to people who are underserved as defined by the World Bank (2021) and extended to include by Ozili (2023). Information asymmetry theory, technology acceptance models, and institutional theory are among the main theoretical cornerstones of DFI, as access, usage and quality of the digital financial service, and the problem of vulnerable populations and small businesses continue to persist. MSMEs have their own financial challenges that include information opacity and high prices, especially in emerging economies where credit evaluation systems are poor. Studies further suggest that financial exclusion inhibits the development of MSMEs by decreasing the working capital and creating lost efficiency. Meanwhile, the research indicates that the availability of formal services increases earnings and employment opportunities substantially.FinTech solutions such as digital payments, lending, financial management applications, and InsurTech have modified the methods of financing of MSMEs. These innovations use alternative data and machine learning to determine the credit risk, which will allow wider access to financial services. In India, efforts like Unified Payments Interface (UPI) have done a lot in ensuring the cash flow and efficiency in transactions of MSMEs run more smoothly. The new research associates DFI with the improvement of MSME performance, which has positive effects on sales, turnover, and the ability to cope with economic shocks caused by the use of digital financial services. Yet, the results are not evenly distributed in the regions and sectors, with enterprises which have an opportunity to be enhanced with technology and enterprises based in urban areas having a greater advantage. The digital financial inclusion is investigated in terms of its sustainability (in terms of economic, social, and environmental effects), and the inclusive business model attempts to introduce low-income communities to the value chains. The concept of the fortune at the bottom of the pyramid proposes the establishment of economic feasibility of formerly marginalised markets, and attaining both social and business success with the help of DFI.

Research Gaps

Although current literature sets conceptual connections between digital financial inclusion and the growth of MSMEs, there are still serious gaps in the literature. To begin with, empirical studies quantitatively estimating these relationships in emerging economy settings are few. Second, it has been found that most of the studies concentrate on one aspect of DFI or MSME performance, and they have not provided comprehensive assessments. Third, contextual factors that moderate the effects of DFI need to be further explored, such as the nature of infrastructures in the region, sector, and regulatory environment. Lastly, little has been done on the sustainability aspects of technology-based financial inclusion among MSMEs. The proposed paper fills these gaps with the help of an extensive empirical examination of the DFI-MSME relations in India.

RESEARCH METHODOLOGY

This paper uses a sequential, mixed, explanatory design that entails the synthesis of quantitative data collected through primary surveys with qualitative data collected using semi-structured interviews in the analysis of the connection between digital financial inclusion (DFI) and the development of micro, small, and medium-sized enterprises (MSMEs). It puts forward a conceptual model postulating that DFI plays a role in MSME development by affecting how these businesses perform in terms of better access to loan facilities, efficiency in operations, financial management, and market penetration. Also, it encompasses mediating factors such as digital literacy and the quality of infrastructure. This study assumes that the operational growth of MSME is positively correlated with DFI (H1), that DFI is correlated with employment generation (H2), operation efficiency is predicted by access to digital lending (H3), the adoption of digital payments (UPI) is predicted by market expansion (H4), and the results of H5 indicates that digital financial literacy will moderate the DFI-MSME growth relationship.

The study focuses on registered MSMEs in Maharashtra, Gujarat, Tamil Nadu, Karnataka and Uttar Pradesh, and its stratified purposive sampling will consider the various economic development levels, industrial diversity, and digital infrastructure. On the Cochran formula computed at a confidence level of 95 with a margin of error of 5 per cent, a sample size of 385 MSMEs was calculated, including 46.8% micro enterprises, 35.1% small enterprises and 18.1% medium enterprises organised in terms of manufacturing (42%), services (38) and trade (20). A structured questionnaire was used in data collection that was divided into five sections based on the demographic data, DFI indicators, the MSME performance measures, barriers/enablers to DFI, and sustainability practises. DFI was measured on a composite index that measured the access to digital banking, the use of digital payments, the involvement in digital lending, the use of financial tools, and digital literacy and responses were rated in a Likert scale. The performance of MSMEs was evaluated using the types of measurements, which include revenue increase, employment, market expansion, operational enhancement, and innovation, including both objective measures and perceptual measures.

The main data collection period was between January and April 2024 by using the online survey (62 per cent), face-to-face interviews (28 per cent), and telephone surveys (10 per cent) in order to guarantee an effective sample which is representative of digital access variance. The quantitative results were complemented with complementary qualitative information, which was obtained through interviews with 25 stakeholders (MSME owners, FinTech executives, banking officials and policy experts). Secondary data would be seen through reports, publications, and financial databases, which provide more insight. A test of reliability was done with Cronbach's alpha, and the values were found to be above 0.70 in all the constructs, with content validity being conducted by the experts. Construct validity was established through an exploratory factor analysis. The method of data analysis was multidimensional, but SPSS was applied in quantitative data analysis, which included descriptive statistics, correlation, regression, moderation analysis, and ANOVA. Thematic analysis of qualitative data in NVivo showed major enablers, barriers, and implications of the sustainability of DFI issues.

Ethical Considerations

The research adhered to institutional ethical guidelines, with informed consent obtained from all participants. Confidentiality and anonymity were ensured through data coding and secure storage. Participation was voluntary, with no incentives offered that might bias responses.

DATA ANALYSIS AND INTERPRETATION

Descriptive Statistics

Sample Characteristics

The sample size of 385 MSMEs had different characteristics. Micro enterprises (46.8) predominated by size, with small (35.1) and medium enterprises (18.1) coming behind, which indicates the real population structure of MSME in India. This was as sectorally distributed as manufacturing (42%), services (38%), and trade (20%). Geographically, 48 percent were operated in cities, 32 percent in semi urban vicinities, and 20 percent in the rural areas. Enterprise age was between the newly established (<2: 15%), well-established (>10: 28%), and most (57: 3-10)

Digital Financial Inclusion That Is Found To Be Relevant At The Specified Level

DFI indicators were analysed to show differences in the modes of adoption. Access to digital banking was also relatively high, with 78.4 of the MSMEs having at least one digital banking account. Nevertheless, the active usage was lower: 64.2 per cent practised online banking, and only 52.3 per cent were using a mobile banking app. There was a high success of digital payments, as UPI has become the leader. Surveys of MSMEs showed that 82.1% of surveyed MSMEs accepted UPI payments, 68.7% used mobile wallets and 45.3% provided payments based on QR codes. The average number of digital transactions was 45 in the case of micro-enterprises and 320 in the case of medium enterprises, on average, every month. The participation in the digital lending platforms was also low, as MSMEs were only utilising the services of digital lending platforms in 34.6%. The most prevalent of them were

government-supporting platforms (MUDRA, Standup India) (58.2%), next comes bank-affiliated FinTech platforms (31.4%), and independent FinTech lenders (10.4%). The average credit value was quite different as micro enterprises had an average loan of [?]1.2 lakhs and the medium enterprises obtained an average loan of [?]24.5 lakhs. The adoption of financial management tools was also low: 41.2 per cent used the digital accounting software, 28.6 per cent used inventory management systems, and 19.4 per cent integrated ERP solutions. Significantly higher adoption was observed in the urban MSMEs (56.3) as compared to rural ones (18.7%). Knowledge test-based and self-reported confidence measures of digital financial literacy were varied to an extent. The mean of the sample (58.4 with SD = 18.2) was rated in the range of 0 to 100 with significant variations based on education level, location and size of enterprise. The medium and macro enterprises ranked much higher (M = 71.3 and M = 49.6, respectively**).**

MSME Growth Indicators

The analysis on revenue growth showed that most of the MSMEs are recording positive growth. In the 2021-2024 years, 68.3% of the companies showed growth in revenues, and the average rate of change over a compound year (CAGR) in the sample was 12.4%. The growth rates also differed widely depending on the size (medium enterprises: 15.7% CAGR; micro enterprises: 9.2% CAGR) and sector (services: 14.1; manufacturing: 11.8; trade: 10.5). There were steady but insignificant growths in employment. There was a 2.3 per cent growth in the number of employees in surveyed MSMEs on average over the 3 years, which is equivalent to 18.7 per cent growth of baseline employment. The share of medium enterprises was disproportionate at 8.4 new employees, and that of the micro enterprises was 0.8 employees. The market expansion indicators showed that 54.2 per cent of the MSMEs broadened their customer base, 38.6 per cent ventured into new geographical markets, and 31.4 per cent diversified the provision of their products/services. This growth was facilitated to a large extent by digital channels, with 62.3% of expanding MSMEs crediting their success to the use of online marketing and sales channels. Fifty-nine point seven per cent of MSMEs reported improvements in operational efficiency, in the form of lower transaction times (47.2%), lower administrative costs (41.3%), better inventory management (36.8%), and improved cash flow (52.1%).

Correlation Analysis

Pearson correlation analysis examined relationships between digital financial inclusion dimensions and MSME growth indicators. Results are presented in Table 1.

The DFI Composite Index showed good positive relationships with all MSME growth indicators. The highest correlation was observed between DFI and growth in revenue ($r = .742$, $p < .001$), and then there was market expansion ($r = .681$, $p < .001$), operational efficiency ($r = .664$, $p < .001$) and generation of employment ($r = .628$, $p < .001$). The findings indicate that high scores on digital financial inclusion are linked with better performances of MSMEs in several aspects, especially market expansion ($r = .718$, $p < .001$) and revenue growth ($r = .673$, $p < .001$). This result also conforms to the qualitative findings that digital payments are associated with customer reach expansion by a higher count of younger and more digitally savvy consumers, namely, the DFI variables ($r = +.534$, $p = 0.001$) and the probability of DFI ($r = +.557$, $p = 0.001$).

Regression Analysis

Multiple Linear Regression: DFI Impact on Revenue Growth

A multiple linear regression analysis examined the predictive power of digital financial inclusion for revenue growth, controlling for firm characteristics. Results are presented in Table 2.

The regression model explained 55.1% of variance in revenue growth ($R^2 = .551$, $F(9, 375) = 51.23$, $p < .001$), indicating strong predictive power. The DFI Composite Index emerged as the strongest predictor ($\beta = .452$, $t = 7.73$, $p < .001$), indicating that a one-standard-deviation increase in DFI is associated with a 0.452-standard-deviation increase in revenue growth, controlling for other variables. This provides strong support for Hypothesis 1.Firm size significantly influenced revenue growth, with medium enterprises showing 4.78 percentage points higher growth compared to micro enterprises ($\beta = .241$, $p < .001$), and small enterprises demonstrating 2.34 percentage points higher growth ($\beta =$

.156, p = .009). This size effect likely reflects resource advantages and economies of scale.Location significantly affected outcomes, with rural MSMEs experiencing 2.67 percentage points lower revenue growth than their urban counterparts (β = -.158, p = .005), even after controlling for DFI levels. This suggests that location-specific challenges—such as infrastructure deficits and market access limitations—constrain growth independently of financial inclusion. Digital infrastructure quality emerged as a significant predictor (β = .168, p = .003), indicating that the enabling environment for digital technologies matters beyond individual firm DFI levels. Years in operation showed modest but significant positive effects (β = .145, p = .006), suggesting experience advantages.

Regression Analysis: DFI Impact on Employment Generation

A second regression model examined DFI's impact on employment generation (Table 3).

The model explained 47.8% of the variance in employment generation (R^2 = .478, F(7, 377) = 48.94, p < .001). DFI significantly predicted employment generation (β = .378, t = 6.22, p < .001), supporting Hypothesis 2. Firm size showed a substantial effect, with medium enterprises having 2.43 more employees than micro enterprises (β = .352, p < .001). Revenue growth strongly predicted employment (β = .312, p < .001), suggesting that DFI's employment effects operate partially through revenue expansion.

Specific DFI Dimensions and Operational Efficiency

To test Hypothesis 3, regression analysis examined how specific DFI dimensions predict operational efficiency (Table 4). Digital lending access significantly predicted operational efficiency (β = .208, p = .001), supporting Hypothesis 3. However, digital financial management tools emerged as the strongest predictor (β = .289, p < .001), suggesting that efficiency gains stem primarily from improved business processes rather than credit access alone. Digital payment usage also had a significant effect (β = .194, p = .001), likely due toshorter transaction times and improved cash-flow visibility.

UPI Adoption and Market Expansion

Regression analysis examining the impact of UPI adoption on market expansion (Hypothesis 4) revealed significant relationships (Table 5). UPI adoption metrics significantly predicted market expansion (transaction volume: β = .267, p < .001; payment methods: β = .243, p < .001), supporting Hypothesis 4. Qualitative data provided context: MSME owners reported that UPI enabled them to serve younger consumers, facilitated online sales, and improved trust through transparent digital transactions.

Moderation Analysis: Digital Financial Literacy

Hierarchical regression was used to test whether digital financial literacy moderates the relationship between DFI and revenue growth (Hypothesis 5). Step 1 entered the control variables; Step 2 added the main effects of DFI and digital literacy; and Step 3 introduced the interaction term.

The interaction term significantly increased explained variance (ΔR^2 = .029, p < .001), indicating moderation. Simple slope analysis revealed that DFI's impact on revenue growth was stronger for MSMEs with high digital literacy (β = .587, p < .001) compared to those with low digital literacy (β = .321, p < .001). This supports Hypothesis 5, which suggests that digital financial literacy amplifies the benefits of DFI.

Comparative Analysis

Differences by Firm Size

ANOVA revealed significant differences in DFI levels across firm sizes (F(2, 382) = 42.67, p < .001). Post-hoc Tukey tests showed that medium enterprises (M = 73.4, SD = 12.3) scored significantly higher on the DFI index than small enterprises (M = 62.1, SD = 14.6) and micro enterprises (M = 51.8, SD = 16.9), with all pairwise comparisons significant at p < .001.However, the DFI-growth relationship remained significant across all size categories, suggesting universal benefits. Interestingly, the relative impact appeared strongest for microenterprises: a one-unit increase in DFI was associated with a 0.58 standard deviation increase in revenue growth, compared with 0.42 for medium enterprises.

This suggests that DFI may help level the playing field, enabling smaller firms to overcome traditional disadvantages.

Sectoral Variations

Manufacturing MSMEs showed the highest average DFI scores (M = 64.7), followed by services (M = 61.3) and trade (M = 55.8). Services MSMEs demonstrated the strongest DFI-market expansion correlations (r = .783), likely reflecting the particular suitability of digital platforms for service delivery. Manufacturing MSMEs showed the strongest DFI-operational efficiency relationships (r = .714), consistent with digital tools enabling process optimisation and supply chain management.

Geographic Disparities

Urban MSMEs significantly exceeded rural counterparts in DFI levels (urban M = 67.4, rural M = 48.9; $t(383) = 11.23$, $p < .001$). However, within rural MSMEs, DFI showed even stronger growth correlations (r = .812) than in urban contexts (r = .694), suggesting transformative potential when rural firms overcome initial barriers. Qualitative data indicate that rural MSMEs face infrastructure challenges (unreliable internet and limited smartphone penetration), but once they gain digital access, they experience substantial benefits from reduced geographic constraints.

Qualitative Findings

Thematic analysis of 25 stakeholder interviews identified key themes:

Enablers:

1. Government initiatives (Jan Dhan, UPI infrastructure, MUDRA schemes) created a foundational digital financial ecosystem
2. Smartphone proliferation democratized access to digital financial services
3. The COVID-19 pandemic accelerated digital adoption by necessity
4. FinTech innovation provided user-friendly, affordable solutions tailored to MSME needs
5. Reduced transaction costs and improved efficiency motivated continued usage

Barriers:

1. Digital literacy gaps, particularly among older entrepreneurs and rural populations
2. Concerns about cybersecurity and fraud deterred some MSMEs
3. Regulatory complexity and compliance burdens challenged smaller firms
4. Infrastructure deficits (internet connectivity, electricity) in rural areas
5. Trust deficits with digital-only financial providers lacking physical presence
6. High costs of digital financial management tools for micro enterprises

Sustainability Dimensions

Interviewees highlighted sustainability benefits, including: (a) Economic: improved resilience through diversified revenue channels and better cash management; (b) Social: enhanced financial inclusion enabling women entrepreneurs and marginalised communities; © Environmental: reduced paper usage and travel requirements for banking transactions.

FINDINGS AND SUGGESTIONS

Key Research Findings

This paper will discuss how digital financial inclusion (DFI) affects the development of Micro, Small, and Medium Enterprises (MSMEs) in India and summarise some of the main discoveries. Strong Positive Relationship: DFI also demonstrates strong positive correlations with MSME growth indicators, in the first place, revenue growth (r =.742), market expansion (r =.681), and operational efficiency (r =.664). The regression analysis confirms that revenue growth

can be explained by DFI, which has a value of 55.1 per cent, explaining the high level of technology-enabled financial inclusion. Variability in DFI-Dimension Impact: There is a range of differences between the relevance of various aspects of DFI to the growth of MSMEs, digital payment systems and, in particular, UPI have strong relations with market growth and revenue growth. Digital management tools positively impact operations, whereas digital lending has average impacts, which contributes to the significance of the multifaceted approach to DFI to achieve the best outcomes. Digital Financial Literacy: A critical moderator, the increased level of digital financial literacy of MSMEs culminates in the increased benefits of DFI services. The findings show that both the capability and infrastructure need to be improved in order to achieve maximum outcomes. Disparities by Size: Not only are there major differences in the levels of DFI by firm size, but also among the limited firms, the medium firms are those that will adopt DFI as compared to the micro firms. The effect of DFI is, however, more significant on smaller firms, and this implies its potential for reducing competitiveness gaps based on size.

Geographic Digital Divide: The rural MSMEs demonstrate significantly worse DFI adoption rates than their urban counterparts because of the issues with infrastructure and literacy. However, rural MSMEs with an increased level of DFI grow tremendously, which shows that there is a lot of unutilized economic potential. Sustainability Co-Benefits: DFI has a range of additional economic benefits in terms of greater economic resilience, social inclusion (especially of women and marginalised groups), and environmental advantages (via less paper use and travel).

Enablers and Barriers in the Ecosystem: Government measures like the UPI infrastructures and the MUDRA loaning should be enacted to aid the growth of DFI-based MSMEs. However, the presence of barriers limiting the use of digital financial services by most MSMEs includes challenges with digital literacy, threats to cybersecurity, and regulatory complications. The theoretical value of the study entails the validation of the relationships between DFI and the performance of enterprises in an emerging economy. It also promotes the knowledge of the various dimensions of DFI. It demonstrates that digital literacy is an important element which, in turn, diversifies the sustainability discourse to show how convergence in technologies can ensure the simultaneous application of economic, social, and environmental objectives.

CONCLUSION

The study examines the impact of digital financial inclusion (DFI) on the development of micro, small and medium-sized enterprises (MSMEs) in India, and its results indicate that DFI has effective results in improving the performance of MSMEs in terms of revenue growth, employment and efficiency of the organisation. The study results are based on the analysis of data on 385 MSMEs in five states and provide a conclusion that DFI, access to digital banking, payment system and financial management tools, explains 55.1 per cent of the variation in revenue growth. It is reported that digital financial literacy is one of the key mediators of these advantages, which necessitates the importance of being able to work with technology in addition to developing the necessary capability. Other issues that the study has dealt with include the rural-urban digital divide that impedes the incorporation of rural MSMEs into formal financial systems. Moreover, the results highlight the importance of DFI in the enhancement of sustainability, social inclusion, and its compliance with Sustainable Development Goals (SDGs). The study recommends some policy interventions to increase digital literacy, enhance infrastructure, and develop user-centred financial products to fit MSMEs without dismissing its weaknesses and proposing future research directions.

ABSTRACT

Diabetes mellitus is a chronic metabolic disorder characterized by high glucose level due to impaired insulin secretion or insulin resistance. It can lead to various complications, including microvascular (retinopathy, nephropathy, neuropathy) and macrovascular (cardiovascular disease) issues. hyperglycaemia mainly affecting people around age of 40 with lack of exercises and sedentary lifestyle. The increase in incidence of disease and its easy growing complications have become threat to healthcare sector even after the discovery of various hypoglycaemic agents and synthetic insulin. These medicines with long term use are reported to have hazardous side effects. In Ayurveda similar condition has been mentioned under the disease spectrum of *Prameha*(~diabetes).The primary objective of treatment is to control hyperglycemia and eliminate the root cause of disease. *Samshodhana* (~purification therapy) is the line of treatment mentioned for the treatment of *Sthula*(~obese) *Pramehi*. Material and Method: In the present case study, a 57 years old female patient consulted to OPD with the complaints of polydipsia, weakness, burning sensation in the feet for 15-20 days. She was already diagnosed with DM by Diabetologist. (RBS-326 mg/dl and HBA1C-13 %) she was treated with traditional Ayurvedic *Panchkarma* therapy i.e, *Vamana Karma*(~therapeutic emesis)and *ShamanChikitsa*(~palliative treatment). Result: Only Ayurvedic *Panchkarma* therapy(~Five-fold purification therapy)were used during the course of the

treatment. On follow-up, a marked improvement was noted in blood glucose levels, with random blood sugar (RBS) at 142 mg/dL and HbA1c at 6.58%.Discussion: The present study emphasizes the role of *Ayurvedic Panchakarma* therapy is bringing a positive result in the management of diabetes mellitus. Conclusion: Ayurvedic *Panchakarma* therapy showed promising results in glycaemic control.

Keywords: Dibetes mellitus, *Prameha*, *VamanaKarma*, *ShamanaChikitsa*, *Panchakarma*

INTRODUCTION

Diabetes mellitus is a clinical syndrome characterized by hyperglycemia due to absolute or relative deficiency of insulin, or both (i.e; defect in insulin secretion, insulin action, or both). The two broad categories of DM are designated type 1 and type 2. It is considered as the fastest growing disorder of present era in public sector, affecting about 9.3% of world population (2019) and may rise up to 10.2% by the end of 2030[1]. Type 1 diabetes mellitus results from autoimmune destruction of more than 90% of pancreatic beta cells and usually occurs in younger individuals, with sudden onset of symptoms such as polyuria, polydipsia, polyphagia, infections, poor wound healing, and weight loss. In contrast, genetic influence is stronger in type 2 diabetes mellitus, where pancreatic beta cell mass remains largely intact but insulin resistance and impaired insulin secretion are present. An increased alpha cell population in type 2 diabetes leads to excessive glucagon secretion, further contributing to hyperglycaemia. Type 2 diabetes mellitus is caused by increased hepatic glucose production, insulin resistance, and impaired insulin secretion. In the early stage, normal glucose levels are maintained by compensatory hyperinsulinaemia. With disease progression, beta cells fail to meet insulin demand, resulting in impaired glucose tolerance and overt diabetes. The onset is gradual and often asymptomatic, with many patients presenting with chronic complications. Obesity, overeating, physical inactivity, and age above forty years are major risk factors. In Ayurveda, *Acharya Charaka*, has classified *Prameha* into two types, i.e. *Sthula Pramehi* and *Krisha*(~lean) *Pramehi* or *Santarpanajanya*(~*prameha*due to over nutrition) and *Apatarpanajanya Pramehi*(~*prameha* due to lack of nutrition)[2].It can also be correlated with the classification given by *Acharya Vagbhata*, i.e. *Dhatu Kshayajanya*(~Due to tissue depletion) and *Avaranajanya*(~Due to functional obstruction) *Prameha*, respectively[3].

According to Ayurveda, *Prameha* is considered as one among the *Mahagada*(~major disease).Sedentary lifestyle, excess of sleep, *Dadhi*(~curd), *Gramya*, *Anupa*, and *Audaka Mansarasa*(~Meat soups prepared from domesticated, marshy-land, and aquatic animals.), milk and its preparations, *Navin Annapana*, *Jeggery* and all *Kapha*(~morbid humors) aggravating factors are responsible for the causation of *Prameha*. The vitiation *Kapha* along with *Kleda*, *Abaddha Meda*(~Unbound fat tissue) and another *Dhatu* leads to *Prameha*. As the disease progress, involvement of *Tridosha*(~three morbid humors) and *Dasha Dushyas* (~major structural components of the body) i.e., *Rasa* (~primary product of digested food), *Rakta*(~blood tissue), *Mamsa*(~muscle tissue), *Meda*(~fat tissue), *Majja*(~bone marrow), *Shukra*(~semen), *Kleda*(~watery waste), *Vasa*(~muscle fat), *Lasika*(~watery component of the skin)and *Ojus*(~essence of all seven *Dhatu*) are also seen.[4]When aggravated *Kapha* vitiates *Meda*, *Mamsa*, increased *Kleda* in body, brings them to *Mootrashaya*(~urinary bladder) and forms 10 types of *Kaphaja Prameha*. Similarly other types of *Prameha* with vitiation of *Pitta* and *Vata Dosha* causes 6 types *Pittaja Prameha* and 4 types of *Vataja Prameha* respectively. *Samshodhana*(~detoxification therapy) is the line of treatment in *Sthula Pramehi* where as in *Krisha Pramehi Santarpana*(~nourishing therapy) is the main line of treatment[5]. Further *AcharyaSushrut* mentions when the disease is fully developed with signs and symptoms one should do *Shodhana Chikitsa*. The *Nidanas*(~aetiology) causing vitiation of *Kapha* and *Pitta* leads to *Dushti* of *Dhatus* and leads to *AvaranaJanya Prameha*[6]. *Samshodhana* specilly *Vamana*(~therapeutic emesis) is helpful in the *Sthula Pramehi* with *AvaranaJanya Samprapti*. Thus, for prevention and control of the disease *Samshodhana* especially *Rutu Shodhana*, *Pathya Ahara*(~compatible food to health) and proper *Vyayama*(~exercise)plays important role.

Case Report

A 57 years old, female patient came to Government Akhandanand Ayurved Hospital on 25th February 2025 and complaining of

- Polydipsia (*Trishnadhikya*)
- Polyurea (*Mutradhikya*)
- Weakness (*Daurbalyata*)
- Burning sensation in the feet (*PadatalaDaha*)
- Weight loss (*SharirbharHras*).

All above symptoms gradually started in 15 – 20 days.
She has no history of any antihyperglycemic medicine in the past.
K/C/O, Hypothyroidism x 6 months
Menstrual History: Menopause for 7 years
Obstetric History:G2 P2 A1 L1 D0
Medicine History-Tab. Thyroxine (100 mcg) (1-0-0)

General examination (Table 1)

Blood examination (Hematological examination) (Table 2)

Personal history
Diet: veg
Addiction: not any
Job: housewife
Past history: jaundice in September 2025
Family history: no any
Surgical history: no any
She was mentally stressed and triggered by demise of a close family member last 1 – 1.5 years

***Ashtavidha pariksha*(~ eight folds of clinical examination)(Date: 19/03/25)**
(Table 3)

Systemic Examination: No any abnormalities were detected in GIT, Respiratory, Cardiovascular and Nervous examination.

***Samprapti*(~Pathogenesis)**
***Dosha*(~regulatory functional factors of the body):** *Kapha Pradhan Tridosha*
***Dushya*(~which gets vitiated):** *Rasa*(~primary product of digested food), *Rakta*(~blood tissue), *Mamsa*(~muscle tissue), *Meda*(~fat tissue), *Majja*(~bone marrow), *Shukra*(~semen), *Kleda*(~watery waste), *Vasa*(~muscle fat), *Lasika*(~watery component of the skin), *Oja*(~essence of all seven *dhatus*)
***Srotas*(~body channel):** *Rasavaha*(~channels of plasma), *Mansavaha*(~fascio-muscular tissue), *Medavaha*(~channels carrying adipose tissue), *Mootravaha*(~urine carrying channels)
Srotodushti: *Sanga*(~obstruction due to contraction of lumen), *Atipravrutti* (~over flow of the contents in the body channels)
***Agni* (~digestive fire):** *Jatharagni* and *Dhatvagni Mandya*(~impaired metabolism)
***Udbhav Sthana*(~site of origin):** *Amashaya*(~stomach)
***VyaktiSthana*(~manifesting site):** *Mutrashay*(~urinary bladder)
***Rogamarga*(~disease pathway):** *Abhyantara*(~entrinsic)

Treatment Schedule
Vamanakarma
(Table 4)
Shodhanartha Snehapana (Table 5)

***Shamana chikitsa*(~Palliative Treatment)**
Shamana Chikitsa (Table 6)

Investigation
Before starting the treatment; routine haematological tests, RBS, HbA1c were done. A brief of the haematological observations is placed at (Table-2)

Criteria for Assessment
The overall assessment of therapy was done by comparing the percentage change in fasting and postprandial blood sugar and glycated hemoglobin levels before treatment and after treatment (i.e., after *Samsarjana*). Besides that, a follow up study of 15 days after *Samsarjana krama* was also done.

Out Come and Follow Up
Table 8
Table 7

RESULT

Ater *Samsarjana* it was found out that there was marked reduction in signs and symptoms in patients especially increased frequency of urination, fatigue, excessive thirst and after completion of *Samsarjana Krama*, previously increased FBS, PPBS and HbA1c came to normal range and maintained within normal limit for consecutive 3 months with *Shamanoushadhi*.

DISCUSSION

According to *Ayurvedic* classics, *Prameha* is a *Kapha-Medojanya Vyadhi*(~*Kapha Meda* dominant disease)where *Kapha Dosha* and *Medadhatu* are the principal factors responsible for the disease manifestation. The *Samprapti* of *Prameha* begins with *Kapha Dosha* vitiation due to *Aharaja* and *Viharaj Nidanas*(dietary and lifestyle related etiological factors) such as excessive intake of *Guru*(~heaviness), *Snigdha*(~sliminess), *Madhur Ahara*(~sweet diet), lack of exercise, and day sleep. This leads to *Agnimandya*(~lack of digestive fire), *Ama Utpatti*(~toxins formation), and accumulation of *Meda* and *Kleda* in the body. The excessive *Kleda* is then expelled through *Mootravaha Srotas*, resulting in *Prameha Lakshanas*(~symptoms) such as *Prabhuta Mootrata*(~polyuria) and *Avila Mootrata* (~turbid urination). In such *Kapha-Medovrudhhi* conditions, *Vamana Karma* is considered the 1st line of *Shodhana Chikitsa*. The primary objective of *Vamana Karma* is to expel the vitiated *Kapha Dosha* from the *Amashaya* and related chennels. By doing so, it helps to break the *Samprapti* of *Prameha* at the initial level itself.

***Purvakarma*(~Preparatory procedures):** *Deepana Pachana* done with *Trikatu Churna* containing *Sunthi*, *Maricha*, *Pippali* is a well-known Ayurvedic formulation. It is having properties of *Ushna(~hotness)*, *Tikshna(~sharpness)*, *Laghu(~lightness)*, *Ruksha(~dryness)*, *Dipana*(~digestive), *Kaphahara(~Kapha*-pacifying*)*, *Medaghna*(~fat reducing). its helps in digestion, relieves *Ama* and anorexia.

Shodhanarta Snehapana* with *Triphala Ghrita: *Triphala Ghrita* combines the properties of *Haritaki (~Terminalia chebula)*, *Bibhitaki (~Terminalia bellirica)*, *Amalaki (~Emblica officinalis)* and *Ghrita*, providing *Lekhana*(~scraping), *Rasayana*(~rejuvenation), *Medohara*, *Kledahara*(~Anti-exudative),and *Tridosha Shamaka* effects. *Triphala* formulations

can reduce fasting blood sugar, HbA1c, total cholesterol, and triglycerides, supporting its role in improving insulin sensitivity and glucose utilization. Thus, *Snehapana* with *Triphala Ghrita* not only prepares the body for detoxification but also exerts direct metabolic benefits on glucose and lipid regulation.

Pradhanakarma*: Madanphala (~Randiadumetorum), Saindhava*(~rock salt), *Madhu*(~honey) is considered as *Shreshtha Vamaka Yoga. Madanphala* having properties of *Ushna*, *Tikshna*, *Vyavayi* and *Vikasi*(~Quickly diffusing and rapidly acting), *Urdhvabhaga Hara*(~Action facilitating upward expulsion). *Bahudrava Sleshma*(~Highly liquefied Kapha)and *Abaddha Meda* are two important factors in pathogenesis of *Prameha*. *Vamana Karma* is described as main *Shanshodhana* procedure for alleviating primarily *Kapha* and to some extent *Pitta* also[7]. It expels vitiated *Kapha* and *Meda* from the *Amashaya*, thereby removing the root cause of the disease. *Vamana* helps in correcting *Agnimandya* and improves digestive and metabolic functions. By clearing obstructed *Shrotas*, it enhances insulin sensitivity and proper glucose utilization. *Vamana* also reduces excess body weight and adiposity, which are important etiological factors in *Prameha*. It helps in restoring *Dosha-Dhatu* balance and normalizing endocrine functions. Thus, *Vamana Karma* effectively controls hyperglycaemia and prevents disease progression and complications in *Prameha*.

Chandraprabha Vati [8] is a polyherbal-mineral combination, indicated for *Prameha*, *Mutrakruchha*(~Dysuria), *Sukrameha*(~Spermaturia), *Medoroga*(~Disorder of fat metabolism) and other disorders. Many ingredients of *Chndraprabha* like *Haritaki*, *Shilajit (~Asphaltum)*, *Guggulu (~Commiphora mukul)* improve *Jatharagni* and *Dhatvagni*, *Lekhana*, *Medohara*, *Rasayana* and *Mootra virechaka*(~diuretic) properties that helps eliminate excess *Kleda* through urine and improving urinary flow

Triphala Kwatha[9]plays an important role in the management of *Prameha* due to its *Deepana*, *Pachana*, *Lekhana*, and *Rasayana* properties. It helps in and reducing *Kapha* and *Meda*, which are the main *Dosha* and *Dushya* involved in *Prameha*. *Triphala* improves metabolism, facilitates proper utilization of glucose, and helps in reducing excess body fat. Its mild laxative and detoxifying action support *Srotoshodhana*s and elimination of metabolic waste. From a modern perspective, *Triphala* possesses antioxidant and hypoglycaemic effects, which help in improving insulin sensitivity and preventing complications of diabetes.

Laghu Malini Vasanta Rasa[10] is a classical herbo-mineral medicine mainly used in chronic fever. It is known to have strengthening and rejuvenating effects, so it is often prescribed in long-standing illnesses where healing along with nourishment of the body is required. Although classical Ayurvedic texts do not specifically mention its use in diabetes, but *Acharya Charaka* and *Acharya Sushruta* have clearly emphasized the need for *Rasayana* (~rejuvenation) therapy in the management of *Prameha*. As diabetes progresses, the metabolism of carbohydrates, proteins, and fats becomes disturbed, leading to weakness and tissue depletion. Considering these effects, the rejuvenating and metabolic-supporting properties of *Laghu Malini Vasanta Rasa* explain why it has been traditionally used by some practitioners in the management of diabetes.

Khadira (~Acacia catechu)**[11]**possesses *Tikta(~bitter)–Kashaya (~astringent)Rasa*, *Lekhana*, and *Kapha–Medohara* properties, which help in reducing excess *Kapha* and *Meda* involved in *Prameha*.

Vijaysara (~Pterocarpus marsupium)[12]is well known for its *Pramehaghna* and hypoglycaemic action; it improves glucose utilization and helps in controlling blood sugar levels.

Kalamegha (~Andrographis paniculata) has *Tikta Rasa*, *Deepana*, and *Pachana* properties, which correct *Agnimandya* and enhance insulin sensitivity.

RutuShodhana helps to remove the embedded *Doshas* out of the body timely, *Vasanthika Vamana* does the abolishment of *Kaphadosha* thus helps in breakdown the *Samprapti* of the disease *Prameha*. It was observed the *Vasanthika Vamana*(~seasonal (spring) therapeutic emesis) showed significant effect in controlling blood glucose level and managing signs and symptoms of *Prameha* like *Prahoota Moothrata*(~polyuria), *Ati Pipasa*(~Polydipsia), *Galatalu*

Shosha(~dryness of the throat and palate),*Daurbalyata*(~weakness) etc. With proper *Samshodhana* along with *Vyayama* and dietary habits one can prevent and control the disease *Prameha* without the use of any antiglycemic agents. Before Treatment (Figure 2). After Treatment (Figure 3).

ACKNOWLEDGEMENTS

The authors sincerely acknowledge the Principal and administrative authorities of Government Akhandanand Ayurved College and Hospital, Bhadra, Ahmedabad, for providing essential facilities and institutional support for this study. We are grateful to the Department of Panchkarma for their continuous guidance and academic support. We also thank the teaching faculty and colleagues for their valuable suggestions and cooperation during manuscript preparation. Special thanks are extended to the patient for cooperation, and adherence to the treatment protocol. The authors further acknowledge the assistance of laboratory and hospital staff. No external funding was received for this study.

ABSTRACT

Drug development heavily relies on the structure-based computer method known as "molecular docking." By identifying the optimal orientation of a ligand to its target molecule with the least amount of free energy in order to create a stable complex, molecular docking improves the effectiveness of detecting the metabolic interaction between two molecules, i.e., the small molecule (ligand) and the target molecule (protein). Docking aids in the discovery of new targeted medicines by identifying tiny compounds that may block cancer-promoting proteins by enhancing drug-target interactions. Researchers can find possible anti-cancer medications with improved specificity and decreased toxicity by screening large reorganizations using molecular docking. Researchers can find possible anti-cancer medications with improved specificity and decreased toxicity by screening large reorganizations using molecular docking. Molecular docking's increasing significance highlights its potential to transform cancer treatment by speeding up the discovery of new medications and enhancing therapeutic results. In comparison to previous cancer therapy approaches, this computational drug design technology can be regarded as more efficient and time-saving. In this review, we provide a brief overview of the function of molecular docking and its significance for target identification and drug development in cancer research. Molecular

docking can therefore be examined as one of the cutting-edge approaches at the forefront of cancer-targeting medication discovery in recent years.

Keywords: Molecular docking, Drug-target interactions, Anti-cancer medication, Target identification, Computational drug design

INTRODUCTION

Cancer is still a serious worldwide public health concern. More than 200 different types of cancer are believed to exist; these are frequently named for the tissue in which the cancer was initially discovered. One of the main causes of death in the twenty-first century and the biggest obstacle to raising life expectancy worldwide is cancer. According to a 2015 World Health Organization (WHO) report, cancer is the second leading cause of death for persons under 70 in 91 countries and the third or fourth leading cause of death in 22 other nations. Additionally, there have been 9.6 million cancer-related deaths and 18.1 million new cancer diagnoses worldwide. As a result, innovative drug development methodologies with lower time and money costs, as well as increased efficiency, are in great demand and would lead to a considerable improvement in world health and life expectancy. Since the successful development ofthe HIV protease inhibitor Viracept in the United States in 1997, which was the first drug design entirely driven by its target structure, computational methods have been a critical tool in drug discovery projects and a cornerstone for new drug development approaches. This expedites and reduces the cost of medication development. The sharp rise in cancer mortality and incidence has become a global health concern [1]. The government, society, medical industry, and scientific communities are all interested in reducing cancer-related fatalities and are hoping for the quick development of safe and effective cancer treatments. An overview of computational-method-aided innovative drug development procedures in general and anti-cancer therapeutic discovery in particular is given in this study. The primary focus of this study was the computational design of anticancer drugs. The process of finding and creating new medicines is costly, time-consuming, and fraught with difficulties. Patients, however, are constantly in need of new medications that are more effective and less dangerous. Apart from the difficulties of target validation and hit finding, poor pharmacokinetics, limited efficacy, and excessive toxicity are often cited as the reasons for a high failure rate in clinical trials[1]. The use of computer-aided drug design (CADD) techniques in drug development is growing in significance. They are essential for effectively and affordably locating possible medication candidates.

By reducing the need for animal models in pharmacological research, these computational methods help create novel, safe drug candidates and make it easier to find new applications for already-approved drugs. Throughout the drug discovery process, they support pharmacologists and medicinal chemists[2]. By effectively directing experimental research toward the most advantageous compounds, computer-aided drug design (CADD) has sped up the drug development process and decreased the time needed. Molecular docking and virtual screening (VS) methods have been shown to be effective substitutes for the time-consuming and expensive experimental high-throughput screening (HTS) method in the field of computer-aided drug design (CADD)[3]. Molecular docking predicts effective ligand-target interactions and accelerates anti-cancer drug discovery. Structure-based drug design (SBDD) utilizes experimentally determined or modelled computationally 3D biological target structures to create ligands with specific electrostatic and spatial characteristics for optimal binding affinity. Conformational search algorithms alter ligand parameters via systematic or stochastic processes to search for energy landscapes with the aim of finding global minima without causing combinatorial explosion. Scoring functions calculate ligand-receptor binding energetics from modelling interactions, desolation, and entropy, types being force-field, empirical, or knowledge-based but usually integrated for accuracy. Covalent drugs have long-term effects through irreversible binding of targets, but their modelling is challenging; docking software such as DOCK, AutoDock, and GOLD solve this through specialized algorithms. Molecular dynamics (MD) models receptor flexibility, generates docking-relevant conformations, and assesses complex stability, though limited by high computational cost and time-scale

constraints. Structural water often mediates ligand binding but poses challenges in docking. Strategies assess water stability to guide retention or displacement during structure-based drug design. Protein-protein interactions are key drug targets. Tools like Q-Site Finder, ANCHOR, and HADDOCK help identify binding pockets and guide docking despite complex, flat interfaces [4].Water molecules critically influence protein–ligand and protein–protein interactions through hydration shells and electrostatic screening. Despite their importance, predicting interfacial water positions remains challenging, though advances like MD simulations and continuum models offer promising solutions for drug design [5].

Types and approaches for Molecular docking

Types of Molecular docking

In molecular docking, two primary strategies are employed to simulate the interaction between a ligand and its target protein: rigid docking and flexible docking. Rigid body docking is a computational approach for predicting molecular interactions by treating both ligand and receptor as inflexible entities. It produces many conformations from surface complementarity, which are then reranked with approximations to binding free energy. An important method in this field is the Fast Fourier Transform (FFT) correlation method, which finds docking space by scoring electrostatic and solvation interactions. Betterments such as polar Fourier correlations and spherical harmonic decomposition have improved rotational search speed. Some docking programs apply these concepts, using atomic contact energy and electrostatic corrections. A few tools avoid grid searches via spherical polar Fourier correlations. Computational efficiency has been further enhanced through GPU acceleration and dedicated processors. These approaches frequently employ binding energy and pseudo-energy terms based on structural restraints. Complementarity of shape continues to be the focus, with certain programs incorporating hydrophobic shape into the scoring. Modern algorithms identify near-native orientations in discretized six-dimensional space by analyzing shape complementarity, electrostatics, and desolvation energies. But rigid body approaches can be less effective in the case of unbound crystal structures, resulting in false positives. For greater accuracy, newer software includes Coulombic and Lennard-Jones potentials and rerank according to desolvation energy. Early docking tools used spherical representations and geometric hashing. Modern programs refine docking through global searches, Gaussian shape fitting, and contact surface optimization. Some toolkits generate macromolecular complexes from rigid monomers using experimental restraints, while others apply local shape descriptors and membrane-specific adaptations to model side-chain and backbone flexibility.

Accuracy of Rigid docking (Table: 1). Flexible docking has proven to be a key improvement over rigid-body methods, acknowledging the dynamic character of both ligands and receptors. In classical virtual docking, ligands are docked to a rigid receptor, but it is clear now that side-chain flexibility plays a big role in binding precision. Receptors are able to change their binding site according to ligand orientation, which is achieved in a high-dimensional space involving translational, rotational, and conformational variables. Today's flexible docking tools allow for receptor and ligand flexibility to enhance pose prediction as well as estimate binding affinity. AutoDock Vina and ICM are among the programs that apply stochastic sampling and energy minimization methods to efficiently sample conformational space. Swarm intelligence techniques, such as particle swarm optimization (PSO), have also improved docking speed and accuracy further, with software such as PSOVina and ParaDockS showing significant gains. Flexible receptor modeling is enabled by algorithms that produce multiple conformations or optimize the position of side-chains. Software such as GalaxyDock, FLIPDock, and Rosetta Ligand incorporate these aspects to model realistic binding environments. Fragment-based and incremental construction strategies also help ligand design by constructing low-energy molecular building blocks in the binding site. High-level scoring functions now blend force field-based, empirical, and knowledge-based estimators to analyze binding poses. Glide, GOLD, and Surflex programs balance ligand flexibility with receptor flexibility, providing better docking accuracy on a wide range of targets. Despite lingering difficulties in simulating solvent effects and entropic contributions, flexible docking remains an increasingly sophisticated tool in structure-based drug design.

Table .2 Accuracy of flexible docking. Rigid docking provides speed and ease of use, which makes it appropriate for initial screening and inflexible systems. Flexible docking is more biologically realistic and predictive, which renders it

more suitable for high-level studies of drug discovery. The two can be chosen based on the flexibility of the target system, the quality of the structural information, and the nature of the objectives of the docking study. With developments in computational techniques, however, combined strategies that offset efficiency with flexibility will probably increasingly take center stage in structure-based drug design[3]. Over the last few years, molecular docking has grown from being used solely in drug-ligand interactions to being applied in protein-protein interactions, which are critical for comprehending biological processes. CAPRI (Critical Assessment of Predicted Interactions) is a fundamental project that compares docking predictions to unpublished crystal or NMR structures. Predictors generate models based on these structures, and evaluators assess them against experimental data. While protein-protein docking shares core principles with ligand docking, its complexity requires specialized tools. Over the past decade, docking methods have evolved from ab initio to interface-guided approaches. The 2009 CAPRI study classifies techniques into three categories: universal methods like ZDOCK and Patch Dock using fast Fourier transforms; mid-range methods such as Rosetta Dock employing Monte Carlo minimization; and restraint-based methods like HADDOCK, which incorporate prior knowledge of interface residues. Benchmark datasets, notably from Weng's group, support validation efforts. To address protein flexibility, the development of Hinge Prot, identified rigid and hinge regions, aiding docking of mobile proteins. The DOT program explores six degrees of freedom, evaluating electrostatic and van der Waals energies to find low-energy configurations. However, docking modelled protein structures remains challenging due to their reduced accuracy compared to experimental data[6].

Approaches for Molecular docking

Different approaches of the molecular docking are given below

Shape Complementarity Approach

This method focuses on matching the 3D shapes of the ligand and receptor surfaces. Using solvent-accessible surface area, it identifies grooves or pockets on the receptor that geometrically complement the ligand. It also considers hydrophobicity by analysing twists in the protein backbone. This approach is computationally efficient and suitable for high-throughput screening. It's often used in pharmacophore modelling, where geometric descriptors help estimate optimal binding energies. Search algorithms like Monte Carlo, Genetic Algorithms, and Exhaustive Methods are employed to explore conformational space.

Simulation Approach

Here, the ligand and receptor are initially separated. The ligand undergoes internal (torsional) and external (rotational/translational) movements to explore conformational space. Each movement alters the system's energy, and the total energy is recalculated. This method accounts for ligand flexibility and provides more accurate modelling of molecular recognition, though it is computationally intensive.

Monte Carlo Approach This random approach gives a random conformation, rotation, and translation to the ligand. A new conformation is created and scored. Metropolis criterion is used to determine whether to accept or not the new pose according to energy differences in order to escape from local minima

Matching Approach

This approach focuses on putting ligand atoms in optimal positions inside the receptor site. It chooses good configurations that can be further optimized.

Ligand Fit Approach

A fast and precise method that docks small molecules into protein active sites by evaluating shape complementarity. It's widely used in structure-based drug design.

Point Complementarity Approach

This technique compares the shapes and chemical properties of interacting molecules at specific points, helping to assess how well they match.

Fragment-Based Method
Ligands are broken into smaller fragments, which are docked individually. These fragments are then linked to form a complete ligand. This method is useful for discovering novel scaffolds.

Distance Geometry Approach It applies what is already known intra- or intermolecular distances to build 3D structures consistent with those restraints. It's especially helpful when partial structural data only is present.

Inverse Docking Method Rather than binding several ligands to a single target, this approach binds one ligand to several possible targets. It predicts off-target effects and toxicity.

Blind Docking Approach
Used when the binding site is unknown. The entire protein surface is scanned to identify potential binding pockets and ligand orientations.

Metropolis Criterion Approach
A refinement of the Monte Carlo method. If a new configuration has a better score, it's accepted. If not, it may still be accepted based on a Boltzmann probability function, allowing exploration of diverse conformations[7].

Steps in Molecular docking
Step I – Protein Preparation: The three-dimensional structure of the target protein is obtained from repositories like the Protein Data Bank (PDB). Prior to docking, the structure undergoes preprocessing to ensure accuracy and compatibility. This includes removing water molecules from the binding cavity, correcting charge states, reconstructing missing residues, and generating appropriate side chains based on defined parameters.

Step II – Active Site Identification: After preparation of protein it's active sites are predicted. Although a protein may contain multiple potential binding pockets, the site relevant to the study must be selected. Typically, non-essential components such as water molecules and heteroatoms are excluded to refine the binding region.

Step III – Ligand Preparation: Ligands can be sourced from chemical databases like ZINC or PubChem, or manually designed using molecular sketching tools such as ChemSketch. During selection, the ligand's drug-likeness is evaluated using Lipinski's Rule of Five, which helps distinguish between drug-like and non-drug-like compounds.

According to this rule, a suitable ligand should ideally meet the following criteria:

i. No more than five hydrogen bond donors
ii. Not more than ten hydrogen bond acceptors
iii. Molecular weight below 500 Daltons
iv. LogP value not exceeding 5 (indicating acceptable lipophilicity)
v. Molar refractivity between 40 and 130

Step IV – Docking and Analysis**:** The prepared ligand is computationally docked into the predicted active site of the protein. The resulting ligand–receptor complexes are evaluated using scoring functions that rank the binding poses based on predicted affinity and interaction quality. The conformation with the most favourable score is typically selected for further analysis[8].

Application of Molecular docking in drug discovery
Molecular docking is a critical computational strategy in drug discovery used to make the prediction of the mode of interaction of small molecules with biological targets. Docking identifies and optimizes lead compounds, deciphers binding modes, and designs drugs from protein structures. Through ligand–receptor simulations, docking speeds up virtual screening and lowers experimental costs. Docking also facilitates natural product research by screening phytochemicals against disease targets. Sophisticated approaches include receptor flexibility in order to enhance

accuracy. In spite of the shortcomings in predicting clinical efficacy, docking is still an effective tool for informing early-stage drug development as well as optimizing the efficiency of structure-based design approaches [9]. Natural products remain a rich source of novel chemical scaffolds, and more attention is being focused on incorporating computer-aided drug design (CADD) methods into natural product-focused research. The most significant trend is the application of molecular docking to predict phytochemicals' potential interaction with disease-related targets. Its predictive power is ready to drive consequential decision-making in drug discovery, allowing researchers to select plant species for biological screening particularly in light of new health threats like COVID-19. Though the guidelines given here are not complete, they provide straightforward advice for scientists, especially newcomers to molecular docking, to include CADD techniques in their natural product research. The method has the potential to be used for maximizing the efficiency and accuracy of natural product screening and lead identification[10]. Molecular docking, despite many developments within the past several decades, remains a subject of controversy about whether it can reliably create clinically suitable drugs. Nonetheless, several successful applications have demonstrated its potential in identifying biologically active compounds across diverse targets. For instance, Schames and colleagues identified a novel binding pocket in HIV-1 integrase, a key enzyme in AIDS therapy, by integrating molecular docking with molecular dynamics simulations. Using Auto Dock alongside the relaxed-complex method, they uncovered a previously unrecognized mode of inhibition, highlighting the value of accounting for receptor flexibility during docking studies[11]. Computational modelling has emerged as a powerful approach for exploring drug-target interactions across various validated anticancer targets. It facilitates the identification of novel inhibitory compounds from small molecule libraries and aids in deciphering their mechanisms of action. Recent studies exemplify this application, including the discovery of new inhibitors targeting the CXC chemokine receptor 2 (CXCR2) using ligand-based pharmacophore modelling[12].

Application in Anti-cancer drug discovery

Molecular docking can be used to identify prostate cancer treatment. With four PRK1 crystal structures (PDB: 4OTG, 4OTD, 4OTI, 4OTH) and the Schrödinger Suite 2014 structure-based virtual screening and QSAR modelling was conducted. Ligands ionized and reduced in size and proteins were built in the OPLS 2005 force field with binding sites defined around significant residues like Ser704 and Glu702. Cross-docking of inhibitors like lestaurtinib and tofacitinib showed the accuracy of docking and stressed the requirement for ensemble docking owing to PRK1's flexible active site. Docking directed the selection of active scaffolds, binding energy and docking scores utilized to order compounds (e.g., staurosporine with $\Delta H = -60.86$ kcal/mol, $IC_{50} = 0.81$ nM). The incorporation of descriptors derived through docking into QSAR models ($R^2 = 0.71$, $q^2 = 0.63$) improved prediction of inhibitory activity. Candidate compounds such as Bartericin B and Vitexin were identified by virtual screening of natural product libraries[12]. The anticancer activity of nomilin against triple-negative breast cancer (TNBC) by using a network pharmacology strategy, eight significant protein targets—BCL2, Caspase3, CyclinD1, EGFR, HSP90AA1, KRAS, PARP1, and TNF. In AutoDock, docking simulations were performed after protein and ligand structure preparation with binding affinities. Nomilin exhibited strong and characteristic interaction with all targets, with binding energies ranging from –6.74 to –9.28 kcal/mol, the highest affinities being found for KRAS (–9.28 kcal/mol) and HSP90AA1 (–8.45 kcal/mol). Molecular dynamics simulations conducted with Desmond verified the long-term stability of nomilin–protein complexes over 100 ns, especially with BCL2, CyclinD1, EGFR, and PARP1. These observations indicate that anticancer actions of nomilin could be mediated by pathways like PI3K/Akt, giving mechanistic insights into its action. Overall, molecular docking here not only confirmed nomilin's multi-targeting potential but also informed target selection prioritization, structure-activity relationship (SAR) exploration, and experimental design. When coupled with network pharmacology and simulation research, docking was pivotal in speeding up the discovery and mechanism of nomilin as a potential lead compound in TNBC treatment[13]. Discovery and optimization of cyclin-dependent kinase (CDK) inhibitors as cancer drugs. Because CDKs such as CDK1 and CDK2 are central drivers of cell cycle progression, their dysregulation results in uncontrollable proliferation, qualifying them as important anticancer targets. By screening natural compounds, synthetic analogs, and repurposed drugs using docking software such as AutoDock, Glide, and MOE-Dock, scientists were able to identify effective inhibitors.

Molecules such as dinaciclib analogs and tangeretin presented high binding energies (–8.7 to –9.3 kcal/mol) with CDK1 residues Ser84 and Asp86, whereas dichlorophenoxymethyl and coumarin-glycosyl derivatives efficiently interacted with CDK2 hinge residues Leu83 and Lys89. Docking not only confirmed the target engagement but also offered mechanistic evidence towards hydrogen bonding and hydrophobic interactions within ATP-binding cavities. Coupled with molecular dynamics simulations and experimental assays, docking was an important tool for prioritizing hits, structure–activity relationship (SAR) optimization, and rational design of selective, effective CDK inhibitors[14].Molecular docking used to screen new pyrimidine–coumarin–triazole conjugates (a–l) as anticancer agents against dihydrofolate reductase (DHFR, PDB: 3SRQ) and tubulin (PDB: 1SA0 and 5J2T). All compounds showed good binding affinities in the range of –6.9 to –9.3 kcal/mol. A number of conjugates established stable hydrogen bonds within the active site of DHFR, as for methotrexate, and others bound well at colchicine and vinblastine binding sites on tubulin, showing potential to interfere with microtubule assembly. Compounds b and h had the highest affinities at the vinblastine and DHFR sites, respectively. Docking thereby confirmed target engagement, ranked the most favorable hits, and gave mechanistic insights into ligand–protein interactions. By integrating docking with QSAR predictions, the study enabled rational lead optimization and supported experimental planning for developing selective anticancer agents[15]. Molecular docking in investigating bioactive compounds of a polyherbal extract as potential prostate cancer target inhibitors, namely the androgen receptor (AR, PDB: 5JJM) and phosphoinositide-3-kinase regulatory subunit 1 (PIK3R1, PDB: 4JPS). Ligands quercetin, catechin, luteolin, and thymoquinone were docked upon optimization using AutoDock Vina via PyRx, whereas protein structures were optimized to establish active binding sites. Quercetin had the highest binding affinities (–9.0 kcal/mol for AR and –9.5 kcal/mol for PIK3R1), which had essential hydrogen bonding interactions with residues such as LEU704, GLN711, and ARG752, signifying stable associations. Docking identified quercetin, catechin, and luteolin as the best lead candidates. Further 100 ns molecular dynamics simulations validated the stability of quercetin–protein complexes. In total, docking confirmed the interaction of herbal compounds with key cancer-relevant pathways, providing mechanistic inputs on PI3K/Akt signaling inhibition and guiding experimental prioritization for drug discovery of prostate cancer[16].

Molecular docking to identify anticancer phytochemicals with potential activity against colorectal cancer by targeting key receptors involved in tumor growth and angiogenesis—HER2, HER3, and VEGFR2. Using UCSF Chimera with AutoDock Vina, 18 phytochemicals such as curcumin, genistein, silibinin, and yuanhuanin were docked alongside standard drugs like lapatinib and sorafenib to benchmark performance. Several phytochemicals exhibited strong binding affinities comparable to approved drugs, with yuanhuanin (–10.2 kcal/mol for HER2), theaflavin (–10.2 kcal/mol for HER3), and genistein (–9.8 kcal/mol for VEGFR2) emerging as top candidates. Docking revealed key hydrogen bond and hydrophobic interactions within kinase domains, suggesting inhibition of EGFR/VEGFR signaling pathways. Overall, docking served as a valuable tool for validating targets, prioritizing promising compounds, and providing structural insights to guide lead optimization, effectively complementing experimental screening in the discovery of natural product-based therapeutics for colorectal cancer[17].Molecular docking of naturally occurring furanocoumarins as potential multitarget inhibitors for breast cancer therapy by targeting ERα (3ERT), PR (4OAR), EGFR (2J6M), and mTOR (4DRH). Using BioSolveITFlexX, flexible ligand docking was performed with validation via RMSD (<2 Å) and drug-likeness screening, where 20 compounds met Lipinski's criteria. Among the tested molecules, xanthotoxol showed the strongest binding across all targets (–13.56 to –18.10 kcal/mol), followed by bergapten, angelicin, psoralen, and isoimperatorin. These compounds formed key hydrogen bonds and hydrophobic interactions with residues such as Arg394 (ERα), Gln725 (PR), Lys745 (EGFR), and Asp68 (mTOR). Docking results indicated multitarget binding potential comparable to standard drugs. Subsequent in vitro assays supported the computational findings, with xanthotoxol exhibiting potent ER antagonism (IC_{50} ~0.72 μM) and reduced EGFR and mTOR activity. Overall, docking guided efficient lead identification, mechanistic understanding, and validation of furanocoumarins as promising breast cancer inhibitors[18].Discovering natural inhibitors of the X-linked inhibitor of apoptosis protein (XIAP), a key regulator that prevents cancer cell death by blocking caspases. Using the XIAP crystal structure (PDB: 5OQW), researchers combined pharmacophore modeling, virtual screening of ~11,000 natural compounds from the ZINC database, and molecular docking via AutoDock Vina to identify potential binders.

Top hits such as Caucasicoside A (–8.0 kcal/mol), Venturicidin B (–7.8 kcal/mol), and Polygalaxanthone III (–7.6 kcal/mol) showed stronger binding than the reference antagonist. Key interactions with residues ASP309, THR308, and GLU314 stabilized the ligands within the XIAP binding pocket. Molecular dynamics simulations confirmed complex stability, while ADMET analysis indicated favorable pharmacokinetics. Overall, molecular docking played a central role in target validation, hit identification, and mechanistic insight, enabling the selection of promising natural XIAP inhibitors for further optimization in anticancer drug discovery[19].NEK7 (NIMA-related kinase 7) as a novel anticancer target due to its key role in mitotic progression and overexpression in various cancers. Fifteen phenylcarbamoylpiperidine-1,2,4-triazole amide derivatives (M1–M15), previously known for anti-inflammatory activity, were evaluated for NEK7 inhibition using AutoDock 4.2 and MOE software, with Dabrafenib as a reference. Docking revealed that compounds M7 (–29.66 kJ/mol), M12 (–31.38 kJ/mol), and M8 showed the strongest binding, forming stable hydrogen bonds and hydrophobic interactions with residues in NEK7's active site. Molecular dynamics simulations confirmed the stability of M7 and M12 complexes, supported by low RMSD and RMSF values. Docking validated NEK7 as a druggable kinase and identified triazole derivatives as promising inhibitors. Computational findings correlated with MTT assay results, demonstrating real anticancer activity and highlighting docking's value in target validation, lead prioritization, and guiding structural optimization for effective anticancer drug design [20]. Anticancer mechanism of Scopoletin, a natural coumarin from fennel, against non-small cell lung cancer (NSCLC) using molecular docking and network pharmacology. Sixteen common targets between Scopoletin and NSCLC were identified, with EGFR, BRAF, and AKT1 emerging as key nodes in the RAS–RAF–MEK–ERK and PI3K/AKT pathways. Using AutoDockTools 1.5.6, Scopoletin showed strong binding affinities—EGFR (–8.0 kcal/mol), BRAF (–7.2 kcal/mol), and AKT1 (–7.5 kcal/mol)—forming stable hydrogen bonds with residues such as GLY-614, SER-615, and LYS-284. These interactions suggest effective inhibition of kinase phosphorylation and downstream signaling. Docking thus validated Scopoletin's potential to target multiple oncogenic kinases and provided mechanistic insight into its antiproliferative action. Experimental validation via western blot confirmed reduced phosphorylation of EGFR, BRAF, and AKT1, supporting the docking predictions and emphasizing Scopoletin's promise as a multi-target lead compound for NSCLC therapy[21].

CONCLUSION

Molecular docking continues to serve as a pivotal tool in structure-based drug discovery, particularly in the search for novel anti-cancer therapeutics. Through the facilitation of rapid prediction of ligand–target interactions, docking speeds hit finding, lead optimization, and offers mechanistic information regarding binding modes. Its application in various malignancies such as prostate, breast, colorectal, lung, and kinase driven cancers showcases its utility in directing the design of synthetic molecules and natural product derivatives. In spite of intrinsic difficulties like receptor flexibility, solvent contributions, and entropic penalties, progress in flexible docking, hybrid algorithms, and coupling with molecular dynamics simulations is continuously enhancing predictive precision. Complemented with ADMET profiling and cheminformatics, docking strengthens the drug ability of computationally discovered leads. Although never a replacement for experimental verification, molecular docking is an integral part of contemporary oncology drug discovery pipelines, linking computational predictions with rational design of targeted, effective, and safer anti-cancer drugs.

ACKNOWLEDGEMENTS

Table 1: Accuracy of Rigid docking

Tool	Performance Highlights
ZDOCK	Predicted correct interface contacts in 47% of unbound–bound cases.
PatchDock	Achieved RMSD < 2 Å in 31 out of 35 cases; correct pose ranked first in 26 instances.
BiGGER	22 out of 25 complexes within 4 Å RMSD; 14 ranked among top 20 solutions.
Cell-Dock	Produced near-native poses in 89% of cases using CELL-256 grid resolution.
FRODOCK	Delivered acceptable solutions in most cases; many with RMSD ≤ 4 Å.
General Limitation	Often fails with unbound crystal structures due to rigid-body assumptions.

Table 2: Accuracy of flexible docking

Tool	Performance Highlights
GOLD	~60% accuracy with RMSD < 1.2 Å; effective for hydrophilic binding sites.
Glide	RMSD < 2 Å in 61% of cases; excels with diverse and complex binding environments.
ICM	Highest reported accuracy (~76% within 2 Å RMSD); ideal for virtual screening tasks.
AutoDock Vina	Enhanced speed and accuracy using Monte Carlo sampling and BFGS optimization.
LigandFit	~60% accuracy; well-suited for docking flexible ligands.
Surflex	~53% success rate; performs well in hydrophobic pockets.
General Limitation	Backbone flexibility and solvent effects remain challenging for all listed tools.

ABSTRACT

Multiple sclerosis (MS) is a chronic autoimmune and neurodegenerative disease characterized by immune-mediated demyelination, neuroinflammation, oxidative stress, and progressive axonal destruction within the central nervous system. Even while disease-modifying medications have advanced, the majority of current treatments focus on immune modulation and are unable to completely preserve neurons or stop the progression of the disease. Therefore , finding a multi-target therapeutic that possesses neuroprotective potential is still a top research topic. In numerous experimental studies, obacunone, a bioactive limonoid molecule mostly extracted from citrus species, has shown notable anti-inflammatory, antioxidant, and neuroprotective activities. Its therapeutic value in MS hasn't been well investigated yet, though. In order to clarify the possible molecular mechanisms behind obacunone's neuroprotective benefits in MS, the current study uses a network pharmacology-based methodology. Using available pharmacological databases, potential targets of obacunone were identified and intersected with MS-related genes to generate a network of compound–target–disease connections. Protein–protein interaction (PPI), Gene Ontology (GO), and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment studies were carried out in order to identify significant biological processes

and signaling pathways. Preliminary findings indicates that obacunone may exert its therapeutic effects through neuroinflammation, apoptosis and autophagy related pathways. These multi-target interactions highlight the potential of obacunone as a promising candidate for adjunctive neuroprotective therapy in MS. Further experimental validation is warranted to confirm these computational predictions.

Keywords: Network pharmacology, multiple sclerosis, obacunone, neuroinflammation, apoptosis.

INTRODUCTION

MS is a chronic demyelinating neurodegenerative pathology of the central-nervous system that significantly compromises the physiological and psychological well-being of affected individuals [1]. The disease progressively attacks the immune system of the myelin sheath of nerve fibers in the central nervous system, which includes the brain, spinal cord, and optic nerves. According to reports, Indian herbal medicine can effectively reverse clinical symptoms like paralysis and tremor, increasing MS patients' quality of life. Phyto-therapeutic agents such as *Withania somnifera, Curcuma longa, Ginkgo biloba, Boswellia serrata,* and *Nigella sativa* are frequently integrated as adjunctive therapies in the clinical management of MS [2]. These herbs are generally valued for their anti-inflammatory, antioxidant, and neuroprotective bioactivities, which may help in reducing inflammation and oxidative stress associated with the disease [3]. Novel models for disease-drug prediction have been developed as a result of rapid advancements in computational biology, molecular biology, bioinformatics, and network pharmacology. Pharmacology is now a potent instrument for investigating the precise targets and routes for the treatment of diseases, thanks to the enormous advancements made in recent years to clarify its mechanisms [4]. This study's goal was to use network pharmacology to assess potentially useful elements in MS treatment.

Natural bioactive compounds have gained considerable attention due to their multi-target pharmacological properties and favorable safety profiles. Obacunone, a limonoid triterpenoid compound derived from citrus plants such as *Citrus* species, has been reported to possess anti-inflammatory, antioxidant, and neuroprotective activities (4). Previous studies indicate that obacunone can activate the Nuclear factor erythroid 2-related factor 2 (Nrf2) signaling pathway, enhance antioxidant defence mechanisms, and inhibit inflammatory mediators through suppression of Nuclear factor kappa-light-chain-enhancer of activated B cells (NF-κB) and mitogen activated protein kinase (MAPK) pathways. These mechanisms are highly relevant to the pathophysiology of MS, where sustained neuroinflammation and oxidative stress serve as a primary driver of demyelination and neuronal damage [5]. A mono-target therapy approach might not be enough to attain the best clinical results given the complex etiology of MS. A developing systems biology-based method called network pharmacology combines computational biology, bioinformatics, and pharmacology to investigate interactions between medications, targets, and illnesses at a systemic level. Network pharmacology, in contrast to conventional "one drug–one target" models, makes it possible to identify multi-target mechanisms and pathway crosstalk, which makes it especially useful for analyzing complicated disorders like MS. Thus, the current investigation uses a network pharmacology-based method to investigate the possible neuroprotective impact of obacunone in the treatment of multiple sclerosis. This study attempts to provide mechanistic explanations of how obacunone may modulate important inflammatory, oxidative, and apoptotic pathways involved in MS pathogenesis by identifying shared molecular targets, building protein–protein interaction networks, and conducting functional enrichment analyses. The findings of this study lay the theoretical groundwork for upcoming experimental verification and the creation of innovative adjunct treatments for MS derived from plants.

MATERIALS AND METHODS

Network Pharmacology:

The bioactive compound's chemical structure was retrieved from PubChem for the network pharmacology study, and internet resources such as Swiss Target Prediction and Target net were used to estimate the compound's putative protein targets. Genes associated with MS were gathered from databases like Gene Cards. A Venn diagram tool was used to identify the overlapping targets between the disease and the chemical. In order to discover important genes, these common targets were then utilized to build a protein-protein interaction (PPI) network using the STRING database and displayed in Cytoscape software. To investigate the biological roles and processes involved, Gene Ontology (GO) and KEGG pathway enrichment analyses were carried out using. In order to comprehend the general mechanism of action, a compound-target-pathway network was finally constructed in Cytoscape [6] .

Target Prediction of Obacunone:

To predict its possible targets, the Swiss Target Prediction (https://www.swisstargetprediction.ch/) and Target Net (http://targetnet.scbdd.com/) platforms were provided the canonical SMILES notation for obacunone, which was taken from the PubChem database. With a particular focus on "Homo sapiens," the Swiss Target Prediction analysis was conducted. UniProt IDs associated with targets that had a likelihood greater than 0 were then filtered out. The targets found on both platforms were then combined to create an extensive list of targets connected to obacunone.

Targets prediction of MS

The term "MS" was utilized to find pertinent targets from the Gene Cards (https://auth.lifemapsc.com/), with an emphasis on Homo sapiens. A full list of targets linked to MS was then produced by combining the targets from both databases.

Construction of PPI Network and Hub genes analysis

The intersection of Obacunone candidate target genes and MS-associated genes was determined to identify common drug-disease targets. A protein-protein interaction (PPI) network was subsequently constructed using the STRING 11.0 (https://version-11-0.string-db.org/) platform, incorporating the combined targets of Obacunone and MS, as identified through Venny analysis. The hub genes within the PPI network for Obacunone against MS were extracted using the Cyto-Hubba plugin of Cytoscape 3.10.1 (https://cytoscape.org/download.html) software.

GO and KEGG pathway enrichment analysis

The Shiny GO 0.80 (https://bioinformatics.sdstate.edu/go80/) database was used to perform GO enrichment and KEGG pathway analyses, elucidating the functional annotations and putative mechanistic underpinnings of the identified targets. P value < 0.05 was considered statistically significant for both GO enrichment and KEGG pathway analysis. Subsequently, an online bioinformatics platform was employed to generate graphical representations of the enrichment analyses, facilitating enhanced data visualization and interpretation.

RESULT

Finding of Obacunone Related Target Genes

After screening the PubChem database, we got the canonical smile and then we used the Swiss target prediction database for the targets of obacunone. Moreover, the Targetnet database also has been employed to identify putative targets of the said compound. We identified 101 potential targets of obacunone from the above mention databases and the Uniprot IDs of targets and deletion of the invalid and duplicated targets has been done manually.

Identification of Multiple Sclerosis Related Target Genes

Following the removal of duplicate targets, we were able to identify 17158 possible MS-associated illness targets after analyzing the GeneCards database.

Prediction of Common Targets Between Obacunone and Multiple Sclerosis

After mapping 120 successful drug targets to 14094 MS-related target genes using VENNY2.1 software, 102 intersection genes were discovered. Refer Figure No. 1.

Construction of PPI network and top 10 interaction identification:

In the String database, PPI network was established consisting of 61 nodes and 108 edges. An edge represents the association between the targets, whereas the nodes represent the targets. The PPI network, constructed using STRING, demonstrates a densely interconnected core of proteins with several distinct functional modules. Key central (hub) proteins has been constructed using Cytoscape software and top 10 target genes such as MAPK1, FYN, CTSL, CTSS, BACE1, DRD2, C5AR1, OPRM1, ALOX5 and CYP2C19 exhibit high connectivity. Refer figure no 3 and 4.

KEGG analysis:

KEGG pathway enrichment analysis of the common targets between obacunone and MS revealed significant involvement of immune, inflammatory, and neurodegeneration-related pathways. Among the most enriched pathways were Fc epsilon RI signaling, T cell receptor signaling, antigen processing and presentation, and natural killer cell–mediated cytotoxicity, highlighting strong immunomodulatory potential. Apoptosis showed a high fold enrichment with notable statistical significance, suggesting a role in regulating immune cell survival and neuroaxonal damage. Additionally, pathways related to sphingolipid signaling, autophagy, lysosome, and phagosome indicate modulation of neuroinflammation and myelin degradation processes. Synaptic pathways, including serotonergic and cholinergic synapses, along with axon guidance, further suggest potential neuroprotective and neuronal regulatory effects. Overall, the enrichment profile supports that obacunone may exert therapeutic effects in MS through coordinated regulation of immune responses, inflammatory signaling, apoptotic mechanisms, and neuroprotective pathways. Refer figure no 4 and table no 1.

GO Biological process:

GO biological process enrichment analysis of the shared targets between obacunone and MS demonstrated significant overrepresentation of processes primarily associated with synaptic function, neuronal signaling, and stimulus response. Highly enriched terms included synaptic signaling, trans-synaptic signaling (anterograde and chemical synaptic transmission), and regulation of cation transmembrane transport, indicating a strong association with neuronal communication and ion homeostasis. Processes related to sensory perception of pain and detection of mechanical stimulus further suggest involvement in neuro-sensory modulation. In addition, significant enrichment was observed in cellular response to chemical, organic, and endogenous stimuli, as well as response to nitrogen- and organonitrogen-containing compounds, highlighting regulatory effects on cellular signaling cascades. Behavioral response to ethanol and feeding behavior also emerged, reflecting neuromodulatory and central nervous system–related functions. Overall, the GO biological process analysis suggests that obacunone may exert therapeutic effects in MS by modulating synaptic transmission, neuronal excitability, ion transport, and cellular responses to inflammatory and chemical stimuli, thereby contributing to neuroprotection and functional regulation. Refer figure no 5.

GO Cellular components:

GO cellular component enrichment analysis of the common targets between obacunone and MS revealed significant localization of shared genes to vesicle-mediated and endolysosomal compartments. The most prominently enriched components included endolysosome lumen, endosome, late endosome, lysosome, lytic vacuole, and vacuolar lumen, indicating strong involvement in intracellular trafficking, degradation pathways, and autophagy–lysosomal processes. Additionally, membrane raft and membrane microdomain regions showed significant enrichment, indicating involvement in immune receptor assembly and signal transduction. Relevance to synaptic integrity and neural transmission was highlighted by the notable enrichment of neuronal structural elements as the somatodendritic compartment, dendrite, dendritic tree, cell body, and synapse. A involvement in vesicular transport

and protein processing is further supported by further enrichment in cytoplasmic vesicles, intracellular vesicles, secretory vesicles, Golgi apparatus, and general vesicle components.

Collectively, these findings indicate that obacunone may influence MS pathology by targeting genes localized to vesicular, endolysosomal, and synaptic compartments, thereby modulating neuroinflammatory signaling, antigen processing, and neuronal function. Refer figure no 6.

GO Molecular function:

GO molecular function enrichment analysis of the common targets between obacunone and MS showed significant enrichment in receptor-mediated signaling, neurotransmitter binding, and catalytic enzyme activities. Dopamine neurotransmitter receptor activity (including Gi/Go-coupled), dopamine binding, melanocortin receptor activity, and glutamate receptor binding (including metabotropic glutamate receptor binding) were prominent terms that emphasized excitatory neurotransmission and G protein–coupled receptor (GPCR) signaling modulation. The role in neuromodulatory pathways is further supported by the enrichment of G protein-coupled opioid receptor activation. Additionally, functions related to fibronectin binding, collagen binding, and proteoglycan binding suggest interactions with extracellular matrix components, which are relevant to neuroinflammation and tissue remodeling in MS. Significant representation of cysteine-type peptidase activity, endopeptidase activity, omega peptidase activity, and catalytic activity acting on proteins indicates regulation of proteolytic and enzymatic processes. RNA polymerase II CTD heptapeptide repeat kinase activity also implies potential transcriptional regulation. Collectively, these findings suggest that obacunone may exert therapeutic effects in MS through modulation of GPCR-mediated neurotransmission, enzyme activity, extracellular matrix interactions, and proteolytic signaling pathways. Refer figure no 7 and table no 2.

DISCUSSION

MS is a complex autoimmune and neurodegenerative disorder characterized by immune dysregulation, demyelination, axonal injury, and progressive neuronal degeneration. Due to its multifactorial pathogenesis, therapeutic strategies targeting a single molecule or pathway often fails to provide the sustained neuroprotection [7]. In this study, a network pharmacology-based approach was employed to systematically explore the potential molecular mechanisms underlying the therapeutic effects of obacunone in MS. These findings demonstrate that obacunone exerts multi-target regulatory effects across immune, inflammatory, apoptotic, synaptic, and vesicular pathways, supporting its viability as a neurotherapeutic lead. A significant junction between compound-associated proteins and genes linked to the disease is highlighted by the discovery of 102 overlapping targets between obacunone and MS. Key hub genes, such as MAPK1, FYN, CTSL, CTSS, BACE1, DRD2, C5AR1, OPRM1, ALOX5, and CYP2C19, were identified by the PPI network analysis. A number of these hubs have a crucial role in the pathophysiology of MS. While FYN is linked to the control of myelin sheaths and oligodendrocyte function, MAPK1 is essential for inflammatory signaling cascades and T-cell activation. Lysosomal proteases CTSL and CTSS are linked to neuroinflammatory reactions and antigen processing. Neurodegeneration and axonal damage have been associated with BACE1. Obacunone may have regulatory effects on the primary inflammatory and neurodegenerative drivers of multiple sclerosis, according to the discovery of these hubs.

The KEGG pathway enrichment study enhanced obacunone's immunomodulatory and neuroprotective properties. Obacunone may affect both adaptive and innate immune responses, as evidenced by significant enrichment in T cell receptor signaling, antigen processing and presentation, natural killer cell–mediated cytotoxicity, and Fc epsilon RI signaling pathways. These findings are especially pertinent because MS-associated demyelination is mostly caused by abnormal T-cell activation and antigen presentation. The apoptosis pathway's significant enrichment points to a function in controlling programmed cell death, which is essential for oligodendrocyte survival and axonal maintenance. Additionally, since sphingosine-1-phosphate regulation is a well-established therapeutic approach for multiple sclerosis, enrichment of the sphingolipid signaling pathway is significant, suggesting potential mechanistic convergence.

GO enrichment analyses showed additional mechanistic overview. Biological process enrichment demonstrated significant involvement in synaptic signaling, regulation of ion transport, and response to chemical stimuli, indicating the potential modulation of neuronal excitability and synaptic transmission. Moreover, result of cellular component analysis indicates localization within endosomes, lysosomes, vesicles, membrane rafts, and synaptic compartments, suggesting that obacunone-associated targets are concentrated in structures critical for antigen processing, intracellular trafficking, and neuroinflammatory signaling. Additionally, molecular function enrichment revealed significant associations with G protein–coupled receptor activity, neurotransmitter binding, and proteolytic enzyme activity, further supporting a role in neuromodulation and inflammatory regulation. Together, these findings suggest that obacunone may treat MS by a coordinated multi-pathway mechanism that includes (i) immune activation suppression, (ii) inflammatory and apoptotic signaling regulation, (iii) synaptic communication and neuronal signaling modulation, and (iv) lysosomal and autophagy-related process regulation. The pharmacological characteristics of obacunone, such as its anti-inflammatory and antioxidant activities, are in good agreement with the systems-level interactions found in this investigation.

Although, this study is based on computational predictions and database-derived targets, which may introduce bias due to database limitations or incomplete annotations. Experimental validation using in vitro and in vivo MS models, such as the experimental autoimmune encephalomyelitis (EAE) model, is required to confirm these predicted interactions. Future studies should also explore molecular docking, gene expression validation, and pathway inhibition assays to further substantiate the mechanistic hypotheses generated here.

CONCLUSION

To sum up, this network pharmacology investigation methodically clarifies the possible molecular pathways through which obacunone can have neuroprotective benefits in MS. Obacunone's multi-target therapeutic potential is highlighted by the discovery of 102 common targets, important hub genes, and a notable enrichment of immunological, apoptotic, sphingolipid, synaptic, and autophagy-related pathways. Obacunone may contribute to neuroprotection in multiple sclerosis by modulating immunological dysregulation, attenuating neuroinflammation, regulating apoptosis, and maintaining synaptic integrity, according to the integrated analysis. These results provide a solid theoretical basis for thinking of obacunone as a possible adjunctive candidate for the treatment of multiple sclerosis, even though more experimental validation is required. They also encourage future translational research in this area.

ABSTRACT

The increasing scarcity of natural aggregates and the environmental burden of construction and demolition waste have driven the development of sustainable alternatives in concrete production. This study presents an experimental investigation into the mechanical and durability properties of green concrete incorporating treated and untreated reused coarse aggregates (RCA) and reused fine aggregates (RFA), along with glass waste, as partial replacements for natural aggregates in M20, M50, and M70 grade concrete. The novelty of the research lies in its comparative evaluation of multiple treatment techniques for recycled aggregates—namely abrasion treatment (RA-AT), cement slurry treatment (RA-CST), and chemical treatment (RA-CT)—and their influence on concrete performance across various strength classes. The primary objective of the study was to assess the effect of varying proportions (10%, 20%, and 30%) of RCA and RFA on workability, compressive strength, flexural strength, split tensile strength, and modulus of elasticity. Standard procedures in accordance with IS 456, IS 516, IS 5816, and IS 1199 were employed for all experimental tests. The findings demonstrated that increasing the percentage of recycled aggregates leads to a reduction in workability and mechanical strength, primarily due to the higher porosity and angular texture of recycled materials. However, concrete mixes with chemically treated recycled aggregates (RC-CT) exhibited significantly better performance compared to other treatment types. For M70 grade, RC-CT achieved a compressive strength of 53.89 MPa compared to 55.76

MPa in normal concrete, indicating a marginal strength reduction with considerable sustainability benefits. Furthermore, code-based predictions of the modulus of elasticity revealed discrepancies when compared with experimental results, especially for recycled mixes.

Keywords: Green Concrete, Recycled Aggregates (RCA and RFA), Glass Waste, Mechanical Properties of Concrete, Aggregate Treatment Techniques

INTRODUCTION

The incorporation of waste glass into green concrete has been investigated extensively, revealing both performance advantages and practical challenges. Through various studies, it has been demonstrated that using waste glass as a partial substitute for cement or aggregates can lead to significant environmental, mechanical, and economic benefits. Environmental impacts were minimized by diverting non-biodegradable glass waste from landfills and reducing greenhouse gas emissions associated with cement production (Olofinnade *et al*., 2019; Arora *et al*., 2022; Ali *et al*., 2021; Olofinnade *et al*., 2018; Ishaq *et al*., 2025; Amran *et al*., 2022). Additionally, natural resources were conserved as glass waste effectively replaced fine aggregates and cement (Olofinnade *et al*., 2019; Olofinnade *et al*., 2018; Hamoudeh *et al*., 2022; Qaidi *et al*., 2022). From a mechanical perspective, improvements in compressive strength have been observed when 10–20% of cement was replaced with finely ground glass powder (Arora *et al*., 2022; Ali *et al*., 2021; Olofinnade *et al*., 2018; Ishaq *et al*., 2025). Flexural and tensile strengths were also enhanced, particularly when glass waste was combined with other materials like steel slag (Ali *et al*., 2021; Hamoudeh *et al*., 2022; Li *et al*., 2022; Khalil and Obeidy, 2018). Microstructural benefits were reported due to the formation of secondary calcium silicate hydrate (CSH) and improved particle packing, which contributed to better durability (Ali *et al*., 2021; Olofinnade *et al*., 2018). Economically, concrete containing glass waste was found to be approximately 19% more cost-effective than conventional concrete, due to lower material costs (Arora *et al*., 2022). However, reduced workability was commonly reported, necessitating mix design adjustments when higher proportions of glass were used (Olofinnade *et al*., 2019; Amran *et al*., 2022). Although alkali-silica reaction (ASR) remains a concern, it was shown that the pozzolanic activity of finely ground glass powder helps mitigate ASR effects (Wen *et al*., 2025). Optimal performance was typically achieved when glass waste replaced up to 25% of natural aggregates or 10–20% of cement (Olofinnade *et al*., 2019; Hamoudeh *et al*., 2022; Arora *et al*., 2022).

Glass waste has also been applied effectively in structural concrete for strength enhancement (Hamoudeh *et al*., 2022; Li *et al*., 2022), in partition walls for fire and thermal resistance (Lu *et al*., 2019), and in foam concrete to improve sound absorption (Mohd Farid Wajdi *et al*., 2025). Workability is generally reduced when recycled aggregates are used. This decline is attributed to the angularity and porous nature of recycled materials, which absorb more water and reduce the ease of flow in the fresh mix (Jhakal, Thakur, and Jain, 2024; Worku, Khawal, and Singh, 2022). In contrast, the incorporation of finely ground glass waste improves workability due to its smooth texture and filler effect, which enhances fluidity (Jhakal *et al*., 2024; Zeybek *et al*., 2022). Regarding compressive strength, recycled aggregates have shown potential to maintain or even slightly improve strength at moderate replacement levels. Notably, up to 40% RCA replacement resulted in comparable strength to conventional mixes (Raman, Nateriya, and Rathore, 2025). The addition of WGP significantly increased compressive strength, especially at 20% cement replacement, where strength gain was most effective. Combinations of WGP with crushed glass further contributed to strength enhancement through microstructural densification (Zeybek *et al*., 2022; Li, Zhang, Zhu, and Liu, 2022). Flexural strength was similarly influenced. Recycled aggregates, when combined with glass waste, maintained or slightly improved the flexural capacity of concrete (Jhakal *et al*., 2024; Raman *et al*., 2025). The use of coarse glass aggregate (CGA) notably enhanced flexural strength by up to 44.78% when a 40% glass content was used, while a 50% blend of fine and coarse glass further elevated performance (Mohammed, Sabir, Saeed, and Omer, 2024; Hamoudeh, Ikotun, and Babafemi, 2022). In terms of splitting tensile strength, concrete with recycled aggregates showed results that were comparable to or slightly below those of natural aggregate mixes, depending on

replacement percentage and treatment quality (Jhakal *et al*., 2024; Raman *et al*., 2025). However, the inclusion of WGP improved tensile performance. A 15% replacement of cement with WGP increased tensile strength by approximately 5.4%, while 20% yielded the most significant improvement (Zeybek *et al*., 2022; Saleh and Hama, 2023).

Selection of test methods and parameters of study

Results of standard tests conducted on cement

In this work, Ordinary Portland Cement (OPC) of 43-grade was utilized, conforming to the specifications prescribed by the Indian Standard IS:12269-1987. The specific gravity of the cement was determined to be 3.12. Cement samples were collected in accordance with the procedures outlined in IS:3535-1986, and testing was carried out based on the relevant specifications of IS:4031-1996. A series of standard tests was conducted to assess the fundamental physical properties of the cement. These tests included the determination of specific gravity, fineness, standard consistency, soundness, and setting times (both initial and final). The results of these tests are presented in Table 1 and have been evaluated against the permissible limits as stipulated in the corresponding Indian Standards. The cement was classified as OPC-43 as per IS 8112. The specific gravity of 3.12 was found to be within the acceptable limit of less than 3.15 (IS 2720 Part 3). The fineness of cement was measured at 8%, which satisfies the requirement of being below 10% as per IS:4031 (Part 1)-1988. A standard consistency of 40% was recorded in accordance with IS:4031 (Part 4)-1988. The soundness was found to be 6 mm, well below the maximum permissible value of 10 mm specified in IS:4031 (Part 3)-1988. Furthermore, the initial setting time was 85 minutes, exceeding the minimum requirement of 30 minutes, and the final setting time was 300 minutes, comfortably within the maximum limit of 600 minutes as specified in IS:4031. These results confirm that the cement used in this research complied with the required standards and was deemed suitable for construction-related applications. Results of standard tests conducted on cement in accordance with Indian Standards (Table 1).

Analysis of Natural Fine Aggregate

The term fine aggregate refers to mineral particles ranging in size from 4.75 mm down to 150 microns. Natural river sand was employed as the fine aggregate, and it conformed to the specifications outlined in the Indian Standard IS:383-1970. The physical properties of the sand were examined in accordance with the procedures specified in IS:2386 (Part III)-1963. Based on its particle size distribution, the river sand was classified under Zone I, indicating coarser gradation suitable for concrete work requiring greater strength and durability. The specific gravity and fineness modulus of the sand were found to be 2.65 and 3.29, respectively. The specific gravity reflects the material's relative density compared to water, while the fineness modulus serves as an index of the average size of particles in the aggregate. To further analyze the gradation, a sieve analysis was conducted, and the results are presented in Table 2. This analysis involved passing the sand sample through a series of standard IS sieves and measuring the amount of material retained on each. The cumulative percentage retained and the percentage passing through each sieve were then calculated. A total sample weight of 2000 grams was used for this test, and the percentage of material retained on the 4.75 mm sieve was found to be 0.1%. The overall fineness modulus, derived by dividing the cumulative weight retained by 100, was computed as 3.29, indicating a relatively coarser sand consistent with Zone I classification. These results confirm the suitability of the river sand for structural and construction purposes. Sieve analysis of natural fine aggregate (river sand) (Table 2).

Total cumulative weight retained (W) = 329.15 g

Fineness Modulus (FM) = W / 100 = 3.29

Weight of sample taken = 2000 g

% Weight retained on 4.75 mm sieve = (2 / 2000) × 100 = 0.1%

Analysis of Natural Coarse Aggregates

Crushed coarse aggregate, which was readily available locally, was utilized in the experimental trials. This aggregate conformed to the specifications established in Indian Standard IS:383-1970. The particle size distribution of the coarse aggregate adhered to the guidelines of IS:2386 (Part I)-1963. The nominal size of the aggregate permitted it to pass through a 40 mm sieve while being retained on a 10 mm sieve, indicating its suitability for use in standard concrete mixes. The specific gravity of the coarse aggregate was determined to be 2.78. Furthermore, the mechanical

properties of both natural and recycled aggregates were evaluated following the provisions of IS:2386 (Part IV)-1963. To assess the gradation of the natural coarse aggregate, a sieve analysis was carried out. The sample used for this analysis weighed 5 kg, and the results, including the retained weights and cumulative percentages, are presented in Table 3. The cumulative percentage retained at the 32 mm sieve was calculated to be 24%, based on the retained weight of 1.2 kg. The fineness modulus, calculated by dividing the cumulative percentage retained by 100, was found to be 3.54. These results confirm that the natural coarse aggregate is within acceptable grading limits and is appropriate for structural applications.

Sieve analysis of natural coarse aggregate (Table 3).

- Total weight of the sample taken = 5 kg
- Cumulative % retained at 32 mm sieve = (1.2 / 5) × 100 = 24%
- Fineness Modulus (FM) = 354 / 100 = 3.54

Evaluation of Treatment Techniques for Natural and Reused Aggregates

In this work, various treatment techniques were assessed for their effectiveness in improving the properties of reused aggregates in comparison to natural aggregates. The tests were conducted to evaluate critical physical and mechanical properties such as specific gravity, water absorption, impact value, crushing value, and abrasion value. The reused aggregates(RA) were processed using three different methods: machine mixing (RA-AT), hand mixing (RA-CST), and chemical treatment (RA-CT). The properties of these treated aggregates were compared with those of untreated natural aggregates, and the results are presented in Table 4. The specific gravity of natural aggregate was found to be 2.78, while that of machine-mixed reused aggregate was 2.47, hand-mixed reused aggregate 2.53, and chemically treated reused aggregate 2.57. These values fall within the acceptable range of 2.5 to 3.0 as per IS code specifications. However, the water absorption for reused aggregates exceeded the IS limit of 2%, with values ranging from 4.31% to 6.34%, indicating a higher porosity. In terms of impact value, all aggregates remained well within the maximum permissible limit of 45%, though reused aggregates showed a slight increase. The crushing values of reused aggregates ranged from 25.1% to 27.89%, which are below the IS threshold of 30%, suggesting their suitability for structural applications. The abrasion values were also within acceptable limits (<50%), with natural aggregate showing the least value at 14.54%, while chemically treated reused aggregates recorded a maximum value of 24.78%.These findings indicate that although reused aggregates have inferior properties compared to natural aggregates, their mechanical characteristics remain within permissible IS limits. Chemical treatment appeared to improve certain aspects, making RA-CT a potentially more viable alternative for sustainable construction practices. Table 4. Results of various treatment techniques for the properties of natural and reused aggregates

Measurement of Workability by using the Slump Test

Although the slump test is a straightforward method, it must be executed with high precision, as any inaccuracies may lead to serious construction issues. To evaluate the workability of different concrete mixtures, sampling and analysis procedures as prescribed by IS:1199 were followed. The slump test was conducted using a standard slump cone, and the slump values were recorded in millimeters. For the preparation of concrete mixes, reused coarse aggregate (RCA) and reused fine aggregate (RFA) were incorporated in replacement proportions of 10%, 20%, and 30%. These aggregates were used both with and without treatment to assess their influence on concrete performance. Specifically, reused concrete labeled as RC(CT) refers to mixtures containing chemical-treated aggregates, while RC(CST) denotes mixes where aggregates were treated using cement slurry. The corresponding slump test values for various replacement levels are illustrated in Figure 1. Slump Value Comparison Between RC(CST) and RC(CT) for M20 Grade Concrete (Figure 1). The compaction factor test is utilized to measure the compactness of concrete, which is a critical indicator of workability. This test is particularly suitable for laboratory settings and is applied to both fresh and partially dried concrete. Figure 2 illustrates the compaction factor values for reused concrete (RC) incorporating varying percentages of reused coarse aggregate (RCA) and reused fine aggregate (RFA). It was observed that the compaction factor decreased as the percentage of fine recycled aggregate increased, leading to a much stiffer mix. This reduction in workability is attributed to the higher water absorption and angular texture of the

recycled fine aggregates, which interfere with fluidity and compaction. Compaction Factor for RC(CST) with M20 Grade Concrete (Figure 2).

Calculating Reused Aggregate Concrete's Compressive Strength

To determine the compressive strength of reused aggregate concrete, tests were conducted using a compression testing machine with a loading capacity of 2,000 kN. The tests were performed in accordance with the guidelines specified in IS 516-1959. Concrete cube specimens with dimensions of 150 mm × 150 mm × 150 mm were prepared, as illustrated in Figure 3. All specimens were cured in water for a period of 28 days prior to testing. For each concrete mix incorporating various proportions of recycled coarse and fine aggregates, 19 specimens were cast. Upon reaching the designated test age, the samples were removed from the curing tank and left to rest at ambient conditions for 10 to 15 minutes. Each cube was then positioned on the steel platen of the compression machine in such a way that the load was applied perpendicular to the casting face. The compressive strength test was conducted at a constant loading rate of 5 kN/s, in strict adherence to IS 516-1959. The compressive strength was computed by dividing the maximum crushing load by the cross-sectional area of the specimen. The results of these tests provide valuable insight into the mechanical behavior of concrete incorporating recycled aggregates and are graphically represented in Figure 3. 28-Day Compressive Strength of Reused Concrete (RC) with M20 Grade (Figure 3).

Flexural and Split Tensile Strength Testing of Reused Aggregate Concrete

A total of 19 concrete mixes of M20 grade were tested, incorporating varying percentages of reused coarse and fine aggregate, both with and without treatment. These tests were conducted to evaluate the flexural and split tensile strength of the mixes. For the flexural strength test, beam specimens measuring 100 mm × 100 mm × 500 mm were prepared and tested in accordance with IS: 516-1959. After being cured in water for 28 days, the beam specimens were subjected to testing by placing them on two rollers with a diameter of 4.5 cm. The flexural strength was calculated by determining the bending moment during the test and dividing it by the section modulus of the beam specimen. The test setup and procedures are illustrated in Figure 4. In addition to the flexural test, split tensile strength was also evaluated using cylindrical specimens with a diameter of 150 mm and a length of 300 mm. These tests were conducted following the guidelines provided in IS: 5816. The specimens were also cured in water for 28 days before testing. The tensile strength tests were performed using a compression testing machine with a maximum loading capacity of 3,000 kN. The test results offer insight into the mechanical performance of concrete incorporating recycled aggregates under tensile and flexural stress conditions. 28-Day Flexural Strength of Reused Concrete (RC) (Figure 4). 28-Day Split Tensile Strength of Reused Concrete (RC) (Figure 5).

Modulus of Elasticity of Concrete: Code-Based Comparisons

In accordance with IS 456:2000, the Indian Standard Code provides a relationship between the modulus of elasticity of concrete and the compressive strength of a cube. This relationship is expressed as: $E_c = 5000\sqrt{f_{ck}}$. A corresponding relationship based on compressive cylinder strength has been specified by the American Concrete Institute (ACI 318), and is given by the formula: $E_c = 4734\sqrt{f_{ck}'}$. Additionally, the British Standard Code of Practice (BS 8110) has defined the relationship between the modulus of elasticity and compressive cube strength using the following expression: $E_c = 20000 + 0.2f_{ck}$. In these expressions, f_{ck} represents the 28-day compressive strength of a concrete cube in N/mm², f_{ck}' denotes the 28-day compressive strength of a concrete cylinder in N/mm², and E_c is the modulus of elasticity at 28 days in N/mm². Comparison of Modulus of Elasticity of Concrete Based on Different Codes (Table 5).

RESULTS AND DISCUSSIONS

The experimental investigation evaluated the performance of green concrete mixes incorporating varying proportions of reused coarse aggregate (RCA) and reused fine aggregate (RFA), both treated and untreated. The performance was assessed in terms of workability, compressive strength, flexural strength, split tensile strength, and modulus of elasticity.

Workability: The slump test indicated a clear decline in workability with increased replacement of natural aggregates by reused aggregates. For M20 grade mixes, RC(CST) and RC(CT) exhibited reduced slump values compared to normal concrete (NC). At 30% RCA replacement, RC(CST) showed a slump of 95 mm compared to 130 mm in NC, while RC(CT) exhibited a strength of 90 mm, indicating that chemical treatment improved the mix's cohesiveness and reduced water absorption compared to cement slurry-treated aggregates. Similarly, the compaction factor values dropped with higher RFA content. The RC(CST) mix of RCA30TRFA50 registered a compaction factor of 0.75, significantly lower than 0.88 for NC, highlighting a stiffer and less workable mix due to the angular shape and higher porosity of recycled aggregates.

Compressive Strength: Figure 3 displays the 28-day compressive strength results. For M20 mixes, NC exhibited a strength of 29.78 MPa, whereas RCA30TRFA50 (with chemical treatment) achieved only 27.05 MPa. For higher grades, such as M70, NC reached 55.76 MPa while the reused concrete (RCA30TRFA50) achieved 53.89 MPa, indicating that performance gaps narrow at higher strengths. Despite the reduction in strength, treated recycled aggregates, especially RC(CT), demonstrated acceptable strength levels in accordance with IS 456:2000 for structural applications.

Flexural Strength: The 28-day flexural strength test results, presented in Figure 4, showed a similar decreasing trend. For M20 grade concrete, the flexural strength of NC was measured at 5.73 MPa, while the RCA30TRFA50 recorded strengths of 5.03 MPa respectively. This decrease is attributed to weaker interfacial transition zones and higher porosity of the recycled materials. Cement slurry treatment(CST) offered slight improvements in bonding performance due to reduced microcracks and better aggregate surface integrity.

Split Tensile Strength: As depicted in Figure 5, split tensile strength also decreased with increased replacement levels. NC reached a strength of 2.29 MPa for M20 grade, whereas RCA30TRFA50 reached a strengths of 2.15 MPa respectively. The reduction in tensile strength was slightly less significant than that observed in flexural tests, indicating a relatively retained bonding capacity between aggregates and matrix when treatments were applied.

Modulus of Elasticity: Table 5 summarizes the comparison between experimental and code-based estimations of elastic modulus. For M20 grade, NC achieved 29.48 GPa experimentally, closely matching the IS 456 prediction of 27.77 GPa. In contrast, RCA30TRFA50 showed a lower experimental value of 23.74 GPa despite an IS 456 estimate of 30.92 GPa, indicating that while empirical formulas provide guidance, the actual elastic behavior of recycled concrete can diverge significantly due to the altered microstructure and increased voids. Notably, BS 8110 underestimates modulus values across all mixes, highlighting the limitations of its static equation for modern recycled material behaviour.

CONCLUSIONS

This experimental investigation evaluated the suitability of reused coarse aggregate (RCA) and reused fine aggregate (RFA), with and without treatment, for use in green concrete across M20, M50, and M70 grades. A total of 19 mixes were assessed based on workability, compressive strength, flexural strength, split tensile strength, and modulus of elasticity. The results confirmed that incorporating recycled aggregates generally reduced workability and mechanical strength. For instance, the slump value decreased from 130mm in normal M20 concrete to 95mm in RC(CST) and 90 mm in RC(CT) when 30% RCA is used. Similarly, the compaction factor dropped from 0.88 (NC) to 0.75 in mixes with 30%RCA and 50% RFA. Despite this, compressive strength remained within acceptable structural limits. In M70 grade, normal concrete achieved 55.76 MPa, while RC(CT) achieved 53.89 MPa—indicating only a 3.4% reduction. Flexural and split tensile strengths also followed similar trends. For M20 mixes, flexural strength dropped from 5.73 MPa (NC) to 5.03 MPa (RC-CST), and split tensile strength from 2.29 MPa (NC) to 2.15 MPa (RC-CST).

Appendix
NC- normal concrete
RC-reused glass as concrete
RCA-reused or recycled glass as coarse aggregate
RFA-reused glass as fine aggregate
RCA10- reused glass as coarse aggregate with 10% normal coarse aggregate replaced
RCA10T-reused glass as coarse aggregate with 10% normal coarse aggregate replaced and treated or washed nicely with water
RFA10- reused glass as fine aggregate with 10% fine aggregate replaced
AT- abrasion treated
CT- chemical treated concrete with HCL solution
CST- cement slurry or hand mixed concrete

ABSTRACT

Women often have a greater anterior body mass due to breast size, which can influence upper-body posture, especially in the head, neck, and shoulder areas. This forward weight may change postural alignment, affecting the sagittal head angle (SHA), craniovertebral angle (CVA), and shoulder angle (SA), potentially causing musculoskeletal strain and neck discomfort. This study aimed to investigate the connection between breast size, cup size, and upper body postural changes using a photogrammetric approach with Web Plot Digitizer Software (WPDS). To evaluate Patho mechanics in various breast and cup sizes affect upper body posture and to determine whether breast size is a factor in neck pain among women. A total of 350 women aged 18–60 years participated in this study. Body mass index (BMI) and pain intensity (measured using the Visual Analog Scale) were documented. Breast and cup sizes were determined using a tape measure. Postural deviations were analysed by examining the SHA, CVA, and SA from standardized side-view photographs using WPDS. Most participants experienced mild neck pain, with no significant link between pain intensity and cup size (chi-square p = 0. 16). Forward head posture was noted in the majority of participants (n = 265) but showed no statistical connection to cup size (p = 0. 41). Cervical angle and rounded shoulders also had non-significant associations (p = 0. 10 and 0. 60, respectively). Although current pain levels were not significantly associated with breast size, the high occurrence of postural deviations, such as forward head posture, indicates a possible risk for future neck pain.

Keywords: Women, Breast size, cup size, Posture, Neck pain, VAS, Sagittal head angle, rounded shoulder.

INTRODUCTION

Alignment of the human body, commonly referred to as posture, is crucial for maintaining musculoskeletal balance and functional efficiency. Optimal posture reduces mechanical stress on muscles and joints, facilitating coordinated movement and preventing pain and dysfunction (1,2). However, the rise in sedentary lifestyles and technology-reliant habits has led to an increase in postural deviations, especially in the upper body. Deviations in forward head posture (FHP), rounded shoulders, and increased thoracic kyphosis have been associated with neck pain, muscle fatigue, and long-term functional impairment (3-7). In women, breast size is a significant yet often overlooked factor that contributes to postural imbalance. Larger breasts create a greater anterior load, shifting the body's centre of gravity forward and increasing the thoracic flexion torque. This biomechanical shift may result in compensatory postural changes such as cervical hyper-lordosis, scapular protraction, and elevation, which in turn affect critical postural angles such as the sagittal head angle (SHA), craniovertebral angle (CVA), and shoulder angle (SA), potentially leading to chronic neck strain and discomfort (8,9,10,11). Although previous research has examined the musculoskeletal effects of macromastia, much of this work has focused on extreme cases and lacks applicability to women with a range of breast sizes (10,12,13). Additionally, the impact of cup size and breast volume on specific postural deviations and their connection to neck pain remains underexplored. Most existing studies have relied on subjective observation or static postural assessments with limited reliability, creating a methodological gap in objectively quantifying postural disturbances. (14)With the development of photogrammetric analysis tools such as the Web Plot Digitizer Software (WPDS), it is now possible to measure these angles with greater precision and consistency (15,16,17). There is a clear need for research that investigates whether women with average or moderate breast sizes also experience postural deviations and if these deviations could lead to neck pain over time. (17)Addressing this research gap could provide valuable insights into clinical practice, ergonomic planning, and preventive strategies targeting musculoskeletal health in women. The present study was designed to explore the relationship between breast size, cup size, and upper-body postural deviations among females. Specifically, it aims to determine whether variations in breast morphology are linked to measurable changes in SHA, CVA, and SA, and whether these changes correlate with the presence or severity of neck pain. By analysing these parameters using objective photogrammetric tools, this study sought to contribute new evidence to the growing field of postural and biomechanical research, with the long-term goal of supporting clinical decision-making in women presenting with neck and shoulder complaints.

MATERIALS AND METHODS

This study was structured as a cross-sectional observational investigation to explore the relationship between breast size, cup size, neck pain, and upper-body postural changes in women. The research involved 350 female participants, aged 18–60 years, chosen through purposive sampling. These participants were drawn from various community environments, including societies, institutions, and hospital staff, to ensure broad representation. Women within the specified age range who willingly agreed to participate and had no previous medical or surgical history were included. Patients with congenital or structural deformities, joint disorders, inflammatory conditions, recent injuries, or surgical procedures were excluded to prevent confounding factors. A sample size of 350 was calculated using G Power analysis, ensuring sufficient statistical power for the research. Data collection tools included a 152 cm measuring tape, a mobile camera, a stadiometer for height measurement, a weighing machine for determining body weight and BMI, a recording sheet, marker pens for identifying anatomical landmarks, and a table with a stool for standardized sitting posture. The Visual Analogue Scale (VAS) was used to measure pain, allowing participants to mark the severity of their neck pain on a 100 mm horizontal line from "no pain" to "worst imaginable pain. " Postural assessment was performed using photogrammetry, which involved taking digital side-view photographs of the participants with precise anatomical markers positioned on the tragus, C7 spinous process, and acromion process. These photographs were then analysed using Web Plot Digitizer Software (WPDS), an open-source digital tool that allows for the measurement of anatomical angles based on marked coordinates. This software was used to measure three primary postural angles: Sagittal Head Angle (SHA) – formed between the lateral canthus and tragus with a

horizontal reference line, indicating head tilt; Craniovertebral Angle (CVA) – created between the tragus and C7 spinous process with a horizontal line, used to assess forward head posture; and Shoulder Angle (SA) – formed at the intersection of a line from the acromion process to the C7 vertebra and a horizontal line, representing shoulder positioning. (17,18)Breast and cup sizes were determined using a standardized method. Breast size was measured by measuring the circumference at the nipple level while the participant was seated upright. Both under-bust and over-bust circumferences were measured for the cup size. The band size was calculated by rounding the under-bust measurement to the nearest whole number and adding 4 in (if even) or 5 in (if odd). The difference between the over-bust and band size was then used to determine the cup size (e. g. , a 3-inch difference corresponds to a C cup)(19)After obtaining written informed consent, demographic data (age, height, weight, and BMI) were recorded. Pain was assessed using the VAS, followed by breast and cup size measurements. Photographs were taken in a controlled environment with standardized lighting and camera distances to ensure consistency across all participants. Anatomical points were marked before imaging to ensure the accuracy of the software-based angle calculations.

SHA is formed between the line connection lateral canthus of eye, middle part of tragus of ear and horizontal line passing through middle part of tragus(canthus-tragus- Horizontal. A increase in angle measured indicate an extension of Upper cervical spine. Cranio-cervical angle is measure between 7th cervical vertebrae to middle part of tragus. A decrease in the angle indicate Forward Head Posture. Shoulder Angle is formed at the line intersection of bony prominence of acromion process and C7 vertebrae. A decrease in the angle indicate forward translation of shoulder in relation to spine. (17) Statistical analyses were performed using SPSS version 20. 0. Pearson's chi-square test was applied to analyse categorical variables and examine associations between breast/cup size and the presence of neck pain and postural deviations. The significance level was set at $p < 0.05$, and all tests were conducted at 95% confidence intervals.

RESULTS

Demographic Data: The research involved 350 female participants, aged 18 to 60 years, selected through purposive sampling. These participants came from diverse demographic backgrounds, with a wide range of body compositions, particularly breast and cup sizes, which was the primary focus of the study. Participants' body mass index (BMI) ranged from underweight to Obesity Class II, covering all BMI categories. This diversity was crucial for examining how breast and cup sizes affect postural deviations and pain in a typical female population. Table 1 summarizes the descriptive statistics for the main outcome measures: VAS (Visual Analog Scale), SHA (Sagittal Head Angle), CVA (Craniovertebral Angle), and SA (Shoulder Angle), which are essential for evaluating the link between postural alignment and discomfort or pain associated with breast size.

Descriptive Statistics: A descriptive analysis was performed to explore the central tendencies and variability of the primary outcome measures. The average VAS score was 0.25 ± 0.565, indicating that most participants experienced little to no neck pain. (19,21). The average SHA (Sagittal Head Angle) was 16.31 ± 7.17 , suggesting some forward head posture deviation in the sample. (3,4)The average Craniovertebral Angle (CVA) was 44.34 ± 6.83 , indicating a mild forward head posture in many participants. (4,6)The average SA (Shoulder Angle) was 50.71 ± 13.50 , showing variation in shoulder positioning, often influenced by breast weight and poor posture. (12,13)These baseline values provide insight into the overall postural characteristics and reported pain levels of the population.

Chi-Square Tests: The relationship between cup size and VAS score was not statistically significant ($p = 0.16$), although women with cup sizes B and C experienced mild to moderate pain more frequently (Table 2), which is consistent with the findings of Myint Oo et al. (12)The association between cup size and forward head posture also did not achieve statistical significance ($p = 0.413$), yet there was a trend toward increased FHP in larger cup sizes, which is in line with previous studies. (18,24,28)For cervical angle and shoulder angle, the associations with cup size

were again non-significant (p = 0. 16 and p = 0. 634 respectively), but visually (via Table 3 &4), deviations such as reduced cervical angles and rounded shoulders were more noticeable in participants with larger breasts. (8,19,22)

Correlation: Although Pearson correlation coefficients were not explicitly provided, trends in the data indicated a positive relationship between increased breast size and postural deviation seen in Table 7, particularly for forward head posture and shoulder protraction—findings that align with previous literature on the biomechanical impact of breast hypertrophy on posture.

DISCUSSION

The present study sought to evaluate the relationship between breast size, cup size, and upper quadrant musculoskeletal outcomes, with a particular emphasis on postural angles—Sagittal Head Angle (SHA), Craniovertebral Angle (CVA), Shoulder Angle (SA)—and neck pain as assessed by the Visual Analogue Scale (VAS) in women aged 18 to 71 years. Although many statistical tests did not yield significant p-values, the directional trends and clinical observations provided valuable insights into the potential biomechanical impact of increased breast volume on postural alignment and discomfort. The data indicated that the majority of participants (81. 7%) reported no pain, with only a small proportion experiencing mild-to-moderate pain, predominantly among those with cup sizes C and D. Although the association between cup size and VAS score was not statistically significant (p = 0. 16), a discernible trend suggested that larger cup sizes were associated with higher pain reports. This finding is consistent with previous research by Myint Oo et al. (12), who identified a higher prevalence of shoulder and neck discomfort in women with larger cup sizes due to anterior weight displacement. (7)

From a biomechanical standpoint, larger breasts exert an anterior pull on the thoracic spine and shoulder girdle, thereby increasing the strain on the posterior neck muscles, particularly the upper trapezius, levator scapulae, and suboccipital groups. Over time, this can result in muscle fatigue, trigger points, and alterations in proprioceptive responses, all of which are recognized contributors to non-specific neck pain. (6,16)A substantial number of participants exhibited forward head posture (FHP), especially those in cup categories B and C. Although the association between FHP and cup size was not statistically significant (p = 0. 413), it remained clinically relevant. The average craniovertebral angle (CVA) was 44. 34°, which is below the standard threshold of 50° often cited in the literature as an indicator of FHP(22). Biomechanically, FHP is associated with increased compression of the cervical spine, altered vertebral alignment, and greater stress on the intervertebral discs and facet joints. Yip et al. (2008) found that lower CVA angles were strongly associated with the severity of neck pain and altered neuromuscular control of the deep cervical flexors. (23)The shoulder angle (SHA) (mean = 16. 31) was also higher in many participants with larger breasts, indicating a forward head tilt, further supporting the concept of anterior chain dominance and posterior chain overload. Rounded shoulder posture, characterized by a reduced scapular angle (SA), was more prevalent among participants with B and C cups, which is consistent with previous studies (10). The mean SA of 50. 71° ± 13. 50 °suggests a mild to moderate anterior rotation of the shoulders, possibly as a compensatory mechanism to balance the breast mass anteriorly through scapular protraction. Continuous gravitational strain on unsupported or heavily loaded breasts may result in a permanent adaptive posture, particularly in sedentary women or those who do not regularly engage in postural correction exercises. Schurter and Letterman (5)also noted that mammary hypertrophy can lead to kyphotic posturing and scapular winging, both of which disrupt the scapulothoracic rhythm and increase stress at the cervical-thoracic junction(16). Although body mass index (BMI) and breast size were not statistically linked to posture or pain, observable patterns were present. Women with a higher BMI, particularly in the overweight and obesity I categories, tended to have larger cup sizes and more noticeable postural deviations. This supports the findings of Coltman et al. (10), who observed that breast size, when adjusted for body mass, still independently contributes to postural changes and discomfort, especially in the upper torso and cervical spine(5). However, it is important to note that BMI alone does not account for fat distribution, which can vary significantly among individuals with similar BMIs. Therefore, future research should include chest-specific anthropometric assessments or dual-energy X-ray absorptiometry-based (DEXA)-based

regional fat analysis. Although clinically significant trends were observed, the absence of statistically significant results in relationships such as pain versus posture and cup size versus craniovertebral or shoulder angles can be attributed to several factors. First, the sample distribution was uneven, with a majority of participants having A and B cup sizes, whereas those with D or E cups—who were anticipated to experience greater postural strain and discomfort—were underrepresented, thereby diminishing the ability to detect significant differences. Second, lifestyle and behavioural factors likely influenced the outcomes; many participants may have consistently worn well-fitted bras, engaged in physical activities, or adopted postural adjustments that mitigated the mechanical strain of breast weight. The cross-sectional design of the study also limits interpretation, as it captures only a single moment in time and does not account for long-term musculoskeletal adaptations or the cumulative effects of ongoing postural deviations.

Although the application of photogrammetry with Web Plot Digitizer Software (WPDS) is both practical and validated, it offers a two-dimensional perspective that may not fully encapsulate the complexities of three-dimensional postural compensation, such as thoracic kyphosis, lumbar lordosis, and pelvic tilting, which can significantly influence cervical and shoulder alignment. The study's findings highlight the necessity of proactive postural screening and early intervention, particularly for women with larger breast volumes who may be at an increased risk of developing postural deviations and musculoskeletal discomfort. Health professionals, including physiotherapists, ergonomists, and primary care providers, should emphasize the importance of proper bra fitting, because inadequate support can result in increased downward traction and anterior load on the spine and shoulders. Additionally, incorporating scapular stabilization exercises and deep cervical flexor strengthening programs into regular physiotherapy routines can mitigate the effects of anterior breast weight. Emphasis should also be placed on ergonomic education, particularly for individuals who spend extended periods in seated or desk-bound positions, to prevent the development of forward head posture and rounded shoulders. Furthermore, implementing routine postural assessments in educational institutions can serve as a preventive measure, allowing for the early detection and correction of postural deviations during formative years. To enhance the understanding and credibility of the relationship between breast size, posture, and musculoskeletal discomfort, future studies should adopt a longitudinal cohort design. This approach would facilitate the observation of postural changes and symptom development over time. A larger and more balanced sample across all cup sizes would enhance statistical reliability and provide a more comprehensive representation of the population, particularly those with larger breast sizes.

Furthermore, future studies should consider contextual factors, such as bra type, support adequacy, duration of wear, physical activity habits, and occupational demands, as these elements likely influence postural dynamics. Employing advanced technologies, such as 3D motion capture systems or digital inclinometers, would yield more accurate and multidimensional assessments of postural deviations. Additionally, it is essential to consider psychosocial aspects, including body image perception, breast satisfaction, and bra-related discomfort, as these may significantly affect the relationship between breast morphology and physical symptoms, contributing to a more comprehensive understanding of the issue.

CONCLUSION

While statistical significance was not achieved, trends indicated that larger breast and cup sizes were linked to forward head posture, rounded shoulders, and mild-to-moderate neck pain. These findings suggest that an increased anterior breast mass may contribute to musculoskeletal strain and postural adaptations. These results underscore the importance of early postural screening, proper bra fitting, and preventive physiotherapy. Overall, the findings support the integration of postural and ergonomic education into women's health programs to enhance musculoskeletal well-being.

ABSTRACT

Diabetic wounds pose a significant therapeutic challenge due its persistent inflammation, oxidative stress, impaired angiogenesis, and delayed tissue regeneration. The present investigation aimed and optimize a transethosomal gel incorporating standardized herbal extracts curcuma longa, withania somnifera, and Moringa oleifera to promote accelerated diabatic wound healing. Transethosomal vesicles were prepared using phosphatidylcholine, ethanol, and Tween 80 as penetration-enhancing components through the thin film hydration method. A Box-Behnken design was employed to optimize formulation variables, including lipid concentration, ethanol content and surfactant ration, and to evaluate their effects on vesicle size, entrapment efficiency and zeta potential.The optimized transethosomal formulation exhibited a mean vesicle size of 164.1±5.2 nm with a low polydispersity index (0.23), high drug entrapment efficiency (81.7%) and a stable negative zeta potential (-37.9 mV). The optimized vesicles were incorporated into a Carbopol 940-based hydrogel to facilate topical application. The Transethosomal gel demonstrated excellent physicochemical stability, sustained drug release over 24h (85.9% cumulative release) and significantly enhanced skin permeation compared to conventional herbal gel. In vitro wound healing assessment using NIH 3T3 fibroblast scratch assay revealed rapid cell migration, achieving 91.6% wound closure within 24h.In-vivo evaluation using streptozotocin-induced diabetic rat models showed the topical application of the optimized Transethosomal gel significantly enhanced wound contraction (95.8% by day 14), collagen deposition, and histopatholical tissue regeneration when compared with control and marketed formulation. The enhanced therapeutic efficacy is attributed to the synergistic antioxidant, anti-inflammatory, antimicrobial and pro-angiogenic

properties of the selected herbal extracts in combination with the highly deformable nature of Transethosomal vesicles. Overall, the developed herbal transethosomal gel represents a safe, biocompatible, and cost-effective topical delivery system for the effective management of chronic diabetic wounds.

INTRODUCTION

Diabetes mellitus is a chronic metabolic disorder characterized by persistent elevation of blood glucose levels due to defects in insulin secretion, insulin action, or both. The global prevalence of diabetes has risen dramatically, making it a major public concern. One of its most debilitating complications is impaired wound healing, particularly in lower extremities, often manifesting as diabetic foot ulcers. These ulcers lead to prolonged hospitalization, increased infection risk, and, in severe cases, limb amputation[1]. Diabetic wound healing is impaired date to multiple pathophysiological alterations, including prolonged inflammation, reduced cellular proliferation, and defective remodelling phases. The stratum corneum acts as a major barrier to drug penetration, and conventional topical formulation (e.g. creams and ointment) often fail to deliver sufficient drug concentration to deeper dermal layers, compounded by rapid clearance from the wound surface.[2,3].

To address these limitations, novel vesicular drug delivery system has emerged. Among them, transethososmes have gained attention for their superior skin penetration due to their highly deformable structure, combining high ethanol content and edge activators. Transethososmes consist of a phospholipid bilayer with ethanol and surfactants (e.g. Tween 80), enabling enhanced flexibility and passage through narrow intercellular spaces of the skin. Incorporating Transethosomes into gel base further improves therapeutic outcomes by increasing viscosity, prolonging residence time, and enabling sustained release.[4]. This study focuses on developing and optimizing a Transethosomal gel loaded with polyherbal extracts of *Curcuma longa , Withania somnifera and Moringa oleifera* to target the multifactorial pathology of diabetic wounds.[5].

Pathophysiology of Diabetic wound Healing/Pathophysiology of Diabetic Wound Healing

Impaired wound healing in diabetes arises from interrelated mechanism. Chronic hyperglycaemia leads to the formation of advanced glycation end products (AGEs), which accumulate in tissues, alter structural proteins, and activate inflammatory pathways, resulting in sustained pro-inflammatory pathways, resulting in sustained pro-inflammatory mediator production.[6]. Oxidative stress is central with elevated glucose enhancing mitochondrial reactive oxygen reactive species (ROS) production, causing lipid peroxidation, DNA damage, and protein modification. This reduces nitric oxide availability, leading to endothelial dysfunction and impaired angiogenesis. Inflammatory dysfunction is evident, with macrophages persisting in a pro-inflammatory M1 phenotype, preventing transition to the repair phase. Elevated TNF-α and IL-6 levels maintain chronic inflammation, delaying granulation tissue formation. Fibroblast dysfunction reduces collagen synthesis and extracellular matrix formation, while decreased vascular endothelial growth factor (VEGF) expression impairs neovascularization, prolonging healing. An effective therapy must simultaneously address inflammation, oxidative stress, impaired angiogenesis and collagen deficiency. [7,8]

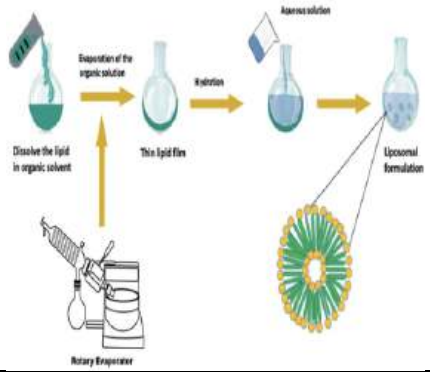
Novel drug delivery system

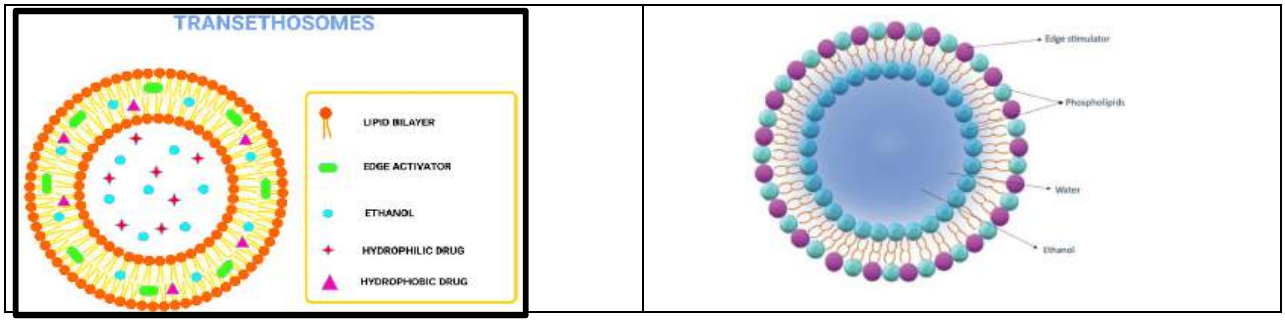
Novel system aims to enhances bioavailability, stability, and targeted delivery while minimizing systemic side effects. Vesicular carriers such as liposomes,niosomes, ethosomes, transfersomes and Transethosomes show promise for dermal application. Liposomes offer limited penetration across intact skin. Ethosomes incorporate high ethanol

for permeability, while transfersomes use edge activators for deformity. Transethosomes combine both, yielding superior elasticity and penetration. Ethanol disrupts stratum corneum lipid organization, and edge activators reduce membrane rigidity, allowing passage through intercellular spaces. Nanoscales size increases surface area for skin interaction.[9,10,11]

MATERIALS AND METHODS

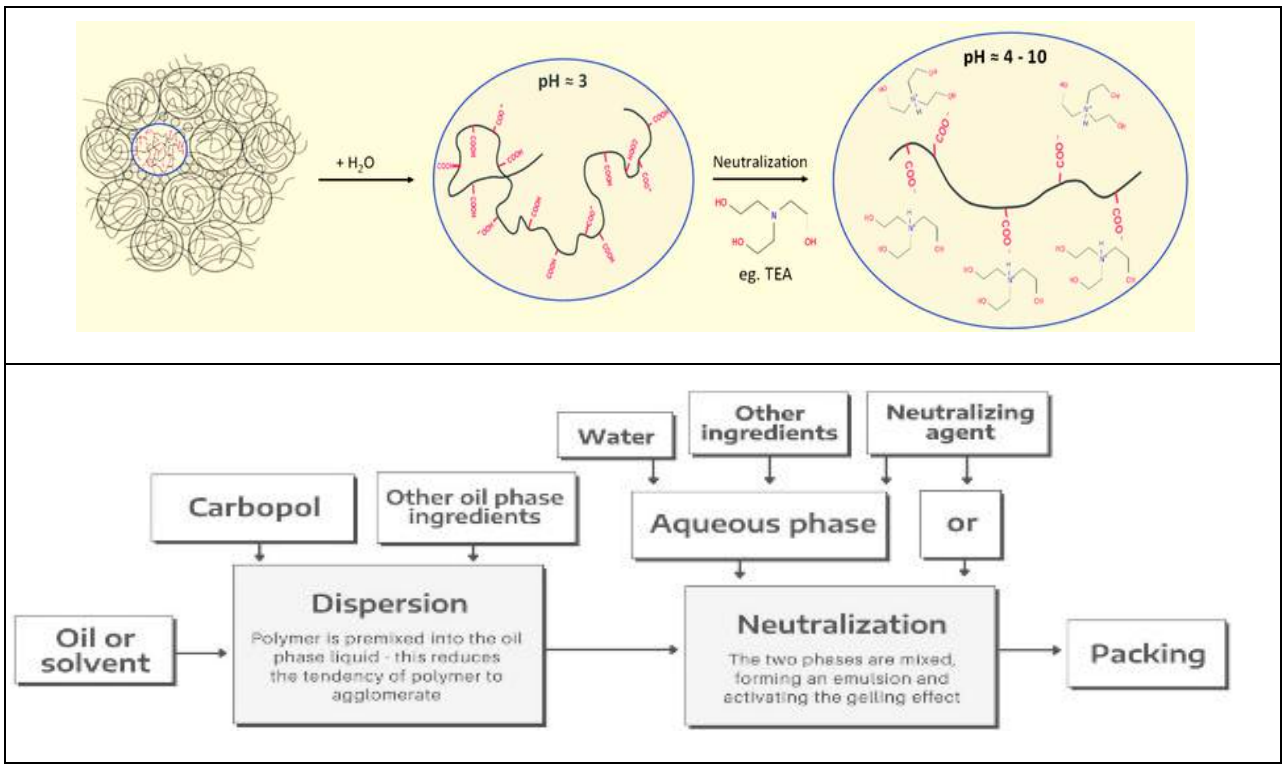
INGREDIENTS	QUANTITY
Soya lecithin	3g
Cholesterol	0.5g
Tween 80	1g
Ethanol	30ml
Carbopol 940	1g
Triethanolamine	q.s.
Distilled water	100g





Formulation and Evaluation Of Polyherbal Transethosomal Gel For Diabetic Wound Healing[12]

Preparation of Polyherbal Extract
The plant materials were authenticated and shade-dried.The dried materials were pulverized to coarse powder.



Extraction was performed using 70% ethanol by Soxhlet extraction for 6-8 hours.
The extract was concentrated under reduced pressure using a rotary evaporator.
The semi-solid extract was dried, weighed and stored in desiccator.

Formulation of Polyherbal Transethosomes (Thin Film Hydration Method)

Step 1: Preparation of Lipid Phase
Phospholipid (2–4% w/v) was dissolved in ethanol (20–30% v/v).
Herbal extract was added to lipid solution
Edge activator (0.5-1% W/V)

Step 2: Thin Film Formation
The mixture was transferred to a round bottom flask
Solvent was evaporated under vacuum using a rotary evaporator at 40°C.
A thin lipid film was formed on the inner wall of the flask
Step3: Hydration Step 3: Hydration
The thin film was hydrated with phosphate buffer (pH 6.8-7.4).
Continuous rotation produced vesicular dispersion
Step 4: Size reduction
The dispersion was sonicated for 10-15 minutes using probe so nicator.
Nanosized Transethosomes (100-250 nm) were obtained.
Step 5: Storage
The formulation was stored at 4°C until further use.
Preparation of Gel Base
The dispersion was allowed to swell for 24 hours.
Glycerine was added as humectant.
Triethanolamine was added dropwise to neutralize and form gel.
pH was adjusted to 6.5–7.0.

Incorporation of Transethosomes into Gel

a) Optimized Transethosomes dispersion was added slowly to gel base.
b) Gentle stirring was performed to prevent vesicle rupture
c) Homogeneous gel was obtained

Evaluation parameters

The gel was evaluated for pH, viscosity, spreadbility, extrudability, drug content uniformity, invitro release(Franz diffusion cell), stability, ex vivo permeation, in vivo scratch assay (NIH 3T3), and in vivo wound healing in streptozotocin-induced diabetic rats.**[13,14,15,16}**

RESULTS AND DISCUSSION

Hydroalcoholic extraction yielded satisfactory extracts rich in flavonoids, phenolics, tannins, and saponins (confirmed by photochemical screening), supporting antioxidant, anti-inflammatory and regenerative activities. FTIR confirmed compatibility with no significant interactions between extracts and excipients. Optimized Transethosomes showed uniform nanosized, high zeta potential and high entrapment efficiency. The Carbopol gel was smooth, homogenous, skin-compatible and appropriately viscous. In vitro release was controlled and prolonged versus conventional gel due to the lipid bilayer reservoirs effect. Ex vivo permeation was markedly higher, highlighting ethanol and deformability benefits. The scratch assay showed rapid fibroblast migration(91.6% closure in 24 hours). In vivo studies in diabetic rats demonstrated superior wound contraction (95.8% by day 14), faster epithelization, enhanced collagen deposition, and better histopathological outcomes compared to control and marketed products. The superior efficacy results from polyherbal synergy amplified by Transethosomal penetration.[17,18,19,20]

ACKNOWLEDGMENT

I express sincere gratitude to my guide, Mr. Kanha Garg, for his constant guidance and support. I thank the Head of the Département and faculty of the School of Pharmacy, ITM University, Gwalior, for facilities and academic support. Heartful thanks to y parents and friends for their encouragement.

CONCLUSION

This research successfully developed and optimized a polyherbal Transethosomal gel for diabetic wound management. The formulation overcomes limitations of conventional system through enhanced permeation, sustained release and synergistic bioactive effect with nanosized vesicles, high EE, stability and superior in vitro/in vivo performance, it emerges as a safe, biocompatible and cost effective option for chronic diabetic wounds.

ABSTRACT

Number triangles and Metallic ratios has been of special interest to many mathematicians for several centuries. Various number triangles have been developed through which we have gained new insights upon understanding the behaviour of numbers.In this paper,we construct a Pascal like number triangle and using this, we explore interesting properties of metallic ratios.These properties will mathematically help us to understand the structure of numbers related to metallic ratios.

Keywords: Pascal Like Number Triangle, Slant Diagonal, Limiting Ratio, Metallic Ratios

INTRODUCTION

Several interesting number triangles have emerged and each such triangle has explored important properties involved with numbers in the triangle. In this paper, we construct number triangle which is a generalized version of well-known Pascal's triangle and using this number triangle we have proved interesting mathematical properties related to Golden Ratio, Silver Ratio and in general Metallic ratio of order m. In particular, we have established the connection between slant diagonal entries of the Pascal Like triangle with that of metallic ratios.

Construction of Number Triangle
Let us first construct a number triangle with natural numbers as entries as detailed below:

For some positive integer m, the number located in kth position of nth row of the Pascal Like Number Triangle displayed in Figure 1 is $a_{n,k} = \binom{n}{k} m^{n-k}$; $k = 0,1,2,3,\ldots,n$ (2.1)

Further we notice from Figure 1, that the numbers written row wise in the number triangle (when read from left to right) are the coefficients of $(m+1)^n$ *where* $n \geq 0$ (2.2)

Using equation (2.1), we now present some results regarding the Pascal Like number triangle presented in Figure 1.

Properties of Pascal Like Number Triangle

Theorem 1: **RowSum and Slant Diagonal Property 1**

For m = 1, Equation (2.1) forms Pascal triangle and the row sum is given by 2^n, where $n \geq 0$ (3.1) and the slant diagonal sum S_n satisfies the limiting ratio property $\lim_{n\to\alpha} \frac{S_{n+1}}{S_n} = \frac{1+\sqrt{5}}{2}$(3.2), where $\frac{1+\sqrt{5}}{2}$is the Golden Ratio.

Proof:

If m = 1, then from Figure 1, we obtain the following number triangle which is the well known Pascal's Triangle.

In view of (2.1), the row sumwith m = 1 is given by $\sum_{k=0}^{n} \binom{n}{k} = (1+1)^n = 2^n$

In order to know the numbers of slant diagonals, first we will enumerate them using the pattern as shown in Figure 2.

Slant diagonal sums are 1,1,2,3,5, 8, . . . which is the well-known Fibonacci sequence. The nth Fibonacci number of the sequence is given by $s_n = \frac{\alpha^n - \beta^n}{\alpha - \beta}, \alpha = \frac{1+\sqrt{5}}{2}, \beta = \frac{1-\sqrt{5}}{2}$. Hence the limiting ratio is given by,

$$\lim_{n\to\infty} \frac{s_{n+1}}{s_n} = \lim_{n\to\infty} \frac{\alpha^{n+1} - \beta^{n+1}}{\alpha^n - \beta^n} = \lim_{n\to\infty} \frac{\alpha - \beta(\beta/\alpha)^n}{1 - (\beta/\alpha)^n} = \frac{\alpha - 0}{1 - 0} = \alpha = \frac{1+\sqrt{5}}{2}$$

This completes the proof.

Theorem 2: **Row Sum and Slant Diagonal Property 2**

For m = 2, Equation (2.1) forms a number triangle and the row sum is given by 3^n, where $n \geq 0$ (4.1) and the slant diagonal sum satisfies the limiting ratio propertylim$_{n\to\alpha} \frac{P_{n+1}}{P_n} = 1 + \sqrt{2}$ (4.2), where $1 + \sqrt{2}$is the Silver Ratio

Proof: From (2.1), if m = 2, we have a number triangle as displayed in Figure 3.

In view of (2.1), the row sum with m = 2 is given by $\sum_{k=0}^{n} \binom{n}{k} 2^k = (2+1)^n = 3^n$

In order to know the numbers of slant diagonals first we will enumerate them using the pattern as shown in Figure 4.

Slant diagonal sums are1,2,5,12,29, 70, . . .

The *n*th term of the sequence is given by $p_n = \frac{\alpha^n - \beta^n}{\alpha - \beta}$, $\alpha = 1+\sqrt{2}, \beta = 1-\sqrt{2}$

Hence the limiting ratio is given by,

$$\lim_{n\to\infty} \frac{p_{n+1}}{p_n} = \lim_{n\to\infty} \frac{\alpha^{n+1} - \beta^{n+1}}{\alpha^n - \beta^n} = \lim_{n\to\infty} \frac{\alpha - \beta(\beta/\alpha)^n}{1-(\beta/\alpha)^n} = \frac{\alpha - 0}{1-0} = \alpha = 1+\sqrt{2}$$

This completes the proof.

Theorem 3:Row Sum and Slant Diagonal Property 3

The row sum of general number triangle in Figure 1 is $(m+1)^n$ (5.1)and if s_n is the slant diagonal sum, then it satisfies the limiting ratio property $\lim_{n\to\infty} \frac{s_{n+1}}{s_n} = \frac{m+\sqrt{m^2+4}}{2}$ (5.2),where $\frac{m+\sqrt{m^2+4}}{2}$ is called the Metallic Ratio of order *m*.

Proof:

In view of (2.1), the row sum of the general Pascal Like number triangle of Figure 1 is given by

$$\sum_{k=0}^{n} \binom{n}{k} m^{n-k} = \sum_{k=0}^{n} \binom{n}{k} m^{n-k} 1^k = (m+1)^n$$

In order to know the numbers of slant diagonals, we will enumerate them using the pattern as shown in Figure 5.

Slant diagonal sums are1, m,m^2+ 1,m^3+ 2m, m^4+ 3m^2+1,. . .

The *n*th term of the sequence is given by $s_n = \frac{\alpha^n - \beta^n}{\alpha - \beta}$, $\alpha = \frac{m+\sqrt{m^2+4}}{2}, \beta = \frac{m-\sqrt{m^2+4}}{2}$

Hence the limiting ratio is given by,

$$\lim_{n\to\infty} \frac{s_{n+1}}{s_n} = \lim_{n\to\infty} \frac{\alpha^{n+1} - \beta^{n+1}}{\alpha^n - \beta^n} = \lim_{n\to\infty} \frac{\alpha - \beta(\beta/\alpha)^n}{1-(\beta/\alpha)^n} = \frac{\alpha - 0}{1-0} = \alpha = \frac{m+\sqrt{m^2+4}}{2}$$

This completes the proof.

CONCLUSION

By introducing simple number triangle (as in Figure 1), which is seen as generalized version of Pascal's Triangle, which we call Pascal Like Triangle, we had proved three interesting theorems in this paper. In particular, if we consider m = 1 in Pascal Like Triangle, we obtain the usual Pascal's Triangle, whose sum of slant diagonal entries has the limiting ratio as metallic ratio of order 1 namely the Golden Ratio, which has fascinating history from ancient to modern times. If m = 2, we have proved that the slant diagonal entries has the limiting ratio equal to the metallic ratio of order 2, which is the Silver Ratio. Finally, by considering the slant diagonal entries of the Pascal Like Triangle in Figure 1, we have proved that its limiting ratio is precisely the metallic ratio of order m. Thus this paper provides an explicit connection between the entries of Pascal Like Number Triangle and the metallic ratios of corresponding

orders. We have also provided the row sums in each case. The results derived in this paper will provide more insights to understand various inter-relationships existing between specific natural numbers and metallic ratios.

ABSTRACT

Although wearable and smartphone-generated digital biomarkers have the potential to revolutionise healthcare, their clinical acceptance is still restricted because of flaws in current validation methods. In addition to developing a thorough credibility assessment model, this study sought to determine whether traditional validation models sufficiently address important gaps pertaining to AI/ML governance, population equity, real-world performance, and implementation feasibility across major international regulatory frameworks (FDA, EMA, IMDRF, and ISO).A mixed-methods comparative analysis of international regulatory guidance revealed persistent shortcomings in AI/ML oversight, demographic fairness, practical efficacy, and implementation preparedness. By extending validation across five domains, the Integrated Digital Biomarker Credibility Assessment Model (IDBCAM) was developed to overcome these limitations. When the framework was applied to three representative case studies; Dexcom G6 continuous glucose monitoring, Apple Watch ECG for atrial fibrillation detection, and smartphone-based digital phenotyping; it showed strong discriminatory capability, successfully differentiating between high, moderate, and low credibility profiles while methodically identifying validation gaps and priority remediation areas.By filling in implementation and regulatory gaps that erode clinician trust, IDBCAM enhances the evaluation of digital biomarkers. The approach promotes international regulatory convergence and enables fair, practical use of digital biomarkers to improve

patient outcomes by integrating lifecycle oversight, risk-proportionate evidence criteria, and stakeholder alignment.

Keywords: Digital biomarkers; Regulatory science; Validation frameworks; AI/ML governance; Real-world performance

INTRODUCTION

Wearable and smartphone-derived digital biomarkers extend biomarker assessment beyond episodic, clinic-based assessments by enabling continuous, real-time monitoring of physiological and behavioural parameters in naturalistic contexts. This change presents prospects for longer-term, more representative insights into treatment response and illness condition, but it also brings with it validation issues with regard to algorithmic mediation, data variability, and practical implementation [1]. While analytical validity, clinical validity, and clinical utility are expected to be met by both digital and conventional biomarkers, current validation paradigms fail to adequately address the complexities specific to digital measures, such as adaptive AI/ML behaviour, population-level equity, sustained real-world performance, and implementation feasibility. The need for an integrated, risk-proportionate framework to evaluate digital biomarkers is highlighted by these gaps, which have led to uncertainty in regulatory evaluation and low clinical trust [2].

Existing validation frameworks and standards

The V3 framework: Foundation of digital biomarker validation: It consists of:

Verification: It is an assessment of technical overall performance in controlled environments that verifies devices as they should be able to capture purported physiological warnings with appropriate precision, minimal measurement errors, and dependable record transmission. [3]

Analytical Validation: It shows that algorithms that process raw sensor data generate reproducible, significant results. Reliability of signal processing, consistency of function extraction, efficacy of artifact rejection, and overall performance of statistical versions are all included in this.

Clinical validation: It mainly establishes meaningful correlation between digital biomarker measures and established scientific objectives, disease states, or fitness outcomes.

Regulatory landscape and current standards

U.S. food and drug administration guidance: In addition to incorporating real-world data concepts and lifecycle thinking for Software as a Medical Device (SaMD), it primarily developed verification and validation expectations for digital health technologies. [4] [5]Expectations for real-world performance monitoring are still inconsistent and varied among submissions.

EMA qualification of digital technology-based methodologies (2024): It promotes early regulatory involvement for digital techniques and places a significant emphasis on clinical relevance, data integrity, ethics, and defined context of use. The guidelines provide inadequate information on AI/ML lifecycle management, post-deployment performance monitoring, and scalability across platforms, as well as weak specificity for independent digital biomarkers, especially those not integrated into pharmaceutical product trials.[6]

IMDRF software as medical device (SaMD) framework (2023): It supported proportionate evidence requirements based on clinical risk and primarily developed harmonised nomenclature and risk-based SaMD classification. The guidance is still at a high level, depends on regional interpretation for implementation, and does not guarantee uniform requirements for transparency, equality assessment, or real-world validation across countries. [7]

ISO 81001-1:2021 (health software standards): It provides strong alignment with risk governance and quality management systems and establishes lifecycle-oriented guidelines for the security, efficacy, and safety of health software. It lacks validation criteria specific to digital biomarkers, especially for AI/ML-driven measurements. There are no specific requirements for population fairness, practical efficacy, or clinical credibility. [8]

MATERIALS AND METHODS

This study represents original methodological research involving the development and empirical application of a novel regulatory credibility assessment framework.

Comparative analysis of regulatory frameworks: International regulatory guidelines and standards pertinent to digital biomarkers were systematically compared. With special emphasis to AI/ML governance, population equity, and real-world performance needs across jurisdictions, the analysis concentrated on convergence and divergence in validation expectations.

Development of the Integrated Digital Biomarker Credibility Assessment Model (IDBCAM): The iterative development of IDBCAM was guided by the results of the comparative analysis. Through five assessment dimensions which includes: technical validation, clinical validation, real-world performance, AI/ML governance, and implementation readiness; the methodology expands on well-known V3 validation concepts: verification, analytical validation, and clinical validation.

Empirical evaluation using case studies: IDBCAM was used to three purposefully chosen case studies that represented variance in biomarker modality, illness domain, and validation maturity in order to assess external validity and practical application. To find validation gaps and establish overall credibility categories, framework dimensions were independently applied using predetermined criteria.In order to assess consistency, generalisability, and the framework's capacity to distinguish between various credibility profiles, cross-case synthesis was then carried out.

RESULTS

Comparative analysis of international regulatory frameworks:

This comparative evaluation systematically examines digital biomarker regulatory techniques across five fundamental frameworks. The results showed that although safety, efficacy, and quality control are emphasised by all frameworks, their approaches to digital health technologies vary greatly. Although the FDA provides very advanced methods, it does not have complete facilities for ongoing algorithm learning and adaptive AI monitoring. The EMA places a strong focus on post-market surveillance and clinical evaluation, but it provides little detail on data-driven personalisation and cross-border interoperability. Although IMDRF serves as a harmonising body by providing conceptual frameworks and terminology alignment, practical enforcement and execution specific to a given sector are still uneven. Although they offer technical depth, ISO requirements particularly those pertaining to statistics control and threat governancedo not effectively contextualise rapidly changing digital biomarkers and dynamic statistics structures.

Gaps and limitations in current approaches:

There are many limitations in V3 as it is currently implemented when compared to the regulatory requirements for digital biomarkers:

AI/ML lifecycle governance: V3 specialises in confirming and validating the degree at particular points in time, but it provides limited explicit guidance on continuing machine-learning model tracking, handling model updates, drift, and adaptive/continuously learning structures.

Population fairness and generalizability: V3 places a strong emphasis on defining a target population, but it no longer systematically requires proof that validation and schooling statistics are demographically numerous or that overall performance is strong across subgroups, which is crucial to regulatory concerns about algorithmic bias and unequal performance in real-world settings.

Real global effectiveness and implementation: Clinical validation in V3 is typically rooted in controlled study settings and does not, by itself, ensure efficacy, adherence, and reliability in everyday practice, particularly when records quality, connectivity, and individual behaviour vary greatly.

Transparency, reproducibility, and documentation: V3 outlines what needs to be verified but is far less prescriptive when it comes to pre-registration, open protocols, reproducible pipelines, and documentation standards, all of which are essential for regulatory review and objective examination of digital biomarkers. (Table 1, Figure 1)

Integrated Digital Biomarker Credibility Assessment Model (IDBCAM)

Framework overview and architecture:

A multifaceted evaluation methodology called as the Integrated Digital Biomarker Credibility Assessment Model (IDBCAM) was created to fill in credibility gaps left by traditional V3 validation techniques. Three levels of hierarchy make up the structure of the framework:

- Five core assessment dimensions forming the foundational evaluation structure,
- Three cross-cutting enablers delivering operational mechanisms,
- Three supporting infrastructures setting up systemic foundations.

Level 1: Five core assessment dimensions: By incorporating the forward-looking credibility domains needed for dynamic, AI-enabled digital biomarkers, IDBCAM expands the V3 framework:

Dimension 1: Technical validation (extends V3 verification and analytical): It confirms sensor accuracy, data integrity, and algorithmic performance under relevant conditions.

Dimension 2: Clinical validation (extends V3 clinical): It establishes meaningful clinical relevance and utility within defined populations and contexts of use.

Dimension 3: Real-world performance validation: It evaluates sustained effectiveness, usability, equity, and reliability in routine clinical and non-clinical environments.

Dimension 4: AI/ML governance: It assesses transparency, bias mitigation, explainability, model updating, and lifecycle control of AI/ML components.

Dimension 5: Implementation readiness: It examines workflow integration, interoperability, economic feasibility, training requirements, and organizational adoption capacity.

Level 2: Three cross-cutting enablers: Three enablers operate across all dimensions to support proportional and lifecycle-aware assessment:

Cross cutting enabler 1: Lifecycle oversight: It emphasizes continuous monitoring and reassessment of performance and safety throughout deployment rather than one-time pre-market evaluation.

Cross cutting enabler 2: Risk stratification: It aligns validation depth with potential patient harm, differentiating low, moderate, and high-risk applications to balance innovation and safety.

Cross cutting enabler 3: Stakeholder alignment: It ensures credibility expectations reflect the perspectives of regulators, developers, clinicians, patients, and payers, supporting feasibility and trust.

Level 3: Three supporting infrastructures: These systemic foundations ensure scalability, interoperability, and sustained credibility. It includes:

Regulatory harmonization; enabling evidence portability and alignment across jurisdictions.

Data infrastructure; supporting interoperability, data quality, and privacy-preserving evidence generation.

Ethical governance; addressing fairness, transparency, accountability, and patient autonomy across the biomarker lifecycle.

DISCUSSION

IDBCAM framework integration and application: Together, these components enable IDBCAM to operate as a cohesive credibility assessment system that may assist clinical and regulatory decision-making across a variety of digital biomarker applications, identify validation gaps, and direct remediation priorities, as described in the results.
Credibility scoring rubric (1-5):(Table 2)

IDBCAM framework application:
Case study 1: High credibility digital biomarker (Dexcom G6 CGM)
Technical: High (enormous sensor validation, analytical rigor, quality systems)
Clinical: High (confirmed HbA1c improvement, decreased hypoglycemia, a couple of RCTs)
Real-World: High (millions of patient-years facts, sustained effectiveness, high satisfaction)
AI/ML: Moderate (predictive algorithms proven, a few transparency limits)[12]
Implementation: High (notable interoperability, mounted workflows, repayment pathways)
Overall: High credibility - gold standard for digital biomarker validation(Figure 2)

Case study 2: Moderate credibility digital biomarker (Apple watch ECG for AF)
Technical: High (rigorous sensor verification, massive-scale validation)
Clinical: Moderate (excessive sensitivity, moderate PPV, limited validation for screening)
Real-World: Moderate (large deployment, equity gaps, implementation challenges)
AI/ML: Low-Moderate (confined transparency, bias evaluation incomplete)
Implementation: Moderate (sturdy usability, workflow integration demanding situations, unclear compensation)[13]
Overall: Moderate credibility - Appropriate for knowledgeable customer use with scientific observe-up(Figure 3)

Case Study 3: Low credibility digital biomarker (Smartphone based digital phenol typing)
Technical: Low-Moderate (device heterogeneity, reliability troubles)
Clinical: Low (susceptible correlations, no application demonstration, small samples)
Real-World: Insufficient (minimum real-global deployment, no equity statistics)
AI/ML: Low (variable transparency, insufficient bias assessment, privacy worries)
Implementation: Insufficient (no workflow making plans, no scientific guidance)[14]
Overall: Low credibility- Research-stage, years from scientific readiness (Figure 4)
Comparative credibility assessment of digital biomarkers: (Table 3)

CONCLUSION

This research shows that current digital biomarker validation paradigms are insufficient to support genuine, widespread clinical use, particularly with regard to AI/ML governance, equity, and actual worldwide application. The study reveals enduring credibility gaps that conventional V3-focused approaches no longer fully address by methodically examining worldwide regulatory frameworks and standards and comparing them with the requirements of sensor-derived measurements. By combining five fundamental assessment dimensions with cross-cutting enablers and supporting infrastructures to provide risk-stratified, lifecycle-conscious, and stakeholder-aligned assessment, the proposed Integrated Digital Biomarker Credibility Assessment Model (IDBCAM) addresses these shortcomings. Validation across case studies shows that IDBCAM can distinguish between varying levels of trustworthiness and exhibit recurrent proof deficiencies, providing regulators, developers, doctors and patients with useful guidance. When taken as a whole, these contributions provide conceptual and practical groundwork for global harmonisation of digital biomarker supervision, enabling more powerful, safe, and fair innovation in data-driven healthcare.

ACKNOWLEDGEMENT

The author sincerely acknowledges the valuable guidance and continuous support from Koushik Yetukuri and Sandeep Kanna throughout this research work. Gratitude is also extended to Chalapathi Institute of Pharmaceutical Sciences (CLPT) who contributed to the successful completion of this study.

Conflict of Interest: The author declares no conflict of interest.

ABSTRACT

This study examines the relationship between memory and soft skills in PreetiShenoy's novels, *The Secret Wish List* (2012) and *Wake Up, Life is Calling*(2019).The importance of soft skills as necessary tools for emotional survival and forming identity in Shenoy's selected works are being examined in this study. It has been looked into the way where the characters' painful memories turn into a channel to self-discovery through soft skills. Through the lens of memory, the research analyzes how the protagonists were able to confront and reinterpret their pasts to overcome life's challenges. This helps them to face their future with a new strength and hope. Both novels show how the characters' emotional growth comes from developing and using soft skills and leads to self-realization and empowerment of the protagonists. This study uses a qualitative research approach to show how Ankita's and Diksha's memories shape their self-perceptions, relationships, and understanding of the world. By combining literary analysis with psychological concepts, this research reveals how Shenoy's portrayal of soft skills and memory provide insights on humans'bounce back ability during tough times.In the end, embracing one's past with the help of soft skills, and cultivating the power to build a better future using emotional intelligence and communication skills is the main discussion of this study.

Keywords: Communication, Emotional Intelligence, Identity, Memory, Trauma, Soft Skills

INTRODUCTION

In this growing AI world, people are learning to live with artificial intelligence starting from AI programmed alarms to AI robots that serve food and teach lessons. Artificial Intelligence has made the world super easy to live. Though AI seems a boon, it also has its drawbacks. Many people lose jobs as AI does many things in just a matter of time. Most importantly, the thinking skills of people started to reduce. People's thinking and memory capacity started to shrink as they started to blindly believe and use Artificial Intelligence. Young minds are facing memory- related problems, which lead to unwanted stress and depression.

Humans are still differentiated from AI only because of the soft skills they hold. '**Soft skills**' are skills that show character traits. These skills decide how well one interacts with others. Usually, they are a definite part of an individual's personality. So they are also called 'People Skills', 'Social Skills' and 'Interpersonal Skills'. These skills are developed throughout the entire life. It helps to characterize a person's relationships with other people. These skills make humans stand unique on the stage of AI. This is because artificial intelligence lacks emotional intelligence. (World Economic Forum)

The bond between literature and soft skills is proved when it gives the readers, thedevelopmentof emotional sensitivity, a sense of beauty and appreciative mind-set. PreetiShenoyis a popular contemporary Indian writerwho writes in English and is fame for her novels that portraypowerful female characters.She is a multi-talented person who also worked as a blogger, columnist, and speaker. Shenoy also specializes in doing portraiture and illustrated journaling. Shenoy holds a position among the five best-selling novelists of India. ("Official Author Biography")

Despite the popularity of Shenoy's fiction, critical engagement with her work remains limited in terms of its psychological and emotional depth. There is identifiable gap in literary research that connects soft skills with trauma recovery and identity formation within Indian fiction, particularly from the perspectives of memory studies.Current studies on shenoy's fictions are focused on either feminist view or themes oriented andleaving unexplored the way soft skills function as narrative devices, survival strategies, and cultural signifiers.

Memory studies provide a powerful lens to explore how individual identity is shaped by both personal and inherited memory. Memory plays a major role in the novel *Wake Up, Life is Calling*(2019) *and The Secret Wish List*(2012). Memory is the past, experienced in the present. Memory serves as a symbolic depiction of the past, which is integrated into social behavior (Ricoeur 45).Memory gives identity. In many places, it serves as evidence and a memory aid in numerous locations. The capacity to store, retrieve and encode knowledge and experiences is known as (Neumann 335). The emphasis is on, how various methods of remembering function as collective representations of the past, how they elevate specific readings of the past and subordinate others and how memory is linked to soft skills and their dual role as demonstrated through the characters of Shenoy's novels. Those may be physical, symbolic, or psychological spaces in Shenoy's narratives where memory and meaning are crystallized, influencing the protagonist's choices and perceptions of the present and affecting future actions also. This study limits itself to soft skills as internalized traits and not professional competencies of a person. Also it does not explore all the novels of Shenoy due to thematic divergence in some works.

The psychological journey of Ankita Sharma, a young lady negotiating the tumultuous consequences of a mental health crisis, is continues in PreetiShenoy's*Wake Up, Life is Calling*(2019). It is the follow-upto the novel*Life Is What You Make It*(2011).The novel demonstrates how soft skills like communication and emotional intelligence function as instruments for identity construction and emotional survival from the standpoint of memory studies. Diksha is the protagonist of the novel *The Secret Wish List*(2012). The mistake that she made at the age of sixteen led to disbelief in her and so, her parents arranged a marriage, when she was nineteen. She became an early mother to her only son,Abhay. Living as a typical Indian mother and wife, Diksha leads a life only to please her parents and husband and to erase her past- kissing her teenage love, Ankit. However a hidden wish list completely changed her life. She

began to live up to them and discovered how to overcome the fifteen years of repression and guilt.Diksha, who was shy at the beginning of the story, evolved into a courageous and self-sufficient character by the end of the novel. (Shenoy, *The Secret Wish List, 2012*)

Emotional Intelligence and Self Discovery

In this study, the Emotional Intelligence (EI) model developed by Daniel Goleman can be used. Self-awareness, self-regulation, motivation, empathy, and social skills are Goleman's five key competencies (Goleman 34). These skills are able to examine how shenoy's protagonists make decisions, resolve emotional disputes and manage relationships.These characters frequently exhibit high levels of emotional intelligence in their attempts to deal with psychological crises rather than passively responding to trauma. The language and tone of the characters witness a significant shift when their EI is low and when their EI is high.

According to Goleman, emotional intelligence is a cluster of skills that includes self-awareness, emotional regulation, empathy, personal growth, and effective communication skills (Goleman 34). In the novel *The Secret Wish List* (2012), Dikshaacknowledges that she is unhappy in her marriage and longs for something more. She had forgotten her passion for dance and the arts after spending fifteen years in an unhappy marriage to Sandeep in order to appease her parents. In the first few chapters of the novel, Dikshawas unaware of what would make her feel content. When Vibha, cousin of Diksha, told her to write a wish list, she hesitated to write first, as she didn't know what her wish was. Later, she wrote randomly some six wishes like going for vacation, snorkeling, learn salsa and so on, to please Vibha. But this list led to self-awareness and gain social skills for her.

Diksha had overcome the emotional repression of her married life and recognizes her emotional needs, by the end of the novel. She encouraged herself to be self-reliant and defended her own choices.After the end of her marriage with Sandeep, she moved in with Ankit, her teenage love.Her salsa instructor, Gaurav opened a dance studio as equal partners with Diksha and started to live financially independent with her nine-year-old son, Abhay. Diksha discovers her strengths and shortcomings through her experiences, leading to significant personal growth and becomesan emotionally intelligent person by the end of the novel.

In *Wake Up, Life is Calling*(2019),Ankita Sharma's descent into bipolar disorder is intricately tied to her unresolved emotional experiences and societal pressures. Her journey of healing is deeply emotional. The development of emotional intelligence becomes very crucial as she learns to recognize, understand, and control her emotional needs and responses. Ankita was able to manage her traumatic memories with the help of emotional awareness.

AsDavid Carusosuggests, "It is very important to understand that emotional intelligence is not the opposite of intelligence, it is not the triumph of heart over head—it is the unique intersection of both" ("David Caruso Quote", quotefancy.com).Shenoy uses Ankita's rehabilitation from mental illness to demonstrate this union of heart and mind. She joins a creative writing course, creates new friendships (Parul and Janki) and a new life to forget her past.
According to memory studies, memory is more than just a passive recollection of the past; it is an active, dynamic process that shapes identity and behavior. Reframing her past is essential to Ankita's emotional survival.She learns to process her experiences through therapy and reflective journaling rather than repressing them. Journaling itself is an example of using emotional intelligence to process trauma from the past in order to comprehend the present.Ankita was fortunate to be surrounded by supportive people. Her emotional recovery was greatly aided by her parents and through certain mental exercise, her lecturer, Mrs. Hayden, helped her get past the past and positively control her emotions. These exercises were a great way for her to let go of the bitterness of the past.

Diksha and Ankitabecame self-discovered persons as a result of these soft skills, which enable them to manage their relationships with others and make their own judgements.Both Diksha and Ankitaused to worry about how other people saw them, but eventually they stopped caring and concentrated on their work, developing into emotionally savvy individuals.

Communication Skills as Catharsis and Agency

Characters use communication to confront silence, stigma, and repression. For Ankita, verbalizing her pain leads to healing. Diksha reclaims agency by speaking up against emotional control. In Shenoy's fiction, communication is a method of meaning-making and survival. Communication, both internal (self-dialogue) and external (verbal and non-verbal interactions), serves as a mode of emotional articulation.

Despite facing challenges and criticism from her husband, Diksha finds ways to cope with her emotions. She channels her feelings through communication and empathizes with her friends,Gaurav and Tanu, who also have relationship problems. Diksha's transformation from a submissive housewife into an autonomous woman is marked by her evolution in communication. For instance, when Diksha tried to converse with Sandeep, "*Sandeep, I want some conversation. I feel a bit taken for granted in this whole deal here. I feel I want to do something with my life….*" he replied to her, "*You made a choice to stay at home. Now you regret it. And you are blaming me and making me the scapegoat…. You act like a mart*yr here" **(**Shenoy, *Secret Wish List* 31-32). Sandeep's remarks quickly destroyed her newly acquired courage. On the other hand, she eventually gained confidence and voice her opinions without fear in the climax of the novel. "*I am speaking from a place of strength that is coming from all the years of suppression. I speak out with courage and conviction…. I have made my choices and I am no longer the old, terrified mouse I used to be.*" (Shenoy, *Secret Wish List* 250).

At first quiet and compliant, Diksha later speaks up asserts her needs in conversations with her spouse, family, and even herself. Diksha was able to confront her past, including the memory of her teenage love through communication as it becomes a liberating force. At the end,Dikshalearns to communicate assertively confronting her spouse and expressing her repressed wants. Communication emerges as a central soft skill in Ankita's journey too. Communication gave a new life and courage to Ankita. She developed the confidence to speak in front of audience by taking part in the college culturals public speaking competition. It acted as a parameter to show the growth of Ankita from a bipolar patient who was once unable to comprehend any word to a successful public speaker. She was on cloud nine when she won the semi-finals.Ankita's capacity for self-expression becomes crucial to her recovery process. Memory studies show how self-portrayal can support identity construction and assist organize painful memories into cohesive wholes. She wrote poems and kept a diary, which are therapeutic outlets that also help her reflect on and reshape her memories.

"*My mind was in a churn. Words formed of their own accord and went around in whirlpools. I was overcome with an urgent desire to write down whatever was in my head. I could sense something larger than life that I wanted to express. I quickly took out my notebook and began writing, as though in a trance. All my conflicting emotions and feelings were pouring out through the tip of my pen. When I finished writing, I lay my head on my desk and closed my eyes"* (Shenoy, *Wake Up* 57).

Furthermore, her emotional development is reflected in her interpersonal communication. She used to be prone to hiding her emotions, but later on, she began looking for real connections. In her interactions with new acquaintances and possible love interests, she was more circumspect but genuine. When she was caged by the words of Joseph (Ankita's MBA classmate) and Freddy (lover of Parul), she underwent great stress and depression and created a self-doubt that she had not been cured of the illness. She relived from it only when she communicated it to her parents. It was a great healing for her, and her depression and self-doubt were erased by her parents' words. Diksha and Ankita's metamorphosis demonstrates how communication as a soft skill facilitates both survival and the development of a new emotionally robust identity.

SUMMATION

Soft skills are the basic human skills. The character of a person is based on the soft skills he or she has. This study aims to show that soft skills are essential not only to business professionals and employees but also to normal civilians to undergo day-to- day events and achieve great heights.Soft skills, memory and emotion play a crucial role in daily life. Memory is the past thatinfluences in the present and shape the future. If one keeps holding the past, he or she will create their own identity based on it. Memory should be a tool for self-improvement rather than self-

destruction. The individual who is able to regulate their emotions is the best person in the world. This can be accomplished when they are emotionally intelligent.

This is what happens in the case of Ankita and Diksha in *Wake Up, Life is Calling*(2019) and *The Secret Wish List* (2012).They were initially imprisoned by the recollection of painful prior experiences. Self-doubt and other negative feelings were triggered as a result of this.But Ankita and Dikshahandled them with care, with the help of Soft Skills and supportive people around them. In *Wake Up, Life is Calling*(2019), PreetiShenoydepictsAnkita as a person, who uses the soft skills to turn past tragedy into emotional fortitude. PreetiShenoyskillfullycombines memory and emotion to show how soft skills may be used as identity- building and survival tools in the aftermath of trauma. Through introspection, emotional regulation, communication, and decision-making, Ankitaregains control over her own narrative through self-reflection, communication, emotional control, and decision-making. In *The Secret Wish List*(2012)Shenoyshows a home-maker who discovers herself in a dilemma whether she wants to live her life for herself or to satisfy the needs of the society. Urged by a twist of events, a wish list is born, and this list changed her life entirely. On accomplishing those wishes, she found herself. Like Ankita, Diksha claimed authority over her story at the end by getting out of the patriarchal constructions. She was determined to live a life as she wished.

The study explored how characters are empowered by emotional intelligence and communication to deal with trauma, social restrictions and emotional disruptions. Both novels show how the characters' emotional development is aided by the acquisition and use of soft skills, which eventually resulted in empowerment and self-realization. PreetiShenoy's protagonists represent aemotional consciousness that views soft skills as survival strategies rather than just social tools. Through cognitive flexibility, emotional control and memory reconstruction, these characters not only recover but also transform.In this light, Shenoy's fictions can be read not just as popular narratives of self-discovery, but as soft skills literatures.Thus, Shenoy'snovels reimagine soft skills as tools of emotional and existential empowerment.

ABSTRACT

Carissa carandas L. (Apocynaceae), commonly known as karonda, is a nutritionally and medicinally important fruit-bearing shrub widely found in South and Southeast Asia. The present study critically summarizes their botanical profile, phytochemical composition, ethnomedical relevance, pharmaceutical uses, safety characteristics, and current study space. The plant is rich with bioactive compounds containing anthocyanins, phenolic acid, flavonoids, triterpenoids, lignans, and cardiac glycosides, which contribute to its antioxidant, anti-inflammatory, antimicrobial, antidiabetic, anticancer, neuroprotective, and hepatoprotective properties as shown in many in-vitro and in-vivo studies. Although promising preclinical discoveries, large variations in extraction techniques, phytochemical image, and experimental models limit translational applicability. Standardization of plant material, advanced study profiles, mechanical validation, and systematic toxicological assessment are necessary for future growth. Overall, *C. carandas* are capable of supporting nutraceuticals and phyto pharmaceutics, justifying rigorously sound analysis that substantiates their clinical utility and curative potential.

Keywords: Bioactive compounds, *C. carandas,* pharmacological activity, in-vitro, in-vivo study

INTRODUCTION

Throughout the human history Plants are essential for their medical properties. They provide herbal materials and chemical compounds used in modern medicines Which are used to treat cancer, infections, and parasitic disease [1].

Several tests, genetic tools and lab studies are used to find out natural compounds. Scientists are deeply studying the plants step by step and during lab studies they understand how the medicines work that helps to discover new drugs [2]. *Carissa carandas* (family Apocynaceae), known as Karonda most used in Southeast Asia as a food, health supplements, and treatment of several health issues [3]. Many chemical compounds are found in different parts of the plants used to treat stomach problems, fever, wound and reproductive disorders Karonda has shown antioxidant, anti-inflammatory, and antimicrobial properties shown by laboratory studies. Researchers are needed for the safety of using this plant [4]. Several studies are done on *Carissa carandas* but the results are not reliable. The extractions process is not similar on different studies and it focuses on different goals and explains plant chemical differently. In this case it is difficult to combine the results and find out specific chemical compounds to treat specific disease [5]. Novel bioassay fractionation and LC-MS/MS identified phenolic acids, anthocyanins and flavonols. But the research is insufficient because many studies are closed early and not fully understood how these compounds act into the body [6]. Therefore, the aim of the present study is to (a) synthesize chemotaxonomic and phytochemical information for *C. carandas's* tissue and extraction tactics; (b) critically summarize the in-vitro, in-vivo, and whole convenient ex-vivo otherwise clinical indication for bioactivities of oversee curative fascination; (c) distinguish the methodological failings and standardization opportunities (analytic techniques, extract coverage, dose-response paradigm); and (d) propose an ordered, evidence-based probe agenda; phytochemistry, mechanism of action analysis, and premature safety/pharmacokinetic analysis toward increment credible translational growth of *C. carandas* rule out steers [7]. The rest of the manuscript follows this organization, deliberately moving from compound proof to cavities and lower to earth following an ascent in medicinal chemistry and preclinical development [8].

Botanical Profile and Distribution of *Carissa carandas* Linn

Carissa carandas (family Apocynaceae) is a long -living plant that also has a thorny shrub. It can survive tough ecology conditions. It is economically important in South Asia for multipurpose use as food, dye, and medicine. *C. carandas* use and growth is expected in the coming years because modern phytochemical research may prove many of its traditional medicinal uses [9]. This plant can grow poor soil that why it is suitable for modern agriculture, biodiversity programs, and value-chain development projects. Nevertheless, the use of official terminology and synonyms during that period underlines the variety and distribution of discourse characteristics [10].

In the 18th century Linnaeus was first correctly described about *Carissa carandas* and placed in the order of Gentianales, kin Apocynaceae, subfamily Rauvolfioideae, this plant group providing alkaloids and different kinds of secondary chemical compounds [11]. The primarily recent taxonomic elements (Kew's universe computerized, Planetary Checklist) dainty *C. carandas* as accept name and list a limited number of synonyms and discrepancies familiar with regional greenery, the current taxonomic stability is crucial for the several phytochemical and pharmacological reports using olden additional common labels, which complicate meta-analysis unless cross-referencing to accepted terminology [12]. Botanically, *C. carandas* is described as an evergreen shrub with sharp spines. It grows 1–3 meters tall but it can grow taller when captivated. The plant is dense and a distinctive pair of spines on the age branch. The leaves grow opposite each other are thick and look shiny on the upper surface. They are oval to oblong in shape and generally 3–8 cm long. The individual flowers are normally terminal elsewhere in the axillary bunch; they are flamboyant, tubular-campanulate, white to creamy, joined by a pleasant corolla and a 5-lobed wing, which enables pollination by generalist insects [13]. The fruits are fleshy berries round to egg-shaped. When they are ripe, they change color into deep-purple black. The ripe fruits are rich in anthocyanins and organic acids. Although unripe fruits and other parts of the plant contain toxic compounds such as cardiac glycosides and terpenoids both their medicinal use and reported toxicity. The roots are woody, sometimes used in traditional medicine [14].

The original, firmly identified *Carissa carandas* variety grows widely in the large area of Hindustan's subcontinent and border line district in the South East. It is also found in Pakistan, Bangladesh, Nepal, Sri Lanka, and parts of Afghanistan. Humans have also circulated it to Southeast Asia, where it now grows naturally in many places [15].
Cultivation and domestication of this plant are expanding in India and nearby regions because it has multiple uses. The plant provides fresh and processed fruits, natural dyes, traditional medicine, and carbon storage. Scientists have

developed various methods to reduce thorns and to improve fruit size and quality[16]. Recent studies on habitat suitability and varietal diversity show that multiple areas have good agro-climatic conditions for cultivation. In the same time Researchers highlighted that traditional knowledge and local plant varieties must be preserved to maintain local biodiversity [17].

Phytochemical Composition

Carissa carandas's phytochemical interpretation is a cross-polar phenolic resin that dominates fruit chemistry. Multiple analytic like HPLC/UPLC-MS, GC-MS, and classical phytochemical screening, converged in the presence of polyphenols (anthocyanins, flavonols, phenolic acid), terpenoids (triterpenes, sterol), cardiac glycoside, lignans, and a variety of minor alkaloid and capricious compounds coexisting with important macromolecules (pectin, sugar, lipids). The diversity of chemical show a wide range of pharmacological effect [18].

The phenolic compounds are a polar fraction of *c. carandas* fruit which show antioxidant, anti-inflammatory, and antimicrobial activity in vitro and in vivo. Anthocyanins produce pigmentation properties in plant parts [19]. The terpenoids is a major class that are particularly represented during the non-polar mixing of branches, roots, and axes. Triterpenes bind with lupeol, ursolic and oleanolic acids and breed diagnostic molecules (carissone, carissic acid, and linked carissane skeleton) have been isolated and structurally validated. The lipophilic metabolites show a cytotoxic property common plant sterols contribute to membrane transitions and bioactivity reports in countless studies [20]. The alkaloid screen and the GC-MS evaluation process shows that root and leaf fraction contain nitrogenous base and N-containing Heterocycle compound. The foam test is used to detect the Saponin confirmed by chromatographic analysis. GC-MS analysis of an unstable oil and fatty acid profile reveals typical plant aldehyde, ketone, and medium-chain fatso acid which may contribute to the smell, preservation characteristics, and bioactivity [21].

The anthocyanins are principal bioactive of karonda fruit. The cyanidin-3-O- glucoside, which is attached to peonidin and malvidin glycoside and several delphinidin derivatives that examined via HPLC-MS and HRMS analysis [22]. The anthocyanins reveal a deep purple hue of ripe fruit and a batch of in vitro antioxidant/anti-inflammatory activities detected in fractionation surveys. The anthocyanin content varies with ripeness and genotype [23]. The small, biodegradable phenolic resin was detected and quantified and it snow anti- inflammatory and antibacterial activities [24]. Triterpenes and native carissane diterpenoids constitute the lipophilic pharmacophore. The genus exact carissic acid and carissone derived function obtained from green plants and roots [25]. Cardiac glycoside and glycosidic lignans, related to oligosaccharide conjugate solutions, it shows a pharmacological action like cardiovascular effect and require careful dose response and safety assessment cardenolide may show a harmful event at lower dose [26].

Distribution of phytochemicals in *C. carandas* is highly organ specific. Fruits are a major base for water-soluble phenolic compounds, especially anthocyanins and flavonol glycoside, The branches, and stems, which contain cardiac glycoside, and alkaloid [27]. Quantitative studies on cultivars and seasons confirms that genotype and crop time affect phytochemical product and it directly affecting nutrition and pharmacology [28]. The phytochemical indication describes *Carissa carandas* as a multipurpose botanist whose fruit-derived phenolic resins require careful pharmacological and toxicological examination prior to curative increase. To move away from descriptive phytochemistry to validate a campaigner, a standard extraction and isolation method quantified MS/NMR phrase photograph, bioassay will be needed [29]. Table 1 illustrates phytochemicals of *Carissa carandas* with mechanism and preclinical evidence

Ethnomedicinal Uses

Traditional and folkloric applications

Around the rural areas of South Asia, *Carissa carandas* holds an important place in folk pharmacopeias. They used fruits, roots, leaves and latex with simplified household remedies to treat many health problems such as gastrointestinal disturbance (diarrhoea, dysentery), fever, skin infection, cough, and wounds [35]. This wide uses due

to plant's ready availability of organoleptic properties and empirical observation of therapeutic benefit, ethnobotanical surveys report for local preparation such as decoction of roots for stomach ailments, leaf poultices for wound healing, and fruit syrups for febrile conditions [36]. Many folkloric applications seem to have biochemical knowledge as communities using fruit decoction for diarrhoea and dysentery would have removed tannin rich fractions because they are astringent and can reduce intestinal secretion; and the tropical leaf poultices for would is believe to get benefit from antimicrobial terpenoids and phenolics [37]. These always includes safety measures (e.g., restricting root decoction to specific duration) there is risk management while taking the plant which reflects both safety measures and then are culturally accepted while underscoring the need of documentation the dosing regimens when its designing with preclinical safety studies [38]. Field studies often highlight the socio-economic dimensions of folk use like karonda markets supply to peri urban consumer both fresh and processed fruits, and sometimes traditional healers combine *C. carandas* with some other botanicals in polyherbal remedies, and it complicates the attribution of observed benefits to a single species. Such practices are common in folk practice, and they create the challenge for reductionist bioassay that guided the approach of fractionation. Some indications are being reported such as wound care, gastrointestinal complaints across ethnobotanical studies which lend weight to prioritizing those indications for rigorous pharmacological validation [39].

Uses in indigenous and Ayurvedic medicine

Cassia carandas occupies a well-recognized place in classical Ayurvedic texts and related indigenous materia medica. Traditionally it has been employed for gastrointestinal complaints, disorders of the spleen and liver, and for inflammatory and suppurative conditions. Ayurvedic practitioners classified plants based on rasa, virya, and vipaka, that is, taste, energetics, and post-digestive effects, respectively, and *C. carandas*; profile was interpreted to see the cooling and drying effect, which are useful in certain toxic imbalances that guided it in compound formation [34]. *C carandas* appeared to be in both the monograph and as the constituent in multi herb remedies in modern surveys of ayurveda which intended for jaundice intermittent fever and tropical ulcers; the roots and barks are used for decoction while fruits are used for dietary tonics [40]. Pharmacognostic and preparatory tradition include methods such as fresh vs dried material, aqueous vs alcoholic extraction which modulate the chemical profile. This knowledge is valuable because the analysis demonstrates the solvent polarity and processing alter the anthocyanin, phenolic and triterpenes balance. In laboratory assay it shows why sometime ayurvedic shows different therapeutic activities from crude [41].

Nutritional and dietary importance

Carissa carandas are eaten fresh and are preserved by pickles, functional food, they are local source of vitamin C organic acid pectin and anthocyanin pigments which gives the nutritional and sensory attributes. Ripe berries contain a huge amount of ascorbic acid and phenolic antioxidant. As nutrients dense food and potential raw material karonda is positioned as both [42]. With ripening stage and cultivar selection, the dietary use intersects with opportunities for value Addition [43]. As for nutrition and medicine, many use karonda fruit as many studies suggested that it has Antioxidant and hepato-protective effect for certain extracts. As per human nutrition studies, it shows carefully controlled clinical trials are lacking and dietary recommendations should be conservative and evidence based for moving forward [44].

Pharmacological Activities

Antioxidant activity

The study shows that methanolic extracts of *Carissa carandas* leaves can neutralize harmful free radicals thus having strong antioxidant activity like vitamin C. [45]**.** The phenolic and flavonoid content present in the fruit extract was found to reduce oxidative stress by scavenging different reactive oxygen species [46]. This work confirms that if extract concentration increases then the antioxidant activity also increases. It proves dose-dependent free-radical scavenging potential of *Carissa carandas* [47]. A freshly prepared aqueous solution of silver nitrate was used for silver nanoparticles synthesis. *Carissa carandas* plant extracts of 5 ml were mixed with 45 ml of silver nitrate solution. The biosynthesis was done at room temperature (25°C) and 60 °C to precisely observe the effect of temperature on the

synthesis of silver nanoparticles. The silver nanoparticles possess antioxidant activity [48]. The ethanol and water mixture (49:51) is the most effective for extracting antioxidant-rich compounds. MAE influences antioxidant activity. Low microwave power (180 W) and short extraction time (3 minutes) increases antioxidant activity because it prevents thermal degradation of bioactive compounds. Acidified solvents increase antioxidant activity but excessive acidity during MAE can decrease extraction efficiency [49].

Anti-inflammatory and analgesic activities

The phytochemical constituents of the *Carissa carandas* extract were screened by GC-MS analysis and it was observed that 11 compounds are present in *Carissa carandas*. Naringin derived from the methanolic fruit extract of carissa carandas is responsible for anti-inflammatory properties and used to treat arthritis [50]. Naringin isolated from *C. carandas* leaves reduces inflammation by lowering nitric oxide levels and decreasing swelling in animals [51]. The Leaf extracts of *Carissa carandas* help to stabilize cell membranes and prevent protein damage which signifies their ability to reduce inflammation and pain [52]**.** Fruit extract of *Carissa carandas* suppress inflammatory markers in immune cells thus indicates their potential role in controlling inflammatory diseases. Phytochemicals such as flavonoids and triterpenoids present in *Carissa carandas* exhibits analgesic effect [53].

Anticancer and cytotoxic activities

Methanolic leaf extract of *Carissa carandas* reduces cancer cell survival and promotes programmed cell death thus shows anticancer activity against colon cancer cells [54]. The Fruit extracts inhibit abnormal cell growth and provide anticancer properties. Phenolic compounds present in *Carissa carandas* is linked with the ability to prevent cancer cell multiplication and induce apoptosis [55]. Anti-cancer activity is determined by using the MTT assay. 27-O-Z-p-coumaroyl ursolic acid, 23-hydroxy ursolic acid extracted from the *Carissa carandas* shows potent cytotoxic activity against the lung cancer cell line NCI-H460. Uvaol provides good selective cytotoxicity against NCI-H460.The 23-hydroxy ursolic acid also having the anti-inflammatory effects [31]. Silver nanoparticles synthesized by *Carissa carandas* leaf extract possess significant cytotoxic effects against breast cancer cell lines [56]**.** Pentacyclic triterpenoids isolated from *Carissa carandas* leaves provides potent cytotoxic activity against multiple human cancer cell lines indicating strong anticancer activity [32].

Antidiabetic and metabolic regulatory activities

Unripe fruit extract of *Carissa carandas* lowers the blood glucose levels in diabetic rats thus proves the antidiabetic activity [57]. Fruit extracts reduce the oxidative stress and inflammation which indirectly helps to improve insulin sensitivity and glucose metabolism. The antidiabetic activity was found to be related to flavonoids and phenolics that regulate carbohydrate metabolism [58]. *Carissa carandas* shows promising metabolic regulatory effects due to its bioactive compounds present in it. Ethanolic fruit extract of *Carissa carandas* significantly lowered both elevated blood glucose levels as well as improved lipid profiles in streptozotocin-induced diabetic rats, indicating antidiabetic potential [59].

Antimicrobial and neuroprotective activities

Leaf and fruit extracts of *Carissa carandas* having antibacterial activity against common urinary tract infection [60]**.** Methanolic fruit extract produces prominent zone of inhibition against bacterial strains thus confirming its antibacterial activity**.** *Carissa carandas* leaf and fruit extracts inhibit the growth of pathogenic bacteria including Streptococcus mutans, Escherichia coli, and Staphylococcus aureus confirms their broad-spectrum antibacterial activity [61]**.** The polar extracts of *Carissa carandas*, can protect the nerve cells from damage caused by multiple toxic substances, thus it possesses neuroprotective activity [62]. Ethanolic root extract of *Carissa carandas* having significant neuroprotective effect [63]. Fig 1 represents the pharmacological activities of *Carissa carandas.*

Therapeutic Implications and Mechanisms

The methanolic extract of *Carissa carandas* roots possesses anti-inflammatory properties. Carissone present in the *Carissa carandas* inhibits the production of pro inflammatory mediators such as Tumor necrosis factor-alpha,

Interleukin-1 beta, Nitric oxide (NO). By inhibiting these mediators, it gives anti-inflammatory effect [33]. A pentacyclic triterpenoid present in *Carissa carandas* leaves named as ursolic acid, induces apoptosis in cancer cells and thus reduces cancer cell growth [64]. In breast cancer development AKT1, HIF1A, PTGS2, and GSK3B were found to be major target proteins. Estrogen, HIF-1, Prolactin, and Th17 signaling pathways are responsible for tumor growth, cell proliferation, and metastasis. *Carissa carandas* show anti-breast-cancer activity by regulating these proteins and pathways. Phytochemicals present in the *Carissa carandas* shows a multi-targeted anti-cancer effect [65]. By the Chemical analysis it is identified that naringin is a major active compound. Naringin neutralize the harmful free radicals like superoxide and DPPH thus it reduces oxidative stress and acts as an antioxidant. Antioxidant activity included neutralization of the free radicals and enhancement of natural antioxidant enzymes [66]. *Carissa carandas* helps the cells to take in more glucose and it shows anti-insulin resistance activities, thus it gives antidiabetic activity [67]. An enzyme names as Hyaluronidase produced by many pathogenic bacteria that helps them to grow and spread infection in the body. The steroidal fraction isolated from *Carissa carandas* strongly inhibits hyaluronidase. *Carissa carandas* indicates good therapeutic potential in preventing the spread of infections and provides antimicrobial activity [68]. This extract stimulates the gut movement by activating muscarinic and histamine receptors, which helps in constipation and it also relaxes intestinal muscles by blocking calcium channels, which helps in diarrhea and intestinal spasms. So, it can treat both constipation and diarrhea [69]. Different parts like leaves, fruits, seeds of *Carissa carandas* extract helps to prevent skin aging by blocking hyaluronidase enzyme. The anti-aging activity is mainly due to the secondary metabolites like phenolic compounds and flavonoids present in the *Carissa carandas* [70].

Experimental Evidence

In-vitro studies

The isolated compounds reduce inflammatory mediator release in cultured immune cells. Fruit extract of *Carissa carandas* inhibited bacterial growth under controlled laboratory conditions**.** The in-vitro anticancer studies shows that the silver nanoparticles derived from *Carissa carandas* was evaluated by the MTT assay and it was performed on cell lines, where cells were given different concentrations of silver nanoparticles. The results shows that it has anticancer activity [71]. The aqueous fruit extract of *Carissa carandas* was evaluated for its anti-diabetic potential using in-vitro cell models and in-vivo type 2 diabetic rat models. In vitro studies show that in LPS-induced 3T3-L1 adipocytes it increases glucose uptake and decreased glycerol release and thus it gives anti-insulin resistance activity and in-vivo studies shows *Carissa carandas* reduces dyslipidemia and thus provides anti-insulin resistance activity [72].

In-vivo studies

The leaves of *Carissa carandas* were extracted with methanol and then defatted with chloroform to yield *Carissa carandas* defatted extract. The extract was chemo profiled using UPLC-MS/MS and naringin was isolated in a high yield. The anti-inflammatory activity of naringin was investigated in-vivo by carrageenan induced hind rat paw edema model at two dose levels 50 and 25 mg/kg. In-vivo analysis shows that Naringin decreased inflammation in rats by using the carrageenan-induced paw edema model and In vitro analysis shows that it inhibited nitric oxide release from activated macrophage cells thus it gives the anti-inflammatory activity [30]. For bacteria, the methanolic and petroleum ether extracts of unripe roots and fruits of *Carissa carandas* were tested against Staphylococcus aureus, Bacillus pumilus, and Vibrio cholerae by using the disc diffusion method and for fungi, they were tested against Candida albicans, Aspergillus oryzae, and Trichophyton azole by using the turbidity method. The effects were then compared with standard medicines like ciprofloxacin for bacteria and fluconazole for fungi. The results shows that it has antimicrobial activity [73].

In vivo analysis shows that the anti-pyretic activity of *Carissa carandas* was evaluated by Brewer's yeast induced pyrexia in albino rats. At a dose of 100 and 200 mg/kg carissa carandas extract showed significant anti-Pyretic activity as compared to paracetamol at a dose of 150 mg/kg. By performing in vivo analysis on male albino rats *Carissa carandas* shows significant neuropharmacological activity [74]. The analgesic activity of *Carissa carandas* was studied in mice by using hot plate and acetic acid induced writhing methods. In analgesic studies, the ethanol extract of

Carissa carandas showed strong analgesic activity at a dose of 100 mg per kg body weight. lt reduces pain responses by 72.67%, which was the highest effect observed [75].

Safety and Toxicity

It is observed that a mice treated with *Carissa carandas* plant extract does not show any acute toxicity up to 2000 mg/kg. High-dose administration of carissa carandas leaf extract did not cause death or toxic symptoms in experimental rats. During the sub-acute toxicity evaluation, no damage is observed in organs of the experimental animals [76]. At an oral dose of 400mg/kg the methanolic extract and its ethyl acetate extract shows antidiabetic activity in diabetic animals. But the ethyl acetate extract is more effective than methanolic extract [77]. The acetone extract of *Carissa carandas* fruits reduced inflammation. Both 100 mg/kg and 200 mg/kg doses exhibits increasing anti-inflammatory effect up to 3 hours. The pick anti-inflammatory activity was observed at 3 hours with the dose of 200 mg/kg. The antioxidant dose of *Carissa carandas* ranges between 0.1 to 1 mg/mL, the antioxidant activity increases when the dose increases toward 1 mg/ml [78]. At a dose of 25 mg/kg *Carissa carandas* leaf extract reduces tumor cell count and increased survival in EAC-bearing mice confirms it is in-vivo anticancer activity [79].

Challenges, Future Research Directions & Conclusion

Many studies on the phytochemicals and biological activity of *Carissa carandas* give confusing results because the studies use different methods. Researchers use different solvents various part of the plant and different drying and extraction process but as a result there are different chemical compositions are found out. This makes it hard to compare results and meta-analyses [80]. It is confusing whether the differences in biological activity are due to natural variation in the plant itself or simply due to differences in how the plant material was prepared. In several cases plant identification, voucher specimens, extraction conditions, and chemical analysis are not reported clearly [81]. The lack of proper standardization and accurate measurement of plant chemicals when studying their biological effects. Anthocyanins, chlorogenic and several phenolic acids, triterpenes, and sometimes cardiac glycoside examined throughout the relevant survey. very few studies go beyond basic LC-MS and identify them correctly using advanced methods like NMR and high-resolution mass spectrometry [82]. Accordingly, most bioactivities are attributed to the petroleum fraction in other words a composite phenolic pool is rather than to the described chemical animal with mensural authority, selectivity, and mechanisms of action. This gap limits proper medicinal chemistry evaluation prioritizes ADME and pharmacokinetic studies [83]. Pharmacology and Toxicology surveys are scarce. Most research is restricted to short-term in vitro tests. For the complete absence of systematic pharmacokinetic data (Absorption, Circulation, Metamorphosis, Elimination) for the main compounds found in *C. carandas* (anthocyanins, triterpenes, and glycosides) dose response relationships are not defined [84]. The detection of Cardiac glycoside in a few non-fruit tissues make safety concerns and shows the need for detailed safety, toxicity, and genotoxicity studies before making any therapeutic claims. Some studies are scarcely carried out. Consequently promising in vitro results cannot be reliably translated into real biological use and the lack of in vivo pharmacokinetic, pharmacodynamic and safety data greatly limits growth toward human studies [85].

Strong research based on solid evidence is needed to overcome these problems. First, researchers should use to identify the plant sample. They extract using through chemical profile (LC-MS/MS chromatogram, marker quantification) and make standard reference extracts will help make results repeatable and comparable between laboratories. These steps are not costly but very important because they decrease wasted experiments and help researchers decide quickly which results are reliable [85]. Combined phytochemistry and bioassay-guided fractionation is necessary for moving active indication from the fraction. For this it required systematic use and contemporary hyponat information that is LC-HRMS, precursory HPLC, NMR), extraneous in-vitro target assay (enzymatic, receptor, antimicrobial panel), and early ADME along with equal competence and reasonable development capability [86]. In fruits value of anthocyanin and chlorogenic type phenolic resins and in greenery and wood triterpenes is given, a parallel nerve pathway between a polar nutraceutical conductor and a lipophilic small molecule conductor is sensible [87]. And then a carefully planned toxicology and phytopharmaceutical undertaking is necessary to see efficient functions. For cardiovascular safety (hERG, in-vitro cardiomyocyte assay, telemetry in-vivo) and extended toxicology are mandatory including cardiotonic or glycosidic motifs in the compounds [88]. It is

also crucial for nutraceutical claims to check Homo sapiens tolerability and Food interaction study. To ensure for good evolution they need timely acquisition of preclinical pledge and small-scale clinical pharmacology that is an ascend dose, food interaction, would alter preclinical pledge [89].

Table 1: Phytochemicals of *Carissa carandas* with Mechanism and Preclinical Evidence

Phytochemical	Chemical Class	Plant Part	Physiological activity	Mechanism of action	Preclinical study model	Ref
Cyanidin-3-O-glucoside	Anthocyanin	Ripe fruit	Antioxidant, anti-inflammatory	Inhibition of COX-2 and iNOS expression	In-vitro	[22]
Delphinidin derivatives	Anthocyanins	Fruit	Antioxidant	ROS scavenging, enhancement of endogenous antioxidant enzymes	In-vitro	[22]
Chlorogenic acid	Phenolic acid	Fruit	Anti-inflammatory, antioxidant	NF-κB pathway inhibition, reduction of pro-inflammatory cytokines	In-vitro, In-vivo	[24]
Flavonols	Flavonoids	Fruit & leaves	Antioxidant, antimicrobial	Membrane disruption in microbes, radical scavenging	In-vitro	[19]
Naringin	Flavonoid glycoside	Leaves	Anti-inflammatory, antioxidant	Inhibition of NO production	In-vivo	[30]
Ursolic acid	Pentacyclic triterpenoid	Leaves	Anticancer, anti-inflammatory	Inhibition of PI3K/Akt pathway	In-vitro	[31]
Oleanolic acid	Triterpenoid	Leaves, roots	Hepatoprotective, anti-inflammatory	Antioxidant enzyme upregulation, inhibition of inflammatory mediators	In-vivo	[20]
Lupenol	Triterpenoid	Roots, stem	Anti-inflammatory, anticancer	Suppression of NF-κB signaling, apoptosis	In-vitro	[32]

				induction		
Carissone	Diterpenoid	Roots	Anti-inflammatory	Inhibition of TNF-α, nitric oxide production	In-vitro	[33]
Cardiac glycosides	Cardenolides	Roots, stems	Cardiovascular activity	Inhibition of Na^+/k^+-ATPase, positive inotropic effect	Preclinical pharmacology & toxicity studies	[34]

ABSTRACT

The rapid expansion of the poultry industry has led to the large-scale generation of poultry feather waste, a keratin-rich by-product that is highly resistant to natural degradation and poses serious environmental concerns. Conventional disposal methods such as incineration and landfilling are environmentally unsustainable and do not allow recovery of the valuable protein content present in feathers. The present study evaluated three eco-friendly bioconversion strategies for effective poultry feather waste management: (i) microbial degradation using keratinolytic microorganisms, (ii) vermicomposting employing selected earthworm species, and (iii) an integrated microbial–vermicomposting approach. Poultry feathers collected from waste disposal sites were initially subjected to microbial pretreatment using indigenous keratinolytic isolates, followed by vermicomposting with native earthworm species, namely *Perionyx excavatus*, *Lampito mauritii*, and *Octochaetona serrata*. The efficiency of degradation was assessed based on physical changes such as weight reduction, texture, odour, and nutrient enrichment of the resulting compost. Compared to individual microbial or vermicomposting treatments, the integrated system achieved significantly faster decomposition and superior stabilization of feather waste. This combined approach enhanced keratin breakdown, improved substrate palatability for earthworms, and produced nutrient-rich, mature compost within a shorter time frame. The study demonstrates that microbial pretreatment coupled with vermicomposting is a sustainable, cost-effective, and scalable strategy for poultry feather waste valorization, contributing to circular bioeconomy and sustainable agricultural practices.

Keywords: Poultry feather waste; Keratinolytic microorganisms; Vermicomposting; Microbial pretreatment; Waste valorization; Circular bioeconomy.

INTRODUCTION

The global poultry industry has expanded rapidly over the past few decades to meet the increasing demand for affordable animal protein. This growth has simultaneously resulted in the large-scale generation of poultry feather waste, which accounts for approximately 5–7% of the total live weight of processed birds [1, 2]. Owing to its fibrous structure and biochemical composition, feather waste represents a major environmental concern when improperly managed. Conventional disposal methods such as land filling and incineration are environmentally unsustainable, energy-intensive, and lead to the loss of valuable protein-rich biomass [3]. Poultry feathers are composed predominantly of β-keratin, an insoluble, highly ordered structural protein stabilized by extensive disulfide bonds, hydrogen bonding, and hydrophobic interactions [4]. These structural features impart exceptional mechanical strength and chemical resistance, rendering feathers recalcitrant to common proteolytic enzymes and natural biodegradation processes. As a result, feather accumulation poses risks such as soil and water pollution, unpleasant odours, and the proliferation of pathogenic microorganisms if not treated appropriately [5].

In recent years, biological treatment strategies have emerged as sustainable alternatives for the valorization of keratin-rich wastes. Among these, microbial degradation using keratinolytic microorganisms has gained significant attention. Several bacterial and fungal species, particularly those belonging to the genera *Bacillus*, *Streptomyces*, *Aspergillus*, and *Trichoderma*, are known to produce extracellular keratinases capable of hydrolyzing keratin into peptides and free amino acids [6,7]. Microbial bioconversion not only reduces waste volume but also facilitates the recovery of value-added by-products such as biofertilizers and protein hydrolysates. However, microbial treatment alone often results in incomplete degradation due to substrate heterogeneity, accumulation of intermediate products, and process limitations at larger scales [8, 9]. Vermicomposting represents another eco-friendly waste management approach that utilizes earthworms and their associated microbial communities to accelerate organic matter decomposition and stabilization. Earthworm species such as *Perionyx excavatus*, *Lampito mauritii*, and *Octochaetona serrata* enhance waste mineralization through mechanical fragmentation, enzymatic digestion, and stimulation of microbial activity [10, 11]. While vermicomposting is highly effective for a wide range of organic wastes, the direct application of this technique to poultry feathers remains challenging due to poor palatability, slow degradation rates, and limited earthworm ingestion of intact keratin fibers [12].

To overcome these limitations, integrated biological treatment systems combining microbial pretreatment with vermicomposting have been proposed as a promising solution. Microbial pretreatment initiates keratin breakdown, weakens the feather structure, and improves substrate accessibility, thereby enhancing subsequent earthworm-mediated degradation [13]. The synergistic interaction between keratinolytic microorganisms and earthworms accelerates organic matter transformation, reduces processing time, and improves compost maturity and stability [14]. Despite these advantages, systematic comparative studies evaluating microbial degradation, vermicomposting, and integrated microbial vermicomposting systems for poultry feather waste conversion remain limited, particularly under tropical and Indian environmental conditions [15]. Therefore, the present study aims to comparatively evaluate the efficiency of microbial degradation, vermicomposting, and an integrated microbial vermicomposting system for the bioconversion of poultry feather waste. The study focuses on degradation efficiency, physical transformation, and stabilization performance to identify an effective, sustainable, and scalable waste management strategy aligned with circular bioeconomy and sustainable agricultural practices.

MATERIALS AND METHODS

Collection and Preparation of Poultry Feather Waste

Raw poultry feathers were collected from local poultry processing and waste disposal sites. The feathers were thoroughly washed with tap water followed by distilled water to remove adhering blood, fat, and impurities. Cleaned feathers were air-dried at room temperature and stored in sterile containers until further use.

Microbial Inoculum Preparation

Indigenous keratinolytic microbial isolates previously characterised for feather-degrading ability were used for microbial degradation experiments. The isolates were cultured in keratin basal medium under optimized laboratory conditions to obtain active inoculum. The prepared microbial suspension was used for feather pretreatment in the microbial degradation and integrated systems.

Vermicomposting System

Vermicomposting experiments were conducted using native earthworm species including *Perionyx excavatus*, *Lampito mauritii*, and *Octochaetona serrata*. Preconditioned earthworms were introduced into plastic vermibeds containing partially decomposed organic matter as bedding material. Moisture content was maintained at 60–70%, and the setup was kept under ambient laboratory conditions.

Integrated Microbial–Vermicomposting System:

For the integrated system, poultry feathers were first subjected to microbial pretreatment for a defined period to initiate keratin breakdown. The pre-treated feather substrate was then transferred to vermicomposting units containing earthworms. This sequential approach was designed to enhance substrate palatability and accelerate overall biodegradation.

Experimental Design and Monitoring Parameters:

Three experimental setups were maintained: (i) microbial degradation alone, (ii) vermicomposting alone, and (iii) integrated microbial–vermicomposting system. All experiments were conducted in triplicate. Degradation efficiency was evaluated based on weight reduction, physical appearance (texture, colour, and odour), and degree of substrate stabilization at regular intervals.

Duration and Environmental Conditions

The experiments were conducted over a fixed experimental period. Temperature and moisture were regularly monitored and maintained uniformly across all treatments to ensure comparability.

Statistical Analysis

All experimental data were expressed as mean ± standard deviation. Comparative analysis among different treatment systems was performed using appropriate statistical tools to evaluate significant differences in degradation efficiency.

RESULTS AND DISCUSSION

Comparative Degradation Efficiency of Poultry Feather Waste

The degradation efficiency of poultry feather waste varied significantly among microbial degradation, vermicomposting, and the integrated microbial–vermicomposting system (Figure 1). In the microbial pretreatment system, feather degradation progressed gradually through the action of keratinolytic enzymes secreted by specialized microorganisms. These enzymes initiated the breakdown of the rigid keratin structure by reducing disulfide bonds and hydrolyzing peptide linkages within the keratin matrix, leading to surface erosion, softening, and partial fragmentation of feathers [13]. Despite these biochemical transformations, complete degradation was not

achieved, which can be attributed to the highly crystalline and compact nature of keratin, limited enzyme penetration into the feather shaft, and the accumulation of partially hydrolyzed intermediates that may inhibit further enzymatic activity. Vermicomposting demonstrated a comparatively higher degradation efficiency than microbial treatment alone, highlighting the role of earthworms in enhancing organic matter transformation. Earthworm activity facilitated physical fragmentation of feathers through muscular grinding in the gizzard, increased substrate aeration, and improved moisture regulation within the vermibed. Additionally, the continuous ingestion and excretion processes stimulated indigenous microbial populations, thereby accelerating keratin degradation and humification processes [10, 11]. However, despite these improvements, a fraction of intact keratin fibers persisted in the vermicompost, indicating that vermicomposting alone is insufficient to overcome the intrinsic recalcitrance of feather keratin without prior structural weakening.

The integrated microbial–vermicomposting system exhibited the highest degradation efficiency, achieving near-complete conversion of poultry feathers within a substantially shorter processing period (Table 1). This enhanced performance can be attributed to the synergistic interaction between microbial keratinolytic activity and earthworm-mediated biodegradation. Microbial pretreatment effectively weakened the keratin framework, increasing substrate palatability and accessibility for earthworms. Subsequent earthworm digestion, coupled with intensified microbial proliferation within the vermined, resulted in accelerated mineralization and stabilization of feather waste. Similar synergistic enhancements in degradation efficiency have been reported in integrated biological treatment systems applied to protein-rich organic wastes, emphasizing the effectiveness of combining microbial and vermicomposting approaches for sustainable waste valorisation [16].

Physical and Morphological Changes During Bioconversion:

Noticeable physical and morphological transformations of poultry feather waste were observed throughout the bioconversion process under all treatment systems, reflecting varying degrees of keratin degradation and substrate stabilization (Figure 2). These changes serve as important indicators of biodegradation efficiency and compost maturity. In the microbial pretreatment system, feathers exhibited initial surface erosion, softening, and partial fraying, particularly along the barbs and barbules. The feather shafts, however, largely remained intact, indicating incomplete structural breakdown. The colour of the substrate shifted slightly from its original whitish appearance to a light yellowish or pale brown tone, accompanied by a mild proteinaceous odour (Table 2). These observations suggest enzymatic weakening of keratin fibers through microbial keratinase activity but insufficient mechanical disruption to achieve complete disintegration. Similar partial morphological changes during microbial keratin degradation have been reported by Brandelli et al. (2010) and Gupta et al. (2013), emphasizing the limitations of microbial treatment when applied alone.

Vermicomposting induced more pronounced physical alterations in the feather substrate. The combined effects of earthworm ingestion, gizzard grinding, and microbial stimulation resulted in visible fragmentation of feathers, darkening of the substrate, and a granular texture. The odour was substantially reduced compared to microbial pretreatment, reflecting improved stabilization and reduced accumulation of proteinaceous intermediates. Earthworm activity enhanced aeration and moisture distribution within the vermined, promoting microbial proliferation and organic matter decomposition [10, 18]. Nevertheless, remnants of feather shafts were still evident, indicating that although vermicomposting enhanced physical breakdown, complete keratin mineralization remained limited due to the inherent resistance of feather keratin.

The integrated microbial–vermicomposting system exhibited the most extensive physical and morphological transformation of poultry feather waste. The final product was characterized by a dark brown to black coloration, fine and homogeneous texture, and an earthy, odourless smell, indicative of advanced humification and compost maturity (Table 2). Feathers were almost entirely disintegrated, resulting in a soil-like material with high stability. This superior transformation can be attributed to the sequential weakening of keratin structures during microbial pretreatment, followed by efficient earthworm digestion and intensified microbial activity within the vermicompost matrix. Previous studies have similarly reported enhanced substrate maturity and improved physical quality in

integrated biological treatment systems compared to single-process approaches [19]. Overall, the observed physical and morphological changes clearly demonstrate that the integrated microbial–vermicomposting system is significantly more effective in transforming recalcitrant feather waste into a stabilized and mature organic product. The synergistic interaction between microbial enzymes and earthworm-mediated processes plays a critical role in overcoming keratin recalcitrance and accelerating waste stabilization, supporting the feasibility of this approach for sustainable poultry feather waste management.

Processing Time, Stabilization Dynamics, and System Performance:

A marked variation in processing time and stabilization dynamics was observed among the microbial degradation, vermicomposting, and integrated microbial–vermicomposting systems, highlighting differences in system performance and overall biodegradation efficiency (Figure 3). Processing time is a critical parameter in waste management, as shorter stabilization periods directly translate into improved operational feasibility and reduced processing costs. Microbial pretreatment alone required a comparatively longer incubation period to achieve partial feather degradation. Although keratinolytic microorganisms initiated biochemical breakdown of keratin through enzymatic reduction of disulfide bonds and peptide hydrolysis, the absence of mechanical disruption limited substrate disintegration. As a result, feather shafts and dense keratin regions persisted, prolonging the time required for stabilization. The accumulation of intermediate degradation products further slowed the degradation process, consistent with earlier observations on microbial keratin degradation systems [13, 20].

Vermicomposting exhibited improved stabilization kinetics relative to microbial treatment, primarily due to the combined effects of earthworm activity and associated microbial processes. Earthworms enhanced processing efficiency through physical fragmentation in the gizzard, improved aeration, and regulation of moisture content within the vermined. These processes facilitated microbial colonization and enzymatic degradation, thereby accelerating organic matter transformation [10, 11]. However, the highly recalcitrant nature of feather keratin limited the rate of mineralization, resulting in extended stabilization periods and incomplete degradation when vermicomposting was applied as a standalone treatment. In contrast, the integrated microbial–vermicomposting system demonstrated the fastest stabilization and superior system performance, achieving near-complete feather degradation within 30–35 days (Figure 2). Microbial pretreatment effectively weakened the keratin structure, increasing substrate accessibility and palatability for earthworms. Subsequent earthworm digestion, combined with intensified microbial proliferation in the vermined, accelerated mineralization and humification processes. The synergistic interaction between microbial enzymes and earthworm biological activity significantly reduced processing time while enhancing substrate stabilization. Similar reductions in processing duration and improvements in system efficiency have been reported in integrated biodegradation studies involving protein-rich and recalcitrant organic wastes [21].

Overall, the comparative analysis of processing time and stabilization dynamics clearly demonstrates the operational advantage of the integrated microbial–vermicomposting system over individual treatment approaches. The reduced processing period, improved degradation efficiency, and enhanced stabilization underscore the potential of this integrated strategy as a scalable and sustainable solution for poultry feather waste management.

Mechanistic Insights into Integrated Bioconversion:

The superior performance of the integrated system can be attributed to complementary biological mechanisms. Keratinolytic microorganisms initiate structural weakening of feathers by disrupting disulfide bonds, while earthworms enhance degradation through mechanical grinding, enzymatic digestion, and stimulation of microbial populations within the vermibed. This synergistic interaction promotes rapid mineralization and humification, resulting in a stable and mature end product. Such integrated approaches align with sustainable waste valorization strategies and circular bioeconomy principles for managing recalcitrant protein-rich wastes (Enciso-Tenorio et al., 2025; Anbesaw, 2022).

CONCLUSION

The present study provides a comprehensive comparative evaluation of microbial degradation, vermicomposting, and an integrated microbial-vermicomposting system for the sustainable bioconversion of poultry feather waste, a highly recalcitrant and environmentally problematic by-product of the poultry industry. The findings clearly demonstrate that each treatment approach contributes uniquely to feather degradation; however, their combined application yields superior outcomes in terms of degradation efficiency, processing time, and end-product quality. Microbial pretreatment alone initiated keratin degradation through enzymatic cleavage of disulfide bonds and peptide linkages, resulting in partial softening and surface erosion of feathers. While this approach effectively weakened the keratin structure, complete degradation was limited due to restricted substrate accessibility and accumulation of intermediate degradation products. Vermicomposting, on the other hand, enhanced physical fragmentation and organic matter transformation through earthworm activity and associated microbial processes, leading to improved stabilization compared to microbial treatment alone. Nevertheless, the inherent resistance of feather keratin constrained rapid mineralization when vermicomposting was applied as a standalone process.

The integrated microbial–vermicomposting system emerged as the most efficient and effective strategy, achieving near-complete feather degradation within a substantially shorter processing period. The sequential interaction between microbial keratinolytic activity and earthworm-mediated digestion created a synergistic effect that accelerated keratin breakdown, enhanced substrate palatability, and promoted rapid humification and stabilization. The final product obtained from the integrated system exhibited a fine, homogeneous, soil-like texture, reduced Odour, and high stability, indicating advanced compost maturity and improved suitability for agricultural and environmental applications. Overall, this study highlights the significant potential of integrated biological treatment systems for the valorisation of protein-rich, keratinous wastes. The demonstrated reduction in processing time, improvement in degradation efficiency, and enhancement of end-product quality underscore the feasibility of this approach as an eco-friendly, low-cost, and scalable solution for poultry feather waste management. By converting a environmentally problematic waste into a value-added organic resource, the integrated microbial-vermicomposting strategy supports circular bioeconomy principles and offers a sustainable pathway for mitigating environmental impacts associated with poultry industry residues. Future studies focusing on nutrient profiling, field-scale validation, and agronomic performance of the final compost will further strengthen the practical applicability of this integrated bioconversion approach.

ABSTRACT

The textile industry is a sustainable consumer of water and it produces enormous volumes of contaminated water with dyes and other chemicals. Algae based remediation technology can provide an excellent resolution for textile water pollution. In the present study focused to decolourisation of azo dye,for that textile effluent diluted at different concentration 10%, 25%, 50% and 75% were inoculated with 5 ml of *Chlorella vulgaris* culture and allowed to grow for the period of 60 days. Sampling was done at regular intervals of 15, 30, 45 and 60 days of incubation then *Chlorella vulgaris* harvested at prescribed interval of time for analysis of pigments, Carbohydrates, RGR, Partial purification of azo reductase for assay and kinetic studies to confirm its efficiency in decolourisation of dye reduction. *Chlorella vulgaris* culture filtrate was collected for estimation of biomass subsequently textile treated effluent used for seed germination studies at laboratory and determined seedling assay to confirm biomass production along with role of degradation of *Chlorella vulgaris,* which act as an indicatorfor the removal of azo dye contamination. The availability of treated water could be confirmed on the production of biomass. The utilization of algae in phytoremediation offers several benefits such as algal growth, high potential for pollutant removal and adaptability to diverse environments. Moreover, the utilization of algae in phytoremediation can enhance nutrient assimilation and increase algal biomass productivity. Algae can also metabolize dye through enzymatic reactions, leading to their degradation and detoxification.Dye toxicity of the effluent might be reduced not only by grown algal culture but also role of azo reductase enzymes of *Chlorella vulgaris*culture involved in the decolourization of textile effluents.

INTRODUCTION

Textile effluent refers to the wastewater generated during various stages of textile manufacturing and finishing processes, including dyeing, printing, scouring, bleaching, finishing, and rinsing. Textile effluents often contain heavy metals and other bio-accumulative toxic substances that pose significant ecological risks. Textile industries are using various chemicals such as wetting process, dyes, surfactants, fixing agents, softeners and other additives in textile wet processing units produce highly complex polluting waste (Villegas-Navarro *et al.,* 2001). The toxic nature of dyeing should be reduced to permissible limits before discharged into water bodies environment. Textile effluents are rich in dyes, salts, surfactants, and toxic metals, contributing to severe aquatic pollution which affects the aquatic ecosystem. The intense coloration limits light penetration in water bodies, thereby suppressing photosynthetic activity in aquatic plants and algae. Dyes are difficult to remove from wastewater due to the aromatic molecular structure that makes them much more stable to light, heat, and oxidizing agents. Synthetic dyes are aromatic, water-soluble, and dispersible organic colorants (Hao *et al.,* 2000), dyes help to make the world more beautiful by coloured substances; however, they cause serious environmental pollution. The use of untreated textile wastewater for irrigation leads to the accumulation of salts and heavy metals in soil, resulting in altered pH, reduced fertility, and impaired seed germination and crop growth. Prolonged application further facilitates the transfer of heavy metals into the food chain, posing risks to food quality and safety (Masum *et al.,* 2025). Human exposure to contaminated water through direct contact or ingestion can result in the intake of toxic dyes and heavy metals. Acute health effects include skin irritation, dermatitis, and gastrointestinal disturbances, whereas chronic exposure has been associated with mutagenic, carcinogenic, and endocrine-disrupting outcomes. Notably, some azo dyes can degrade into aromatic amines, compounds recognized for their carcinogenic potential (Castillo-Suárez et al., 2023; Liu et al., 2024). Azo compounds are one of the oldest industrial sized organic dyes. Azo compounds have low biodegradability nature which influences natural ecosystems and human (Chung &Stevens 1993). Biological method of dye degradation has been focussed by using bacterial strain (Yang 1988).

Algae exhibit a remarkable capacity to interact with dyes in wastewater, utilizing these compounds as substrates through two primary pathways, adsorption, which is an extracellular and metabolic-independent process and absorption which involves enzymatic and metabolic reactions that assimilate dyes into the cellular metabolism (Sarkar and Dey 2021). The present study was focused to evaluate dye degradation by using *Chlorella vulgaris*and the mechanism behind the biodegradability of azo compounds from textile effluent and characterization of its application on agriculture field trails.

MATERIALS AND METHODS

Effluent collection

Textile effluent collected from the total discharged area of textile industry, Muruganpalayam, Tirupur, Tamilnadu (Latitude: 10.982724. Longitude: 77.22399). The collected effluent consisted of a mixture of the discharges from all the stages of textile processing. The effluent was brought in sterile container and was stored at 4°C for further usage.

Growth of *Chlorella vulgaris* culture

Algae *Chlorella vulgaris* cultures obtained from Translational Plant Research Laboratory and Natural Product Research Laboratory, Department of Microbial Biotechnology, Bharathiyar University Coimbatore. *Chlorella vulgaris* cultures were grown in culture with a synthetic nutrient medium. Bold's Basal Medium (BBM) was used as the synthetic culture medium (Nicholas and Bold 1965).Bold's Basal Medium (BBM) for cultivating *Chlorella vulgaris* is prepared using stock solutions that include macronutrients like $NaNO_3$ 25g/L, $Mg.SO_4.7H_2O$ 7.5g/L, NaCl 2.5g/L, K_2HPO_4 7.5g/L, KH_2PO_4 17.5g/L, $CaCl_2.2H_2O$ 2.5 g/L. Trace elements solution: $ZnSO_4.7H_2O$ 4.42g/L, $MnCl_2.4H_2O$ 1.44g/L, MoO_3 0.71g/L, $CuSO_4.5H_2O$ 1.57g/L, $Co(NO_3)_2.6H_2O$ 0.49g/L autoclaved to dissolve these chemicals, H_3BO_3 11.4g/L EDTA-KOH solution: $EDTANa_2$ 50.0g/L, KOH 30.1g/L and $FeSO_4.7H_2O$ with 1.0 ml concentrated $H_2SO_4$4.98g/L.

The cultures were allowed to shake at 50 rpm under a light intensity of 100 µmol photons m^2s^{-1} within 16/8 h light/dark cycle at 25±1°C. The consistency growth algal culture wasensuring cell density thoroughly mixing of the mother cultures between flasks under the hold for every 4 hours till the culture harvested to carried out experimental design prescribed in the work.

Treatment design

Textile effluent dilution ranges 10%, 25%, 50% and 75% were used for experimental setup for 50 ml volume in which inoculated with 5 ml of *Chlorella vulgaris* cell suspensions in each flask from the stock culture was transferred and the synthetic dye Disperse red-1 ($C_{16}H_{18}N_4O_3$/CID 17886 was used in the concentration 40mg/l Control experiments were also performed using flasks with the same dye concentrations but without any cell suspensions to serve as blanks. The percentage of dye removal was determined using equation,

Dye removal (%) = [*C0-Cn* / *C0*] × 100where the *C0* and *Cn* are the initial and final concentrations of Disperse red-1 respectively (Puchana*et al.,* 2018).

Decolourization assay

The aliquot (5ml) of the culture media was withdrawn at different time intervals, centrifuged at 10,000 rpm for 10 min. Decolourization was monitored by measuring the absorbance of supernatant at 518nm (Yang.,1988).The percentage decolourization was calculated as follows.

$$\text{Decolourization (\%)} = \frac{\text{Initial absorbance - Final absorbance}}{\text{Initial absorbance}} \times 100$$

Preparation of sample for enzyme assay

The azo reductase activity was measured to determine in dye degradation in the experimental samples. The culture medium containing diluted textile effluents were centrifuged 7500 rpm for 10 min, the supernatant was used for measure enzyme to which 10%ammonium sulphate was added mixture was incubated for a overnight at 4^0C then centrifuged. The collected supernatant was used as crude enzyme extract to perform enzyme assay. To prepare samples for assays, the cell suspensions centrifuged at 13,000 g for 15 minutes. The collected pellets were then washed thrice with distilled water and resuspended in a suitable solvent. This mixture was subjected to a freeze-thaw process to further break down the cell structures. Subsequently, samples were sonication at 50 kHz in three 10-minute sessions by 3-minute intervals, then applied vortex with 1 mm glass beads followed centrifugation process at 12000 rpm for 10 min to collect the supernatant for enzyme assay.

Assay of azoreductase activity

The reaction mixture consists of 400µl of 50 mM potassium phosphate buffer (pH 7.4) with 200µl of sample and 200µl of Disperse red-1. Reaction mixture without NADH was pre incubated for 4 minutes and the reaction was started by the addition of 200 µl of NADH and the total reaction mixture was 1ml. Dye decolourization was followed by monitoring the decrease in colour intensity at 518 nm at room temperature. The linear decrease of absorption was used to calculate the azoreductase activity (Maier *et al.,* 2004). One unit of enzyme activity was defined as the amount of enzyme that catalyzes the oxidation of one micromolesof dye reduced per minute

Partial purification of Azoreductase enzyme

*Chlorella vulgaris*cell suspensions were collected from the experimental flasks and centrifuged at 10000rpm for 10 min at 4^oC to pellet down the sample for its crude extracts which was subjected for azo reductase enzyme preparation. The pellets were collected and sonicated at 40% power for 10min then to the cell lysate 5 ml of 10% ammonium sulphate added to remove impurities followed by 70% ammonium sulphate added to precipitate enzyme azo reductase protein was settled as pellet under centrifuged at 1000 rpm for 10min under 4^oC The pellet was dissolved in equal volume of 50mM phosphate buffer [pH 7.2] precipitated sample was then desalted by dialysis

against same phosphate buffer overnight under room temperature then filtered through a 0.45µm filter. The resulted fractions (2ml) loaded on DEAE sephadex column chromatography [column packed in 1.5 cm diameter bed with length 10 cm.] subsequently eluted 1.0 mL fractions were collectedat flowrate of 1.0ml /minute fraction with the sample buffer and enzyme activities has been determined in eachfractionand those fractions were showed highest enzyme activities pooled in a single tube concentrated and stored as active purified enzyme preparation for final assay.

Estimation of pigments

Chlorophylls *a* and *b*, along with carotenoidswere extracted from the fresh biomass of *Chlorella vulgaris* using 80% acetone, as outlined by (Lichtenthaler, and Buschmann 2001). The absorbance readings were obtained using a UV-Visible spectrophotometer and from these measurements, the quantities of the pigments were calculated.

Total soluble carbohydrate (TSC)

The TSC content was quantified according to (Irigoye 1992) with slight modification. The procedure involved mixing 100mg dry biomass with 1 mL acetone to remove the pigment interference followed by centrifuge at 13,500g for 15 min. After removing the supernatant, the pellet was mixed with 1 mL ethanol 95% and was centrifuged again. Supernatant was collected and the pellet was mixed with 1mL of 75% ethanol and centrifuge at 10000rpm for 5 min. The supernatants were transferredand take 100µL mixed to this added 1ml of anthrone (30 mg anthrone+2 mL 72% (w/w) H_2SO_4)solution.This mixture was then heated in a boiling water bath for 10 minutes. After cooling, the absorbance of was measured at 625 nm (Marshall 1986). The TSC levels corresponded to the glucose standard curve.

Relative growth rate (RGR)

Relative Growth Rate (RGR) was determined by using the formula suggested by (Williams, 1946). RGR deals with total dry weight which expresses growth in terms of a rate of increase in size per unit of size expressed absolute growth rate and. Negative RGRs are relative decay rates.RGR = In W2 – In W1 / t2 – t1

W2 – final weight of *Chlorella vulgaris*at time

W1 – initial weight of *Chlorella vulgaris* at time

Biomass production

Chlorella vulgaris cultures were collected after prescribed incubation periods, samples were harvested at specified intervals at 15,30,45 and 60 days taken fresh weight then allowed to dry under shade for 2-3 days measured biomass contents are expressed g/dry weight.

Germination studies

The phytotoxicity study was carried out at room temperature (32 ± 2°C) in relation to Vigna radiate seeds (green gram 20 seeds per plate) by watering separately 10ml of *Chlorella vulgaris*of culture effluents in different dilutions were allowed for seeds germinated and in water as used control. After a week the germinated seeds were counted and percentage of germination calculated. The growth parameters were measured after 15 days of growth length of plumule (shoot), radicle (root) and (%) were recorded Germinated seeds were transferred to the pots filled with soil and watered at regular intervals. Finally, the results interpreted after 30 days.

RESULTS AND DISCUSSION

Chlorella is microalgae pertaining to species of the genus chlorella which belongs to the class Chlorophyceae. *Chlorella* is green algae due to the presence of the abundant to chlorophyll a and chlorophyll b. It can be cultivated on simple also in photo bioreactors producing enormous biomass in short time since it needs water, Co_2 and light also small quantities of minerals. Chlorella is a tiny unicellular microalga with round shape cells appear as tiny numerous green spheres. The microalgae which exist in the fresh water environments are efficient and taxonomically diverse. Figure 1 revealed growth of *Chlorella vulgaris* are involved at scavenging of heavy metal, organic waste, dye toxicity

from effluents. In this endeavour, algal biomass has emerged as an option for developing economic and eco-friendly waste water treatment process

Should be below Figure 1. *Chlorella vulgaris* are widely recognized for its potential in different field due to accumulate valuable bioactive compounds, including pigments and antioxidants. Photosynthetic pigments synthesis enhanced in the presences of nutritional sources and white light intensity. Figure 2 indicated the changes in photosynthetic pigments chl a, chl b and carotenoids contents in *Chlorella vulgaris*treated textile effluent concentration ranges from 10% to 75% and results showed increased pigments level at 50% dilution than other concentration of 45 days growth period (Figure 2). *Chlorella vulgaris* cultures harvested at regular sampling time showed gradual increase in pigmentsdue to utilization of organic contents of textile waste water.

Should be below Figure 2. Carbohydrates are main organic compounds and play a role in the biomass production of crops. The efficiency of photosynthesis contributing nutrient cycling and growth determines the overall biomass production.

Should be below Figure 3.

Azo reductase partially purified based on classical purification techniques. It was possible to conduct kinetics studies and reported in table 1. Enzyme had an Optimum Temperature at 40^{o}C and pH 5 displayed on fivefold increase in activity compared to other range of pH and temperature. Enzymes are located at both intra and extra cellular locations if so the protective role of azo reduction might be its ability to catalyze NADH and NADPH and generate large quantities of ROS, these elucidate the biological bases of azo dye removal or reduction and azo reductase enzyme found in *chlorella vulgar*is considered for phytoremediation process.
Table -1.

The enzyme activity was determined in cell fractions, extra and intracellularly for azo reductase crude extracts.The absorbance of the enzyme assay mixture was taken at 502 nm by using spectrophotometer at the 5minutes of regular interval. The absorbance was found to be decrease, which indicates that the NADH is working as coenzyme for azoreductase. Intracellular azoreductase enzyme was identified. Each step of purification, the activity was assayed and it was found that the specific activity of the enzyme increased after each step of purification. Protein concentration was found to be (530 mg/ml;1120 mg/ml) in crude extract and the enzyme activity was found to be (1.68 U/mg; 4.26 U/mg).In addition to providing nutrition values of microalgae can be explored for a variety of other uses such as fertilizer and pollution control. Certain species of algae can be land applied for use as an organic fertilizer either in its raw or semi decomposed form. In this context microalgae have several useful characteristics which enable them to be used in a variety of ways.

Chlorella vulgaris cultures were harvested at regular time interval noted as 15,30,45 and 60 days of culture growth at textile effluents (Figure 4). Biomass production of *Chlorella vulgaris* increased from 15 day to 60 days of culture growth at 50% effluent treated set up of experiment up to 45 days of than other concentration results revealed that 50% textile effluent favourable increased growth due efficient activity of Azoreductase influences biomass content thereby removed dye colour of the textile waste water in various concentration of treatment at regular intervals provided for culture growth.
(Figure 5).

The relative growth rate of *Chlorella vulgaris* in textile effluents varies significantly depending on the nutrient concentrations, pH, temperature and light intensity. The RGR could reach rates up to 1.7-5.0 g/L/ 45days at 25^{o}C with higher light intensity. Textile effluent (at 50% dilution) showed successful growth of *Chlorella vulgaris*under optimal conditions. Figure 5 showing peal productivity at specific inoculum found to have a remarkable growth rate *Chlorella vulgaris* microalgae a promising candidate for diverse application also developed an opportunity to recover valuable resources. However, microalgae biotechnology is still a developing field also should improve the adoption of

microalgae cultivation especially in the commercial viability in low value applications has critical implications on productivity and sustainable adoption of microalgae cultivation. Germinated seedling were showed the emerged stage of shoots and roots from *Vigna radiate* seeds and the length of shoot varied with respect to concentration of culture filtrate used in the experiments. The maximum shoot length obtained in 50% of textile effluents treated with *Chlorella vulgaris*(Figure 6) than other concentrations were used in the experiments. Reuse of treated water showed significance of azo dye degradation thereby reduced toxicity ultimately enhanced algal growth has multiple applications in biotechnology field.

(Figure 6) . Textile waste water treated with *Chlorella vulgaris* offers many advantages such as used for seeds germination studies, significantly increase the relative growth rate of algae and its biomass at specified sampling period during the experimental periods. The growth of algae was increased as the dilution increased up to 50 then it was observed reduced that the cells grown in control and other dilute effluents. The results indicated that the 50% of diluted effluents reported higher synthesis of pigments and accumulation of carbohydrates in the cells rather than control and higher concentration of effluents reflected algal cell growth reduction there by confirmed enhanced growth and other estimated parameters were due to utilizing capacity of oxidizable organic compounds for its growth. The azoreductase enzyme plays a significant role in breaking down azodyes by cleaving the azo bond (N=N) which are common in synthetic dyes. Algae mediated azo dye degradation is of interest in waste water treatment and remediation process enabling both enzymatic degradation and adsorption of the dyes onto algal cells. Experimental results suggested that *Chlorella vulgaris*algae can be used as decolourized agent for textile effluents.

CONCLUSION

The textile waste water treated is used for irrigation could be confirmed by analysed of decolourization and dye reduction which emphasize reuse of water for agricultural fields and helps to protect aquatic environments (Cristina Becerra-Castro*et at.,* 2015) wastewater reuse in the crucial requirement to the crops and improve sustainability of economic benefits.Phycoremediation is one of the valuable approaches to remove toxicity as eco- friendly and cost-effective practice. In the present work, an attempt was focused to consider microalgae as potential agent for colour removal, and seen solution for emerging pollutant problems by using*Chlorella vulgaris*green microalgae to remediate textile effluent contaminated environment.

ABSTRACT

The present study analyses the application of Discourse Analysis (DA) into English reading instruction in English as a Foreign Language (EFL) classroomsin order to improve reading skills among students at the first year of engineering degree.DAdeals with the methods on how people understand and interpret meaning in texts, conversations, and other forms of communication.Reading skill has been a fundamental skill in terms of cognitive development of an individual, career growth and also in fostering critical thinking skills of an individual. Above all reading plays avital role in improving one's perception about life and helps in finding one's solace in life. Learners of English language often face several difficulties in developing reading skills in English. Hence application of DA will aid learners in EFL classrooms, to understand not only particular words or sentences but also the overall meaning, structure and purpose of a text. The role of DA in improving the reading skills of EFL learners is vital. Hence this study sheds light on the fact that the usage of DA in English reading comprehension will enhance the ability of reading and understanding among students.

Keywords: Discourse analysis, EFL classrooms, reading comprehension, vocabulary and English skills.

INTRODUCTION

The present study focuses on how Discourse Analysis enhancesthe language that is used in communication especially among the first year students of engineering degree. It aims at strategies of discourse analysis into English reading instruction in EFL classrooms to improve reading skills among students at the first year of engineering degree. It studies the ways in which words, sentences, and ideas are connected in order to form meaningful communication in a particular context. Reading is complex yet central to any English language program and it is one of the most important receptive skills. Reading skill helps an individual to function, contribute and develop better. Several studies conducted in the field of language teaching advocates that there exists a correlation between reading and personality development. Reading habit helps readers to nourish their minds and keep the mental faculties sharp and intact.

Need for Discourse Analysis

Difficulties in developing reading skills are common amongEFL learners. Difficulty with the understanding of grammar and sentence structure, inadequate vocabulary, limited background knowledge and lack of confidence are some of them. Discourse analysis helps learners understand individual words or sentences, overall meaning, structure and purpose of a text. The role played by DA in improving the reading skills of EFL learners is indomitable. Hence this study sheds light on the fact that the usage of DA in English reading comprehension will enhance the ability of reading and understanding among students. It also discusses the applications of discourse analysis in language classrooms as an attempt to improve the quality of language learning.

English as a Foreign Language denotes learning English in a country where English is not the native language. Unlike ESL – English as a Second Language which is taught to learners living in English speaking countries, EFL students learn English in an environment where they rarely encounter the opportunity to use the language outside the classroom. In other words, EFL learners are students studying English in countries where English is not the main language and the range of the learners is diverse.

While developing reading skills EFL learners face many difficulties because English is not widely used in their daily environment. They do not get enough opportunities to practice reading regularly as they have limited exposure to the language outside the classroom. Therefore, they struggle with restricted vocabulary and unacquainted sentence structures. This results in partial or incorrect interpretation of texts. In addition, they find it tough to identify the main ideas as well as the purpose of the writer. The learners also tend to translate each word into their native language which affects their reading fluency and comprehension. Cultural differences will also create misperception, as learners may not be familiar with the context or background knowledge required to understand a particular text. These factors hinder the reading ability among EFL learners and reduce their confidence and motivation to read.

Discourse analysis otherwise called discourse study was developed during the 1970s as a distinct academic discipline. The word ‘discourse’ is taken from the Latin word “discursus” which indicates conversation or speech. DA denotes the analysis of language beyond the level of a single sentence, examining the structure and organization of connected speech or text (Zellig Harris 1952). However, in the present-day academic and linguistic contexts, the concept of discourse has evolved so much to integrate a broader prospective of understanding the use of language and communication. It is not controlled by any individual’s ordinary conversations or speeches rather it includes all communication forms that contributes to the creation of meaning and understanding in a given context.

Implementing Discourse Analysis in the Teaching of English Grammar

Applying discourse analysis in the teaching of grammar in EFL classrooms is widely acclaimed by language teachers. Discourse analysis focuses on how grammatical forms function in real life situation and communication rather than teaching grammar as isolated rules. According to Michael McCarthy (1991), grammar teaching mustsupport learners to produce meaningful communication by understanding how grammatical structures frequently occur in both

spoken and written discourse. This approach allows learners to practice the target language more naturally and appropriately.

EFL learners often attempt to use English language without fully understanding its grammatical system. A strong knowledge of grammar is essential for producing discourse, for interpreting and understanding it. This is proven from the fact that grammar helps the users of any language to detect relationships between ideas, track the flow of information, and grasp messages more effectively. For example, English language comprises more than forty conjunctions. This which can be difficult to for an EFL learner to learn. In spoken communication conjunctions like "and," "but," "so," and "then" are used frequently. These words may carry different meanings depending on the context, particularly the conjunction **"**so." It has two meanings such as indicating a purpose and also explaining **the** cause or result. As noted by Heriyawati (2016), these conjunctions not only create cohesion within a text but also help speakers connect their statements with what has already been said during a conversation. Therefore, discourse analysis helps learners understand how grammar functions in authentic communication, making language learning more practical and effective.

Discourse Analysis in Teaching English

The employment of discourse analysis in teaching English **is** beneficial in EFL classrooms. EFL learners need not only the knowledge of phonology, vocabulary, and grammatical structures but also understand discourse patterns and socio-cultural aspects of language use. While analysing the significance of DA, Guy Cook (1989) states that "discourse analysis helps language learners understand how sentences are connected to form meaningful communication in real contexts, which improves their overall language learning." Brian Paltridge (2006) notes that "discourse analysis supports language learning by helping students understand patterns of language use in different contexts and genres." Hence EFL students must be exposed to various discourse patterns in different communicative situationsfor effective language learning.To achieve **this** authentic reading materials must be supplied and active classroom participation should be encouraged. Reliablelearning materials include written texts but also recordings, transcripts, speeches, and both fiction and non-fiction books. These materials act as real examples of how language is used in different contexts and structures.

When engaged with such materials, learners become familiar with natural language patterns and strategies of communication. In addition, classroom activities such as discussions, role-plays, and group tasks should also be held in order to enable students to practice these patterns in meaningful ways. This exposure advances their understanding of discourse thereby preparing them to handle unexpected real-life communication situations with confidence and competence.

Implementing Discourse Analysis in the Teaching of Vocabulary in English

It is important for teachers to provide EFL learners with meaningful **semantic contexts**that is**meaning-based environment** in which a word appears. The words and sentences around it provide clues that help learners**guess the meaning** without using a dictionary.

Example:She wanted to buy a jacket because the weather was cold.

Even if learners do not know the word "jacket," the context "weather was cold" helps them guess that it is something worn to keep warm.

Thisallows students to learn the functions of words naturally in communication rather than memorising them in isolation. Teachers can introduce rhetorical devices such as synonyms, antonyms, and collocations to strengthen learners' lexical knowledge. Introducing novelty in classroom activities like filling in blanks with appropriate words, identifying synonyms, and making collocations reassures active participation as a result it also reinforces understanding. The above stated activities not only improve recalling of vocabulary but also help learners identify words and their relationships, thereby enhancing total reading comprehension and language proficiency.

CONCLUSION

Language learning and teaching can occur better by building a community in the classroom as this will definitely pave way for effective language learning and would help the learners to be engaged in real life contexts. This would facilitate the learners to immerse themselves in reading and this becomes easy to gain knowledge and skills for achieving a successful communication which is the ultimate goal of learning a language for a learner. From the present study it can be concluded that the assimilation of **Discourse Analysis**in EFL classrooms plays a substantial role in improving students' reading comprehension and overall language proficiency. Discourse analysis helps learners understand how ideas are connected within a text and how meaning is constructed in different contextsby focusing on language in use instead of isolated grammatical rules or vocabulary items. This approach enables students to identify the structure, purpose and message of a text more effectively. In conclusion, the effective use of reliable materials, contextual vocabulary teaching, and impactful classroom activities, discourse analysis motivates learners to actively engage with language learning. It also benefits them develop important reading strategies such as predicting, inferring, and interpreting information as they are given adequate exposure during classroom activities. Consequently, students gain confidence and competence in understanding English texts. Thus the integration of discourse analysis into English language instruction will definitely increase the reading abilities of EFL learners and contribute to more effective language learning for this process goes far beyond the analysis words and sentences and establishes a deeper understanding of how language is used.

ABSTRACT

Agnikarma, one of the ancient para-surgical procedures described in Ayurveda, has been gaining renewed attention as an effective modality in pain management. This technique involves the therapeutic application of controlled heat to specific sites using various instruments such as Panchadhatu Shalaka, Tamra Shalaka, or modern cautery devices. The principle is based on Dahana karma (therapeutic cauterization), which alleviates pain by pacifying vitiated *Vata* and *Kapha Doshas* and improving local circulation. An analysis of published research articles from 2021 to 2025 highlights the efficacy of Agnikarma in conditions such as plantar fasciitis, tennis elbow, osteoarthritis, cervical spondylosis, sciatica, and other musculoskeletal disorders. Most studies consistently report significant pain relief, improved mobility, and minimal recurrence when compared with conventional therapies. *Agnikarma is* also noted for its safety profile, cost-effectiveness, and rapid symptomatic relief without major complications. Overall, the evidence suggests that *Agnikarma* is a promising, non-pharmacological intervention in pain management. Integrating classical principles with contemporary research validates its role as a sustainable therapeutic option in both primary and complementary healthcare. However, larger randomized controlled trials and long-term follow-ups are still required to establish standardized protocols and enhance global acceptance.

Keywords : "*Agnikarma*", "pain management", "*Vata Vyadhi*", "Thermal therapy", "*Ayurvedic* para-surgical procedures", and "*Agnikarma* clinical trials".
Timeframe: Articles published from January 2021-2025 are reviewed.

INTRODUCTION

Pain, or *Shoola*, is a common clinical complaint encountered across all systems of medicine. While modern pharmacological interventions like NSAIDs and opioids are widely used for pain relief, their long-term use is often associated with side effects and dependency. In contrast, traditional systems like *Ayurveda* offer holistic and sustainable alternatives grounded in centuries-old practices. One such time-tested therapeutic procedure is *Agnikarma*, a para-surgical intervention described in the ancient *Ayurvedic* compendia. *Agnikarma* involves the application of a heated metallic instrument *(Dahanopakarana)* to specific sites on the body, leading to controlled thermal injury and subsequent healing. This procedure has been traditionally indicated in *Vata-Kapha* dominated disorders, especially those associated with chronic or localized pain. He further classifies the types of instruments based on the material such as *Loha* (Iron), *Tamra* (Copper), *Suvarna* (Gold), *Rajat* (Silver) each with different thermal properties suited for specific tissue types and conditions[1]. *Agnikarma* was considered superior to *Ksharakarma* (chemical cauterization) and *Shastrakarma* (surgical methods) in certain cases due to its minimal invasiveness and immediate symptomatic relief. Over time, the technique evolved, with regional variations and innovations like using *Tapta Guda* (heated jaggery), herbal sticks and modern heat probes now being used in clinical practice. Despite its ancient origins, *Agnikarma* remains relevant today due to its effectiveness, low risk profile, and compatibility with both traditional and integrative medicine models. Recent clinical studies have shown promising outcomes in conditions such as sciatica (*Gridhrasi*), osteoarthritis (*Sandhigata Vata*), cervical spondylosis (*Manyagata Vata*), calcaneal spur, and migraine (*Ardhavabhedaka*), placing *Agnikarma* in a prominent position in integrative pain management strategies.

The purpose of this article is to conduct an analytic review of *Agnikarma* as a modality for pain management, incorporating both classical references and contemporary clinical evidence to understand its therapeutic value and limitations.

METHODOLOGY

Aim of the study

The present review aims to analytically evaluate the therapeutic effectiveness of *Agnikarma* in the management of pain related disorders by exploring classical *Ayurvedic* references and systematically reviewing clinical studies published in peer-reviewed and UGC-listed journals.

Study Design

This study follows a narrative analytic review design, integrating data from classical texts, recent clinical trials, case studies, and observational studies to assess the scope, efficacy, safety, and limitations of *Agnikarma* in pain management.

Sources of Data

The literature review included:

1.Classical *AyurvedicSamhitas:*

* *Sushruta Samhita*
* *Charaka Samhita*
* *Ashtanga Hridaya*

2. Databases and Journals Searched:

* PubMed
* Google Scholar

Inclusion Criteria

* Studies involving *Agnikarma* as a primary or adjunct treatment for pain-related conditions.
* Clinical trials (randomized/non-randomized), case reports.

* Articles published in English or with English abstracts.
* Studies published in UGC-listed or peer-reviewed *Ayurvedic* journals.

Exclusion Criteria
* Studies without clear pain-related endpoints.
* Articles not mentioning therapeutic outcomes of *Agnikarma.*
* Animal studies or in-vitro trials.
* Duplicate data and no peer-reviewed online sources.

RESULT

A total of 34 published articles were critically reviewed and categorized into different classifications, with the aim of understanding and consolidating the mechanisms of applied therapy and the quality of documentation in a single comprehensive source. Among which total 34 articles have been published in Google scholar and one article published in Pubmed.Among which 16 articles were case reports and 19 articles were clinical studies.Total 7 were on *Vatakantaka* ,6 were on *janu sandhigata Vata*, 5 were on *Gridhrasi*, 4 were on Avabahuka, 1 were on migrane, 2 were on trigger finger,1was on lateral epicondylitis,1 was on inguinal hernia,1 was on Achilles tendinitis,1was on De Quervain's tenosynovitis,1 was on *Bahya Arsh,* 1 was on calceneal spur, 1 was on Mashaka.

Case Study

A role of *Agnikarma* in the Management of *Vatakantka*Wsr Plantar Fascitis -A Single Case Study Hetal Ramani et.al.,reported Pain relief after the first sitting and complete relief after third sitting.[2]*Agnikarma* (Therapeutic heat burn) an unique approach in the Management of *Vatakantka*Wsr to Plantar Fascitis- A Single Case Study,RiddhiGanatra et.al., reported after one month patient got complete relief in pain.[3]*Agnikarma* with *Kshaudr a*(honey) along with adjuvant *Ayurveda* Therapy in the Management of trigger finger- A Case Study Riddhi jitendra Kumar Ganatra et.al., reported that on follow up observation of 9 month, the patient had no pain.[4] A Clinical case Study of *Agnikarma* with *Panchdhatu Shalaka* in Trigger finger Dr. Gadve B.N. et.al.,reportedPatient got complete relief of symptoms in a period of 4 weeks.[5]*Agnikarma* with *TamraShalaka* in the Management of *Gridhrasi*Wsr to Sciatica-ACase Study Season Koju et.al., reported that the patient got Pain relief.[6]*Agnikarma* with *Kshoudra* for Pain Management in De Quervain's Tenosynovitis- A Single Case Study Anju DR et.al.,reported the successful use of Agnikarma with Kshoudra.[7] Role of *Agnikarma* in the Management of *Avabahuka*- A Case ReportMahesh Kumar et.al.reported after five sittings of *Agnikarma* Pain in the shoulder reduced.[8] Management of *Janu Sandhigata Vata*Wsr to Osteoarthritis of Knee Joint with modified method of *Agnikarma* by use of Electrocautery- A Case Report Krishna Rathodet.al.,report advocate that Agnikarma with electrocautery having satisfactory result.[9] Efficacy of *Agnikarma*in the *Vatakantka*Wsr Plantar Fascitis- A Single Case StudyKrishan Dev C.P.et. al.,reported that patient got relief in pain completely on 3rdsittings.[10] Effect of *Agnikarma*by *Panchdhatu Shalaka* in the Management of Calcaneal Spur- A Single Case StudyDr. Sandhya Kushwaha et.al., reported after first sitting of *Agnikarma* heel pain relieved partially and complete reduction in heel pain after four sittings.[11] Management of *Parshnishool* (Heel Pain) due to *Vatakantaka* (Calcaneal spur) with *Agnikarma*,Divya Jadhav et.al., reported there was no pain over heel to the patient.[12] Animmediate Pain relief with *Agnikarma* Therapy for Acute episode of Migrain Headache- A Case Report, Praveen Balakrishnan et.al.,reported that the patient got immediate pain relief.[13]*Ayurvedic*Management of *Janu Sandhigat Vata*Wsr to Knee Osetoarthritis- A Case Study, Dr. P. SrikanthBabu et.al., reported susscessful use of Agnikarma.[14] Mangement of *Vatakantka* (Plantar Fascitis) by *Agnikarma*- ACase Study, Dr. Sunil kumar Pandey et.al.,reported that Patient got complete relief from sign and symptoms after fourth sitting and there was no any recurrence of symptoms in 2 month of follow up period.[15]Role of *Agnikarma* in *Avabahuka* with special reference to Frozen Shoulder- A Case Study, Dr.S.Singh et.al reported that Agnikarma intervention is an effective remedy modality in Avabahuka disorder.[16] Efficacy of *Agnikarma*(Cauterization) in the Management of *Mashaka*(Elevated Mole) –A Case Study, Jagriti Gautam et.al.,reported that after four weeks,lesion had healed without complaints of bleeding, wound infection,pain or scarring and *Agnikarma* was highly successful and curative.[17]

Clinical Study

A Comparative Clinical Study of *Agnikarma* with *Suvarna Shalaka* (Rod of Gold) and *Panchdhatu Shalaka* (Rod made of Five metals) in *Janu sandhigata Vata*,Sj Lobo et.al., reported that the Agnikarma using Suvarna Shalaka is found to be more beneficial than Agnikarma using Panchdhatu Shalaka in the prime symptoms of *Janu sandhigata Vata* (Osteoarthritis).[18] A Protocol for Treatment of *Avabahuka* (Frozen Shoulder) with *Agnikarma* and Topical Diclofenac Sodium Gel,Mahesh Kumar et.al., reported that the *Agnikarma* have good result in *Avabahuk*a patient particularly that fails to respond with drugs therapy.[19]Effect of Therapeutic Burn with Copper Rod (*Agnikarma* with *Tamra Shalaka*) in the Management of Osteoarthritis of Knee (*Janu sandhigata vata*), Dr. Manjula chavan Matekar reported that Agnikarma with Tamrashalaka were found significant effect in *Janu sandhigata vata*.[20]A Comparative Clinical Study to evaluate the efficacy of *Agnikarma* with *Godanta* in the Management of *Gridhrasi* WSR to more advantage over *Agnikarma* with *Godanta Shalaka [21]*[1] A Clinical Case Study of *Agnikarma* with *Panchdhatu Shalaka* in *Avabahuka* WSR to Frozen Shoulder,Dr. BabasahebN.Gadve reported that significant improvement in pain and shoulder joint movement in patient [22] A Comparative Clinical Study to evaluate the effect of *Agnikarma* and *Raktmokshana* in the Management of *Kati Sandhigatvata*Wsr to *Lumbar Spondylysis*, Foram Joshi reported that *Agnikarma* was found more effective [23] A Randomized open label control Clinical Study to evaluate the efficacy of *Kshoudra* as *Dahaopkarna* for the Pain Management in *SanayuVikara* with special Reference to Achilles Tendinitis, Anju DR.et.al., reported that *Agnikarma* reduces local inflammation ,thus result in reduction of pain and improves the range of motion.[24] Effect of *Agnikarma* with *Kshoudra* over Ankle and Foot in Sciatica due to L4-L5 Intervertebral Disc Prolapse, Shalumol et.al., reported that *Agnikarma* with *Kshoudra* done over ankle and foot gives immediate relief of pain and numbness of sciatica due to L4-L5 intervertebraldisc prolapse.[25] An Open Label Double arm Clinical Study to compare the effect of *Agnikarma* with *Tapta Kshoudra* and *Panchdhatu Shalaka* in Lateral Epicondylitis (Tennis Elbow)- Case Series, Anju Maria Joseph et.al., reported that *Agnikarma* is very effective procedure and Agnikarma with TaptaKshoudra is as effective as *Agnikarma* with *PanchadhatuShalaka* in Lateral Epicondylitis (Tennis Elbow)[26].A Clinical Study to Evaluate the Effectiveness of *Agnikarma* in the Management of Direct Inguinal Hernia, H.K.R.weerakoon reported that Agnikarma demonstrating greater effictivness.[27]. A Comparative Study of*JanuBasti* With *Sahachar Tail* and *Agnikarma* with *Tamra Shalaka* in *Janusandhigata Vata* (Osteoarthritis), Dr.Manjula Vishal Matekar reported thatJanubasti with sahacharTaila and *Agnikarma* with *Tamra shalaka* were found significant effect in janusandhigatavata. [28]. A Comparative Clinical Study of *Siravedha* and *Agnikarma* in the Management of *Gridhrasi*,J Vaneetkumar et al. reported that *Agnikarma* gives better effect than *Siravedha* in the Management of *Gridhrasi.*[29]A Comparative Clinical Study on *Agnikarma* along with *Panchatikta Gugglu* in the Management of *Janu Sandhigatavata* (Osteoarthritis of Knee Joint), Manisha M.Kapadiya et al., reported that *Agnikarma*has an analgesic effect on Pain Management in patients of *Sandhigatavata*. [30]. Efficacy of *Agnikarma*and *Siravedha* along with *Rasna Saptaka Kwatha* orally in the Management of *Vatakantka* (Plantar fasciitis)- An open - labeled Randomized Comparative Clinical Trail, Ganatra et al, reported that *Agnikarma* along with the oral administration of *Rasnasaptaka Kwatha* provided a better effect in the relief of heel pain than *siravedha* along with the oral administration of *Rasna Saptaka Kwatha*. [31]. To Evaluate the efficacy of *Agnikarma* after *Siravyadhana* in Pain Management of *Gridhrasi* WSR to Sciatica: A Randomized Controlled Clinical Trail,MadhuriSuryakantBiradar et al, reported that the combined action of *Siravyadhana* and *Agnikarma* proved more effective [32]. Evaluation of add on efficacy of *Agnikarma* with *Siravyadha* in Pain Management of *Gridhrasi* WSR to Sciatica- A Randomized Comparative Clinical Study, Priyanka K et al, reported that *Agnikarma* followed with *Siravyadha* is found more effective than the *Siravyadha* alone in the management of *Gridhrasi. [33].* Clinical Aspect of Effect of *Agnikarma*with *Mrittikashalaka* in *Vatakantka*Wsr to Calceneal Spur, Umesh A Vaidya et al, reported that Pain was lessened significantly after the Agnikarma sitting [34]. Effect of *Agnikarma* in the Pain Management of *Janu Sanhigata Vata* (Knee- Osteoarthritis) WSR to Inflammatory Biomarkers (Ns-CRP, TNF and IL 6)- An Open labeled Clinical Trail,Himanshi vats et al, reported that *Agnikarma* was found effective on inflammatory biomarkers and in the pain management of Knee osteoarthritis [35].

CONCLUSION

From 2021–2025, the evidence base for *Agnikarma* as a pain-modulating intervention has expanded across musculoskeletal and peri-articular conditions—most frequently knee osteoarthritis, plantar fasciitis, lateral epicondylitis, trigger finger, sacro-iliac/low-back pain, and myofascial trigger points. Across studies, *Agnikarma* consistently demonstrates meaningful short-term pain reduction and functional improvement, with low rates of transient, self-limiting adverse events when performed by trained clinicians under aseptic precautions. Proposed mechanisms integrate classical *Ayurvedic* concepts (*vāta-śamana, śūla-praśamana, srotoshodhana, raktastambhana*) with modern hypotheses—counter-irritation, thermal neuromodulation, micro-coagulation of nociceptive endings, local hyperemia, and heat-induced collagen remodeling. However, the methodological quality remains mixed: small samples, heterogeneity in technique (*śalākā* type, temperature, dot number/pattern, intervals), non-uniform outcome measures, short follow-up, and limited blinding/comparators restrict certainty and generalizability. Early signals suggest *Agnikarma* can be comparable or additive to conventional care (physiotherapy, NSAIDs, orthoses) and may defer injections in select cases, but robust head-to-head data are scarce. Overall, current literature supports *Agnikarma* as a safe, cost-conscious adjunct or alternative for select painful conditions-particularly where conservative care has plateaued and corticosteroid injections are undesirable-provided standardized technique and careful case selection. Strengthening the field now requires rigor, standardization, and longer horizons of observation.

ABSTRACT

Astraeus hygrometricus, an ectomycorrhizal wild edible mushroom of high nutritional, medicinal, and economic value, has long been constrained by its slow growth, host dependency, and poor adaptability to conventional cultivation methods. In recent years, the development of controlled tissue culture units has emerged as a promising strategy to overcome these limitations and enable sustainable propagation independent of natural forest ecosystems. This review critically examines current knowledge on the in vitro cultivation of *A. hygrometricus*, with a particular focus on advances in tissue culture–based systems, including explant selection, culture media composition, carbon and nitrogen sources, mineral ion regulation, growth regulators, and environmental parameters such as pH, temperature, aeration, and light. The role of calcium signaling, polysaccharide-mediated matrix stabilization and microbial co-culture (e.g., yeast supplementation) in supporting hyphal integrity and metabolic activity is discussed. Challenges associated with mycorrhizal dependency, phenolic sensitivity, slow biomass accumulation, and morphological instability are highlighted, along with strategies to mitigate these issues through medium modification and bioreactor-assisted culture units. Furthermore, the review explores the potential of tissue culture systems for secondary metabolite production, mycelial biomass generation, and conservation of genetic diversity. By integrating mycological, physiological, and bioprocess perspectives, this article provides a comprehensive framework for the rational design of advanced tissue culture units aimed at scalable cultivation of *A. hygrometricus*, paving the way for its commercial utilization, conservation, and biomedical exploitation.

Keywords: *Astraeus hygrometricus*, Ectomycorrhizal fungi, in-vitro tissue culture, Mycorrhizal dependency, secondary metabolite production, bioreactor-assisted cultivation

INTRODUCTION

The wild edible mushroom Astraeus hygrometricus, commonly known as "Kurkure Chhatu" or hygroscopic earthstar, occupies a unique ecological and socio-economic niche across tropical and subtropical forests of Asia. It is highly valued not only as a seasonal food delicacy but also for its reported medicinal properties, including antioxidant, anti-inflammatory, and immunomodulatory activities. Ecologically, *A. hygrometricus* functions as an ectomycorrhizal (ECM) fungus, forming obligate symbiotic associations with forest tree species, thereby contributing to nutrient cycling, soil structure stabilization, and host plant fitness. Despite its importance, the species remains uncultivated at a commercial scale, and its availability depends almost entirely on sporadic natural fruiting events and forest-based harvesting (Boa, 2004; Smith & Read, 2008). Increasing anthropogenic pressure on forest ecosystems, coupled with rising market demand, has intensified overharvesting of *A. hygrometricus*, raising concerns regarding population decline, habitat disturbance, and loss of genetic diversity (Christensen & Larsen, 2005). Unlike saprotrophic mushrooms, ECM fungi such as *A. hygrometricus* exhibit slow mycelial growth, strong host-derived carbon dependency, and complex mycorrhizal signaling requirements, all of which severely limit their amenability to conventional cultivation techniques. Fruiting body induction under artificial conditions remains particularly elusive, as it is tightly regulated by host interaction, seasonal cues, and poorly understood molecular pathways (Martin et al., 2016; Moore et al., 2011).

In this context, advanced in vitro tissue culture systems have emerged as a promising alternative for overcoming forest dependency while enabling sustainable biomass production, germplasm conservation, and controlled metabolite synthesis. Progress in explant selection, axenic culture establishment, and culture media engineering—particularly optimization of carbon and nitrogen sources, mineral nutrition, calcium signaling, and extracellular polysaccharide stabilization—has significantly improved mycelial survival and growth under laboratory conditions. Complementary strategies such as microbial co-culture, low-shear bioreactor systems, and environmental fine-tuning have further expanded the feasibility of scaling ECM fungal cultures beyond petri dishes (Papagianni, 2004; Stanbury et al., 2017). Simultaneously, molecular and genomic advances have reshaped our understanding of *A. hygrometricus* biology. DNA barcoding and phylogenetic studies have revealed cryptic species diversity and host-associated genetic structuring, emphasizing the need for genetically informed conservation and cultivation strategies (Phosri et al., 2007; Schoch et al., 2012). Emerging tools such as transcriptomics, metabolomics, CRISPR-based functional genetics, and AI-assisted optimization now offer unprecedented opportunities to rationally design culture systems that mimic symbiotic conditions while enhancing growth and secondary metabolite production (Kohler et al., 2015; Camacho et al., 2018).

Against this backdrop, the present review synthesizes current knowledge on the in vitro cultivation of *Astraeus hygrometricus*, focusing on physiological constraints, culture system innovations, and biotechnological opportunities. By integrating mycological, molecular, and bioprocess perspectives, this work aims to provide a comprehensive foundation for developing scalable, sustainable, and conservation-oriented cultivation strategies that can transition *A. hygrometricus* from forest-dependent harvesting to controlled production, benefiting biodiversity conservation, rural livelihoods, and biomedical exploitation

Taxonomy and Phylogenetic Context

Originally placed within the genus Geastrum based on morphological similarities, the earthstar fungus Astraeus was later reclassified into the family Astraeaceae following molecular phylogenetic analyses of nuclear ribosomal ITS and LSU rDNA sequences. Early molecular studies demonstrated that *Astraeus* is phylogenetically distinct from *Geastrum*, despite convergent morphological traits (Phosri et al., 2004; Hosaka et al., 2006). Subsequent multilocus and ITS-based barcoding investigations revealed that the widely reported species Astraeus hygrometricus represents a species complex comprising several cryptic taxa distributed across Asia and other continents (Phosri et al., 2007; Phosri et al., 2013). These studies identified clear phylogeographic clustering patterns correlated with geographic distribution and ecological niches, suggesting regional endemism and evolutionary divergence. Host-associated

genetic differentiation has also been observed, particularly in populations associated with specific ectomycorrhizal tree partners, indicating co-evolutionary structuring. More recently, environmental DNA (eDNA) metabarcoding approaches using ITS markers have enabled non-invasive detection of *Astraeus* species in soil ecosystems, facilitating biodiversity monitoring and ecological mapping without reliance on sporocarp collection. Collectively, ITS sequencing, phylogeographic analyses, host-linked divergence studies, and eDNA-based detection have substantially refined species delimitation and evolutionary understanding within the *Astraeus hygrometricus* complex.

Biology of Mycorrhizal Dependency

The ectomycorrhizal fungus Astraeus hygrometricus establishes symbiotic root associations typical of ectomycorrhizal (ECM) systems, including the formation of a dense fungal mantle enveloping root tips and the development of a Hartig net that penetrates intercellular spaces of the root cortex without breaching host cell walls (Smith & Read, 2008; Brundrett, 2009). Through this specialized interface, a tightly regulated bidirectional nutrient exchange occurs: host trees allocate photosynthetically derived carbon—primarily in the form of glucose, sucrose, and other soluble carbohydrates and organic acids—to the fungal partner, while the fungus enhances host mineral nutrition by mobilizing and transferring phosphate, nitrogen (as ammonium and amino acids), and essential micronutrients from the soil (Smith & Read, 2008; Courty et al., 2010). Like other ECM fungi, *A. hygrometricus* is largely dependent on host-derived carbon for growth and sporocarp production, reflecting obligate or near-obligate biotrophy under natural conditions (Martin et al., 2016). This strong carbon dependency presents a major constraint for axenic cultivation; therefore, decoupling or substituting host-derived carbon flux—through optimized carbohydrate supplementation and metabolic conditioning in vitro—remains central to successful artificial propagation and experimental cultivation of this species.

Establishment of Axenic Cultures

In vitro culture of Astraeus hygrometricus has primarily relied on carefully selected explant sources, including inner glebal tissues excised aseptically from immature basidiomes, actively growing hyphal tips obtained from surface-sterilized sporocarps, and cultures initiated through controlled spore germination assays. Inner gleba is often preferred due to its reduced exposure to environmental contaminants compared with the outer peridium, while hyphal tip isolation enables the recovery of relatively clean, actively dividing mycelium (Smith & Read, 2008; Lakhanpal, 1996). Spore germination, although valuable for genetic and developmental studies, is frequently limited by dormancy and host-dependent physiological requirements characteristic of ectomycorrhizal fungi. To minimize microbial contamination, optimized sterilization protocols typically involve a sequential 70% ethanol pre-wash to disrupt surface lipids and transient microbes, followed by treatment with 0.1% mercuric chloride for deep disinfection; however, due to toxicity concerns, sodium hypochlorite solutions are increasingly used as safer alternatives (Kumar et al., 2010; Singh et al., 2012). Despite these refinements, contamination by fast-growing bacteria and saprophytic fungi remains a major barrier to successful axenic establishment, reflecting the ecological origin of *A. hygrometricus* sporocarps and their intimate association with soil microbiota.

Culture Media Engineering

Successful axenic cultivation of Astraeus hygrometricus depends heavily on culture media engineering tailored to the physiological requirements of ectomycorrhizal (ECM) fungi. Basal media commonly adapted for ECM growth include Modified Melin–Norkrans (MMN) medium, originally formulated to support symbiotic fungi, Pachlewski medium and modified formulations of Murashige and Skoog medium supplemented with reduced mineral strength and organic additives (Melin & Norkrans, 1948; Marx, 1969; Smith & Read, 2008). Carbon supplementation is critical because ECM fungi are dependent on host-derived carbohydrates; glucose, maltose, trehalose, and sucrose are routinely evaluated as primary carbon sources. Among these, trehalose has been reported to enhance osmotic and oxidative stress tolerance and stabilize fungal membranes and proteins, thereby improving mycelial vigor under in vitro conditions (Elbein et al., 2003; Müller et al., 2001). Nitrogen nutrition significantly influences biomass yield and enzymatic activity, with ammonium salts, nitrate, casein hydrolysate, and yeast extract commonly incorporated either singly or in combination to balance inorganic and organic nitrogen availability (Read & Perez-Moreno, 2003). Empirical optimization studies indicate that maintaining carbon-to-nitrogen (C:N) ratios in the range of 20:1 to 30:1

generally promotes favorable mycelial expansion and metabolic stability in ECM cultures. Collectively, precise adjustment of basal formulation, carbon quality, nitrogen form, and C:N ratio remains fundamental to overcoming the obligate symbiotic tendencies of *A. hygrometricus* and enhancing reproducible in vitro growth.

Mineral and Calcium Signaling

Calcium plays a central regulatory role in the growth and morphogenesis of ectomycorrhizal fungi, including Astraeus hygrometricus, where intracellular Ca^{2+} gradients function as key second messengers controlling polarized hyphal development. Localized Ca^{2+} influx at the hyphal apex governs tip extension and directional growth, while oscillatory calcium signaling modulates cytoskeletal organization and vesicle trafficking required for sustained apical elongation (Levina et al., 1995; Steinberg, 2007). Calcium availability also influences hyphal branching frequency by regulating actin dynamics and Spitzenkörper stability, thereby affecting colony architecture and exploratory capacity. Beyond morphogenesis, Ca^{2+} contributes to cell wall integrity through crosslinking of negatively charged polysaccharides and stabilization of chitin–glucan networks, enhancing mechanical strength and resistance to environmental stress (Bowman & Free, 2006). In vitro studies on ectomycorrhizal fungi demonstrate that controlled $CaCl_2$ supplementation in culture media can optimize extracellular calcium availability, promoting improved structural robustness and more uniform mycelial growth without inducing ionic toxicity when maintained within physiological concentrations (Smith & Read, 2008). Thus, strategic modulation of Ca^{2+} levels represents an important component of mineral optimization in culture media engineering for *A. hygrometricus* and related ECM taxa.

Polysaccharide Matrix Stabilization

In ectomycorrhizal fungi such as Astraeus hygrometricus, extracellular polysaccharides (EPS) form a hydrated matrix surrounding hyphae that contributes significantly to colony stability and environmental resilience. EPS production enhances biomass cohesion by promoting hyphal aggregation and biofilm-like structuring, thereby improving mechanical stability during in vitro cultivation (Wingender et al., 1999; Sutherland, 2001). These polysaccharide matrices also provide protection against oxidative stress by scavenging reactive oxygen species and limiting diffusion of harmful metabolites, while simultaneously aiding in the retention and localized concentration of secreted enzymes and secondary metabolites within the mycelial microenvironment (Flemming & Wingender, 2010). Among the major structural components, β-glucans—particularly β-(1→3) and β-(1→6)-linked glucans—play critical roles in maintaining cell wall architecture and hyphal rigidity (Bowman & Free, 2006). Beyond structural function, fungal β-glucans are widely recognized for their immunomodulatory properties, interacting with host pattern-recognition receptors such as Dectin-1 to stimulate innate immune responses (Brown & Gordon, 2003). Therefore, EPS and β-glucan dynamics are integral not only to structural stabilization and stress adaptation in *A. hygrometricus* cultures but also to its potential biomedical and nutraceutical relevance.

Growth Regulators and Morphogenesis

Although fungi do not exhibit the same obligate dependence on classical plant growth regulators as higher plants, exogenous supplementation with phytohormone analogues has been shown to influence morphogenesis and developmental dynamics in several filamentous fungi, including ectomycorrhizal taxa such as Astraeus hygrometricus. Indole-3-acetic acid (IAA), a principal auxin, is known to modulate hyphal elongation, branching frequency, and mycelial density, partly through its effects on membrane permeability and cytoskeletal organization; notably, many fungi can both produce and respond to IAA-like compounds (Fu et al., 2015; Chanclud & Morel, 2016). Cytokinins have been reported to affect fungal cell division patterns and may alter colony morphology and biomass distribution under in vitro conditions, particularly in symbiotic fungi interacting with plant roots (Hinsinger et al., 2011). Similarly, gibberellic acid (GA_3) has been implicated in modifying hyphal extension rates and differentiation processes, although responses are species-specific and concentration-dependent. While these compounds are not essential for fungal growth, controlled supplementation in culture media can modulate differentiation, enhance hyphal density, and potentially influence sporocarp initiation pathways in ECM fungi. Thus, strategic application of plant-derived growth regulators represents an experimental tool for morphogenetic optimization in *A. hygrometricus* culture systems.

Environmental Optimization

Environmental optimization is critical for sustaining vigorous mycelial growth of ectomycorrhizal fungi such as Astraeus hygrometricus under axenic conditions. Empirical studies on ECM taxa indicate that temperature ranges between 24–28 °C generally support optimal enzymatic activity and hyphal extension, reflecting adaptation to subtropical and temperate soil environments (Smith & Read, 2008; Marx, 1969). Culture pH maintained between 5.5 and 6.2 favors nutrient solubility, membrane transport efficiency, and extracellular enzyme stability, particularly for phosphorus- and nitrogen-mobilizing systems (Read & Perez-Moreno, 2003). Adequate but not excessive aeration is essential, as oxygen availability regulates respiratory metabolism and biomass accumulation, while overly vigorous agitation may disrupt hyphal networks. Light is not required for vegetative growth in most ECM fungi; indeed, dark incubation often enhances mycelial proliferation by minimizing photo-oxidative stress and redirecting metabolic energy toward hyphal expansion rather than differentiation (Moore et al., 2011). Collectively, maintaining moderate aeration, slightly acidic pH, controlled temperature, and predominantly dark conditions provides an optimized environmental framework for consistent in vitro propagation of *A. hygrometricus*.

Co-Culture Strategies

Co-culture strategies have emerged as promising tools to enhance axenic establishment and physiological performance of ectomycorrhizal fungi such as Astraeus hygrometricus. Supplementation with yeast, particularly Saccharomyces cerevisiae, can improve vitamin availability (e.g., B-complex vitamins), amino acids, and other growth factors that support fungal metabolism and biomass accumulation under in vitro conditions (Kawai et al., 2006; Smith & Read, 2008). Yeast-derived metabolites may also partially mimic rhizospheric nutrient exchange, creating a quasi-symbiotic microenvironment that reduces strict host dependency. Beyond yeast interactions, certain mycorrhiza helper bacteria (MHB) are known to stimulate hyphal growth, branching, and symbiosis-related gene expression in ectomycorrhizal fungi (Garbaye, 1994; Frey-Klett et al., 2007). These bacterial partners can enhance signaling pathways involved in root recognition, nutrient mobilization, and oxidative stress tolerance, thereby facilitating mycorrhizal competence. Such microbial consortia-based approaches suggest that controlled co-culture systems may serve as effective platforms to modulate metabolic activity, activate symbiosis-associated genes, and improve in vitro cultivation efficiency of *A. hygrometricus*.

Bioreactor Systems

Scale-up cultivation of ectomycorrhizal fungi such as Astraeus hygrometricus increasingly relies on controlled bioreactor systems that support uniform nutrient distribution and environmental regulation. Advanced configurations include stirred tank bioreactors, airlift bioreactors, packed-bed systems, and temporary immersion systems, each offering distinct hydrodynamic and mass-transfer characteristics (Papagianni, 2004; Stanbury et al., 2017). Stirred tank reactors provide efficient mixing and oxygen transfer but may expose delicate hyphal networks to mechanical shear stress, potentially disrupting filament integrity. Airlift bioreactors, in contrast, utilize pneumatic circulation to achieve lower turbulence and improved oxygenation with reduced mechanical damage, making them suitable for shear-sensitive mycelial cultures. Packed-bed and immobilized-cell systems allow hyphal attachment to inert supports, promoting biomass stability and high cell density while minimizing agitation-related stress. Temporary immersion systems further balance nutrient exposure and aeration by alternating between liquid contact and gaseous phases, thereby enhancing oxygen diffusion and metabolic activity. Because filamentous fungi exhibit pronounced shear sensitivity due to their elongated, branching morphology, low-turbulence designs and optimized aeration rates are essential to preserve structural integrity and maximize biomass productivity in scaled-up cultivation platforms.

Secondary Metabolite Potential

The ectomycorrhizal fungus Astraeus hygrometricus is increasingly recognized for its secondary metabolite potential, with reports describing antioxidant constituents, anti-inflammatory metabolites, immunomodulatory polysaccharides, and diverse phenolic compounds isolated from its fruiting bodies and mycelia (Barros et al., 2008; Heleno et al., 2015). Antioxidant activity has been attributed largely to phenolic acids and flavonoid-like compounds that scavenge reactive oxygen species, while anti-inflammatory effects are associated with modulation of pro-

inflammatory mediators in vitro. Immunomodulatory activity is primarily linked to β-glucan–rich polysaccharides, which interact with host immune receptors and enhance innate immune responses (Brown & Gordon, 2003). Controlled tissue culture systems provide a strategic platform for enhancing metabolite production by enabling precise manipulation of nutrient composition, carbon-to-nitrogen ratios, elicitors, pH, and aeration—factors known to regulate fungal secondary metabolism (Calvo et al., 2002; Stanbury et al., 2017). Consequently, in vitro cultivation of *A. hygrometricus* offers not only a sustainable biomass source but also a scalable approach for targeted amplification of bioactive metabolites under reproducible conditions.

Genetic Stability and Molecular Tools

Genetic stability assessment is essential during repeated subculturing of ectomycorrhizal fungi such as Astraeus hygrometricus to ensure preservation of phenotypic traits and metabolite profiles. Molecular marker systems including Random Amplified Polymorphic DNA (RAPD), Inter-Simple Sequence Repeats (ISSR), Simple Sequence Repeats (SSR), and Internal Transcribed Spacer (ITS) profiling are widely employed to monitor genetic fidelity, detect somaclonal variation, and confirm species identity in cultured mycelia (Williams et al., 1990; Zietkiewicz et al., 1994; Schoch et al., 2012). RAPD and ISSR markers provide rapid genome-wide polymorphism screening, while SSRs offer higher reproducibility and co-dominant inheritance patterns suitable for population-level resolution. ITS sequencing, recognized as the universal fungal DNA barcode, enables precise taxonomic confirmation and contamination detection in axenic cultures (Schoch et al., 2012). For long-term germplasm conservation, cryopreservation—typically involving storage in liquid nitrogen with appropriate cryoprotectants—maintains genetic stability by minimizing metabolic activity and reducing mutation rates during prolonged storage (Smith & Ryan, 2012). Together, molecular marker surveillance and cryogenic preservation strategies form a robust framework for maintaining genetic integrity and reproducibility in *A. hygrometricus* culture systems.

Conservation and Commercial Implications

In vitro cultivation of Astraeus hygrometricus presents significant conservation and commercial advantages, particularly given its ecological role as an ectomycorrhizal forest species and its high ethnomycological value in parts of Asia. Wild harvesting of edible and medicinal macrofungi has been associated with localized population decline and habitat disturbance, especially in biodiversity-rich forest ecosystems (Boa, 2004; Christensen & Larsen, 2005). Establishing controlled cultivation systems reduces pressure on natural populations, thereby contributing to forest conservation and sustainable resource management. Moreover, standardized in vitro and scaled-up production ensures year-round biomass availability independent of seasonal fruiting cycles, improving supply chain stability and product quality consistency (Chang & Miles, 2004). Commercial cultivation initiatives can also support rural and forest-dependent communities by generating alternative income streams through value-added mushroom products and nutraceutical development. From a biodiversity perspective, ex situ cultivation and germplasm preservation strategies safeguard genetic resources while minimizing destructive extraction practices. Thus, biotechnological cultivation of *A. hygrometricus* aligns ecological sustainability with economic development, offering a model for integrating conservation biology and fungal biotechnology.

Challenges

Despite its biotechnological promise, cultivation of Astraeus hygrometricus faces several persistent challenges. Ectomycorrhizal (ECM) fungi typically exhibit slow radial mycelial growth under axenic conditions compared with saprotrophic species, reflecting their evolutionary adaptation to symbiotic carbon acquisition rather than rapid substrate colonization (Smith & Read, 2008). Mycorrhizal signaling complexity further complicates cultivation, as successful development in nature depends on finely tuned molecular exchanges between fungal hyphae and host roots, including signal molecules, phytohormone-like compounds, and nutrient feedback mechanisms (Martin et al., 2016). Induction of fruiting bodies remains particularly difficult, since sporocarp formation in ECM fungi is influenced by host association, soil microenvironment, seasonal cues, and poorly understood genetic regulators, making consistent in vitro fruiting unreliable (Moore et al., 2011). Additionally, cultures are often sensitive to phenolic oxidation, where accumulation of oxidized phenolic compounds in media can inhibit hyphal growth and lead to browning or cellular damage, especially during tissue isolation from sporocarps (Lakhanpal, 1996).

Addressing these constraints requires integrated optimization of media chemistry, signaling mimetics, environmental control, and possibly host-assisted or co-culture systems to better replicate natural ecological conditions.

Future Directions

Future research on Astraeus hygrometricus should increasingly integrate omics-driven and computational strategies to overcome current cultivation bottlenecks. Omics-guided medium design—leveraging genomics, metabolomics, and systems biology—can identify nutrient transporters, metabolic bottlenecks, and stress-response pathways to rationally tailor culture formulations (Martin et al., 2016). Transcriptomic profiling of ectomycorrhizal symbiosis has already revealed suites of symbiosis-induced genes involved in signaling, carbohydrate metabolism, and small secreted proteins, providing molecular targets for improving axenic growth and symbiotic competence (Kohler et al., 2015). Emerging genome-editing tools such as CRISPR/Cas systems offer opportunities for targeted pathway modulation, including manipulation of secondary metabolite clusters and regulatory genes influencing morphogenesis, although their application in ECM fungi remains technically challenging (Nødvig et al., 2015). Synthetic mycorrhizal mimetic systems—designed to replicate host-derived signaling molecules and rhizospheric cues—may help decouple strict plant dependency and enable controlled fruiting induction. Additionally, artificial intelligence (AI)-assisted culture optimization, integrating machine learning with multivariate growth datasets, can accelerate parameter refinement and predictive modeling of biomass and metabolite yield (Camacho et al., 2018). Collectively, these interdisciplinary approaches promise to transform *A. hygrometricus* cultivation from empirical optimization toward precision fungal biotechnology.

CONCLUSION

The ectomycorrhizal mushroom *Astraeus hygrometricus* represents a biologically significant and socio-economically valuable forest resource whose sustainable utilization demands a transition from wild harvesting to scientifically guided cultivation systems. Its obligate symbiotic lifestyle, slow radial growth, complex mycorrhizal signaling, and fruiting induction barriers collectively explain the historical difficulty in achieving reliable in vitro propagation. However, advances in explant selection, sterilization strategies, media engineering, mineral and calcium signaling optimization, extracellular polysaccharide stabilization, and environmental fine-tuning have considerably improved mycelial establishment and biomass production under controlled conditions.

Integration of molecular tools—including ITS profiling, population-level genetic markers, and transcriptomic insights—has strengthened taxonomic resolution and genetic stability monitoring, while cryopreservation strategies support long-term germplasm conservation. Emerging approaches such as co-culture systems, low-shear bioreactor platforms, omics-guided medium design, CRISPR-based pathway modulation, and AI-assisted culture optimization collectively signal a paradigm shift from empirical trial-and-error methodologies toward precision fungal biotechnology.

Importantly, successful in vitro and scaled cultivation of *A. hygrometricus* holds profound conservation implications by reducing pressure on forest ecosystems, safeguarding biodiversity, and enabling year-round production. Simultaneously, it opens avenues for controlled enhancement of bioactive secondary metabolites with nutraceutical and therapeutic potential. Future research must therefore prioritize mechanistic understanding of symbiotic signaling, fruiting induction pathways, and metabolic regulation to bridge the gap between laboratory-scale mycelial growth and commercial-scale production. Through interdisciplinary integration of mycology, molecular biology, and bioprocess engineering, *Astraeus hygrometricus* can be transformed from a seasonally harvested wild mushroom into a sustainable biotechnological resource that balances ecological preservation with economic development.

ABSTRACT

A (CS-FMA) was synthesized to evaluate anticancer activity against MCF-7 breast cancer cell line. The structure of the ligand was confirmed from FT-IR, NMR spectral studies. Estrogen receptor (ER) selective agonists are considered potential therapeutic agents for a variety of pathological conditions, including uterus and breast cancers. Their development is particularly challenging, since differences in the ligand binding cavities of two ER subtypes are minimal. We have carried out rational design of new salicylaldoxime derivatives which display unprecedentedly High-level ER selectivity for this class of compound, both in binding affinity and in cell-based functional assays. An endogenous gene expression assay was used to further characterize the pharmacological action of inhibit proliferation of a breast cancer cell line *in-vitro*.

Keywords: CS-FMA synthesis, Estrogen receptor (ER) selective agonists, MCF-7 breast cancer cell line, Salicylaldoxime derivatives, Anticancer activity

INTRODUCTION

2-((E)-2-((3R,6R)-5-methoxy-6-((E)-(phenylimino)methyl)tetrahydro-2H-pyran-3-yl)-1-methyl-ll[4] diazeyl) phenolSince carbonyl groups, chitosan are regarded as one of the best choices for enhancing chitosan's antibacterial properties. With an imine characteristic group, the Chitosan Schiff basis (-RC=N-) was reported by [2]. A chemical molecule called aniline has an amino group linked to a phenyl group and aniline has good antibacterial and anti-microbial activity [3]. the Investigated were impacts of common ions, especially Salicylaldoxime and carbonate as a collector for hydroxyl ion functional group, and structure was identified [4]. Salicylaldoxime is phenol ring bioisosteric replacement, a characteristic operative unit of the majority of estrogen receptors (ER) ligands.Estrogen receptors (ER ⌾) are nuclear transcriptional regulators of the ways in which estrogenic substances work physiologically. Many of the activities carried out by these receptors take place in the nucleus, where they bind to related DNA regulatory sequences and influence the transcription of particular target genes [5-8].

Polycondensation (also called *condensation polymerisation*) is a type of polymer-forming chemical process in which small molecules (monomers) react together to form a large polymer molecule with high molecular weight, and a small molecule such as water, alcohol, HCl, etc., is released as a by-product during each step of the reaction[9]. Bio-composite were synthesized by condensation process for the first time. This compound is high- quality and high-purity Bio-composite (CS-FMA). A newly synthesized compound (CS-FMA) expected to display remarkably high subtype this compound will be proven to behave as a full ER agonist and to initiate transcription as genes, highlighted where there is very high ER ⌾ potency-selectivity, which is unprecedented for this chemical class of ligand.

EXPERIMENTAL SECTION

MATERIALS AND METHODS

The compound salicylaldoxime, chitosan and aniline with a purity of 99% were from Sigma-Aldrich. The solvent Acetic acid and DMSO for used in the synthesis with 99% purity of the Analytical Reagent. Without additional purification, they were used after being obtained from Sigma-Aldrich.

Characterization and Analysis

Fourier transform infrared spectroscopy (FT-IR).

FT-IR has been recorded to analyze the functional group. The wavelength range 400 – 4000cm-1 was recorded using the instrument PERKIN ELMER LS 45.

NMR (Nuclear Magnetic Resonance), ^{1}H NMR and ^{13}C NMR

The NMR spectra were recorded on the BRUKER 80 and 80MHz high-performance nuclear magnetic resonance benchtop.

Thermal study (TG-DSC)

TG-DSC study analyze the thermal stability of the sample. Instrument on a NETZS CH STA 449F3 in following nitrogen gas using a heating rate of 20°C /10.0(K/min)/1400°C.

RESULT AND DISCUSSION

FT-IR Structure confirmation

The functional group for this new compound has been confirmed by the FT-IR spectrum and it's shown that the occurrence of the vibration that stretchesthe imine linkage 3457.97 cm^{-1} (C=NH) at a C6 position of chitosan is a sharp

band that replaced the broad amide band of chitosan. concomitantly an identifiable band of the amine groups 1489cm^{-1} diminished indicating its spectral-domain related to the high-frequency O-H stretching vibrations 3936 cm^{-1} and 3850 cm^{-1} is due to intra and intermolecular rearrangement of the hydrogen bonding network during the gelation process[10]. The formation of the azo (N=N) bond at a C3 OH-N position of chitosan and salicylaldoxime was confirmed by the sharp band 1729 cm^{-1}. C-N stretching of an Aniline band at 1272 cm^{-1} . The as-symmetric stretching of salicylaldoxime and Aniline[14].The bond 2126 cm^{-1} is due to the CH=N stretching of chitosan and aniline. FI-IR inCS-3CA (Fig 1).

NMR Spectroscopy

^{1}H-NMR and ^{13}C-NMR spectral studies

The structure of this compound was confirmed by ^{1}H NMR and ^{13}C NMR spectroscopy analysis. The solution ^{1}H-NMR (H-2 in 8.583 and H-6 in 4.881) and ^{13}C-NMR (C-3 C=N-OH and C-6 C=N) is a confirmed structure of the Bio-composite[11]. The signal from 153.38ppm to 154.72ppm confirmed the C=N-OH with H+ anions turned assays co-ordination of H+ anions turned assays co-ordination of H+ anion and NH_2 co-ordinates with chitosan in CS-FMA bio-composite. The multiplets from 111.79ppm to 152.17ppm due to the aromatic carbons in the new CS-FMA bio-composite of 3-Chloro aniline and salicylaldoxime. There are doublet, triplet, and quadruplets 21.45ppm to 40.35ppm due to amine NH_2 in the ring structure. The structure was confirmed by NMR spectrum. ^{1}H-NMR (Fig 2). ^{13}C- NMR (Fig 3).

Thermal Analysis

The TG-DTA study provides reliable data about the melting-point, phase transition and mass changes of the sample. The TG/DTA curve of the CS-3CA Figure 7 and 8. Shows a 1st decomposition temperature 131.8°C with minimum (-51.46%) and decomposition temperature 188.6°C with minimum (-45.87%), mass loss indicating the loss of water molecules only. To the title, CS-3CA the completed dissociation and its correlation with minimum weight loss well into the TG curve[13]. The sample measured for its real density, the resulting data are shown on the TG curve, and the sharp exothermic at 188.6°C represents a phase change is shown in Figure DSC curve exhibits partial two endothermic peaks observed on its heating curve, first endothermic peak is assigned as the heat capacity of enthalpy (137.7°C) and second endothermic peak as enthalpy of melting (191.5°C), which is shown in Table 1 and Figure 6.

Activation energy: The Arrhenius method has been used to measure the activation energy of the phase transition. The value obtained for the phase change in high-temperature is Ea = 179.9 kJ/mol. The value represents the adequate energy that stimulates both nucleation and development. This calculation represents the Activation energy (1)

$$IN\left[IN\left(\frac{1}{y}\right)\right] = \left(-\frac{E_a}{R}\right)$$

TG (Fig 4). DSC (Fig 5). Thermodynamical parameters (Table 1).

CONCLUSION

In this work, the CS-FMA was confirmed by first time in C-3 and C-6 oxidation of chitosan. The Double Schiff bases HC=N and C=N on chitosan demonstrated. The results show the variation of the chemical structure on Anti-cancer activity in Bio composite CS-3CA. The FT-IR spectrum showed mass losses and the presence of double Schiff based Imine groups in the compound CS-3CA.^{13}C-NMR (C-3 C=N-OH and C-6 C=N) is a confirmed structure of the Bio-composite. The double bonds of CS-3CA chains can be involved in a polymerization process.TG/DSC used to confirmed the thermal reactions has the potential to provide high level of Thermal stability, Activation energy confirmed.TG used on the effect of the endothermic polymerization reaction of the Bio polymer.

ABSTRACT

This study analyses sentence construction errors among ESL learners through the deep focus of Systemic Functional Linguistics (SFL). Students frequently overlook how sentences function as meaning-making resources, leading to recurrent errors, while they often rely on prescriptive grammar rules. Framing on Halliday and Matthiessen's SFL model, the research examines errors across the three metafunctions of language: ideational, interpersonal, and textual. For writing and spoken, scripts and samples are collected from learners and analyzed at the clause level using SFL tools of transitivity, mood, and theme. Writing and spoken errors are classified not only structurally but also functionally—for instance, misused processes and participants (ideational), incorrect mood and modality (interpersonal), and disrupted theme-rheme progression or cohesion (textual). The investigation demonstrates how these realizations falsify intended meaning and affect communication. The study proposes pedagogical strategies informed by functional grammar, such as theme-rheme exercises, mood analysis activities, and transitivity-based tasks, beyond error identification. By reconstructing sentence, errors as choices that interrupt meaning rather than as mere grammatical mistakes, the research contributes to more effective, meaning-oriented approaches to ESL instruction.

Keywords: SFL, ideational, interpersonal, textual, theme-rheme, ESL.

INTRODUCTION

The scrutiny of errors in sentence construction, English as a Second Language (ESL) contexts has traditionally been controlled by prescriptive grammar approaches. While overlooking how sentences function as meaning-making resources, these approaches often accentuate rightness in terms of syntactic structure. Systemic Functional Linguistics (SFL), as developed by Halliday and distended by Matthiessen, offers a more holistic framework by considering language as a social semiotic system in opposition. This paper analyses sentence construction errors among ESL learners through a specific framework of SFL, specifically focusing on the three metafunctions of language: ideational, interpersonal, and textual. this study aims to identify errors that go beyond structural inaccuracies and instead reveal how learners' misrealizations warp intended meaning and hinder communication by applying SFL tools such as transitivity, mood, and theme.

LITERATURE REVIEW

Traditional ESL error investigation has often classified mistakes into grammatical, lexical, and syntactic errors (Corder, 1967; Richards, 1971). While such arrangement helps identify surface-level issues, it does not adequately account for how errors intervene with meaning-making processes in reliable communication. Systemic Functional Linguistics gives a structuralview on grammar, emphasizing how language choices enact meaning (Halliday & Matthiessen, 2014). SFL's metafunctional model—ideational, interpersonal, and textual, offers tools to examine how learners use language to represent experience, negotiate interaction, and organize information (Eggins, 2004; Martin, 1992). Previous research applying SFL to ESL contexts (Schleppegrell, 2004; Fang & Schleppegrell, 2008) has depicted that functional grammar can bring out deeper patterns of difficulty on the far side prescriptive. errors. Studies have demonstrated that ESL learners often battle with theme-rheme progression (North, 2005), modality (Paltridge, 2006), and transitivity choices (Halliday, 1994). These difficulties signal that learners' errors are not simply about incorrect forms but reflect challenges in mapping meaning into grammatical resources.

METHODOLOGY

Written essays and spoken transcripts are collected from intermediate ESL learners in a classroom setting. Written samples aretired from narrative and argumentative essays, while spoken samples are collected from classroom discussions and oral presentations. Errors are examined at the clause level of Ideational metafunction, using SFL tools, which analyzed through transitivity (process types, participants, and circumstances), Interpersonal metafunction, analyzed through mood structures (declaratives, interrogatives, imperatives) and modality (obligation, probability, inclination) and Textual metafunction, analyzed through theme-rheme series, cohesion, and information flow.Errors are categorized into misrealizations within each metafunction, demonstrating how these affect meaning.

FINDINGS AND DISCUSSION

Common ideational errors encompass the abuse of processes and participants. For example, learners may use material processes where mental processes are required (e.g., "I look the Television" instead of "I watch the Television"). Such errors *misinterpret* the experiential meaning and distort the intended message. Learners often conflict with mood choices and modality. Incorrect use of interrogatives (e.g., "You are leaving?" instead of "Are you leaving?") leads to uncertainty in negotiation of interaction. Dubiety of modality (e.g., "He must can go") results in pragmatic failure, as the strength of responsibility or possibility is misinterpreted. Errors in theme-rheme progression interruptcoherence. Learners frequently repeat themes unnecessarily or fail to

hold a logical flow, leading to disconnected language unit. For example, "The teacher explained. The teacher gave homework. The teacher told us" reflects limited thematic fluctuation, reducing textual coherence. It becomes evident that learners' mistakes are not merely breaches of grammar rules but disruptions in meaning-making, by viewing these errors functionally. This adjusts with the view that sentence construction errors should be re-framed as choices that fail to realize intended meanings.

Implications of Pedagogy

Activities that promote students to change themes and maintain cohesive progression can improve textual metafunction realization. Dialogue tasks and Role-playcan help learners experiment with mood and modality, strengthening their interpersonal metafunction competence. Exercises direction on different process types (material, mental, relational, verbal, behavioral, existential) can enhance learners' ability to map experiences effectively. Incorporating functional grammar into ESL curricula can foster a meaning-oriented approach to language learning, rather than teaching grammar as isolated rules.

CONCLUSION

This study underlines the importance of analyzing sentence construction errors through the framework of SFL. Educators can move beyond structural correctness and address how learners' language choices affect meaning-making by focusing on ideational, interpersonal, and textual metafunctions. Pedagogical strategies planted in SFL not only enhance learners' grammatical accuracy but also improve their communicative competence. Ultimately, reconstructing errors as disruptions of meaning rather than mere rule violations provides a more effective approach to ESL instruction.

ABSTRACT

Pre-Menstrual Syndrome (PMS) is a group of symptoms that occur in women, typically between ovulation and the menstrual cycle, and usually affects women aged 18 to 40 years. It has possible causes such as hormonal dysregulation, insufficient progesterone levels during the secretory phase of the menstrual cycle, aberrant neurotransmitter responses to ovarian signalling, abnormal aldosterone function, and inappropriate hypothalamic-pituitary-adrenal (HPA) activity. PMS has signs and symptoms such as behavioral signs, including overeating or food cravings, weariness, sleeplessness, dizziness, and changes in sexual interest. Psychological signs such as restlessness, loneliness, low self-esteem, irritability, anger, depression, weeping and distress, anxiety, stress, fluctuating emotions, problems in focusing, disorientation, and memory loss. There are also risk factors such as body mass index, family history, cigarette smoking, coffee intake, nulliparity, and psychological history. It can be diagnosed by noting the symptoms and referring to a gynecologist. It can be treated with pharmacological therapy, which includes Selective Serotonin Reuptake Inhibitors, diuretics, hormonal therapy, bilateral oophorectomy, and hysterectomy. Non-pharmacological therapy includes lifestyle changes, stress management, exercise, vitamins, minerals, and magnesium intake. Patients should be

counselled about the disease so that they have a proper understanding of the disease and do not neglect any symptoms that can lead to further complications.

Keywords: Pre Menstrual Syndrome, Pre Menstrual Dysphoric Disorder, Polycystic Ovarian Disease, Hormonal Replacement Oestrogen, Cognitive Behavioural Therapy, Depression, Anxiety.

INTRODUCTION

Premenstrual syndrome is not well understood, but it can be widely defined as any group of physical and psychological signs that recurs frequently during the fertile stage of the menstrual cycle and lasts for a minimum of a week during the follicular stage of the cycle, and causes anxiety and deterioration of function.[1]. Premenstrual dysphoric disorder (PMDD) is a term used to describe more severe affective symptoms in females. While the exact cause of many illnesses is unknown, evidence points to a role for the abnormal regulation of neurohormones and neurotransmitters. Alternative causes for symptoms must be examined before investigating PMS or PMDD because both are diagnoses of exclusion. [2]. Approximately 90% of women experience premenstrual symptoms at some point in their lives. According to estimates, 20 percent–30 percent of women suffer from clinically significant PMS or signs that are moderate to severe in intensity and impair the woman's ability to function. To treat PMS effectively, which affects between 3% and 8% of women and as many as 40% of women, it is critical that medical practitioners comprehend the condition. Two hypotheses have been proposed regarding the cause of PMS. The ovarian hormone cycle is involved in both.[3]. The same blood levels of either of the steroid hormones are present in females suffering from PMS or not, and certain females are especially sensitive to progesterone. Serotonin, an endogenous messenger known to regulate the state of mind, is decreased by estrogen and progesterone. PMS is triggered by the ovarian cycle, as it does not occur before puberty, during pregnancy, or after menopause. [4]

Menstruation Cycle

Menstrual phase: The uterine lining is shed. Follicular phase, where follicles mature and the uterus prepares for pregnancy. The ovulatory phase is marked by ovulation and the fertile period. Luteal phase, when the uterus prepares for possible implantation or the cycle restarts if no fertilization occurs.**[5]** Menopause (No More Menstrual Cycle): Menopause, a biologically normal process, signals the end of a woman's fertile years. With an average age of 51, it typically occurs between the ages of 45 and 55. Hot flashes, nocturnal sweats, mood changes, irregular periods, vaginal dryness, and difficulty sleeping are typical menopause symptoms. [6] Menarche: Menarche is the first menstrual cycle that occurs in females from the age of ten to 16 years. [7]

CAUSES

The cause of premenstrual syndrome is unknown. Because PMS signs appear along with the hormonal variations of the menstrual cycle, hormonal disproportions such as estrogen surplus and progesterone shortage have been hypothesized.[8]. A study from Egypt discovered a link between PMS and a high intake of sweet-tasting foods such as cakes, cupcakes, cookies, candies, biscuits, chocolate, junk food such as burgers, pizza, French fries, chilli chicken, ice cream, soda, etc., and coffee use, which may be very harmful because it may cause anxiety and sleeping problems. Although numerous etiologies have been proposed, none have been proven to be the major cause of PMS symptoms. [9] Possible factors include hormonal dysregulation, insufficient progesterone levels during the secretory phase of the menstrual cycle, aberrant neurotransmitter responses to ovarian signalling, abnormal aldosterone function, inappropriate hypothalamic-pituitary-adrenal (HPA) activity, nutritional inadequacies, and environmental factors. [10].

Clinical Presentation

Behavioral signs include overeating or food cravings, weariness, sleeplessness, dizziness, and changes in sexual interest. Psychological signs like restlessness, loneliness, low self-esteem, irritability, anger, depression, weeping and

distress, anxiety, stress, fluctuating emotions, and problem in focussing, disorientation, memory loss. Pain in the head, mastalgia, back ache, pain in stomach, bloating, increase in body weight, inflammation of extremities, fluid detainment, vomiting tendency, and muscle and joint ache are some of the physical symptoms.[11] [12]

Risk Factors

Body mass index: Serious PMS is more likely to advance in people with a BMI > 27.5 kg/m2. [13] Cigarette smoking- Smoking was independently linked to a greater risk of PMS during youth and early adulthood. [14]. Alcohol intake: Women consuming excessive amounts of alcohol experience PMS more frequently, and it aggravates PMS symptoms. [15]. Coffee intake- Caffeine is a stimulant that helps us stay awake. It can also make us feel more exhausted or irritable as a result of it interfering with our sleep patterns, resulting in unfavorable PMS symptoms like anxiety and irritability. Age: PMS is more common in females in their late twenties to early forties.

Family history

A female is more likely to develop PMS if her mother had the condition. Pregnancy history Nulliparity (never having given birth) has been linked to PMS in several studies [16] Psychological history- PMS risk may be higher in women who have had or are now experiencing emotional or anxieties, including depression.[17].

Pathogenesis of PMS

Premenstrual syndrome can be causedby hormonal alterations that occur after ovulation. The symptoms are not linked to particular gonads or non-gonadal hormones that can appear promptly in the middle or post-luteal phases. Premenstrual symptoms get correlated with progesterone production by the ovary.[18]. Changes in the levels of ovarian sex hormones (estrogen and progesterone) cause PMS. Estrone, estradiol ,and estriol are the main hormones that make up estrogen, with estradiol being the most potent. Because these hormones can penetrate through the blood-brain barrier (BBB), thus their binding proteins that are located in the brain (in the hippocampus and hypothalamus), allopregnanolone and pregnanolone are generated by these hormones.[19][20]. The neuroendocrine theory proposes that women with PMS experience alterations in various crucial neurotransmitters, such as serotonin and gamma-aminobutyric acid (GABA), which affect peripheral neuroendocrine functions. Increased prolactin levels or an increase in prolactin's sensitivity to its effects, changes in the breakdown of sugar, impaired hypothalamic-pituitary-adrenal (HPA) axis, resistance to insulin, specific dietary fluid deficits, hereditary factors, and dysfunctional HPA axis function are all potential causes of PMS.[21][22]

The two most significant neurotransmitter systems involved in the development of symptoms are the GABAergic and serotonergic systems. When progesterone metabolites from the corpus luteum and brain bind to a neurosteroid-binding site, the outermost layer of the GABA receptor is altered, rendering the receptor resistant to subsequent activation and ultimately lowering central GABA-mediated inhibition. Some birth control pills contain progestogens, which may likewise negatively affect the GABAergic system by a related mechanism.[23] [24]

Complication

Premenstrual dysphoric disorder (PMDD), [25] premenstrual syndrome depression, [26] menstrual migraine, [27] Polycystic Ovarian Disease (PCOD), and polycystic ovary syndrome (PCOS) [28] and if Polycystic Ovarian Disease is not treated, it can lead to infertility. [29]

Diagnosis

According to American College of Obstetricians and Gynecologist (ACOG) Criteria

To evaluate PMS, a physician or gynecologist must confirm that the patient is experiencing symptoms that may be affective or somatic (Table 1.1). This helps the doctor to access which drug is best suited for the patient (Table 1.4).[30]

Flowchart 1- Algorithm for diagnosing Pre Menstrual Syndrome [30]

The following signs should be present in females with PMS:

- For at least three menstrual cycles, symptoms should be present for five days before the actual menstruation starts.
- Terminate within 4 days after the start of a period
- Hinderance with normal daily activities.[30]

TREATMENT

Before contemplating medication, females with suspected PMS should have their past illnesses checked for conditions including depression, dysthymia, anxiety disorders, and hypothyroidism. A history that evaluates the prevalence of these characteristics (refer flowchart 1), as well as domestic violence, should be collected in light of the potential linkages between PMS and sexual abuse, as well as with post-traumatic stress disorder to further prescribe the management for it (Table 1.4).[32] The effectiveness of SSRIs in managing PMS/PMDD has been demonstrated in numerous clinical trials, considering normal response rates for active treatments between sixty to 90 percentage vs thirty to 40 percentage for placebo. SSRIs lessen mood symptoms and physical issues while enhancing public interaction and lifestyle standards. Many people think that SSRIs ought to be used as the preferred therapy for people suffering from PMS who exhibit severe mood issues.[33] [34] . PMS can be treated with greater efficacy with SSRIs (Table 1.2) than with antidepressants, which mostly alter noradrenergic transmission, indicating that their influence on the illness goes beyond what an antidepressant would have. [35]

Other Pscychotic Drugs

Alprazolam, a high-affinity benzodiazepine, has inconsistent efficacy data; however, it may be a useful adjunct therapy for women who mention acute stress or premenstrual insomnia as major problems. Due to the possibility of dependence, treatment with alprazolam should be closely monitored, especially if the patient has a history of substance misuse. Alprazolam at a dose of 0.375 to 1.5 mg is administered during the luteal phase. Alprazolam should only be used as an alternative therapy if selective serotonin reuptake inhibitors do not produce the desired results.[37] [38]

Diuretics

Only one diuretic, spironolactone, an aldosterone antagonist with structural similarities to steroid hormones, has been proven to be useful in treating PMS symptoms such as breast pain and fluid retention. Spironolactone, when taken daily in doses of 25–100 mg. Hyperkalaemia and antiestrogenic side effects are common.[39] [40]

Hormonal Interventions

The purpose of hormone therapy for PMS is to halt the naturally occurring hypothalamus-pituitary-gonadal cyclicity that produces the signs, not just to repair hormonal aberration. To do this, a long-acting Gonadotropin Releasing Hormone (GnRH) Agonist can be utilized, and they are clearly very successful.[41]. Levonorgestrel-containing intrauterine devices are another way to prevent a reprise of gestagen-induced complaints; after the endometrium has undergone atrophic transformation, systemic hormone concentrations via this mode of administration are negligible. PMS is also eliminated by other methods to limit ovarian cyclicity, such as bilateral ovariotomy surgery (which can be performed laparoscopically). Ovarian preservation is generally advised for younger females; if an individual is suffering from serious PMS, ovarian preservation may be contraindicated, and the individual might elect to have her ovaries removed. [42]

Administering estrogen at levels that prevent ovulation is one of the easiest methods to eliminate PMS symptoms. Instead of oral medication, which is typically indicated, estrogen delivered as a skin patch or hypodermic implants has been suggested (Table 1.3). Patches may require dosages of 100, 150, or 200 g, which are frequently higher than those necessary for hormone replacement therapy but lower than those required for oral contraceptives. To stop endometrial hyperplasia, the patient will require a progestagen unless she underwent a hysterectomy.[43][44]

Hysterectomy and Bilateral Oophorectomy

Women who do not respond to medical therapy have a long-lasting good response to bilateral oophorectomy and medical and surgical hysterectomy. [46]

NON-PHARMACOTHERAPY

LIFESTYLE CHANGES

Numerous methods are regarded as lifestyle modifications, which still need to be thoroughly demonstrated in intensive investigations. But developing healthy exercise and stress-reduction habits might enhance general emotions of wellbeing.[47]

Symptom Charting And Validation of PMS

Keeping track of symptoms helps to confirm the diagnosis and may be useful for predicting when symptoms will likely appear, giving the patient a greater sense of control.[48]

Education

Teenagers need to understand the anatomy of menstruation and how the symptoms are related to hormonal changes. [49]

Stress Management

Additionally, stress-reduction techniques, including yoga, breathing exercises, massage, reflexology, imagery meditation, and light therapy, may be taught to young people, or they may be sent for them. [50]

Cognitive Behavioural Therapy

Psychotherapy, such as cognitive behavioral therapy, may be beneficial if stress symptoms are more severe. [51]

Exercise

Some women have reported that regular exercise reduces their PMS symptoms compared with being inactive. Exercise's effectiveness may be connected to the endorphins released, which work to counterbalance any potential reductions in endorphin levels during the secretory phase.[52]

Minerals

In a well-designed multicenter study, calcium (1,200 mg/day) as calcium carbonate was found to lessen both psychological and bodily signs. In several trials, magnesium (200 to 400 milligram a day) appeared more beneficial than a placebo in reducing depressive symptoms and water retention.[53]

Vitamins

In the past, pyridoxine was extensively used, particularly for managing emotional PMS symptoms. However, it is believed to offer little benefit. Another issue is that dosages greater than 100 mg/day might cause peripheral neuropathy. It was found that taking 400 IU of vitamin E daily helped with somatic and emotional symptoms. However, there is not much proof of its effectiveness.[54]

Magnesium

Magnesium may be helpful in reducing PMS symptoms when taken daily in doses ranging from 200 mg to 400 mg. [55]

Vitamin E

Up to 600 international units (IU) of vitamin E per day might effectively reduce PMS-related depression and physical symptoms including breast soreness and tenderness.[56]

Herbal Preparation

In several trials, it has been discovered that Vitex agnus-castus, also known as chasteberry, at a dose of 20 mg/day reduces PMS symptoms better than a placebo. Chasteberry may affect gonadotropins, estrogen, progesterone, and prolactin [57].

Acupunture

Acupuncture, a conventional Chinese medicine, is occasionally used to manage PMS symptoms. Manual stimulation of acupressure sites has been used to alleviate PMS as a no-needle substitute for acupuncture.[58]

Dietary Supplementations

Evening primrose oil has gained popularity, but it appears to have no effect. However, studies on a person's eating habit that increase the amount of complex carbohydrates in the food suggests advantage, which may be brought on by improved tryptophan transport into the brain, which in turn causes a brief increase in the synthesis of this transmitter.[59][60]

CONCLUSION

Premenstrual syndrome (PMS) is a significant clinical condition affecting a large demographic of women, driven by complex interactions between ovarian hormones and neurotransmitters, such as serotonin and gamma-aminobutyric acid (GABA). Diagnosis requires prospective symptom charting over multiple cycles, adhering to the ACOG criteria to ensure accuracy. Management should follow a stepped-care algorithm as outlined by the RCOG guidelines, starting with lifestyle modifications and nutritional support, progressing to pharmacological interventions such as SSRIs and hormonal therapies for more severe cases, with the goal of restoring daily functioning and quality of life.

Table 1. Diagnostic symptoms for Pre-Menstrual syndrome [31]

Affective	Somatic
Depression	Mastalgia
Angry outbursts	Abdominal bloating
Aggression	Headache
Anxiety	Swelling of extremities
Confusion	
Social withdrawal	

Table 2. The drugs and doses of Selective Serotonin reuptake inhibitors are as follows- [36]

Clomipramine	50-75 milligram per day or for half cycle
Citalopram	20-40 milligram per day or for half cycle
Escitalopram	10-20 milligram per day or for half cycle.
Fluoxetine	20-60 milligram per day or for half cycle
Paroxetine	20-30 milligram per day or for half cycle
Paroxetine – CR	12.5-25 milligram per day or half cycle
Sertraline	50-150 milligram per day or half cycle.
Venlafaxine	50-200 milligram per day or half a cycle.
These drugs have side effects such as sexual dysfunction, nausea, jitteriness.	

Table 3 - The doses and side effects along with some interventions are as follow- [45]

DRUG	DOSE	SIDE EFFECT
Oestradiol	A dose of 200 microgram Oestradiol should be administer twice a week via a skin patch.	Dermatitis
Oestradiol hypodermic implant must be combined with oral progestogen intermittently, or with intrauterine progestogen	100 microgram hypodermic implant of oestradiol	Mastalgia
Drosperinone-ethinyl oestradiol	3 milligram Drosperinone plus 20 microgram ethinyl Oestradiol for 24 days	Mastalgia

Table 4- Algorithm for the management of PMS according to Royal College of Obstetricians and Gynaecologist (RCOG) [61]

First Line	Supplemental/conservative medicine: Cognitive behavioral therapy, exercise, and vitamin B6 Hormonal: Combination new-generation tablet (continuously or cycled) Non-Hormonal: (Days 25 to 28) In continuous or luteal phase SSRIs in low doses
Second Line	Hormonal: From days 17 to 28, provide micronized progesterone (100 milligram or 200 milligram) together with 100 microgram oestradiol patches- (orally or vaginally), Or Levonorgestrel Intrauterine system (LNG-IUS). Non-Hormonal: Continuously using high dosage SSRIs or luteal phase
Third Line	GnRH analogues used with hormone replacement treatment (HRT) add-back [Continuous combined oestrogen + progesterone, such as 100 mg/day of micronized progesterone in the form of micronized progesterone patches, two to four doses of oestradiol gel, or 2.5 milligram of Tibolone]
If everything fails	Operational procedures with or without hormonal replacement therapy (HRT)

ABSTRACT

Microorganisms constitute an integral component of human welfare due to their extensive applications in agriculture, healthcare, and industrial biotechnology. Diverse microbial groups, including bacteria, fungi and algae, play a pivotal role in sustaining life and improving overall quality of living. In agriculture systems, microbes contribute significantly through biofertilization, biological pest management, and enhancement of soil fertility, thereby promoting environmentally sustainable farming practices. In the medical field, microorganisms serve as indispensable sources for the development of antibiotics, vaccines, probiotics, and other therapeutic agents essential for disease prevention and treatment. Furthermore, industrial processes extensively rely on microbial activity in fermentation technologies, waste management, and the production of biofuels and other value-added products, contributing to economic growth and ecological balance. Continuous advancements in microbial biotechnology have further expanded their utility, reinforcing their importance in addressing global challenges related to health, food security, and environmental sustainability. This review highlights the multifaceted roles of microorganisms in human welfare, emphasizing their significant contributions to human health, environmental protection, and industrial development.

Keywords: Microorganisms; Human welfare; Antibiotics; Environmental sustainability

INTRODUCTION

Microorganisms are present in almost every environment and can be both useful and harmful to humans. They are widely used in various industries for the production of important compounds and other valuable products. These tiny living organisms, commonly called microbes, cannot be seen with the naked eye due to their extremely small size. Even though they are microscopic, they play a very

significant role in nature as well as in human life. Microbes include a wide range of organisms such as bacteria, fungi, viruses, algae, and protozoa. They exist everywhere- form the deepest oceans to the highest mountains- and are even found inside the human body, where they contribute greatly to maintaining Earth's ecosystems.

Microorganisms have played a vital role in improving human life since ancient civilization, particularly through the use of fermentation for food preparation and preservation. Over time, their applications have broadened significantly, now encompassing the manufacture of antibiotics, vaccines, biofuels, and even the remediation of contaminated environments. As the field of microbiology continues to advance, the potential uses of microbes are expanding in innovative ways, helping to address major global challenges such as sustainable agriculture, renewable energy production, and disease management. Although microbes are often linked to illness, most of them are harmless or even beneficial. In reality, they are essential for fundamental processes including nutrient cycling, fermentation, and digestion. Microorganisms also play a crucial role in environmental functions like decomposing organic waste and

maintaining soil fertility. Beyond natural ecosystems, they are indispensable in numerous industries, supporting food production, biotechnology, medicine, and environmental conservation. Microorganisms are found everywhere and interact ecologically with nearly all living organisms. In a similar way, humans constantly engage in interactions with microbes, which may result in effects that are either temporary or long-lasting. Certain bacterial infections are difficult to manage because they do not respond effectively to low doses of antibiotics. To eliminate harmful microbes, drug combinations are often required. Human body cells possess defense mechanisms that help fight pathogenic microorganisms and are far more numerous than microbial cells present in the body. Microbes also play a vital role in essential biological processes such as metabolism and contribute to maintaining health by combating invading pathogens. For instance, recent discoveries and applications related to microbes show great potential for future advancements in areas like food production, biotechnology, medicine, and environmental protection.

Recent advances in genetic engineering, synthetic biology, and genomic technologies have greatly broadened the capabilities and applications of microorganisms. These innovations allow scientists to accurately edit microbial DNA, fine-tune metabolic pathways, and design synthetic microbial consortia with specific, customized functions. By harnessing the natural versatility of microbes and improving biotechnological techniques, researchers and industries are able to create environmentally friendly and efficient solutions for future challenges. Microorganisms are vital contributors to sustainable agriculture, as they improve soil fertility, stimulate plant development, suppress plant diseases, regulate pests, and facilitate nutrient cycling. Nitrogen-fixing bacteria such as *Rhizobium*, *Bradyrhizobium*, and *Azospirillum* transform atmospheric nitrogen into plant-available forms, thereby decreasing dependence on chemical fertilizers.

Microbes also establish endosymbiotic associations with higher organisms. In humans, gut-resident bacteria support overall health by strengthening immune responses, producing essential vitamins like folic acid and biotin, and fermenting complex compounds that the body cannot digest on its own. In the future, many pharmaceuticals and food additives may need to be evaluated for their effects on the gut microbiome. It is already well recognized that probiotics can enhance well-being and that microbial communities in the intestine are strongly influenced by diet and medications. Microorganisms play a central role in advancing research across biotechnology, biochemistry, genetics, and molecular biology. Among them, *Saccharomyces cerevisiae*, a species of yeast (baker's yeast) and *Schizosaccharomyces pombe* (The rod-shaped yeast *Schizosaccharomyces pombe*) serve as key model eukaryotic systems because of their simple cellular organization, rapid growth, and amenability to genetic manipulation. These features render them particularly valuable for genetic research, genomics, and proteomics, including studies focused on recombinant protein expression. Likewise, the prokaryotic bacterium *Escherichia coli*, which is easy to cultivate and genetically engineer, is extensively

employed as a model organism for understanding fundamental biological processes and for biotechnological applications.

Microbes in Industrial Production

Microorganisms have played a fundamental role in industrial science for more than a century, owing to their vast enzymatic diversity and wide-ranging metabolic capabilities. The introduction of recombinant DNA technology has transformed industrial microbiology by enabling the development of advanced expression systems and the redesign of biosynthetic pathways through metabolic engineering to generate novel compounds. In addition, directed evolution strategies have facilitated the creation of enzymes with enhanced stability, improved catalytic efficiency, and altered substrate specificity. The increasing availability of genome sequences from industrially relevant microbes has provided deep insights into their genetic architecture and enzymatic potential. Furthermore, modern approaches such as functional genomics, proteomics, and metabolomics are extensively applied to identify new bioactive molecules for therapeutic applications and highly efficient enzymes for industrial catalysis[02].

Microbial activity is fundamental to the production of a broad range of industrial products and significantly influences numerous manufacturing processes. Microorganisms such as bacteria, fungi, and algae serve as powerful biological tools that drive biochemical transformations with high efficiency. Their involvement enables industries to enhance output, reduce environmental impact, and lower operational costs. By harnessing these living systems, companies can develop eco-friendly processes, improve product quality, and achieve more sustainable and economical production methods across sectors such as pharmaceuticals, agriculture, food processing, and biotechnology.

Industrial application of microorganism encompasses a wide range of sectors including:-

- Food and Beverage production
- Biopolymers
- Enzymes and Amino Acids
- Antibiotics
- Chemicals and Dies
- Bio-fuels.

Food and Beverage production

Microorganisms are widely recognized for their involvement in food spoilage, where they cause undesirable changes in taste, smell, and texture. At the same time, many microorganisms are extremely valuable for food processing and preservation. Even though some microbes are pathogenic, others are deliberately used in the production of a wide range of fermented foods and beverages at both household and industrial levels. Microbial fermentation is essential in the manufacture of dairy products and alcoholic drinks. Common examples include yogurt, curd, sour cream, buttermilk, bread, and cheese, all of which rely on microbial activity for their unique characteristics. In addition, microorganisms are used to ferment vegetables, which enhances their flavor and extends shelf life. Popular fermented vegetable products include pickles, sauerkraut, soy sauce, kimchi, and olives. [03].

Biopolymers

Microbial polymers are biodegradable macromolecules synthesized by microorganisms during the fermentation of various substrates, where they function as energy reserves, structural components, or protective layers such as capsules, slimes, and biofilm matrices. These biologically derived polymers possess diverse chemical structures and physical characteristics that make them highly attractive for a wide range of industrial, environmental, and medical applications. Owing to their renewability, biodegradability, and biocompatibility, microbial polymers serve as sustainable alternatives to conventional petroleum-based plastics. Their versatility allows them to be tailored for

specific functions, including packaging materials, drug delivery systems, tissue engineering scaffolds, and agricultural inputs. Based on their origin, composition, and functional roles, microbial polymers can be broadly classified into different categories, reflecting their varied structures and applications.

- Polysaccharides
- Polyamides
- Polyesters
- Polyanhydrides

Microorganisms function as efficient biological factories capable of transforming a wide range of carbon and nitrogen substrates into numerous intracellular and extracellular biopolymers, particularly under specific stress conditions. Among these biopolymers, polyhydroxyalkanoates (PHAs) and exopolysaccharides (EPS) have attracted considerable attention due to their biodegradability and versatility. Several microbial species, including *Bacillus myscoides*, *Halomonascerina*, and *Pseudomonas resinovorans*, have been identified as promising PHA producers. The biopolymers synthesized by these organisms exhibit diverse chemical compositions and structural characteristics, enabling their application across multiple fields such as drug delivery systems, tissue engineering, eco-friendly packaging materials, and environmental remediation technologies.

Enzymes

Enzymes are present in every living cell and therefore occur in all microorganisms. A single microbial strain is capable of synthesizing numerous enzymes that participate in hydrolytic, oxidative, reductive, and other metabolic reactions. Because of their remarkable specificity and efficiency, enzymes are among the most valuable biomolecules used extensively in both industrial processes and biomedical applications. The progress in enzyme technology has been driven largely by the discovery and utilization of microbial sources. Microorganisms are especially attractive for enzyme production since they can be cultivated at low cost, grow rapidly, and can be genetically modified to enhance enzyme yield and performance. As a result, microbial enzymes have largely replaced those derived from plants and animals in many applications [07].

The advent of recombinant DNA technology has revolutionized enzyme production by enabling the high-level expression of valuable enzymes from microbial, plant, and animal sources. This technology allows scientists to introduce specific genes into suitable host organisms, leading to enhanced yields and consistent enzyme quality. Among the various production approaches, submerged fermentation (SmF) [06] and solid-state fermentation (SSF) [05] are the most commonly used techniques. Both methods provide controlled environments that support microbial growth and enzyme synthesis, making large-scale and cost-effective production possible for diverse industrial applications.[07].

Antibiotics

Microorganisms constitute one of the most significant natural reservoirs of antibiotic compounds and remain fundamental to the discovery and development of drugs used to treat serious infectious diseases. A wide range of bacteria and fungi synthesize bioactive metabolites that inhibit or destroy competing microorganisms, and many of these substances have been harnessed as therapeutic agents. From early discoveries such as penicillin to modern semi-synthetic and engineered derivatives, microbial products have transformed the management of infections in humans, veterinary medicine, and crop protection. Even today, ongoing exploration of diverse microbial habitats continues to yield novel molecules with potential to address emerging and drug-resistant pathogens, underscoring the enduring importance of microorganisms in antimicrobial research and development.A large proportion of clinically used antibiotics originate from microbial metabolites, highlighting the extraordinary biosynthetic potential of these organisms. Species of the genus *Bacillus*, in particular, are prolific producers of peptide antibiotics, many of which show strong activity against Gram-positive bacteria. In contrast, certain compounds such as polymyxin, colistin, and circulin display selective potency toward Gram-negative pathogens, while others including bacillomycin, mycobacillin, and fungistatin are primarily effective against fungi such as molds and yeasts. Continued discovery and characterization of antibiotics have revealed

considerable diversity in their chemical structures and biological behaviors, leading to classification based on attributes such as origin, spectrum of activity, and functional type. This diversity underpins their wide-ranging applications and supports ongoing efforts to identify novel antimicrobial agents. [05].

Microbial Pigments

Microbial pigments represent a diverse group of naturally occurring colour compounds produced by bacteria, fungi, and microalgae, exhibiting a wide range of chemical structures and biological activities. These pigments are increasingly gaining attention due to their biodegradable nature, low toxicity, and environmentally sustainable characteristics, making them suitable alternatives to synthetic dyes. Owing to their stability, safety, and multifunctional properties, microbial pigments hold significant promise for application as natural colorants in food products, cosmetics, textiles, and pharmaceutical formulations. Furthermore, advances in biotechnology and fermentation technology have enhanced the feasibility of large-scale pigment production, reinforcing the importance of microorganisms as valuable sources of eco-friendly pigments for industrial use.[09]

Microbial pigments play diverse and essential roles that contribute to the survival and ecological success of microorganisms. These compounds enhance adaptability to varying environmental conditions by providing protection against harmful ultraviolet radiation and oxidative stress caused by reactive oxygen species. Many microbial pigments exhibit antibacterial and antifungal properties, enabling microorganisms to inhibit competing species and maintain dominance over available space and nutrients. This defensive capability supports ecological balance while preventing colonization by rival microbes within the same habitat. In addition to their protective and competitive functions, certain pigments participate directly in cellular energy processes, such as photosynthesis, where they facilitate light absorption and conversion into usable chemical energy. Collectively, these multifunctional roles highlight the biological significance of microbial pigments in microbial physiology and environmental interactions.

Microbes in biotechnology

Biotechnology involves the utilization of living organisms and their biological products for large-scale industrial applications. Microbial biotechnology specifically deals with the use of microorganisms or their derivatives in various biotechnological processes. Also referred to as industrial microbiology, this field has existed for a long time but has gained significant advancements with the development of genetic engineering. Modern techniques allow scientists to manipulate DNA outside living cells, create novel genetic combinations, control gene expression through regulatory mechanisms, and introduce targeted mutations. Through these approaches, industrial microorganisms can be genetically modified by mutation or recombination to enhance their metabolic capabilities and improve efficiency for specific biotechnological applications. [10]. Advances in genetic and protein engineering have significantly enhanced the potential of genetically engineered microorganisms (GEMs) as customized biocatalysts. These developments allow scientists to combine specific metabolic pathways or enzymes from different organisms into a single host, enabling targeted biochemical reactions. This breakthrough demonstrated the medical potential of genetic modification and stimulated rapid growth in molecular cloning techniques, which facilitate the transfer of beneficial genes between organisms to produce desirable traits. Recombinant DNA (r-DNA) technology has since found widespread applications in fields such as agriculture, pharmaceuticals, gene therapy, vaccine development, and environmental bioremediation. Furthermore, progress in genomics, bioinformatics, synthetic biology, and advanced single-cell imaging techniques has accelerated innovation in microbial biotechnology. Emerging areas such as microbiome engineering and microbial-based bioenergy production hold great promise for transforming healthcare, industry, and environmental sustainability.

Genetic Engineering

Genetic engineering, commonly referred to as genetic modification, involves the deliberate alteration of an organism's DNA using advanced molecular techniques. This process includes the removal, addition, or modification of specific base pairs to introduce desirable traits or eliminate harmful characteristics, such as virulence genes in microorganisms. In earlier times, humans unknowingly modified microbes through traditional

fermentation processes to produce foods like bread, cheese, and wine. However, modern genetic engineering allows precise manipulation of microbial genomes for industrial, medical, and biotechnological purposes. Among microorganisms, bacteria and yeast—particularly lactic acid bacteria (LAB) and *Saccharomyces cerevisiae*—are widely used as model organisms in genetic engineering due to their ease of cultivation, genetic flexibility, and economic importance.

Vaccines

Vaccines represent one of the most significant achievements in modern medical science, playing a crucial role in the prevention and control of infectious diseases. However, with the continuous emergence of new and re-emerging pathogens posing global health threats, there is a growing need for ongoing innovation and refinement in vaccine development strategies. The design and production of vaccines are inherently linked to the study and application of various microorganisms, which serve as essential tools in understanding disease mechanisms, inducing immune responses, and developing effective immunization approaches against current and future pandemics. Microorganisms have always played an essential role in human existence, and their significance has rarely been debated. However, recent global health crises have demonstrated that infectious disease outbreaks are highly unpredictable. Even well-studied pathogens can undergo minor genetic changes that may lead to severe and widespread impacts on human populations. During a pandemic, vaccination strategies must prioritize safety, effectiveness, specificity, affordability, and rapid development. Ideally, vaccines should be scalable for mass production and easily distributable to affected regions within the shortest possible time frame. Based on their development principles and technological approaches, vaccines are broadly categorized into different types. [12]

Live attenuated vaccines

Attenuated vaccines are developed using live pathogens that have been deliberately weakened through genetic or laboratory modification so that they lose their ability to cause disease while retaining their capacity to stimulate the immune system. These modified microorganisms can replicate to a limited extent within the host, closely mimicking a natural infection without producing clinical illness. As a result, they trigger strong and long-lasting immune responses, including both antibody-mediated and cell-mediated immunity, which provide effective protection against future exposure to the actual disease-causing organism.

For example-

- Smallpox
- Rabies
- Tuberculosis/BCG
- Yellow fever
- Rotavirusreassortants
- Varisalla
- Cold-adaptedinfluenza
- Zoster

Inactivated vaccines

These are the vaccines which uses a strain of a bacteria or virus that has been killed with heat or chemical. This dead version of virus or bacteria is then injected into the body to elicit immune response [12]. Some examples are-

- HepatitisA
- Polio
- Rabies
- Pertussis
- Rickettsia
- Tick-borneencephalitis

- Japaneseencephalitis
- Cholera

Genetically Engineered and vectored vaccines

Genetically engineered vaccines are produced using recombinant DNA technology to modify pathogens or to generate specific antigenic proteins in suitable host systems such as bacteria or yeast. Instead of administering the whole pathogen, these vaccines introduce selected antigens that stimulate a protective immune response with improved safety. Vectored vaccines use harmless viruses or bacteria as carriers to deliver genes encoding target antigens into host cells, allowing the body to produce the antigen internally and trigger both humoral and cellular immunity[22]. Some examples are -

- Lymevirus
- Human Papillomavirus
- Meningococcal Proteins
- HepatitisB
- Adenovirus

Purified Protein and Polysaccharide Vaccines

Purified protein and polysaccharide vaccines are tupe of vaccines that contain purified capsular polysaccharide from bacteria, which can induce sufficient immunogenicity without the incorporation of the organism itself within the host body [17]. Some of them are-

Diphtheriatoxoid

- Tetanus Toxoid
- Anthrax protein
- Pneumococcal Conjugate
- Meningococcal Conjugate
- Typhoidps.

Microbes in Waste management

Microorganisms are fundamental to the natural recycling of organic matter in the environment. Since all naturally occurring materials are biodegradable, they can be decomposed by living organisms such as bacteria and fungi. Over time, microbes have proven to be highly beneficial in addressing various environmental challenges faced by humans. They have been effectively utilized in areas such as medical and veterinary science, genetic engineering, environmental conservation, and the treatment of municipal and industrial waste. In many cases, microbial-based approaches have offered more practical and economical solutions compared to conventional chemical or mechanical methods. The application of microbial technology has been particularly significant in waste management, where microorganisms contribute to biodegradation, bioremediation, nutrient recycling, and detoxification, thereby supporting environmental sustainability.

Microbial technology involves the use of selected microorganisms under controlled conditions to remove pollutants from different environments. While traditional culture-dependent methods were initially used to study microbes, modern culture-independent techniques have expanded our understanding of microbial diversity and their potential applications. Advances in technology have facilitated the use of diverse microbial communities in managing solid and liquid waste. Methods such as composting, anaerobic digestion, and bioremediation are widely employed in solid waste treatment. Similarly, wastewater treatment has been improved through processes like activated sludge systems,biofilm-based treatments, biosorption, and microbial electrochemical technologies. Additionally, harmful substances such as synthetic dyes and petroleum pollutants have been successfully degraded or removed from wastewater using microbial-based approaches.

ABSTRACT

This paper presents a study on the transitivity patterns in the academic writing of engineering students using the theoretical framework of Systemic Functional Linguistics propounded by M. A. K. Halliday. In Systemic Functional Linguistics, the clause is seen as a representation or illustration of experience through different process types, participants, and circumstances. The present research identifies how experiential meaning is constructed in the written discourse of English as a Foreign Language (EFL) learners in an engineering context. Data for the study were collected from paragraph writing tasks produced by first-year engineering students. The texts were categorised into clauses and analysed according to the six process types identified in the transitivity system. The six process types are material, mental, relational, verbal, behavioural and existential processes. The study focused on the distribution of these process types and the patterns of other entities, namely, participants and circumstantial elements that supplement them. The findings indicate that the material processes dominate the students' writing. This reflects the students' tendency to describe actions and procedures, which is characteristic of technical discourse. Relational processes occur with sufficient frequency, primarily in definitions and descriptions, while mental, verbal, behavioural, and existential processes appear less frequently. The results suggest that although students can represent experiential meanings related to technical activities, their writing demonstrates limited variation in process types. The study insists on the importance of strengthening the learners' awareness of clause structures and process types in academic writing. By incorporating transitivity analysis into language instruction, teachers can help students improve their linguistic resources effectively for expressing complex ideas in academic contexts.

Keywords: Transitivity analysis, Systemic Functional Linguistics, Clause analysis, Experiential meaning, Engineering students' writing style, EFL Academic writing.

INTRODUCTION

Language plays a crucial role in the understanding and expression of knowledge in academic contexts. In higher education, specifically in technical and professional disciplines such as engineering, students are expected to express complex ideas with good clarity and systematically through written discourse. In academic writing, effective organisation of meaning through clause structures are more important than vocabulary and grammatical accuracy. Therefore, clauses function as central units through which writers present experiences, construct logical relations, and convey information in a coherent manner. Systemic Functional Linguistics (SFL)developed by M. A. K. Halliday and further elaborated by Christian M. I. M. Matthiessen is an effective theoretical framework that examines how meaning is composed and presented through clauses. According to this framework, language performs three meta functions, namely, ideational, interpersonal, and textual. The ideational meta function, especially its experiential component, explains how language represents human experiences. Within this, the transitivity system plays a key role in analysing how processes, participants, and circumstances are comprehended and expressed through clauses. Transitivity analysis classifies processes into six types. They are material, mental, relational, verbal, behavioural, and existential. Each process type reflects a diverse way of representing experience in language. For instance, material processes express actions and events, mental processes represent cognition or perception, and relational processes establish relationships of identification or attribution. By examining the distribution of these processes in written discourse, researchers can understand how writers construct meaning and organise their knowledge and interpretation in writings.

In the perspective of English as a Foreign Language (EFL), studying the clause structures is particularly important because students often face difficulties in expressing and communicating complex ideas in academic writing. Engineering students, whose academic focus is primarily technical,rely heavily on certain types of processes such as material processes that describe actions, procedures, and technological operations. While this tendency exhibits the nature of technical discourse, it may also reveal the limitations in the linguistic resources used to express different kinds of experiential meanings. Earlier studies in Systemic Functional Linguistics have proved that transitivity analysis is an effective tool for examining patterns in student writing and identifying the linguistic resources that learners employ to represent experience in academic texts. Such analyses can reveal complex clause structures, students' preferred choice of process types, and the ways in which participants and circumstances are presented within the clauses. Understanding these patterns can provide the language teachers with valuable insightsto improve the students' academic writing skills.

Despite the flourishing interest in functional approaches to discourse analysis, relatively few studies have focused on the clause structures used by engineering students in EFL contexts. Examining these patterns can contribute to a better understanding of how learners compose experiential meaning in academic discourse and how their linguistic choices reflect the communicative demands of technical education. Therefore, the present study aims to analyse the transitivity patterns in the academic writing of engineering students using the framework of Systemic Functional Linguistics proposed by M. A. K. Halliday. By studying the distribution of process types and the composition of participants and circumstances in student writing, the research seeks to explore how experiential meaning is structured in the clauses of engineering students' academic texts.

The findings of this study are expected to contribute to both linguistic research and language pedagogy. From a linguistic perception, the study offers empirical evidence on clause patterns in EFL academic writing. From a pedagogical perspective, the work highlights the importance of developing students' knowledge about different clause structures and transitivity processes to enhance the effectiveness and clarity of their academic writing.

Research Objectives

The present study analyses the structures of the clauses used in the academic writing of engineering students using the framework of Systemic Functional Linguistics. The specific objectives of the study are:

1. To identify the process types used in the clauses of engineering students' academic writing.
2. To analyse how participants and circumstances are comprehended and presented in these clauses.
3. To study the frequency distribution of different transitivity processes in student writing.
4. To identify and understand how students express experiential meaning through clauses in English academic discourse.

Research Questions

The study is guided by the following research questions:

1. What process types are most frequently used in the clauses of engineering students' academic writing?
2. How are participants and circumstantial elements realised within these clauses?
3. How do engineering students represent experiential meaning through their clause structures?
4. What patterns emerge in the distribution of transitivity processes in student writing?

LITERATURE REVIEW

Transitivity analysis has been extensively used in linguistic research to study how language represents experience through clause structures. Within the framework of Systemic Functional Linguistics (SFL) proposed by M. A. K. Halliday (2014), the clauses are the primary units through which experiential meaning is realised. According to Halliday (2014), the transitivity system illustrates how processes, participants, and circumstances work together to represent events, states, and actions in the discourse. This framework classifies processes into six major types - material, mental, relational, verbal, behavioural, and existential processes. In their comprehensive description of English grammar, Christian M. I. M. Matthiessen and Halliday (2014) further elaborate that each process type reflects a particular way of construing experience. Material processes represent actions and events in the physical or external world, while mental processes signify cognition, perception, and emotion. Relational processes establish relationships between entities, typically expressing identification or attribution. Verbal processes involve acts of speaking, behavioural processes represent physiological or psychological behaviour, and existential processes express the existence of entities or events.

Several studies have used transitivity analysis to observe the patterns in different types of discourse. Ruquaiya Hasan (1985) highlights that transitivity patterns can reveal the way in which speakers and writers decode reality and conceptualise meaning within social contexts. From this perspective, analysing clause structures provides insights into how language users conceptualise their experiences and communicate them through writing. Transitivity analysis has also been widely applied in the study of academic and educational texts. In this regard, Brian Paltridge (2012) highlights that discourse analysis provides tools to examine how linguistic features function in real academic contexts.

Suzanne Eggins (2004) notes that analysing and understanding the process types in student writing help researchers understand how learners organise knowledge and represent ideas in academic discourse. Such analyses often reveal that writers at the beginner level rely solely on certain process types, which may show limited linguistic resources or practices related to the discipline. In the context of English as a Foreign Language (EFL), transitivity analysis has been used to explore the linguistic characteristics of students' writing. Geoff Thompson (2014) argues that examining transitivity patterns can help identify how learners present experiential meanings and how their linguistic choices differ from those of experienced writers. These studies prove that learners often display limited variation in process types, particularly in academic writing. Research has also shown that disciplinary contexts have influence on the distribution of process types in writing. Technical and scientific writing often emphasises material and relational processes, as these processes are commonly used to describe procedures, mechanisms, and definitions. As observed

by Jim Martin (2007), the linguistic choices made by writers are closely related to the communicative goals of specific disciplines. Although previous studies have explored transitivity patterns in various forms of discourse, fewer studies have examined the clause structures used by engineering students in EFL contexts. Understanding these patterns can provide valuable insights into how students represent experiential meaning in academic writing and how language instruction can support the development of effective academic discourse.

METHODOLOGY

Research Design

The study adopts a qualitative and quantitative descriptive research design. The analysis is conducted using the transitivity technique of Systemic Functional Linguistics.

Participants

The participants of the study are thefirstyear engineering students studying English as part of their undergraduate programme.

Data Collection

Data collection was done through a paragraph writing task. Students were asked to write a short academic paragraph (150–200 words) on a technical or academic topic such as:

- Importance of renewable energy
- Role of technology in modern education
- Advantages of artificial intelligence

Data Preparation

The collected texts were:

1. Transcribed and compiled into a corpus.
2. Categorised into individual clauses, since the clauses are the primary unit of analysis in the transitivity system.

Analytical Framework

The clauses were analysed according to the transitivity system proposed by M. A. K. Halliday, which classifies processes into six types. They are:

- Material processes
- Mental processes
- Relational processes
- Verbal processes
- Behavioural processes
- Existential processes

For each clause, the following elements were identified:

- Process
- Participants
- Circumstances

Data Analysis

The analysis involved:

1. Identifying the process type in each clause.
2. Identifying participants associated with the process.
3. Identifying circumstantial elements such as time, place, manner, cause, etc.

4. Calculating the frequency distribution of each process type.

The results were then interpreted to understand how students construct experiential meanings through clause structures.

Sample Clause Analysis

Below is a sample clause analysis demonstrating how the transitivity framework is applied.

Example 1

Sentence:

Students use renewable energy to reduce pollution.

Participant	Process	Participant	Circumstance
Students	use	renewable energy	to reduce pollution

Process Type: Material Process

Explanation:

The clause represents an action performed by the Actor ("Students") on a Goal ("renewable energy").

Example 2

Sentence

Engineers believe that renewable energy is important.

Participant	Process	Phenomenon
Engineers	believe	that renewable energy is important

Process Type: Mental Process

Example 3

Sentence

Renewable energy is an important solution.

Carrier	Process	Attribute
Renewable energy	is	an important solution

Process Type: Relational Process

RESULTS AND DISCUSSION

The collected student texts were categorised into clauses and analysed according to the transitivity framework proposed by M. A. K. Halliday. A total of 250 clauses were identified in the data collected from the students. Each clause was examined to determine its process type as well as the associated participants and circumstantial elements.

Distribution of Process Types

The analysis revealed the following distribution of process types:

Process Type	Frequency	Percentage
Material	118	47.2%
Relational	72	28.8%
Mental	28	11.2%
Verbal	16	6.4%
Existential	10	4%

Process Type	**Frequency**	**Percentage**
Behavioural	6	2.4%

The results show that material processes constitute the largest proportion of clauses in the students' writing. These processes typically represent actions, operations, or procedures. These findingsalign with the nature of engineering discourse, which frequently involves descriptions of technical activities and processes.
Examples from the student corpus include clauses such as:

"Engineers develop new technologies to improve energy efficiency."

In this clause, the participant 'Engineers' functions as the 'Actor' performing the material process 'develop', while 'new technologies' serves as the Goal.
The second most frequent category is relational processes, which are commonly used in definitions and descriptions. For example:

"Renewable energy is an important resource for sustainable development."

Here, the relational process links the carrier 'Renewable energy' with the attribute 'an important resource.' This pattern exhibits the explanatory and descriptive nature of academic writing.
Mental processes appear less frequently in the data. These processes express cognitive or perceptual states, as seen in clauses such as:

"Scientists believe that renewable energy will solve future energy problems."

The relatively low frequency of mental processes suggests that students focus more on describing external actions rather than expressing cognitive or evaluative perspectives. Similarly, verbal, behavioural, and existential processes occur only occasionally in the corpus. Verbal processes are used in contexts where students refer to statements or explanations made by experts, while existential processes are used to introduce the presence of certain phenomena. Overall, the results indicate that the students' writing is governed by material and relational processes, which together account for more than three-quarters of the clauses analysed. This not only reflects the technical orientation of engineering discourse but also indicate limited variation in the linguistic resources used by the students.

From a pedagogical perspective, these results imply that language instruction could benefit from integrating awareness of transitivity patterns and clause structures. By developing students' understanding of different process types, teachers can help the learners to expand their linguistic knowledge and produce more varied and effective academic texts.

CONCLUSION

The present study examined the clauses in the academic writing of engineering students using the transitivity framework of Systemic Functional Linguistics as developed by M. A. K. Halliday. By analysing the distribution of process types, participants, and circumstantial elements in students' writing, the study focused on understanding how experiential meaning is presented in the academic discourse of English as a Foreign Language (EFL) learners. The analysis revealed that material processes constitute the largest proportion of clauses in the students' writing. This finding indicates that the students frequently describe actions, procedures, and technological activities, which is consistent with the nature of engineering discourse. Relational processes also occur frequently, particularly in contexts where students define concepts or describe the characteristics of technological systems. Together, material and relational processes dominate the students' texts, reflecting their focus on describing actions and establishing conceptual relationships.

In contrast, mental, verbal, behavioural, and existential processes occur less frequently in the corpus. The relatively limited use of mental processes suggests that students seldom express cognitive or evaluative perspectives in their writing. Similarly, verbal processes are used mainly when referring to statements or explanations provided by experts or sources. These findings indicate that the students' writing relies on a limited range of transitivity patterns, which may limit the variety and depth of experiential meanings expressed in their texts. The study shows that transitivity analysis provides valuable insights into the linguistic resources used by learners in academic writing. By examining the interaction between processes, participants, and circumstances, researchers can understand how students organise their ideas and represent knowledge through clause structures. Such analysis is particularly useful in EFL contexts, where learners may face challenges in expressing complex meanings in English.

From a pedagogical perspective, the findings highlight the importance of incorporating functional approaches to grammar in language instruction. Raising students' awareness of different process types and clause structures can help them develop a broad range of linguistic resources for expressing their ideas in academic discourse. Teachers can integrate activities that encourage learners to analyse and practise various clause patterns, thereby improving both the clarity and sophistication of their writing.

Overall, this study contributes to the research works on transitivity analysis in academic discourse and highlights the value of Systemic Functional Linguistics as a framework for investigating learner writing. Future research may extend this work by examining larger corpora of student writing or by comparing the transitivity patterns of learners from different disciplinary backgrounds.

ABSTRACT

Environmental factors are widely recognized as major determinant factors of human health and make a significant contribution to the global burden of disease. Rapid industrialization, urban growth, an agricultural intensification, and climate change have led to an increasing human exposure to environmental stressors, including air and water pollution, hazardous chemicals, occupational hazards and extreme climatic events. These exposures have impacts on health throughout the life course and are implicated in the development of respiratory and cardiovascular diseases, neurological diseases, metabolic dysfunction, reproductive impairment, and malignancies. This review synthesizes the current state of scientific knowledge of the effects of environmental factors on human health by combining epidemiological knowledge with mechanistic knowledge from environmental toxicology. Particular attention is paid to air pollution, water contamination, chemical exposures, climate change and characteristics of the built environment. The review also identifies vulnerable populations which are exposed and susceptible to a greater degree by virtue of biological, social and economic factors. Despite progress in environmental monitoring and regulation, there are still considerable knowledge gaps in the area of cumulative exposures, low dose effects as well as interactions between environmental and social determinants of health. Strengthening interdisciplinary research and environmental governance and

evidence-based policy is key to reducing the risk of environmental health problems and sustainable development.

Keywords: Environmental health; Air pollution; Climate change; Chemical exposure; Public health.

INTRODUCTION

Human health is inextricably connected with the quality of the environment. Environmental determinants are physical, chemical, biological and socio-economic factors other than the individual that determine both risk of disease and overall well-being. According to global assessments environmental risks are a substantial proportion of preventable morbidity and mortality, especially in low- and middle-income countries [1]. Historically improvements in sanitation conditions, drinking water quality and air pollution control have resulted in significant public health improvements. However, the current environmental challenges are becoming more and more complicated, more global and are motivated by anthropogenic activities. Industrial emissions, fossil fuel combustion, land-use change, and climate variability have contributed to the increased exposure of people to environmental hazards [2]. Unlike the short-term effects of acute toxic incidents, their effects characterized by modern environmental health events which often result from chronic exposures with low-level fluxes time-courses and interactions in susceptibility of the individual's genotype as well as the course of life [3]. This review is designed to provide a synthesis of the current state of knowledge with regard to environmental determinants of human health and to identify some key mechanistic pathways and areas for future research as they relate to environmental protection and public health policy.

Environmental Determinants and Their Influence On Human Health Outcomes

Air Pollution

Air pollution is one of the most extensively studied environmental health hazards. Major pollutants include particulate matter ($PM_{2.5}$ and PM_{10}), nitrogen oxides, sulphur dioxide, ozone, and volatile organic compounds [4]. Long-term exposure to fine particulate matter is strongly associated with increased mortality from cardiovascular and respiratory diseases [5]. The major environmental stressors that have impacts on health in humans were represented in Table 1. At the biological level, inhaled pollutants induce oxidative stress and chronic inflammation, leading to endothelial dysfunction, altered autonomic regulation, and impaired pulmonary defence mechanisms [6]. These processes contribute to asthma, chronic obstructive pulmonary disease, ischemic heart disease, stroke, and lung cancer [7]. Emerging evidence also links air pollution to adverse pregnancy outcomes and neurodevelopmental disorders [8].

Water Pollution

Access to safe drinking water is essential to human health, but water contamination is an environmental problem. Chemical pollutants like arsenic, lead, mercury, nitrates, and pesticide residues etc. are commonly found in surface and ground water sources [9]. Chronic exposure to arsenic via water for drinking has been linked to cardiovascular disease, diabetes, neurological impairment and cancer of various types [10]. Mechanistic studies suggest that numerous waterborne contaminants disturb mitochondrial function, cause oxidative DNA damages and impact gene expression by epigenetic mechanisms [11]. In addition to chemical risks, a lack of sanitation and microbiological contamination still result in a huge load of water-borne infectious diseases, especially in vulnerable populations [12].

Chemical Exposures

Human exposure to synthetic chemicals is via the air, water, food, through the workplace, and from consumer products. Persistent organic pollutants, pesticides, plasticizers and industrial solvents are of particular concern because of their bioaccumulative properties and long biological half-lives [13]. Many chemicals are endocrine

disruptors and affect the hormonal regulation and metabolic processes [14]. Others have genotoxic effects which result in damage to DNA and dysfunction of repair mechanisms [15]. Epigenetic changes stimulated by chemical exposure have been linked as a preceding factor in the developmental origins of chronic disease, including early-life chemical exposures as a risk factor for adulthood health [16]. The biological plausibility of these associations is illustrated in Figure 1.

Climate Change

Climate change is another rapid and critical factor that determines human health. Increasing global temperatures have led to more frequent and more severe heatwaves, contributing to heat-related illness, dehydration, renal failure and decompensation of cardiovascular function [17]. Extreme weather events, e.g., floods and storms raise risks for injuries and infectious disease outbreaks and mental health disorders [18]. Climate-driven changes in the environment also affect the distribution of vector-borne diseases, leading to the increased geographical distribution of malaria, dengue and other infections [19]. Indirect impacts are food insecurity, undernutrition, population displacement and resultant health challenges [20]. The interconnected direct and indirect health effects of climate change are illustrated in Figure 2.

Occupational and Built Environment Factors

Occupational exposures to dusts, metals, solvents and radiation continue to be equally important causes of preventable disease [21]. Prolonged exposure to silica and asbestos causes pulmonary fibrosis and malignancy while solvent exposure has been linked to neurotoxicity and liver damage [22]. The built environment has an effect on health through the quality of housing, the design of cities, the transportation system and access to green spaces. Poor indoor air quality and overcrowding is a source of increase in respiratory morbidity, while green environments have been associated with better mental health and reduced cardiovascular risk [23].

Vulnerable Populations and Environmental Inequalities

Environmental exposures are disproportionately distributed among populations. Children, pregnant women, elders and socio-economically poorer communities are more vulnerable because of physiological sensitivity, cumulative exposure and an inability to access health care [24]. Population groups with high biological sensitivity or disproportionate exposure to environmental hazards are summary in Table 2. Environmental injustice has been an important issue that perpetuates the already existing health disparities in society and the need for equity-focused environmental policies [25].

Knowledge Gaps And Future Directions

Despite a lot of progress, significant knowledge gaps exist in the understanding of the health effects of combined exposures, low dosage effects, and long-term effects of emerging contaminants. Greater integration of environmental monitoring, epidemiology, and mechanistic toxicology is required to provide information for the development of evidence-based regulation or prevention strategies [26].

CONCLUSION

Environmental factors have profound and multifaceted impacts on human health via linkages between biological and social pathways. Air and water pollution, chemical exposures, climate change and occupational hazards are seen collectively to contribute to the global burden of disease. Addressing these challenges requires established environmental governance, interdisciplinary research and policies focused on protection of vulnerable populations. Advancing environmental health is key to achieving sustainable development and the public health resilience of people.

Table 1. Major environmental factors, dominant exposure pathways, underlying biological mechanisms, and associated human health outcomes.

Environmental factor	Dominant exposure pathways	Underlying biological mechanisms	Associated human health outcomes
Ambient air pollution	Inhalation of particulate matter ($PM_{2.5}$/PM_{10}), nitrogen oxides, ozone, Sulphur dioxide from traffic, industry, and energy production	Oxidative stress, chronic airway and systemic inflammation, endothelial dysfunction, altered autonomic regulation	Asthma, chronic obstructive pulmonary disease, ischemic heart disease, stroke, lung cancer
Indoor air pollution	Inhalation of smoke from biomass fuels, tobacco smoke, volatile organic compounds from household materials	Impaired pulmonary defense, oxidative injury to airway epithelium, immune modulation	Acute respiratory infections, chronic respiratory disease, adverse pregnancy outcomes
Water contamination	Ingestion of contaminated drinking water containing heavy metals, nitrates, pesticides, microbial pathogens	Mitochondrial dysfunction, oxidative DNA damage, disruption of enzymatic and metabolic pathways	Gastrointestinal infections, neurological impairment, cardiovascular disease, diabetes, cancers
Chemical pollutants	Dietary intake, dermal contact, occupational exposure to pesticides, persistent organic pollutants, plasticizers	Endocrine disruption, genotoxicity, epigenetic modification, immune dysregulation	Reproductive disorders, developmental toxicity, metabolic syndrome, hormone-related cancers
Climate change-related stressors	Heat exposure, extreme weather events, altered vector ecology, food and water insecurity	Heat stress, dehydration, inflammatory responses, altered disease transmission dynamics	Heat-related illness, infectious diseases, malnutrition, mental health disorders
Occupational hazards	Inhalation or dermal contact with dusts, metals, solvents, radiation in workplace settings	Cumulative tissue toxicity, chronic inflammation, cellular damage	Occupational lung disease, neurotoxicity, musculoskeletal disorders, malignancies
Built environment factors	Poor housing quality, indoor pollutants, limited green space, urban heat island effects	Chronic stress activation, reduced physical activity, prolonged pollutant exposure	Cardiovascular disease, respiratory morbidity, anxiety, depression
Noise pollution	Chronic exposure to traffic, industrial, and urban noise	Neuroendocrine stress response, sleep disturbance, autonomic imbalance	Hearing loss, hypertension, cardiovascular disease, impaired cognitive performance
Radiation exposure	Medical, occupational, and environmental radiation sources	DNA damage, chromosomal instability, impaired cellular repair mechanisms	Increased cancer risk, reproductive and developmental effects

Table 2. Population groups with increased vulnerability to environmental exposures and their predominant environment-related health risks.

Population group	Key environmental exposures	Determinants of increased vulnerability	Predominant health risks and outcomes
Infants and young children	Indoor and outdoor air pollution, contaminated drinking water, pesticide residues, second-hand smoke	Immature detoxification systems, rapid growth and organ development, higher intake per body weight	Impaired lung development, neurodevelopmental deficits, increased susceptibility to infections
Pregnant women	Air pollutants, heavy metals, endocrine-disrupting chemicals, heat extremes	Physiological and hormonal changes, placental transfer of toxicants, increased metabolic demands	Preterm birth, low birth weight, developmental toxicity, pregnancy complications
Older adults	Ambient air pollution, heatwaves, indoor pollutants, chronic noise	Reduced physiological reserve, impaired thermoregulation, higher prevalence of chronic disease	Cardiovascular events, respiratory exacerbations, heat-related illness, cognitive decline
Occupationally exposed workers	Dusts, metals, solvents, pesticides, radiation, prolonged noise	Repeated and prolonged exposure, insufficient protective measures in some settings	Occupational lung disease, neurotoxicity, hearing loss, elevated cancer risk
Socio-economically disadvantaged communities	Proximity to industrial emissions, poor housing, inadequate sanitation, unsafe water	Limited access to healthcare, nutritional stress, environmental injustice	Higher burden of chronic disease, infectious diseases, reduced life expectancy
Urban populations	Traffic-related air pollution, noise, urban heat island effects	High population density, limited green space, sedentary lifestyle patterns	Cardiovascular disease, respiratory morbidity, stress-related mental health disorders
Rural and agricultural populations	Pesticide exposure, biomass fuel smoke, contaminated groundwater	Occupational exposure, limited regulatory oversight, restricted healthcare access	Acute and chronic poisoning, respiratory disease, neurological effects
Indigenous and marginalized groups	Environmental degradation of traditional lands, contaminated natural resources	Dependence on local ecosystems, limited political representation	Nutritional deficiencies, chronic disease, loss of health resilience

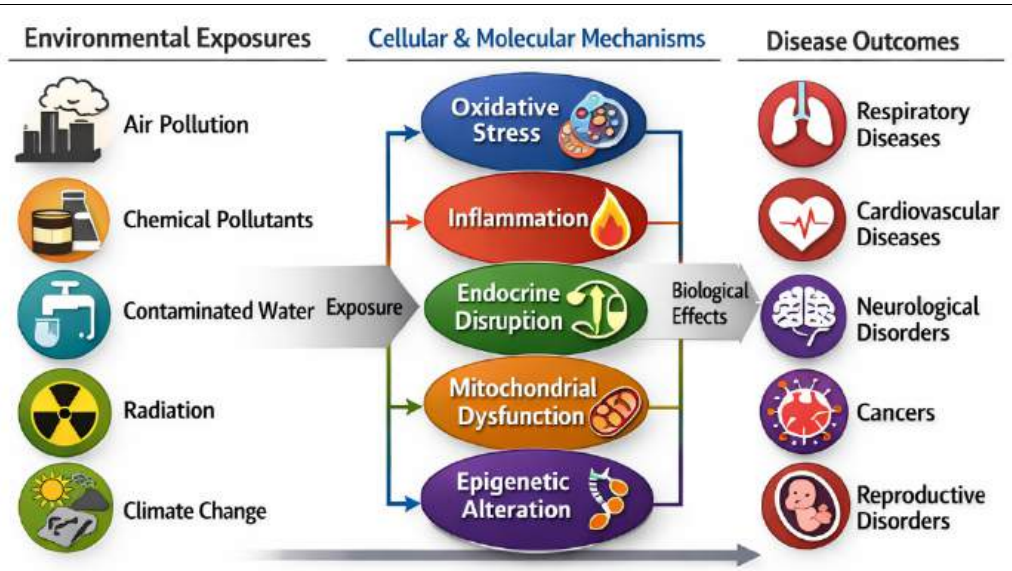

Figure 1. Pathways linking environmental exposures to biological mechanisms and disease outcomes

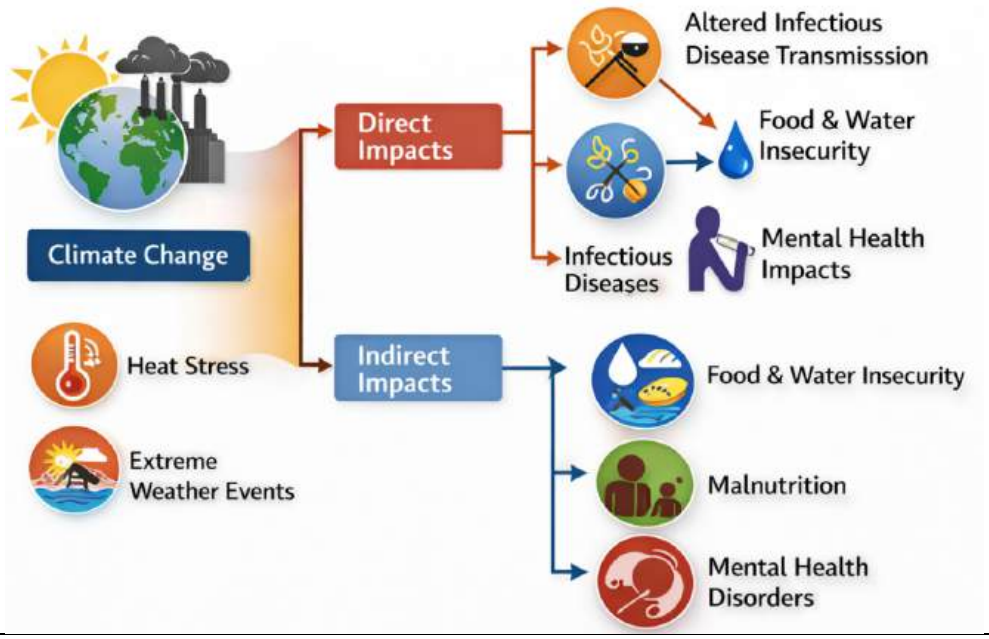

Figure 2. Direct and indirect health impacts of climate change

ABSTRACT

This study examines the economic contributions of registered migrant workers in Tiruvallur district, Tamil Nadu, with a focus on the construction, manufacturing, and service sectors. Tiruvallur, part of the Chennai metropolitan region, has witnessed rapid industrial and infrastructure growth, leading to increased dependence on migrant labour. The study employs both primary and secondary data, including records from the Labour Department under the Inter-State Migrant Workmen Act, 1979, and structured questionnaires administered to 60 randomly selected registered migrant workers across the three sectors. The findings reveal that migration is influenced by both push and pull factors. Construction and service sector workers primarily migrate due to push factors such as unemployment, low wages, and debt, whereas manufacturing sector workers are attracted by pull factors, including higher wages, better employment opportunities, and improved living conditions. Sectoral analysis indicates that manufacturing offers better educational and income profiles, stable employment, formal wage payments, and higher savings, whereas construction and service workers experience irregular work, long hours, and lower financial security. Overall, registered migrant workers constitute over 83% of the workforce in the construction and manufacturing sectors, highlighting their critical role in sustaining industrial and urban growth in the district. Regression analysis confirms that economic variables—income, expenditure, savings, and migration factors—significantly influence the type of employment migrant workers undertake. Despite their contributions, challenges persist in terms of job security, social protection,

housing, and access to welfare services. This study emphasizes the need for strengthened labour welfare policies, skill development programs, and social security measures to enhance both the well-being of migrant workers and their economic contributions. The findings provide actionable insights for policymakers aiming to promote inclusive and sustainable regional economic development.

Keywords: Migrant workers, Tiruvallur district, economic contribution, labour migration, push-pull factors, manufacturing, construction, service sector, labour welfare.

INTRODUCTION

Labour migration has emerged as a significant feature of India's contemporary economic landscape, particularly evident in rapidly industrializing regions. Migrant workers play a crucial role in sustaining urban and suburban economies by addressing labour shortages, supporting industrial expansion, and contributing to infrastructure development. In recent years, the registration of migrant workers under various state and central welfare schemes has gained policy importance, aiming to improve labour management, social security, and economic inclusion. Therefore, understanding the economic contributions of registered migrant workers at the district level becomes essential for informed policy-making and regional planning. Tiruvallur district, located in the northern part of Tamil Nadu and part of the Chennai metropolitan area, has emerged as a major hub of industrial and infrastructure development. The district boasts a wide range of economic activities, including manufacturing, construction, power generation, and related service sectors. The rapid expansion of these industries has increased the reliance on migrant workers, particularly registered migrant workers, who form an integral part of the district's workforce. Their participation has not only enhanced productivity but has also impacted local labour markets, consumption patterns, and overall economic output. Despite their growing importance, the economic activities of registered migrant workers in Tiruvallur district remain insufficiently explored. Most existing studies focus on state-level trends or the social challenges faced by migrant workers, with limited attention given to district-specific economic contributions. This gap highlights the need for a centralized analysis that assesses how registered migrant workers contribute to sectoral development, job creation, and overall economic growth at the local level.

Objectives

To probe into push and pull factors of registered migrant workers contribution to the Manufacturing, Construction and Service sector in the study area.

Hypothesis

H_{01}: Push and Pull factors have no significant influence on the contribution of registered migrant workers to the manufacturing, construction, and service sectors in the study area.

Statements of the problem

Migrant workers play a significant role in the workforce of Tiruvallur district, particularly in the construction, manufacturing, and service sectors. Despite government efforts to register them for their welfare and regulation, their economic contribution at the district level remains largely unexplored. Most studies focus on social issues or state-level trends, leaving a gap in understanding sector-specific impacts. Challenges such as lack of registration, informal employment, and wage disparities may limit their productivity and economic contribution. Consequently, the lack of clear data on registered migrant workers prevents policymakers from fully appreciating their role in local economic development. This study attempts to bridge this gap by analysing the economic contributions of registered migrant workers in Tiruvallur district.

Scope and significance of the study

This study analyses the economic conditions of registered migrant workers in the Tiruvallur district of Tamil Nadu, focusing specifically on low- and semi-skilled workers based on push and pull factors. It examines various economic variables, including wages, working hours, and remittance practices, and also considers social factors such as living conditions and workplace challenges. Using primary and secondary data, this study highlights the often-underestimated contributions of migrant workers and aims to inform policymakers regarding labour welfare policies. It also emphasizes the importance of fair wages and improved working conditions for enhancing labour productivity.

Overview of Reviewd Literature and Research Gap

This study examines the migration of people from one place to another due to factors such as social development, economic growth, unemployment, education, natural disasters, and political changes. The study analyses the demographic trends, socio-economic drivers, employment, and living conditions of inter-state migrant workers in India. It also assesses the legal protections provided by the Inter-State Migrant Workmen Act of 1979 and the challenges they face in the construction, manufacturing, and service sectors. To mitigate the economic and social impacts, the study recommends an integrated, rights-based policy approach, including strengthening laws, improving social welfare programs, government interventions, and establishing updated data collection systems. Chellappa(2025) Migrant workers in the Indian construction industry face significant risks due to safety deficiencies and cultural barriers. This study identified key factors affecting their safety through a literature review and expert Delphi surveys. The first round refined these factors, while the second round highlighted education, risk attitudes and safety training as key issues. The third-round prioritized strategies, emphasizing the need for safety training in the native languages of migrant workers, effective communication and a positive safety culture. These findings are intended to guide industry stakeholders in improving the safety of migrant workers. The Delphi panel included nine experienced safety experts with relevant academic backgrounds. Alvarado, Mariana et.al (2025) Have studies the business migration is a significant form of labour migration, primarily involving intra-corporate transferees, service providers, and business visitors. This type of migration is facilitated by trade agreements and national laws, allowing migrants to temporarily stay in their home countries and maintain their employment contracts. This understudied migration, which accounts for almost half of all regulated labour migration within Switzerland, is strongly associated with trade and investment relations and multinational corporations. In contrast, trade agreements that facilitate this type of labour migration have no formal effect.Joseph, Lincy et. al (2025) A study conducted in Doha, Qatar, found that Indian migrant construction workers face numerous challenges in employment, housing, health and social adaptation. Key themes included job insecurity, financial hardship, language barriers, overcrowded housing, limited healthcare access and mental and physical health issues, among others. The findings underscore the need for improved mental health services, sustainable employment policies, better living conditions and access to culturally appropriate healthcare. M. Mathan, (2025) The study examined the socio-economic conditions and legal protections for interstate migrant workers in the hotel sector of Tirunelveli district, and highlighted significant challenges in the enforcement of workers' rights. Of the 75 respondents surveyed, many workers face wage cuts (66%), unpaid overtime (73%), and workplace accidents (66%). Despite laws such as the Interstate Migrant Workers Act of 1979 and ILO conventions, enforcement is weak, largely due to illiteracy and lack of union representation among migrant workers. Economic need influences 46% of migration decisions, with younger workers accepting poor working conditions. The study called for reforms such as awareness programmes, better enforcement, and improved social protection to improve migrant worker protection in India's hospitality sector.

This study focuses on registered migrant workers in the construction, manufacturing, and service sectors. Most studies have concentrated on the informal sectors and unregistered workers, highlighting the socio-economic challenges faced by migrant populations, such as job security, living conditions, and access to welfare programs. By examining the contributions and challenges of registered migrant workers, this study aims to address their grievances and thereby guide policy and labour welfare initiatives.

MATERIALS AND METHODS

This study is based on fieldwork encompassing qualitative and quantitative methods, secondary and primary data have been collected. This data has been gathered from the records of workers registered with the Labour Department under the Inter-State Migrant Workmen (Regulation of Employment and Conditions of Service) Act of 1979 (online portal registration up to December 2025), and from newspapers, magazines, and websites. The objective of this study is to examine the employment opportunities of migrant workers from other states working in the construction, manufacturing, and service sectors in Tamil Nadu, based on push and pull factors, and to investigate the reasons for such migrations and the associated opportunities. Furthermore, registered migrant workers were selected. From this group, a total of 60 individuals were randomly selected, 20 from each sector (construction, manufacturing, and service), and primary data was collected. A structured questionnaire was used to collect data from the migrant workers. This was further strengthened through field surveys, direct field observations,informal discussions with workers, employers, and officials, and conversations with local citizens and workers.

RESULTS AND DISCUSSIONS

This table-1 illustrates the distribution of migrant workers across three key economic sectors: construction, manufacturing/industries, and services. A total of 111,387 workers is registered, and their contributions are presented in both absolute numbers and percentages. The largest share of migrant workers is in the manufacturing and industrial sectors. These sectors employ 47,097 workers, representing 42.28% of the total. This indicates that the industrial and manufacturing sectors rely slightly more on migrant workers than the construction sector. The construction sector employs 45,983 migrant workers, accounting for 41.28% of the total. This shows that construction is a significant employment sector for migrant workers. The service sector has the lowest proportion, with 18,307 workers, representing 16.44% of the total. This suggests that migrant workers are less concentrated in service-oriented jobs compared to industrial and construction work. The table highlights that migrant workers are predominantly employed in the manufacturing and construction sectors, with these two sectors together accounting for over 83% of the total registrations. While the service sector is important, it employs a relatively smaller proportion of migrant workers.

The table 2 shows that migration is influenced by both push and pull factors, but their importance varies across sectors. Among construction workers, migration is driven primarily by push factors rather than pull factors. Unemployment is the most significant factor, affecting 13 workers (21.7%). Low wages and debt repayment each affect 3 workers (5%). Climate and agricultural failure play a minor role (1 worker, 1.7%). No pull factors (such as better wages or job opportunities) were reported for this group. This similarly shows that construction workers migrate mostly due to economic hardship and lack of opportunities in their home areas. Manufacturing sector workers are influenced solely by pull factors. Higher job opportunities and permanent employment were cited by 7 workers (11.7%), better wages by 6 workers (10%), better living conditions by 4 workers (6.7%), and through friends or relatives already working there by 3 workers (5%). No push factors were reported in this case. This indicates that manufacturing sector migration is opportunity-driven and is motivated by better jobs, wages, and living conditions. Similar to construction workers, service sector workers migrate primarily due to push factors. Unemployment is the main reason, affecting 14 workers (23.3%), followed by debt repayment affecting 4 workers (6.7%). Low wages affect 2 workers (3.3%). No pull factors were reported. This shows that service sector workers are mostly compelled to migrate due to economic pressures.

The table illustrates the educational level, income, expenditure, and savings patterns of workers engaged in the construction, manufacturing, and service sectors. It indicates that manufacturing employment has attracted relatively better-educated workers, while construction and service jobs primarily employ workers with secondary education. Manufacturing offers comparatively higher income opportunities, while service workers are concentrated in the lower income bracket. Lower expenditure among construction and service workers reflects lower income levels and

basic consumption patterns. Manufacturing workers demonstrate better savings capacity, while service workers experience financial vulnerability. The analysis reveals that manufacturing sector workers are relatively better off in terms of education, income, spending capacity, and savings. In contrast, construction and service sector workers are predominantly those with secondary education, earning lower incomes, having lower expenditures, and possessing limited or negative savings, indicating economic insecurity. This highlights significant disparities in economic activity and employment opportunities across different types of jobs.

Table 4 show that Manufacturing sector workers (33.3%) are employed continuously throughout the year, indicating stable employment. Employment for construction sector workers is largely irregular (18.3%) and seasonal (8.3%), with only 6.7% having permanent jobs. Service sector workers (33.3%) are also engaged in irregular employment. This shows that the manufacturing sector provides the most stable jobs, while job security is not consistent in the construction and service sectors. Working hours per day: All manufacturing sector workers (33.3%) work 8 hours a day, reflecting stable working conditions. All construction and service sector workers (33.3% in each sector) work more than 10 hours a day, indicating long and arduous working hours. Compared to the manufacturing sector, long working hours are a significant problem in the construction and service sectors. Wage payment method: All manufacturing sector workers (33.3%) receive monthly wages, indicating formal employment arrangements. The majority of construction sector workers receive daily (18.3%) or weekly (8.3%) wages, with only a small number receiving monthly wages (6.7%). Most service sector workers receive daily wages (30%), with a small proportion receiving weekly wages (3.3%). Regular monthly wages are primarily found in the manufacturing sector, while construction and service sector workers rely on short-term and less secure wage payment methods.

Hypothesis testing

Null Hypothesis (H_0)

The predictors have no significant effect on current type of work

Alternative Hypothesis (H_1)

The predictors have a significant effect on current type of work.

The ANOVA results show that the regression model is statistically significant with an F value of 4.098 and a p-value of 0.006. Since the p-value is less than 0.05, it indicates that the model provides a good fit to the data. This means that the independent variables The predictors together have a significant influence on the dependent variable, current type of work. The regression sum of squares (9.184) out of the total sum of squares (40.000) shows that the model explains approximately 23% of the variation in the current type of work. The remaining variation is due to other factors not included in the model and random error. Overall, the ANOVA table confirms that the predictors jointly contribute to explaining differences in the current type of work.

Push and pull factors are the reasons why migrant workers are attracted to the Tiruvallur district.

Chennai, the capital of Tamil Nadu, and its neighbouring districts of Tiruvallur and Kanchipuram, have emerged as a major hub for Special Economic Zones (SEZs) and Information Technology/Information Technology Enabled Services (IT/ITES). Tamil Nadu is a leading manufacturing hub in India, particularly the Tiruvallur and Kanchipuram districts, which have a strong base in various sectors such as automobiles, textiles, electronics, and leather goods. Tamil Nadu ranks first in the country in terms of the number of factories and industrial employment. It has also earned the title of 'Detroit of Asia' for its dominance in the automotive sector. Excelling in exports in the electronics, automotive components, and apparel sectors, and supported by strong government support and infrastructure facilities (SIPCOT, TIDCO), the state has cemented its position as an industrial powerhouse. Furthermore, it is also promoting growth in high-potential sectors such as electric vehicles, aerospace, and renewable energy components.

As a result, there is a high population density here, and the service sector, particularly the food industry and retail businesses, focuses on meeting the needs of the people. Therefore, there are numerous job opportunities in these sectors, making this district a preferred destination for migrant workers. At the same time, it is also considered a safe

district. Hence, migrant workers invite their family members and friends here, which is evident from the fact that they are from the same state and even the same village. They also live in nuclear families. Similarly, unskilled, semi-skilled, and less educated individuals find employment in the sectors here. Furthermore, this construction sector, encompassing both manufacturing and service industries, includes both experienced and inexperienced workers, with experienced workers receiving higher salaries. Workers from other states report that while salaries are higher here, the cost of living is also high. These migrant families have transferred their ration cards here, allowing them to obtain subsidized goods, which has helped reduce their expenses.

When examining whether migrant workers in the construction and service sectors have excessively long working hours and how they are affected by them, the reality is that this is not the case. Working hours are divided into shifts and implemented with the consent of the migrant workers. Despite the lack of formal legal regulations, they are employed based on humanitarian principles. At the same time, migrant workers voluntarily work overtime and receive commensurate wages. When asked why they work long hours, they respond, "We came here to earn money." While in some places they are exploited due to inhumane working conditions and low wages, these workers leave those places. Sometimes, if they have received an advance payment, they are forced to work until the debt is repaid; such practices are reprehensible. In such situations, they must be vigilant and cautious. Government intervention becomes necessary in these circumstances.

CONCLUSION

This reveals that migration is primarily driven by economic needs and opportunities. Push factors such as unemployment, low income, poverty, and lack of alternative livelihoods compel workers to migrate from their native regions. Simultaneously, pull factors such as better job opportunities, higher wages, industrial growth, and improved infrastructure attract migrant workers to Tiruvallur. Registered migrant workers play a crucial role in the district's economic development by fulfilling labour demands in key sectors such as construction, manufacturing, services, and the informal economy. Their contribution enhances productivity, supports industrial expansion, and sustains urban development. Furthermore, the remittances they send back to their home regions contribute to poverty reduction and improve the well-being of their families. However, migrant workers face challenges such as job insecurity, limited access to social security, inadequate housing, and restricted access to basic services. Addressing these issues through effective registration, labour welfare policies, skill development programs, and social security measures will not only improve the living conditions of migrant workers but also strengthen their overall contribution to the local economy. Migrant workers are an integral part of Tiruvallur district's workforce, and ensuring their inclusion and well-being is essential for achieving sustainable and inclusive economic growth.

LIMITATIONS OF THE STUDY

This study has analysed migrant workers across the district until December 2025, based on online website registrations under the Tamil Nadu Inter-State Migrant Workmen (Regulation of Employment and Conditions of Service) Act, 1979. It specifically includes only those migrant workers registered with three particular establishments: a construction company, a manufacturing company, and a specific restaurant.

ABSTRACT

The study examines and explores the optimistic values in ShashiDeshpande's select novels and other select literary voices. Human life seems to be filled with happiness, but scratching the glossy surface of human life brings the need to discover optimism in each aspects of life. Though people are gifted with wealth and social status, there is a lack of contentment as the expectation of their inner self is very high. People compare and compete with each other that result in distress and they also lose their patience to accept and learn from failure and criticism. Human beings struggle to accept their roles and they are prejudiced of their own actions. This research analyses positive aspects that enrich human lives, and helps people create happiness by going beyond their barriers acknowledging that only positive attitude will bring progress in life.

Keywords: contentment, patience, Happiness, Inner self, Progress

INTRODUCTION

Optimism is the faith that transits to accomplishment. Nothing can be achieved in life without confidence and hope.Samuel Johnson, the famous English writer opines: "The natural flights of the human minds are not from pleasure to pleasure, but from hope to hope." Wordsworth, a major English poet of Romantic period, expresses in his poem *The Daffodils* that optimism can be sensed everywhere on earth. As Wordsworth sees the sight of the golden daffodils in the poem *The Daffodils* and enjoys the bliss of solitude and feels stress free, ShashiDeshpande's character Sumi also enjoys the spider that makes its web and realises that if people have the attitude to discover, to enjoy, to love, and to admire nature, their pensive mood will definitely be transformed into a peaceful one in life. It is one of the best sources to keep human beings calm and happy.Sumi learns to realise the realities of life and becomes very hopeful and manages to keep herself calm and happy by investing her time in admiring nature.

Rabindranath Tagore states in his work *My Reminiscences* (1912) that he was in utmost misery and hopelessness and also assumed that he missed thewholething in the world when his mother reached the heavenly abode.In the beginning he struggled to surpass the sufferings but with each passing day, he was able to recuperate. He compared his life with a young plant that surrounds by darkness and tries to stretches itself and finally finding its way to light. Like Rabindranath Tagore, the character Urmi in the novel *The Binding Vine* stretches herself to find new way to move on with her life when the death of her daughter Anu threw the darkness of negation just as Rabindranath Tagore did when his mother died. Thus, Urmi registers in the minds of the readers to realise that human life is comprised of joys and sorrows and should stop exaggerating their sufferings.

Eleanor Roosevelt, an American politician propounds 'Optimism' as: "No one can hurt you without your consent. Nobody can take our self- confidence and self- esteem without our permission" (This is My Story 1939). Similarly, Jeeja, Nayana in *That Long Silence* never lose their confidence and never feel humiliated despite their husband's domination and inhuman treatment. The characters Nayana and Jeeja assert that the positive energy in a person is the basic source to build the six SC's in life, the self-confidence, self-conscious, self-confession, self-correction, self-command and self-creation. Positive thinking makes a person feel proud and prestigious of his existence. Therefore, it is natural that positive thinking helps people in controlling their emotions and leading a contented life.

Anthony A. Rose brings the words of Joy (Jinghui) Xu, Vice President and Human Resource Officer, Asia Pacific Region of Pepsi Co expresses:To grow up in failure and adversity with optimism is her personal motto. As he mentioned people have to understand that life is not a bed of roses. It is the failurethat sets the stepping stone for triumph and happiness.The author aslo says that is his positive hope that made him a better human being, a better leader, a better wife, a better daughter, and a better mum. (206 Daddy's Logic). Thus, the author expresses that some of the factors in life do not remain in the hands of human beings like losing the loved ones, sickness and death, and so people should possess the power of resilience in life. A Christmas pantomime called *Mother Goose rhyme* expresses the view of Optimism as:

If there is a solution, try to discover it
If there be none, never mind it. (1765)

Mother Goose rhymes communicate to people to get adapted to what is inevitable and devastating and to move on with the other objectives in life without wasting time and energy. Likewise, Shashi Deshpande's character Yamuna Bai in the novel *A Matter of Time* has never loses her objective of starting a school despite her tragedies in life. Helen Keller, a popular author wrote a book on 'Optimism' called *My Optimism*. In this essay she advocates thatoptimism is the faith that transits to accomplishments and happiness in life. And nothing can be done with lack of hope and confidence. Helen Keller's mother and her teacher, Anne Sullivan, took great pain in teaching her the pains and pleasures of human life and that helped her to create a remarkable place not only in the field of literature but also in the hearts of people.

Anita Desai, one of the eminent Indian writers professes to the students of literature. She says that usually a feeling of disappointment follows the book, because what she hoped to write is not what she actually accomplished, however it becomes a motivation for her (The Sidney Harman – Residence program 2003). As she mentioned writing became a great source of inspiration. Similarly Shashi Deshpande's characters likeMira and Sumi comprehended that every disappointment in life is an opportunity for human beings to foster their achievements. Arthur Miller, an American playwright and essayist, states in *Tragedy and the Common Man*: "Tragedy makes a person more optimistic rather than a comedy" (3). Optimistic mindset is also created in people through their discouragement and humiliation and it also paves way for their growth. ShashiDeshpande's characters like Shakutai, Charu, ,Aru ,Gopal and Mira explore their own experiences of poverty and it is their experience that motivates them to be optimistic even in the darkest of times.

In the world that changes rapidly,Human beings have to remain motivated all the time and acquire the skills that transform weakness to strength. Winston Churchill, a British Statesman states that a pessimist sees the difficulty in every opportunity; an optimist sees the opportunity in every difficulty. Likewise, Sumi's daughters Aru, Charu and Seema help people to move beyond and cross the boundaries of their comfort zone to lead a better life. A researcher from Chafey College opines that Optimism has been the medicine to improive the immune system and it has been helping balance their lives. He also says that gratitude is the most important quality that a human being must possess and that quality is completely connected with optimism and has been rooted that grateful people are happier, and less stressed, and are also less depressed. The portrayal of Belinda and Aru's grandmother bring the importance of being happy in the midst of all struggles. ShashiDeshpande says that human beings have forgotten the art of keeping themselves happy but they need people around them to cheerful always. Therefore, self-consciousness of one's own facial expressions play an important role as it conveys reflects and leads to change in the society.

The right attitude is one the key values that leads to accomplishment in life.The famous story of an unknown makes the readers understand the value of having right attitude. A rich man sent his son on anexpedition to the countryside with the determination to show him the miseries and struggles that the poor people undergo in their day-to-day lives. The boy spent a day and night in the farm of every poor family and returned home. He told his father that he hasone dog and the poor people on the roadside have many dogs. He has a swimming pool that reaches to the center of the garden and they have a stream that's boundless. He has a lamp in the garden, they have stars. His father was speechless. (*What Makes a Person Rich?*)

As the author expressed, ShashiDeshpande's characters understand over the course of life that right attitude is an important key for a positive change in human beings. One should know to value not only his/her own assets but also others' belongings and the sentiments attached to them. P.G Woodhouse, an English author, humorist and scriptwriter, propounds in *Money for Nothing*: "I know this is not the life I want but I also know that this is what my life is and I have to" (1928). As the author mentioned, ShashiDeshpande makes her readers realize through her characters that people who crafts an opportunity through the impediments will lead a contended life.

Lyubomirsky, a researcher advocates: "Life is a mishmash of mellifluousness and strain, life and death, ups and downs. Optimism comes to picture when one needs positive energy to move on" (2001). Peterson, a researcher studies optimism as: "an inherent aspect of human nature, and showed that optimism is highly beneficial, and is linked to good mood, perseverance, achievement, and physical health" (2000). These researchers have proved in their work that only people with positive attitude can experience better health and happiness. As the author says Positive attitude acts as medicine for people to recoup from the natural calamities.Wellner and Adox (2000) express in one of their articles positive thinking is the key to success and contentment and there is plenty of researches to back the claim. Studies have shown that positive thinking can decrease pressure and improve emotional well-being of human beings. In recent days, health issues are found in majority of people because of tension and pressure at homes and at work places, and so it is one's own responsibility to keep one's mind peaceful and clean eliminating the negative thoughts. Certainly, ShashiDeshpandes characters Kalyani and Belinda bring the importance of keeping oneself calm to lead a healthy life even at the most difficult time in their lives.

As Norman Vincent Peale, an American minister opines in his book *The Power of Positive Thinking for Young People* that people have to fill their minds with creative thoughts and generosity. Manjari in the novel Moving On realises that positive thinking helps her to focus on her assets and adds to her charisma in life just as Norman Vincent Peale quoted in his book. Thus, analysing the positive aspects in the novels of ShashiDeshpande widens the horizon of optimistic thinking in the minds of the readers. Her characters are conceptualised to bring in hope, love, compassion, reconciliation, humanity and help the readers to look at each obstacle as yet another opportunity to grow in their lives.

ABSTRACT

Natural polyphenols are a well-known category of secondary metabolite particular used as multi-target therapeutics in chronic disease therapy due to their antioxidant,anti-inflammatory and anti-proliferative actions. The major ones are flavonoid (e.g.quercetin, kaempferol, catechin), phenolic acid (e.g. gallic acid, caffeic acid), stilbene(e.g. resveratrol) and curcuminoid (e.g. curcumin). These compounds have been shown to be effective against many chronic diseases, including cancer (breast, colorectal, prostate), cardiovascular diseases (atherosclerosis, hypertension),neurodegenerative diseases (Alzheimer, Parkinson), diabetes (type 2), as well as inflammatory disease (rheumatoid arthritis, inflammatory bowel disease) by regulating pathways such as NF-KB, PI3K/Akt/mTOR and MAPK, inhibiting oxidative stress, apoptotic resistance. These are however hampered by pharmacokinetic limitations such as low aqueous solubility, low oral bioavailability(less than 10 percent in most cases), rapid degradation via phase I/II enzymes, first-pass effect, gastrointestinal pH instability and low tissue penetration. Enhancing solubility through encapsulation, prolonging circulation through PEGylation,controlled release to stimuli (pH, enzymes), and targeted delivery through ligands(e.g., folate, antibodies) are some of the main properties of nano carriers (liposomes,polymeric nanoparticles e.g., PLGA, chitosan, solid lipid nanoparticles, dendrimers).The systems also ensure that the polyphenols are not degraded and facilitate cellular through endocytosis and reduce off-target effects..

Keywords: polyphenols, drug delivery systems, nanoparticles, chronic diseases, nanotechnology.

INTRODUCTION

Polyphenols are some of the most common and widespread natural compounds in the plant kingdom, with over 8,000 different structures identified so far[1]. The presence of multiple phenolic hydroxyl groups in aromatic rings present in these secondary metabolites exhibits excellent antioxidant and biological activities. Wherever you check your food may contain polyphenols. It is anyhow present in modern diets whether it is in fruits or tea [2]. Over the past decades, polyphenols have attracted a great deal of scientific interest, mainly due to the epidemiological evidence showing that diets rich in plant foods lower the risk of chronic diseases. According to a new umbrella review that includes 32 studies and assesses 24 health outcomes, there are harmful links between the intake of dietary flavonoids and the risk of type 2 diabetes mellitus, cardiovascular diseases, breast, colorectal and lung cancers and mortality [3-5]. These bioactive molecules can modulate several cellular targets simultaneously as opposed to regular pharmacological agents which have only one target. According to, polyphenols are active against cancer, heart disease, neurodegenerative diseases, diabetes, and inflammation. These effects are thought to occur by various mechanisms, including free radical scavenging, enzyme inhibition, signals transduction pathways manipulation, and alteration of gene expression. The dietary polyphenols and gut microbiota interactions are becoming a major factor influencing the bioavailability and health effects. Gut bacteria can metabolise complex polyphenols into bioactive metabolites causing systemic effects [6].

Clinical translation of polyphenols is associated with profound challenges, primarily arising due to their poor bioavailability, despite promising pharmacological profiles. These issues include their poor water-solubility, low chemical stability, extensive first-pass metabolism and rapid systemic elimination [7]. Recent advances in drug delivery technologies, particularly nanotechnology-based approaches and metal-phenolic networks (MPNs), have emerged as promising strategies to circumvent these limitations and unlock the full therapeutic potential of polyphenols[8,9]. This review provides a comprehensive examination of natural polyphenols as multi-target agents in chronic diseases, with particular emphasis on their pharmacokinetic limitations and the innovative drug delivery strategies being developed to enhance their clinical utility.

Classification of Polyphenols

Polyphenols are chemically diverse compounds that can be classified based on their chemical structure, number of phenolic rings, and the structural elements connecting these rings shown in Figure 1. The major classes include flavonoids, phenolic acids, stilbenes, lignans, and tannins, each encompassing numerous individual compounds with distinct biological activities[2].

Flavonoids

The flavonoids, which include a variety of molecules, are the most abundant and well-studied polyphenols. Structurally the flavonoids share a basic C6-C3-C6 skeleton. As shown in ring A, the presence of two aromatic rings connected by a three-carbon chain (the C3 part of thi) and which can be a substituent on one of the aromatic rings. Flavonoids come in many different kinds. This includes flavonols and flavones, which are lower in the structure of it onto the f band. Flavonoids are substances that have antioxidant and anti-cancer functions and other effects [1].

Phenolic Acids

Phenolic acids are generally classified into two main groups, namely hydroxybenzoic acids (gallic acid, protocatechuic acid) and hydroxycinnamic acids (caffeic acid, ferulic acid, coumaric acid). These compounds are present in various plant foods and have antioxidant and anti-inflammatory action. Gallic acid has better bioavailability than most polyphenols. Also, it acts as a building block for other complex polyphenolic components [7].

Stilbenes and Lignans

Stilbenes, most notably resveratrol originating in grapes and wine, is an important anti-aging and cardioprotective compound that is receiving attention. Flaxseeds and whole grains contain lignans; compounds that have a phytoestrogen effect. These compounds are known to mitigate the risk of various cancers that rely on hormones for their growth. The two classes show significant biological activity' despite showing lower dietary abundance in comparison to flavonoids and phenolic acids represent in Table 1[9].

Mechanisms of Action as Multi-Target Agents

The many health-promoting qualities of polyphenols rely on diverse yet interconnected mechanisms of action. The multi-target nature of these drugs allows them to exert simultaneous multimodal actions on the disease process. As a result of these properties, they hold promise of superior efficacy over conventional single-target drugs shown in Figure 2 [5].

Antioxidant Effects

One of the best-known properties of the polyphenols is their antioxidant activity. The ability of these compounds to scavenge free radicals by donating a hydrogen atom, chelate transition metal ions that catalyze oxidative reactions, modulate behaviour of one's own antioxidant enzyme systems such as superoxide dismutase, catalase and glutathione peroxidase provides their antioxidant defensive actions. According to a study reported by ScienceDirect, researchers recognized that the majority of the phenolic compounds have been characterized as colourless and weakly acidic to neutral molecules. The phenolic hydroxyl structure acts as an electron donor by stabilizing free radicals thereby preventing lipid, protein and DNA peroxidation.

Anti-Inflammatory Activity

Diseases that are quite common have an underlying mechanism of chronic inflammation. Polyphenols are quite effective against inflammation and help to cure it through different paths. These substances block the activation of activator protein-1 (AP-1) and nuclear factor-kappa B (NF-kappaB), which are responsible for the expression of pro-inflammatory cytokines, chemokines, and adhesion molecules. Recent investigations demonstrate that polyphenols can greatly lower the levels of IL-1beta, TNF-alpha, and IL-6, as well as raising anti-inflammatory cytokines such IL-10 and IL-4[10]. The action of cyclooxygenase or COX and lipoxygenase or LOX enzymes is regulated by polyphenols. This reduces the production of inflammatory mediators.

Anti-Cancer Mechanisms

Polyphenols target various stages of cancer to exhibit anti-cancer activity. The substances have the capacity to positively affect the ability of a cancerous/busy cell to divide, alter the regularity of the ongoing cell cycle phase by targeting cell regulatory proteins, induce apoptosis by instigating both intrinsic and extrinsic pathways and inhibit angiogenesis by inhibiting PEGF (Plasma-VEGF signalling). Recent studies have demonstrated breast cancer cell regulation of different genes following cell proliferation and invasion in a dose-dependent manner by modifying DNA methylation and chromatin remodelling by EGCG[11].Polyphenols also have an anti-metastatic function through matrix metalloproteinase modulation and epithelial-mesenchymal transition.

Cardioprotective and Neuroprotective Effects

The possible beneficial effects of polyphenols on the heart may include improving endothelium function, decreasing oxidation of low-density lipoprotein (LDL) cholesterol, inhibiting platelet aggregation, and improving blood pressure. A recent meta-analysis showed that there was an inverse association between (poly)phenol intake and cognitive impairment. [12].Polyphenols have been indicated to enhance NO bioavailability, resulting in vasodilation and improved vascular tone. In particular, resveratrol has been shown to activate sirtuin-1 (SIRT1), which mimics caloric restriction to offer protection from cardiovascular and neurodegenerative diseases [1].

Antidiabetic Properties

The presence of polyphenols in cacao can help enhance the glycaemia. Resveratrol, in particular, has been shown to activate sirtuin-1 (SIRT1). This mimics caloric restriction and protects the heart and brain [13].The compounds also reduced diabetes complications by blocking advanced glycation end-product formation and lowering oxidative stress in diabetic tissues[1].

Pharmacokinetic Limitations

Polyphenols are substances with remarkable biological activity evident in test tube assessments. However, their clinical effectiveness is decidedly limited due to poor pharmacokinetic characteristics. It is important to know the restrictions so that we can improve bioavailability and effectiveness (Figure 3)[7].

Poor Bioavailability

The absorption of polyphenols varies significantly from one chemical to another, the plasma concentrations of total metabolites range from 0 to 4 micromol/L after the intake of 50 mg aglycone equivalents. Among polyphenols, the ones most readily absorbed in our system are gallic acid and isoflavones, while proanthocyanidins, galloylated catechins from tea, and anthocyanins are least absorbed. The urinary excretion of polyphenols may vary greatly, from 0.3% to 43%, depending on the type[7].The bioavailability is poor due to various reasons such as low solubility in water, poor intestinal permeability, and extensive presystemic metabolism.

Absorption and Metabolism

The majority of dietary polyphenols, being glycosides or esters, are not absorbable in native forms. Absorption cannot take place until hydrolysis by enzymes in the intestine or microflora in colonic. While being absorbed, polyphenols get methylated, sulfated, and/or glucuronidated in the liver and intestinal epithelium. This is known as phase I and II metabolism. EGCG, a key polyphenol in green tea, has low bioavailability due poor absorption in the small intestine. Studies isolated gut strains which convert EGCG into 5-(3',4'-dihydroxyphenyl)-gamma-valerolactone (M5), a substance with potential anti-inflammatory and anticancer properties [14].

Chemical Instability and Rapid Clearance

Under physiological and environmental conditions, polyphenols are chemically unstable and easily degradable. Factors such as pH, temperature, light, oxygen and metals ions could promote oxidative degradation of polyphenols. Catechins and anthocyanins are very likely to degrade. The products of polyphenol breakdown and polyphenols themselves are expelled from the body rapidly through the urine and bile. The products of polyphenol metabolism have elimination half-lives in the range 2–12 h. They would benefit from frequent dosing to maintain effective therapeutic concentrations [7].

Advanced Drug Delivery Approaches

A great deal of research works has been done to overcome the pharmacokinetic limitation of polyphenols. The goal of these technologies is to improve solubility, protect against degradation, improve intestinal absorption, prolong circulation time, and target tissues (Figure 4, Table 2)[9, 5].

Nanoparticle-Based Delivery

The delivery of polyphenols using nanoparticle formulations is considered to be very promising. Researchers have developed a variety of nanoparticles, including those made of lipids, polymers and metals. The benefits of these systems comprise improved solubility of lipid-soluble polyphenols, protection against degradation, controlled release kinetics, and active targeting via surface modification[4]. Recent studies have demonstrated that kaempferol-loaded CaCO3 nanoparticles with cancer cell membrane coating achieve targeted delivery and amplified calcium overload cancer therapy[15].

Metal-Phenolic Networks (MPNs)

Metal-phenolic networks represent a revolutionary advancement in polyphenol delivery, formed through coordination between polyphenols and metal ions such as iron (III), manganese (II), and platinum. MPNs exhibit pH-responsive disassembly properties that enable targeted release in acidic tumor microenvironments or endosomal compartments[8]. A recent study demonstrated that Mn2+ and amphiphilic PEG-polyphenol MPNs incorporating a radiosensitizer can effectively inhibit tumor growth via sensitizing radiation and triggering STING-pathway-mediated immunostimulation[16]. Platinum-based MPNs using tannic acid and oxaliplatin prodrug have shown synergistic antitumor effects by promoting apoptosis and enhancing antitumor immune responses[17].

Liposomes and Phytosomes

Liposomes are vesicles which enclose a phospholipid bilayer and hydrophilic or even hydrophobic compounds. Polyphenolic substances like quercetin can fight diseases and infections while offering anticancer properties and promoting good heart health among others. PEGylated liposomes that co-encapsulate resveratrol and docetaxel can efficiently inhibit cell growth and induce apoptosis in prostate cancer [5]. Phytosomes represent a specialized form in which polyphenols are complexed with phospholipids through hydrogen bonding, resulting in improved membrane permeability and bioavailability. Studies have shown that phytosome formulations can increase polyphenol bioavailability by 5- to 10-fold compared to conventional preparations.

Polymeric Carriers and Nanogels

Various natural as well as synthetic polymeric materials can serve as polyphenol carrier. Chitosan, a naturally occurring polysaccharide, is by far the most widely used polymer due to its biocompatible, biodegradable, and mucoadhesive properties. Likewise, engineered polymers like PLGA and PEG can allow a controlled release of the polyphenols that they carry and ensure sustained circulation.Nanogels with pore structures and large surface/volume ratios have shown excellent encapsulation ability for the entrance and entrapment of drugs. Furthermore, the treatment was enhanced a pH-and thermo-responsive nanogel loaded with doxorubicin and curcumin[5].

Gut Microbiota-Polyphenol Interactions

The bidirectional interaction between dietary polyphenols and gut microbiota has emerged as a critical determinant of polyphenol bioavailability and health effects. The gut microbiome plays a pivotal role in converting complex polyphenols into bioactive metabolites with improved systemic effects on host physiology and metabolism[6].

Microbial Metabolism of Polyphenols

Approximately 90-95% of dietary polyphenols reach the colon where intestinal microbes break them down into small-molecule metabolites. These metabolites, including short-chain fatty acids (SCFAs) and phenolic acids, can be readily absorbed and exert systemic effects[18]. Isoflavones such as daidzein are converted by gut bacteria to equal, a metabolite with potent estrogenic and anti-inflammatory properties. Ellagitannins from berries and pomegranates are metabolized into urolithins, which exert potent anti-inflammatory and anticancer activities[19].

Gut-Brain Axis and Neuroprotection

Polyphenol metabolites produced by gut microbiota contribute to neuroprotection by crossing the blood-brain barrier to exert anti-inflammatory, antioxidant, and cognitive effects. Recent systematic reviews have demonstrated that polyphenols can prevent neurodegenerative diseases by affecting cerebral blood flow, neurogenesis, synaptic plasticity, protein aggregation, mitochondrial dysfunction, neuroinflammation, and oxidative stress in the central nervous system[20]. Interventions with sesamol, quercetin, and resveratrol have consistently demonstrated elevations in key metabolites including acetate, propionate, and butyrate, correlating with enhanced memory performance and reduced neuroinflammation in Alzheimer's disease models.

Modulation of Gut Microbiota Composition

Polyphenols can modulate gut microbiota composition by promoting the growth of beneficial bacteria such as Bifidobacterium, Lactobacillus, and Akkermansiamuciniphila while inhibiting pathogenic species. A recent meta-analysis highlighted the prebiotic effect of polyphenols and their relationship with inflammatory markers in individuals with overweight or obesity[10]. Tea polyphenols including epicatechin inhibit the growth of Clostridium and Enterococci, while resveratrol promotes the growth of Lactobacilli and Bifidobacteria and increases butyrate production[21].

Challenges and Future Directions

The delivery systems for polyphenols have improved significantly in the last few decades. However, there are still challenges that must be overcome before these systems can be commonly used in the clinic [4][5].

Current Challenges

The chemical instability of polyphenols poses challenges for formulation development and storage. Many polyphenols are easily oxidized, especially under basic conditions, necessitating careful handling and formulation design. The potential for non-specific interactions between polyphenols and biological components may lead to unwanted side effects or reduced bioavailability due to binding to plasma proteins. Scale-up of nanotechnology-based delivery systems from laboratory to industrial production presents additional challenges related to manufacturing consistency, quality control, and cost-effectiveness[9].

Safety and Regulatory Considerations

The safety of nano formulations requires thorough evaluation, as the altered biodistribution and prolonged circulation of encapsulated polyphenols may lead to unexpected toxicities. Regulatory frameworks for nanotechnology-based drug products are still evolving, and the lack of standardized testing protocols poses challenges for clinical translation. The potential for polyphenol-drug interactions must be carefully evaluated, as these compounds can modulate the activity of drug-metabolizing enzymes and transporters[22].

Future Directions

Future research should focus on developing multifunctional delivery systems that combine multiple therapeutic modalities, such as chemotherapy, photothermal therapy, and immunotherapy, within a single nanoplatform. The integration of imaging capabilities with therapeutic delivery would enable real-time monitoring of drug distribution and treatment response. Personalized approaches considering individual variations in polyphenol metabolism, particularly the role of gut microbiota in generating bioactive metabolites, represent promising directions for optimizing polyphenol therapy. Well-structured clinical trials are needed to establish safety, efficacy, and dosage guidelines for nano formulated polyphenols[8].

CONCLUSION

Natural polyphenols represent a promising class of multi-target therapeutic agents with demonstrated efficacy against various chronic diseases including cancer, cardiovascular diseases, neurodegenerative disorders, and diabetes. Their ability to modulate multiple cellular pathways simultaneously through NF-kappaB, Nrf2, PI3K/Akt/mTOR, and AMPK signalling offers potential advantages over conventional single-target pharmaceuticals. The emerging understanding of polyphenol-gut microbiota interactions has revealed additional mechanisms through which these compounds exert their health benefits. However, the clinical translation of polyphenols has been hampered by their poor bioavailability, chemical instability, and rapid clearance. Advanced drug delivery systems, particularly those based on nanotechnology and metal-phenolic networks, have shown remarkable promise in overcoming these limitations. Nanoparticles, liposomes, phytosomes, polymeric carriers, and MPNs have demonstrated the ability to enhance polyphenol solubility, protect against degradation, improve intestinal absorption, prolong circulation time, and enable targeted tissue delivery. As research in this field continues to

advance, the development of next-generation polyphenol delivery systems with multifunctional capabilities will likely transform these natural compounds into clinically viable therapeutics. Addressing the remaining challenges related to manufacturing scale-up, safety evaluation, personalized medicine approaches, and regulatory approval will be essential for realizing the full therapeutic potential of natural polyphenols in the prevention and treatment of chronic diseases.

ACKNOWLEDGEMENTS

The authors express their gratitude to the Brainware University administration for their unwavering support and motivation, and to the Department of Pharmaceutical Technology for
providing the necessary support.

CONFLICT OF INTEREST

The authors declare no conflicts of interest.

Table 1:Types of different dietary polyphenols, representative compounds, and primary dietary sources.

Class	Representative Compounds	Major Dietary Sources
Flavonoids	Quercetin, kaempferol, catechins, anthocyanins	Fruits, vegetables, tea, wine
Phenolic Acids	Gallic acid, caffeic acid, ferulic acid	Coffee, cereals, berries
Stilbenes	Resveratrol, pterostilbene	Grapes, wine, peanuts
Lignans	Secoisolariciresinol, matairesinol	Flaxseeds, whole grains
Tannins	Ellagitannins, proanthocyanidins	Tea, wine, berries, nuts

Table 2. Comparison of advanced drug delivery systems for polyphenols and their key advantages.

Delivery System	Key Features	Advantages
Nanoparticles	Polymeric, lipid-based, metal-phenolic networks	Enhanced solubility, controlled release, targeting
Liposomes	Phospholipid bilayer vesicles	Biocompatibility, dual drug loading
Phytosomes	Phospholipid-polyphenol complexes	Improved membrane permeability
Polymeric Micelles	Amphiphilic block copolymers	Solubilization of hydrophobic compounds
Solid Lipid NPs	Solid lipid core matrix	Stability, controlled release, scalability

ABSTRACT

Huperzine A (HupA) is a sesquiterpene alkaloid isolated from *Huperzia serrata* and developed by the Chinese Academy of Sciences as a potential nootropic and anti-Alzheimer's agent. Owing to its favorable neuropharmacological properties, HupA has advanced to Phase III clinical trials in China for the treatment of Alzheimer's disease (AD). The limited natural availability of HupA in plant sources has prompted the development of sustainable production strategies, including in vitro plant tissue culture, endophytic fungal biosynthesis, and optimized total and semi-synthetic chemical synthesis to meet growing therapeutic demand. At the molecular level, HupA acts as a potent, selective, and reversible inhibitor of acetylcholinesterase (AChE), exhibiting high affinity for the enzyme's catalytic active site. This action results in sustained elevation of synaptic acetylcholine levels, thereby enhancing cholinergic neurotransmission in the hippocampus and cerebral cortex—regions crucial for cognition and memory. Beyond cholinesterase inhibition, accumulating evidence indicates that HupA exerts multimodal neuroprotective effects, including attenuation of glutamate-induced excitotoxicity via NMDA receptor modulation, reduction of oxidative stress, suppression of neuroinflammatory responses, and regulation of apoptotic pathways.

Pharmacokinetic evaluations reveal that HupA demonstrates high oral bioavailability, efficient blood–brain barrier penetration, and prolonged AChE inhibitory activity compared to established cholinesterase inhibitors such as donepezil, rivastigmine, and galantamine. These attributes contribute to its sustained therapeutic efficacy. Despite its extensive clinical use in China, acceptance of HupA in Western countries remains limited, primarily due to inconsistent clinical outcomes and the lack of large-scale, well-designed randomized controlled trials. Given the multifactorial pathogenesis of AD, involving cholinergic dysfunction, amyloid-β deposition, tau pathology, oxidative stress, and neuroinflammation, HupA emerges as a promising candidate with potential disease-modifying effects. Preclinical and clinical studies in mild to moderate AD patients consistently report cognitive improvement, underscoring its therapeutic potential.

Keywords: Huperzine A, Huperzia serrate, Alzheimer's disease, Acetylcholinesterase and Clinical trials.

INTRODUCTION

Huperzine A, a naturally derived alkaloid isolated from *Huperzia serrata*, was developed by the Chinese Academy of Sciences as a potential nootropic agent for the treatment of Alzheimer's disease (AD). Currently, huperzine A is undergoing Phase III clinical trials in China for AD management. Its therapeutic mechanism is primarily attributed to the slow, selective, and reversible inhibition of acetylcholinesterase (AChE), leading to enhanced cholinergic neurotransmission. Alzheimer's disease is neuropathologically characterized by the accumulation of neurofibrillary tangles and neuritic plaques and represents one of the leading causes of mortality among the adult population. Existing pharmacotherapies are largely symptomatic and do not address disease progression [1]. Comprehensive evaluations of the chemistry, pharmacology, and clinical efficacy of huperzine A suggest its promise as a contemporary therapeutic candidate for AD. To overcome limitations associated with its low natural yield, renewable production methods have been established through in vitro plant culture techniques, alongside advancements in chemical synthesis processes. Pharmacological studies confirm that huperzine A exhibits potent, selective, and reversible inhibition of AChE.

Pharmacokinetic investigations demonstrate that huperzine A possesses favorable systemic distribution and central nervous system penetration. Although human toxicity data remain limited, preclinical animal studies indicate minimal cholinergic adverse effects at therapeutic dose ranges. Clinical trials have reported cognitive improvement as assessed by standardized instruments such as the Mini-Mental State Examination (MMSE), Memory Quotient (MQ), Alzheimer's Disease Assessment Scale–Cognitive Subscale (ADAS-Cog), and Activities of Daily Living (ADL) scores. Phase II trials revealed significant memory enhancement at a dose of 0.4 mg, whereas no comparable benefit was observed at 0.2 mg. Notably, MMSE scores demonstrated marked cognitive improvement at the higher dose. Evidence further suggests that huperzine A is well tolerated for treatment durations of up to 24 weeks at doses reaching 0.4 mg, supporting its potential as a viable therapeutic alternative for Alzheimer's disease [2].

HUPERZINE

()-Huperzine A belonging to Huperziaceae, Lycopodiaceae, and Selaginella plant families that contain trideca-2(7),3,10-trien-5-one. The chemical was extracted from the dried herb of Huperzia serrata; the yield of huperzine A varies from 0.0047 to 0.025% based on the method of plant collection and extraction [3]. New techniques for chemical synthesis and biological production have been developed in response to the need for a dependable source of huperzine A, given the low yield naturally existing in plants and increasing demand for the compound. Studies conducted in vivo and in vitro revealed that the activity of chemically produced ()-huperzine A was equivalent to that of naturally occurring ()-huperzine A [4]. This study evaluated many synthetic and biological techniques for processing ()-huperzine A. Huperzine A is thought to enhance overall cognitive function, address behavioural disturbances, improve global status, and boost functional performance [5].

The majority of clinical trials conducted in China provide evidence for its usage in improving cognitive function. As of right now, China has approved huperzine A at 0.2 mg twice day for treatment of AD [6]. There is contradicting information regarding huperzine A's use in the US, despite the drug being widely used in China. This is mostly because there aren't enough large-scale, multicenter, randomized control trials that are well-designed. There's little doubt that concurrent clinical trials will give us additional knowledge about how to use huperzine A to treat AD.

Manufacturing of Drug Substance

In order to address the limited natural occurrence of huperzine A in plants and to fulfil the growing need for the chemical in research and medicine dosage manufacture, scientists have spent the last thirty years investigating several ways to increase the compound's prevalence [7]. This has involved the creation of procedures for both the enhanced production via various biological processes, notably the preparation of biosynthesis, and the domain of chemical synthesis[4]. Because of its compact and rigid framework, huperzine A is a really unusual molecule containing fused pyridone moiety [8].

After the stereoisomers of huperzine A were identified, ()-huperzine A is considerably effective than (ξ)-huperzine A [9,10]. Research into the synthetic preparation of huperzine A began in late 1989 and recently Koshiba et al described improved protocol for the entire of ()-huperzine A preparation. Some crucial elements of their methodology were notably different from those of earlier research. First off, a commercially accessible anhydride served as the foundation for the whole synthesis procedure. They originally developed the bicyclic ring system with this chemical. The Wittig reaction phase was one of the biggest distinctions between this process and those that have been previously published. Earlier synthetic pathways involving this step typically result in the predominant production of the undesired (Z)-isomer. To address this difficulty, Koshiba et al [8]. added vinyllithium and treated the allyl alcohol intermediate with SOCl2 to enhance the production of the particular isomer. Subsequent reactions then made it possible to create ()-huperzine A in 23 stages with a 1.8% total yield.

Formulation

The production, enhancement, and characteristics of loaded nanostructured lipid carriers (NLC) containing Huperzine A (Hup A), a successful treatment for Alzheimer's disease in ancient Chinese Medicine. NLC was effectively produced by modifying the processes of melt ultrasonication and high pressure homogenization. The solid lipids in the emulsifiers were soybean phosphatidylcholine (Spc), liquid lipids Miglyol (R) 812, solid lipid Cetyl Palmitate (CP), and solutol HS15. Box-Behnken design with 3 components and levels was used to find the best formulation. Formulation's ratio of lipid: drug, amount of mixed lipid, and amount of emulsifier combination were all looked at as independent factors. The dependent variables studied were particle size, drug loading and entrapment efficiency. The characteristics of the nanoparticles, including morphology, dependent variables and drug release behaviour was assessed. The findings revealed that “the proposed nanoparticles had nearly spherical particles with an average size of 120 nm and a zeta potential of -22.93 ± 0.91 mV”.It is possible for the EE (%) and DL (%) to achieve values of 1.46 +/- 0.05% and 89.18 +/- 0.28%, respectively. With Hup A loaded NLC, differential scanning calorimetry (DSC) revealed no recrystallization propensity. Hup A was released from NLC in vitro in stages, with a burst release observed at the beginning and a protracted release lasting up to 96 hours. According to the findings, the Hup A loaded NLC system that has been demonstrated may be a useful delivery method for increasing drug loading capacity and achieving regulated drug release.

Non-Clinical Studies

Research has also suggested that HupA therapy may be superior to traditional medication and psychotherapy for treating epilepsy and dementia. Meanwhile, HupA has a dose-and time-dependent impact that can greatly enhance the cognitive function in Alzheimer's disease patients. In numerous animal models of neurological disorders, low dosages of HupA have been demonstrated to significantly improve cognitive impairment, lower neuroinflammation, improve neuroprotection by raising cortical inhibition, and influence these processes. Furthermore, HupA has been shown to have greater penetration strength, greater bioavailability, and the ability to inhibit AChE for a longer

period of time when compared to other cholinesterase inhibitors including donepezil, rivastigmine, and galantamine [12].

Non-Clinical Pharmacology

Behavioural Test Analysis

Since the Morris water maze test accurately measures spatial memory ability, it is frequently used to evaluate the effectiveness of medications in AD models. A platform hidden beneath opaque water is used for the training, which takes place in a circular swimming pool. After being placed in the water, the animal is led to the platform. The probe test, which lasts for 60 seconds after the animal has been trained for days, involves letting it swim freely. The amount of time spent in the target quadrant and the escape delay are the markers for spatial memory. Seven out of the sixteen articles were tested, and the forest plot looked at the two markers that were previously mentioned. Image J (Rawak Software Inc., Stuttgart, Germany) and RevMan 5.4 (Cochrane Community, London, UK) were used to study the data. The escape delay meta-analysis included 91 rats and 30 mice. The time spent in the target quadrant was assessed for 30 mice and 70 rats. 0.1 mg/kg and 0.2 mg/kg was designated as 1 and 2, respectively.

Both rats and mice given huterzine A exhibited noticeably shorter escape latencies. The studies' heterogeneity, however, is significant (I2 (mice) = 56%, p = 0.13; I2 (rats) = 74%, p = 0.004). In the rat subgroup, there is considerable heterogeneity in the amount of time spent in the target quadrant (I2 (rats) = 92%), whereas there is a significant (p = 0.004) increase in time in the mice group with low heterogeneity (12 = 0). The research employed various Alzheimer's disease (AD) models, including APPswe/PS1dE9 mice, quinolinic acid-induced AD, AMPA-induced AD, Aβ-induced AD, and D-galactose-induced AD. This notable variety in models might account for differing results. Surprisingly, amount of time spent in the target quadrant was not elevated by huperzine A [13].

Neuroprotective Mechanism Analysis

Inhibition of Aβ pathway

Numerous studies have discovered neuroprotective strategies, including as modulating the cholinergic system, attenuating mitochondrial dysfunction, inhibiting Aβ aggregation or associated pathways, and controlling apoptotic factors. Huperzine A has been demonstrated to exhibit inhibitory action on Aβ aggregation or associated pathways; Aβ levels were quantified through investigations employing immunohistochemistry and ELISA. Huperzine A therapy enhanced the non-amyloidogenic pathway in the brains of APP/PS1 mice and considerably declines the levels of soluble Aβ40 and Aβ42 in both cortex and hippocampus. A diet high in iron could, however, undo these modifications. Huperzine A also decreased ABAD levels, oligomeric Aβ42, Aβ plaques, and mitochondrial dysfunction. To establish the Aβ burden, other investigations employed immunohistochemistry, thioflavin S, and Congo red staining. The findings demonstrated that Huperzine A therapy significantly decreased the quantity of Aβ plaques in the hippocampus and cortex, with the hippocampus group exhibiting low heterogeneity and the cortex group exhibiting high heterogeneity. Overall, studies on a variety of brain areas have demonstrated the potential neuroprotective effects of huperzine A.

Enhancement of Cholinergic Activity

It has been noted that the brains of AD patients have lower levels of choline acetyltransferase (CAT/ChAT), but the process of developing AD can be stopped by upregulating the levels of ChAT in the cortex and hippocampus. AChEIs (donepezil, rivastigmine, galantamine) and memantine are currently approved medications for the treatment of AD; huperzine A is well-known for its effectiveness in treating cholinesterase inhibitors (ChEIs). Research has indicated that huperzine A is more effective than AF64A in attenuating memory deficits caused by AChE in the cerebral cortex and hippocampus. AChE activity has been demonstrated to be inhibited by huperzine A; notable enhancement was noted in the rat subgroup and inhibition in the mouse subgroup.

Pharmacokinetic Studies

Based on in vitro findings, liver liposomes (HLMs) do not significantly inhibit or induce CYP enzyme activities, nor do they metabolize HupA at clinically relevant quantities. This goes against earlier research in renal liposomes

(RLMs), where it was discovered that CYP1A2 metabolized primarily at a concentration in line with its plasma levels of therapeutic HupA. The metabolic stability experiment carried out in RLMs indicates that the HupA can be digested at a concentration of 10 ng/mL with a t1/2 of 61.9 minutes. The difference between HLMs and RLMs indicates that more clinical trials are required to guarantee pharmaceutical safety and that findings made from rat studies should not be applied to humans. In rats and mice, HupA is primarily distributed in the kidney and liver, and it is primarily excreted from kidney. According to the in vivo investigation, older patients expelled 35% of their total HupA through urine 48 hours after receiving a single dose. Additionally, the study discovered that HupA was mostly removed from the kidney in an unaltered state. *In vitro* metabolic stability research and the *in vivo* pharmacokinetic investigation showed HupA was primarily removed from the kidney intact. According to the study, modifications in CYP isoenzyme activities can affect a drug's plasma concentration, pharmacokinetic mechanism, and therapeutic characteristics. To predict possible drug interactions, a dosage of 20 ng/mL HupA—250 times higher than the current dosage—is probably not acceptable. Given HupA's low CYP isoenzyme interaction propensity, there may not be any medication interactions in clinical settings. HupA is primarily intended for older patients; hence, it could be a good substitute for elderly AD patients who require combination medication therapy with hypoglycemia or hypotensive medications. To reduce adverse effects, HupA should be used in conjunction with medications that are excreted by the kidneys, however care should be taken regarding the possibility of DDI. To completely assess the potential for medication interactions brought on by the co-administration of HupA, more extensive clinical research is required [14].

Toxicology

There were no morphological or behavioral changes in animals exposed to huperzine. Thirty minutes after being treated to 625 μg/kg of huperzine, the last group experienced tonic-clonic seizures. Among the markers under investigation are TBARS, FRAP, GR, caspase 3, and a few other biochemical markers. The temporal and parietal lobes were more susceptible to huperzine's highest dose, which also enhanced caspase 3 activity in the cerebellum, frontal lobe, and temporal lobe. Temporal and parietal lobes showed the most noticeable lipid peroxidation, while the frontal lobe, cerebellum, spleen, and kidney all showed increased expression of GR. The biochemical markers remained constant and did not indicate any signs of disease. According to the study's findings, exposure to huperzine significantly increased brain lipid peroxidation, and as dosage grew, the ratio of AST to ALT decreased. The ability of huperzine to lower lipid peroxidation and oxidative stress, as shown by elevated GR and TBARS levels. The rise in antioxidants is greater than the amount of direct oxidative stress, indicating that even a small amount of oxidative stress can cause antioxidants to respond appropriately. It has been observed that huperzine A lowers oxidative stress and nerve apoptosis. On the other hand, it has been discovered to cause mild liver damage, resulting in a dose-dependent reduction in the AST/ALT ratio. Huperzine A also has the capability to inhibit caspase 3 activity induced by amyloid beta and reduce amyloid beta levels generated by oxidative stress. Huperzine can have negative effects in addition to being associated with the strengthening of antioxidant barriers. Through the cholinergic anti-inflammatory route, huperzine's effect on the immune system can boost cognitive abilities. Unfounded expectations are inappropriate since the role of huperzine in antioxidant homeostasis is poorly known [15].

Administration in Animals

In an in vivo trial with dogs, transdermal Huperzine A (HupA) patches demonstrated effective controlled release compared to oral treatment. The patches had a longer t_{max}(24 hours vs. 3 hours), lower C_{max} (3.4 ng/ml vs. 9.8 ng/ml), and generally stable serum levels over 84 hours. They also resulted in localized and mild cutaneous adverse reactions, making them suitable for administration twice a week. Research has also shown that administering HupA intranasally disperses it more evenly throughout the rat brain than administering it intravenously. In addition, when delivered intranasal as demonstrated in rats, HupA has a C_{max} of 190 μg/l at a t_{max} of 41 min. Rat liver microsomal HupA metabolism mostly proceeds through CYP1A2, a monooxygenase belonging to the cytochrome P450 superfamily of proteins that catalyzes processes including drug metabolism. Mass spectroscopy and nuclear magnetic resonance have identified 13,14-Epoxy HupA, a metabolite of HupA, in rat blood; however, it is not obvious whether this is the chemical that is expelled and whether it has biological activity.

Furthermore, through pregnane X receptor-related pathways, in LS174T (colorectal adenocarcinoma) cell lines, HupAinduces CYP3A4 mRNA and protein expression. Similarly, although total CYP levels did not rise, oral administration of HupA at doses of 0.1, 1, and 2 mg/kg over 14 days showed changes in CYP3A4 activity which was observed to increase CYP1A2 transcription and protein production in rat liver microsomes. If these findings are applied to humans, they may indicate that CYP1A2-metabolized medications and HupA interact; however, more research is needed to confirm this. Studies on animals have shown that radiolabeledHupA is primarily (73%) eliminated in urine; nevertheless, more research in humans is required.

Clinical Studies

Pharmacology

Acetyl cholinesterase is strongly, competitively, and reversibly inhibited by huperzine A, blocking endogenous acetylcholine breakdown. Compared to existing inhibitors such as tacrine, donepezil, rivastigmine, and physostigmine, it is more potent, or equally potent. Little is known regarding its impact on AD, despite the existence of suggested mechanisms of action. Inhibiting acetyl cholinesterase may improve cognitive improvement in AD patients. Five sites—the active-site gorge, the parent chain ketone group of His440, ethylidene Me group, the H-bonding with Tyr130, and hydrophobic interactions—are where huperzine A interacts with acetyl cholinesterase. The enhanced potency of huperzine A over other inhibitors can be explained by these interactions. Huperzine A holds promise for treating Alzheimer's disease (AD) due to its protective effects against cytotoxicity and apoptosis induced by H2O2, β-amyloid protein, glutamate, ischemia, and staurosporine. It is better than other acetyl cholinesterase inhibitors because it binds to both acetyl cholinesterase and peripheral butyrylcholinesterase. Huperzine A is a desirable alternative for treating AD because it likewise inhibits the NMDA receptor ion channel without causing psychotic effects and has few negative cholinergic effects [2].

Pharmacokinetics

Drug development relies heavily on pharmacokinetic studies, and huperzine A's pharmacokinetic characteristics have been investigated. Twelve human individuals in good health were given a single oral dose of 0.4 mg in the form of a tablet during an in vivo research. The study discovered a biphasic pharmacokinetic profile, which is characterized by rapid absorption and distribution and a delayed rate of elimination. Huperzine A has an area under the plasma vs. time curve of 2450.34233.32 mg/l min and was dispersed broadly in the body, even managing to breach the blood-brain barrier. Six Chinese participants received a single dosage of 0.99 mg in a tablet study, and reversed-phase HPLC was used to measure the drug's plasma concentrations. Additionally, the study showed that huperzine A was removed at a more modest rate and that it was rapidly absorbed and distributed widely throughout the body [2].

Toxicology

Although huperzine A is not hazardous to humans, research on animals have reported subtle to modest cholinergic side effects. The LD50 is 2-4 mg/kg and 0.6 mg/kg/d in rats and rabbits respectively. Heart and brain problems are caused by high dosages of huperzine A. Acute cholinergic toxicity has been reported in dogs, with 0.1 mg/kg/d being the "no-observed adverse effect threshold" (NOAEL) for dogs [2]. Reduced toxicity of β-amyloid: Extracellular senile plaques are made up of β-amyloid (Aβ) fragments, which result from the proteolysis of the membrane-bound amyloid precursor protein (APP). Aβ fragments are produced by the β/γ-secretase amyloidogenic pathway, which cleaves APP into insoluble form, and soluble α-APP fragments are produced by the α-secretase non-amyloidogenic pathway. It has been demonstrated that Aβ triggers apoptotic responses, which could result in AD therapy choices. Multiple studies showing a link between Ach-E activity and Aβ generation have shown that AChE co-localizes with Aβ deposits in AD patients and forms a stable complex with Aβ, promoting the cluster of Aβ deposits. This bond increases the neurotoxicity of the Aβ deposit and changes the enzymatic activity of AChE [17].

Treatment Regimen in Humans

Every tablet containing the active medicine contains 50 μg of HupA. For eight to twenty-four weeks in a row, patients in the HupA group were given oralHupA pills. The daily mean dosage varied between 300 and 500 μg and

patients in the control group were given blank pills. In a study conducted by Zhang et al, in addition to this vitamin E (100 mg/day) was administered to both treatment and control groups [18].

Efficacy and Safety

Four RCTs with 474 participants—two single-blind and two double-blind trials showed that MMSE and ADL scores were improved when huperzine A was used instead of a placebo. Regression analysis revealed a similar trend for ADL and improved efficacy with time for MMSE. The huperzine A group experienced minor peripheral cholinergic side effects more frequently than the placebo group [19].

Adverse Effects

With frequent adverse medication reactions that impact neuropsychiatric, gastrointestinal, general, and cardiovascular diseases, the effectiveness of ChEIs is still inadequate, especially in patients with advanced AD. In order to address the rising incidence of AD, new, focused, safe, and effective treatments are required. Anorexia, indigestion, bradycardia, insomnia, nasal obstruction, ankle oedema, diarrhoea, dizziness, festinating gait, headache, hyperactivity, hypopraxia, moderate abdominal pain, nausea and vomiting are the adverse effects that are anticipated [20].

CONCLUSION

The pathogenesis of Alzheimer's disease is not well understood, which makes it difficult to identify a suitable treatment. A naturally occurring substance from Huperzia serrata moss called huperzine A has been suggested as a possible AD therapy. Humans with mild to moderate AD and animal models have both benefited from favourable cognitive augmentation in clinical trials. However, doctors in USA are unable to prescribe huperzine A as a routine treatment for memory problems like dementia due to the death of research-backed literature regarding the drug's safety and effectiveness. Approval of huperzine A as conventional treatment for AD and other dementias may be aided by a more extensive, carefully planned phase III clinical trial.

Conflict of Interest

The authors have no conflicts of interest regarding this investigation**.**

ABSTRACT

Majority of people worldwide have an access to social media and own a smartphone every day. Due to this online dependence, this study explores the impact of social media use on emotions and offline relationships with closed ones. This study has adopted quantitative research approach which includes collection of primary data from 312 participants who completed an online survey having close-ended questions based on 5-point Likert scale related to emotional well-being, interpersonal relationships, and social media use. It is observed that social media addiction has significantly affected interpersonal relationships, resulting in increased loneliness and reduced satisfaction from interpersonal relationships. There is also a rise in communication issues and conflicts, as excessive use of social media can result in neglecting personal interactions as well as misunderstandings. In addition, reduced self-esteem and social comparison are some of the common issues among social media addicts, further affecting interpersonal relations. It is important to address social media addiction to foster more fulfilling and healthier relationships in this day and age.

Keywords – Interpersonal relationships, social media use, emotional wellbeing, social networking, personal interactions

INTRODUCTION

With the increased dependence on social media in this day and age, people are more and more interconnected than ever. It could be perceived that people are more satisfied than ever as they are connected to others. In a study, people who were more socially active offline had higher psychological wellbeing and life satisfaction (Nezlek et al, 2002). Social interaction tells a different story in the virtual world, especially when those online relations affect their offline interpersonal relations. Over the past decade, there has been an exponential use of social media which has redefined the way communication is done with one another (Christensen, 2018). There is a significant psychological impact of the use of social media on interpersonal relationships, redefining how people communicate, connect and relate to their near and dear ones. Social media also impacts social dynamics as platforms provide new avenues for interaction transcending time limitations and geographical boundaries. With platforms like Twitter, Facebook, Instagram, etc., people can connect with family, friends, and near and dear ones irrespective of geographical distance, building a sense of consistency in relationships. It can increase intimacy or feelings of closeness as well as connectedness as people can constantly access information and updates on others' lives, improving the quality of interpersonal relations (Valkenburg & Peter, 2007).

However, use of social media also comes with its complexities and challenges in interpersonal relations. One important impact is doing social comparison. In this phenomenon, people subconsciously compare their achievements, appearances, and life updates to those posted by others through social media. It can result in feelings of jealousy, inadequacy, and reduced self-esteem as people may look down upon themselves. They feel that their own lives are more miserable than others (Tandoc et al, 2015). In addition, likes, shares, and comments on social media provide instant gratification and validation to strengthen further seeking of external validation and create dependency on it, potentially affecting expressive and genuine connections in connections in real-life (Kross, 2013). Overall, social media provides unexpected opportunities for communication and connection. But it has various impacts on interpersonal relationships, affecting both negative and positive aspects of human relation.

Research Gap

There has been a drastic rise in the prevalence of addiction of social media among young adults and teens due to the rise of social media platforms, posing a drastic effect on interpersonal relations and psychological health (Twenge and Campbell, 2018). Increased engagement with social media not just increases the feelings of loneliness and isolation, but also affects the quality of personal interactions, reducing the growth of genuine interpersonal relations (Levenson, 2017). Irrespective of increasing recognition of extreme psychological effects of social media addiction, there is still lack of research and empirical evidence on effects of social media on emotions and interpersonal relationships.

Research Objectives

To determine the social media usage patterns of users
To determine the impact of social media usage on interpersonal relationships
To find out the impact of social media usage on emotional well-being

Hypotheses

H1 – There is a significant impact of social media usage on interpersonal relationships
H2 – There is a significant impact of social media usage on emotional well-being

RESEARCH METHODOLOGY

This study adopts quantitative research approach to collect real-life and in-depth insights related to objectives of this study. This approach is significant to collect primary evidence and numerical data from participants.

The target sample for this study included social media users aged 18 to 45 years old. Google Form was distributed on Facebook pages, Twitter, email, and other platforms and prepared using self-structured questionnaire (having questions based on 5-Point Likert scale). All the aspiring participants were welcome to take a survey for a few minutes. The target sample size was 500 participants out of which 312 participants completed the survey. When it comes to analyze primary data, SPSS software and Excel spreadsheet were used to collect and interpret primary data. SPSS software was used to conduct frequency distribution of responses and to conduct one-sample t-test for hypothesis testing.

Data Analysis

Age distribution shows that the majority of participants 265 (85%) are aged 25 to 34 years. There are 31 participants (10%) within the 18 to 24 age group, which is evidence of the fairly young audience. The last 16 participants (5%) fall into the 35-44 years age group, meaning that the representation of older people is negligible. Table 1 and Figure 1 also indicate that the majority of participants were young adults, with fewer participants from the youngest and oldest age category. The study sample is mainly male with 296 (95%) of the participants being males. However, 16 participants (5%) are female and their number is much smaller compared to male participants. This significant difference draws attention to an almost exclusive representation of males in the study sample. These findings, as presented in Table 2 and Figure 2, show gender differences; consequently, the generalization of the study findings across various gender groups may be affected. There are 125 (40%) participants who spend 3 to 5 hours on social media, 108 (35%) participants spend 1 to 2 hours on social media, 64 (21%) participants spend more than 5 hours on social media, and only 15 (5%) participants spend less than one hour on social media (Table 3) (Figure 3).

Social Media Use

There are 124 (40%) participants who use Instagram most widely, 110 (35%) participants use YouTube most frequently, 62 (20%) participants use Facebook most frequently, and 16 (5%) participants use LinkedIn most frequently (Table 4) (Figure 4). When it comes to purpose of using social media, 126 (40%) participants use social media for news and updates, 91 (29%) participants use social media for entertainment purposes, 63 (20%) participants use social media for professional networking, and 32 (10%) participants use social media for staying connected to their friends and family (Table 5) (Figure 5). There are 202 (65%) participants who rarely or never post their pictures, videos or updates, 62 (20%) participants post their pictures, videos, or updates once in a month, and only 48 (15%) participants do that every day (Table 6) (Figure 6).

Impact of social media use on relationships

The research also finds that the perception people have for social media concerning strengthening of ties with close friends and family members is also divided. A large number of participants, 77 participants (25%), responded that they disagree with the statement and 76 of them (24%) responded strongly disagree. Also, there are sixty-three participants, that is, twenty percent of the participants who are not sure about this issue. As for the second statement, 64 participants (21%) are indifferent and 32 participants (10%) are even negative. The results presented in Table 7 show that the participants represented different opinions about the effects of social networks on interpersonal relationships.

The results show that a big portion of participants argue that social media has led to conflicts or misunderstandings in the relationships. Particularly, 141 participants (45%) are disagreeing and 76 participants (24%) highly disagree on the statement. At the same time, 63 participants (20%) are in the 'uncertain' category, meaning that their opinions are not entirely clear. On the other hand, 32 participants only strongly agreed with the statement, which shows that a few participants blame conflict or misunderstanding on social media. The following findings presented in Table 8 show that there is mixed perception regarding the effects of relationship between users of social media.

Here in table 9, the majority of participants are free from social comparison with others and feeling sad due to posts in social networks. In particular, 47 participants (15%) state that they are contrary to that, and 123 participants (39%) are contrary to that at a high level. But 62 participants that is 20% of the participants have developed a mixed feeling, they are in a fix. On the other hand, 64 (21%) participants partly agree while 16 (5%) participants strongly partly agree.

Impact on Emotions

These are the results show that people have different perceptions about the effect of use of social media on mood. A similar percentage, 78 (25%) participants deny the statement and another 45 (14%) participants are neutral. On the other hand, 95 participants (30%) partially agree, and 16 participants (5%) firmly agree, as presented in Table 10. There are 78 (25%) participants who disagree and 30 (10%) participants who strongly disagree that social media usage for long time makes them feel down, while 94 (30%) participants were not sure, 47 (15%) participants agree and 63 (20%) participants strongly agree (Table 11). The results show that the overall attitudes towards the question whether time spent on social media causes anxiety/stress are rather split. The remaining 48 participants (15%) and 91 participants (29%) strongly disagree. However, 110 participants (35%) could not make up their minds, which infers ambiguity. On the other hand, 32 participants (10%) partially hold this belief, 31 participants (10%) fully believe in it. The following table, table 12, shows how the participants' emotional experience differs regarding the use of social media. The research also reveals some ambivalent attitude toward the effects of social media on the mental state of people. 31 participants (10%) of the participants strongly agree, while 62 participants (20%) strongly disagree. A further 140 participants (45%) are still unclear, which shows that uncertainty is still quite high. On the other hand, 47 participants (15%) participants partially agree and 32 participants (10%) fully agree. These results, presented in Table 13, show that there are opposite views concerning the link between the usage of social media sites and mental health consequences.

Hypothesis testing

When it comes to perform hypothesis testing, one sample t-test was performed using SPSS software. In Table 14, Mean score of 2.676 indicates general acceptance that social media has improved relationships of participants with closed ones. Participants usually acknowledge that social media has led to misunderstandings or conflicts in their relationships to some extent (Mean = 2.266). Participants frequently compare their lives to others through their posts on social media and it leads to sadness (Mean = 2.369). Confidence interval of 95% further supports validity of responses. In addition, value of significance is $p<0.05$, which shows statistically significant measures. Even though close relationships are improved by social media, it also brought conflicts and negative emotional outcomes because of comparison. Hence, Hypothesis-1 is approved, i.e., there is a significant impact of social media usage on interpersonal relationships.

In Table 15, Mean score of 2.657 suggest that participants feel that social media has positively affected their mood most of the time. Participants are more likely to feel down after using social media in the long term (Mean = 3.112). This is a prominent trend on social media due to high t-value. Participants constantly feel stressed or anxious because of the time they spend on social media (Mean = 2.564). Participants generally agree that there is a negative impact of social media on their mental health (Mean = 2.859). Significance of this finding is further improved by the tight confidence interval and high t-value. There are significant p-values in all four measures. It confirms that there are both negative and positive emotional impacts of social media. Though social media uplifts mood quickly, overuse of it is strongly related to participants feeling stressed, down, and facing negative impacts on their mental health in the long term. Overall, there is a nuanced relationship between emotional well-being and use of social media, where moderation is important. Hence, Hypothesis-2 is approved, i.e., a significant impact of social media usage on emotional well-being ($p<0.05$).

DISCUSSION AND CONCLUSION

Social media has a profound and multidimensional impacts on psychological well-being of users and their interpersonal relationships. Social media addition can cause declined personal communications, feelings of isolation and loneliness, and reduced intimacy. In addition, increased engagement with social media may deteriorate quality of relationships, as people prefer virtual relationships over genuine connections with their near and dear ones. In addition, social media addiction can increase strain on relationships and existing interpersonal conflicts as people may experience comparison, jealousy, and insecurity caused by online personas which have been curated. The constant behaviors of seeking validation and availability in social media also affects genuine relationships and causes trust issues. In addition, social media addiction is pervasive and can neglect real-life obligations and relationships, which further affects dynamics of interpersonal relationships. Future studies should focus on knowledge of in-depth mechanisms on the impact of social media addiction on relationships. They can adopt preexisting theories like "Social Exchange Theory" and Attachment Theory for valuable insights on how relationships, patterns, and attachment styles have been shaped by social media. In addition, future studies can adopt principles from "Self-Determination Theory" which can focus on the role of competence, autonomy, and relativity in developing healthy digital behaviors in terms of interpersonal relationships. While exploring such theoretical models, researchers can add better knowledge of complex interrelation between interpersonal relations and social media addictions.

When it comes to practical interventions, they should be based on both theoretical models and empirical evidence to address the emotional effects of social media addiction on personal relations effectively. It could consist of the development of digital detox programs which are designed for families or couples, along with "cognitive behavioral therapy (CBT)" interventions which can target various thought patterns related to use of social media. In addition, researchers can include relationship education programs focused on communication skills and media literacy, encouraging people to navigate online spaces while retaining personal relationships. Practitioners may focus on the value of setting boundaries, building proper relationships and devoting quality time offline to build strong relationships in a highly digital world.

ABSTRACT

Chitra Banerjee Divakaruni is one of the utmost remarkable and significantly complimented writers of Indian origin, owning an extensive national and international readership since her debut publication. Her fiction relentlessly demonstrates a intense confront with the lived occurrences of migratory Indian womankind. Born in Kolkata, Divakaruni drifted to the United States for her studies, and her subjective confronts with relocation and ethnic adaptation organizes the approachable core of her fictitious work. She has conveyed ayearning to "go beyond silence" by giving voice to the battles, objectives, and resilience of migratory women as they traverse intriguing and frequently restrictive contexts. The plots of Chitra Banerjee Divakaruni exemplify the complex psychological miseries of womanhood by foregrounding their adversities, aspirations, and resilience in the disguise of disaster. This study discerns the psychosomatic fidgets and accomplishments that womenfolk may flout transversely across innumerable unrestricted and subjective backgrounds.

Keywords: Psychological, migration, conflict, responsive turbulence, emotional chaos, immigrants,tension, cognition, alienation

INTRODUCTION

The manuscripts of Chitra Banerjee Divakaruni discover the psychological encounters of women while engaging with ideas of individualism, ethnic skirmish, interpersonal interactions, and liberation. Speaking at IIT Gandhinagar, Divakaruni remarked, "My migration made me a writer because I missed my life in Kolkata," a proclamation that

précises her perpetual anxiety with ideas of relocation and disruption. Consequently, diaspora concerns the different cultures, migrants, their identities and their means for migration. This cultural opposition frequently sets diasporic personalities in a chaos of psychological dispute demonstrated by alienation, annoyance, and responsive turbulence. Neelu Jain perceives that Divakaruni structures tales and ethnicities through her characters, demonstrating the attempts of immigrants to sustainIndian cultural beliefs for their families in an alienground. As an award-winning South Asianwriter, Divakaruni presents anidiosyncratic realistic depiction of the impasse of Indian women folk, accentuating their endurance, silent submission, and prejudiced humiliation within a chieflymale-dominated humanity.

Divakaruni exclaims: "Women in particular respond to my work because I am writing about them… I want people to relate to my characters, to feel their joy and pain…" (Chaturvedi 55). Drawing upon her own lived experiences of migration, Divakaruni proficiently interlaces domains of native customs with those of mass culture. Chitra Divakaruni principally focuses on the disputes and emotional struggles of migrant women. Her female characters, especially when they move to alien lands, recurrently experience intense alienation and a sense of loss as they endeavor for self-identity and belonging. In their quest for identity and respect, migrant women frequently bear intense psychological conflict, resulting in psychological agony, shock, anger, distress, and persistent emotional turmoil. Divakaruni dexterously depicts these complex psychological dimensions, offering a meticulous and compassionate interpretation of women navigating displacement and selfhood.

Psychoanalytic evaluation proposes a robust framework for the analysis of literature, as it recommends effective insights into the unconscious forces that shape characters' behavior and the symbolic meanings embedded within literary texts. By exposing hidden psychological processes beneath the surface of narratives, this methodology, rooted in the theories of Sigmund Freud and Carl Jung, enables a deeper and more nuanced understanding of literary works. Psychological agony denotes a state of intense mental suffering or inner torment arising from emotional, cognitive, or psychological challenges. This concept encompasses a wide range of emotional struggles, including despair, fear, and anguish. Jung's theories explore the multifaceted psychological conditions represented in literature.

She reflects on her mother's dilemma, which she recognizes as her own: coming from a conventional background, her mother would have been amazed by a man like him (OG 215). After finishing her schooling, she becomes engaged to Rajat, a stage that promises emotional stability. However, this truth disrupts Korobi's serene life and propels her into an identity crisis, forming the central conflict of the novel: "Why did she (Anu) name me Korobi?" (OG 08). This question marks the beginning of her identity struggle. Divakaruni presents a realistic portrayal of Indian society, where Anu becomes a victim of rigid beliefs. She lives submissively throughout the narrative. Sarojini represents a rigid, patriarchal, and conservative mindset that separates a child from her lineage and distances a father from his child. It is she who undergoes psychological conflict due to Anu's displacement.

Korobi becomes deeply distressed when she discovers that she is the daughter of an Afro-American man. This realization fills her with shame and self-rejection, profoundly affecting her self-esteem: "I'm illegitimate?... I'm a bastard?" (OG 245). Her turmoil is intensified by societal norms that condemn illegitimacy. Divakaruni highlights an Indian social structure that marginalizes children born outside marriage. This realization is tied to Anu's cultural and geographical displacement, which ultimately leads to Korobi's fractured identity. Korobi decides to travel to America in search of her father and her identity. She leaves India to escape her suppressed condition. Rajat expresses his love and urges her to focus on the present, but Korobi remains determined. She says:

"Rajat, you don't understand! I'm shocked and hurt, yes, but I'm excited too… I have a father now!" (OG 67)
Divakaruni portrays Korobi as a strong-willed woman who follows her heart despite societal expectations. She postpones marriage, asserting her need for self-discovery. This defies traditional Indian values that prioritize family over individual desire.

Her grandmother Sarojini eventually places faith in her determination. Korobi consciously sacrifices her relationship in pursuit of self-identity. Concepts like liminality, hybridity, and transculturation become relevant here. Homi Bhabha's idea of liminality explains identity formation between cultures, while Naficy discusses the creation of new hybrid identities. Korobi's migration is influenced by both push and pull factors. Her decision is not impulsive but shaped by emotional and social pressures. Lee's push-pull theory explains how opportunities and aspirations motivate migration. Through her journey, Korobi evolves from passivity to self-assertion. She seeks independence and redefines herself. Divakaruni portrays women striving for love, autonomy, and dignity while navigating societal expectations.

Migration, though challenging, offers women opportunities for growth and empowerment. Divakaruni emphasizes the transition from restriction to independence, portraying diaspora as both struggle and transformation. Rajat's nostalgia reflects the diasporic conflict between past and present: "I long for our home…" (OG 154). This highlights the emotional tension of belonging. Divakaruni's characters attempt to balance tradition with modernity. Korobi's journey reflects courage and determination to redefine identity. Her migration is a conscious choice driven by self-discovery rather than external compulsion. Exile, in Divakaruni's works, becomes a constructive force in shaping identity. Through struggle, her protagonists achieve psychological liberation. Edward Said's view of exile as both loss and transformation resonates here. Divakaruni presents women supporting each other, forming bonds of solidarity. Migration becomes a pathway to independence rather than merely a consequence of hardship. Ultimately, her works depict transformation, empowerment, and the redefinition of identity. Displacement, though painful, allows growth, adaptation, and self-realization. Her narratives show that exile is not merely loss but also renewal and empowerment.

ABSTRACT

During the stage of development, children can face a range of challenges, including psychosocial, biological and family-related issues. It's essential to closely assess a child's mental health, understand their needs, and provide the right support and intervention when needed. Early detection of psychological problems makes it easier to tackle them effectively. The objective of this study was to Develop, validate and check the test-retest reliability of the Children Psychosocial Status Assessment Questionnaire (CPSAQ) for 8–16-year-old children, including all the pertinent domains and items pertaining to children psychosocial status. A cross-sectional research was carried in the senior secondary international school at Mullana – Ambala, Haryana for 3 months on 300 children between the ages of 8 and 16 years. The questionnaire was developed with reference to literature search and expert opinion. Both content and construct validity were used to examine the questionnaire's validity. The Cronbach Alpha reliability coefficient, item-total score correlation coefficient, and test-retest reliability were all investigated to assess the questionnaire's Reliability. Exploratory factor analysis yielded three factors with an eigenvalue of more than one. The first, second and third factors achieved eigenvalues of 6.03, 3.38, and 1.25 with percentages of variance 40.2, 22.5 and 8.3 respectively. The questionnaire was found to have a Cronbach's Alpha reliability score of 0.999, a test-retest reliability score of 0.998, and an item-total

score correlation coefficient of r=:0.998. This newly developed questionnaire was found to be valid and reliable to measure psychosocial status of school going children.

Keywords: Child, Mental Health, Survey and Questionnaire; Test-retest reliability, Factor analysis.

INTRODUCTION

Children at the phallic stage may have psychological, biological, physical, or family issues in addition to psychosocial issues.[1] It is critical to evaluate children's psychological condition, ascertain their requirements, and implement the appropriate intervention in response[2]. It is simpler to address psychological issues at the appropriate time when they are diagnosed early. Later in life, psychosocial issues may become more challenging to resolve and may give rise to distinct emotional and behavioural issues [3-5]. Post traumatic stress disorder (PTSD), anxiety, and depression are examples of emotional issues that typically manifest in later childhood [4]. Since, many youngsters lack the vocabulary and cognition necessary to articulate their emotions intelligibly, it can be challenging for parents or other caregivers to identify them early on [6]. Additionally, many caregivers and physicians struggle to differentiate between severe and protracted emotional distresses that should be considered illnesses and developmentally typical emotions (like as sobbing or fear) [7]. Chronic medical conditions such as atopic dermatitis, obesity, diabetes, and asthma are frequently linked to emotional issues like disordered eating patterns and low self-esteem, which lower quality of life [8,9,10]. It will be possible to determine how children are influenced by their circumstances and how they respond to them if psychosocial disorders are diagnosed early[11]. The understanding of detecting psychological disorders in children has increased in the past several years. To identify psychosocial issues in children, a number of questionnaires have been established. Research has been done to ascertain the validity and reliability of these questionnaires [12,13]. Nevertheless, no questionnaire has been created to assess the psychosocial standing of school-age children in the 8–16 age range. Because of their developmental traits, children can present difficult cases for detection of psychosocial issues. Consequently, it is imperative to have a measurement instrument that is both valid and reliable in order to evaluate the psychosocial condition of children aged 8 to 16. The objective of this study was to develop, validate, and assess the test-retest reliability of the Children Psychosocial Status Assessment Questionnaire (CPSAQ) for children aged 8–16 years, encompassing all relevant domains and items related to their psychosocial status. The study will add literature to maximize the potential use of this psychosocial assessment questionnaire for the researchers and clinicians for consideration in future contexts.

METHODOLOGY

The current cross – sectional study was undertaken during the period September 2024 to October 2024 in a senior secondary international school at Mullana – Ambala, Haryana. Ethical permission was obtained from Institutional Ethics Committee, with reference number IEC-284-P. The study was conducted as per declaration of Helsinki and ethical principles adopted by World Medical Association. The study has got ethical clearance from Institutional Ethical Committee of a tertiary care super speciality hospital.The study was conducted in three stages. During the first stage, an extensive literature search and review was undertaken to create the items related to the psychosocial status assessment questionnaire in school going children. In the second stage, the Delphi process was adopted to validate the created content. An electronic invitation was sent to 10 experts and out of which 8 experts gave the consent for the content validation. After the content validation the proposed questionnaire was implemented on 300 school children for checking its construct before that informed consent was taken from parent, teachers and children. Test-retest reliability was checked in the final stage.

Development

Development of items: Items that were corresponded to psychosocial assessment were identified and developed by means of an extensive literature search and direct interviews from experts.

Literature Search – An electronic search was conducted from the databases namely Cochrane Library, PubMed, Scopus and Web of Science to retrieve the relevant articles published as full text, in English Language in the last 10 years. Search terms used were children, fitness, psychology, social. Appropriate boolean operators like AND, OR was used. Electronic permission was obtained from the experts whom have participated in the validation process. From available 26 articles, 05 present questionnaires were referred in the formulation of first draft of the questionnaire. [14-18]

Experts interviews (direct) – Three physiotherapists with an experience of over decade working in the field of children health were interviewed to prepare domains for psychosocial assessment of school children and to obtain selected items.

Content validation

Delphi Method - The questionnaire was validated using Delphi method, professionals and speciality experts with an experience of atleast 8 years or more were contacted. To participate in the Delphi survey for content validation, ten experts were communicated by means of emails and 8 experts responded and agreed to validate the questionnaire. Out of 8 respondents, the experts were informed to provide the feedback about the relevant items on a 4 – point Likert questionnaire with choices denoted as 1 = Not Relevant, 2 = Somewhat Relevant, 3 = Quite Relevant, 4 = Highly Relevant. The ultimate draft of the questionnaire consists of item which scores 0.8 as item-content validity index (I-CVI) score as recommended by Lynn. [19] An item which scores less than 0.8 is not considerable. The Delphi process continuation persists until the questionnaire attains an average score 0.8 as content validity index.

Draft Questionnaire after Delphi Survey: The final draft is attached as Appendix for the ready reference.

Construct validity: For the checking of construct validity the questionnaire was circulated among 300 school children with age between 8 – 16 years. 300 responses were recorded and exploratory factor analysis was conducted for dimension reduction.

Test- retest reliability testing: Test-retest reliability was conducted among 51 school children with age of 8 – 16 years the reliability data was collected in two consecutive sessions with an interval of 48 hours.

Statistical Analysis

The analysis consisted of the results obtained from the literature review, expert interviews and after removal of duplication are presented in the tabulated manner. Every individual item was checked and recorded as per I-CVI. The general validity of the constructed questionnaire including the item group that was needed is shown as questionnaire content validity index (S-CVI) at the end of the Delphi survey. To decide upon S-CVI, both the universal agreement (UA) and the average method were included. According to Lynn, an outstanding validity was recommended if the I-CVI and S-CVI scores were obtained 0.78 and 0.90 respectively.[20]

Factor analysis and Test- retest reliability testing was done by using SPSS 20 version.

Factor analysis: Exploratory factor analysis was conducted for dimension reduction. Kaiser–Meyer–Olkin (KMO) and Bartlett's Test was conducted to check the sample adequacy[21]. Principal component analysis was carried out for data extraction. Factor retention was decided based on scree plot and eigen value more than one. Varimax component was used for factor rotation.

Reliability testing: Normality of the data was established with Shapiro-Wilk test. As the data follows normal distribution, for relative reliability testing, Intraclass Correlation and Pearson correlation was estimated. Additionally, Cronbach's alpha was done to determine the internal consistency of the measures. For absolute reliability, minimal detectable change (MDC), standard error of mean (SEM), regression analysis with least squared method was conducted.

RESULTS

A total of seven outcome measures were used to prepare the preliminary draft of the questionnaire. Items were added in the direct expert views phase. The final draft of the questionnaire after the removal of duplication was sent for content validation. In Table 1, the items included in the preliminary draft along with their sources are displayed. The items that were failed to achieve 0.8 I-CVI after the first Delphi survey were excluded. In the first round, 4 items did not attain 0.8 I-CVI and were removed from the final questionnaire. Hence a second round Delphi survey was conducted and all the 15 questions achieved more than 0.8 I-CVI score also 0.85 S-CVI score was achieved. As per Lynn criteria [19] this score is sufficient to retain all the items in the final draft of the questionnaire. Please Insert Table 1 almost here Total 15 items were included in the actual questionnaire as shown in the Table 1. The questionnaire S-CVI was achieved as 0.86 and it denotes that the questionnaire has got good content validity.

Factor analysis: The KMO measure (0.883) and Bartlett's test of sphericity ($p < 0.001$) indicated that the assumptions for factor analysis were met. Also, it indicates the adequate samples were recruited. Exploratory factor analysis yielded three factors with eigen value more than one. The first, second and third factor achieved eigen value of 6.03, 3.38, 1.25 with percentage of variance 40.2, 22.5 and 8.3 respectively. Table no.1 represented the respective eigen values. The scree plot (Figure:1) represented the 3 factors and the elbow joint is formed between the factor no three and four. [21]

Reliability analysis: Reliability analysis of CPSAQ showed excellent agreement between the two sessions (ICC:0.998). Pearson r also denotes excellent correlation between the two readings (r:0.998). The internal consistency of the data recorded was also found to be excellent. (Cronbach's alpha: 0.999). The absolute reliability was estimated by using scatter plot with linear regression. The line of best fit for the scores of CPSAQ is seen surrounded by the set of scores that are close to each other. The regression line is drawn scores by the method of least squares. Most of the data are within the 95% of confidence interval limit and only 3 outliers were found. The R^2 value is 0.996 which indicates a small percentage of variability between the two measures. The regression coefficient value (0.998) and MDC value (0.109) also confirms the less amount of variability in the scores. Please Insert Table 2 almost here

DISCUSSION

The present study designed and verified the psychosocial status assessment of the school going children aged between 8 – 16 years. Five items failed to attain the necessary I-CVI value and are, therefore were removed from the final questionnaire. This may be due to their weaker impact as compared to other items, as per the previous literature and experts' opinion, thus making them redundant to be included. According to Lynn criteria, panel of eight experts were included in the Delphi survey method for the content validation. Panel discussion was considered deemed to be inferior than Delphi survey, as dominant experts may influence the opinions of the other experts [22]. An excellent content validation score was obtained for the proposed questionnaire according to the consideration of the inputs from the extensive literature survey and the opinions of the experts. All the items were related to the routine activities of the children and their impact on their psychosocial health. The strength of this questionnaire is its quick application and later scoring to assess the psychosocial health in school-going children as overall and on item basis. This will help the assessors to notice the item/s to be worked upon to contribute towards the nourishment of the psychosocial health of the children. The newly developed CPSAQ exhibits excellent reliability, as evidenced by ICC: 0.998, Cronbach's alpha: 0.999, Pearson r 0.998. This high reliability indicates that the questionnaire consistently measures the intended constructs with minimal error variance. Several factors contribute to this excellent reliability includes Items were rigorously selected based on thorough literature review and expert input, ensuring they accurately reflect the target constructs. The precise wording and clear instruction and detailed guidelines for administration, minimize variability in testing conditions, reducing potential sources of error. The questionnaire was validated on a sufficiently large and diverse sample, enhancing the generalizability of the findings.The positive aspects of this toll includes researchers and practitioners can be confident that the questionnaire provides accurate

and consistent assessments of psychosocial well-being by enhancing ability to detect change (MDC: 0.109) in psychosocial functioning allows for effective monitoring of interventions and treatment progress. CPSAQ demonstrates significant utility in both educational and clinical settings. Within educational contexts, educators can utilize this tool to identify students requiring additional support, facilitating timely intervention and the implementation of individualized programs designed to cultivate resilience and promote emotional well-being. Concurrently, psychologists and mental health professionals can employ this questionnaire to monitor changes in psychosocial well-being over time, informing and refining treatment strategies. Furthermore, this questionnaire provides a valuable resource for researchers investigating the efficacy of various interventions aimed at enhancing psychosocial health in school-aged children.

Limitations

Limitations of the study includes, lack of linguistic and cultural adaptations, the practical administration of the tool was perform only in English medium school which can cause sampling bias.

CONCLUSION

The newly developed questionnaire has got excellent content validity and can be used in the clinical practice. In the future studies criterion related validity, reliability testing and psychometric properties should be examined to maximize the potential of use of this psychosocial assessment questionnaire in the clinical settings and for consideration in research contexts.

ABSTRACT

Fucoidan is a sulfated and complex polysaccharide, which is mainly produced by the brown macroalgae and is known to possess a wide range of therapeutic applications. In this review, the chemistry and structural differences of fucoidan are explored along with its biological action, especially the bone health, cancer therapy, and the regulation of gut microbiota. Major structural variables that determine its functionality are monosaccharide content, molecular mass, sulfation extent and location, and glycosidic bonds. It has been experimentally demonstrated that fucoidan has the ability to prevent osteoporosis by increasing the osteoblast differentiation and decreasing the osteoclast formation, thus being a potential treatment for the disease. Fucoidan has been shown to have selective anticancer effects in oncological research by inhibiting apoptosis, mitochondrial dysfunction, oxidative stress, and cell cycle regulation with enhanced effectiveness in low-molecular-weight and modified forms. In addition, fucoidan is a fermentable material of the microbiota of the gut, which contributes to the growth of beneficial microorganisms, augments short-chain fatty acid concentrations, enhances intestinal barrier integrity, and decreases inflammation. Pharmacokinetic experiments indicate that high-molecular-weight fucoidan is poorly absorbed and, on the contrary, depolymerized forms are better absorbed. Although there are preclinical and emerging clinical results that are promising, there are problems associated with structural variability, standardization, and clinical validation. This review is a synthesis of the available information about fucoidan as a marine-based nutraceutical and its possible uses as a complementary factor to alleviate issues with the bone, cancer, and microbiota.

Keywords: Fucoidan, *Undaria pinnatifida*, Marine polysaccharides, Sulfated polysaccharides, Structure–activity relationship, Bone health, Osteoporosis, Anticancer activity, Gut microbiota modulation, Prebiotics, Nutraceuticals, Therapeutic applications.

INTRODUCTION

Fucoidan is a marine-derived sulfated polysaccharide of brown macroalgae, with structural diversity and potential in curing diseases[1]. The structural heterogeneity of fucoidan depends on the species of algae, the environment, and the mode of extraction, which further influence biological activities[2]. Mechanistically, fucoidan modulates bone remodeling, exhibits selective cytotoxicity in cancer and enhances the effects of gut microbiota through the production of short-chain fatty acids[SCFA]. According to pharmacokinetic investigations, molecular weight and sulfation patterns of fucoidan determine the absorption, distribution, and biological efficacy. Fucoidan with high-molecular-weight has low bioavailability because of poor systemic absorption, but depolymerized forms exhibit improved bioavailability and tissue penetration. Although preclinical and early clinical research indicate promising therapeutic potential of fucoidan, there are still problems, including variation in its composition, unstandardized preparations and absence of large-scale studies[3]. This review incorporates the recent findings on the chemistry, biological effects, and clinical uses of fucoidan with emphasis on bone and cancer, and the modulation of gut microbiota. It correlates structural properties with functional performances and clinical implications, which indicates the potential and translational issues of fucoidan as a marine-based nutraceutical and therapeutic agent. **Figure 1** schematically illustrates its marine origin, chemical identity, and major therapeutic applications, including bone health, cancer, and gut health.

Marine polysaccharides as emerging therapeutic biomolecules

The marine polysaccharides, which are based on marine algae, microorganisms, and invertebrates, are receiving interest as therapeutic biomolecules because of their structural diversity, biocompatibility, and diverse biological activities. Some of the important polysaccharides, such as carrageenans, fucoidan and alginates, are multifunctional bioactivated with low toxicity and high biodegradability. The development of marine biotechnology and methods of extraction has increased the isolation of these polysaccharides, which has facilitated their use in biomedical applications like cancer treatment and drug delivery. Their capacity to regulate cellular signaling and host-microbe interactions makes them desirable tools in the treatment of complex diseases, which makes them a good next-generation therapeutic agent[4,5].

Botanical and geographical overview of fucoidan

Fucoidan is present in the cell wall of brown macroalgae, and especially in the family Phaeophyceae. It helps in maintaining structural integrity, and it helps in safeguarding against environmental forces. Different genera, such as Undaria, Fucus and Sargassum synthesize fucoidan variants that have different monosaccharide compositions and molecular weights. Undaria pinnatifida is of great interest, as it is a highly productive plant and its chemical composition is stable and predictable, with its biological properties, osteogenic stimulation, and anticancer properties. In contrast, Fucus and Ascophylum fucoidans exhibit a greater molecular weight and different sulfation patterns, whereas genera in the tropics yield complex structures with significant biological advantages. The influence of the environmental factors on the yield of fucoidan and its structure is immense and therefore requires meticulous taxonomic and geographic records in order to be used as a therapeutic agent[6,7].

History of Fucoidan Discovery

Fucoidan is one of the largest marine polysaccharides of the edible brown alga wakame [Undaria pinnatifida] and has gained great biomedical attention with a variety of biological activities. The term fucoidan was initially described by Kylin [1913] as a marine polysaccharide of brown algae. Kylin [1915] later determined fucoidan as a polysaccharide, and Bird and Haas [1931] showed its localization to the algal cell wall. The biological importance of fucoidan was realized when Springer et al. [1957] discovered its anticoagulant property, and it was subsequently purified by Bernardi and Springer [1962]. According to Marinova [2023], the commercial potential of fucoidan was achieved in the 1970s, when Sigma [USA] commercialized it as a functional substance[8,9].

Structure Activity Relationship [SAR] of Fucoidan

Fucoidan has a characteristic biochemical type of structure, with α-[1-3]- and α-[1-4]-linked L-fucose residues and different sulfation patterns. Besides fucose, fucoidan is composed of a different ratio of other neutral and acidic monosaccharides such as galactose, mannose, xylose, glucose and glucuronic acid. The relative concentration of these minor sugars differs with several factors, including algal part, harvest season, environmental factors, and the methodology of extraction. Galactose is generally the most common secondary monosaccharide, and it is a part of the branched parts of the polymer, whereas glucuronic acid adds negative charges that determine the solubility and molecular interactions. This heterogeneity adds to the structural complexity of fucoidan and makes it difficult to accurately classify, which results in a difference in reported compositions in different studies.One of the characteristic chemical properties of fucoidan is the presence of sulfate groups that are essential in determining its physicochemical and biological properties. Sulfation usually takes place at C-2 or C-4 positions of the fucose residues, but sulfation at C-3 has been observed in some fractions. The extent of sulfation is quite diverse and typically ranges between 15 and more than 30 per cent by weight, and is highly dependent on extraction conditions and algal maturity[10]. It has been shown that changes in its molecular weight and sulfate concentration affect its activity on osteogenic signaling and cancer cell behavior, immune regulation, and gut microbiota. The key structural determinants of fucoidan bioactivity and their corresponding biological implications are summarized in Table 1, highlighting the critical role of sulfation position, molecular weight, and linkage type in defining therapeutic outcomes.

Analytical characterization of Fucoidan: Importance and Methodological Overview

Fucoidan is a sulfated polysaccharide that is a complex with biological roles that are dependent on its monosaccharide content, linkages, sulfation, molecular weight, and branching. Its analytical characterization is vital with fluctuations in the extraction processes and sources of algae. Several chromatographic and spectroscopic methods are used to study fucoidan, which provides comprehensive information on the compositional, conformational, and functional characteristics of this polysaccharide, justifying its use in therapy. The principal analytical techniques used for fucoidan characterization, along with the specific structural parameters they resolve, are summarized in Table.2.

Fucoidan in Bone Health and Skeletal Disorders

Fucoidan is a potential bioactive polysaccharide in marine biology of bone, which has anabolic and anti-resorptive effects. In order to understand the bone-forming effects of fucoidin, Kim et al. [2015] discovered that fucoidin enhances osteogenic differentiation of human mesenchymal stem cells by increasing alkaline phosphatase activity and mineral deposition through the up-regulation of BMP-2 and activation of ERK/JNK - Smad1/5/8 pathways[27].To add to these cellular results, Hwang et al. [2016] found that oral intake of low-molecular-weight fucoidan induced osteogenic marker expression in vitro and led to an increase in bone mineral content and density in vivo in murine models, indicating that nutraceutical or dietary interventions to address age-related bone loss might be possible[28].In addition to anabolic activity, fucoidan has been shown to have anti-resorptive effects. Kim et al. [2014] identified that fucoidan has a significant anti-resorptive effect by suppressing receptor activator of nuclear factor-κB ligand[RANKL]-induced osteoclast differentiation, inhibiting the activation of p38 mitogen-activated protein kinase [p38 MAPK], c-Jun N-terminal kinase [JNK], extracellular signal-regulated kinase [ERK], and nuclear factor-κB [NF-κB], and suppressing the expression of nuclear factor of activated T-cells, cytoplasmic 1 [NFATc1**]** and other osteoclastogenic genes[29].Notably, the application of fucoidan is also applicable in bone tissue engineering. The study of Jin et al. [2011] compared poly-e-caprolactone/fucoidan composite scaffolds with polymer controls and found that fucoidan enhanced mesenchymal cell adhesion and mineral deposition, which was superior to polymer controls[30].On the same note, Devi et al. [2022] used fucoidan in the alginate-hydroxyapatite-graphene oxide scaffolds which promoted osteogenic differentiation of the stem cells suggesting that they can be used in composite biomaterials[31].According to the report by Xie et al. [2024], fucoidan-hybrid hydroxyapatite nanoparticles did not only stimulate osteogenesis of periodontal ligament stem cells but also decreased the production of pro-inflammatory cytokines like tumor necrosis factor-alpha[TNF-a] and interleukin-1 beta [IL-1b]during inflammatory stress, which indicated potential use in periodontal bone loss, and other inflammatory skeletal diseases[32].Zhang et al. [2024] have shown that the sulfated galactofucan of Sargassum fusiforme is effective in preventing osteoporosis in

ovariectomized mice since it suppresses the development of osteoclasts and promotes the growth of osteoblasts. The process includes the inhibition of nuclear factor of activated T-cells cytoplasmic 1-mediated osteoclastogenesis and stimulation of runt-related transcription factor 2 and osteogenic markers genes which result in improved bone microarchitecture and enhancement of bone mineral density[33].**Figure 3** shows how fucoidan biotransformation affects the outcome of osteoclast inhibition and bone health. Increasing the application of fucoidan in the treatment of inflammatory bone diseases, Studies have discovered that fucoidan-hybrid nano-hydroxyapatite particles increased osteogenic differentiation of periodontal ligament stem cells and decreased pro-inflammatory cytokines, including tumor necrosis factor-alpha and interleukin-1 beta[34]. Hamrun et al. [2025] demonstrated that fucoidan-incorporated biomaterial scaffolds improved key parameters such as alkaline phosphatase activity, collagen type I deposition, osteocalcin expression, and runt-related transcription factor 2 signaling in stem cell models, thus facilitating osteogenic differentiation and matrix mineralization for regenerative bone repair[35].

Anticancer Properties of Fucoidan

Cancer development entails unregulated cell proliferation, cell death resistance, oxidative stress and cell-cycle damage. This has resulted in research on bioactive compounds, which attack cancer cells. Fucoidan has potential as an anticancer agent as it has been shown to cause apoptosis, mitochondrial dysfunction and alteration of survival signaling pathways in different cancer models.Cruz Riquelme et al. [2024] extracted a fucoidan fraction [FLt] of Lessonia trabeculata and evaluated its cytotoxicity on 4T1 murine triple-negative breast cancer cells by using different assays, such as MTT, Annexin-V/PI, caspase-3/7 activity, and qRT-PCR, and concentrated on the transcripts associated with apoptosis. The study found that FLt and doxorubicin had an IC50 of 561 mg/mL and 0.04mg/mL, respectively. FLt induced apoptosis, demonstrated enhanced caspase-3/7 activity and DNA fragmentation, and also increased pro-apoptotic transcripts [caspase-8, caspase-9, AIF] and decreased anti-apoptotic transcripts [Bcl-2, XIAP]. The study showed that FLt triggers intrinsic and extrinsic pathways of apoptotic processes, and decreases anti-apoptotic processes, which are typical of efficacious cytotoxic anticancer agents[36].Cholaraj and Venkatachalam [2024] explored the use of fucoidin [SF-PB], extract frpm *Padina boergesenii,* in the treatment of cervical carcinoma [HeLa]. They described SF-PB in terms of FT-IR, NMR, HPLC and ESI-MS and performed antioxidant studies. The findings showed that the IC50 of cytotoxicity was about 38 mg/mL, and about 54 percent inhibition was found at 40 mg/mL. It was revealed that SF-PB caused apoptosis which is the nuclear condensation, elevated level of ROS, caspase-3 activation, and G1 phase cell-cycle arrest. Interactions with apoptotic proteins were confirmed with the help of molecular docking. At 250mg/ml, the environmental toxicity tests showed a benign profile.

The results indicate that the use of ROS-induced mitochondrial damage triggers caspase-dependent apoptosis and proliferation arrest, which is why SF-PB was shown to be an excellent in-vitro anticancer agent[37].The study by Kumaran et al. [2024] examined the effects of fucoidan obtained using Turbinaria decurrens on cancer cells [A549] of the lung. The fucoidan was extracted using heat water, ethanol precipitation, and ion-exchange purification, and its structure was characterized using Size Exclusion Chromatography with Multi-Angle Light Scattering[SEC-MALLS], NMR, FT-IR, ESI-MS. Through biological assays, the purified fucoidan was found to have dose and time-dependent cytotoxicity in the A549 cells with effective concentrations of approximately 250 -1g/mL, and low toxicity in normal HEK293 cells. The action mechanism is characterized by mitochondrial membrane depolarization, increased expression of pro-apoptotic [Bax/Bad], decreased expression of anti-apoptotic Bcl-2, and S–M phase cell-cycle arrest. The results indicate intrinsic apoptosis that is regulated by the regulation of the mitochondrial pathways, where the selectivity of fucoidan to cancerous cells as opposed to normal cells is significant, with a strong relationship existing between its sulfate pattern, its 14-sylvanate backbone structure and its activity[38].Nguyen et al. [2024] investigated fucoidan of *Turbinaria decurrens* by the methods of SEC-MALLS, IR, ESI-MS, NMR and SAXS.

They obtained hydrolyzed and low molecular weight fractions and conducted anticancer tests on HT-29 colon cancer cells, with IC50 of 5.41 +- 0.36 to 73.52 +- 2.54 mg/mL depending upon molecular weight and branching properties. The study concluded that the reduced molecular weight, smaller dispersion, and short-branched rod shapes enhanced anticancer activity[39]. Zhou et al. [2024] compared the antitumor activities of acetylated Undaria pinnatifida fucoidan [ASA-UPFUC] and native UPFUC on A549 NSCLC cells, and grafted fucoidan with aspirin and

described the product.. ASA-UPFUC presented a much lower IC50 of 49.09 mg/mL, which implies a higher potency. The compound caused an increase in reactive oxygen species [ROS], a decrease in mitochondrial membrane potential and an optimization of apoptosis markers. Molecular docking proposed better interaction with TRAIL receptors The research arrived at the conclusion that acetylation increases solubility, charge density, receptor binding, and causes apoptosis to block the NF-kB survival pathways[40].The synthesis of Turbinaria decurrens and Sargassum cinereum fucoidan-based gold nanoparticles [F-AuNPs] was synthesized by El-Newehy et al. [2025] to treat hepatocellular carcinoma. The methods of characterization were UV-Vis, TEM, XRD, FTIR and DLS. The nanoparticles exhibited antioxidant and cytotoxicity properties with the IC50 values of 377.6 mg/mL in HepG2 cells and the IC50 of normal BNL cells was more than 1000 mg/mL. There were strong interactions with COX-2 [-7.1 $kcalmol^{-1}$] and TERT [[-5.4 $kcalmol^{-1}$]. The results indicated cell-cycle arrest in G0/G1 and prevented the proliferation of DNA, which implied increased uptake and effectiveness of nanoparticles with less toxicity against normal cells[4].

Fucoidan and Gut Microbiota Modulation

The gut microbiota is crucial for intestinal health, immune responses, and metabolism, with disruptions linked to inflammation and disease. Fucoidan, a non-digestible marine polysaccharide, has gained interest for influencing microbial composition and interactions by serving as a substrate accessible to microbiota. Qingsen Shang et al. [2016] studied the effects of the brown algae fucoidan on C57BL/6 mice, and they used high-throughput 16S sequencing to determine the changes in gut microbiota. The results showed a growth of beneficial *Lactobacillus* and *Ruminococcaceae* and a decrease in the opportunistic taxa such as *Peptococcus*. Fucoidan was used as a non-digestible substrate, which increased fiber-degrading and short-chain fatty acid-producing bacteria, which is a sign of prebiotic effects. Moreover, the decreased serum lipopolysaccharide-binding protein was also a sign of decreased systemic inflammation and endotoxemia, which underscores the effect of fucoidan in enhancing probiotic bacteria, as well as, reducing inflammatory indices in mouse models[41].

In the study by Zheng et al. [2023], the isolation and characterization of Undaria pinnatifida fucoidan [UPF] was conducted in the dietary-fiber-deficient C57BL/6 mice. UPF supplementation led to reduction of Proteobacteria and SCFA-producing taxa, especially of the phylum Bacteroidetes. The proposed mechanisms emphasize the role played by UPF in the replenishment of fermentable sulfated polysaccharides to the colon microbes, facilitation of microbial fermentation, and the increase in short-chain fatty acids such as butyrate, and thus enhancing mucosal health. Secondly, UPF increased tight-junction and mucin gene expression which implies a protective microbiota-metabolite-epithelium axis.The results demonstrate that UPF promotes intestinal barrier functions, decreases pro-inflammatory cytokines [IL-1b, TNF-a], and changes serum lipid metabolites, and provides systemic metabolic advantages relating to modulation of microbiota[42].Shu Wang et al. [2023] had a randomized clinical trial to evaluate the efficacy of fucoidan in eliminating H. pylori when used as an adjunct in eradicating H. pylori in standard quadruple therapy. The patients were given fucoidan or control and the findings showed that fucoidan could preserve the beneficial microbiota such as Bifidobacterium and reduce the elimination of beneficial taxa by antibiotics. Fucoidan and synbiotics combination therapy also increased butyrate-producing microbes and decreased the number of harmful pathogens like *Klebsiella* and *Escherichia-Shigella.* Fucoidan can serve as a fermentable fibre, which enhances short-chain fatty acid synthesizers, and probably prevents H. pylori adhesion. It has also been shown that patients undergoing fucoidan treatment to manage gastrointestinal symptoms, as well as with microbial diversity when on antibiotics alone, which contributes to the significance of microbiota preservation[43].

The study by H. Wang et al. [2024] was an open-label randomized clinical trial evaluating the impact of fucoidan [Laminaria japonica] and synbiotics in patients that received bismuth quadruple therapy to H. pylori. The research found that fucoidan supplementation caused a rise in alpha-diversity and an increase in beneficial microbial taxa and reduced the growth of pathogenic Escherichia-Shigella.The suggested mechanisms are a prebiotic effect that leads to an increase of short-chain fatty acid [SCFA] producers during antibiotic use, and a symbiotic relationship with probiotics that contributes to microbial resilience. Also, fucoidan and synbiotic seemed to ameliorate antibiotic-induced dysbiosis, which was associated with better gastrointestinal symptom patterns[44].Lin Wang et al. [2020] examine how Ascophyllum nodosum fucoidan changes under the conditions of antibiotics incorporated in mice to

cause model dysbiosis. It is established that fucoidan supplementation can be used to normalize the useful microbial taxa and suppress the growth of the harmful ones. Mechanistically, fucoidan facilitates fucose-grabbing bacteria and short-chain fatty acid [SCFA] producers to recolonize the gut, and it decreases gut inflammatory response by regulating microbial metabolites and host immune responses. The results indicate the role of fucoidan in the process of colonic health restoration in the conditions of antibiotic recovery, which has been demonstrated by the improvement of mucosal markers and a decrease in inflammation[45].In Karina Hogsgaard et al. [2023], the authors examined the impact of L-fucose and fucoidan on human fecal microbiota in in vitro fermentation of the samples. The research found that fucose prominently increases the cross-feed of fermentation, leading to increased production of propionate and butyrate. Although Fucoidan is not as fermentable as an intact polymer, certain fucose-using microbes metabolise it or after it has been partially depolymerised, explaining its dependence on molecular weight observed in vivo. These data support the significance of microbial metabolism of fucose and cross-feeding to assist in short-chain fatty acid [SCFA] production in response to fucoidan and explain why fucoidans of lower molecular weight or those that are partially degraded can have more effective prebiotic properties[46].

Preclinical and clinical studies

The cumulative evidence of preclinical and clinical studies shows that fucoidan has attractive unrealized therapeutic potential.Low-molecular-weight fucoidan [LMW-Fuc] at doses of 5-10mg/kg [intraperitoneal] has been shown to have a significant positive effect on bone mineral density, trabecular microarchitecture, and mechanical strength, and osteoclast differentiation by inhibition of RANKL-mediated signaling and suppression of bone resorption markers [TRAP, CTX-1] in preclinical bone studies, especially in ovariectomized rat models[53].More recent biomaterials research has also demonstrated that incorporation of fucoidan into composite scaffolds [e.g., hydroxyapatite/fucoidan hydrogels] can increase local bone regeneration of critical-sized calvarial or femoral defects through angiogenic stimulation, growth factor retention [BMP-2] and improving new bone formation than controls, but scaffold compositions and loading levels vary across studies[54].The most recent biomaterials studies have also indicated that incorporation of fucoidan into composite scaffolds [e.g. hydroxyapatite/fucoidan hydrogels] can positively influence the local bone regeneration in critical-sized calvarial or femoral defects by facilitating angiogenesis, trapping growth factors such as BMP-2, and enhancing the formation of new bone in comparison to controls, although scaffold compositions and loading levels differ across studies[55,56].In vitro fermentation of human feces and in vivo dysbiosis of mice Preclinical studies focused on gut microbiota have confirmed that both the hydrolyzed and native fucoidan fractions [e.g. 1% w/v fermentation substrate in vitro; 50-200 mg/kg/day oral in mice] selectively enrich beneficial taxa like *Bifidobacterium* and *Lactobacillus*, increase total short-chain fatty acids [particularly acetate and propionate] Such microbial changes are associated with decreased systemic inflammatory signatures and enhanced gut barrier activity, which supports hypothesized gut-bone and gut-immune axes[57,58]. The results of a randomized controlled trial of patients with metastatic colorectal cancer undergoing chemotherapy showed that the oral administration of the low-molecular-weight fucoidan, at about 4g/day, resulted in better scores the quality-of-life scores and some immunologic biomarkers than placebo. This implies that it is tolerable and may be used as an adjunctive treatment in supportive oncology care, although the sample sizes are small [28 treatment vs 26 control subjects][59]. There is also growing translational interest, as indicated by several clinical trials registered on ClinicalTrials.gov. In adults with metabolic disease and gut microbiome endpoints [completed]; NCT06295588 is a feasibility pilot trial of oral fucoidan supplementation on cancer survivor fatigue and inflammation; NCT05437887 assessed the effects of fucoidan on gut microbiota in atopic dermatitis with 3 months oral supplementation; NCT03422055 tested the tolerance and biodistribution of 99mTc-labelled fucoidan [radiolab]. The best safety and tolerability are generally reported in these trials, but are constrained by limited cohort sizes, heterogeneous formulations [varying Mw, sulfation and excipient profiles] and surrogate outcomes [microbiota composition, symptom scales, biomarker changes] instead of clinical endpoints[60–63].

Pharmacokinetics and Bioavailability

Fucoidan is not readily absorbed passively by the intestine because it has a high molecular weight and a dense negative charge; nevertheless, it is observed to be systemically absorbed after oral administration of fractions with low molecular weight. The drug is selectively excreted to the liver and spleen, renal and biliary system and

eliminated mainly by the kidney and bile. Moreover, fucoidan is resistant to gastric acid and digestive enzymes and arrives at the colon intact [or partially], where it is fermented by gut microbiota. This results in partial microbial enzyme depolymerization, which results in oligosaccharides and metabolites, including short-chain fatty acids, which are associated with anti-inflammatory, metabolic, and bone-protective effects. Also, fucoidan is more bioavailable when of low-molecular-weight, and low-molecular-weight fucoidan is more bioavailable and better penetrating of tissues. Sulfation and positional distribution of sulfation also tune protein binding, receptor interactions and anticoagulant activity, which are critical factors that determine the therapeutic effect of sulfation in many diseases, including cancer, and inflammatory diseases[64].

Challenges and Future Perspectives

Although there are good prospects, there are a number of challenges that are critical. The consistency of fucoidan preparations in terms of algal species and geographic source, extraction regimen, molecular weight distribution, and sulfation signature is in urgent need of standardization so that it can be reproducible and translated to the clinic. To decipher gut-bone and gut-cancer mechanistic axes, integration of high-level structural elucidation with multi-omics technologies, such as microbiomics, metabolomics and transcriptomics, will be necessary. Individualized nutrition plans utilizing personal microbiome data can also optimise fucoidan-based interventions, and sustainable fish farming and green harvesting technologies should be focused on so that large-scale production can be made sustainable. Lastly, there should be well-powered clinical trials with chemically defined fucoidan preparations and clinically meaningful endpoints that need to be utilized to determine evidence-based therapeutic use[65,66].

CONCLUSION

Fucoidan is a marine sulfated polysaccharide that has great therapeutic possibilities based on its chemical structure like the molecular weight and the level of sulfation. It supports the differentiation of osteogenic cells and inhibits the bone remodelling, with its applicability to osteoporosis and inflammatory diseases. Also, it has anticancer effects with apoptosis and oxidative stress regulation, particularly in low-molecular-weight forms. Fucoidan also has an overall beneficial effect on gut health by modulating the composition of the microbial flora and improving the intestinal functionality, which is related to bone and immune systems. Sourcing and preparation of fucoidan however, are different, thus, hampering clinical applications. In the future, the consistent formulations and stringent clinical trials are critical in its prospective application as a nutraceutical and therapeutic in the treatment of bone diseases, cancer and gut diseases.

Table 1. Chemical Determinants of Fucoidan Structure–Activity Relationships and Their Therapeutic Implications

Structural Feature	Chemical Description	Structural Variability	Biological Activity	Therapeutic Effect	References
Monosaccharide backbone	Predominantly α-L-fucopyranose residues	Fucose content varies with species and tissue	High fucose enhances bioactivity and receptor binding	Anticoagulant, anticancer, and bone health	[11]
Anomeric configuration	α-configuration of L-fucose	Highly conserved	Provides conformational stability and specificity	Immune and selectin interactions	[12]
Glycosidic linkages	α-[1→3] or alternating α-[1→3]/α-[1→4]	Species-dependent	Determines 3D conformation and bioactivity	Anticancer, anticoagulant activity	[13]
Degree of sulfation	Sulfate ester groups on fucose OH groups	~15–30% [w/w]	Higher sulfation increases electrostatic interactions	Anticoagulant, antiangiogenic activity	[14]
Sulfation position	C-2, C-4, occasionally C-3	Position-specific	Sulfation pattern more important than total sulfate	Coagulation factor binding	[15]
Branching	Galactose,	Linear vs	Alters flexibility	Antioxidant,	[16]

pattern	mannose, xylose side chains	branched	and accessibility of sulfate groups	immunomodulatory activity	
Minor monosaccharides	Galactose, glucuronic acid, glucose	Variable proportions	Fine-tunes solubility and charge	Anti-inflammatory, prebiotic activity	[17]
Acetyl groups	O-acetyl substitution	Low abundance	Modulates hydrophobicity and stability	Anti-inflammatory activity	[18]
Charge distribution	Spatial sulfate/uronic acid arrangement	Homogeneous vs clustered	Determines protein-binding affinity	Growth factor inhibition	[19]
3D conformation	Helical or extended chains	Linkage-dependent	Controls receptor accessibility	Cell signaling modulation	[20]

Table 2. Analytical Techniques Used for Fucoidan Characterization

Analytical Technique	Method Type	Key Information Obtained	Relevance to Fucoidan Characterization	Reference
Ion-exchange chromatography [IEC]	Chromatographic	Separation by charge; fractionation by sulfation	Essential for isolating fucoidan fractions with different sulfate contents for SAR studies	[10]
Size-exclusion chromatography [SEC]	Chromatographic	Molecular weight distribution and polydispersity	Distinguishes high- and low-molecular-weight fractions for activity profiling	[21]
High-performance liquid chromatography [HPLC]	Chromatographic	Monosaccharide composition after hydrolysis; purity estimation	Used to quantify fucose and minor sugars for compositional profiling	[22]
Fourier-transform infrared spectroscopy [FT-IR]	Spectroscopic	Functional groups [sulfate esters, OH, glycosidic bonds]	Rapid confirmation of sulfation and backbone features	[23]
2D NMR [COSY, HSQC, HMBC]	Spectroscopic	Glycosidic linkages; sulfation positions; branching	Resolves fine structural features and bonding patterns	[24]
Mass spectrometry [MALDI-TOF, ESI-MS]	Spectroscopic	Oligosaccharide molecular masses; sulfation profiles	High-resolution mass info for sequence and substitution	[25]
LC-MS coupling	Hyphenated technique	Molecular mass with chromatographic separation	Enables sensitive analysis of complex mixtures	[26]

Table 3. Experimental Studies [2020–2024] Investigating the Effects of Fucoidan on Gut Microbiota Composition, Mechanisms, and Host Physiology

Author	Algal source/fucoidan type	Model	Microbial taxa altered	Host physiological outcomes	Reference
Li et al. [2024]	Purified fucoidan	DSS-induced colitis mice;	↑ *Bacteroidetes*; ↑ SCFA-producers	↓ IL-1β / IL-6 / TNF-α; improved colonic	[47]

	[structurally characterized; extracted from *U. pinnatifida*]	Peyer's patches focus	[Ruminococcaceae, Lachnospiraceae]; restored diversity	histology and barrier integrity; elevated fecal SCFAs.	
Yang et al. [2024]	*Undaria pinnatifida* fucoidan [UPF]	C57BL/6 mice [chow/HFD] with exercise performance readouts	↑ *Akkermansia*, ↑ *Lactobacillus*, improved Firmicutes/Bacteroidetes ratio	Increased voluntary running, ↑ muscle mitochondrial/energy gene expression [PGC-1α, COX4, IGF1], metabolic benefits correlated with taxa shifts	[48]
Zheng et al. / Frontiers in Nutrition [2024]	*Undaria pinnatifida* fucoidan [UPF]	Mice — dietary-fiber deficiency or HFD models	↓ Proteobacteria [reduction of dysbiosis markers]; ↑ SCFA-associated taxa	↑ tight-junction & mucin gene expression; ↓ pro-inflammatory cytokines [IL-1β, TNF-α]; improved lipid metabolism	[49]
Wimmer et al. [2025]	*Undaria pinnatifida* fucoidan [characterized UPF]	In-vitro short-term SHIME® gut model coupled to Caco-2/THP-1 co-culture [human-relevant gut simulation]	Stimulation of saccharolytic / butyrogenic genera [donor-dependent]; reduction of some potentially harmful genera	Increased butyrate [proximal/distal colon compartments], anti-inflammatory cytokine profile in co-culture model; mechanistic support for butyrogenic + immunomodulatory effects	[50]
Wu et al. [2025] — *Microbiome*	Sulfated dietary fibers including fucoidan [various brown seaweeds]	In vitro [human isolates/ex vivo fecal communities] + in vivo recovery experiments	Fucoidan protected a broad spectrum of gut isolates; supported recovery of commensal taxa after antibiotics	Fucoidan facilitates microbial recovery post-antibiotic exposure in vivo; protection depends on Mw and sulfation content — translational implications for antibiotic co-therapies	[51]
Du et al. [2026]	Fuc-S [ultrasonically degraded fucoidan derivative; low-MW, characterized]	STZ/HFD-induced Type-2 diabetes mice	↑ *Bacteroides acidifaciens* and other beneficial taxa; ↑ total SCFAs	Alleviated diabetic liver injury: improved antioxidant enzyme activity [SOD, CAT], decreased MDA; ↑ tight-junction proteins [ZO-1, occludin]; improved glucose & lipid parameters	[52]

ABSTRACT

Herbal constituents have multiple effects on the human body. These polypharmacological actions could contribute to the mitigation of complex pathologies, such as chemoresistance in cancer therapy and pathogenesis of Alzheimer's disease. Two central proteins implicated in these conditions are acetylcholinesterase (AChE) and P-glycoprotein (P-gp). This study Aimed to investigate the inhibitory effects of phytochemical constituents on acetylcholinesterase (AChE) and P-glycoprotein (P-gp). It also screens their binding affinities, physicochemical drug-like properties, and safety profiles to identify suitable multimodal drug candidates for therapeutic intervention. The crystal structures of acetylcholinesterase (AChE, PDB ID: 4EY7) and P-glycoprotein (P-gp, PDB ID: 6QEX) were retrieved and validated at high resolution before molecular docking procedures because of their importance in drug metabolism. A curated library of plant-derived compounds was filtered using criteria for drug-amenable compounds and docked using AutoDock Vina. The protein-ligand interactions of the most promising candidates were analyzed and underwent thorough ADMET profiling using SwissADME, pKCSM, and ProTox-III, allowing for an assessment of their pharmacokinetic behavior and potential toxicological liabilities. Berbamine, berberine, berberrubine, hydrastine, and quercetin, which belong to the flavonoid and alkaloid classes, are potent inhibitors that bind avidly and interact with essential domains of both target proteins. Pharmacokinetic analysis (ADMET profiling) showed that hydrastine and berberrubine have favorable properties, such as high systemic bioavailability, blood-brain barrier permeability, metabolic stability, and low cytotoxicity. Of interest is the fact that hydrastine is neither a substrate of P-

glycoprotein nor metabolized by liver pathways; therefore, it has a longer half-life within the central nervous system, which translates into an enhanced safety profile. The herbal constituents hydrastine and berberrubine show potential for inhibiting acetylcholinesterase (AChE) and P-glycoprotein (P-gp). They exhibit good molecular interactions and favorable pharmacological and toxicological characteristics. These attributes indicate that they may be a basis for the development of phytotherapeutic agents for Alzheimer's disease and multidrug-resistant tumors. Prospective investigations should utilize these compounds in animal models, optimize chemical designs, and evaluate synergistic actions with existing therapeutics to aid clinical translation.

Keywords: Herbal compounds, acetylcholinesterase (AChE), P-glycoprotein (P-gp), molecular docking, multi-targets.

INTRODUCTION

Herbal medicines have long been acknowledged as having a multifaceted therapeutic potential in the treatment of diverse diseases and are often observed to have a simultaneous multi-target effect [1] at a molecular level. This polypharmacological characteristic is highly beneficial for the management of complex disease states, in which the coordinated regulation of disparate biological processes can be beneficial to achieving better clinical results. Unlike conventional single-pathway single-target pharmaceuticals [2], herbal pharmaceuticals generally consist of a heterogeneous range of bioactive components with the property of together working synergistically in the regulation of multiple biological mechanisms, and therefore suggesting increased efficacy and tolerance for resistance/adverse events [3]. The recent pharmacological researches have focused on characterization of specific constituents of the herb that interact with well defined molecular targets involved in various pathological conditions [4]. The strategy of simultaneous targeting of two or more tumoral pathways is of much interest, in particular in diseases wherein overlapping or interconnected pathogenesis mechanisms are characteristic, as simultaneous modulation of several targets may be more comprehensive in terms of therapeutic benefit [5]. Being based on distinct molecular pathways involved in different processes of the disease, such herbal agents offer a promising approach for the development of multifaceted drug combination patterns which more effectively respond to the inherent complexity of human disease in comparison to traditional monotherapies [6]. In the current investigation, we tested the efficacy and mechanisms of action of a selected herbal agent which affects two molecular mechanisms responsible for two different diseases. The chose of these targets was grounded on their critical roles during the advance of the disease and on their therapeutic potential [7]. Combining in vitro assays, molecular docking studies and functional analyses we attempted to understand the biochemical and cellular effects of the natural compound based on its interaction with the intended targets [8]. A good knowledge of these interactions will provide useful information about the pharmacodynamics of the compound and its ability to invoke therapeutic effects in different disease situations [9]. This dual-target drug discovery program not only adds to our understanding of the complex interaction between herbal compounds and biological systems but also forms part of the general paradigm of the multi-target therapeutic development [10].By exploiting the inherent complexity of herbal medicines, the present research efforts are aimed at the development of novel treatment strategies with enhanced capability to cope with multifaceted challenges associated with various chronic and acute disease states [11]. Ultimately, the results that emerge from this investigation can potentially fill the empirical void for the rational design of herbal based multi-target therapies, which would significantly broaden the scope of treatments presently available to patients and their efficacy [12].

MATERIALS AND METHODS

Protein Preparation

In the present study, principal protein targets were chosen because of their role in the pathogenesis of Alzheimer's disease: acetylcholinesterase (AChE) and P-glycoprotein (P-gP), the latter being involved in multidrug resistance in malignancies[13]. Three-dimensional coordinates for both proteins were retrieved from protein Data Bank under the accession code 4EY6 (AChE) and 6QEX (P-gP). The choice of such structures was made based on an extensive survey of resolution and structural quality values[14]; thus, low resolution values represent more accurate coordinates of atoms and consequently, increase the docking accuracy. The selected models had better resolutions, and 4EY6 and 6QEX had resolution of 2.40 Å and 2.30 Å, respectively, which provided reliable structural representation[15]. Ramachandran plot analysis using the PROCHECK web server (Figure 1) showed that most of the residues are located in the favoured regions of the conformation thus confirming the stereochemical integrity of the protein backbones. Protein preparation was performed in UCSF Chimera[16]. Although multiple chains were included in initial data sets, chain A was the chain that was used in all cases of one protein, because it includes all of the catalytic site residues, and allows for methodological consistency. Structural integrity checks consisted of checking over the entire backbone, and atoms not found in the backbone were properly listed[17]. Gaps were then patched using the Docker Prep module of UCSF Chimera in this process hydrogen atoms were added, partial charges were assigned, solvent molecules and unbound ions were removed and side chains that were missing were reconstructed[18]. Each protein was then engaged in an energy minimisation to optimise conformations and remove high-energetic interactions which could result in compromised docking outcomes and the conformations were saved in PDB format. AutoDock Tools 1.5.7 was used to create grid boxes for each protein, dimensions and coordinates (x, y, z)[19] were carefully documented to make sure of active site comprehensive coverage. Finally, co-crystallised ligands were removed, and the proteins were converted to PDBQT format, making it suitable for the following molecular docking investigations[20]. Ramachandran Plot of PDB ID: 4EY7 (AChE) and PDB ID: 6QEX (P-gp) (Figure 1).

Dataset Preparation

The selection of compounds for this study was based on the Phytochemicals and Ethnobotany Database of Dr. Duke where exhaustive searches for plants and chemicals, bioactivity, and ethnobotanical information [21] were carried out using both the scientific and the vernacular nomenclature. A total of 29,585 compounds of plant and chemical origin were retrieved. These natural products were selected because of their unique structural diversity and prospective biological action against neurodegeneration targets and cancerous cells [22]. To get a handle such as the compounds had druglike properties as well as a favorable probability of successful oral bioavailability, they were utilized the Biovia Discovery Studio platform which would filter the compounds according to Lipinski's rule of five as well as other drug likeness. The filters applied were molecular weight (less than/equal to 500 Da), less than/equal to 10 hydrogen bond acceptors, less than/equal to 5 hydrogen bond donors, polar surface area and less than/equal to 5 rotatable bonds [23]. This filtering procedure resulted in a reduced group of 159 compounds with desirable physicochemical features for possible drug development. For later use in docking studies, the 159 compounds were first extracted as a CSV (Excel) file that contained compound identifiers and SMILES notations [24]. The SMILES strings were then recovered and saved in text file form. ChemDraw 3D was then used to convert the 2D structures of the 98 compounds selected for this study into 3D conformation, which was converted to PDBQT format using AutoDock Vina. During this conversion an MMFF94 force field energy minimization of 0.000001 kcal/mol/A gradient [25] was used and optimized 3D conformers were generated. This careful preparation meant that the compounds were appropriately optimised for subsequent analysis using the docking software. Finally, the 2D structures of the most promising candidates were generated using ChemDraw (22) software [26].

Docking Studies

Docking investigations were performed using the AutoDock Vina software, the graphical user interface of which (GUI) is available with MGL Tools 1.5.7. A Perl script was written to dock a set of ligands. The produced docking

outputs from AutoDock Vina were further visualised using Biovia Discovery Studio 2021 to aid in the study of interaction [27].

Drug-Likeness Studies

Initially, the selection from the Dr. Duke database was screened by Lipinski's Rule of Five to be basic on drug-likeness. Subsequently, a more extensive pharmacokinetic analysis using SwissADME and pKCSM [28] was performed to further refine our selections. While Lipinski's rules focus on basic issues such as molecular weight and lipophilicity, SwissADME allows the assessment of a wide range of other pharmacokinetic parameters, such as solubility, Blood-Brain Barrier (BBB) permeability, and P-glycoprotein (P-GP) substrate state. The pKCSM web server revealed further information about pharmacokinetic properties, such as intestinal absorption, metabolic information, total clearance, and AMES toxicity [29], which provides information about mutagenicity and skin sensitization properties. The same online tool, Protox-III, was used for toxicity assessment. By combining the analyses from SwissADME, pKCSM, and ProTox-III, a comprehensive and multi-faceted analysis was provided, favoring the selection of compounds with favorable ADME properties and low predicted toxicity [30].

RESULT AND DISCUSSION

The docking protocol was evaluated by selecting high-quality protein structures (characterized by resolutions greater than 2.5 Å) (4EY6 at 2.40 Å; 6QEX at 2.30 Å) to ensure accurate positioning of the atoms, a prerequisite for obtaining accurate results in docking. The stereochemical integrity of these proteins was checked by Ramachandran plot analysis, where the majority of residues resided in favorable regions, thus confirming reliable backbone conformations. Protein preparation involved keeping only chain A of the protein which contains the catalytic site, and the missing backbone and side chain atoms were optimized using UCSF Chimera's DockPrep tool, hydrogen atoms were added, charges were assigned and extraneous molecules were removed. Energy minimization was performed to optimize the conformations of the proteins and remove unfavorable interactions. Grid boxes were generated using AutoDock Tools (1.5.7) to comprehensively cover the active site for docking purposes. Co-crystallized ligands were deleted, and the proteins were converted to pdbqt-form to ensure compatibility with the docking software. This careful planning and validation of a docking protocol ensured a strong and valid docking protocol, thus improving the accuracy and reproducibility of molecular docking studies performed using AutoDock Vina, followed by subsequent interaction analyses.

Structure-based Virtual Screening

Screening and Docking Studies of Phytochemicals

Following the validation of the docking protocol, the marine natural product collection from the Dr. Duke Natural Product Database was screened. Lipinski's rule of five was applied using Biovia Discovery Studio 2021 to ensure that, from the first load of 159 compounds, only compounds that proved to be compliant were retained (n=98). These compounds were then used for molecular docking with acetylcholinesterase (AChE; PDB ID: 4EY7) and P-glycoprotein (P-gp; PDB ID: 6QEX). Galantamine and verapamil were used as standard reference inhibitors for AChE and P-gp, respectively. Compounds ranking according to the values of their docking score (in kcal/mol) were considered eligible for a deeper study (these compounds were further investigated). Tables 1 and 2 show the 2D structures and docking scores of the best compounds against AChE and P-gp, respectively. For AChE (4EY7), the best-ranking ligands were Berbamine, Berberine, Berberrubine, Quercetin and Hydrastine. For P-gp (6QEX), the best-ranked molecules were Berbamine, Berberine and Berberrubine. The results of the observed docking scores of these compounds suggest their potential as effective inhibitors.

Key Interaction in AChE and P-gp Active sites

Based on empirical evidence and data obtained from molecular docking studies, the following amino acid residues were revealed to have critical effects in the inhibition of acetylcholinesterase and P-glycoprotein:

AChE (4EY7)

1. The aromatic residue Tyr A:337 is involved in the π–π stacking interactions and plays a role in stabilizing the aromatic binding of the ligand.
2. The hydrophobic contacts of tryptophan A:286 play a crucial role in anchoring the inhibitor.
3. Serine A:203 routinely forms hydrogen bonds, which helps increase the binding interface stability.
4. Glutamic acid A:202 may be responsible for electrostatic stabilization via ionic interactions.
5. The residues Tyr A:124 and Phe A:295 are often involved in hydrogen bonding and therefore add to the complex stability.

P-gp (6QEX)

TRP A:232: The anchor residue provides a basic anchor that allows the ligand to bind to the receptor via p–p interactions, which are supported by the stacking of aromatic rings against rings on the tryptophan residues, adding to the overall stability of the complex.

ALA A:229: The hydrophobic compartment is defined as the compartment containing the residue enclosing the ligand. A p-alkyl interaction is evidenced by the accommodation of the aromatic part of the ligand in a hydrophobic pocket formed by alanine, thus stabilizing the molecule.

PHE A:343: The phenylalanine residue creates a "sandwich" effect when combined with TRP A:232 which places the ligand in between the two aromatic moieties. In Model 4, it plays a dual role as a hydrogen bond donor and acceptor, contributing to directional stability.

GLN A:990: But in contrast to the hydrophobic residues, which have characteristics of adhesion, this glutamine acts as a specific "latch," making a conventional hydrogen bond, that will precisely match either a ligand's oxygen or nitrogen atom.

SER A:228: This serine has a relatively weaker C-H bond, thus indirectly paving the way for precise positioning of the ligand in the binding pocket.

Docking Score of AChE (4EY7) and 2D Structure (Table: 1). Docking Score of P-gp (6QEX) and 2D Structure (Table: 2).

Analysis of Top Compounds with 2D Interaction Reference

The selected compounds showed good binding interactions with the active binding sites of residues critical for acetylcholinesterase and P-glycoprotein. These interactions are shown two-dimensionally in diagrams given in Figures 3 and 4 for acetylcholinesterase and P-glycoprotein, respectively. Figure 2. 2D Interactions of (a)Galantamine, (b)Berbamine, (c)Berberine, (d)Berberrubine, (e)Hydrastine and (f)Quercetin as AChE inhibitors. Figure 3. 2D Interactions of (a)Verapamil, (b)Berbamine, (c)Berberine, (d)Berberrubine, (e)Hydrastine and (f)Quercetin as P-gp inhibitors. The comparative molecular docking study highlights the intricate interaction mechanism of alkaloids and reference compounds with two important biological protein targets, P-glycoprotein (P-gp) and acetylcholinesterase (AChE). Within the P-gp binding site, the binding partners take advantage of an overall hydrophobic environment, which is characterized by a cleft harbouring the aromatic residues TRP A:232 and PHE A:343, which act as essential anchor points. These residues promote good π-p stacking and π-alkyl interactions, which play a central role in stabilizing the ligand in the pocket. In addition to these hydrophobic contacts, the presence of hydrogen bonds with polar residues such as GLN A:990 and GLN A:347 strengthens the localization of the ligand, further suggesting a dual mechanism of hydrophobic and polar contacts to boost the affinity and specificity towards P-gp. In contrast, the binding site for AChE involves a different but related interaction landscape, which is centered around the enzyme's aromatic-rich gorge, which in this case is probably the peripheral anionic site. Here, the ligands interact mostly with tryptophan residues TRP A:86 and TRP A:286 via π–π stacking and T-shaped interactions, which play a crucial role in sustaining stable ligand positioning inside the gorge. These aromatic interactions are enhanced by contacts involving the polar groups of the serine residues SER A:125 and SER A:293, which are probably involved in binding

specificity and orientation. Overall, these findings indicate that despite acting on structurally distinct proteins, the alkaloids and reference molecules can follow the same pharmacophoric strategy, which exploits the expenditures of aromatic moieties to form extensive networks via π- intermediates with tryptophan-rich regions. This is a conserved mode of interaction and is important to consider for the design of ligands with high affinity for binding to both P-gp and AChE, specifically, aromaticity and spatial complementarity.

FUTURE DIRECTION

To exhaustively test the pharmacological potential of these compounds as inhibitors of acetylcholinesterase (AChE) and P-glycoprotein (P-gp), further studies were conducted.

Drug-likeness Analysis: The expression "Employing SwissADME to guarantee favourable pharmacokinetic attributes" refers to the use of a computational tool (SwissADME) for the uptake and confirmation of a pharmaceutical entity with favorable properties regarding absorption, distribution, metabolism, and excretion. This methodology-based approach makes it easier to predict the possible therapeutic efficacy and safety of the entity for clinical administration.

ADMET Analysis: The pKCSM framework uses graph-based molecular signatures to predict important ADMET properties, including absorption, distribution, metabolism, excretion, and toxicity. This methodology allows for the early evaluation of pharmacokinetic behavior and safety profiles, leading to higher efficiency in the drug discovery process and in the selection of compounds. Future studies, taking advantage of the molecular data presented in this study, will help to find and refine the therapeutic candidates for Alzheimer's disease.

Drug Likeness Study SwissADME

SwissADME study of compounds (AChE) for drug-like properties.

The pharmacokinetic characteristics of the acetylcholinesterase (AChE) inhibitors were analyzed using the SwissADME software to predict the central nervous system (CNS) bioavailability of the anti-Alzheimer's therapeutics for 4EY7 (Table 3). All compounds had a bioavailability score of 0.55; however, the blood-brain barrier (BBB) permeation and P-glycoprotein (P-gp) substrate status of the compounds showed great variability. Galantamine, berberine and berberrubine exhibited BBB permeability but were classified as P-gp substrates, a fact that may modulate the synaptic concentrations. In contrast, hydrastine showed BBB permeability but not P-gp substrate, suggesting the possibility of CNS permeation and retention. In contrast, berbamine and quercetin were predicted to be non-BBB permeant due to their molecular weight and polarity, respectively, which restricts their therapeutic efficacy as neuronal compounds. SwissADME study of compounds (AChE) for drug-like properties (Table 3).

SwissADME study of compounds (P-gp) for drug-like properties.

The pharmacological properties of the investigated compounds were evaluated using SwissADME (Table 4) to complement their molecular interactions with human P-glycoprotein (PDB ID 6QEX). The alkaloids berberine and berberrubine were predicted to be substrates for P-glycoprotein, similar to verapamil, suggesting a possible competition for binding with the efflux pump drug-binding pocket. Hydrastine showed permeability for the blood-brain barrier without being a P-glycoprotein substrate, indicating that it has a higher retention than other substrates. Berbamine and quercetin have low permeability through the blood-brain barrier, which can limit their use in the central nervous system, despite their affinity for P-glycoprotein. SwissADME study of compounds (P-gp) for drug-like properties (Table 4). Figure 4 and 5. (AChE and P-gp) boiled egg model.

pKCSM ADMET Analysis

ADMET profiling was performed to evaluate the pharmacokinetic safety and metabolic stability of acetylcholinesterase (AChE) inhibitors as candidates, as described in detail in Table 5. In the context of oral neurotherapeutics, hydrastine, berbamine, berberine, and berberrubine showed better absorption from the human

intestine, with an absorption rate of above 90%, which is similar to that of galantamine (93.8%). In contrast, quercetin's absorption rate was comparatively low at 77.2 per cent. Hydrastine and berbamine have different advantages regarding metabolic considerations. Berberine and berberrubine act as substrates for CYP2D6 and inhibitors of CYP3A4, which poses a potential hazard for patients with Alzheimer's disease because of potential drug-drug interactions. Hydrastine and berbamine displayed metabolic inertia. All compounds investigated had favorable safety profiles, with no evidence of mutagenicity or cutaneous sensitization. Hydrastine was found to have the most balanced ADMET profile, with high bioavailability, metabolic stability, and safety, leading to its prospective development *in vivo*. ADMET Prediction of selected Compounds (AChE) (Table 5). ADMET profiling was performed to evaluate the pharmacokinetic safety and metabolic stability of AChE inhibitors, which are prospective candidates for therapeutic use, as summarized in Table 5. Within the range of orally administered neurotherapeutics, the human intestinal absorption fractions of Hydrastine, Berbamine, Berberine, and Berberrubine exceeded 90 per cent, resembling that of Galantamine, which possesses a fraction of 93.8 per cent. Quercetin showed a much lower absorption fraction (77.2%) than that of catechin. Metabolically, Hydrastine and Berbamine have different benefits. Unlike Berberine and Berberrubine, which are substrates of CYP2D6 and inhibitors of CYP3A4, respectively, and owing to this metabolic status, which causes potential drug-interaction liabilities in Alzheimer's disease cohorts, Hydrastine and Berbamine exhibited their status of metabolic inertness in the borderline state. Moreover, each compound exhibited a favorable safety profile with no mutagenic potential or skin sensitization. Notably, Hydrastine showed the most favorable composite ADMET profile, combining high bioavailability, good metabolic stability, and an acceptable safety margin, providing a scientific rationale for its development as a prospective candidate for in vivo development. ADMET Prediction of selected Compounds (P-gp) (Table 6).

Protox-III Toxicity Analysis

To assess the safety profiles of potential acetylcholinesterase (AChE) inhibitors, organ toxicity was evaluated using the ProTox-III platform. The analysis of the results of the computer calculations showed that Hydrastine and Berberrubine showed favorable safety profiles compared to galantamine. Whereas Galantamine exhibited immunotoxicity and cytotoxicity, both Hydrastine and Berberrubine were predicted to be inactive towards cytotoxicity, hepatotoxicity, carcinogenicity and mutagenicity, only displaying immunotoxicity that is particularly observed in alkaloids. In comparison, Berberine, Berbamine and Quercetin were considered to raise safety concerns; Berberine and Quercetin were predicted to be active for carcinogenicity and mutagenicity while Berbamine was predicted to have mutagenic activity. Consequently, Hydrastine is the best candidate for meeting the goal of 4EY7 because it offers a lower risk of adverse effects than any other candidate drug. Toxicity prediction of standard and selected compounds (acetylcholinesterase) (Table 7). A thorough evaluation of the translational potential of P-glycoprotein modulators from a toxicology standpoint was conducted using ProTox-III. The reference inhibitor verapamil showed a good safety profile, showing inactivity in hepatotoxic, carcinogenic, mutagenic, and cytotoxic endpoints, with no activity, except for immunotoxicity. Hydrastine and berberrubine had toxicity profiles similar to that of verapamil, with possibly similar safety margins. In contrast, berbamine, berberine, and quercetin showed significant toxicological concerns, with berberine and quercetin predicted to be carcinogenic and mutagenic, whereas berbamine had mutagenic activity. Consequently, hydrastine and berberrubine appear to be the best candidates for designing P-gp (6QEX) efflux pump inhibitors. Toxicity prediction of standard and selected compounds (P-glycoprotein) (Table 8).

CONCLUSION

This investigation describes the prospective value of selected phytochemicals as dual inhibitors of acetylcholinesterase (AChE), an enzyme involved in the pathophysiology of Alzheimer's disease, and P-glycoprotein (P-gp), a determinant of multidrug resistance in oncology. By implementing stringent protein preparation protocols, such as taking full advantage of the high resolution of crystal structures and stereochemical validations, a powerful platform associated with reliable computational docking was implemented. A structure-based virtual screening of a heterogeneous repertoire of phytochemicals (refined for drug-likeness and optimized for improved docking

functionality) identified superior compounds such as Berbamine, Berberine, Berberrubine, Hydrastine and Quercetin. These molecules exhibited significant affinities and formed large interactions with crucial active site residues in both targets, implying their ability to simultaneously modulate AChE and P-gp. Detailed analyses of the docking led to the identification of conserved pharmacophoric motifs that these agents share with the receptor through mainly aromatic pi-pi stacking and hydrogen bonding to important residues (Trp, Tyr, Ser, and Gln) nestled within the active sites. The conservation of this interaction profile in structurally disparate proteins highlights the polypharmacological potential of the compounds, and they are therefore especially suited to treat complex pathologies that involve several pathological pathways. Further refinement was performed by comprehensive drug-likeness and ADMET profiling using the tools SwissADME, pkCSM, and ProTox-III, which assessed pharmacokinetic parameters, blood-brain barrier permeation, metabolic stability, and toxicity indices. Hydrastine and Berberrubine were the best candidates, showing better bioavailability, good CNS penetration, and a very low toxicity signature compared to conventional inhibitors. Hydrastine's inability to serve as a non-substrate for P-gp, combined with metabolic inertness, implies enhanced CNS retention and a lower propensity for drug-drug interactions, a crucial advantage for neurotherapeutic applications. The synergy of these findings supports the viability of developing herbal-derived multi-action (multi-target) therapeutics that take advantage of the innate polypharmacology of natural constituents. Such an approach has the potential to increase therapeutic efficacy and safety by modulating several disease-relevant targets simultaneously and overcoming the limitations associated with single-target agents, such as the development of resistance and adverse event profiles. Future studies should focus on the in vivo validation of these compounds to provide support for their efficacy and safety profiles, with the goal of structural optimization to improve their target specificity and pharmacokinetic characteristics. Additionally, evaluation of synergistic interactions between these agents, as well as between these agents and existing therapies, could provide an additional way to boost treatment outcome. Collectively, this work serves as a strong foundation for the rational design of novel multi-target phyto-therapeutics for neurodegenerative disorders and cancer multidrug resistance, which will continue to move this field towards the pursuit of more efficacious and holistic therapeutic strategies.

ACKNOWLEDGMENT

The authors thank all the persons involved in this computational analysis. The authors express their appreciation to the Parul Institute of Pharmacy and Research for their support in this research process, which was conducted in the absence of external funding.

AUTHOR CONTRIBUTION

Chailvi Kumari carried out the main computational investigations involving the preparation of proteins, selection of compound datasets, molecular docking study and evaluation of drug-likeness and ADMET profile. She conducted data acquisition, *in silico* experiments, and interpreted the preliminary findings. Pinkal Patel gave academic guidance and supervision in the whole research process. She contributed to the study design, validation of the methodologies used, critical review of the data analysis, and refinement of the manuscript. Under her mentorship, the scientific stringency and coherence of the study were ensured. Chailvi Kumari and Pinkal Patel have made equal contributions to the preparation of this manuscript including discussions on the findings and approval of the final version before submission.

ABSTRACT

This study explores scriptotherapy, or expressive writing therapy, as a healing tool for traumatised sexual assault victims. Drawing on James W. Pennebaker's expressive writing framework, three victims underwent a six-week structured writing intervention involving emotional expression, letter writing, storytelling, and reflective exercises. Qualitative analysis of the participants' writings reveals a gradual shift from negative emotional states such as fear, anger, and alienation toward psychological resilience and optimism. The findings demonstrate that expressive writing effectively reduces emotional upheaval and fosters recovery by providing a safe, private space for self-expression. This study concludes that scriptotherapy holds significant therapeutic potential as an accessible and cost-effective self-help method for trauma recovery.

Keywords: scriptotherapy, scriptotherapy, victims, self-expression.

INTRODUCTION

The current paper focuses on scriptotherapy (expressive writing therapy) as a method to help traumatized victims. Based on the educational psychologist James W. Pennebaker's framework presented in the book *Writing to Heal*, the study examines three sexual assault survivors who participated in structured writing exercises over a two-month intervention period. The participants documented their emotional upheavals through these writing sessions. A qualitative analysis of their language indicates signs of trauma recovery and growing psychological resilience. The findings suggest that expressive writing can help traumatized individuals overcome emotional distress.

Educational psychologists James W. Pennebaker, Joshua M. Smyth, and Richard Helm note that "the process of disclosing stressful or traumatic events is often essential," and that expressive writing (FEW) is linked to

improvements in health and well-being across various populations (Smyth and Helm 229). Because FEW requires minimal involvement from others, is inexpensive, and portable, it holds strong potential as a self-help method for stress and trauma recovery. Similarly, Bonnie Goldberg in *Room to Write: A Daily Invitation to a Writer's Life* explains what makes someone a writer and emphasizes that writers interpret the world through imagination, humor, and sensory awareness. Through daily exercises and reflections, she encourages readers to cultivate creative observation and writing habits (Goldberg 42). In *Into the Heart of Writing: Writing for Your Life*, Deena Metzger presents writing as both a creative and spiritual journey, demonstrating how storytelling fosters inner healing (Metzger 63–65). Tristine Rainer in *Your Life as Story* shows how personal experiences can be shaped into meaningful narratives, helping individuals gain self-knowledge (Rainer 28). Likewise, Christina Baldwin in *Life's Companion* views journal writing as a path to personal and spiritual growth (Baldwin 51). Pat Schneider in *Writing Alone and with Others* provides practical techniques to overcome fear and self-criticism, enabling individuals to express personal experiences, including trauma (Schneider 74).

While these studies emphasize writing as a healing tool, the present study addresses a gap by modifying the techniques suggested in *Expressive Writing: Words That Heal* to suit the needs of the selected participants.
A written document serves as a recorded representation of thoughts and emotions. According to James W. Pennebaker, individuals often feel more comfortable expressing repressed emotions through writing than through speech. Writing allows individuals the freedom to articulate thoughts that they may hesitate to share verbally. In this study, the researcher examines how structured writing helps traumatized individuals express and process their emotions. A six-week writing intervention was conducted, which helped participants gradually overcome their emotional distress.

The study adopts writing techniques from *Expressive Writing: Words That Heal* by James W. Pennebaker and John F. Evans. The program includes 20-minute daily writing sessions and was modified for the participants. The six-week program included:

- Week 1: Writing about deepest thoughts and emotions
- Week 2: Letter writing
- Week 3: Creative expression (poetry/drawing)
- Week 4: Storytelling
- Week 5: Self-reflective writing
- Week 6: Writing about dreams and future aspirations

Three participants were selected, and each completed structured exercises recorded in workbooks. A warm-up session encouraged free writing to ease participants into the process.

Description of Exercises

Exercise 1:
A four-day process where participants wrote about their deepest emotions, untold thoughts, current emotional state, and unresolved issues related to trauma.

Exercise 2:
Letter writing, including letters to family, perpetrators, or themselves. This helped participants express suppressed emotions and communicate indirectly.

Exercise 3:
Creative expression through poetry or drawing, allowing participants to explore hidden thoughts freely.

Exercise 4:
Storytelling, where participants created narratives (fiction or non-fiction) to process experiences creatively.

Exercise 5:
Self-reflective writing focusing on personal habits, strengths, and self-awareness, encouraging self-actualization.

Exercise 6:
Future-oriented writing about dreams, ambitions, values, and purpose in life.

After analyzing the writings, the researcher identified common patterns among participants:

- Social alienation
- Longing for parental love
- Emergence of suicidal thoughts
- Desire for independence
- Gradual shift from negative to positive thinking

Alienation:
Participants experienced rejection from family, friends, and society. This led to withdrawal, mood swings, guilt, and fear of social interaction.

Longing for Parental Love:
All participants expressed a deep desire for parental affection, especially maternal support. Being separated from their families intensified their emotional distress.

Suicidal Thoughts:
Although initially absent, suicidal ideation emerged due to social isolation and neglect. Two participants had attempted suicide but were saved.

Hesitation:
Participants initially resisted writing about trauma. However, after the first session, they reported relief, indicating the cathartic effect of writing.

Desire for Independence:
Participants expressed a strong need for autonomy and control over their lives.

Transformation of Thoughts:
Early writings reflected sadness, anger, and fear, while later sessions showed positivity, self-acceptance, and hope. Participants reported improved sleep, social interaction, and emotional stability.

Questionnaire

0	1	2	3	4	5	6	7	8	9	10
Not at all					**somewhat**					**a great deal**

1) To what degree did you express your deepest thoughts and feelings?
2) To what degree do you currently feel sad or upset?
3) To what degree do you currently feel happy?
4) To what degree was today's writing valuable and meaningful for you?
5) Briefly describe how your writing went today.

According to the results of this questionnaire given to them in every end of the session,

- The percentage level of expression has increased.
- Degree of their sadness decreased.
- They find these writing sessions are really helpful for them.

All the three subjects mentioned that they completely relaxed after the writing sessions. Subjects were happy about their behavioural changes. Subject one mentioned that she would write her thoughts down if any misfortune happens to her. They felt these sessions were meaningful to their life. Subject two requested the researcher to

distribute the 'writing session book' to other people like them. she mentioned that "I had a positive thought that I could reunite parents" All these things proved that all the three subjects were recovered from their trauma and emotional upheavals using 'writing' as tool.

ABSTRACT

Medicinal plants are known to possess a wide range of bioactive compounds that contribute to their therapeutic properties. Understanding the chemical composition of medicinal plants is crucial for validating their traditional uses and identifying new bioactive molecules. *Justicia beddomei* (C.B.Clarke) Bennet, is commonly known as Chittadalodakam or Cheriya aadalodakam and belongs to the family Acanthaceae. It is an evergreen medicinal plant used in the traditional medicine system for treating various diseases such as leprosy, thirst, fever, vomiting, cough, asthma, bronchitis, and inflammation. The present study aimed to investigate the phytochemical screening of *Justicia beddomei* leaf extracts and to identify the bioactive compounds by HR LC-MS QTOF analysis. The preliminary phytochemical screening of leaf extracts was done by a serial soxhlet extraction method with solvents of increasing polarity (hexane, chloroform, ethyl acetate, and methanol). The qualitative and quantitative phytochemical screening was carried out to detect the presence of various phytoconstituents. The HR LC-MS analysis of the methanolic leaf extract was done to identify the bioactive compounds. The preliminary phytochemical screening revealed that the methanolic leaf extract, showed the widest spectrum of phytoconstituents, such as alkaloids, carbohydrates, reducing sugar, glycosides, proteins, flavonoids, terpenoids, phenolics, tannins, and saponins. The quantitative results indicated that the methanolic leaf extract is rich in phytoconstituents, with the highest abundance of alkaloids. The HR-LCMS analysis detected the important quinazoline alkaloids, namely peganine, vasicinol, vasicinone, and anisotine from

this plant. The detection of the highest abundant compound, peganine, which is also known as vasicine, in the HR-LCMS analysis of *J. beddomei* leaf extract is of particular significance and contributes substantially to the biological potential of the plant.

Keywords: *Justicia beddomei*, Acanthaceae, alkaloids, peganine,HR-LCMS QTOF

INTRODUCTION

Medicinal plants are rich sources of bioactive compounds that are responsible for their pharmacological and therapeutic activities. The Indian traditional medical system flourished because of the diversity and abundance of medicinal plants. Acanthaceae is a large family of dicotyledonous plants comprising more than 4300 species and distributed worldwide, and many species possess medicinal properties and are used in traditional system of medicine[1]. The largest genus of Acanthaceae is *Justicia,* which comprises about more than 600 species distributed in the tropical and pan-tropical regions, nearly 50 species occur in India and are distributed in the temperate regions [2]. Among them, *Justicia adhatoda* (syn. *Adhatoda vasica*; commonly known as Valiya aadalodakam) and *Justicia beddomei* (syn. *Adhatoda beddomei*; commonly known as Chittadalodakam or Cheriya aadalodakam) are particularly noted for their medicinal significance. *J. beddomei*, is an evergreen medicinal plant that serves as an important source of the drug vasaka, widely used in the indigenous systems of medicine [3], and is considered therapeutically superior to the allied species, *J. adhatoda*. This plant exhibits a wide range of phytochemicals and is frequently used in traditional systems like Ayurveda, Siddha, and Unani as a diuretic, antispasmodic, expectorant, anti-asthmatic, febrifuge, styptic, and tonic. It is traditionally used in the treatment of ailments such as leprosy, fever, thirst, vomiting, cough, bronchitis, asthma, and inflammation. This plant is mainly known for treating various respiratory disorders. The therapeutic properties of *J. beddomei* are mainly attributed to its alkaloidal constituents such as vasicine, vasicinol, vasicinone, vasicol, and vasicinolone, which have been reported for bronchodilatory, antispasmodic, and expectorant activities. Recognising its medicinal properties, it has been adopted by modern medical practitioners too. However, most of the studies are focused on *J. adhatoda* instead of *J.beddomei*, because of the unavailability of the plant material as well as the lack of sufficient background information. Furthermore, Ayurvedic medical practitioners are misidentified with allied species and use them for medical purposes. Although previous studies have provided preliminary insights into its medicinal applications and chemical constituents, substantial gaps remain in the comprehensive understanding of its phytochemical profile. Therefore, conducting detailed phytochemical studies on *J. beddomei* is essential for elucidating the bioactive compounds responsible for its traditionally reported medicinal properties. These investigations not only support the validation of its medicinal claims but also establish a scientific foundation for understanding their pharmacological potential. So that, the present study aims to evaluate the phytochemical profile of the plant by performing both preliminary qualitative and quantitative analysis of its leaf extracts to determine the most effective solvent for extracting phytoconstituents. The study aims to identify the major bioactive compounds of *J.beddomei* using HR-LC-MS QTOF analysis, a modern and reliable technique. This study provides a foundation for a more detailed phytochemical investigation, which can support the subsequent isolation and characterization of key bioactive compounds responsible for the plant's biological activities.

MATERIALS AND METHODS

Collection and authentication of plant material

The plants were collected from Irinjalakuda (10.3804 ^{0}N,76.2074 ^{0}E), Thrissur district, Kerala. They were maintained at the Medicinal Plant Garden, Department of Botany, University of Kerala, Thiruvananthapuram. A voucher specimen was maintained at the Herbarium, Department of Botany, University of Kerala (Voucher No: KUBH 11520).

Preparation of extract

Leaves of *J. beddomei* were washed with distilled water, shade-dried at room temperature for 10-12 days, and finely powdered. About 15 g of the powdered material was subjected to successive solvent extraction using a soxhlet apparatus with 150 mL of solvents of increasing polarity: hexane, chloroform, ethyl acetate, and methanol. Each extraction was performed for 6-10 hrs under controlled heating, and the resulting extracts were concentrated under reduced pressure using a rotary evaporator. The extracts were dried, transferred to pre-weighed glass vials, stored at 4 °C, and their physical characteristics, including consistency and colour, were recorded following a standard colour chart [4].

Percentage yield of extracts

The percentage yield of each solvent extract was calculated to determine the efficiency of the extraction process. It was determined using the formula:

Percentage yield (%) =Weight of the crude extract / Weight of powdered plant material×100

Qualitative phytochemical screening

The leaf extracts of *J. beddomei* were subjected to preliminary phytochemical screening to detect the presence of major classes of secondary metabolites, following standard protocols [5][6].

Detection of Alkaloids

Dragendorff's Test: A few mL of the diluted extract was treated with 1 mL of Dragendorff's reagent along the side of the test tube, and the appearance of a yellow precipitate indicated the presence of alkaloids.

Wagner's Test: The extract was mixed with 3-4 drops of Wagner's reagent, and a reddish-brown precipitate confirmed the presence of alkaloids.

Detection of Carbohydrates

Barfoed's Test: One mL of the extract was combined with an equal volume of Barfoed's reagent and heated for two minutes. Formation of a red precipitate indicated monosaccharides.

Seliwanoff's Test: One mL of the extract was mixed with 3 mL of Seliwanoff's reagent and gently heated for one minute and a rose-red colour indicated the presence of ketose sugars.

Detection of Reducing Sugars

Benedict's Test: A mixture of 0.5 mL of the extract and 0.5 mL of Benedict's reagent was boiled for two minutes, and a colour change from green to yellow indicated reducing sugars.

Fehling's Test: One mL of extract was mixed with equal volumes of Fehling's solutions A and B, heated in a water bath, and the formation of a red precipitate confirmed reducing sugars.

Detection of Glycosides

Keller-Killiani Test: One mL of diluted extract was mixed with 2 mL of glacial acetic acid and 1–2 drops of 2% ferric chloride solution, followed by careful addition of 2 mL concentrated sulfuric acid along the tube side. A reddish-brown ring at the interface indicated glycosides.

10% NaOH Test: 0.2 mL of extract was added to 1 mL of diluted H_2SO_4 and heated for 15 minutes. After cooling, the solution was neutralized with 10% NaOH, then 0.2 mL each of Fehling's solutions A and B was added, and a brick-red precipitate confirmed glycosides.

Detection of Proteins

Biuret Test: Two mL of extract were mixed with 1 drop of 2% copper sulphate, 1 mL of 95% ethanol, and a few KOH pellets. A pink colour indicated proteins.

Ninhydrin Test: Two mL of extract were treated with two drops of freshly prepared ninhydrin solution, and gently heated. A purple coloration indicated proteins.

Detection of Flavonoids

Alkaline Reagent Test: One mL of extract was treated with a few drops of NaOH solution. A bright yellow colour formation that became colourless upon acid addition indicated flavonoids.

Lead Acetate Test: One mL of extract was mixed with a few drops of 10% lead acetate solution and the formation of a yellow precipitate confirmed flavonoids.

Detection of Phenols

Iodine Test: One mL of extract was treated with a few drops of dilute iodine solution, and a temporary red colour indicated phenolic compounds.

Ferric Chloride Test: A few drops of 5% $FeCl_3$ solution were added to the extract, and the development of dark green or bluish-black colour confirmed phenols.

Detection of Terpenoids

Salkowski Test: Two mL of extract were mixed with 2 mL chloroform and 1-2 drops of concentrated H_2SO_4 along the tube side. A reddish-brown colour at the interface indicated terpenoids.

Copper Acetate Test: The extract was dissolved in water, and 3-4 drops of copper acetate solution were added, and an emerald-green colour confirmed terpenoids.

Detection of Tannins

Braymer's Test: One mL of extract was diluted with 3 mL of water and 3 drops of 10% $FeCl_3$ solution; a blue-green colour indicated tannins.

Gelatin Test: The extract was dissolved in 5 mL of water, followed by 1% gelatin solution and 10% NaCl. The formation of a white precipitate confirmed tannins.

Detection of Saponins

Foam Test: About 0.5 g of extract was vigorously shaken with 5 mL of water. Formation of stable foam lasting 2-3 minutes indicated saponins.

Quantitativephytochemical screening

Quantitative estimation of major phytochemicals, including alkaloids, tannins, phenols, saponins, flavonoids, and terpenoids, was performed on leaf extracts using standard methods.

Quantification of Alkaloids

Alkaloid content in the plant extract was quantified by treating 1 mL of extract with 2 N HCl, followed by filtration. The filtrate was mixed with bromocresol green and phosphate buffer, then extracted with chloroform to form an alkaloid-dye complex in the organic layer. The chloroform layer was collected, diluted to 10 mL, and its absorbance measured at 470 nm using a UV-Visible spectrophotometer. Alkaloid levels were determined by comparison with a reserpine standard curve and expressed as milligrams of reserpine equivalents per gram of extract[7].

Quantification of Tannin

Tannin content was measured using the Folin-Denis method, where 1 mL of plant extract was diluted to 7.5 mL with water, mixed with Folin-Denis reagent and sodium carbonate, and brought to a final volume of 10 mL solution. After standing at room temperature, the absorbance was recorded at 700 nm using a UV-Visible spectrophotometer. Tannin levels were determined against a tannic acid standard and expressed as milligrams of tannic acid equivalents per gram of extract[8].

Quantification of Phenol

Total phenolic content was determined using the Folin-Ciocalteu method, where 0.1 mL of extract was mixed with Folin-Ciocalteu reagent and water, followed by the addition of 20% sodium carbonate after 3 minutes. The mixture was briefly heated in a water bath, cooled, and its absorbance measured at 650 nm. Phenolic levels were calculated using a gallic acid standard curve and expressed as mg gallic acid equivalents per gram of extract[9].

Quantification of Saponin

Total saponin content was estimated using the vanillin-sulphuric acid method. The extract was mixed with vanillin and sulphuric acid, incubated at 60 °C for 15 minutes to develop colour, then cooled, and its absorbance was measured at 535 nm. Saponin levels were calculated using an oleic acid standard and expressed as mg oleic acid equivalents per gram of extract[10].

Quantification of Flavonoid

Total flavonoid content was measured using the aluminium chloride method. The extract was sequentially treated with sodium nitrite, aluminium chloride, and sodium hydroxide, diluted to a final volume, and the absorbance was recorded at 510 nm. Flavonoid levels were determined using a quercetin standard and expressed as mg quercetin equivalents per gram of extract[11].

Quantification of Terpenoids

Total terpenoid content was determined using the vanillin–perchloric acid method. The extract was reacted with vanillin and perchloric acid, incubated at 60 °C for 45 minutes, cooled, and stabilized with glacial acetic acid. Absorbance was measured at 548 nm, and terpenoid levels were calculated using a linalool standard, expressed as mg linalool equivalents per gram of extract[12].

HR-LCMS-QTOF Analysis of methanolic leaf extract

The methanolic leaf extract, showing the highest phytochemical content, was selected for detailed profiling using HR-LCMS-QTOF. Leaves were shade-dried, powdered, and extracted with methanol via soxhlet, then filtered, concentrated, and stored at 4 °C. The HR-LCMS-QTOF analysis was performed on an Agilent 6550 iFunnel Q-TOF system with a ZORBAX Eclipse Plus C18 column, using a gradient of 0.1% formic acid in water and acetonitrile. The extract was filtered, diluted, and injected, with mass spectrometry conducted in positive and negative modes for high-resolution full-scan and MS/MS data. Metabolites were tentatively identified based on accurate mass, retention time, and fragmentation patterns using spectral databases.

RESULTS AND DISCUSSIONS

The leaf extracts obtained were varied in colour, consistency, and yield, reflecting the effect of solvent polarity on phytochemical extraction. All the extracts were sticky, with hexane yielding 1.2% (ivy green), chloroform 6.6% (lettuce green), and ethyl acetate 4.3% (cyprus green). Methanol (agathia green) gave the highest yield of 12.1%, likely due to its polarity, which efficiently extracts a broad range of bioactive compounds, making it the most suitable solvent for obtaining pharmacologically active constituents. Preliminary phytochemical screening of the leaf extracts showed that metabolite distribution varied with solvent polarity. Hexane extract contained alkaloids, terpenoids, phenolics, and tannins. The chloroform extract had alkaloids, flavonoids, terpenoids, and phenolics, and the ethyl

acetate extract included alkaloids, flavonoids, terpenoids, phenolics, tannins, and saponins. Methanol extract exhibited the broadest spectrum, encompassing alkaloids, carbohydrates, reducing sugars, glycosides, proteins, flavonoids, terpenoids, phenolics, tannins, and saponins. Its high polarity allows the extraction of both primary and secondary metabolites, explaining its higher yield and frequent use in phytochemical studies. The observations are represented in Table No.1. The study supports the previous reports on the rich phytochemical composition of *J. beddomei* and *J. adhatoda*, showing that methanolic extracts contain a wide range of metabolites, including alkaloids, carbohydrates, reducing sugars, glycosides, proteins, flavonoids, terpenoids, phenolics, tannins, and saponins. These findings align with earlier investigations reporting alkaloids, flavonoids, tannins, phenolics, saponins, glycosides, carbohydrates, and steroids, highlighting the medicinal relevance of these species [13]. Table No. 1: Preliminary phytochemical analysis-Qualitative. +Indicates presence and- indicates absence AL- Alkaloids, CA-Carbohydrates, RS-Reducing sugar, GL-Glycosides, PR-Proteins, FL-Flavonoids, TR-Terpenoids, PH-Phenolics, TN-Tannins, SP-Saponins, CM-Coumarins. Phytochemical yield obtained in quantitative analysis varied with solvent polarity, with hexane extracting mainly nonpolar compounds like terpenoids and flavonoids, chloroform yielding higher terpenoids and flavonoids, and ethyl acetate extracting notably high alkaloids. Methanol, being highly polar, gave the highest overall yield. The results indicate that methanol is the most effective solvent for obtaining a broad spectrum of bioactive metabolites, particularly alkaloids. Solvent polarity significantly influences extraction efficiency, with methanol proving most effective in this study, yielding 12.1% extract. The methanolic extract contained the highest levels of alkaloids, phenolics, flavonoids, terpenoidsand detectable saponins consistent with previous reports [14]. Methanol's high polarity allows it to dissolve a wide range of polar and moderately polar compounds, making it the preferred solvent for comprehensive phytochemical extraction in pharmacological studies. The results are given in Table No. 2. Table No.2: Preliminary phytochemical analysis-Quantitative. *Data taken as triplicates and represented as mean ±standard error. HR-LCMS analysis of *J. beddomei* methanolic leaf extract revealed a diverse phytochemical profile, with positive electrospray ionization (ESI) detected 18 compounds across retention times of 2.08-20.97 min.

The positive ESI produced more intense and well-resolved peaks, highlighting nitrogenous metabolites such as alkaloids and indole derivatives, whereas negative ESI mainly detected acidic compounds like phenolic acids and glycosides.This suggests that the extract is predominantly composed of compounds with high proton affinity, such as alkaloids, flavonoids, terpenoids, and other nitrogen or oxygen-containing secondary metabolites that readily form $[M+H]^+$ or metal-adduct ions. The HR-LCMS analysis conducted in both positive and negative electrospray ionization (ESI) modes, and the corresponding base peak chromatograms are presented in Figure No. 1 and Figure No. 2. HR-LCMS chromatogram (+ESI) of leaf extract of *J. beddomei* (Figure No. 1). HR-LCMS chromatogram (-ESI) of leaf extract of *J. beddomei* (Figure No. 2). In contrast, the negative ESI chromatogram showed comparatively fewer and less intense peaks, reflecting the selective ionization of only those constituents capable of forming stable deprotonated ions ($[M–H]^-$), primarily acidic phytochemicals such as phenolic acids, polyphenols, and certain glycosides. The major peaks in negative mode were largely confined to the early and mid-retention time regions, indicating the presence of polar acidic compounds, whereas late-eluting hydrophobic constituents were poorly represented due to inefficient deprotonation. Overall, the comparison demonstrates that positive ESI mode provides a more comprehensive metabolic fingerprint of *J. beddomei* leaf extract. The HR-LCMS detected compounds along with their retention time, accurate mass, molecular formula, abundance, and DB difference (ppm) are depicted in Table No. 3. HR-LCMS detected compounds of the methanolic leaf extract of *J. beddomei* (Table No. 3). Early eluting compounds such as 2(N)-methyl-norsalsolinol, vasicinol, peganine, and N-acetylserotonin represent low-molecular-weight, polar alkaloids and indole derivatives, which readily undergo protonation and show high ionization efficiency, as reflected by their strong signal intensities.The exceptionally high abundance of peganine suggests its dominance in the extract and highlights the alkaloid-rich nature of *J. beddomei*. Mid-retention time compounds, including vasicinone, evodiamine, cynometrine, aspidospermine, anisotine, and moschamine, belong predominantly to quinazoline, indole, and other nitrogen-containing alkaloid classes, further supporting the preference of positive ESI mode for nitrogenous secondary metabolites. The detection of biologically significant molecules such as gibberellin and isopentenyl adenosine indicates the presence of plant growth regulators and nucleoside derivatives, respectively, contributing to the biochemical complexity of the extract.

Late-eluting compounds such as 6-pentadecyl salicylic acid, chlorophyll c, and euphornin represent high-molecular-weight, less polar constituents, including long-chain phenolic acids, pigments, and terpenoid derivatives, which elute later due to stronger hydrophobic interactions with the stationary phase. Overall, the phytochemicals observed in the positive ionization mode of HR-LCMS analysis revealed that alkaloids constituted the predominant metabolite class, followed by phenolic compounds, and cytokinins, while pigments and terpenoids are present only in trace amounts. The results indicate the alkaloid-rich metabolic profile of *J. beddomei*. The heatmap shows a clear variation in abundance among the different classes of phytochemicals, indicated by the colour gradient from lighter to darker shades (Figure No. 3). Alkaloids displays its highest abundance. Phenolics and cytokinins exhibits, high but substantially lower abundance. Peptides exhibit moderate abundance. In contrast, terpenoids and especially pigments appear in very low abundance relative to the other phytochemical classes. Heatmap showing phytochemical composition-abundance levels (Figure No. 3). The high abundance of bioactive compounds in the methanolic extract of *J. beddomei* aligns with previous reports on the pharmacological importance of *Justicia species*. Flavonoids, phenolics, terpenoids, and alkaloids are known for their anti-inflammatory, bronchodilatory, and antioxidant activities. Earlier studies identified quinazoline alkaloids such as vasicine, vasicinone, and deoxyvasicinone in polar solvent extracts, with up to 23 alkaloids, including new quinazoline homologs, reported [15]. Consistent with these findings, the present study showed methanol yielded the highest alkaloid content, with key compounds including peganine, vasicinone, vasicinol, and anisotine. The HR-LCMS MS zoomed spectrum of the most abundant bioactive compound peganine detected from the methanolic leaf extract of *J. beddomei*, is given in Figure No. 4. HR-LCMS MS zoomed spectrum of peganine (Figure No. 4).

CONCLUSION

The present study confirms that solvent polarity critically influences the extraction efficiency and phytochemical composition of *J. beddomei* leaves, with methanol found as the most effective solvent. The methanolic extracts yielded the highest quantity of bioactive compounds, including alkaloids, phenolics, flavonoids, terpenoids, saponins, and other primary and secondary metabolites. The HR-LCMS analysis further revealed a diverse phytochemical profile, with alkaloids, particularly quinazoline derivatives such as peganine (vasicine), vasicinol, vasicinone, and anisotine, as the predominant class.The high abundance of alkaloids, specifically peganine, supports the therapeutic potential of *J. beddomei*. Overall, the study highlights methanol as a superior solvent for comprehensive phytochemical extraction and confirms *J. beddomei* as a rich source of pharmacologically significant bioactive alkaloids, providing a scientific basis for its traditional medicinal use and future pharmacological exploration.

ACKNOWLEDGEMENTS

The authors sincerely acknowledge the National Medicinal Plants Board, Ministry of Ayush, New Delhi, for providing financial support through the project entitled "Germplasm Conservation and Phytochemical Evaluation of *Adhatoda beddomei* C.B. Cl. (Cittaadalodakam)." The authors are thankful to the Head, Department of Botany, University of Kerala, for providing the necessary facilities to conduct the present study.

ABSTRACT

Training plays a pivotal role in capacity development, serving as a fundamental mechanism for enhancing the skills, knowledge and competencies of individuals and organizations. In agriculture, training might include modern farming techniques, pest management strategies, of sustainable practices, which can significantly enhance productivity and environmental stewardship by focusing on practical and relevant skills. Training helps individuals and organizations stay competitive and efficient. ATMA offers a very good opportunity to farmers by organizing trainings to work closely with trainees in developing a more skilled and educated workforce. The training programmes of ATMA are multipurpose to cover not only the varied needs of a person but also the entire needs of a village or community. The present study was conducted in Mannargudi and Nannilam blocks of Thiruvarur district. Proportionate random sampling procedure was applied to select 120 respondents from twelve selected villages, six each from these two blocks. A well-structured and pre-tested interview schedule was used for the collection of data. The collected data were analysed and tabulated using appropriate statistical tools. The respondents were categorised under medium level (40.84 per cent) based on their skill-oriented training needs.

Keywords: Training, Agricultural production, Sustainability, Rural women.

INTRODUCTION

Training provides an opportunity to the farmers, especially women to get awareness of agricultural technologies as well as the shift in agricultural development approach through farming enterprises. India faces the most challenging task of transferring the fast-emerging agricultural technologies to sustain and increase in farm productivity and economic viability of farming. A variety of extension programmes are implemented for creating awareness, educating and motivating the farmers, farm women and rural youth to adopt and manage the new agricultural technologies in the field. This is one of the major contributing factors for making India. The concept of Agriculture Technology Management Agency (ATMA) has been initiated in 1999 by Ministry of Agriculture, Government of India under the National Agricultural Technology Project. ATMA is an independent organization aided by the NATP with 5 the goal of linking research and extension work with the help of stakeholders for enhancing the agriculture production including the marketing access, capacity building and empowerment of the farmer for sustainable agriculture development (Sahu *et al*., 2013). The ATMA idea proposes a paradigm shift in agriculture development strategy and implementation from "top down" to "bottom up." ATMA is a decentralized, demand-driven extension method that relies on the strengths of several stakeholders. ATMA was registered society and responsible for dissemination of technology at the district level through Strategic Research and Extension Plan (SREP). It can receive fund directly from GOI/States and membership fees, beneficiaries' contribution etc. It may become primarily responsible for all district-level technology transfer activities. ATMA offers a very good opportunity to farmers by organizing trainings to work closely with trainees in developing a more skilled and educated workforce. The training programmes of ATMA are multipurpose to cover not only the varied needs of a person but also the entire needs of a village or community. It covers agricultural technology, home crafts, childcare, family welfare, cooperation, animal rearing and management, fisheries, beekeeping, cottage industries etc., depending upon the needs of an area and the people. ATMA impart trainings and education with a view to raise the level of knowledge, attitudinal changes and testing and transferring of recommended improved farm technologies to bridge the gap between production and productivity and to increase self-employment opportunities among the farming community. The training programmes of ATMA are being conducted for fulfilling the mandate. The training programmes are planned to meet the immediate requirements of the farming community. Trainings are scheduled at appropriate time to impart knowledge of suitable technology before the start of the season. Because of the diversity in crop, climate and different methods of cultivation farmers are grouped as farmer interest groups to provide appropriate training packages to the groups. The ATMA have concentrated on training to the rural for getting acquainted with special skills through trainings to secure some employment or practice on their farms. Efforts have also been concentrated to empower the women by giving them vocational trainings. While designing the training programmes, the concept of farming system is considered to make the enterprises commercially viable. The training starts from farmers/rural women production units such as fields, dairy units, poultry units, mushroom unit, beekeeping unit, preservation unit, nursery raising etc. and closes with discussion. The vocational training programmes consider all methods and mean which will result in skill development and entrepreneur in rural women in the areas of their interest (Singh, 2017).

METHODOLOGY

The present study is an ex-post-facto research design that was adopted as a strategy of investigation to obtain answer to the research questions. Thiruvarur district in Tamil Nadu was purposively selected for the study. Thiruvarur district consists of ten blocks. In these ten blocks, Mannargudi and Nannilam blocks were selected and six villages were selected from each block where the maximum number of women trainees engaged in training programmes organized by ATMA in Thiruvarur district. Thus, a total of twelve villages were identified for the study. A total of 120 samples were selected from the twelve villages by using proportionate random sampling. Proportionate random sampling ensures all samples in the population have same probability of selection irrespective of their cluster size. A well-structured interview schedule was used for collection of data. Training needs are defined as the competency of the individuals required to do their occupation effectively. To measure the skill-oriented training needs of the respondents a checklist was prepared on the preferred areas of training in agripreneurship viz, mushroom

production, apiculture, value addition, dairy cattle, poultry and fisheries. Sub areas of each training were also included. Then the respondents were asked to give their responses as Most needed, Needed and Not needed and scores given as 3,2, and1 respectively. Then, percentage analysis was worked out for further information.

RESULTS AND DISCUSSIONS

Overall skill-oriented training needs

It could be observed from the Table-1, that 40.84 per cent of the respondents were categorised under medium level based on their skill-oriented training needs followed by high (35.83 per cent) and low (23.33 per cent) level based on skill-oriented training needs. The reason for most of the respondents is in medium level of skill-oriented training needs might be due to the heterogenous nature of trainees and they varied in their training requirements. This suggests that while they may already possess basic skills, they require further enhancement and upskilling to improve productivity adopt modern techniques or start income-generating activities. This result is in line with the findings of Prajapati *et al*., (2019) and Bhasker Krishna (2024). Distribution of respondents according to their overall skill-oriented training needs (Table 1).

Training needs in mushroom production

It could be observed from the Table-2 that packaging and marketing was perceived as highest with mean score 2.93 of the trainees followed by nutritive value of mushroom with mean score 2.86, economics of mushroom and Spawn production with mean score 2.83 Substrate preparation with mean score 2.70, Post harvest handling and value addition with mean score 2.68, Pest and disease management with mean score 2.60, Management of spent compost with mean score 2.42 and Infrastructure requirement with mean score 2.41. The reason for the highest mean score on training need in packaging and marketing of mushrooms might be due to that clearly reflects a shift in rural women's approach from simply growing mushrooms for household consumption or local sale to treating mushroom production as a business enterprise. This need reveals a growing awareness of the importance of value chain development, branding and customer engagement all essential traits of an entrepreneurial mindset. Rather than focusing solely on cultivation, women are now interested in how mushrooms are presented, preserved, promoted and positioned in the market key elements that determine both market success and income generation. Distribution of respondents according to their training needs in mushroom production (Table 2).

Training needs in apiculture

The results in the Table-3 indicated that among the ten different sub areas of training in apiculture marketing and business of honey bees was found to be most needed area of training as perceived as highest with mean score 2.96 which is followed by value addition of honey with mean score 2.93, bee keeping aspects with mean score 2.85, apiary management during different seasons with mean score 2.83, purity testing with mean score 2.75, export of honey with mean score 2.69, bee enemy and disease with mean score 2.60, bee keeping equipment's with mean score 2.50, honey extraction and essential operations with mean score 2.33 and bee biology with mean score 2.02. The reason for the highest mean score on marketing and business of honey bees might be because rural women increasingly recognize that successful marketing is essential for transforming beekeeping into a sustainable income-generating activity. They often face challenges in accessing formal markets, dealing with middlemen, and getting fair prices for their produce. Training in marketing helps them overcome these barriers. Distribution of respondents according to their training needs in apiculture (Table 3).

Training needs in value addition

The data collected on training needs of the ATMA trainees in value addition were shown in Table-4 that the most needed training needs were quality control and management attaining mean score of 2.85 which is followed by manufacturing and preservation techniques of different products 2.75, export promotion techniques with mean score 2.69, procurement of raw materials with mean score 2.68, packaging and marketing techniques with mean score 2.60, advertising of product and brand promotion with mean score 2.58, production technology with mean score 2.34,

technology upgradation with mean score 2.18 and financial management and credit support with mean score 2.12. The reason for the highest mean score on quality control and management might be due to that the rural women are increasingly aware of the importance of standardization and consistency in value added products. It shows that high training need in quality control indicates that rural women recognize the importance of maintaining product standards to access broader and better markets. Distribution of respondents according to their training needs in value addition (Table 4).

Training needs in dairy cattle management

The results given in the Table-5 revealed that the most needed training areas were prevention and control of mastitis with highest mean score 2.91 which is followed by loaning process and facilities with mean score 2.75, prevention and control of repeat breeding and cause of mastitis with mean score 2.69, silage making with mean score 2.65, feed preparation and management with mean score 2.62, breed characteristics and cause of repeat breeding with mean score 2.41. The reason for the highest mean score on prevention and control of mastitis might be due to that women are aware of the impact of diseases on income and are seeking knowledge to proactively. It revealed that rural women involved in dairying are not merely concerned with routine animal care, but are increasingly aware of the broader factors affecting productivity and profitability. Distribution of respondents according to their training needs in dairy cattle management (Table 5).

Training needs in poultry farming

From the Table-6, it could be observed that highest mean score (2.93) mean score was observed by the area of new breed (Giriraj/ Swarnadhara) which is followed by azolla feeding (2.87), scavenging habit (2.80), housing system (2.67), balanced poultry feed (2.66), vaccination (F1) (2.43) and lime stone grit feeding (2.41). The reason for the highest mean score on new breed (Giriraj/ Swarnadhara) might be because growing awareness among rural women of the benefits of scientific and improved poultry farming practices and indicating that rural women are actively seeking ways to increase egg and meat production and improve disease resistance and survival rates. Distribution of respondents according to their training needs in poultry farming (Table 6).

Training needs in fisheries

It could be observed from the Table-7 that preparation/construction of pond was perceived as highest with mean score 2.95 which is followed by water quality management with mean score 2.91, selection of fish species with mean score 2.71, integrated fish cum agriculture with mean score 2.70, integrated fish cum poultry farming with mean score 2.66, balance feeding with mean score 2.65, fish marketing with mean score 2.51, stocking density of fish species with mean score 2.34, integrated fish cum duck farming with mean score 2.12 and integrated fish cum pig farming with mean score 1.70. The reason for the highest mean score on pond construction might be due to the strong awareness that the design and structure of a pond directly impact the success of aquaculture. Improper or unscientific pond construction often leads to Water leakage and poor retention and difficulty in draining and harvesting. Distribution of respondents according to their training needs in fisheries (Table 7).

CONCLUSION

Majority of the respondents (40.84 per cent) were categorised under medium level based on their skill-oriented training needs. Packaging and marketing were perceived as highest with mean score 2.93 in mushroom production. Marketing and business of honey bees was perceived as highest with mean score 2.96 in apiculture. In value addition it was found that quality control and management perceived as highest with mean score 2.85. In dairy cattle management it was found that prevention and control of mastitis perceived as highest with mean score 2.91. In the area of poultry farming it was found that new breed (Giriraj/ Swarnadhara) perceived as highest with mean score 2.93. In fisheries it was found that preparation/construction of pond was perceived as highest with mean score 2.95.

ABSTRACT

This paper explores the works of Jesmyn Ward *Salvage the Bones* and *Sing, Unburied, Sing,* through the lens of environmental injustice and ecofeminism to provide a critical study of the way in which racialized poverty and structural negligence define the experiences of Afro-American communities. Jesmyn Ward has clearly depicted the imbalance of natural disasters and ecological neglect on marginalized Black families. This results in enlightening the complex interaction of gendered inequality, intergenerational trauma, and the destruction of the environment. The study presents the criticism of the exploitation of women and nature and the perseverance and agency of her characters by using ecofeminist paradigm. Ward refers environmental disasters to both concrete and symbolic forms of structural oppression with his detailed descriptions of how human beings are dealing with the after-effects of Hurricane Katrina and their legacy of racial violence. This essay argues that the works by Ward offer a rich vision of resistance and healing through storytelling, communal strength, and reclaiming land and memory besides illuminating on the interrelationality of racism, gender and environmental fragility. These narratives of Ward's are a strong reminder of the long-standing connections between social justice and ecological justice in the era of expanding climate disasters.

Keywords: Environmental Injustice, Ecofeminism, Racism, Poverty, Intergenerational Trauma, Resilience, Climate Crises, Marginalized Communities, Systemic Oppression, Black Feminism and Climate disasters.

INTRODUCTION

Systemic racism, economic disparity, and social neglect are the primary causes of environmental injustice; therefore, they are the unequal exposure of vulnerable populations to environmental risk. These differences are not a

coincidence.Instead, they are the results of the historical discriminatory practices according to which certain groups, in this case African Americans, are the most vulnerable to the natural disasters and environmental hazards. Environmental injustice is often manifested through the poor living conditions, contact with industrial toxins, and insufficient infrastructure that is incapable of bearing the impact of environmental disasters among the black people of the United States. Ecological vulnerability and institutional neglect relate in a way that stresses the immediate need to learn the intrinsic connection between racial and socioeconomic injustices and environmental issues. Jesmyn Ward, one of the most famous contemporary Afro-American writers, explores these relationships in her novels *Salvage the Bones* (2011) and *Sing, Unburied, Sing* (2017). Both works are set in the rural South which is a region of poverty, racial oppression, and environmental vulnerability. Ward narrates the story in a way that sheds light on the daily realities of marginalized black communities. Furthermore, the sufferings of black communities are compounded by their poor relationship with nature. She praises the resilience and collective spirit of these communities, but at the same time she denounces the underlying inequalities that make the communities to be disproportionately affected by natural calamities such as Hurricane Katrina using dramatic visuals and the emotionally charged school of thought, which is too personal.

Ward also intertwines the exploitation of nature with the exploitation of women, particularly Black women who more often than not are exploited through their work and the fact that they care about people but are never considered when it comes to the issue at hand. According to Carolyn Merchant and Vandana Shiva, ecofeminism has placed a strong emphasis on ecological justice, and social justice since the degradation of nature is reflected by other forms of oppression like the oppression of women. Ward expands this concept by focusing on how black women are the driving force of community resilience. Moreover, they carry the burden of environmental racism as well. Her female characters face the world of harsh challenges in which the impacts of poverty, racial violence, and natural disasters intertwine. However, she makes them employ some sense of agency and take care of their families and societies.

This essay presents a discussion of environmental injustice as portrayed by Ward in both *Salvage the Bones* and *Sing, Unburied, Sing* and how the environmental decline and natural disasters are used as literal and metaphorical loci of systematic violence. *Salvage the Bones* uses Hurricane Katrina as a metaphor to emphasize the systemic injustices that exacerbate the negligence Blacks, who are poor families, face. Even the soil seems to become a place of trauma and recollection in *Sing, Unburied, Sing,* which implies the injustices of the past that continue to haunt Afro-American communities.

This paper will argue with an ecofeministperspective that the work by Ward not only exposes such forms of injustices, but also shows how the oppressed communities are strong enough to reclaim their agency and body narratives. The stories by Ward compel the reader to reconsider the way racial equality, gender and environmental justice are related to each other by highlighting the life of Black women and their connection to nature. Her story not only underlines the importance of viewing issues of the environment in terms that incorporate historical injustice aspectsbut also focuses on the views of the most affected group of people. By this, Ward offers a promise of resistance and optimism through the strength and mutual reliance of those who are oppressed, as well as, she criticizes the systems that support thosewho commit these injustices.

Ecofeminism: Theory and Importance in Afro-American Literature

The ecofeminism began in the 1970s initiated by Francoise d'Eaubonnechallenges the oppressed women and the environment at the same timeby patriarchal orders to take advantage of both in monetary terms and in power structure. It supports an intersectional approach to justice based on race, gender, class, and ecology since it links environmental degradation either to social hierarchies as discussed by scholars like Carolyn Merchant and Vandana Shiva. Ecofeminism plays with racial and historical oppression in Afro-American literature. Since enslavement to the present environmental racism, the African Americans, particularly the black women, have been subjected to institutional exploitation, which relates to work and land. Authors like Toni Morrison and Alice Walker focus on the correlation between the identity, land and resilience; Jesmyn Ward explores these issues thoroughly in *Sing,*

Unburied, Sing and *Salvage the Bones.* In the stories told by Ward, black women are shown as guardians of the land and society who resist the negligence of the system and endure ecological disasters. An instance such as Hurricane Katrina is an environmental negligence, as well as the persistence of underprivileged groups in *Salvage the Bones*. Similarly, *Sing, Unburied, Sing* connects the two issues: the racial injustices and the environmental injustices through the land being a place of traumas and memory.

Ecofeminism views Afro-American literature as dominated by the perseverance of minorities and reprimands institutionalized oppression. This synergy is best demonstrated in the works of Ward, which employs the natural world to explore the lived experiences and resistance of Black people as well as giving a way to seek justice and reconciliation.

Salvage the Bones as a Background of Hurricane Katrina

The upcoming hurricane Katrina is a backdrop to Ward in his Salvage the Bones that underscores the structural injustices that the Black communities in rural South have to face. The main family in the story is not left with sufficient resources and support to prepare or to recuperate the storm. This omission is the manifestation of the unequal protection that minority groups enjoy whenever environmental disasters strike, as it is put by Robert D. Bullard (Bullard, Dumping in Dixie, p. 24). Ward portrays such vulnerability in her characters as Esch remarks. "When the storm comes, it will drown us all the same, but it will leave us poorer than before" (162).

The lives of the Black families who are already marginalized in terms of wealth and protective barriers are already vulnerable; the hurricane is a physical and symbolic devastation.

The use of land and memory in Sing, Unburied, Sing

In *Sing, Unburied, Sing,* Ward turns her emphasis to the land itself as being scarred by the environmental and historical violence. The setting of the novel is Mississippi where the black people have been in bondage with poor, the sharecropping, and slavery ever since time immemorial. Pop stats that the world turns into a warehouse of pain, which is passed down through generations: “This land soaked up the blood of men who didn’t own it but worked it, like it could one day be theirs. It never was” (*Sing, Unburied, Sing*, p. 54).

The environmental racism manifestation is mirrored in the relationship between racialized work and environmental exploitation. The environmental impacts of structural inequality in the form of polluted streams and barren land are left to be dealt by the black communities as Ward points out. The Salvage the Bones Salvage the Bones Mudaraba and Fuzzy. Ecofeminism is inclined to investigate the similarities in the productive forces of nature and the productivity of the work of women. The lack of a mother in Salvage the Bones is an indication of the importance given to the caring role of women as well as its exploitation. Esch recalls how her mother took care of their garden, and this indicates an ecofeminist ethic of care even though the family was not well off: Ward uses fluid imagery to describe familial care, noting that "Mama’s hands were calloused, but they moved like water over the plants, coaxing them to grow" (45). The fact that the family garden was destroyed by the storm is used as a metaphor of the greater damage done by the lack of attention to patriarchy and environmental racism. Nevertheless, Esch herself as she observes provides an example of a form of resilience between ecological and human life.

“We’ll plant again. The storm can’t take that from us” (*Salvage the Bones*, p. 178).

Generation to Generation Trauma and Recovery in Sing, Unburied, Sing.

Just like environmental degradation is an intergenerational problem, the issue of ecofeminist critiques is often aimed at the transmission of trauma. Sing, Unburied, Sing has a spiritual and ecological guide, Mam who urges her family to respect the earth and also confront its violent history. As Jojo is informed by Mam,

“This land has seen so much suffering, but it’s also where we’re strongest. We come from it, and we give back to it” (112).

This dichotomy of suffering and healing is an indication of ecofeminism where nature and humanity are interdependent. Ward claims that the key to terminating the trauma cycles and becoming resilient is restoring these relationships.

Resistance and Resilience

In addition to survival, the heroes of Ward face institutional oppression through reclaiming their narratives. Esch and Jojo are both seen to be aware of the sufferings of their societies, and they use their struggle to find power. Esch thinks that a narrative is important in Salvage the Bones: "If I don't remember, if I don't tell it, then who will? The storm will wash it all away" (*Salvage the Bones*, p. 183). The unrelenting spirit of memory and testimony is also represented as ghosts in Sing, Unburied, Sing. Ward highlights narration as one of the ways of resisting the systematic and environmental erasure through g iving a voice to the voiceless.

Community Resilience and the Role of Women.

Ward highlights how women have contributed to building resilience among the less privileged communities. Ward presents black women as an instrument of survival in face of social and environmental violence, either with Mam as a spiritual anchor or with Eschas having a will to take care of her unborn baby. This aligns with the notion of womanism that Alice Walker released, which celebrates an act of strength and creativity on the part of Black females to sustain their societies (Walker, In Search of Our Mothers Gardens, p. 89).

CONCLUSION

Sing, Unburied, Sing and Salvage the Bones by Jesmyn Ward are powerful examples of how long-term effects of institutional neglect and environmental racism imposed on Black communities can be. Ward commends the perseverance and agency of her characters and chastises human and natural resources exploitation using an ecofeminist worldview. In addition to the aspect of environmental injustice, Ward has woven tales of tragedy, survival, and resistance to create a positive image of how human beings and the planet are interdependent with each other. Her literature is an appeal to action, urging her readers to solve the structural injustices that facilitate social and environmental injustices. The stories by Ward are timely becauseit focuses on how climatic change unfairly impacts marginal communities. As a result, they remind us of how even things are at their worst, human strength can still surprise us with great endurance.

ABSTRACT

Congenital muscular dystrophies are a group of muscle disorders, characterised by hypotonia and weakness usually from birth, with a slowly progressive clinical course and is caused by genetically determined defects in structural proteins of muscle. The most important diagnostic tools are creatine kinase (CK), nerve conduction velocity (NCV) studies, magnetic resonance imaging (MRI) of the brain, muscle biopsy, and specific genetic or metabolic testing. As per *Ayurveda*, it can be considered as *Sahaja Vatavyadi*, pertaining to *mamsa shosha* and *dhathugata ama* due to *dhathwagni mandya*. 5-year-old girl diagnosed with autosomal dominant congenital muscular dystrophy having the complaints of delayed motor development, difficulty in head holding and rising to sitting posture, inability to stand or walk without support and was managed using ayurvedic treatment principles. Her investigations showed increased levels of Creatinine phosphokinase, myopathic changes in electromyography and heterozygous variation in the exon4 of the LMNA gene. Treatment protocol was planned considering the principles *of Shosha, Phakka roga* and *Vatavyadhi*. The patient showed remarkable improvement in motor development. The promising clinical results highlighted the efficacy of Ayurvedic management in congenital muscular dystrophies.

Keywords: Congenital muscular dystrophy, *Sahaja Mamsa Shosha, Dhatugata Ama, Balapanchakarma*

INTRODUCTION

Congenital muscular dystrophies [1] are a group of muscle disorders, characterised by hypotonia and weakness usually from birth, with a slowly progressive clinical course and is caused by genetically determined defects in structural proteins of muscle. Most of these disorders are inherited and linked to specific genes and affect the synthesis of various proteins at the plasma membrane extracellular matrix interface. The deletion or malformation of specific proteins secondary to inherited or de-novo mutations results in abnormal protein structure or function and thereby causing muscle weakness. The most common mode of inheritance is autosomal recessive. The incidence of Congenital muscular dystrophy in population-based studies is 0.89/100000children[2]. The most important diagnostic tools are muscle biopsy, specific genetic or metabolic testing, creatine kinase (CK), nerve conduction velocity (NCV) studies and magnetic resonance imaging (MRI) of the brain.[3]. As per ayurveda, it can be considered as *Sahajavyadhi*[4](~genetic disorders) involving *Mamsa shosha*(~degeneration of muscle tissue)and *dhathugata ama*(~metabolic toxicity) occurring due to *Dhathwagni mandya* (~ reduced digestive fire). The long-term prognosis of this disease is really poor and life expectancy of affected children is less. The most common cause of morbidity and mortality is secondary to respiratory or cardiac complications due to muscle weakness[5]

PATIENT INFORMATION

A 5-year-old girl, the only child of non - consanguineous parents came to the *Balachikitsa* OPD of Govt. *Ayurveda* College, Kannur. The chief complaints were delayed gross motor development, difficulty in head holding and rising to sitting posture, inability to sit straight, stand or walk without support. She attained partial head holding at 1 ½ year of age, turning over not attained and sitting with support at 3 years. Fine motor, language and social milestones were normal. There was no history of muscular pain. She required assistance in performing daily activities of living. Her social, cognitive and language skills were good. She also had recurrent fever and diarrhoea, occurring every month since infancy. Each febrile episode would cause many days of fatigue and loss of appetitein the child. The perinatal period was uneventful. There was no relevant family history.

Clinical Findings

The higher mental functions and coordination were intact. Motor system evaluation revealed extreme generalised hypotonia with marked axial hypotonia, reduced deep tendon reflexes, preserved sensations, muscle wasting and reduced muscle power especially in the trunk and lower limbs. Her posture was lordotic. On abdomen palpation, there was Grade I tenderness. Cranial nerves, respiratory and cardiovascular system examination were normal. Vignos and Brooks Scale score[6]was 9 and 4 respectively given in Table 1. *Dasavidha Pariksha /Srotopariksha* of the case is explained in Table 2

Timeline

The whole course of treatment lasted for 9 months. The timeline of treatment is given in Table 3.

Diagnostic Assessment

Onset of symptoms right from infancy, delayed gross motor development, hypotonia, muscle wasting, increased CPK levels, myopathic changes in EMG and relevant findings in genetic testing led to the diagnosis of Congenital muscular dystrophy.

Investigations: Increased levels of Creatinine phosphokinase were detected. Electromyography showed myopathic changes. In genetic testing, a heterozygous variation in the exon4 of the LMNA gene was detected which suggested autosomal dominant congenital muscular dystrophy [7]. Echocardiography, EKG and MRI were not done.

Therapeutic Intervention

Treatment protocol was planned considering correction of *Jataragni* and *Dhatvagni*(~digestive and metabolic correction), removing *dhatugata ama* (~metabolic waste) and addressing the vitiated *Kaphanubandha Vata*(~association

of body humours) with due consideration to *Pitha*. *Pitha* needed to be in a *Saamyavastha* (~congenial state) to prevent *Dhatupaka* and further damage to tissues. Treatment principles of *Shosha*(~cachexia), *Phakka Roga*(~motor developmental delay)and *Vatavyadi*(~neurological disorders) were incorporated. The medications are listed in [Table 3].

Follow Up and Outcome

The patient showed remarkable improvement in motor development. Axial hypotonia and of the limbs reduced and the child was able to hold her neck and body steadily in the upright posture. She could slowly rise herself to a sitting position and also hold her body in cat - camel posture. Muscle power increased and the child started walking slowly without support for a few minutes. She could raise hands above her head and eat and drink without any assistance. Brooks and Vignos Scale score reduced from 9 and 4 to 4 and 1 respectively.

DISCUSSION

Considering the clinical features, *Samprapthi Ghatakas*(~pathological components) were analyzed and the condition was diagnosed as a *Sahaja Sannipataja Vyadhi* with *Vatakapha* dominance and involvement of *Sarvadhathus* especially *Mamsa Dhathu*. Recurrent fever and diarrhoea was due to hampered *Jataragni*. The pathogenesis is as follows. The *Sahaja Nidana (~geneticfactors)* affecting *Beejabhaga*[8] (~genetic components like chromosomes) led to affliction of *Vatapithothara Sannipatha Dosha Dusti* (~vitiation of body humours with more involvement of *Vata* and *Pitha*) and *Rasaraktha(~ blood and circulation)* and *Mamsa Dhatwagni Mandya* resulting in improper formation of *Mamsadhathu* (~muscle tissue). The *Dhatuksaya* (~reduction in the quality and quanity of structural elements) led to further vitiation of *Vatadosha* and *Pitha dosha*. *Pitha Kopa* led to *Dhathupaka Avastha* (~destruction of tissues)leading to destruction of *Peshis (~muscles)* and *Mamsashosha*. The affliction of *Kapha* in the *Mamsa* and *Snayus*(~tendons and ligaments) led to *Shlathangata* (~hypotonicity) and lack of *Sthairya*(~compactness). The *Rogamarga*(~disease pathway)was *Madhyama*(~middle). In the first few days, *Shadangam Kasayam*[9] and *Uramarunnu Gulika*[10] were given to improve the gut immunity. Slowly the recurrence of the febrile episodes and diarrhoea stopped and the nutritional status began improving. After the *Agni* became stable, focus was given on the *Dhatwagnimandya* and *kapha* vitiation. Thus, *Agasthya Rasayana*[11], *Vilwadi Gulika*[12]and *Shaddharanam Gulika* [13] were given along with *Uramarunnu Gulika*. The muscle tone began improving and the child slowly began sitting without support for a few minutes. Then importance was given to the muscle strength and improvement in maintaining immunity and the body posture. Thus, *Indukantham Kasayam*[14]and *Shatpala Gritham*[15] were selected to reduce the *Mamsa Shosha*(~reduced quality and quantity of muscle tissue). Then *Rasnadashamoola Ghritam*[16] which can be used in the later stages of *VatavyadhiChikitsa(~*management*)* was selected which produced increased strength and muscle tone by which the child started slowly taking a few steps with support. Along with the internal therapy, external therapies were also given. *Udwartana*[17]with *yava Kolakulathadi Churnam*[18], *Kadikizhi*[19], *Patrapottala Swedam, Navadhanya Lepam, Katipichu* and *Kseeravasthi* were the procedures carried out in this case. *Yavakolakulathadi Churnam*is the combination of *Kola, Kulatha, Suradaru,*

Rasna, Masha, Atasi, Tila, Kushta,Vacha, Shatahwa in equal amounts which accounts for half the quantity and *Yava*as rest of the amount. *Udwarthana*helps in improving the body circulation which further facilitates epidermal absorption of active principles in the drugs. *Kadikizhi*[19] or *Dhanyamla Pinda Sweda*(~a therapy based on bolus of dry powders dipped in fermented diluted gruel) with *Kolakulathadi Churnam[20]* reduces the laxity of the body and increases the compactness. As per the text *Sahasrayoga*, fermentation of *Tandula* (*Oryza sativa*), *Pruthuka* (Pressed form of rice), *Laja* (Puffed form of rice), *Kodrava* (*Paspalum scrobiculatum*), *Nagara (Zingiber officinale), Nimbuka (Citrus aurantifolia), Deepyaka (Trachyspermum involucratum)* and water is done to prepare *Dhanyamla.*[21]. Even though *dhanyamla* has *ushna teekshna guna*(hot and penetrating quality), this, when used as external application helps to reduce vitiation of *Vata*,*Kapha* and also *Pitha*due to its *sparsa Seethala*(~ cool to touch) property. In addition, the heating process helps in the release of water-soluble active compounds from the drugs, enhancing their therapeutic effects.[22] *Patrapottala* sweda is the bolus-based therapy using *Vatahara Patra*(~leaves which subsides the vitiation of *Vata*), *grated* coconut,

lemon, turmeric *and Eranda Thailam(~castor oil)*. It improves the tone of the body, relieves stiffness, pacifies the morbidity of all doshas in the joints andbrings about lightness in the joints, muscles and soft tissues [23]. *Navadhanya lepa*is the application of a paste consisting of nine different drugs and cereals like *Godhuma*(~wheat), *Shali(~rice), Mudga(~green gram), Masha(~black gram), Kulatha(~horse gram), Ila(~ sesame seeds), Methika(~fenugreek)* and two varieties of millet. This therapy increases the compactness of *Mamsamedo Dhatu*(~soft tissues). Only in the last part of the treatment, oleaginous treatments like *Katipichu*(~application of thin pad of cotton dipped in oil on the lower back)and strength improving medicinal enema like *Kseeravasti*(~medicated milk and ghee- based enema)were administered. *Ksheeravasthi* is apt for *Sukumara Purusha* (~persons who are unable to bear sufferings) and children, who cannot tolerate other decoction enemas.

CONCLUSION

In dystrophies, arresting the progression of the disease is the main focus area of treatment. The current case shows the strength of ayurvedic medications in increasing the quality of life in degenerative disorders. With ayurvedic treatment the child who was unable to hold head for more than a few seconds and sit without support started taking a few steps without support. The promising clinical results highlighted the efficacy of *Ayurvedic* management in congenital muscular dystrophies.

LIMITATIONS

Since this is a single case study, it calls for a further exploratory studies like controlled trials or case series, before developing a standard protocol for the treatment of Congenital Muscular Dystrophies.

PATIENT PERSPECTIVE

The parents observed a significant improvement in the motor development and muscle hypotonia in the child.

DECLARATION OF PATIENT CONSENT

The author certifies that she has obtained patient consent form, where the patient and parents have given consent for reporting the case and other clinical information in the journal. The patient and parents understand that his name and initials will not be published and due efforts will be made to conceal his identity, but anonymity cannot be guaranteed.

Financial Support and Sponsorship
Nil.

Table 3: Timeline and Therapeutic intervention

From Date	To Date	Observation at start	Intervention	Observation at end
15/01/2024	15/02/2024	- Recurrent loose stools - Poor appetite - Hypotonia	Shadanga Paneeyam 150 ml 6 hourly - Uramarunnu Gulika 1 tab(125 mg)-1-1 (before food)	Loose stools subsided - Appetite improved - Improvement in hypotonia
16/02/2024	14/03/2024	Floppiness No head control	Repeat the above medication *Agasthya Rasayana* 1tsp twice daily *Vilwadi Gulika* ½ thrice daily with lukewarm water	Hypotonia reduced slightly Head holding improved
15/03/2024	17/04/2024	Not attained sitting milestone	*Indukantham Kasayam*50 ml twice daily *Shatpala gritham* 1tsp twice daily one hour before food	Child started sitting without support for a few minutes
26/05/2024	17/07/24	Cannot maintain upright body posture Failure to thrive	*Rasnadasamoola Gritham* 1tsp twice daily one hour before food *Shaddharanam Gulika* ½ twice daily with honey	Posture improved Weight gain
18/07/2024	18/07/2024		IP admission Continued internal medicines	The patient feels better
19/07/2024	27/07/2024	Poor Weight bearing	*Udwarthanam* with *yavakolakulathadi churnam*	Parents report that the child bears her weight better when she is held
28/07/2024	11/08/2024	Cannot stand with support	*Kadikizhi* at lukewarm temperature	Holds on to the railing for a few minutes
12/08/2024	18/08/24	Stands with support for a few minutes	*Patrapottala swedam* with only slight pressure application	Stands with support longer

19/08/2024	26/08/2024	Not attained walking	*Navadhanya lepam* applied lukewarm	Tries to take a step with support
27/08/2024	31/08/2024	Not attained walking	*Katipichu* with chinchadi thailam for 45 minutes *Kseeravasthi* with *dasamoola kseeram, rasnadasmoola gritham and balathailam*	Started walking with support when helped to a standing position
01/09/2024			Discharged	Advised to continue the same medication
23/09/2024			Follow up	Started walking a few steps without support
30/02/2025			Follow up	Walking a few steps without support

ABSTRACT

Digital Twin (DT) technology is emerging as a promising approach for enhancing the design and efficiency of clinical trials through advanced computational modeling. By integrating artificial intelligence, real-world data, and predictive analytics, DTs offer new possibilities for trial optimization and evidence generation. However, their adoption poses regulatory challenges due to the absence of DTspecific governance frameworks. Regulatory agencies currently assess DT applications under existing software- and model-based regulatory pathways. Understanding this evolving regulatory context is essential for the responsible integration of DTs into clinical research. This study adopted a qualitative, regulatory-focused review and case study approach to examine the current governance of Digital Twin (DT) applications in clinical trials. Regulatory frameworks and guidance from major authorities, including the United States, Europe, the United Kingdom, and India, were systematically analyzed to identify principles relevant to DT oversight. In addition, three representative DT case studies were evaluated using a regulatory lens to assess context of use, validation strategy, and regulatory acceptability. Based on these analyses, a conceptual regulatory framework tailored to the Indian clinical research environment was proposed. The analysis revealed that no regulatory authority has established DT-specific clinical trial guidance. DT applications are currently assessed under existing regulations for software-based systems, model-informed drug development, and real-world evidence. Case study evaluation demonstrated a clear regulatory maturity gradient, with population-level and analytically embedded DTs showing higher regulatory readiness compared to patient-specific DTs, which remain largely exploratory. Common regulatory expectations across jurisdictions included transparency, risk-proportionate validation, data governance, and lifecycle oversight. Digital Twin technologies are

increasingly recognized as supportive tools in clinical trial methodology; however, their regulatory acceptance remains incremental and context-dependent. In the absence of dedicated DT regulations in India, a structured, risk-based regulatory framework can facilitate responsible adoption while ensuring participant protection and scientific integrity. Early regulatory engagement and alignment with established regulatory principles will be critical to advancing DT-enabled clinical trials.

Keywords: Digital Twin, Clinical Trials, Regulatory Framework, Artificial Intelligence, Real-World Evidence and Digital Health Regulation

INTRODUCTION

Advances in biomedical research and clinical practice increasingly highlight the limitations of conventional experimental and clinical trial approaches in addressing the complexity of human health and disease[1]. Interindividual variability, dynamic disease progression, and heterogeneous treatment responses continue to challenge the efficiency, generalizability, and scalability of clinical research. These challenges underscore the need for advanced computational frameworks capable of supporting predictive, personalized, and adaptive decision-making in healthcare [2]. Recent advances in artificial intelligence (AI), machine learning (ML), and digital health technologies (DHTs) have expanded the feasibility of data-driven approaches in clinical research. DHTs including wearable sensors, mobile health applications, and telemedicine platforms enable the continuous collection of real-world patient data, offering new opportunities to improve patient monitoring, outcome evaluation, and clinical insight. By leveraging these technologies, researchers can better capture longitudinal disease trajectories and evaluate the effectiveness of therapeutic interventions [3]. Clinical trials, however, continue to face persistent challenges such as high costs, long timelines, recruitment inefficiencies, and limited participant diversity [4,5]. These issues compromise both the scientific validity and equity of trial outcomes. Advanced computational and simulation-based approaches can complement traditional trials by enabling virtual evaluation of study designs, forecasting outcomes, and optimizing recruitment strategies [4]. Moreover, computational approaches provide tools to address diversity and inclusion challenges in clinical research. Historical underrepresentation of certain demographic groups, structural barriers to participation, and biases in data collection and analysis have limited the generalizability of findings [5]. Modeling and simulation frameworks can help identify bias, evaluate outcomes across diverse populations, and support adaptive trial strategies to enhance equity. Despite their potential, the adoption of advanced computational technologies in healthcare remains uneven. Regulatory uncertainty, ethical considerations, data governance challenges, and limited familiarity among clinicians and patients continue to hinder implementation and trust [6]. The existing research landscape is heterogeneous, ranging from conceptual studies to early-stage applications, resulting in a fragmented evidence base and limited consensus on best practices [1]. Against this backdrop, the present study objectives to examine the integration of digital twin–enabled computational approaches in healthcare, with a focus on their application in clinical research [4]. By synthesizing existing evidence, identifying methodological and regulatory challenges, and highlighting opportunities for invention, this work seeks to support the responsible and effective implementation of advanced digital technologies in clinical trials and custom made medicine [1].

Conceptual Framework and Evolution of Digital Twin Technology: Digital Twin (DT) technology has emerged in response to the increasing complexity of physical, biological, and clinical systems that cannot be adequately addressed using conventional experimental or static modeling approaches [7]. The historical foundations of DTs can be traced to engineering and aerospace applications, including early system replicas used during the NASA Apollo program, with the formal DT concept later articulated within product lifecycle management frameworks in the early 2000s [8]. Conceptually, a DT is defined as a dynamic virtual representation of a physical entity that is continuously synchronized with its real-world counterpart through bidirectional data exchange, enabling real-time monitoring, simulation, and prediction [5]. The growth of DT technology has been driven by advances in artificial intelligence,

computational modeling, and digital health technologies, facilitating its expansion from industrial systems to healthcare, clinical trials, and pharmaceutical and biopharmaceutical domains [6]. The construction of DTs typically involves three core components—a physical system, a virtual model, and an integrated data communication framework—often supported by AI-driven or hybrid mechanistic–data-driven computational models to capture complex system dynamics [9]. Based on functionality and modeling strategy, DTs can be classified into descriptive, predictive, and prescriptive types, as well as mechanistic, data-driven, and hybrid DTs, with implementations ranging from component- and process-level twins to fully personalized patient-specific digital twins [10]. Collectively, recent studies highlights the rapid emergence of DTs as a foundational digital paradigm with transformative potential in healthcare and life sciences, while also emphasizing the need for standardized methodologies, regulatory frameworks, and ethical governance to support safe and effective real-world adoption [5].

Rationale for studying DT in clinical trials: Conventional clinical trials remain limited by high costs, long durations, ethical constraints, and restricted ability to reflect patient-specific variability in disease progression and treatment response. These challenges reduce trial efficiency and delay the translation of therapeutic innovations into clinical practice. Recent literature highlights that existing trial designs are increasingly inadequate for addressing complex, heterogeneous diseases and the growing request for personalized evaluation strategies [11]. Digital Twin–enabled approaches offer a compelling opportunity to complement traditional clinical trials by enabling *in silico* evaluation of interventions using virtual representations of patients. Evidence from clinical trial–focused position papers indicates that Digital Twins can support faster evidence generation, reduce reliance on large control groups, and ethically optimize trial designs, particularly in settings where patient recruitment is inadequate or placebo exposure is problematic [4]. Moreover, meta-reviews and scoping analyses emphasize that, despite growing interest, Digital Twin applications in health field remain fragmented and insufficiently validated in real clinical research environments. Clinical trials provide a controlled and regulated setting in which the predictive performance, reliability, and limitations of Digital Twin models can be systematically assessed. Studying Digital Twins within clinical trials is therefore necessary to bridge the gap between conceptual promise and translational applicability [1].

METHODOLOGY

Overall Methodological Design: This study adopts a comparative multi-case methodological design to explore how digital twin (DT) technologies are applied across stages of clinical research and clinical trials. Three carefully selected original research cases were used to represent distinct DT paradigms: population-based mechanistic *in-silico* trials, patient-specific clinical digital twins, and AI-generated trial-level digital twins. Together, these cases span preclinical safety evaluation, personalized therapeutic decision support, and clinical trial efficiency enhancement, allowing systematic comparison of DT construction, validation approaches, and translational relevance [12, 13, 14].

Case Selection Strategy: Cases were selected using a purposeful, criteria-driven approach to ensure methodological rigor and relevance rather than random inclusion. Only original research studies that implemented an explicit and operational digital twin model were considered. Studies were required to demonstrate direct relevance to clinical trials or trial-like evaluation, such as *in-silico* trials, virtual drug testing validated against clinical outcomes, or DT integration within randomized controlled trial analyses [12, 13, 14, 15]

Inclusion Criteria: Original peer-reviewed research articles, Explicit construction and application of a digital twin model, Quantitative outcomes linked to clinical or trial endpoints, Clear description of modeling, simulation, or prediction workflows and Validation against experimental, clinical, or clinical-trial data

Case 1: Human *in-silico* drug trials demonstrate higher accuracy than animal models in predicting clinical pro-arrhythmic cardiotoxicity [16]. This case study is based on a large-scale *in silico* drug trial framework employing human ventricular electrophysiological models to predict pro-arrhythmic risk of pharmaceutical compounds.

Regulatory Context: The study operates within the evolving regulatory paradigm that recognizes computational modeling and simulation (M & S) as supportive tools in preclinical safety assessment. Although not positioned as a replacement for regulatory-mandated assays, the *in silico* approach aligns with international regulatory initiatives such as model-informed drug development (MIDD) and the Comprehensive in vitro Proarrhythmia Assay (CiPA), which encourage integration of human-relevant non-animal methodologies.

Regulatory Methodology: From a regulatory standpoint, the methodology demonstrates three elements critical for acceptability:
Defined context of use: The digital models are explicitly used for risk prediction and stratification, not for direct clinical decision-making. This clear limitation aligns with regulatory prospects for non-clinical decision-support tools.

Population based modeling for uncertainty assessment: Regulators requireevaluation of inter-individual variability and uncertainty. The construction of a population of over 1,200 human ventricular models enables systematic assessment of variability, strengthening model credibility.

Comparative benchmarking against accepted assays: The *in-silico* outputs are bench marked against established experimental systems (animal wedge preparations and stem-cell–derived cardiomyocytes). This triangulation addresses regulatory concerns regarding model validation and external consistency.

Regulatory Relevance: The study illustrates how digital twin–like human models can function as: Supportive evidence in regulatory safety submissions**,** Tools to reduce reliance on animal testing and Mechanisms to improve early risk identification

Case 2: Clinical application of virtual antiarrhythmic drug test using digital twins in patients with recurrent AF [17]. This case study is derived from a clinical investigation using patient-specific cardiac digital twins to conduct virtual antiarrhythmic drug testing following atrial fibrillation ablation

Regulatory Context: Unlike population-level *in silico* trials, this study introduces individualized digital twins, raising additional regulatory considerations related to: Software-driven clinical decision support**,** Personal health data integration and Reproducibility and governance of adaptive models.

The study is conducted without regulatory endorsement for clinical decision-making, reflecting an exploratory regulatory posture.
Regulatory Methodology: From a regulatory framework perspective, the methodology demonstrates:

Separation of virtual testing from clinical prescribing: Treating physicians were blinded to virtual drug testing results. This deliberate separation ensures that the digital twin outputs did not influence patient management, maintaining compliance with existing clinical trial regulations.

Retrospective validation strategy: Regulatory risk is mitigated by using retrospective analysis rather than prospective intervention. This approach aligns with early-stage regulatory evaluation of AI-based tools.

Predefined model inputs from published sources: Ion-channel effects of drugs were derived from previously published data, addressing regulatory expectations for traceability and scientific justification of model parameters.

Regulatory Implications
This case study highlights how patient-specific digital twins may be positioned, from a regulatory standpoint, as: Decision-support technologies under investigation, Tools requiring prospective regulatory qualification before clinical integration and Systems necessitating enhanced oversight for data governance, explainability, and validation

Importantly, the authors allow the need for prospective randomized studies, reinforcing alignment with regulatory norms for evidence generation prior to adoption.

Case 3 Using AI-generated digital twins to boost clinical trial efficiency in Alzheimer's disease [14]. This case study is derived from a multicentre investigation that evaluated the practice of AI-generated digital twins (DTs) as prognostic covariates to improve efficiency in Alzheimer's disease clinical trials

Regulatory Context: The study is situated within a mature regulatory environment in which artificial intelligence and advanced statistical methods are increasingly accepted, provided that randomization integrity, Type I error control, and transparency are preserved. Unlike exploratory digital twin applications, this work explicitly aligns its methodology with existing regulatory guidance from major agencies, including acceptance pathways established by the U.S. FDA and the European Medicines Agency (EMA). From a regulatory standpoint, the digital twins are not positioned as external control arms or substitutes for placebo groups. Instead, they are incorporated as prognostic covariates within conventional randomized controlled trial (RCT) analyses, a strategy that is already recognized by regulators.

Regulatory Methodology: The regulatory strength of this case lies in its methodological positioning, which directly addresses common regulatory concerns associated with AI-driven models:

Preservation of Randomization: The DTs are used solely as covariates in the statistical analysis model (prognostic covariate adjustment, PROCOVA). Randomization and treatment assignment remain unchanged, ensuring unbiased estimation of treatment effects—a core regulatory requirement.

Pre-specification and Model Locking: The AI model used to generate DTs was trained, validated, and locked using historical trial and observational data before application to the target trial. This satisfies regulatory expectations for pre-specification and prevents post hoc model manipulation.

Regulatory-Accepted Statistical Framework: The use of covariate adjustment is a well-established analytical approach in regulatory science. By embedding DTs within this framework, the study ensures compliance with guidance on covariate adjustment for drugs and biologics, rather than introducing an entirely novel analysis paradigm.

Independent Validation Across Multiple Datasets
Regulatory credibility is strengthened through validation of the DT model on multiple independent clinical trial datasets, demonstrating generalizability and mitigating concerns of overfitting or trial-specific bias.

Regulatory Acceptance and Precedent: A key regulatory feature highlighted in this case is the explicit reference to formal regulatory qualification. The prognostic covariate adjustment methodology (PROCOVA), when combined with AI-generated DTs, received a positive qualification opinion from the EMA as a novel methodology suitable for medicines development. This represents one of the clearest examples of regulatory acceptance of DT-enabled methodologies for use in pivotal trial analyses. Furthermore, alignment with FDA guidance on covariate adjustment reinforces the acceptability of this approach in U.S. regulatory submissions, particularly for late-phase trials.

Regulatory Implications: From a regulatory framework perspective, this case demonstrates that, AI-generated DTs could be acceptable when embedded within established statistical methodologies, Regulatory risk is significantly reduced when DTs do not replace control arms and Model transparency, validation, and pre-specification are critical enablers of acceptance The study illustrates a low-risk regulatory pathway for DT adoption, positioning DTs as tools that enhance efficiency without altering the fundamental evidentiary standards required for drug approval.

Relevance to the Proposed Indian Regulatory Framework: This case directly informs the proposed Indian framework by demonstrating: A viable supportive-use category for DTs under a risk-based classification, The importance of locking models prior to trial initiation and The feasibility of DT integration without introducing regulatory uncertainty. Such an approach could be realistically adopted in India under existing clinical trial rules, provided appropriate guidance and oversight mechanisms are established.

Methodological Significance: This case represents a regulatory benchmark for digital twin adoption, showing that DTs can transition from exploratory tools to regulator-qualified methodologies when designed in arrangement with existing regulatory principles rather than in opposition to them.

Comparative regulatory analysis of digital twin applications in clinical trials: The three case studies represent distinct regulatory maturity levels of Digital Twin applications in clinical research ranging from supportive *in silico* safety assessment, through exploratory patient-specific virtual testing, to formally qualified DT methodologies for pivotal trials. Together, they illustrate a regulatory progression pathway relevant for framing future DT governance, particularly in jurisdictions such as India.

RESULTS

Across the three case studies, Digital Twin (DT) technologies were consistently applied as supportive, non-standalone tools within clinical research and trials. DTs demonstrated value in improving predictive accuracy, trial efficiency, and understanding of patient variability, while remaining aligned with existing regulatory expectations. Clear definition of context of use emerged as the primary determinant of regulatory acceptability. Population-based *in silico* trials (Case 1) and patient-specific digital twins (Case 2) were positioned as exploratory or supportive methodologies, avoiding direct influence on clinical decision-making. In contrast, AI-generated DTs used as prognostic covariates in randomized trials (Case 3) achieved the highest regulatory maturity by embedding DT outputs within established statistical frameworks, preserving randomization and evidentiary standards. Robust model validation, transparency of assumptions, traceability of data sources, and lifecycle governance were common regulatory enablers across cases. Formal regulatory acceptance was observed only when DTs complemented—not replaced—conventional trial designs, as demonstrated by EMA qualification in Case 3. Overall, the findings indicate that DT adoption is feasible under a risk-based regulatory approach, with supportive-use DTs representing the most realistic near-term pathway, including within the Indian clinical trial context.

DISCUSSION

Regulatory Landscape for Digital Twin Applications in Clinical Trials: Digital twin technology is increasingly investigated in clinical research as a means to model patient-specific disease trajectories, optimize trial design, and generate artificial or virtual comparators. Despite growing interest, DTs challenge conventional regulatory paradigms because they integrate artificial intelligence (AI), real-world data (RWD), software systems, and predictive modeling. At present, no global regulatory authority has issued DT-specific guidance for clinical research. Instead, DT-related applications are evaluated under existing frameworks governing software as a medical device (SaMD), model-informed drug development (MIDD), real-world evidence (RWE), and AI/ML-based medical software.

United States Regulatory Perspective: The Food and Drug Administration (FDA) has established the most advanced engagement with computational modeling approaches relevant to DTs. Through its Model-Informed Drug Development (MIDD) program, the FDA encourages the use of quantitative models to inform trial design, dose selection, and regulatory decision-making. In parallel, the FDA's Real-World Evidence (RWE) Framework allows the use of real-world data to support regulatory submissions in defined contexts. DT-based approaches, including synthetic control arms and predictive patient models, may be considered as supportive evidence within regulatory submissions, provided that their context of use, validation strategy, transparency, and bias mitigation are clearly

defined. Furthermore, DT platforms incorporating AI components may fall under existing SaMD and AI/ML regulatory policies, which emphasize lifecycle management, performance monitoring, and change control. Currently, acceptance of DT-enabled evidence remains case-specific and supplementary rather than standalone[18, 19, 20].

European Regulatory Perspective: Within the European Union, the European Medicines Agency (EMA) supports the usage of advanced modeling and simulation through its Modeling and Simulation Working Group. EMA recognizes the potential role of computational models and RWE in clinical development but applies stringent scientific and methodological scrutiny. DT applications in clinical trials are generally limited to trial optimization, hypothesis generation, and exploratory analyses. EMA requires rigorous external validation, justification of data sources, and clear articulation of uncertainty before such models can be considered in regulatory decision-making. In addition, DT systems using patient data must obey with General Data Protection Regulation (GDPR) requirements. The forthcoming EU AI Act is expected to further influence regulatory oversight of DTs by classifying high-risk AI systems used in healthcare[21, 22, 23].

United Kingdom Regulatory Perspective: The Medicines and Healthcare products Regulatory Agency (MHRA) has adopted a progressive stance toward digital health innovation. Through initiatives such as the AI and Software Change Programme and the Innovative Licensing and Access Pathway (ILAP), MHRA encourages early engagement between developers and regulators. DTs are primarily viewed as advanced clinical decision-support or trial-design tools, rather than direct evidence generators. Emphasis is placed on adaptive algorithm governance, post-deployment monitoring, and real-world performance evaluation. While DT-specific guidance is absent, MHRA's flexible regulatory sandbox approach provides an enabling environment for pilot DT-based trial methodologies. [24,25]

Indian Regulatory Perspective: In India, the Central Drugs Standard Control Organisation (CDSCO) has not yet issued explicit guidance on DTs, AI-driven modeling, or virtual clinical trials. Clinical research is regulated under the New Drugs and Clinical Trials Rules (2019), while digital and software-based products may fall under the Medical Device Rules (2017). Currently, DT applications are probably considered for the exploratory or supportive research tools, requiring approval from institutional ethics committees. Regulatory acceptance of DT-based evidence in India is expected to rely heavily on precedents established by the FDA and EMA, along with robust validation data and ethical justification. The absence of a dedicated AI or DT regulatory pathway represents a significant gap in the Indian context[26, 27].

Comparative Regulatory Overview: Across jurisdictions, regulatory authorities acknowledge the potential value of DTs but maintain a cautious, evidence-based approach. DT-generated outputs are generally acceptable as supportive evidence, while primary reliance on DTs for efficacy or safety decisions remains limited. Common regulatory expectations include model credibility, transparency, data governance, and ongoing performance monitoring.

Considerations for the Regulatory Framework of DT in Clinical trials:

Background and Need: Digital Twin (DT) technologies are increasingly explored to upgrade the clinical trial design, patient stratification, and synthetic control arms. In India, clinical research is regulated by the Central Drugs Standard Control Organisation under the New Drugs and Clinical Trials Rules (2019). However, there is currently no dedicated regulatory pathway addressing DTs or AI-driven predictive models in clinical trials. This regulatory gap necessitates a structured, risk-based framework to ensure scientific validity, ethical compliance, and patient safety while enabling innovation.

Scope of the Framework The proposed framework applies to DTs used in the Clinical trial design optimization, Virtual or synthetic control arms and redictive outcome modeling and patient stratification**.** DTs intended for direct therapeutic decision-making fall outside the present scope and would require stricter medical device regulation.

Core Components of the Framework

Context of Use and Regulatory Classification: Each DT application should explicitly define its context of use, which determines the level of regulatory oversight:

Exploratory DTs: Hypothesis generation and feasibility analysis

Supportive DTs: Trial enrichment and comparator modeling

Influential DTs: Affecting eligibility criteria, endpoints, or dosing
