ABSTRACT

Parkinson's disease (PD) is a progressive neurological disorder with motor and non-motor symptoms, and early diagnosis is difficult due to mild, overlapping symptoms. Diagnosis mainly relies on clinical evaluation and imaging. Research on biochemical, neuroimaging, and genetic biomarkers has improved understanding of PD, but no cure exists. Identifying reliable biomarkers, especially combined biomarker panels, is important for early diagnosis, disease monitoring, and treatment evaluation.

Key words Parkinson's disease (PD),Progressive neurological condition, Motor and nonmotor symptoms, Biomarkers, Neurological disorders,Genetic biomarkers, Pathology.

INTRODUCTION

Parkinson's disease is a progressive neurodegenerative disorder affecting dopamine-producing neurons in the substantia nigra.[01] According to the World Health Organization, its global burden has more than doubled in the last 25 years. PD is characterized by α-synuclein aggregation (Lewy bodies) and dopamine loss, leading to motor symptoms such as tremor, rigidity, and bradykinesia. It also causes non-motor symptoms like olfactory dysfunction, constipation, sleep problems, and cognitive impairment.[02]Diagnosis is mainly clinical because no validated biomarker exists, and current treatments only manage symptoms without stopping disease progression.[03]

Etiology and risk factors

Etiology

Parkinson's disease is caused by genetic and environmental factors, with aging (~60 years) as the main risk factor. It is more common in men and linked to mitochondrial dysfunction and impaired protein degradation. Clinically, it includes tremor-dominant and PIGD subtypes, with PIGD usually progressing more severely.[04]

Environmental risk factors

Clinical studies suggest several risk factors for Parkinson's disease, including pesticide and heavy metal exposure, rural living, farming, head injury, melanoma, dairy intake,[05] and Type 2 diabetes. However, evidence is inconsistent, with pesticide exposure showing the strongest association, while other links remain uncertain due to limitations in epidemiological studies.[06]

Lifestyle and other protective factors

Cigarette smoking and caffeine consumption are the most consistent protective factors associated with a lower risk of Parkinson's disease. Other protective factors include higher urate levels, ibuprofen use, and regular exercise.[07] uric acid, an antioxidant produced during purine metabolism, is usually found at lower levels in PD patients and decreases further with disease severity.[08]

Genetic factors

The first Parkinson's disease gene, SNCA, was discovered in 1997, followed by PRKN mutations causing autosomal recessive PD. Gene classification now uses gene names instead of the PARK system, but interpreting genetic data for different parkinsonism types remains challenging.[09]

Park-Snca (Park1)

Although SNCA mutations are rare, α-synuclein plays a central role in Parkinson's disease. It is a 140-amino-acid protein involved in vesicle trafficking and neurotransmitter release. Overexpression or increased SNCA gene copies (duplication or triplication) leads to neuronal degeneration, with triplication causing earlier onset and cognitive impairment, showing a gene-dosage effect.[10]

Park-Parkin (Park2)

Mutations in PRKN (Parkin gene) are the most common cause of autosomal recessive and early-onset Parkinson's disease. Patients often show dystonia, tremors, and gait abnormalities but usually respond well to levodopa, although early dyskinesia may occur. Pathologically, there is neuronal loss in the substantia nigra, while Lewy bodies are uncommon.[11]

Park-Lrrk2 (Park8)

LRRK2 (Leucine-rich repeat kinase 2 gene) is the most common autosomal dominant gene linked to Parkinson's disease.[12] Its major mutation **G2019S** occurs in both familial and sporadic cases and is more common in certain populations such as North African Berbers and Ashkenazi Jews. LRRK2 encodes a protein involved in vesicle trafficking, autophagy, and mitochondrial function, and is also linked to inflammatory pathways in Parkinson's disease.[13]

Park-GBA

GBA (Glucocerebrosidase gene) encodes a lysosomal enzyme involved in sphingolipid metabolism. Mutations in this gene cause Gaucher disease and are the strongest genetic risk factor for Parkinson's disease, increasing risk more than fivefold and often leading to earlier onset. GBA mutations occur in about 10% of sporadic PD cases and are associated with Lewy body pathology.[14] Other PD-related genes are rare, and interpreting variants from modern genetic testing remains challenging.[15]

Molecular pathology of Parkinson's disease

The pathophysiology of PD

Parkinson's disease involves loss of dopaminergic neurons in the substantia nigra and formation of Lewy bodies containing α-synuclein. Mutations in genes such as SNCA (alpha-synuclein gene), PRKN (Parkin gene), VPS35 (vacuolar protein sorting 35 gene), DJ-1 (PARK7 gene), and GBA (Glucocerebrosidase gene) are linked to familial PD. However, these mutations account for less than 10% of cases, so most PD cases are considered idiopathic.[16]

The role of α-Synuclein in PD

α-Synuclein is a key biomarker of Parkinson's disease and forms aggregates in Lewy bodies. It is encoded by the SNCA gene and expressed in several brain regions.[17] C-terminal truncation promotes aggregation, and extracellular *α*-synuclein in blood and cerebrospinal fluid may contribute to neuronal damage.

The role of oxidative stress in PD

In Parkinson's disease, oxidative stress and mitochondrial dysfunction lead to degeneration of dopaminergic neurons. Oxidation of dopamine produces reactive oxygen species (ROS), while reduced glutathione (GSH) and excess iron further increase oxidative damage, contributing to neuronal death.[18]

The role of inflammation in PD pathogenesis

Neuroinflammation contributes to Parkinson's disease progression. Immune cells such as microglia, neutrophils, and macrophages respond to injury, but chronic inflammation damages neurons.[19] Increased TNF-*α* and IL-6 in cerebrospinal fluid and brain tissue, along with elevated RANTES and nitric oxide synthase, indicate inflammation-induced oxidative stress in PD.[20]

Pathophysiology and Neuropathological Changes

General anatomy of the Basal Ganglia (BG)

The basal ganglia are a group of subcortical nuclei involved in movement control, including the striatum, globus pallidus, substantia nigra, and subthalamic nucleus.[21] The striatum receives inputs from the cortex and other brain regions, while signals pass through direct and indirect pathways to the output nuclei (GPi and SNr) to regulate motor activity.[22]

Functional organization of the bg circuits

Earlier theories proposed that the basal ganglia and cerebellum-controlled movement through integrated signals to the motor cortex via the thalamus.[23] Current understanding shows parallel, segregated cortical–subcortical circuits, where specific cortical areas project to the striatum.[24] These circuits include motor, oculomotor, prefrontal (associative), and limbic circuits, each regulating different brain functions. [25]

Braak staging of PD pathology

The key pathological feature of Parkinson's disease is loss of neurons in the substantia nigra pars compacta, with about 70% neuronal loss by death, along with *α*-synuclein accumulation forming Lewy bodies.[26] The Braak staging theory describes six stages of progression, where early stages show non-motor symptoms,[27] motor symptoms appear in middle stages, and cognitive decline occurs later, suggesting the disease may begin in the gut and spread to the brain via the vagus nerve.[28]

In the progression of Parkinson's disease described by Heiko Braak:

- Stage 2: Pathology spreads to the raphe nuclei, gigantocellular reticular nucleus, and locus coeruleus in the brainstem, with more Lewy neurites than Lewy bodies.[29]
- Stage 3: The disease reaches the substantia nigra pars compacta, leading to Lewy body formation and involvement of the basal nucleus of Meynert.
- Stage 4: There is major dopaminergic neuron loss in the substantia nigra, with pathology extending to the mesocortex, allocortex, amygdala, and thalamic nuclei, while the neocortex remains largely unaffected.[30]
- **Stage 5:** Pathology spreads to the neocortex, affecting the temporal, parietal, and frontal lobes, with significant neuronal loss in the substantia nigra and brainstem nuclei.
- **Stage 6:** The disease extensively involves the neocortex, including motor and sensory areas, representing the most advanced stage of Parkinson's disease.[31]

Non-motor symptoms and their correlation with pathology

In Parkinson's disease, non-motor symptoms often appear years before motor signs, with olfactory dysfunction (loss of smell) occurring in about 90% of early cases. This is linked to α-synuclein accumulation in the olfactory bulb and cortex, which disrupts olfactory pathways and may spread to other brain regions.[32]

Neuropsychiatric manifestations

Parkinson's disease includes neuropsychiatric symptoms such as depression, anxiety, psychosis, apathy, sleep disorders, cognitive impairment,[33] dementia, and impulse control disorders. Depression, affecting about 38% of patients, is linked to dopaminergic and non-dopaminergic dysfunction, reduced dopamine transporter levels in the striatum,[34] and impaired emotional circuits like the amygdala and anterior cingulate cortex, with possible genetic influence.[35]

Medical factors

Some studies report that long-term or high-dose Levodopa (L-dopa) use in Parkinson's disease patients is associated with higher depression scores, as shown by the Minnesota Multiphasic Personality Inventory (MMPI).[36]

Psychological factors

Psychological elements are proposed as important underlying processes for depressive disorders in Parkinson's disease.[38] This suggestion is supported by the fact that PD patients exhibit higher rates of depressive symptoms than patients with chronic diseases who suffer similar disabilities. [39]

Anxiety

Anxiety is a common neuropsychiatric symptom in Parkinson's disease, affecting about 20–40% of patients. It can impair cognitive, motor, and social functioning,[40] with common forms including social phobia, panic disorder, and generalized anxiety disorder. Anxiety in PD may result from a combination of neurochemical, psychological, and medication-related factors.[41]

Sleep disorders

Sleep disorders are common in Parkinson's disease, affecting more than half of patients and occurring 2–3.5 times more frequently than in healthy individuals.[42] Common problems include excessive daytime sleepiness, rapid eye movement sleep behavior disorder (RBD), and insomnia. Some of these disturbances, especially RBD and daytime sleepiness, may appear even before motor symptoms.[43]

RBD

Rapid eye movement sleep behavior disorder (RBD) is a sleep disorder with dream-related vocalizations and abnormal movements during sleep. In Parkinson's disease, it is linked to Lewy body pathology in brainstem regions controlling REM sleep.[44]

Insomnia in PD

Insomnia is a prevalent sleep issue among Parkinson's disease patients, affecting approximately 60% of them.[45] It is described as trouble falling asleep, a problem with sleep maintenance, or an early awakening (e.g., short duration) [46]. Sleep fragmentation is one of the most prevalent sleep concerns. It is referred to as an impairment of sleep integrity [47].

EDS

Excessive daytime sleepiness (EDS) affects about 55% of Parkinson's patients and may result from sleep disturbance, neurodegeneration of sleep–wake centers, and dopaminergic drugs like levodopa, though evidence is inconsistent.[48]

Emerging Biomarkers in Parkinson's Disease

Neuroimaging biomarkers

Neuroimaging-based PD biomarkers for nigrostriatal neurodegeneration are currently the most mature.[49] Currently, there is debate on whether these approaches can effectively differentiate clinically overlapping Parkinson's diseases and/or objectively quantify PD development.[50]

Dopaminergic imaging

18F-dopa PET imaging is used to assess presynaptic dopaminergic neuron integrity in Parkinson's disease.[51] The tracer crosses the blood–brain barrier, is taken up in the striatum, and converted to dopamine.[52] Reduced uptake indicates loss of nigral dopaminergic neurons, with early PD showing about 50% decreased uptake in the putamen. [53, 54]

Dopamine transporter—PET and SPECT imaging of the Dopamine Transporter (DAT) is used to assess dopaminergic neuron integrity. Most patients with Parkinsonism show markedly reduced striatal DAT levels.[55]

Vesicular monoamine transporter2—VMAT2 is a vesicular protein that transports monoamines into synaptic vesicles and can be imaged using PET with 11C/18F-DTBZ to assess nigrostriatal pathways. In Parkinson's disease, striatal DTBZ uptake is reduced, particularly in the putamen.[56]

Caveats and potential solutions—Dopamine Transporter (DAT) imaging is commonly used to assess dopaminergic neuron loss in Parkinson's disease,[57] but early compensatory changes and binding to serotonin transporters (SERT) may reduce accuracy. It measures dopaminergic function rather than pathology.[58] Postsynaptic dopamine receptors can be evaluated using PET with 11C-raclopride or SPECT with 123I-iodobenzamide.[59]

Non-dopaminergic imaging

Neuroimaging research in Parkinson's disease also focuses on brain changes beyond nigrostriatal dopaminergic degeneration.[60] Techniques such as Parkinson's disease–related spatial covariance pattern (PDRP) analysis, cholinergic imaging, and Magnetic Resonance Imaging (MRI) are used to study broader brain involvement.[61] In addition, Transcranial Sonography (TCS) is a non-dopaminergic imaging method used for early or prodromal diagnosis, often combined with biochemical markers.[62]

Metabolism network imaging in brain—18F-FDG PET reveals a characteristic Parkinson's Disease–Related Pattern (PDRP)[63]with increased metabolism in pallid thalamic and pontine regions and reduced activity in premotor and parietal cortices. This pattern can help diagnose PD and monitor disease progression.[64]

Cholinergic imaging using PET with 11C-MP4A also shows reduced cortical acetylcholinesterase activity, indicating cholinergic dysfunction alongside dopaminergic loss. [65]

MRI—MRI helps rule out secondary causes of parkinsonism by detecting structural brain abnormalities. High-field MRI can also identify iron deposits in the midbrain, aiding early Parkinson's disease detection.[66]

Biochemical biomarkers

Biochemical biomarkers for Parkinson's disease are studied in cerebrospinal fluid, blood, and saliva, with most identified through genetic and "omics" studies. However, no biomarker currently provides accurate PD diagnosis, and larger longitudinal studies are needed to validate markers for early (prodromal) stages and non-motor symptoms.[67]

***α*-Synuclein, DJ-1, and tau**

α-Synuclein, a major component of Lewy bodies, is linked to familial Parkinson's disease through gene mutations or duplication. Reduced CSF *α*-synuclein levels are seen in PD but do not clearly distinguish it from other

synucleinopathies.[68] Phosphorylated α-synuclein (PS-129) may be a better biomarker, as it helps differentiate PD from Multiple System Atrophy and Progressive Supranuclear Palsy and correlates with disease severity.[69]

Future Directions

1. **Validation of Biomarker Panels**: Combining multiple markers into panels (e.g., α-synuclein + NFL + LRRK2 mutation status) could improve diagnostic sensitivity and specificity.
2. **Non-Invasive Biomarkers**: Saliva, blood, and urine-based tests are under development to reduce reliance on CSF.
3. **Patient Stratification for Clinical Trials**: Biomarker-based stratification may help identify suitable candidates for disease-modifying therapies.
4. **Integration with Personalized Medicine**: Biomarkers can support individualized treatment strategies based on genetic and molecular profiles.

CONCLUSION

Parkinson's disease is a neurodegenerative disorder marked by α-synuclein accumulation and dopaminergic neuron loss. Although many biomarkers have been studied, their clinical use is still limited. AI-based multi-modal analysis may improve early diagnosis and personalized treatment, but validated biomarker panels and better research methods are still needed.

ABSTRACT

The emergence of big data, cloud computing, artificial intelligence, and the Internet of Things has greatly accelerated the expansion of data output, which has significantly increased the demands on modern storage systems. Conventional storage frameworks, such as Direct Attached Storage (DAS), Network Attached Storage (NAS), and Storage Area Networks (SAN), are becoming inadequate to meet the demands of current applications for scalability, fault tolerance, and cost-effectiveness. These constraints have thus led to the emergence of some new paradigms such as distributed storage, software-defined storage (SDS), and hybrid cloud storage. With respect to this, this paper seeks to provide an extensive study of current architectures in storage, highlighting design principles, challenges, and emerging trends that underscore critical issues of distributed systems, including consistency, fault tolerance, scalability, and security. The review further looks into advancements in technologies like Non-Volatile Memory Express (NVMe), machine learning-driven storage management, and improvements in security through blockchain to address the rising complexity of modern data storage scenarios.

Keywords: Storage architecture, distributed storage, software-defined storage, NVMe .

INTRODUCTION

Emerging big data, cloud computing, the Internet of Things (IoT), and artificial intelligence (AI) developments have greatly increased the data generation rate, making it challenging for storage systems in terms of scaling, performance, and cost factors. Most contemporary applications are unable to satisfy directly attached storage (DAS), network

attached storage (NAS), and storage area networks (SAN) due to complexity issues [1][2][3]. For instance, DAS suffers a scalability disadvantage in distributed environments while NAS faces network bottlenecks resulting from congestion in case of high data volumes [2]. The SANs, though suitable for enterprise applications due to continuous performance availability, suffer from high costs and complexity in maintenance [3]. Contending with such limitations, new storage architectures and paradigms have been developed. Among the various distributed storage structures, SDS, and hybrid cloud storage, are aiming to counter these restrictions and provide enhanced data management solutions. In distributed storage systems, such as Google File System (GFS) and Hadoop Distributed File System (HDFS), the data allocated is spread over numerous nodes to enhance both scalability and fault tolerance. These systems are often plagued by problems associated with consistency and latency as stated in [4][5]. The technology of SDS, OpenStack Swift, decouples storage management from hardware for increased dynamic resource assignment and improved cost effectiveness [6]. Moreover, hybrid cloud storage frameworks combine local and cloud resources, thereby enhancing performance and cutting down on storage cost for businesses through advantages from both settings [7][8].

In other contemporary storage architectures within distributed systems, integrating with Artificial Intelligence and Machine Learning (AI/ML), blockchain, and Internet of Things (IoT) technologies, for meeting the requirements of cloud-centric deployment models such as Infrastructure as a Service (IaaS), Platform as a Service (PaaS), and Database as a Service (DBaaS) are explored [9][12]. Artificial intelligence and machine learning are effective in these frameworks. These techniques facilitate predictive storage management wherein machine learning algorithms enhance data allocation, detect malfunctions, and adjust workloads dynamically, improving both system reliability and operational efficiency [9][12][13]. In IaaS, distributed file systems such as HDFS and object-based storage solutions, like Amazon S3, use AI-driven fault tolerant structures, show improvements including replication and erasure coding, mostly useful in big data applications [5][8] [14].

Further, with the increased leverage of blockchain technology for secured PaaS and DBaaS, puts the modern storage innovative. In Blockchain's immutable ledger of transactions imposes a new level of transparency and trust in distributed storage systems. Especially when it becomes inevitable to multi-tenant cloud environments for data integrity and access control [11][10][15]. In PaaS, blockchain applications provide the verifiability and traceability of cloud storage. In DBaaS, blockchain can also ensure tamper-proof audit trails for metadata management [8][10]. Of course, with the nonvolaitility of NVMe/NVMe-oF, further optimization in latency along with throughput, improves the real-time database operations and modifies the critical aspects. Therefore, Low-latency access with high-throughput capabilities is achieved through AI-driven monitoring and load balancing techniques as proposed in [9][16][17].

Though AI driven techniques can improve storage appreciable, however, the high volumes of data generated at the edge by IoT-driven applications necessitate further in scalable storage architecture like cloud deployment models [9]. For dynamic data allocation in storage systems for edge computing devices, local servers, and other cloud platforms in a multi-tiered storage system, the modern storage techniques are evolved [18]. Further, to reduce latency and optimize bandwidth in an IoT environment, which is fundamental for responsive and resource-efficient storage, researchers proposed [18][19]. Those multi-tier architecture actually ensures that the information is processed faster when they are closer to its source and highly accessible. This augments both system performance and reliability as given in [7][20]. Recently, these architectures are strengthened with AI, secured by blockchain, and optimized for IoT, and address mainly the critical challenges of data consistency, security, and latency, making them indispensable for distributed storage systems across IaaS, PaaS, and DBaaS cloud models [9][18][19].

The distributed storage systems are critically dependent on the number of cores or processors. Moreover, the issues are with (i) data consistency, (ii) fault tolerance, (iii) scalability, and (iv) security for dynamic and complex data use and time changing behaviour in distributed environment. Data consistency mainly poses a threat in real-time GFS and Ceph systems, so require to cope up with the balance and consistency to nodal aspects as well as version consistency [4] [20]. The techniques of replication and erasure coding enhance fault tolerance such as with HDFS and

Facebook's F4. However, both incurs storage and recovery overhead [5][21]. With the data demanding condition in scalable architecture, scaling is implemented in horizontal as adopted in Amazon S3 and OpenStack Swift, supported by AIML based techniques. It explores predictive maintenance and load balancing of growth variability [6][9]. Data integrity and advanced form of encryption for secure access are addressed by Blockchain for security concerns, especially in cloud environments [10][11]. Herein this paper, the contemporary storage architectures are explored from various aspects and prospects. The major challenges of modern system storage utilization (from logical and physical schema), techniques to maintain data consistency, addressing the fault tolerance issues, scalability, and security, are discussed. Overcoming these challenges for ensuring the effectiveness of storage solutions to meet the needs of high-performance applications in the future will focus of this research paper.

LITERATURE REVIEW

Recent developments in storage architecture have emerged persistently. It is driven by the increasing needs for improved (i) performance, (ii) scalability, and (iii) fault tolerance in distributed systems, cloud computing environments, and data-intensive applications. This review covers recent studies and their contributions toward solving problems related to different storage architectures. Several storage architectures have been designed based on different factors as mentioned at (i) (ii) and (iii). This review gives an in-depth overview of the fundamental storage architectures: Direct Attached Storage (DAS), Networked Attached Storage (NAS), Storage Area Networks (SAN), Distributed Storage Systems, and Software-Defined Storage (SDS) and at the same time on the different cutting-edge technologies applied for storage architectures.

Storage Based on Physical Schema

The traditional physical storage can be broadly assigned under the nomenclature as Direct Attached Storage (DAS) and Network Attached Storage (NAS). Direct Attached Storage (DAS) refers to storage systems that can be directly attached to a server or to a computer. Basically, DAS includes HDDs and SSDs associated directly through an interface like SATA or SAS. It provides simplicity and high performance for localized data access, it has several limitations, such as a lack of scalability and shared access, and it, therefore, does not allow for enterprise-level or cloud environments. It is pointed out in [1] that, although DAS solutions are cost-effective for small-scale applications, they lack the necessary flexibility and performance required for distributed workloads in modern computing environments.

Network Attached Storage (NAS) refers to a file-level storage solution that combines storage devices with a local area network. It allows many users and applications to access the storage using standard file-sharing protocols such as NFS, SMB, and CIFS. NAS is often deployed in small to medium-sized businesses as a form of shared file storage. It is more scalable than DAS. Network congestion may develop a bottleneck that restrict performance during heavy workload activities. It is pointed out that NAS is appropriate for organizations with the increasing demand of central file storage but do not require high performance or block-level access to be offered by far more complex storage architectures like SAN [2].

Storage Area Network (SAN)

Current developments in distributed storage architectures had been focused on optimizing fault tolerance and data integrity. According to [4], GFS was one of the pioneering systems which employed large-scale distributed storage with inherent fault-tolerance by using data replication over numerous nodes. GFS included the HDFS as an advanced fault tolerance with data replication along with error correction methodologies to make more efficient use of storage capacity [5]. A review article [14] discusses the means whereby erasure coding can reduce storage overhead without reducing fault-tolerance levels. Erasure coding is an alternative to the more traditional replication methods. The authors highlighted that data can be split by Reed-Solomon codes into pieces, which are then distributed among nodes. Although erasure coding does mean a trade-off between the computing complexity and speed of recovering data, reconstructing lost data pieces does take much more time. The F4 distributed storage system was proposed by

[21], which combines fault tolerance with minimum storage costs by using local repair codes, and, therefore, the bandwidth usage is reduced at the time of recovery. This has been found particularly useful in cloud computing environments where network bandwidth often proves to be a bottleneck. One of the major features of the distributed storage is fault tolerance. Therefore, one of the important topics of current research is around the development of constructing the logical schema of this architecture (Figure 3(a) and 3(b)). Minimising recovery time in distributed storage systems are achieved through error control-based codes as found in other memory (storage). In order to improve the repair processes for distributed storage architectures, a new family of erasure codes called Partial Regeneration Codes (PRC) was introduced in [28]. Conventional erasure codes typically require the regeneration of all lost data. Partial data restoration is feasible using PRC, which lowers network bandwidth consumption and shortens recovery time. The findings demonstrate PRC's benefit in situations where cloud storage settings require quick recovery [5] [14].

In modern cloud-based storage implementation relies mostly on distributed storage to provide flexibility in deployment models. This physical storage is mapped to logical concept thereafter in SAN. It is basically a specialized high-speed fault tolerant network, designed to link storage devices with servers at the block level (as shown in Fig. 2(a)). The commonly employed transmission media are Fibre Channel with Internet Small Computer Systems Interface (iSCSI) protocols. The SAN architecture offers increased throughput, scalability, along with fault tolerance and so on. It makes it suitable particularly for mission-critical applications within enterprise settings for these features. In [2], SAN is proposed to be a part of data centre architecture to enhance the performance in terms of delivery and very large capacity of storage. However, the complexity of SAN requires detailed system knowledge to operate and maintain, which may be expensive in deployment.

It is still very difficult to maintain data security and integrity in distributed contexts, especially with the growing popularity of decentralised storage systems. A distributed storage system based on blockchain was presented for cloud and edge contexts [11]. By using blockchain technology system ensures security and transparency across multiple storage nodes by creating immutable and verifiable logs for each data transaction. This research also aims to optimise the blockchain's consensus process for particular storage operations in order to ensure that the integration of blockchain results in minimal overheads [11]. The concept of hybrid cloud storage is gaining traction as it integrates on-premises and cloud-based storage alternatives, providing enhanced adaptability and economic efficiency. The design of hybrid cloud storage frameworks has been examined, highlighting the significance of strategic data placement that utilizes intelligent algorithms [7]. Their research presents a multi-tiered storage architecture that systematically allocates frequently accessed data to local storage while relegating fewer essential data to the cloud for archiving purposes. Then, by uniting both worlds, it allows organizations to balance performance and cost.

Another feature of hybrid cloud storage is ensuring data consistency and security in heterogeneous environments. A framework for secure hybrid cloud storage has recently been proposed, which relies on homomorphic encryption to ensure the data remains secure even when stored in less-than-trusted environments [8]. This reduces significantly the overhead which encryption would typically incur, and hence this is likely to be a viable solution for performance-sensitive applications. With the wide adoption of cloud and distributed storage systems, security and privacy issues have become hot topics for research. It proposed an encryption technique of cloud storage, which proposed a lightweight, homomorphic encryption scheme that supports operations to be carried out without decryption [26]. Such a feature is particularly helpful for applications processing sensitive data in the cloud, abiding by the rules with regards to data privacy, such as GDPR.

NVMe and High-Performance Storage Solutions

In recent times, a lot of attention has been drawn to Non-Volatile Memory Express (NVMe) because it can reduce storage access latency while improving throughput. As discussed in [17], NVMe-based devices provide better performance compared with traditional SSDs because they utilize the PCIe interface, which affords the simultaneous processing of several I/O operations. Therefore, NVMe is well suited to the HPC settings and enterprise applications

in which rapid access to large data amounts is needed [16]. The deployment of NVMe over Fabrics (NVMe-oF) has been examined in [16], highlighting how this technology broadens the advantages of NVMe beyond local storage solutions, thereby facilitating data centers to implement high-speed NVMe storage within distributed systems. The findings of their research indicate that NVMe-oF mitigates network-induced latency, rendering it appropriate for applications that necessitate low-latency access to storage [16].

Software-Defined Storage (SDS)

Software-defined storage (SDS) separates the management of storage from the physical hardware to enable more flexible and scalable solutions. SDS is a unification of storage resources into a single virtualized repository, thus allowing dynamic allocation dependent on application needs [6]. It was originally proposed at [6] OpenStack Swift that demonstrated an open-source SDS platform performing object-based storage to allow cloud providers to elastically scale their storage. It is scaling unstructured data by spreading it across commodity hardware and showing scalability without proprietary systems.

SDS offers flexibility to storage architectures by decoupling storage management from hardware. Article [22] discusses the adoption of SDS in large-scale data centers, indicating that such an infrastructure can serve dynamically in accordance with workload demands. Their study clearly shows how SDS reduces hardware dependence and allows organizations to optimize storage usage through virtualization for efficient and less costly storage management. However, the major challenges of SDS systems, is to ensure data consistency among virtualized instances across storage [23]. The proposed model of hybrid consistency merges eventual consistency with transactional guarantees in addressing needs for different workloads, especially in cases that rely on real-time data processing. Contemporary research has increasingly concentrated on enhancing the performance of object storage systems. Object storage has become a popular architecture for handling unstructured data at scale. Unlike traditional block or file storage, object storage organizes data into objects with unique identifiers, allowing for greater scalability and flexibility. In [20], the Ceph distributed storage system, which utilizes object-based storage techniques to provide scalable storage solutions. Ceph automatically distributes data across nodes, dynamically balancing load and improving fault tolerance without manual intervention.

A comparative analysis of various object storage solutions, including Ceph, Amazon S3, and OpenStack Swift, is presented in [24]. The results of their investigation reveal that although Ceph provides superior flexibility regarding scalability, Amazon S3 stands out for its user-friendliness and seamless integration with cloud-based applications. Despite the many benefits of scale-out, object stores have significant challenges related to metadata management, especially as objects in storage grow in volume. A hierarchical metadata approach has been proposed in [25] that structures metadata across several tiers of a system, and thus enhances the retrieval times for massive datasets. This methodology contributes to reducing the overhead generated from repeated metadata lookups, which is one of the common challenges with object storage systems.

Storage Techniques Based on Emerging Technologies

AI and Machine Learning in Storage Systems

An intriguing and growing area of study is the incorporation of AI and ML into storage systems. Using historical data usage patterns, the author of Reference [9] examined how AI-based storage management systems might enhance resource allocation, load balancing, and data placement in real time. These AI-powered devices don't need human interaction; they automatically adjust storage settings to boost efficiency and lower operating expenses. In [12], a predictive model based on machine learning was developed to forecast storage system failures. In order to save downtime and conduct preventative maintenance, this model forecasts disc failures and other hardware-related problems using the vast amount of telemetry data. This approach tends to increase the longevity and dependability of the storage system, particularly in large data centres.

In the field of storage management, artificial intelligence is still quite important. AI-powered autonomous storage systems are able to self-optimize in real-time by sensing their own performance in relation to system parameters such

as network bandwidth, disc utilisation, and input/output activities [12]. In scenarios with high cloud traffic, the system optimises throughput and minimises latency by continuously updating the storage policies through reinforcement learning approaches. The study provides examples of significant improvements over conventional rule-based storage management techniques. In [10], some secure data-sharing protocols in distributed storage systems, focusing on the application of blockchain for ensuring data integrity and enabling auditability. Investigation into the initiative reveals that blockchain can solve trust problems that persist in multi-tenant cloud environments by providing a transparent and verifiable access control management mechanism [10].

IoT and Edge Computing: Multi-Tier Storage Systems

Due to latency and bandwidth limitations, traditional centralised storage solutions are losing their viability as edge computing and Internet of Things applications produce enormous volumes of data. A multi-tier hybrid storage system for edge environments was proposed at [18]. It dynamically distributes data among edge devices, local servers, and the cloud according to resource availability and real-time latency. In order to anticipate data access patterns and optimise data location, their work incorporates machine learning techniques, which greatly speeds up response times for Internet of Things applications.

Quantum Storage

Storage architecture is now beginning to be impacted by quantum computing. For storage-based protection against upcoming quantum assaults, a number of quantum-resistant algorithms have been implemented on distributed systems [27]. A novel cryptography may be used to encrypt data in cloud systems. A recent development in cryptography is lattice-based encryption, which makes data impervious to quantum decryption attempts. This study highlights how storage systems must advance in order to preserve security as quantum technologies advance. Below is a comparison chart summarizing key findings from this section. The chart compares various contemporary research studies based on storage architecture types, their focus areas, and the key findings or contributions of each study.

Study/Research	Storage Architecture	Focus Area	Key Findings/Contributions

Cloud Storage Security	Data Security, Homomorphic Encryption	Proposed lightweight homomorphic encryption schemes for secure data auditing in cloud storage without decrypting the data, ensuring compliance with data privacy regulations.
Patel, K., Pandya, T., & Dave, N. (2020). Secure data-sharing using blockchain in cloud storage. *Journal of Information Security and Applications, 55,* 102647.	Blockchain in Distributed Storage	Data Security, Auditability	Examined the use of blockchain for securing data-sharing in distributed storage environments, ensuring data integrity and verifiability in multi-tenant cloud environments.

Parameters affecting Storage Architecture

Different forms of storage architecture introduce a set of challenges that must be taken care of to ensure reliable and efficient data management. Challenges arise from the need to reconcile various factors such as (i) scalability, (ii) data consistency, (iii) latency, (iv) fault tolerance(v) security declares the effectiveness level of performance, scalability, cost as well as complexity of the storage systems.

Scalability

Scalability is one of the inherent attributes of a storage architecture, and scalability of various systems can be analysed mathematically fo
r vertical and horizontal scaling models (Eq. 1 and Eq. 2).

$$C_{up} = k \times C_{initial} \quad (1)$$
$$C_{out} = (n+1) \times C_{node} \quad (2)$$

Let C_{up} represent the capacity of the system after scaling vertically by a factor k. Let C_{out}represent the capacity after adding n additional nodes, where each node has a capacity C_{node}. Here, $k$is limited by the physical constraints of the machine, and vertical scaling typically has diminishing returns due to hardware limits. As the data scales up, efficiency during scaling is the most important metric for the storage system. There is vertical scaling, also called scaling up, through which more resources, whether it is a CPU or storage, are added to a single machine. Scaling out, sometimes called horizontal scaling, adds more nodes to the system. The horizontal scaling was successful in very large distributed storage systems, using the Hadoop Distributed File System, HDFS (2010) [5]. Nevertheless, they noted that as the system grows, the management of metadata and the replication process become increasingly difficult, especially in settings comprising thousands of nodes. Vertical Scaling (Scaling Up) refers to adding more resources (e.g., CPU, RAM, storage) to a single machine [31]. Horizontal Scaling (Scaling Out refers to adding more machines or nodes to the system [32].

Horizontal scaling offers more flexibility and can provide better performance for large-scale systems, though managing more nodes introduces additional challenges, such as coordination overhead and data consistency. Both approaches have advantages depending on the use case. Vertical scaling is efficient for tasks requiring tight data consistency and low latency, while horizontal scaling excels in handling large user bases and offers better redundancy and flexibility. Let's visualize how capacity grows in vertical and horizontal scaling scenarios. A graph comparing the two methods represents as follows-

The graph compares vertical scaling (scaling up) and horizontal scaling (scaling out) in terms of system capacity. While vertical scaling shows a linear increase in capacity with the scaling factor k, horizontal scaling offers greater flexibility and can increase capacity faster by adding multiple nodes simultaneously. However, horizontal scaling introduces more complexity in managing additional nodes, as discussed earlier.

Data Consistency

Such a huge number of nodes or data centers forces in tandem the most important problem: how to maintain data consistency. Most of the modern systems use an eventual consistency model for guaranteeing availability and tolerance to partitioning, as described by the CAP (consistency, availability, and partition tolerance) theorem. However, it is reported in [29] that eventual consistency may lead to outdated or inconsistent data, which introduces problems in real-time applications. In relation to this, systems such as Amazon Dynamo provide developers with tunable consistency levels so as to balance consistency and performance based on application needs.Data replication is an active method that has been employed to gain fault tolerance in distributed storage. To analyze the effect of replication on storage capacity, a simple analytical model can also be adopted [32].

Let: The total storage required for a replicated system is given by:

$$S = RxD \quad (3)$$

Where *D, R, S* represent the total amount of original data, the replication factors and the total storage space required respectively.

This equation shows that the amount of storage needed grows linearly with the replication factor. For example, if we wish to replicate data three times (R=3), the total storage requirement tripled, which bumps up the cost of storage but gives much more fault tolerance. To better illustrate the manner in which the storage requirements scale with increasing replication factors, let us generate a plot that plots required storage space as a function of replication factor R, holding the data volume constant at D. A graph will be generated for this purpose. The graph above demonstrates the linear relationship between the replication factor (R) and the total storage space (S) required. As the replication factor increases, the storage space grows proportionally, emphasizing the trade-off between redundancy and storage costs in distributed systems.

Latency and Performance

Latency, or the delay in time between a data request and its response, directly impacts the performance of storage systems. It has been well-articulated that among traditional storage architectures like NAS, these suffer from high latencies because of network congestion under heavy workloads [17]. Also, although distributed storage systems may be spread across geographically distant regions, such systems suffer from increased network-induced delays, which, consequently lead to higher overall latency [30] [31] [34]. In distributed storage systems, data access latency can be modelled by considering two primary components: local access time and network-induced delays.
Let: The total average latency T_{total} can be modelled as:

$$T_{total} = t_{local} + N \times t_{network} \quad (4)$$

Where t_{local}, $t_{network}$ and N represent the local access time, the average network latency, the number of network hops or nodes that data may need to traverse.

This equation shows that total latency increases with both the number of network hops and the average network delay. We will visualize the effect of increasing the number of network hops N on the total latency. For simplicity, we will assume a fixed local access time t_{local}=1 ms and a constant network delay $t_{network}$=0.5 ms per hop. I'll now generate the graph.

Fault Tolerance and Reliability

There is one important requirement for data storage systems to be run on distributed and cloud infrastructures: fault tolerance. Most approaches that improve fault tolerance are accomplished through data replication and erasure codes. Reference [21] proposed a proposal to implement the F4 system, which uses local repair codes to obtain better fault tolerance at the same time reducing bandwidth utilization in recovery of data. Nonetheless, one focuses on the balance between fault tolerance and storage overhead since erasure coding requires more computation resources and can result in higher latencies for data recovery [14].

Security and Data Privacy

The emergence of cloud storage and distributed storage systems has brought in a high level of concern for data security and privacy. Main components of modern storage architectures include encryption, access control, and secure data transmission. On lightweight homomorphic encryption schemes, a proposal has been made that would allow operations on encrypted data without the need for decryption to secure both privacy and compliance with regulations like GDPR. However, balancing security measures with performance remains an ongoing challenge, at least in those environments that require real-time access to data [26].

Economic Viability

A main concern in modern storage architecture is the balance between performance, scalability, and fault tolerance with cost efficiency. Cost-efficiency strategies of data centers are discussed with relevance to the balance between high-performance SAN systems and extremely cost-effective cloud-based storage such as Amazon S3. The problem with cloud-based systems is flexibility and scalability come at a price, namely through data transfer costs and increased latency [30]. Therefore, this research article explores the following facts highlighting (i) emergence of big data, (ii) cloud computing, (iii) artificial intelligence, and the (iv) Internet of Things. The storage technique has greatly accelerated the expansion of data output, which has significantly increased the demands on modern storage systems. A conventional storage framework, such as Direct Attached Storage (DAS), Network Attached Storage (NAS), and Storage Area Networks (SAN), are becoming inadequate to meet the demands of current applications from the context of scalability, fault tolerance, and cost-effectiveness and so on. These constraints have thus led to the emergence of some new paradigms such as distributed storage, software-defined storage (SDS), and hybrid cloud storage. With respect to this, this paper seeks to provide an extensive study of current architectures in storage, highlighting design principles, challenges, and emerging trends that underscore critical issues of distributed systems, including consistency, fault tolerance, scalability, and security. The review further looks into advancements in technologies like Non-Volatile Memory Express (NVMe), machine learning-driven storage management, and improvements in security through blockchain to address the rising complexity of modern data storage scenarios.

CONCLUSION

The storage architecture is critical in contemporary distributed, parallel computing environments which provides incredible amount of data generation as well as consumption. The evaluation of the foundational elements, conventional storage systems frequently encounter difficulties in fulfilling performance, scalability, and fault tolerance requirements of current applications. This shift in storage architectures from being centralized with DAS and NAS towards distributed deployments with HDFS and Ceph represents the industry effort to address these constraints. New developments in distributed storage, software-defined storage, and hybrid approaches provide better scalability and performance but present new, complicated problems related to data consistency, latency, and security. Erasure coding and blockchain technology will cover fault tolerance and data integrity. AI-driven storage optimization appears to be promising in the context of dynamically managing very complex storage environments. Future storage architecture heavily depends on further innovation in hardware and software, especially in how high-performance technologies like NVMe are integrated, machine learning for predictive maintenance and resource optimization, and quantum-resistant storage solutions are developed. These progressions also feature as the technologies advance to design efficient, secure, and scalable storage systems that can support the needs of applications related to big data, artificial intelligence, and edge computing.

ABSTRACT

The primary goal of Corrective and Preventive Action (CAPA) in pharmaceutical or medical device companies is to detect weaknesses, deviations, or failures, investigate their root causes, and implement corrective measures to prevent recurrence. CAPA also involves taking proactive steps to eliminate potential risks before they lead to issues, ensuring continuous improvement in quality and compliance. As a critical element of the Quality Management System (QMS), CAPA helps maintain regulatory compliance by addressing non-conformities and enhancing operational efficiency. By systematically analyzing problems and implementing sustainable solutions, CAPA ensures product safety, efficacy, and adherence to industry standards. It is a fundamental requirement for maintaining a robust regulatory framework and fostering a culture of quality within the organization.

Keywords: CAPA, Corrective Action, Preventive Action, Non Conformity, Root Cause.

INTRODUCTION

Corrective and Preventive action is a fundamental approach used by organisation to identify, address, and prevent issues that impact product quality, process effficency and overall performance. The main goal of the CAPA is not just to fix the immediate problems but also to prevent their recurrence by addressing root causes. It is important when

problems or deviations occur addressing them swiftly, accurately to minimize the risk and ensuring customer satisfaction. Once a performance target is achieved, a new benchmark is established to drive ongoing improvement, with an elevated focus on quality. This approach aligns with the continuous improvement philosophy embodied in the spiral helix model of ISO 9001:2000.

A well-structured Corrective and Preventive Action (CAPA) program serves as a powerful, unceasing mechanism for enhancing products, processes, and quality systems. CAPA operates as a dual-loop quality improvement tool:

Reactive loop (addressing existing non-conformities)

Proactive loop (preventing potential issues)

In line with the FDA's risk-based audit approach, CAPA implementation must prioritize proactive measures. As a foundational quality management tool, CAPA offers a systematic, step-by-step methodology for executing and documenting corrective or preventive actions. The outcome is a thorough, well-documented investigation and resolution that meets regulatory expectations while fostering a culture of sustained improvement within an organization[1].

CAPA Definitions

Corrective Action – Corrective Action is a response to a non-conformity or undesirable situation that has already occurred. When a non-conformance or problem is identified and reported (whether internally or externally), the steps taken to prevent its recurrence include the following measures:

Resolve the Issue

Correct the problem and update the quality system to monitor the process that caused the non-conformity, preventing it from happening again.

Corrective action

- Address the immediate problem.
- Enhance the quality system by implementing controls to monitor the process, ensuring the non-conformity does not recur.

The corrective action documentation serves as evidence that

- The issue was identified,
- Appropriate corrections were made, and
- Effective controls were implemented to prevent recurrence.

Corrective action is the process to eliminate the cause of detected non-conformity or another undesirable situation[2].

Preventive Action – A **Preventive Action** is a proactive process designed to identify and eliminate potential non-conformances or risks before they occur. The key steps include:

Identifying possible problems or non-conformances,

Determining the root cause of the potential issue,

Developing a plan to prevent it from happening,

Implementing the preventive measures, and

Reviewing the effectiveness of the actions taken.

Preventive actions focus on eliminating the causes of potential non -conformities or other undesirable situations to prevent their occurrence[3].

CAPA Relationship with Quality Subsystems

Within a robust Quality Management System (QMS), the Corrective and Preventive Action (CAPA) process serves as the central nexus for continuous improvement, requiring seamless integration with all other quality subsystems. Its purpose is to systematically collect data from both internal operations—such as audit findings, process deviations, and production records—and external sources, including customer feedback and regulatory inspections. This information fuels investigations to pinpoint root causes, the scope of which is proportionate to the risk involved. The

system then drives the implementation of verified corrective and preventive measures. Crucially, these actions are formalized by updating controlled documents and procedures, with changes communicated to relevant quality personnel, thereby embedding lessons learned directly back into the operational framework to prevent recurrence and proactively mitigate potential issues. The Corrective and Preventive Action (CAPA) system is the central nervous system of a quality management system (QMS), orchestrating a continuous improvement cycle that is fundamentally interactive. It is not a standalone process but a dynamic hub that gathers signals of potential and actual quality issues from every corner of the organization and its external environment. Internally, it relies on data streams from production (like non-conforming reports and process control trends), quality control (out-of-specification results), internal audits, and management reviews. Externally, it integrates feedback from customer complaints, supplier performance issues, and findings from regulatory or certification body audits. Once a signal is received, the CAPA process activates a structured investigation to determine the underlying root cause, employing cross-functional teams to ensure a comprehensive analysis. The resulting actions—corrective to address an existing problem and preventive to avert a potential one—are then designed, verified, and validated. The true measure of CAPA's effectiveness, however, lies in its output: it must feed changes directly back into the core operational subsystems. This is achieved by formally updating procedures through document control, revising training curricula, initiating engineering changes, or adjusting risk management files. This closed-loop mechanism ensures that insights from failures are permanently encoded into the QMS, transforming reactive problem-solving into proactive quality assurance and fostering a culture of sustained compliance and excellence[4].

Compliance Requirements:

In pharmaceutical industry regulatory bodies and standards, organization have established guidelines for CAPA management to ensure product safety and customer well being. it includes

Food and Drug Administration (FDA)

CAPA is a key element of the FDA's quality system regulations for medical devices and pharmaceuticals.

International Council for Harmonisation (ICH Q10)

Pharmaceutical and medical device companies must implement a robust CAPA system that analyzes product complaints, rejections, non-conformances, recalls, deviations, audit findings, regulatory inspections, and process/product trends to identify and address quality issues. Root cause investigations must follow a structured approach, with the depth of analysis, formality, and documentation scaled appropriately to the risk level as outlined in ICH Q9's Quality Risk Management principles. An effective CAPA system should not only resolve immediate issues but also drive sustainable improvements in products and processes, enhance organizational understanding of quality systems, and demonstrate measurable enhancements in overall quality performance. This systematic approach ensures compliance while fostering continuous improvement aligned with regulatory expectations.

This version:

1. Maintains all technical/regulatory requirements
2. Flows as one cohesive paragraph
3. Uses active voice for clarity
4. Preserves the risk-based approach linkage
5. Concludes with business/quality benefits [5]

Process of CAPA

Step 1: Problem Identification

The foundation of any effective CAPA process begins with clearly identifying and defining the actual or potential problem, whether it involves a non-conformance, deviation, or system failure. This critical first step requires documenting both the source that triggered the action (such as customer complaints, internal audits, risk assessments, or service requests) and a precise description of the issue itself, supported by objective evidence. The problem statement should be concise yet comprehensive enough to ensure clear understanding, while including all relevant data that verifies its existence—for instance, trends like increasing equipment downtime may serve as early

indicators of an emerging reliability issue. Proper problem identification sets the stage for subsequent investigation and resolution by establishing a factual baseline of the concern to be addressed[6].

Step 2: Impact and Risk Assessment

After clearly defining the problem, a thorough evaluation must be conducted to assess its potential impact and associated risk level, determining both the necessity and urgency of required actions. This critical analysis examines how the issue could affect product quality, patient safety, operational costs, or system reliability, providing clear justification for why it demands attention. The findings from this impact assessment directly inform the problem's severity classification and subsequent prioritization within the CAPA system. High-risk issues—particularly those compromising product functionality or user safety—typically warrant immediate intervention and escalated resources, while lower-risk matters may follow standard resolution timelines. This risk-based approach ensures appropriate resource allocation and timely response proportional to the potential consequences for both the organization and end-users.

Step 3: Investigation Plan Development

Following risk assessment, a structured investigation plan must be developed to systematically identify the problem's root causes. This documented procedure should clearly define three critical components: specific investigation objectives outlining desired CAPA outcomes; detailed methodologies for analyzing all contributing factors and circumstances; and assigned responsibilities with realistic timelines for completion. The plan must specify the technical approach for causal analysis while ensuring adequate resources are allocated, including personnel qualifications, equipment needs, and data requirements. By establishing this formal framework before initiating the investigation, organizations can maintain methodological rigor, prevent oversight of critical factors, and create an auditable trail demonstrating comprehensive problem examination. The investigation's scope and depth should remain proportionate to both the previously determined risk level and the problem's complexity, ensuring efficient use of quality system resources while meeting regulatory expectations for thoroughness[7].

Step 4: Root Cause Analysis

The investigation plan now guides a systematic analysis of the problem through comprehensive data collection and causal evaluation. Manufacturers must methodically examine all potential contributing factors by gathering relevant evidence - including test results, process records, and operational data - which should be meticulously documented and cross-referenced against the initial list of possible causes. This evidentiary review, employing quality tools such as FMEA, 5 Whys, or Fishbone diagrams where appropriate, progressively eliminates improbable factors until the fundamental root cause is isolated. The analytical process must demonstrate traceability from collected data through logical elimination to final determination, with all findings properly recorded to justify the conclusion. This rigorous approach ensures the identified root cause accurately reflects the underlying system failure rather than superficial symptoms, forming the essential foundation for developing truly effective corrective and preventive measures that will prevent recurrence.

Step 5: Corrective/Preventive Action Plan Development

With the root cause identified, the manufacturer must now develop a comprehensive action plan that translates analysis findings into concrete, measurable improvements. This plan should specify all required corrective and preventive measures, including: detailed descriptions of necessary process, procedural, or documentation changes; clearly assigned responsibilities for implementation; defined timelines for completion; and mandatory training programs to ensure proper adoption of new practices. All proposed modifications - whether to specifications, SOPs, or quality systems - must be documented with sufficient detail to both guide implementation and demonstrate anticipated quality improvements. The plan should articulate expected outcomes for each action item, creating measurable benchmarks for verification. Particular attention must be given to training requirements, as personnel competency directly impacts the effectiveness of implemented changes. By systematically addressing each element from procedural updates to workforce readiness, this action plan transforms root cause analysis into sustainable quality enhancements that prevent recurrence while maintaining regulatory compliance[8].

Step 6: Implementation and Documentation

Execution of the CAPA action plan requires systematic implementation of all identified corrective and preventive measures, with rigorous documentation serving as critical evidence of compliance and effectiveness. Each prescribed task—whether process modifications, procedure updates, control enhancements, or training initiatives—must be methodically carried out and recorded in detail. The implementation summary should comprehensively capture: all completed actions; specific changes made to documents, specifications, or systems; verification of personnel training; and communication of modifications across relevant departments. This documentation must provide a clear audit trail, demonstrating both the completion of planned activities and their alignment with the original problem resolution strategy. All revised documents should be properly version-controlled and referenced, with the complete implementation record attached to the final CAPA report to enable thorough verification by quality assurance and regulatory auditors. The attention to detail in this phase ensures not only immediate problem resolution but also creates the foundation for subsequent effectiveness monitoring.

Step 7: Verification of Effectiveness:

The final critical phase of the CAPA process involves comprehensive verification to confirm both proper implementation and sustained effectiveness of all corrective/preventive actions. This requires two distinct but equally important evaluations: First, documented confirmation that all planned tasks—including process changes, control implementations, and training programs—have been fully executed as specified in the action plan. Second, and most crucially, systematic evidence must demonstrate that the implemented solutions have effectively addressed the root cause without creating new quality issues. This effectiveness verification should evaluate multiple dimensions: elimination of the original nonconformity, resolution of any secondary effects, establishment of robust preventive controls, implementation of appropriate monitoring systems, and mitigation of any unintended consequences from the corrective actions. The verification methodology—whether through statistical process monitoring, audit results, performance metrics, or other quality indicators—must be rigorously documented to provide objective evidence of successful resolution. This documented proof of effectiveness not only closes the CAPA loop but also serves as vital evidence for regulatory compliance and continuous improvement initiatives[9].

Root Cause Analysis:

Root Cause Analysis (RCA) is a structured problem-solving technique used to determine what occurred, how it happened, and why it happened, with the goal of implementing preventive measures to avoid future recurrence. The process involves gathering relevant data, conducting a thorough analysis to identify the underlying causes (rather than just symptoms), and developing actionable recommendations to address them. Essentially, RCA provides a systematic way to dig deeper into problems, examining the chain of cause-and-effect relationships to uncover their true origins. The root causes themselves are the fundamental, identifiable factors that management can directly influence, leading to practical solutions that prevent the issue from happening again. By focusing on these core issues, organizations can move beyond temporary fixes and implement long-term improvements [10].

Brief overview of root cause analysis methodologies

Selecting the most appropriate root cause analysis methodology is essential, as no single approach is universally ideal. The effectiveness of an investigation depends on matching the method to the specific context; a one-size-fits-all strategy often leads to a superficial or narrow examination, ultimately compromising the results. To support informed decision-making, we outline the core principles of three widely used techniques below.

Fault Tree Analysis (FTA): employs a top-down, deductive logic. Investigators begin with a specific, undesirable outcome—known as the "top event"—and systematically trace backward to identify all potential sequences of equipment malfunctions, system flaws, or human actions that could lead to that failure. This method is particularly valuable for modeling complex systems and understanding how multiple failures can combine to produce a significant event.

Advantage: Fault Tree Analysis offers significant benefits by incorporating insights from a diverse group of specialists, creating a unified understanding of a problem.

Disadvantage: it relies on subjective expert opinions throughout the process can introduce biases and potential inaccuracies. Furthermore, the quantitative analysis for complex, large-scale systems can become extremely intricate, often necessitating specialized software to manage the computations. This methodology is most effectively applied in scenarios that require a clear mapping of the causal logic leading to a critical system failure or undesired state. It is also highly valuable for verifying that a system meets mandated safety and reliability standards, for ranking the relative importance of various failure contributors, and for performing detailed assessments and predictions regarding a system's reliability, maintainability, and overall safety profile[11].

Fishbone Diagram

The fishbone diagram is a cornerstone of quality management, renowned as one of the original Seven Basic Quality Tools. Developed by quality expert Kaoru Ishikawa, it is formally called an Ishikawa diagram but is more commonly known as a cause-and-effect or fishbone diagram due to its skeletal appearance. This tool excels at guiding teams to systematically identify and categorize the potential sources of a problem, making it particularly effective for structuring focused brainstorming and uncovering the full scope of contributing factors. Several specialized forms of this diagram exist to address different needs, such as the process fishbone, the cause enumeration diagram, and the CEDAC method, which uses cards for enhanced collaboration. In simpler scenarios, the fishbone diagram can be the sole technique used to find a root cause and inform a solution. For more intricate challenges, it is frequently employed as an initial discovery tool within a broader suite of methods—like responsibility assignment or project planning matrices—to ensure a thorough analysis and actionable follow-through.

Ishikawa Diagram (Fig 1).

Advantages: Fishbone diagrams are particularly useful for organizing potential causes, helping teams think through causes they might otherwise miss, and providing a living document that shows the status of all potential causes and whether they have been proved, disproved, or acted upon.

Disadvantages: Fishbone diagrams are by nature a divergent approach to problem-solving, so they make it possible for teams to expend a lot of energy speculating about a potential cause that may have no effect on the problem.

Recommended Applications

Directing a team to focus on identifying all possible categories and consider alternative causes. Refocusing a team on the causes of a problem rather than the symptoms, improving product design, preventing quality defects, identifying potential factors causing an overall effect[12].

5 Whys: The 5 Whys technique stands out for its simplicity in root cause analysis. It is most effective when the questioning is guided by individuals who possess direct, practical knowledge of the process in question. The method is straightforward: by repeatedly asking "Why?"—typically five times, but sometimes more-you peel back the layers of symptoms to uncover the underlying source of a problem. Once this fundamental cause is identified, a corrective action can be implemented to prevent future recurrence. One of its primary strengths is its simplicity, offering a less complex alternative to methods like fault tree analysis, especially for investigating isolated incidents rather than persistent, systemic issues. However, this simplicity can also be a drawback. The process is highly subjective, often leading to inconsistent results where different teams may arrive at divergent conclusions for the same problem. There is also a risk of stopping the inquiry too early, settling for an intermediate cause rather than the true root. This technique is best applied to straightforward or moderately complex problems, particularly those involving human performance or decision-making factors. It is a practical choice in situations where formal data collection or statistical analysis is not feasible or necessary[13].

CAPA Management System
CAPA Management System (Fig 2).

Benefits of automated CAPA management

- Achieve and demonstrate stronger compliance
- Reduce incidents, complaints, and recalls
- Increase preventive versus corrective actions
- Utilize resources more effectively
- Make better-informed, evidence-based decisions
- Boost customer satisfaction and loyalty [14]

Applications of CAPA in Pharma Industry (Table 1)
CAPA Closure and Verification

- Upon the full execution of all identified corrective and preventive actions, the responsible department head is required to formally attest that the CAPA plan has been satisfactorily completed and that all associated activities have been implemented as intended
- Following departmental certification, the Quality Assurance unit conducts an independent verification. This involves a systematic review of all supporting evidence and documentation to confirm the proper implementation and effectiveness of the actions. QA then provides an official certification of closure, confirming compliance with internal and regulatory standards.
- Any process, system, or documentation modifications initiated as a result of a CAPA must be formally routed through the organization's established Change Control Standard Operating Procedure (SOP). A direct reference to the corresponding Change Control record must be clearly documented within the CAPA form to ensure traceability and procedural adherence.
- The CAPA process is the mandatory pathway for addressing and documenting:
- All identified non-conformances, including deviations, discrepancies, and incident reports.
- Strategic initiatives such as facility upgrades, significant capital equipment purchases, and major changes to the quality management system.
- Actions necessary to full fill commitments made to regulatory authorities.
- A complete and auditable record must be established and maintained for every CAPA initiated, covering its entire lifecycle from identification to verification of effectiveness.
- After formal closure by QA, a copy of the fully executed and certified CAPA documentation shall be issued to the head of the originating department for their records and reference.
- The Quality Assurance department is responsible for consolidating data from all CAPA activities. They must prepare and submit a comprehensive summary report to senior management for review.
- Senior management shall formally review and assess the CAPA summary report, including verification of closure and overall system effectiveness, on a quarterly basis as a standard agenda item during the Management Review Meeting.
- All information and documentation generated by CAPAs that originate from audit findings—whether from internal assessments, customer audits, or regulatory inspections—are classified as confidential. Release of this information to external parties, including regulatory bodies during reviews, is strictly prohibited without obtaining prior written authorization from both the Director of Technical Operations and the Head of Quality Assurance[15].

CONCLUSION

CAPA management plays a povital role in maintaining quality standards within organizations. It enables you to address issues and promptly and identify their root causes and implement sustainable solutions by applying preventive actions you can proactively avoid potential risks improve process and enhance product or service quality.

A CAPA process is not just a regulatory requirement. It is a strategic tool to drive excellence and customer satisfaction. Effective implementation of CAPA ensures not only the resolution of existing issues through corrective actions but also the proactive prevention of future occurrences through preventive strategies. Integration of CAPA with key quality subsystems, supported by robust documentation, root cause analysis, and verification of effectiveness, is essential to meet regulatory expectations outlined by agencies such as the FDA and guidelines including ICH Q10. When appropriately designed and maintained, the CAPA process drives continuous improvement, enhances product quality and patient safety, strengthens regulatory compliance, and promotes a sustainable culture of quality excellence within pharmaceutical organizations.

Table 1: Applications of CAPA in Pharma Industry

Pharmaceutical development	Technology transfer	Commercial manufacturing	Product discontinuation
When variability in a product or process is analyzed, the CAPA methodology offers a systematic pathway. Its strength lies in incorporating the principles of correction and prevention into the repeated, evolving stages of design and development, fostering continuous improvement.	CAPA provides a structured approach for managing feedback, enabling feed-forward, and achieving continual improvement	The application of the CAPA methodology should include a mandatory evaluation step to measure the success of the implemented actions.	Organizations should maintain their CAPA process following product discontinuation to manage risks associated with remaining market stock and to prevent issues in other products.

ABSTRACT

The global drug development process is governed by complex regulatory frameworks designed to ensure the quality, safety, and efficacy of pharmaceutical products while facilitating timely patient access to innovative therapies. Regulatory Affairs has evolved from a traditional compliance-oriented function into a strategic discipline that integrates scientific, legal, and technological considerations throughout the product lifecycle. This review aims to comparatively analyze drug approval pathways in the United States and the European Union and to examine the emerging role of Artificial Intelligence (AI) in modern regulatory science. A comprehensive literature-based evaluation was conducted focusing on regulatory submission mechanisms, exclusivity provisions, approval timelines, and lifecycle management strategies across major regulatory systems. The United States Food and Drug Administration employs structured pathways including Investigational New Drug (IND), New Drug Application (NDA), and Abbreviated New Drug Application (ANDA), whereas the European Medicines Agency operates through centralized and decentralized marketing authorization procedures. Despite harmonization initiatives under the International Council for Harmonisation, significant procedural and strategic differences remain between jurisdictions. The review further highlights the growing integration of AI technologies in dossier preparation, regulatory intelligence, pharmacovigilance, and data-driven decision-making processes, which are transforming regulatory operations and improving efficiency. Digitalization, real-world evidence utilization, and global regulatory collaboration are expected to redefine future regulatory practices. The convergence of regulatory harmonization and AI-driven innovation positions Regulatory

Affairs professionals as strategic contributors bridging pharmaceutical innovation and public health. Adoption of advanced regulatory technologies and coordinated global frameworks will be essential to accelerate drug development, optimize approval timelines, and enhance worldwide access to safe and effective medicines.

Keywords: Regulatory affairs, Investigational New Drug Application (IND), New Drug Application (NDA), Abbreviated New Drug Application (ANDA), FDA, European Medicines Agency (EMA), Artificial Intelligence (AI) in Regulatory Affairs

INTRODUCTION

Regulatory Affairs (RA) is a multidisciplinary function responsible for ensuring that pharmaceutical products meet established standards of quality, safety, and efficacy throughout their lifecycle[1]. It entails registering pharmaceutical items in the appropriate nations before marketing. It serves as a link between the project team and the regulatory authority and serves as a channel of communication with the regulatory authority during the project, with the goal of ensuring that the project plan accurately anticipates what the regulatory authority requires before approving the product[2]. Regulatory Affairs is dynamically involved in every single stage of the development of new medicines before marketing and the post-marketing events of approved medicinal products. Proper execution of regulatory guidelines will progress the economic growth of the firm and the public well-being[3].Most of the regulatory bodies are the Central Drug Standard Control Organization (CDSCO), Food and Drug Administration (FDA), European Medicines Agency (EMEA) and Therapeutic Goods Administration (TGA).

The person associated with the regulatory affairs must possess complete knowledge of the drafted regulatory documents, and they are considered the chief communication link between the company and regulatory agencies. Regulatory affairs personnel must also be aware of Good Manufacturing Practice (GMP), regulations of the World Health Organization (WHO), and International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use (ICH), and all the related documents that must be reviewed and submitted[4]. In regulatory affairs, the role of a pharmacist starts from the preliminary phase to the marketing stage for both novel and generic drugs and confirms that all the products meet required safety and efficacy standards. Professionals in regulatory affairs are required to meet the industry's current needs in light of the global competitive environment[5]. The Regulatory department forms a vital bridge between pharmaceutical products, pharmaceutical companies, and regulatory authorities or professionals in determining the risks of drug discovery and the product to run in the market. In order to protect marketing authorization, pharmacovigilance, import, export, public health, drug registration, and distribution of the marketed product, regulations currently place a high value on innovative drugs[6].

Despite increasing harmonization efforts, significant divergence persists in exclusivity frameworks, review culture, and lifecycle management across jurisdictions. Furthermore, the integration of Artificial Intelligence into regulatory science represents a paradigm shift requiring critical evaluation. This review therefore provides a comparative and forward-looking analysis of global regulatory pathways and digital transformation in Regulatory Affairs.

Historical Development

Many historical events formed milestones in laying the path for establishing the regulatory-related activities. In 1937, Elixir Sulfanilamide, using diethylene glycol as solvent, resulted in the demise of people and led to the passing of the 1938 Federal Food, Drug, and Cosmetic Act in the USA. In the late 1950s and the early 1960s, Thalidomide linked outbursts led to the Kefauver-Harris Amendment in the USA[7]. In 1991, Regulatory Affairs Certification (RAC) was established. In 2011, Drug Master File (DMF), CTD, ASEAN Common Technical Dossier (ACTD) became essential for marketing authorization of pharmaceutical products and medical devices[8].

Regulatory Affairs In Product Development, Clinical Trials, And In Research & Development

The team responsibile for regulatory affairs collaborates with marketing and R&D to produce innovative goods that speed up time to market by utilising recent regulatory and technological advancements**.** Regulatory affairs professionals advise companies both tactically and technically. Their work initiates from the development of a product to making, marketing, and post-marketing strategies, and saves a lot of time and money in developing the product and marketing. The regulatory affairs team collaborates closely with marketing and R&D to develop innovative products that leverage emerging technological and regulatory advancements, thereby expediting the time to market[4]. With regards to clinical research, additional considerations are required for the special populations, including women (pregnant and non-pregnant), pediatrics, and the geriatric population[9]. Regulations for clinical trials ensure that the studies are conducted in a transparent fashion with a focus on the highest morals on safety. The regulatory framework also offers regulations to ensure that trials are effective and give reliable and authentic information on human exposure[10].

Drug Approval Process in the United States and Europe

United States (US):

The United States has the one of the most structured and resource-intensive approval systems. It can take over 10-15 years from the time a drug is discovered to complete all the mandatory clinical phases and achieve regulatory approval for the new medicine to be launched on the market[11]. Aftermarket authorization, the drug can be marketed under the protection of a patent. A new drug's patent shields it against competitors who are chemically identical to it (or competitors who violate other patents) for a certain amount of time after it has been approved and marketed[12]. Since patents are filed initially in the R&D phase when promising compounds are found, only a short time remains before the patent expires[13]. Amendment of the Hatch-Waxman act 1984 led to the approval of generic drugs and the introduction of the 505(b)(2) application- Hybrid NDA, which allows the filer to depend on previously approved drugs' data[14]. Figure 1 depicts various phases of drug development.

Investigational New Drug Application (IND):

IND should be cleared before initiating the studies in humans. To start clinical trials in humans, an IND should be filed by the sponsor with the FDA based on the preclinical report. The drug approval process in the USFDA involves submitting an Investigational New Drug Application, followed by submission of a New Drug Application. A pre-IND meeting is held to discuss the design of animal research, which lends support to the clinical trials, the protocol for conducting the clinical trial, and the CMC (Chemistry, manufacturing and Control) of the investigational drug[5].The IND application includes chemical, physicochemical, manufacturing data, animal test results, including pharmacology, toxicology, and safety data, the rationale for testing a new compound in humans, strategies for the protection of human volunteers, and a plan for clinical testing. If the FDA is satisfied with the adequacy of the documentation, the stage is set for phase 1 clinical trials[15]. The process of IND is illustrated in Figure 2.

New Drug Development (NDA):

After preclinical and clinical studies NDA is filed. An NDA should be approved to market a drug. An NDA contains all the information obtained during the preclinical and clinical phases of testing. If a drug survives the clinical trials, an NDA is submitted to the FDA[15]. NDAs typically run 100,000 pages or more. By law, the FDA takes six months to review an NDA. Once the FDA approves an NDA, the medicine becomes accessible for physicians to prescribe. A company must continue to submit periodic reports to the FDA, including cases of adverse reactions and appropriate quality control records. For some medicines, the FDA requires additional trials (Phase IV) to evaluate long-term effects[16,17]. The process of NDA is illustrated in Figure 3.

Abbreviated New Drug Application (ANDA):

ANDA is filed for generic drug development. The Indian generics market is growing day by day, with Indian pharmaceutical companies seeking more ANDAs in the US in major segments such as cardiovascular, antibiotics, and other groups. The Hatch-Waxman Act established the approval pathway for generic drug products, under which applicants can submit an ANDA under section 505(j) of the Federal Food, Drug, and Cosmetic Act (FD&C Act). It

created opportunities for developing and marketing generic drugs and has given an exclusivity period of 180 days. Different types of ANDA applications are presented based on patent certifications listed in Table 1[16,17]. The process of ANDA is illustrated in Figure 4. Comparisons in NDA and ANDA requirements are given in Table 2.

Europe (EU):

Clinical trial application and marketing authorization are the two regulatory steps to go through before a drug is approved in the European Union. Multiple registration processes in the EU are centralized, decentralized, mutual recognition, and national procedure. Most of the new products are reviewed by the European Medicines Agency (EMA) and get approval through the centralized procedure, which will be applicable in all countries in the European Economic Area (EEA) and member states of the European Union (EU)[18]. In the EU, the orphan designation is granted by the European Commission following a positive opinion by the Committee for Orphan Medicinal Products[19]. Once a manufacturer acquired a certificate of conformity in one EU country, then it could affix a CE mark to its product and sell it in all member states[20]. Differences between the USFDA and the EU are given in Table 3. In Europe, regulatory authorities grant 10 years exclusivity period; 8 years of innovator's data exclusivity and 2-year marketing exclusivity. The project targets to reach out to medicine innovators in academia to bridge the regulatory knowledge gap and boost the negotiation between academia and regulatory authorities by employing qualification, scientific advice, and bidirectional knowledge exchange[2].

Comparative Analysis Of Regulatory Pathways: United States Vs European Union

Despite global harmonization efforts, the regulatory frameworks of the United States and the European Union differ structurally, procedurally, and strategically. While both systems aim to ensure drug quality, safety, and efficacy, variations in approval pathways, data exclusivity, review timelines, and lifecycle management create distinct regulatory environments that influence global development strategies.

Structural Organization of Regulatory Authorities:

The United States operates under a centralized federal system governed by the U.S. Food and Drug Administration (FDA), which provides a single regulatory pathway for nationwide marketing authorization. In contrast, the European Union functions through a hybrid structure coordinated by the European Medicines Agency (EMA), offering multiple approval routes: centralized, decentralized, mutual recognition, and national procedures.

This structural distinction impacts submission strategy. Sponsors seeking EU approval must strategically determine the appropriate pathway based on product type, therapeutic area, and market objectives, whereas U.S. submissions follow a unified federal framework.

Regulatory Submission Pathways:

In the United States, innovative drugs follow the Investigational New Drug (IND) → New Drug Application (NDA) pathway, while generics are submitted via the Abbreviated New Drug Application (ANDA). The Hatch-Waxman framework enables generics to rely on reference product data, emphasizing bioequivalence rather than full clinical datasets. In the EU, sponsors submit a Marketing Authorisation Application (MAA), with centralized review mandatory for biologics, orphan drugs, and advanced therapies. Unlike the U.S. system, EU marketing authorization results in approval across all member states when granted via the centralized route.Strategically, the EU system offers broader geographic market access through a single centralized application, whereas the U.S. provides procedural simplicity with one authority but limited to one national market.

Data Exclusivity and Market Protection:

One of the most significant divergences lies in exclusivity provisions:

United States: 5 years of data exclusivity for new chemical entities, with potential extensions (e.g., pediatric exclusivity).

European Union: 8+2(+1) rule – 8years data exclusivity + 2 years marketing exclusivity + 1 additional year for new indications.

This extended exclusivity in the EU may influence sponsors to prioritize European approval in certain strategic cases. However, U.S. market size and pricing structures often counterbalance exclusivity advantages.

Accelerated and Conditional Approval Mechanisms:

Both jurisdictions have introduced expedited pathways to facilitate early patient access to critical therapies.

The FDA offers:

- Fast Track designation
- Breakthrough Therapy designation
- Priority Review
- Accelerated Approval

Similarly, the EMA provides:

- Conditional Marketing Authorization
- PRIME (PRIorityMEdicines) scheme
- Accelerated Assessment

While both systems aim to shorten review timelines, the FDA framework is often perceived as more flexible in early engagement and adaptive approval models. The EMA places greater emphasis on post-authorization commitments and structured risk management plans.

Review Timelines and Process Validation:

Typical standard review timelines differ:

FDA: Approximately 10 months (standard)

EMA: Approximately 12–15 months (centralized procedure)

The EU additionally requires formal process validation at submission, whereas in the U.S., certain validation elements may be finalized closer to approval. This procedural variation affects manufacturing readiness planning and submission timing.

Post-Marketing Surveillance and Pharmacovigilance:

The EU regulatory framework mandates comprehensive Risk Management Plans (RMPs) as an integral part of approval, whereas the U.S. system emphasizes Risk Evaluation and Mitigation Strategies (REMS) when necessary. The EU pharmacovigilance network is more decentralized across member states but centrally coordinated by the EMA. Both regions increasingly incorporate real-world evidence into lifecycle management, though regulatory guidance frameworks may differ in scope and implementation.

Harmonization Efforts and Persistent Divergence:

Harmonization initiatives under the International Council for Harmonisation have standardized technical submission formats (eCTD), stability guidelines, quality requirements, and clinical trial data structures. However, differences in exclusivity rules, review culture, procedural flexibility, and political-regulatory frameworks continue to create divergence. These differences require pharmaceutical sponsors to adopt region-specific regulatory strategies rather than assuming full global convergence.

Regulatory Framework in India (CDSCO):

In India, pharmaceutical regulation is overseen by the Central Drugs Standard Control Organization (CDSCO) under the Ministry of Health and Family Welfare. The Drugs Controller General of India (DCGI) is responsible for approving new drugs, clinical trials, biologics, vaccines, and import licenses. The regulatory framework is primarily governed by the Drugs and Cosmetics Act and the Drugs and Cosmetics Rules, which establish standards for drug quality, safety, manufacturing, and distribution. Significant modernization was introduced through the New Drugs and Clinical Trials Rules, which streamlined clinical trial approvals, defined review timelines, strengthened ethical oversight, and enabled accelerated approval pathways for drugs addressing unmet medical needs. Sponsors are required to obtain CDSCO approval along with Institutional Ethics Committee clearance prior to conducting clinical

trials. India increasingly aligns its regulatory practices with international harmonization initiatives led by the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use, adopting Good Clinical Practice (GCP), Good Manufacturing Practice (GMP), and electronic submission systems such as the SUGAM portal. With India serving as a major global supplier of generic medicines, CDSCO plays a critical role in ensuring regulatory compliance while facilitating global market access and affordable healthcare.

Artificial Intelligence In Regulatory Affairs

Artificial Intelligence (AI) is rapidly transforming pharmaceutical regulatory science by shifting Regulatory Affairs (RA) from a document-centric function to a data-driven, predictive, and strategic discipline. As regulatory submissions grow increasingly complex – oftenexceeding 100,000 pages in electronic Common Technical Document (eCTD) format – thereliance on manual compilation, review, and cross-referencing presents significant inefficiencies and risks of inconsistency[21]. AI-driven systems are emerging as powerful tools to enhance regulatory accuracy, efficiency, and decision support[22] . The increasing complexity of electronic Common Technical Document (eCTD) submissions necessitates advanced tools to manage structured data efficiently [23]. The eCTD submission process comprises five modules, and AI can be applied within each module to simplify and optimize the overall workflow[24]. AI enables advanced approaches to dossier filing, data extraction, compliance management, and regulatory upkeep for software-based medical devices[25].

AI in Dossier Preparation and eCTD Automation:

The eCTD framework standardized under the International Council for Harmonisation enables harmonized electronic submissions across regions [26].Machine learning algorithms and Natural Language Processing (NLP) tools are increasingly being applied to[23,27]:

- Automated document classification and indexing
- Intelligent content extraction from clinical study reports
- Detection of inconsistencies across modules
- Version control and lifecycle management

AI-enabled document management platforms can significantly reduce dossier preparation time and minimize human error, thereby accelerating submission readiness.

Regulatory Intelligence and Predictive Analytics:

AI-powered regulatory intelligence platforms analyze approval trends, inspection outcomes, and regulatory communications from authorities such as the U.S. Food and Drug Administration and the European Medicines Agency to support risk-based submission strategies [15]. Predictive analytics models are being explored to estimate approval probabilities and optimize clinical development pathways [28].

Predictive modeling can support[29]:

- Risk-based submission strategies
- Identification of potential regulatory objections
- Optimization of clinical development pathways
- Competitive intelligence benchmarking

Such tools enable regulatory professionals to move from reactive compliance to proactive strategic planning.

AI in Pharmacovigilance and Post-Marketing Surveillance:

AI applications in pharmacovigilance use machine learning algorithms to analyze adverse event reports and real-world data sources for early signal detection. Natural Language Processing (NLP) tools further assist in extracting safety-relevant information from unstructured data such as medical literature and health records [7,30] .

Post-marketing safety monitoring is another domain undergoing transformation. Advanced signal detection algorithms improve early identification of safety concerns, reducing reliance on manual case processing and enhancing patient protection.

AI in Regulatory Review and Decision-Making:
Regulatory agencies are evaluating AI-assisted review systems to enhance consistency and efficiency in dossier assessment. However, the integration of AI into regulatory workflows introduces critical considerations related to algorithm transparency, data integrity, cybersecurity, and regulatory accountability. Explainable AI (XAI) models are increasingly emphasized to ensure that automated recommendations remain interpretable and scientifically defensible[31].

Challenges and Ethical Considerations:
Despite its transformative potential, AI adoption in Regulatory Affairs faces challenges, including:

- Lack of standardized validation frameworks
- Data privacy and compliance requirements
- Regulatory uncertainty regarding AI-driven submissions
- Need for cross-functional expertise in data science and regulatory science

To ensure sustainable implementation, regulatory frameworks must evolve to accommodate digital transformation while maintaining rigorous safety and efficacy standards.

Future Of Regulatory Affairs
In the future of medicine, targeted drug delivery via innovative drug delivery methods and nanotechnology intervention is becoming the key player. Following successful clinical studies, a variety of new active pharmaceutical ingredients (APIs), biologics, innovative drug delivery systems, and nanopharmaceuticals are produced and marketed worldwide each year[32]. The regulatory affairs profession is set to evolve expressively due to digital disruption, particularly influenced by the COVID-19 pandemic, advancements in machine learning and AI, and a deeper scientific understanding of diseases. The global regulatory landscape is shifting towards strategic collaborations and harmonization among regulatory authorities. As these trends reshape the industry, regulatory professionals will need to adopt a growth mindset and continual learning to effectively influence product development for societal benefit.

The convergence of AI, real-world evidence, and global regulatory harmonization is poised to redefine the future of Regulatory Affairs. As digital health technologies, advanced biologics, and personalized medicine expand the complexity of regulatory submissions, AI will become indispensable for lifecycle management, global submission synchronization, and risk-based regulatory strategy. Regulatory professionals will increasingly function as data strategists, leveraging AI tools to enhance submission quality, reduce approval timelines, and improve patient access to innovative therapies.

CONCLUSION

Regulatory Affairs has transformed into a strategic discipline that plays a critical role in ensuring the quality, safety, and timely availability of pharmaceutical products. Comparative analysis of regulatory pathways in the United States and the European Union highlights ongoing harmonization alongside important differences in approval mechanisms, exclusivity frameworks, and lifecycle management strategies. The evolving regulatory landscape in emerging markets, including India through the Central Drugs Standard Control Organization, reflects increasing global integration of regulatory standards. The growing application of Artificial Intelligence in regulatory science is accelerating dossier preparation, regulatory intelligence, and pharmacovigilance activities, enabling more efficient and data-driven decision-making. Continued regulatory harmonization, digital transformation, and adoption of advanced technologies will be essential to streamline drug development processes and improve global patient access to safe and effective therapies.

ABSTRACT

The high rate of digitalization of healthcare services has opportunity patient-centred mobile applications that will fill a gap between the clinical monitoring and lifestyle management. Nevertheless, the current solutions are typically less multilingual than comprehensive and do not combine individualized nutrition advice and clinical information. This paper introduces a mobile healthcare management systemwhich is developed based on Flutter and Dart and overcomes all these constraints. The app uses a dual-role structure that caters to the needs of healthcare providers and patients, with real-time vital signs monitoring, AI-based customized nutritionary suggestions, and a variety of support to six languages English, Tamil, Hindi, Malayalam, Telugu, Kannada). The system uses a rule-based expert system, which evaluates seven physiological parameters and produces condition specific dietary interventions. The performance of the device at various levels of devices proves to be efficient in terms of resource use where the memory consumption is less than 400MB and the ability to scroll at 60 FPS is smooth. The multilingual implementation has 97-99% medical terminology translation fidelity also with less than a language switching latency. This paper is a viable innovation in the field of digital healthcare that is both accessible and culturally-appropriate to linguistically diverse populations.

Keywords: Mobile Health, Flutter Framework, Cross-platform development, AI nutrition, Multilingual Healthcare, Chronic disease management, Patient-centred care, Dart program, Provider pattern and Digital health.

INTRODUCTION

The worldwide trend to embrace the patient-centric healthcare frameworks has increased the pace of implementing mobile health (mHealth) applications to manage chronic illnesses, as well as clinical workflows optimization. Nevertheless, three key issues continue to be present in existing digital health solutions:a lack of integration between clinical monitoring and lifestyle intervention tools, lack of non-English language coverage especially in linguistically diverse areas such as India and a lack of cross-platform access which makes digital health solutions less accessible to various device ecosystems. This paper will solve these issues by using a single mobile application that was developed using Flutter, a UI toolkit created by Google to develop native compiled applications using one codebase. In contrast to the conventional Electronic Health Records (EHR) systems where the main emphasis is placed on the clinical data storage, It is a holistic health management ecosystem as it combines the real-time physiological monitoring with the AI-based nutrition advising engine. The app can help healthcare providers and patients in a separate operation interface, but still have a common base architecture. The six language implementation is multilingual and implements complex Indic scripts properly, and the barrier to adoption of the healthcare apps by the older and rural population in India is very high. The nutrition module uses an expert system based on rules and takes and examines seven key parameters that include blood pressure, blood sugar, heart rate, haemoglobin, cholesterol, body mass index and SpO2 to provide personal dietary advice with foods to eat and foods to avoid depending on the identified health conditions.

LITERATURE REVIEW

The digital health has transformed into an AI powered, sophisticated ecosystem of record-keeping. There are three main areas that are emphasized in the existing literature, which are integrated clinical monitoring, AI-based nutrition, and Remote Patient Management (RPM). The adoption of AI has transformed the conventional models of healthcare into digital models that have shown clinical effectiveness. Park *et al*. [4] and Lee *et al*. [1] conducted randomized trials that found that systems integrating AI dietary management with continuous glucose monitoring (CGM) had a significant influence on diabetes compared to usual care. In a similar manner, Multi-service models based on proactive prevention of cardiovascular diseases and health promotion were also proven by M *et al*. [3] and Gomez-Garcia *et al*. [11]. The old inaccuracy of manual food diaries is being solved by AI - namely Computer vision and Natural Language Processing (NLP). Phalle and Gokhale [5] and Abeltino *et al*. [6] have conducted a review of the replacement of manual logging with digital tools, whereas Rouhafzay *et al*. [15] have emphasized that image-based calorie counting can be used in diabetes. This is being further developed by generative AI; Sun *et al*. [10] confirmed an LLM-based "AI Dietitian" and Ayman *et al*. [19] suggested an automated intelligent diet companion, Nutri Buddy AI. Proactive care has been transformed by AI that is integrated with the Internet of Medical Things (IoMT). Shaik *et al*. [8] and Sarkar *et al*. [17] described the method of predictive tech improvement of telemedicine, and Damera *et al*. [12] and Motwani *et al*. [14] examined the cloud platform and machine learning architecture around these systems. Hands-free health management is also being made possible by innovative hardware (e.g., AI-driven smart glasses tested by Wang *et al*. [9]) that enable it. To function effectively, these tools should be incorporated into the lifestyles of the patients. Joachim *et al*. [2] applied the behavioural science to develop so-called nudge-inspired platforms, and Anisha *et al*. [13] tested conversational agents that served as virtual carers. Finally, the innovations will assist patients and clinicians in providing individualized cardiometabolic care [16] [18].

MATERIALS AND METHODS

The system was developed in a systematic, modular manner using the Model-View- Controller (MVC) architectural pattern to make it easy to scale, maintain and can be used across different platforms. This part describes the technical implementation, system architecture and development process used to establish a single digital healthcare management system.

System Architecture

It uses a layered architecture in an implementation of the Provider pattern of state management: Figure 1. Layered architecture of HealthFlow mobile application

Layer Responsibilities

Presentation Layer: Stateless and Stateful Flutter widgets: Use the user interactions, and presentation user interfaces. Consumer pattern Widgets utilize Provider pattern, and are automatically rebuilt with changes in underlying data.

Business Logic Layer: Services that are based on ChangeNotifier and which integrate the business rules, data transformations, and external integrations. Dependency Services Dependent widgets may be notified of state changes and update their reactive UIs.

Data Layer: Data models of serialization and deserialization on a JSON data format, access to the database using sqlite, and storage of data using SharedPreferences. Models are value objects that are set in stone thereby offering predictable state management.

Dual- Role Access Architecture

The app will apply role-based access control (RBAC) that gives different interfaces to the healthcare provider and the patient

The system functionality is divided into a few functional groups that include patient, doctor, and shared. The dashboard gives patients important cards of vital signs and medication lists, as well as upcoming appointments, and the doctors have access to patient statistics, the schedule of their day, and critical cases; both users have profile management and notification functions. In vitals management, patients are able to input seven vital parameters themselves and see trend visualizations, but doctors can monitor patient vitals, view historical trends as well as get alerts; all using a common status classification system of Normal, Alert, or Critical. The nutrition module allows patients to get customized food suggestions and meal planning assistance and doctors to go over patient nutrition plans; both can benefit AI-driven dietary suggestions. In the appointments module, patients may make appointments, change or cancel them, and doctors may organize their schedule and accept or reject visits; the common features include choosing between video and face-to-face consultations and adding notes. In the case of medical records, patients can see the prescriptions, the laboratory report and upload files, but doctors write prescriptions and read patient files; the ability to manage documents and download them is the common approach. Under the communication aspect, patients and doctors will be able to communicate with each other and with everyone in the respective messaging and read receipt-supported secure messages. Lastly, patients and doctors have the ability to control language preferences and notifications, profile and logout in settings, and there is joint support with six languages and dark mode.

Data Models and Persistence

The application makes use of three major data modelling using JSON serialization to integrate the API and data storage in the database

User Model: This is a representation of doctors and patients whose fields are role specific. Some of the common attributes are unique identifier, name, email, phone, and role designation. Fields of specialization in medicine and license number are doctor-specific. Such fields as age, gender, blood group, and date of birth are patient-specific.

Appointment Model: Senior data Bidirectional relationships with doctors and patients. The attributes are unique appointment ID, patient and doctor identifiers, date, type of appointment (video/in-person), status (pending/confirmed/completed/cancelled), and clinical notes.

Nutrition Model: Summarizes the dietary guidelines using organized foodstuff. The Food Item class will have name, category (fruits/ vegetables/grains/protein/ dairy/nuts), URL of image, description of health benefit, recommendation

flag. Nutrition Recommendation class is a combination of the identified health condition, customized instructions, and lists of foods to consume and those to avoid, and the vital signs that prompted the recommendation.

Feature Selection and Dataset Selection.

One of the key distinguishing characteristics of this paper is the use of data-driven feature selection. The dataset that we have used is the Health Flow Patient Dataset, which is a repository of 1,000 and more patient records over a 2-year period of time that are anonymized.

Evaluation of the data showed

At least two co-morbidities (e.g., Diabetes + Hypertension) were found in 78 percent of the patients observed. The most volatile measures were Blood Pressure and Blood Glucose which were changing every day. The dietary adherence became the largest element in setting control over these vitals.

Selected Features

The "Vital 7" Tracking: We selected monitoring based on the 7 parameters with the strongest correlation with the incidence of acute health events in our dataset: Systolic BP, Diastolic BP, Fasting Blood Sugar, Heart Rate, SpO2, Haemoglobin and BMI.

Dual-Role Access: The dataset demonstrated that the adherence of the patients increased by forty percent in case a doctor could see the data. The interface was therefore constructed so that we had a different interface (Dashboard view) to the Doctors and a different interface (Entry view) to the Patients.

Offline-First Architecture: To accommodate rural deployment, all the data are initially stored in a local SQLite database, and the data loss is zero when the connectivity is low.

Artificial Intelligence-based Nutrition Recommendation System.

Algorithm Workflow

Step1: Ingestion

The engine reads the recent record of the vital 7 of the database.

Step2: Condition Mapping

IF Systolic Above 140 OR Diastolic Above 90 Flag Hypertension.

IF Sugar > 140= Flag Hyperglycemia.

IF BMI 30 and above Flag Obesity.

Step3: Scoring Matrix

The system traverses on a database of food item. Every food product is labelled with properties (e.g. highSodium, lowGI, richIron).

Base Score: 100.

Penalty: -60 points on highSodium foods in case of user has Hypertension.

Bonus: +40 points on highPotassium foods in case of user having Hypertension.

Step4: Ranking

The foods are ranked by the final score.

Score > 100: Recommended.

Score < 100: Avoid.

Food Database and Categorization.

The dietary instructions are also specific to the health conditions in that they focus on the consumption of nutrient-enriched foods and avoid excessive amounts of harmful substances. In the case of high blood pressure, fruits, vegetables and fish are recommended since they are rich in potassium and omega-3 and foods with high sodium content should be avoided. Fiber- and protein-rich foods have a beneficial effect on blood sugar regulation, and

refined carbohydrates and added sugars are avoided. Management of cholesterol is emphasized on the use of healthy fats and soluble fibre and reduced saturated and trans fats. To control weight, low-calorie, high-protein, and high-fibre foods are promoted, whereas the refined sugars and high-energy rich snacks are minimized. Low haemoglobin demands iron containing and vitamin, but not iron absorption inhibitor, foods. A healthy diet comprising of whole food is recommended in the name of maintaining good health and any form of overconsumption of processed foods and sweet foods should be reduced.

Appointment Management System

Gets all the appointments with a given doctor and date. Filters off cancelled appointments. Datetimes of conforming appointments are translated to formatted times. Computes set difference between all the slots and booked slots. Available slots can be used to select patients. Appointment state machine diagram (Figure 2).

Comparison Market Analysis: Gap Recognition.

In an effort to establish the position of this system in the existing mHealth environment, we made a feature-by-feature comparison of the system with competitor global and regional healthcare applications.

Feature comparison: Health Flow vs. existing mHealth solutions (Table 1).

RESULT AND DISCUSSION

The system was tested on three levels including Clinical Accuracy, System Performance and User Usability.

Clinical Accuracy (Validation of Data)

Clinical Accuracy

The AI Nutrition Engine was run on 200+ patient records of the dataset to simulate the recommendations.

RESULTS

Hypertensive Profiles: At BP of more than 140/90, the system was capable of recognizing the correct: High Sodium foods as avoid in 100 percent (90/90) cases.

Diabetic Profiles: The system prioritised the Low GI foods 100 per cent (76/76) cases that the third one had a Glucose level more than 140mg/dL.

Conflict Resolution: In situations (e.g., Diabetic + Anaemic) where the diet could be contradictory, the scoring system could prioritize the foods that satisfied both criteria (e.g., the Lean Red Meat was punished in heart patients and rewarded in anaemia, the scoring system could set the food the appropriate level of points basing on the extent of the vital deviation).

Performance Benchmarks

To provide a realistic environment of the developing markets, we tried the application on a low-end Android device (2GB RAM). Performance Metrics (Table 2). High-Fidelity UI elements (shadows, gradients) could be run efficiently with the help of the efficient rendering engine of Flutter, even on limited hardware.

Comparison Analysis: System vs. Manual Entry.

In order to confirm the effectiveness of the AI engine, we compared its recommendations with the manual dietary planning done by clinical staff (Standard Care). As shown in Figure 3 the HealthFlow system was shown to outperform the others especially in the cases of complex co-morbidity where we used the F1-Score as the most important performance metric.

F1-Score Balance: Although, the human error rate is 82.0% because of manual insertions in complicated situations, the system scored 100% on the test group.

Co-morbidity Resolution: The difference was greatest in patients with conflicting conditions (e.g., Diabetes + Hypertension) when the accuracy of manual planning reduced to 72.4% with the mental burden of conflicting guidelines. The rule-based engine was 100 percent accurate due to the strict following of the pre-programmed logic of penalty/reward. F1-Score Comparison: Manual Entry vs. Rule-Based Algorithm (Figure 3).

CONCLUSION

This paper is taking the concept of decentralized healthcare to the next level as it incorporates a complete package of functions that are aimed at empowering a user to take control of their health. In its most simple form, the app can bring together real-time monitoring of vital signs in a seamless manner where the intended users and their medical professionals will have access to the latest health information. This is supported by a sophisticated AI-based nutrition engine, which does not only analyse eating habits, but also provides custom recommendations based on certain health objectives and conditions. The multilingual nature of the platform also contributes to increasing accessibility, thus making it very inclusive to users with different linguistic backgrounds and puts language at a disadvantage in the way of quality health management. The real difference with the paper is that they have a promise of providing convenient and efficient health management experience to a broad spectrum of users, including those who need to focus on general wellness and people with chronic illnesses. Further into the future, It is working on integrations with mainstream wearable devices, which will allow collecting even more data and provide smoother user experiences. Also, the future implementation of predictive health analytics is expected to transform the nature of preventative care by informing the users about their health risks before they occur. These innovations have enabled it to become one of the pioneers of the next generation of digital healthcare solutions, which are aimed at actively, individually, and affordably managing the health of everyone.

ABSTRACT

One crucial component of the pterygoid process, the Pterygoid plates (PP). They are composed of two laminae, the medial (MP) and lateral pterygoid plates (LP). The primary muscles of mastication, the pterygoids- medial and lateral are attached to the pterygoid plates. Besides, the most prevalent non-dental pain complaint in the maxillofacial area is a series of orofacial pain illnesses known as temporomandibular disorders (TMD). In some TMD patients abnormal patterns of lateral pterygoid muscle activity are found and the muscle is attached to pterygoid plates. So, action of the muscle can affect the morphometry of the pterygoid plates. Since the most advanced three-dimensional technology for hard tissue analysis is Cone Beam Computed Tomography (CBCT) through which a detailed analysis of the pterygoid plates can be done

Keywords: abnormal, Pterygoid, muscle, plates, pain

INTRODUCTION

One of the 22 bones that make up the skull is the butterfly-shaped sphenoid bone. This single bone, which is situated in the cranium's midline, is essential for joining the neurocranium to the bones of the face. One crucial component of the pterygoid process, the Pterygoid plates (PP).Each pterygoid process divides into a medial and a lateral pterygoid plate after projecting inferiorly from the point where the body of sphenoid bone and larger wing meet. The pterygoid hamulus is a little hook-shaped structure located near the inferior tip of the medial pterygoid plate. They are composed of two laminae, the medial (MP) and lateral pterygoid plates (LP).The primary muscles of mastication, the pterygoids- medial and lateral are attached to the pterygoid plates. Along with, the pterygomandibular raphe,

superior pharyngeal constrictor: and tensor veli palatini is also attached to the pterygoid plates. All these contribute significantly in jaw movements [1]. The eustachian tube, the cricopharyngeal Eustachian, and the foramen ovale are further significant structures that are connected to PP. It is a crucial component of pre-procedures for mid-face reconstruction, such as rapid maxillary expansion and Lefort I fracture reconstruction. Therefore, understanding and analyzing the anatomical variances in PP is extremely essential as it aids in both diagnosing the underlying reason and planning different treatments appropriately [2].

Besides, the clinical term for musculoskeletal conditions affecting the temporomandibular joints (TMJs) and the musculature that surrounds them is temporomandibular disorder (TMD). One of the main features of the disorder is pain and is the primary feature to lookout for care for the patient [3]. In some TMD patientsabnormal patterns of lateral pterygoid muscle activity are found and the muscle is attached to pterygoid plates. So, action of the muscle can affect the morphometry of the pterygoid plates. Since the most advanced three-dimensional technology for hard tissue analysis isCone Beam Computed Tomography (CBCT) through which a detailed analysis of the pterygoid plates can be done. So, in this literature review we will be discussing about the morphometry of pterygoid plates with age, sex and temporomandibular disorders.

Pterygoid plates

At the base of the pterygoid process of the sphenoid bone are the lateral and medial pterygoid plates. The inferior segment of the lateral pterygoid muscle attaches to the external side of this plate, which forms part of the medial border of the infratemporal fossa. On the other hand, the bulk of the deep section of the medial pterygoid muscle attaches to its internal side, which creates the infralateral limit of the pterygoid fossa. Sousa et al (2022) [4] obtained angular measurements formed from the junction of the bilateral pterygoid processes of the sphenoid bone through computed tomography scans of the conical beam of the sphenoid bone, in order to correlate them with the estimation of gender and age in a human identification process. 602 computed tomography (CBCT) scans were selected out of which 301 were males and 301 females. They found no correlation between increasing age and the angles formed by bilateral pterygoid processes. But a statistically significant difference between the values of the angles between males and females on the left and right sides, was found (p- value = 0.0008).

Lateral Pterygoid Muscle

The lateral pterygoid muscle has two heads and is distinguished by its short and sturdy form. The superior head is derived from the surface of the greater wing of the sphenoid bone and the infratemporal crest, whereas the inferior head is derived from the outside of the lateral pterygoid plate. These muscle fibers unite and stretch laterally and backward, ending at the pterygoid fovea on the anterior side of the mandible's neck. Furthermore, parts of the superior head are attached to the front and medial borders of the articular disc and the temporomandibular joint capsule [5].

According to Gray's Anatomy, the LPM consists of two parts with different origins: the superior and inferior heads. The LPM's merged heads insert onto a depression on the front of the mandible's neck (i.e., the pterygoid fovea), and a part of the upper fibers may be attached to the capsule of the TMJ and the anterior and medial borders of the TMJ disc. The LPM insertions are typically internal to the mandibular notch [6].

Temporomandibular Disorders:

A range of musculoskeletal illnesses involving discomfort and/or dysfunction in the masticatory muscles, temporomandibular joints (TMJ), and related structures are collectively referred to as temporomandibular disorders (TMD). there is a broad category of pathological problems that fall under the purview of the stomatognathic / masticatory system which is referred to as temporomandibular disorders. hat result in pain when performing certain functions (sucking, speech, and mastication), increased sensitivity at the level of the TMJ and/or masticatory muscles, potential range of motion limitations, joint noises, and otological symptoms [8-12].

It is the most prevalent kind of non-odontogenic orofacial pain, and patients may exhibit symptoms such as jaw mobility limits, TMJ sounds when moving their jaws, and discomfort in the face, head, or teeth. TMD patients also

frequently have comorbid painful and non-painful disorders [13-14]. Also, there is a clinical concept which is most widely accepted is that the disturbance in the activity of lateral pterygoid is one of the major etiological factor for temporomandibular joint disorder. Patients with temporomandibular disorders (TMD) report restrictions, noises during mandibular motions, and pain in the masticatory muscles and/or TMJ [11]. According to their data demonstrated that TMD is one of the most commonly diagnosed forms of musculoskeletal pain in all age groups. According to one theory, the lateral pterygoid muscle in the TMJ disorder becomes hyperactive or hypoactive, the superior and inferior branches of the muscle are not coordinated, or there is an issue with the muscle's ability to control and stabilize the TMJ.

Nearly one-third of individuals suffer with temporomandibular dysfunction (TMD), a prevalent illness. It has been proposed that the LPM may eventually become overactive in TMD sufferers. causing the displacement of the anterior and medial discs [15-16] Guerrero et al. postulated that the asymmetry of the LPP may result from the hyperactivity of LPM (the inferior head of LPM originates from the lateral surface of LPP) [2]. Chronic LPM spasm may result from articular disc dislocation. The lateral surface of the LPP gradually remodels as a result of this high muscle tension, which may condition its elongation over an indeterminate amount of time [2].

A study was performed by Annapoorani S et al to analyze the anatomical characteristics of pterygoid plates (PP) and relation of PP asymmetry with TMDs. 100 Cone Beam Computed Tomography images samples were analyzed. Morphometric analysis of the shape, thickness, and angulation of PP was done. Five different shapes of PP were noted, the tapered form was more prevalent ($P < 0.01$), and the needle form had the least thickness, which is susceptible to fracture. Males had increased thickness than females in medial and lateral pterygoid ($P = 0.005$) [7]. A study done by Sousa et al have stated that out of 602 patient they assessed (301 males, 301 females), they found no significant correlation between increasing age and the angulations of the pterygoid processes. Although statistical differences between the sexes regarding the angles were analyzed [4]. Swati P and Sushmini Hegde[17]found increased LPP lengths on the same side of the TMD. Their results were comparable with those reported by Guerrero., et al [2]. and Ueki., et al [18] supporting the fact that TMD cause an increase in length of the pterygoid plates. However, there are no standardized measurement of LPP reported in literature in the general population.

Eberliköse H et al investigated relationship between anatomical variations of the lateral pterygoid plate (LPP), including its angle and proximity to the condyle, and the prevalence of temporomandibular disorders (TMD) for which 189 Cone Beam Computed Tomography (CBCT) images were analyzed. They found a statistically significant higher average LPP length in females compared to males. No significant differences in LPP-condyle distances and angles between genders was found. A positive correlation between lateral plate angles and TMJ disorders (p = 0,044), suggested a potential biomechanical linkage [19]. In a study done by Patil AS and Sable RB (2009) Lateral pterygoid muscle (LPM) was evaluated in Non TMD subjects(control group) as well as TMD patients(study group). In control group, the LPM in 86.67% patients appeared normal with no pathological changes in the muscle. Statistically significant presence of fatty degeneration was noted in the study group. MRI abnormalities of the lateral pterygoid showed close associations with the main symptoms of TMD i.e. all patients (100%) with pain and condylar hypermobility had significant presence of fatty degeneration in LPM [20].

Luo D et al performed a study to investigate the selected anatomical factors that can potentially influence temporomandibular joint (TMJ) clicking in young adults by assessing TMJ structures and lateral pterygoid muscle (LPM) function using magnetic resonance imaging MRI and they found that LPM accounted for the highest proportion among masticatory muscles with tenderness in all TMJ clicking subgroups. Therefore, in the TMJ clicking group, the LPM texture was less defined, more uniform in gray scale, and more similar to local texture [21].

DISCUSSION

New explanatory etiologic models, including multifactorial and biopsychosocial models, have been developed as a result of the widespread acceptance that TMDs constitute a group of illnesses affecting the stomatognathic system. Since these models of etiology possess a great deal of flexibility in choosing the right etiologic agents, and the related treatment approaches chosen are likewise rather diverse. Greene [22] examined the genesis of TMDs and showed that there isn't a single etiologic agent—or even a mix of agents—that can be distinguished from other potential agents. Individual anti-etiologic treatments have not been shown to be effective in reducing or stopping the etiologic agent they are intended to target. Schwartz[23] was the first investigator who proposed that muscle spasm is a primary etiological factor in initiating pain and dysfunction in the temporomandibular region.

Guerrero et al postulated that hyperactivity of lateral pterygoid muscles can cause asymmetry on the LPP. This may help to understand why people experience discomfort and TMD. Numerous studies show alterations in the mandibular or maxillary growth that may be consistent with either hyperplasia or hypoplasia [24]. There are, however, no known syndromes or disorders of the sphenoid bone that could only affect its pterygoid process [25]. Internal degeneration, which typically starts with articular disc displacement, is the result of TMJ dysfunction. A prolonged spasm in the lateral pterygoid muscle, namely to the superior fascicle that primarily inserts on the outer wing of the pterygoid tubercle and on the antero-medial pole of the articular disc, may result from this displacement, which could be brought on by trauma or a permanent mild damage.

Some studies in the past have validated by their findings to explain lateral pterygoid muscle spasms are a common occurrence in TMD patients. Over an indeterminate amount of time, this increased muscle tension causes the pterygoid tubercle's outer wing to gradually remodel, which may condition its elongation.When comparing groups with and without TMD by gender, no statistically significant differences were discovered by Guerrero et al. This was in line with Peck's (2007) findings, which showed that muscle activity rather than a patient's gender influences bone remodeling [26].

Given that all care must be evidence-based and properly sequenced, knowledge of the LPP lengths can also be helpful in elucidating data that implies etiology and symptomatology are inextricably related.

CONCLUSION

Conclusively, the study highlights a possible connection between LPP morphometry and TMD and casts doubt on the notion that LPP anatomical abnormalities may have a substantial influence on TMD or may be the cause of TMDs. This offers a fresh approach to clinical treatment and research, highlighting how crucial it is to take into account minute anatomical variations while treating TMD.

Table 1: Review Of Studies Done In Past Assessing Pp, Lateral Pterygoid Muscles And TMJDs

S.No	AUTHORS	AIM	RESULTS
1	Naidoo LC (1996)	To reexamine the meniscal attachment of the lateral pterygoid muscle, in particular, the upper head of this muscle.	in 65% of specimens, the upper head of the lateral pterygoid muscle was attached to the medial aspect of the capsule, meniscus, and to the pterygoid fovea of the condyle. In 27.5% of specimens, the upper head was attached solely to the condyle; in the remaining 7.5% of cases, there were other types of attachments of the lateral pterygoid muscle to the meniscus.
2	Ueki K, Hashiba Y, Marukawa K, Nakagawa K, Okabe K, Yamamoto E (2009).	To determine the location of the descending palatine artery and the structure of the pterygomaxillary region.	no significant correlations between measurements of cephalograms and those of the descending palatine artery and PPs. There were significant differences between right and left in lateral plate length and thickness of PP. There were significant differences between men and women in right width of PP, right thickness of PP, left posterior length, and left thickness of PP.
3	Patil AS and Sable RB (2009).	to evaluate the effects of stabilization appliance on lateral pterygoid muscle in patients suffering from TMD with help of MRI	A clinically significant increase in size of the muscle was seen in 90% of the patients indicating a decrease in atrophy of the muscle.
4	Sharma R (2011)	to clinically evaluate the outcomes of pterygoid disjunction (PD) carried out as the primary treatment modality for reducing disc displacement type of internal derangement (ID) of temporomandibular joint (TMJ) refractory to conservative management and arthrocentesis.	All 30 cases showed improvement. After 1 year follow up 6 cases were in Di 0 and 22 cases were in Di I and 2 cases were in Di II of clinical dysfunction index. From which we can co-relate that post surgically all the patients were benefited by this procedure. PD as a primary surgical option significantly reduces pain and improves function in the refractory cases of reducing disc displacement type of ID of TMJ.
5	Guerrero ME, Beltran J, de Laat A, Jacobs R. (2015)	To evaluate the relationship between pterygoid plate asymmetry and temporomandibular joint disorders.	Statistically significant differences were found between measurements of the lateral pterygoid plates on the site that had pain and the contralateral site ($p<0.05$). The average length of the lateral pterygoid plates (LPPs) in patients with TMD was 17.01±3.64 mm on the right side and 16.21±3.51 mm on the left side, and in patients without TMD, it was

			11.86±1.97 mm on the right side and 11.98±1.85 mm on the left side. Statistically significant differences in the LPP length, measured on CBCT, were found between patients with and without TMD ($p<0.05$).
6	Bernal-Mañas CM, González-Sequeros O, Moreno-Cascales M, Sarria-Cabrera R, Latorre-Reviriego RM.(2016)	To evaluate the anatomy of the temporomandibular joint (TMJ), particularly at the level of the lateral pterygoid muscle and to describe the features of the lateral pterygoid muscle and the exact location of its insertions.	They described that muscle is inserted into the disc, capsule, condyle, and the pterygoid fovea, through muscle and tendon fibres that alternate, giving it the characteristic of a multipennate muscle. This insertion caudally exceeded the pterygoid fovea and descends to near the lingula of mandible. A profuse pterygoid venous plexus surrounds the whole joint complex, and also the insertion zone of the lateral pterygoid muscle.
7	Kamble V and Mitra K (2016)	to investigate the correlation between Lateral pterygoid muscle (LPM) attachment type and Anterior disc displacement (ADD), disc degeneration or articular surface degeneration among the population of central India.	Statistically significant difference was found between the type of LPM attachment and ADD. No statistically significant difference was found between LPM attachment type and disc degeneration or articular surface degeneration.
8	Swati P and Sushmini Hegde (2020)	to evaluate a potential relationship between LPP measurements and Internal Derangements of temporomandibular joint (TMJ), using cone-beam computed tomography (CBCT).	The LPP measurements in patients from the study group were increased compared to the control group. Further, in females, the mean LPP length on left side was significantly increased in the study group compared to the control group.
9	Lai YC, Yap AU, Türp JC (2020)	to establish the prevalence of temporomandibular disorders (TMDs) in patients seeking orthodontic treatment and to determine the association between the presence of TMD and sex, age and malocclusion.	TMD prevalence ranged from 21.1% to 73.3%. The frequency of painful TMD signs/symptoms varied from 3.4% to 65.7%, while non-painful signs/symptoms ranged from 3.1% to 40.8%. The percentage of males and females presenting with TMD varied from 10.6% to 68.1% and 21.2 to 72.4%, respectively. TMD prevalence was higher among females The TMD prevalence in patients seeking orthodontic treatment was high, with many individuals presenting painful TMD signs/symptoms.
10	Odabaşı O, Erkmen E, ÖzlemÜçok C, Akif Bakir M, YıldızerKeriş E,	to evaluate the pterygomaxillary region in regards to the Le Fort I osteotomy using cone-beam	the distance between the descending palatine canal and the piriform rim was found to be longer in males. Medial plate

	Şahin O. (2021)	computed tomography (CBCT) images.	was longer on the right and left in females. The thickness of the pterygomaxillary region was longer in females. The distance between the pterygomaxillary fissure and the descending palatine canal was longer on the right.
11	André Luca Araujo de Sousa, Baldomero Antonio Kato da Silva, Sergio Lúcio Pereira de Castro Lopes, Jean de Pinho Mendes, Paulo Henrique Viana Pinto, Antonione Santos Bezerra Pinto (2022)	To obtain angular measurements formed from the junction of the bilateral pterygoid processes of the sphenoid bone through computed tomography scans of the conical beam of the sphenoid bone, in order to correlate them with the estimation of gender and age in a human identification process.	There was no correlation between increasing age and the angles formed by bilateral pterygoid processes. statistically significant difference between the values of the angles between males and females on the left and right sides.
12	Annapoorani, S.; Christy, A. Winnifred; Thambi, T. Jones Rajadeva; Mahalakshmi, R. (2023)	To evaluate relation between PP asymmetry and resulting temporomandibular joint disorders (TMJD).	Five different shapes of PP were noted, the tapered form was more prevalent ($P < 0.01$), and the needle form had the least thickness, which is prone to fracture. Three different shapes of PF were noted, namely U, V, W. V shape was more common. Males had increased thickness than females in medial and lateral pterygoid ($P = 0.005$).
13	Eberliköse H, Öztürk K, Akyol R, Bilecenoğlu B. (2024)	to investigate the relationship between anatomical variations of the lateral pterygoid plate (LPP), including its angle and proximity to the condyle, and the prevalence of temporomandibular disorders (TMD), to improve diagnostic accuracy and therapeutic approaches for TMD.	statistically significant higher average LPP length in females compared to males with no significant differences in LPP-condyle distances and angles between genders. a positive correlation between lateral plate angles and TMJ disorders was found, suggesting a potential biomechanical linkage.
14	Luo D, Yang H, Yuan M, Wang D, Qiu C, Zhou R, Gao Y, Xu R, Yang J, Xu Z. (2024)	to investigate the selected anatomical factors that can potentially influence temporomandibular joint (TMJ) clicking in young adults by assessing TMJ structures and lateral pterygoid muscle (LPM) function using magnetic resonance imaging (MRI).	The proportion of any articular disc or condylar morphology class did not differ significantly between the TMJ clicking and HC groups. The articular disc position did not differ significantly between the TMJ clicking and HC groups. In the TMJ clicking group, the presence of masticatory muscle dysfunction differed significantly between the clicking and non-clicking sides. Moreover, the LPM accounted for the highest proportion among masticatory muscles with tenderness in

			all TMJ clicking subgroups. Therefore, in the TMJ clicking group, the LPM texture was less defined, more uniform in gray scale, and more similar to local texture.

ABSTRACT

Comprehending documents for receipts and tickets is crucial in workplace automation; nevertheless, precise extraction is challenging due to varied layouts, multilingual information, and real-world capture artifacts such blurriness, noise, and perspective distortions. Traditional OCR-focused pipelines often execute text detection and recognition, subsequently utilizing downstream transformers for key-value extraction; nevertheless, OCR inaccuracies transmit to subsequent stages, frequently compromising structural consistency, particularly in nested fields. A Unified Vision-Language Transformer, UniVLDocFormer, was created to directly produce structured JSON from document images in an end-to-end process without OCR. The model integrated visual patch tokens with schema-conditioning prompts within a singular transformer backbone, employed layout-aware encodings for spatial reasoning, utilized schema-guided constrained decoding to maintain hierarchical validity, and implemented a grounded pointer mechanism to enhance numerals and identifiers. Experiments with CORD receipts and train ticket papers exhibited continuous improvements over robust baselines. UniVLDocFormer attained an F1 score of 79.71% and a TED-based accuracy of 85.49% on CORD, as well as an F1 score of 89.48% and a TED-based accuracy of 92.18% on Train Ticket, surpassing UDOP's performance of 75.54% F1 and 80.12% TED, and 87.52% F1 and 90.41% TED. The findings validated that OCR-free unified generation enhanced both value accuracy and structural integrity

INTRODUCTION

Due to its significance in several real-world applications, information extraction from visually rich texts is a significant research issue that continues to be actively studied [1],[2],[3],[4]. In recent years, there has been an increasing interest in the study topic of Visual Document Understanding (VDU), which includes layout analysis, visual question answering, and document parsing [5]. In traditional VDU methods, textual information is extracted from the document using Optical Character Recognition (OCR) [6], [7], [8], [9]. These Vision-Language (VL) methods then use the document's visual tokens, OCR text, and spatial data as input to produce predictions. OCR as a pre-processing step during training and inference, however, introduces extra latency and computational expenses [10]. Furthermore, mistakes that started in the OCR stage might spread to the VL model and impair its functionality [11], [12]. An alternate method for VDU is the OCR-free technique [13]. In this case, specific OCR text extraction is not required since the document picture is given straight into the vision-language model as input. Typically, the architecture comprises of a visual encoder, which is followed by a language model [14],[15] that takes both the input query and the visual representation as input. It is anticipated that the model will learn to read internally before completing the downstream operation. A thorough pre-training phase is carried out to provide the vision model reading skills in order to eliminate the necessity for OCR input [10],[16]. Because of these difficulties, accurate and scalable document comprehension requires OCR-free, layout-aware, and structure-constrained modeling.

By attempting to extract entities and their interactions in a structured format, structured information extraction (SIE) expands on this challenge. Tables, figures, layout, and typography all add to the visual richness of the information found in documents. SIE must work on document pictures, which often lack dependable OCR outputs, in contrast to standard NLP tasks [17], [18], that presume plain text with a predetermined reading sequence. This is especially important in commercial settings, where documents like invoices or receipts are kept as pictures or PDFs and structured data like key-value pairs or line items is manually obtained a method that is laborious and challenging to scale. Therefore, it is both practically and scientifically important to automate SIE with great efficiency and precision.
To get beyond the limitations of traditional OCR-driven pipelines, recent research has investigated end-to-end OCR-free document interpretation. One of the first transformers to map document pictures directly to structured outputs without the need for external OCR was the Donut model, which outperformed conventional methods in terms of speed and accuracy [10]. Similar to this, DocParser suggests an OCR-free information extraction paradigm that performs competitively on visually rich documents without requiring separate text reading phases [19]. Additional development in this field includes coordinate-aware end-to-end document parser, which combines coordinate extraction and sequence creation to enhance spatial awareness [20].

Despite recent advancements, there are still significant drawbacks to current OCR-free document comprehension techniques, such as loosely connected architectures, poor layout awareness for high-resolution documents, and unconstrained decoding that often results in incorrect or insufficient structured outputs. Without explicit grounding techniques, it is still difficult to extract numerically rich fields like totals, dates, and IDs. In order to address these problems, we suggest UniVLDocFormer, an OCR-free Unified Vision–Language Document Transformer for structured information extraction and end-to-end document comprehension. In order to generate structured output from document pictures represented as layout-aware visual tokens, UniVLDocFormer employs a single transformer backbone that models visual layout, semantic content, and direct JSON creation under the guidance of schema prompts.
UniVLDocFormer uses a layout-aware efficient attention method that reduces computation while maintaining global context in order to increase scalability and robustness. This approach combines local window attention with global layout tokens. Furthermore, a grounded copy-pointer technique enhances extraction accuracy for numeric and alphanumeric fields, and schema-guided decoding imposes structural restrictions to guarantee correct and full JSON outputs. When combined, these elements allow for reliable, effective, and precise OCR-free document comprehension of a variety of real-world texts.

The main contributions of this paper are summarized as follows:

- Unified Vision–Language Transformer: We propose a single-backbone OCR-free transformer that jointly models visual perception, semantic reading, and structured output generation in an end-to-end manner.
- Layout-Aware Efficient Attention: We introduce a hierarchical local–global attention mechanism that enables scalable processing of high-resolution document images with improved layout understanding.
- Schema-Constrained Structured Decoding: We design a schema-guided decoding strategy that guarantees valid and complete JSON outputs, significantly improving key–value extraction accuracy.
- Copy-Grounded OCR-Free Extraction: We incorporate a pointer-based generation mechanism that enhances the extraction of numeric and alphanumeric fields without explicit OCR.

Extensive experiments on real-world document datasets demonstrate that UniVLDocFormer achieves superior accuracy, robustness, and efficiency compared to existing OCR-based and OCR-free document understanding approaches.

Related works

This section reviews prior work on structured information extraction and OCR-free document understanding, highlighting the limitations that motivate the proposed UniVLDocFormer. Early techniques [21], [22] described the SIE issue as a computer vision challenge to either segment or identify things from documents. On the other hand, because of the limitations of the formulation, they are unable to handle the connection of entities. More recent techniques [23], [24] address SIE by combining layout/visual information with text inputs to transformers and extracting entities using an NLP formulation. This is made possible by the introduction of transformers [25] and their use in NLP that has been successful. Other techniques [4], [26] seek to describe the connection between text inputs using graph neural networks. These approaches consider the text inputs to be nodes in a graph and model the relationship between them. The SPADE [27] approach presents a graph decoding technique that is based on learnt pairwise affinities between extracted items. This scheme is used to extract the connection between things.

Recent end-to-end OCR-free information extraction methods, have been presented in order to address some of the constraints that are associated with OCR-dependent methods [10]. The encoder-decoder method is used by the bulk of these systems. On the other hand, the encoders that are utilized are either incapable of accurately modeling global dependence when they are primarily composed of Convolutional Neural Network (CNN) blocks or they do not assign sufficient privilege to the extraction of character-level features when they are primarily composed of Swin Transformer [28]. The information extraction problem, along with several other VDU challenges, has seen the proposal of end-to-end techniques in recent years. Both [29],[30] used a CNN-based encoder and a recurrent neural network in conjunction with a decoder that uses an attention mechanism. Nevertheless, these two methods have low accuracy and perform poorly on tiny datasets.With the help of a multi-modal context block that bridges the gap between the visual and natural language processing tasks, [31] created TRIE++, a model that learns concurrently both the text reading and the information extraction tasks. A software called visual information extraction system was introduced by [32], which is capable of doing text detection, recognition, and information extraction concurrently. However, the whole document annotation must be taught for both TRIE++ and VIES.

An encoder-decoder architecture known as Donut was suggested by [10]; it is comprised of a Swin Transformer encoder and a Bart-like decoder. The Dessurt model, which represents visual tokens, query tokens, and the answer, was provided by [13]. This model handles three streams of tokens. A technique known as cross-attention is used across many streams in order to facilitate the sharing and transfer of information into the response sphere. Dessurt makes use of a modified version of the Swin windowed attention algorithm, which is able to pay attention to the query tokens, in order to analyze the visual tokens. Donut and Dessurt have obtained promising results; nonetheless, they do not offer sufficient precedence to local character patterns, which results in outcomes that are not ideal for the information extraction objective.

Recent OCR-free approaches, evaluation tasks and datasets, conclusions, and limits are summarized in Table 1, which also highlights shortcomings in numeric and textual extraction and schema-constrained output. Although there has been a lot of improvement in reading documents without OCR, most current methods still use unconstrained decoding, which may lead to structurally problematic outputs including missing fields, wrong nesting, and inconsistent data types, especially for numbers and letters. A few techniques concentrate on global visual or layout representations, but they don't do a good job of modeling fine-grained character-level patterns, which are necessary for accurate structured information extraction. Also, relying too much on prompt design, task-specific supervision, or QA-oriented goals makes it hard to apply what you've learned to more complicated, real-world documents with different layouts and noise. A significant disadvantage in previous studies is the lack of explicit schema-guided decoding coupled with robust visual grounding, which hinders assured structural and semantic consistency in the produced outputs. The proposed UniVLDocFormer fills these gaps by combining visual grounding with a pointer/copy mechanism and using schema-guided limited decoding during inference. This guarantees precise numeric extraction, strong layout comprehension, and the production of valid, comprehensive, and schema-compliant structured outputs without the need of OCR.

Background

UniVLDocFormer is a unified vision-language transformer that can interpret documents and extract structured information without using OCR. UniVLDocFormer is different from standard OCR-dependent pipelines since it directly maps document pictures to structured outputs. It does this by merging visual representation learning, layout modeling, and autoregressive structured generation into one end-to-end framework. This method solves some of the biggest problems with reading documents in the real world, such high-resolution images, different layouts, text in more than one language, and pulling out areas that are full of numbers or letters.

Input Representation

Let the input document image be denoted as $I \in \mathbb{R}^{H\times W\times 3}$,, where H and W indicate the height and breadth of the document, respectively, and the final dimension corresponds to the RGB channels. It is easier to work with the picture if it is broken up into patches that don't overlap and are P×P in size. A learnable projection layer linearly projects each patch I_p onto a d-dimensional embedding space:

$$x_p = \text{PatchEmbed}(I_p) \in \mathbb{R}^d, p = 1, \dots, N \quad (1)$$

where $N = \frac{H\cdot W}{P^2}$is the total number of patches. This patch-based representation keeps local visual characteristics while making the space less complicated, which is similar to tokenization in natural language processing.

To record the layout of a document and its spatial structure, each visual token $x_p$is given:

Absolute 2D positional embeddings$e_p^{pos} \in \mathbb{R}^d$to keep track of where things are in the picture grid.

Layout-aware embeddings$e_p^{layout} \in \mathbb{R}^d$on the normalized coordinates of the patch bounding box $(x_{\min}, y_{\min}, x_{\max}, y_{\max})$ to represent the geometric connections between fields.

So, the combined token embedding is:

$$v_p = x_p + e_p^{pos} + e_p^{layout} (2)$$

To set the model up to work with a certain output schema, a series of learned prompt tokens s_1,…,s_M is added to the visual token sequence:

$$V = [v_1, \dots, v_N, s_1, \dots, s_M] (3)$$

This lets the model work with different output formats, such as bills, receipts, or forms, without having to retrain the backbone. Theoretically, schema-conditioning is based on prompt-based conditioning in transformers, which has been demonstrated to help models focus on characteristics that are important for a certain task.

Unified Transformer Backbone

A stack of Ltransformer blocks process the concatenated sequence V. Each block has multi-head self-attention (MHSA) and feed-forward networks (FFN) with residual connections:

$H^{(l)} = \text{MHSA}(H^{(l-1)}) + H^{(l-1)}, H^{(l)} = \text{FFN}(H^{(l)}) + H^{(l)}$

Mixed Attention Strategy

A mixed attention mask is used to allow two different activities to happen at the same time in the same backbone:

Bidirectional attention between visual tokens that models global layout dependencies and captures local context. This ensures that the spatial connections between fields, such as "Invoice Number" and its value, are well understood.

Causal attention among output tokens, which lets structured sequences like JSON be generated in an autoregressive way while maintaining the relationships between output fields.

At each transformer layer, output tokens pay attention to the entire visual token memory. This gives structured field extraction a direct basis without requiring external OCR. The model can naturally comprehend reading order, spatial hierarchies, and semantic significance since it learns both visual and textual elements simultaneously. This aligns with principles in multi-modal representation learning.

Pointer / Copy Mechanism

In many real-world documents, such bills, receipts, and forms, important information is commonly shown as lengthy alphanumeric IDs, numerically packed fields, or structured key-value pairs. Standard autoregressive token generation may not be able to duplicate these values precisely because of faults in tokenization or a lack of vocabulary. To fix this, UniVLDocFormer adds a pointer/copy mechanism to the output head. This lets the model choose whether to produce tokens from the vocabulary or copy visual characteristics straight from the input picture.

In a formal sense, each output token $y_t$is made by putting together a weighted sum of:

Distribution of vocabulary$P_{\text{vocab}}(y_t)$, which shows the usual transformer forecast for the language.

Copying distribution over visual tokens v_p, weighted by attention scores $\alpha_{t,p}$ that match the output token with the right visual patches:

$P(y_t) = (1 - g_t)P_{\text{vocab}}(y_t) + g_t \sum_{p=1}^{N} \alpha_{t,p}\, v_p$Here, $g_t \in [0,1]$ is a learned gating scalar that balances the effects of vocabulary generation and visual copying. The attention weights α_(t,p) are calculated using typical multi-head attention techniques between the output token queries and the visual token memory $\{v_1, \ldots, v_N\}$.

This approach makes sure that IDs and key values are reproduced exactly and with the right number of digits, which is very important for jobs that involve extracting structured information. The method is based on pointer-generator networks, which are often used in sequence-to-sequence tasks where perfect token copying is important, such text summarization, table-to-text creation, and machine reading comprehension.

Schema-Guided Constrained Decoding

UniVLDocFormer uses schema-guided restricted decoding during inference to make sure that the outputs it creates follow the intended structure and meaning. Let S be the goal schema, which says:

- Necessary keys and fields,
- Structures that are hierarchical or nested,
- Field types (for example, string, number, or date).

The generated token sequence

$\hat{Y} = \{y_1, \ldots, y_T\}$is limited so that:

$\hat{Y} \in S$Where $\hat{Y}$ represents the sequence of output tokens generated by the model, from $y_1$to y_T,, corresponding to the structured fields in the document. By constraining Yˆ to belong to S, the model ensures that the output respects all structural rules defined in the schema, including hierarchy, required fields, and data types.

This makes sure that the outputs are legitimate, complete, and match the intended schema. The technique makes sure that complicated documents follow hierarchical nesting rules, that fields aren't missing or out of alignment, and that structured data (such JSON objects) is formatted correctly. UniVLDocFormer can provide strong end-to-end OCR-free document comprehension by using visual grounding via the pointer/copy method, autoregressive generation, and schema enforcement. It reliably pulls out organized information from documents with different layouts, high-resolution inputs, and noisy real-world situations, while keeping the meaning and structure of the outputs the same. The overall architecture of UniVLDocFormer is shown in Figure 1, which highlights its end-to-end OCR-free document understanding pipeline that combines schema-guided decoding, autoregressive structured generation, and visual grounding for reliable information extraction across a variety of document layouts.

The experimental technique overview was crafted to facilitate a controlled comparison between OCR-free generation-based methods and robust OCR-dependent document AI benchmarks. A singular integrated model was trained in a multi-task framework utilizing both CORD receipts and Train Ticket samples, with dataset-specific prompt tokens conditioning the model to produce the relevant structured JSON outputs according to each dataset schema. Robust picture augmentations were employed during training to enhance resilience against background noise and capture distortions, especially for fixed-layout tickets, while ensuring uniform preprocessing and decoding protocols across all methodologies.

The model's performance was assessed using structure-aware and field-aware metrics derived from the decoded structured outputs. Field-level precision, recall, and F1-score were calculated through exact key–value matching post-canonicalization, whereas TED-based accuracy was assessed by transforming predicted and ground-truth JSON into trees and evaluating normalized tree edit distance to indicate both hierarchical accuracy and value fidelity.

Data collection

Two publicly accessible benchmark datasets were developed to assess OCR-free document comprehension under varying layout complexity and linguistic contexts. The Consolidated Receipt Dataset (CORD) was chosen to exemplify receipt parsing featuring varied layouts and intricate semantic structures, whereas the Train Ticket benchmark was selected to illustrate fixed-template extraction in Chinese, incorporating genuine imaging artifacts and background noise.

CORD comprised 1,000 receipt photos along by corresponding structured annotations and text in the Latin alphabet. The annotation ontology consisted of 30 distinct fields encompassing item-level and transactional characteristics, including menu name, count, and total price. It featured intricate hierarchical frameworks with nested groups (for instance, item lists depicted as items>item> {name, count, price}), facilitating the assessment of both field accuracy and structural integrity in OCR-free extraction.

Dataset link:
https://huggingface.co/datasets/naver-clova-ix/cord-v1

The Train Ticket benchmark was a static dataset featuring background noise and imaging distortions, intended for the extraction of a concise collection of important variables from a uniform template. The dataset included 1,530 synthetic photos and 320 real images for model development, with 80 real images allocated for evaluation. Each example comprised eight essential text fields: ticket number, beginning station, train number, destination station, date, ticket rates, seat category, and name. The textual content mostly comprised numerals, English letters, and Chinese characters, facilitating multilingual OCR-free extraction evaluation under consistent spatial priors.

Data preprocessing

Image Standardization and Color Space Conversion

All document images were normalized to a uniform visual representation prior to model training. Each sample was decoded and transformed into three-channel RGB, thereafter scaled to a uniform input resolution to provide stable tokenization of visual patches and consistent receptive coverage across datasets. The downstream training resolution was intentionally regulated based on the known sensitivity of OCR-free document transformers to input scale, with higher resolutions enhancing robustness by maintaining small characters and intricate layout details.

Resolution Normalization and Pixel Intensity Normalization

Spatial normalization retained document geometry by upholding the original aspect ratio when scaling and implementing padding as necessary, so eliminating layout distortion that could otherwise modify the relative positioning of fields. Pixel intensities were normalized to a constrained numeric range and standardized for model compatibility, ensuring that variations in illumination among scanners and camera images did not overshadow learning signals. The preprocessing pipeline preserved multilingual character evidence within the picture domain, avoiding dependence on external OCR outputs. This approach corresponded with the OCR-free objective and ensured uniform treatment of both Latin-alphabet receipts and Chinese tickets at the input stage.

Data Augmentation for Robustness

Robust on-the-fly data augmentations were implemented to enhance resilience against real-world capture situations, namely addressing background noise and imaging aberrations in fixed-layout tickets. Augmentations encompassed photometric and degradation effects, including adjustments to brightness and contrast, shadow simulation, motion blur, Gaussian blur, and JPEG compression, alongside geometric perturbations such as perspective transformation and slight elastic distortion to replicate viewpoint alterations and paper deformation. These modifications aligned with standard document synthesis and post-processing techniques that have demonstrated the enhancement of OCR-free document models in the context of domain shift. Ground-truth annotations were standardized into a deterministic structured format before sequence production. Field keys were aligned to a uniform naming convention within each dataset schema, hierarchical structures were maintained for receipt samples with nested item groups, and fixed-depth key–value mappings were upheld for ticket samples. The structured targets were serialized into a linear token sequence with a schema-aware representation that maintained JSON brackets, separators, and field boundaries, facilitating direct monitoring of content accuracy and structural validity during autoregressive decoding.

Model Building

A unified vision-language transformer, named UniVLDocFormer, was developed to immediately convert a document image into a structured JSON format, eliminating the need for external text detection and recognition processes. The model architecture was chosen to mitigate two practical limitations identified in traditional pipelines: error propagation from OCR to subsequent understanding modules and insufficient structural consistency during independent field-level extraction. A singular cohesive backbone was employed to concurrently learn visual reading, layout reasoning, and structure-aware generation in an end-to-end fashion across both receipt-style documents with nested hierarchies and fixed-layout tickets containing multilingual information. The model functioned on a consolidated token stream composed of visual patch tokens and task-conditioning prompt tokens. Each input image was divided into non-overlapping patches and mapped into a d-dimensional embedding space. To maintain document layout indicators crucial for field localization, each patch embedding was enhanced with two elements: a 2D positional encoding and a layout-aware encoding based on normalized spatial coordinates. The resultant patch token representation was formulated as:

$$X_i = W_p p_i + e_{pos}(i) + e_{lay}(i)$$

Where p_i signifies the flattened pixel vector of the i-th patch, W_p represents the learned projection matrix, and $e_{pos}(i)$ and $e_{lay}(i)$encode absolute two-dimensional position and layout properties, respectively. Task prompts were

incorporated as learnt embeddings to condition the model on dataset-specific schemas, allowing a single network to produce varied structured outputs for diverse document formats. A consolidated transformer backbone analyzed the concatenated sequence with mixed attention masking to concurrently facilitate bidirectional visual context modeling and autoregressive structured generation. Visual tokens were permitted to attend bidirectionally to represent global structure and long-range interdependence, while output tokens were produced autoregressively under a causal mask. Cross-modal grounding was accomplished by enabling output tokens to reference visual tokens during the decoding process. Masked self-attention was calculated at each transformer layer as:

$$Attn(Q,K,V) = softmax\left(\frac{QK^T}{\sqrt{d}} + M\right)V,$$

where M is the composite mask that facilitates bidirectional attention for visual tokens and causal attention for output tokens, while maintaining access for output tokens to the complete visual memory. To enhance computational efficiency on high-resolution documents, attention was structured in a layout-aware fashion through local aggregation within spatial neighborhoods, utilizing a limited set of global summary tokens. This approach preserved both fine-grained reading signals and page-level structure without necessitating full quadratic attention across all patches. Structured outputs were produced as token sequences denoting JSON objects. Training supervision was implemented via instructor forcing with a conditional next-token goal that optimized the likelihood of the ground-truth sequence based on the input image and the dataset prompt. Generation loss was defined as:

$$L_{gen} = -\sum_{t=1}^{T} \log p(y_t | y_{<t}, X),$$

where X represents the collection of visual tokens and $y_{<t}$ signifies the tokens that have been generated before. To enhance precision in numerals and lengthy alphanumeric IDs typically found in receipts and tickets, a grounded pointer method was incorporated, enabling tokens to be generated from either a predefined vocabulary distribution or copied from visually grounded attention over patch memory. The ultimate token probability was modeled as:

$$p(y_t) = \lambda_t p_{vocab}(y_t) + (1 - \lambda_t) \sum_i \alpha_{t,i} 1[g(i) = y_t]$$

And λ_t regulated the balance between vocabulary creation and replication, $\alpha_{t,i}$ represented attention weights assigned to visual tokens at step t, and $g(i)$ correlated a visual token index with the most likely symbol it endorsed according to the model's internal representation. This approach enhanced dependability for elements such as ticket numbers, dates, totals, and prices without incorporating OCR as an independent subsystem. Schema-guided structured decoding was utilized to enhance output validity and comprehensiveness. The decoding procedure adhered to dataset-specific key sets and structural restrictions, ensuring that output sequences consistently corresponded to the required JSON structure, with hierarchical nesting maintained for receipt item groups and single-occurrence fields retained for fixed-layout tickets. This design guaranteed that the model's learning aim was congruent with the evaluation target by concurrently optimizing content accuracy and structural integrity inside a cohesive vision-language transformer framework.

System Configuration and Training Parameters

All studies were conducted on a solitary NVIDIA A100 GPU within a CUDA-enabled environment. The training and inference pipeline was executed via Hugging Face Transformers in conjunction with the TIMM (PyTorch image models) library, employing half-precision (fp16) arithmetic during training to enhance memory and throughput efficiency. Optimization was conducted utilizing the Adam optimizer alongside a diminishing learning rate schedule. The initial learning rate for task fine-tuning was established at 3×10^{-5}, accompanied by a 300-step warmup and a total of 30 epochs; the training and validation batch sizes were 8 and 1, respectively. Gradient clipping was

implemented with a maximum gradient norm of 1.0. maximum decoder sequence length for fine-tuning was established at 768 tokens. The input resolution was configured to 1280×960 for CORD and 960×1280 for the Train Ticket assignment to maintain the legibility of small text across various layouts.

Model Evaluation

Model predictions were translated into structured JSON and transformed into tree representations that maintained key-value relationships and nested group hierarchies. The output quality was measured using field-level F1 and tree edit distance (TED)-based accuracy, which collectively evaluated value correctness and structural integrity in the generated parses. Field-level F1 assessed the precise alignment of extracted field information with the ground truth, whereas TED-based accuracy gauged the overall resemblance between predicted and ground-truth trees, encompassing nested structures. Field-level precision, recall, and F1-score were calculated by perfect key-value correspondence. Let TP, FP, and FN represent the aggregate counts of true-positive, false-positive, and false-negative key–value pairs over the evaluation set. Precision, recall, and F1 score were calculated as follows:

$$Precision = \frac{TP}{TP + FP}$$

$$Recall = \frac{TP}{TP + FN}$$

$$F1 = 2 \times \frac{Precision \times Recall}{Precision + Recall}$$

The accuracy based on **TED** was calculated using the predicted tree (pr) and the ground-truth tree (gt) using normalized tree edit distance. Normalization employed the edit distance between an empty tree (\phi) and the ground-truth tree to adjust the score according to the goal structure size, with negative values truncated to zero. The per-sample TED-based accuracy was computed as:

$$Acc_{TED}(pr, gt) = max\left(0, 1 - \frac{TED(pr, gt)}{TED(\emptyset, gt)}\right)$$

The dataset-level accuracy across (N) samples was calculated as:

$$Acc_{TED} = \frac{1}{N}\sum_{n=1}^{N} Acc_{TED}(pr, gt)$$

This metric encompassed both partial overlaps and hierarchical accuracy, which were not represented by field-level matching alone.

Algorithm 1 UniVLDocFormer: OCR-Free Structured Document Understanding

RESULTS AND DISCUSSION

Results were derived via a standardized evaluation process, wherein each dataset was divided into non-overlapping training and testing subsets, with 80% of samples allocated for model building and 20% designated only for testing. All reported metrics were calculated independently on the held-out test segments of each dataset to maintain schema integrity, as CORD had hierarchical receipt structures with 30 fields, whilst the Train Ticket benchmark utilized a flat template with eight fixed keys. Structured predictions were converted into JSON, standardized, and assessed using field-level precision, recall, and F1-score, along with TED-based accuracy, to measure both value accuracy and structural integrity. The comparative performance was evaluated against competitive document understanding baselines and representative state-of-the-art transformer models chosen to encompass complementary paradigms, including prompt-based document foundation modeling, multimodal fusion with layout-aware representations, and language-independent layout reasoning for multilingual extraction. This comparison determined if OCR-free unified generation enhanced robustness and structural preservation compared to established document AI systems, using identical preprocessing and evaluation methods.

The performance of the UniVLDocFormer on the CORD reception benchmark demonstrated consistent improvements over all baselines in both field-level and structure-aware metrics. DocFormer attained 70.84% precision and 68.92% recall, yielding a 69.87% F1-score and 74.26% TED-based accuracy, indicating modest efficacy in extracting key-value information while exhibiting diminished dependability in maintaining nested reception structures. LiLT enhanced these metrics to 72.15% precision, 71.02% recall, and a 71.58% F1-score, achieving 76.41% TED-based correctness, indicating superior multilingual representations and better alignment between textual content and layout. UDOP established a more robust baseline with 76.43% precision, 74.68% recall, 75.54% F1-score, and 80.12% TED-based accuracy, indicating enhanced structured creation through prompt-based conditioning. UniVLDocFormer attained superior performance with 80.52% precision, 78.93% recall, and a 79.71% F1-score, in addition to 85.49% TED-based accuracy. The enhancements in both F1 and TED-based accuracy indicated that the integrated vision-language framework not only bolstered the accuracy of extracted values but also maintained the hierarchical structure in intricate receipt schemas. The enhancement in recall compared to baselines signified more comprehensive field coverage, while the rise in TED-based accuracy demonstrated a reduction in structural modifications necessary to convert predictions into the ground-truth tree, which is especially critical for CORD, where nested item groups and recurring structures prevail in the annotation format.

In the Train Ticket benchmark, all techniques exhibited elevated absolute scores because to the fixed template and reduced field set; still, UniVLDocFormer consistently outperformed the baseline models. DocFormer achieved 83.12% precision and 81.64% recall, resulting in an F1-score of 82.37% and a TED-based accuracy of 86.48%, demonstrating robust performance under stable spatial priors, although exhibiting susceptibility to background noise and imaging distortions. LiLT enhanced the outcomes to 85.04% precision, 84.21% recall, 84.62% F1-score, and 88.73% TED-based accuracy, aligning with its language-agnostic architecture and appropriateness for texts comprising digits, English letters, and Chinese characters. UDOP attained 88.12% precision, 86.93% recall, 87.52% F1-score, and 90.41% TED-based accuracy, indicating efficient prompt-driven generation for fixed-field extraction.

UniVLDocFormer achieved superior performance, with 90.31% precision, 88.71% recall, and an 89.48% F1-score, while TED-based accuracy reached 92.18%. The margin above UDOP indicated that the proposed unified token modeling and schema-guided generation enhanced both the accuracy of extracted values and the stability of the structured output amidst noise and distortions. The rise in recall signified a decrease in the omission of essential fields, while the steady enhancement in TED-based accuracy illustrated improved adherence to structure, even within a dataset characterized by relative simplicity, where errors frequently stem from visually impaired areas and multilingual character configurations. The bar plot illustrates a comparative analysis of precision, recall, F1-score, and TED-based accuracy for four models assessed on two benchmarks with differing attributes. Both datasets reveal a continuous ranking trend: DocFormer attains the lowest overall scores, LiLT shows moderate enhancements, UDOP demonstrates robust performance, and UniVLDocFormer achieves the highest results across all presented parameters. This pattern demonstrates that the suggested unified vision-language framework enhances both field-level accuracy (precision, recall, and F1-score) and structure-level fidelity (TED-based accuracy) compared to rival transformer baselines.

The distinction across models in the CORD dataset is increasingly evident, especially regarding TED-based accuracy. This behavior illustrates the intricacy of CORD annotations, wherein nested item groupings and hierarchical relationships enhance the necessity for generating structurally coherent outputs. The proposed UniVLDocFormer demonstrates concurrent enhancements in recall and TED-based correctness, indicating greater completeness of extracted fields and reduced structural inconsistencies in the resulting hierarchy. In the Train Ticket dataset, all algorithms attain elevated absolute values because to the consistent layout and reduced number of fields. Notwithstanding this, UniVLDocFormer retains its preeminent status across all metrics, demonstrating that the methodology is resilient even against background noise and imaging defects. The aggregated findings from both datasets demonstrate that the proposed model generalizes proficiently over diverse document layouts and multilingual content, while ensuring robust structure preservation, as evidenced by the enhancements in TED-based accuracy. The table presents a comparative assessment of OCR-dependent document understanding baselines and

the proposed OCR-free UniVLDocFormer across two benchmarks. The OCR column denotes if a method utilized an external OCR engine for text tokenization before subsequent modeling. On CORD, UniVLDocFormer attained an F1-score of 79.71% and a TED-based accuracy of 85.49%, exhibiting competitive performance relative to robust OCR-based transformers while preserving superior structure-level fidelity compared to various OCR-dependent pipelines. In the Train Ticket dataset, UniVLDocFormer achieved an F1-score of 89.48% and a TED-based accuracy of 92.18%, demonstrating effective extraction under stable layout settings despite background noise and imaging distortions, while mitigating OCR-related error propagation. The results indicate that end-to-end OCR-free structured generation attained performance comparable to, and in some instances surpassing, OCR-based methods, especially in terms of structure retention and multilingual robustness.

The ablation results indicated that every component of UniVLDocFormer significantly contributed to both field-level accuracy and structural integrity across the two benchmarks. The complete setup attained optimal performance, achieving 79.71% F1 and 85.49% TED-based accuracy on CORD, and 89.48% F1 and 92.18% TED-based accuracy on Train Ticket, thereby validating that the integrated design enhanced both extraction quality and structured output integrity. The elimination of robust augmentations resulted in a moderate decrease in both datasets, diminishing CORD performance to 77.86% F1 and 83.12% TED-based accuracy, while Train Ticket performance decreased to 87.94% F1 and 90.76% TED-based accuracy. This reduction demonstrated that augmentation-driven robustness significantly contributed to managing appearance variability in receipts, as well as background noise and image defects in rail tickets. The removal of layout-aware encoding resulted in a significant decline, especially on CORD, where hierarchical extraction is heavily reliant on spatial cues, reducing the F1 score to 75.21% and TED-based accuracy to 80.03%. A comparable yet lesser loss transpired on Train Ticket, achieving 86.88% F1 and 89.12% TED-based accuracy, indicating that fixed-layout documents continued to gain from explicit spatial modeling for consistent key localization.

The greatest significant decline was noted upon the removal of schema-guided limited decoding, yielding 73.64% F1 and 77.18% TED-based accuracy on CORD, and 85.31% F1 and 87.45% TED-based accuracy on Train Ticket. The significant decline in accuracy associated with TED underscored that constraint-aware decoding markedly enhanced structural validity and diminished hierarchy-related mistakes, particularly in nested receipt schemas. The elimination of the pointer/copy mechanism resulted in a performance decrease to 74.82% F1 and 78.54% TED-based accuracy on CORD, and to 86.02% F1 and 88.26% TED-based accuracy on Train Ticket. This trend indicated that grounded copying enhanced the accuracy of numeric and alphanumeric data, including prices, totals, dates, and ticket identities, which are frequent sources of errors in OCR-free creation. The ablation trends demonstrated that schema-guided constrained decoding and layout-aware encoding were the primary determinants of structural correctness, as evidenced by TED-based accuracy, while robust augmentations and the pointer mechanism contributed supplementary improvements in robustness and value fidelity across both datasets.

The CORD dataset sample prediction demonstrates comprehensive structured extraction from a receipt image featuring hierarchical content. The left panel displays the original receipt, and the middle and right panels exhibit the ground-truth annotation and the expected annotation, respectively, in a JSON-style hierarchy. The anticipated output maintained the hierarchical menu structure and accurately retrieved item-specific key–value pairs for three entries, encompassing item names together with their respective counts and prices, while also aligning with the transactional summary fields in the total section (total price, cash price, and change). The strong correlation between the predicted structure and the actual data suggests that hierarchical organization and field binding were preserved despite the presence of visually impaired areas and small-font text in the receipt image. The example prediction from the Train Ticket dataset demonstrates OCR-free extraction from a fixed-layout ticket that includes background noise and capture distortions. The left panel displays the original train ticket image, while the right side juxtaposes the ground-truth annotation with the predicted annotation, indicating that the projected output aligns with the ground truth for the sample. This outcome illustrates the reliable extraction of essential ticket information from multilingual content,

where digits, English letters, and Chinese characters coexist, and it verifies that the structured fields were accurately produced despite the interference of noise and imaging artifacts characteristic of authentic ticket photographs.

DISCUSSION

The experimental results indicated that the integrated vision-language model attained enhanced extraction quality and structural preservation across both benchmarks, consistent with the goal of OCR-free structured document comprehension. On CORD, UniVLDocFormer attained an F1 score of 79.71% and a TED-based accuracy of 85.49%, surpassing the most robust baseline (UDOP) by 4.17 percentage points in F1 and 5.37 percentage points in TED-based accuracy. These results signified enhancements in both value accuracy and hierarchical consistency, crucial for receipts with nested item groups. The enhanced structural fidelity resulted from schema-guided limited decoding, which minimized malformed outputs and hierarchical mistakes, and from layout-aware encoding, which maintained spatial cues necessary for associating item attributes with the appropriate groups. On the Train Ticket dataset, UniVLDocFormer achieved an F1 score of 89.48% and a TED-based accuracy of 92.18%, surpassing UDOP by 1.96 percentage points in F1 and 1.77 percentage points in TED-based accuracy. Despite the fixed ticket layout and reduced field set, the ongoing enhancements indicated that the model retained its robustness against background noise and imaging aberrations while processing multilingual characters.

The ablation analysis corroborated these interpretations, revealing the most significant degradation upon the removal of schema constraints, with CORD TED-based accuracy declining from 85.49% to 77.18% and Train Ticket decreasing from 92.18% to 87.45%, thereby affirming that constrained generation was the primary factor influencing structural reliability. Layout-aware encoding significantly impacted performance, especially on CORD, where its elimination resulted in a 5.46-point decrease in TED-based accuracy, underscoring the need of hierarchical extraction on spatial reasoning. Robust augmentations and the pointer method enhanced resilience and numerical accuracy, evidenced by moderate declines upon their removal, which correlated with recurrent inaccuracies in prices, totals, and identifiers during OCR-free creation. Comparisons with OCR-dependent baselines demonstrated that competitive accuracy was attained without the propagation of OCR-induced errors, reinforcing the notion that end-to-end generation can supplant OCR-centric pipelines in structured extraction tasks. Notwithstanding these advantages, the system was vulnerable to significant blur and substantial occlusion, rendering fine characters visually irretrievable, while the autoregressive decoding strategy heightened inference latency relative to pure token-classification techniques on extensive documents.

CONCLUSION

A cohesive vision-language transformer, UniVLDocFormer, was created and assessed for OCR-free document comprehension and organized information extraction. The methodology standardized inputs via resolution-consistent preprocessing and robust augmentations, trained a singular multi-task model guided by dataset-specific prompts, and assessed outputs using field-level F1 and TED-based accuracy to evaluate both value correctness and structural fidelity. The outcomes on CORD and Train Ticket shown consistent enhancements above rival transformer baselines, with the suggested technique attaining the highest precision, recall, F1-score, and TED-based accuracy across both datasets. The observed improvements were substantiated by ablation results, indicating that schema-guided limited decoding and layout-aware encoding were the primary factors enhancing structural accuracy, whilst augmentations and the pointer method bolstered robustness and numeric/alphanumeric dependability. These findings corroborated the aim of eradicating OCR dependence while preserving robust extraction efficacy across variable-layout receipts and fixed-layout multilingual tickets. Future efforts will focus on enhancing efficiency and robustness for bigger page sizes and more demanding acquisition situations through the integration of accelerated decoding techniques, enhanced resolution-adaptive tokenization, and extensive pretraining across various document domains. Practical deployment scenarios encompass automated expense and invoice processing for financial

workflows, digitization of tickets and transport documents in multilingual contexts, and extensive back-office data entry automation, wherein OCR-free pipelines mitigate cascading recognition errors and streamline system maintenance while generating directly machine-readable structured outputs.

Table 1. Recent OCR-Free Document Understanding Methods For Structured Information Extraction

Ref	Methodology	Key Datasets / Tasks	Main Findings	Limitations / Research Gaps
[33]	OCR-free MLLM framework using multi-scale visual pyramids with hierarchical feature aggregation and cross-attentive pooling; instruction tuning for text position learning	DocVQA, TextVQA, document QA tasks	Efficient handling of diverse font sizes; reduced visual tokens with minimal information loss	No explicit schema-constrained decoding; limited grounding for numeric field extraction
[34]	High-resolution DocCompressor guided by low-resolution global features; three-stage training for multi-page reasoning	Multi-page DocVQA, cross-page QA	Strong multi-page understanding with >50% latency reduction; high token efficiency	Focused on QA; structured IE and JSON-level constraints not explicitly modeled
[15]	Instruction-tuned OCR-free MLLM trained jointly on language-only, V&L, and document instruction datasets	LLMDoc, DocVQA, document instruction benchmarks	Strong zero-shot generalization; improved fine-grained document understanding	Weak explicit layout reasoning; unconstrained structured output generation
[35]	Knowledge distillation and pruning applied to DONUT for sparse OCR-free VDU	Invoice and receipt KIE datasets	54% model size reduction with preserved performance; suitable for edge deployment	Inherits DONUT's unconstrained decoding; limited layout and numeric grounding
[20]	OCR-free sequence generation with token-triggered coordinate decoding; weakly supervised training	Document parsing, layout analysis, DocVQA	Joint text parsing and coordinate extraction; strong spatial awareness	No schema enforcement; numeric/alphanumeric extraction remains error-prone
[36]	Unified structure learning with structure-aware parsing, multi-grained localization, and layout-preserving H-Reducer	DocStruct4M, DocVQA, table & chart benchmarks	Strong layout and structure reasoning; SOTA on multiple VDU benchmarks	High training complexity; structured IE depends on prompt design
[37]	Prompt-guided vision encoder enabling query-aware visual feature extraction; language-masking pretraining	DocVQA, TextVQA, dense DU tasks	Improved focus on task-relevant document regions; strong prompt conditioning	Not designed for direct structured output generation; lacks schema-guided decoding

ABSTRACT

Indian governance via grassroots is highly associated with fiscal power of Gram Panchayats. Local taxes form a valuable portion of own revenue in Panchayats, but the collection of taxes has been characterized by delays in procedure, lack of transparency and non-compliance of returns. The adoption of digital platforms to assess and collect tax has been one of the main reforms encouraged in the recent years under the e-Governance and Digital India programs. The present paper analyzes the concept of digital tax collection in Gram Panchayats and its usage issues, its effectiveness, its acceptance by stakeholders, and problems with implementation. The paper is an empirical study based on primary data among Panchayat officials and taxpayers which has been gathered using structured questionnaires and is complemented by secondary data sources like government reports and policy documents. The analysis shows that digital tax collection has led to improved transparency, speed and quality maintenance of records, thus improving administration of revenue at local level. Simultaneously, the research outlines the enduring limitations such as the lack of digital literacy, infrastructural shortages, the propensity to change, and the issues associated with the security of data. The article claims that although the potential of digital tax collection to improve the Panchayat finance is high, it can only succeed through the institution capacity building, inclusive digital literacy programs, and long-term policy support.

Keywords: Digital Tax Collection; Gram Panchayats; E-Governance; Local Public Finance; Digital Payments; Rural Governance.

INTRODUCTION

The Panchayati Raj system is one of the pillars of the decentralized system of government of India, which is expected to guarantee democratic participation and inclusive development of the government at its grassroots level. The Panchayat among the three levels of the Panchayati Raj Institutions (PRIs) have the most basic place; they are the most basic level of the governmental interaction with the rural people. It has the responsibility of a very broad spectrum of civic, developmental, and regulatory duties, including the supply of the most basic of amenities, like sanitation, drinking water, the maintenance of rural roads and paths, street lighting, drainage, and the solid waste management and the execution of numerous welfare and poverty alleviation programmes. Availability of viable and consistent financial resources is of paramount importance to the effective execution of these duties. The financial capacity does not only dictate the quality and sustainability of the delivery of the public service, but also the autonomy, accountability, and responsiveness of the local governments. In this regard, fiscal decentralization has been said to be a key ingredient of democratic decentralization in which the local bodies mobilize resources with local needs and priorities.

Financial Resources of Gram Panchayats and the Role of Local tax.

There are three large sources of finances to Gram Panchayats:

(i) Own-source revenues such as local taxes, fees and user charges;

(ii) Intergovernmental transfers, including grants, and common taxes by state governments; and

(iii) Scheme based funds obtained in centrally and state-sponsored development programmes.

Among them, revenue that is owned by itself especially by local taxes on houses, property, water use, markets, and trade activities have been central in making it financially sustainable. Local taxes do not only increase the amount of funds available but also enhance the financial accountability connection among taxpayers and Panchayat administrations. When Panchayats depend more on the self-generation, it is more likely to respond to the local needs and become more responsible in-service provision.

The role of own-source revenue in overall Panchayat income is notably low in most states in India despite this theoretical significance. The actual fiscal decentralization has been patchy and selective even though the 73 rd Constitutional Amendment Act, 1992 gave Panchayati Raj Institutions constitutional recognition and given state governments the power to authorize the Panchayats to raise, collect and appropriate taxes. As such, most Gram Panchayats are still very reliant on higher government grants that tend to be conditional and slow to arrive.

Weaknesses of the Conventional Tax Collecting Systems.

The conventional approaches in the administration of taxes are one of the greatest causes of poor financial status of Gram Panchayats. Tax investigation, billing, documentation and collection is mainly manual and paper based. Typically, the taxpayers have to travel to the Panchayat offices physically and usually during the working hours to pay in cash. This system is very expensive in terms of transaction to both taxpayers and Panchayat officials. Administerially, manual systems are susceptible to errors in evaluation and record management, duration in updating tax registers, and tracing arrears. Lack of real time data would restrict proper monitoring and planning. Moreover, transactions conducted in cash height the risk of revenue leakages, misappropriation as well as corruption thus compromising transparency and trust. The net effect of all these inefficiencies is poor compliance and realization of revenue in form of taxes.

Introduction of Digital Tax Collection in Gram Panchayats.

Over the past few years, due to the realization of the weakness of traditional systems, a number of state governments have proposed the implementation of digital tax collection systems as an extension of wider e-Governance and digital public administration reform. These initiatives include the use of information and communication technologies (ICT) in assessing taxes, billing, managing databases and online payment using web portals, mobile

applications and online financial management systems. The digital tax collection systems allow taxpayers to view their tax information, get their bills electronically, and pay taxes through online systems of UPI, debit card, net banking, and mobile wallets. In the case of Panchayat administrations, it eases the maintenance of records automatically, real time tracking of collections and automatic generation of analytical reports to aid planning and budgeting. These reforms can be aligned to the goals of the Digital India Programme that intends to enhance transparency, efficiency and citizen-centric governance by digitalizing government.

Advantages of local government Digital Tax Collection.

There are several advantages of digitalization of taxes collection to Gram Panchayats. It saves administrative expenses because it minimizes paperwork and does not use human resources by maximizing the accuracy of tax assessment and record-keeping and reducing discretionary authority and human intervention. Tax payment by citizens also becomes easier through digital systems and thus would promote voluntary tax pay and expand the tax base. Besides, the financial independence of Gram Panchayats can be enhanced by enhanced revenue collection by digital means, whereby the Gram Panchayats would plan and execute development operations efficiently. Availability of sound financial information facilitates evidence-based decision making and responsibility to both senior management and the local society.

Conceptual Framework

The theoretical used in the study is rooted in the assumption that the implementation of digital tax collection systems will have an effect on the outcomes of governance due to the better organizational processes. Online payment portals, mobile apps and embedded databases are also digital tools that are likely to increase the efficiency level of the company through minimizing the manual aspect of the business and allowing real-time tracking of revenues flows. Within the framework, digital tax collection is the independent variable, and results, including efficiency in the collection of revenues, transparency, accountability, and taxpayer satisfaction are dependent variables. Digital literacy, the infrastructure available, and the capacity of the institutions are moderating variables that determine the effectiveness of digital tax systems

REVIEW OF LITERATURE

The current literature on digital administration of taxes and rural e-Governance in general narrows down to the point that it has been argued that digital technologies can dramatically increase efficiency, transparency, accountability, and revenue performance in the government. In a pivotal systematic review, which has been created following PRISMA guidelines, and where 96 academic sources are used, Bassey et al. (2022) work out a conceptual framework of digital tax administration in its systemic form, placing it in the context of an information and communication system network. It applies four related dimensions such as contextual factors (political, legal, and institutional), stakeholders (taxpayers, officials, agencies), technology (AI, data analytics, e-filing), and outcomes (efficiency, compliance, governance outcomes) and the study suggests that digital tax systems can only succeed under the condition that technological adoption is integrated with trust-building mechanisms and institutional preparedness. Notably, the review points to significant research gaps, including the lack of investigation of the developing country setting, little consideration of socio-political and cultural influences, and excessive dependence on technological adoption models, including TAM and UTAUT, to the detriment of tax compliance and governance systems.

Within the rural development context, the literature points out that ICT-facilitated governance projects would be geared towards enhancing accessibility of the services, lowering transaction cost, and transparency to the rural population. Rama Rao (n.d.), in a series of case-based reviews of the Indian e-Governance efforts like Bhoomi, Gyandoot and Warana, has shown that the ICT interventions could be used to streamline service delivery and enhance the governance outcomes in the cases where the interventions were backed by sound infrastructure, process reengineering and commitment of the institutions. Nevertheless, it is also found that the study faces some enduring challenges in terms of sustainability such as poor backend integration, poor local language interfaces, poor revenue

models, and poor capacity building. These results indicate that technology in its own right cannot be successful, but that systemic changes in administration and citizen-oriented design were the key to long-term success. In line with this point of view, Sangeetha (n. d.) is considered to analyze the issue of digital governance in rural administration based on the examples of the Digital India, Common Service Centres, UMANG, Digi Locker, UPI, and e-NAM flagship initiatives. The paper has identified increased transparency, access to services, and engagement by the citizen, especially during the COVID-19 era. However, it highlights that it is still limited by persistent limitations like the lack of rural connectivity, digital illiteracy, cybersecurity issues, and socio-economic marginalization that still restrict the inclusivity and performance of rural e-Governance. All of these studies support the thesis that rural digital governance should solve the infrastructural and human-capital shortcomings, as well as solve the technological implementation.

The further explanation of the potential and constraints of digitalization is presented by more specific studies about online tax collection on the grassroots level. The article by Waghunde et al. (2025) offers a technological solution to transforming Gram Panchayat taxation with the help of QR payments and combined digital solutions. The empirical analysis of digital and manual system shows that their transaction speed, accuracy, transparency, revenue realization, and corruption reduction are improved. Nevertheless, the authors recognize that the lack of digital literacy, change resistance, connectivity and lack of thorough legal infrastructure are important obstacles to scalability and its long-term adoption. On the same note, Mandiri et al (2024) in their case study of the land and building tax digitalization in Indonesia show that the use of virtual accounts, GIS integration and multi-channel payment systems can significantly improve taxpayer compliance and administrative efficiency. However, the issues of the age of databases, digital disparities, and system reliability remain, suggesting that the digital changes to taxes should be followed by constant updating of the data and capacity enlargement.

In a larger digital adoption sense, Sindakis and Showkat (2024) present empirical results of rural India, which indicate that demographic, socio-economic, and perceptual variables (education, digital literacy, perceived usefulness and ease of use) play a crucial role in technology adoption as part of Digital India Programme. They note that they are seeing the adoption of digital services, especially among the youth and women, which might be a gradual reduction in the rural digital divide. However, the paper recommends mobile-first, inclusive design, and long-term infrastructure and digital literacy investment to make rural locations equally digitally transformed. These empirical findings are further supported by theoretical additions to the literature in e-Governance and public finance. Heeks (2018) holds that digital systems could help to decrease the information asymmetry, and in developing countries, it is possible to improve service delivery whereas Bird and Zolt (2015) state that tax administration aided by technology could lead to improved compliance and decreased administrative expenses. Scholars like Rao and Singh (2019) always emphasize the underdeveloped revenue base and fiscally constrained independence of Panchayats in the Indian context because of these problems, they blame the low tax effort, insufficient practices in tax assessment, and ineffective systems of tax collection. Although reports like the one by Bhatnagar (2020) record positive gains of online property tax and user-charge collection, including lower transaction costs and better documentation, others warn that the gains of digitalization are unevenly distributed, especially in the rural regions that are faced by connectivity and skills limitations (World Bank, 2021).

Generally speaking, despite the fact that the existing literature offers considerable information on the topic of digital governance, tax administration, and the level of rural technology uptake, there is limited empirical evidence on the subject of the digital tax collection process on the Gram Panchayat level and its effects on the work of the Gram Panchayat.

Research Gap

Majority of studies follow a macro-level approach or urban local governments related to tax collection, Tax administration and rural development. There is no study related to implementation, efficiency, and difficulties of digital tax collection in Gram Panchayats. This article is focusing the above areas which is not covered in the earlier studies.

Statement of Problem

The digital tax collection at the Gram Panchayat level has a number of challenges, even though it has the potential of being helpful. The rural community lacks proper access to the internet, electricity, and access to digital devices. A great number of rural taxpayers do not have the required level of digital literacy to operate online platforms on their own, and thus, they are excluded and rely on intermediaries. On the administrative side most of the Panchayat officials are poorly exposed to digital systems and lack support in their training on how the systems can be operated and maintained. The unwillingness to change, the fear of higher accountability, and the issues of data security and privacy are additional factors that impede the successful implementation. These issues highlight the importance of capacity building, development of infrastructure, and easy user system design.

Research Data sources

Both primary and secondary data sources were used in the study.

The primary data were gathered using structured questionnaires that were prepared separately between the Panchayat officials and the taxpayers. The questionnaire included close-ended statements (measured on Likert scale) which address issues like level of digital implementation, effectiveness of digital tools, user satisfaction, transparency, convenience, and problems with digital tax collection. The questionnaires were personally administered so as to be clear and have a high response rate.

Various sources such as government publications, Panchayat records, official reports and policy documents, websites and academic journals were used to gather secondary data. These helped to get background data about the initiatives of digital governance, the method of tax collection, and policy framework, which allowed supporting the interpretation of primary data and underpinning the study with analytical foundations. The primary data shall be used in the analysis of 100 respondents (94 taxpayers and 6 Gram Panchayat officials) conducting the survey in Oro Halli and Jadigenahalli Panchayats. To provide statistical rigour the analysis of data was conducted with the help of percentage analysis and mean score, Chi-square test and using independent sample t-test.

RESEARCH METHODOLOGY

Research Design

The current research paper is based on the descriptive and analytical research design in investigating the digital tax collection, Gram Panchayats. According to the descriptive research design, the researcher describes the current systems of digital tax collection, the scope of their application, and the essence of digital tools introduced at the Panchayat level systematically. This design will assist in gathering factual information about awareness, use, and features of operational sites of digital tax. The analytical type of research design is used to determine the efficiency of digital tax collection systems by analysing the obtained responses of Panchayat officials and taxpayers. It helps the researcher to evaluate the connection between variables ease of use, transparency, time efficiency, accuracy and the user satisfaction. The mixed research design gives the detailed picture of present situation and performance of the digital tax collection in Gram Panchayats.

Study Area

The research design was based on the sampling of the Gram Panchayats in one of the districts, in which digital tax collection systems have already been officially introduced and implemented. The study area was selected based on the availability of the Panchayats, digital infrastructure as well as the use of digital tax systems in the collection of revenues. The application of Gram Panchayats that had working digital systems guaranteed the applicability and validity of the study findings. The area chosen is a typical example of rural administrative units that are undergoing digital transformation thus rendering the outcomes applicable in comprehending the measures of the implementation of digital governance projects at the grassroots level.

Sample Design

There were two large groups of respondents in the study population:

The Panchayat officials who are directly involved in taxation administration like Panchayat Development Officers, clerks, and tax collectors. Local taxpayers who pay taxes to Panchayat online. **Purposive sampling method** was applied to sample those respondents who have good knowledge and experience of digital tax collection systems. This approach made sure that the data that was collected were pertinent and useful to the study purposes. The sample size of 100 respondents was large enough to ensure sufficient representation of administrators and taxpayers and adequate analysis of the perceptions, effectiveness, and issues related to digital tax collection.

Tools and Techniques

To obtain the study objectives, the data collected were processed, classified, and analysed with the help of relevant statistical tools. The analysis of demographic characteristics of the respondents was carried out through percentage analysis, and the distribution of responses with regard to the level of digital tax system implementation was understood. The analysis of the mean score has been used to gauge the effectiveness of digital tax collection tools as well as gauge the views and perceptions of taxpayers and Panchayat officials towards digital tax collection practices. The higher mean scores were the sign of more effectiveness and positive perceptions. Rudimentary ranking was done to determine and rank the critical problems, challenges and areas of concern encountered in digital tax collection which assisted in designing appropriate policy recommendations. These analytic instruments facilitated the organized interpretation of the data and presented substantial information on the performance and acceptance of digital tax collection systems of Gram Panchayats.

Objectives

1. To investigate the level of digital tax collection system implementation in Gram Panchayats.
2. To determine the opinions of taxpayers and Panchayat officials towards digital tax collection

Data analysis and interpretation

Demographic Characteristics of the Respondents.

Table 1 gives the demographic profile of the respondents. Among the 100 respondents, 58 percent of the respondents were males and 42 percent were females. Most of the respondents (46 percentage) were aged between 31-45 years, and it is an indication that they are engaged in economic and civic activities. In terms of level of education, 62 percent of the respondents had attained secondary education or more implying a fair ability to utilize digital channels. Almost two out of three participants stated that they had previously used digital payment systems either UPI, mobile banking, or online portals. The demographic information implies that a high percentage of the respondents has the minimum educational and technological contact that can lead to the adoption of the digital tax collection systems.

The analysis in terms of percentage showed that 72 percent of the respondents paid Gram Panchayat taxes using digital methods and 28 percent still use manual payment modes. In the digital users, UPI-based payments were the majority (46%), followed by Panchayat web portals (18%) and mobile applications (8%). It means that there is a gradual and consistent transition to the digital collection of taxes at the Panchayat level.

Digital tax collection system effectiveness was evaluated on a five-point Likert scale with a strong disagree (1) as one end and a strong agree (5) as the other end. The review of the perceptions of the respondents utilized mean score analysis.

One-Sample t-test on Digital Tax collection Systems Effectiveness.

In order to further support the effectiveness of digital tax collection systems using the parameters of efficiency as the measure of effectiveness, a one-sample t-test was conducted on the parameters of effectiveness provided in Table 2. The test was completed to check whether the measured mean scores had a significant difference with the neutral benchmark of 3.00 in the five-point Likert scale that designates a moderate or indifferent range of effectiveness.

Hypotheses

Null Hypothesis (H0): The average effectiveness parameter is 3.00, which means that there is no significant effectiveness of the digital tax collection systems. Alternative Hypothesis (H1): The average score of the effectiveness parameters is much higher than 3.00, which means that digital tax collection systems have high effectiveness.

One-Sample t-Test

According to the outcomes of the one-sample t-test, the mean values of all the parameters of effectiveness are statistically significant at the level of 5 per cent ($p < 0.05$). This means that the perceptions of respondents in terms of effectiveness of digital collection of tax are considerably greater than the neutral level of these values and cannot also be explained by random change. The largest t-values were found to be with the parameter Digital tax payment saves time and Digital tax collection improves transparency which proves that these are the most considerable gains of digitalisation on the level of Gram Panchayat. These results show that the digital tax systems have significantly minimized the delays in the process and enhanced transparency in the tax transactions. Even though the parameter "Ease of use of digital tax system" has obtained a relatively lower mean score, t-test demonstrates that the parameter score is still significantly higher than the neutral score. That implies that although there are some usability issues, especially when it comes to the less-digitally literate taxpayers, the system is considered to be effective in general.

FINDINGS AND RECOMMENDATION

The researcher found that the implementation of digital tax collection systems in Gram Panchayats is at a high level, with 72 per cent of the respondents reporting the use of digital payment methods like UPI, Panchayat web portal, and mobile application and 28 per cent of the respondents rely on manual methods. This analysis indicates that digital collection of tax has greatly enhanced the efficiency of tax collection especially in terms of saving time as the highest mean score of 4.21 was recorded. There has also been an increase in transparency and accountability with an average of 4.08 which means that there is less room to manipulate the system as well as an increase in trust in Panchayat administration of tax. Digital record keeping has been effective in reducing errors and controversies with an average score of 3.94 proving greater accuracy and reliability of tax records. Even though the ease of use of digital systems had a relatively lower mean score of 3.76, it was still statistically significant which indicates that the problem of usability still remains primarily because of decreased digital literacy of some groups of taxpayers. The general satisfaction of the digital tax collection system was great, with an average of 4.02. The results of the one-sample t-test indicate that all the effectiveness parameters are significantly above the neutral benchmark value of 3.00 at the 5 per cent level of significance, and consequently the null hypothesis is rejected and the alternative hypothesis is accepted.

RECOMMENDATIONS

According to the results, the study suggests the enhancement of digital infrastructure in rural settings with the help of providing steady internet access, constant access to power, and the sufficient level of technological equipment of Gram Panchayat offices. It should also implement capacity-building efforts in which the Panchayat officials are trained on the effective use, maintenance, and monitoring of digital tax systems. Digital literacy programs and awareness campaigns must be arranged to make taxpayers more inclusive and easily adoptable and specifically focused on elderly citizens and digitally marginalized groups. The digital tax platforms must be restructured to be more friendly, mobile and in the local languages to increase accessibility. The common service centres and Panchayat help desk should be extended to assist taxpayers who experience challenges when using online services without assistance. Moreover, effective data security and data privacy practices should be introduced to protect the information of taxpayers and gain trust in digital solutions. State governments must provide long-term policy support and funding to make digital tax collection efforts at the grassroots level to be long-term and scalable.

CONCLUSION

The paper concludes that digital tax collection systems have brought about major changes in the management of revenue collection of Gram Panchayats by improving efficiency, transparency, accuracy and satisfaction to taxpayers. The statistical analysis of the empirical evidence shows clearly that digitalisation has led to shorter procedural delays, better accountability, enhanced record management, and improved local tax collection. In spite of such positive results, such issues as the digital illiteracy, infrastructural constraints, change resistance, and data security concerns are still present and impact the implementation effectiveness. Hence, the implementation of digital tax collection must not be considered only as technological change but as an institutional change that needs to be sustained through investment in infrastructure, human resources, and design-oriented towards people. Digital tax collection through proper policy changes, capacity building and inclusive digital approaches can greatly empower fiscal independence, quality of governance and service delivery at Gram Panchayat level.

ABSTRACT

India is experiencing a silent yet alarming rise in obesity, with prevalence rate of 7.51% and ranking 183rd globally, which is transforming it from an affluence condition to a widespread public health challenge in recent decades. This increase is attributed to rapid urbanization, sedentary lifestyles, rising consumption of calorie-dense processed foods, and declining physical activity. The National Family Health Survey (NFHS-5) reported that 24% of women and 22.9% of men in the 15–49 age groups are overweight or obese, showing a significant jump from NFHS-4. In Ayurved, obesity is classified as ***Sthaulya***, a disorder **of** *Meda dhatu* metabolism, arising from *Agnimandya* (digestive fire impairment), ***Kapha*** vitiation, and accumulation of *Ama* (toxins). The condition is described as a ***Tridoshaja Vyadhi***, primarily driven by over-nutrition (*Santarpana*), sedentary habits (*Avyayama*), and improper diet (*Guru-Snigdha-Madhura Ahara*). This review integrates modern epidemiological trends with classical Ayurvedic concepts by analyzing data from NFHS, WHO, and ICMR-INDIAB studies, along with Ayurvedic compendia like *Charaka Samhita* and *Ashtanga Hridaya*. Ayurvedic interventions including *Nidana Parivarjana*, *Pathya-Apathya*, *Shamana* (e.g., *Triphala, Guggulu*), and *Shodhana* (e.g., *Vamana, Lekhana Basti*) offer sustainable, individualized treatment. Bridging classical Ayurvedic principles with contemporary data-driven insights can offer an effective, culturally resonant strategy for addressing India's obesity epidemic through holistic, preventive care.

Keywords : Obesity, Epidemiology, *Sthaulya*, Non-Communicable disease, Ayurvedic management

INTRODUCTION

According to the World Health Organization (WHO), Obesity is defined as an abnormal and excessive accumulation of fat which presents risk to health [1] . The metric used for classification for obesity is Body Mass Index (BMI), calculated as weight in kg divided by height in m^2. The standard WHO classification is: Underweight: <18.5 kg/m^2, Normal: 18.5–24.9 kg/m^2, Overweight: 25.0–29.9 kg/m^2, Obese: ≥30.0 kg/m^2, however, for Asian populations, due to higher metabolic risks at lower BMI levels, the Asia-Pacific guidelines define overweight as BMI ≥23.0 kg/m^2 and obesity as BMI ≥25.0 kg/m^2 [2]. These region-specific cutoffs are now widely accepted for South Asian populations, including India, due to their relevance in predicting non-communicable disease (NCD) risks. Globally, obesity has tripled since 1975. According to the Global Burden of Disease (GBD) 2019, high BMI was the fourth leading risk factor for mortality worldwide, contributing significantly to ischemic heart disease, stroke, type 2 diabetes, and certain cancers [3]. The largest demographic and health survey (DHS) in India, National Family Health Survey (NFHS-5, 2019–21) reported that 24% of women and 22.9% of men in the 15–49 age group are overweight or obese (BMI ≥25), a marked increase from 20.6% (women) and 18.9% (men) in NFHS-4. First to fourth round of NFHS had measured general obesity through BMI measurement and In NFHS-5, abdominal or central obesity through waist circumference was measured [4]. The ICMR-INDIAB study (2021) estimated that nearly 135 million Indians are affected by overweight or obesity, with rapid increases noted in both urban and rural populations [5]. The trajectory of obesity in India shows a steep climb over the past four decades. Increased consumption of processed food, calorie-dense foods and sedentary lifestyle get in practice due to urbanization and economic development. Rural obesity is also rising, especially among middle-aged and elderly populations, due to lifestyle westernization. Child and adolescent obesity is emerging as a significant concern, fueled by screen time, junk food, and decreased physical engagement [6].

In *Ayurveda*, obesity is described under the umberalla of *Sthaulya,* a disorder of *Meda dhatu* metabolism. It is considered as a *Tridoshaja Vyadhi* with dominance of *Kapha dosha* and *Meda dhatu*, which is caused by *Santarpana Hetu* (excessive nourishment) and *Agnimandya* (digestive fire dysfunction).

Cause of Sthaulya [7]: तदतिस्थौल्यमतिसम्पूरणाद्गुरुमधुरशीतस्निग्धोपयोगादव्यायामादव्यवायाद्दिवास्वप्नाद्धर्षनित्यत्वाद-चिन्तनाद्बीजस्वभावाच्चोपजायते। (Charaka Samhita, Sutrasthana 21/3.)

- Overnourishment through excessive food intake.
- Consumption of heavy, sweet, cold, and oily foods (e.g., dairy, sweets, fried items).
- Lack of physical activity or exercise.
- Absence of sexual activity (which here may symbolize stagnation or lack of natural energy expenditure).
- Sleeping during the day, which disturbs metabolism.
- Constant indulgence in pleasure, luxury, or enjoyment (harṣa).
- Overthinking or worry (mental factors).
- Genetic/hereditary constitution (bīja svabhāva).

Classical Features (Lakshanas) of Sthaulya include [7]:

- *Ayatam* (excessive bulk)
- *Sthulam* (excessive fat accumulation)
- *Atipipas* (excessive thrist)

Pathogenesis (Samprapti):

- Excessive intake of *Guru-Snigdha-Madhura Ahara* (heavy, sweet, oily foods),
- A*vyayama* (Sedentary lifestyle) and *Divaswapa* (day sleeping) increase *Kapha* and *Meda.*
- This leads to *Srotorodha* (obstruction of channels), disturbed lipid metabolism, lethargy, and accumulation of *Ama* (metabolic toxins) [8].

Thus, the Ayurvedic view aligns with modern concepts of metabolic syndrome (*Sthaulya*) and offers preventive and therapeutic modalities via *Shodhana* (purification), *Shamana* (palliative therapy), and *Pathya-Apathya* (dietary and behavioral corrections).

METHODS

This integrative review was conducted and a structured approach was employed to gather and synthesize data from modern epidemiology and classical Ayurved.

Data Sources and Selection -

Relevant literature was collected from biomedical databases including PubMed, Scopus, Google Scholar, and the AYUSH Research Portal, along with reports from NFHS (Rounds 2–5), ICMR–INDIAB, and WHO. Ayurvedic data were sourced from Charaka Samhita, Ashtanga Hridaya, and Sushruta Samhita.

Studies and reports published between 1990 and 2024 were included. Inclusion criteria comprised:

- National epidemiological data,
- Peer-reviewed Ayurvedic and clinical studies on *Sthaulya*,
- Classical Ayurvedic references.

Non-Indian data, anecdotal articles, and studies not focused on obesity or Ayurvedic management were excluded.

Data Analysis-

Prevalence trends were stratified by year, gender, age group, and urban-rural setting, and presented in tables and charts. Ayurvedic concepts were organized thematically under Nidana, Samprapti, Lakshana, and Chikitsa.
Management protocols were classified as:

- ***Nidana Parivarjana*** (elimination of causative factors),
- ***Shamana*** (herbal formulations such as *Triphala*, *Guggulu*),
- ***Shodhana*** (procedures like *Vamana*, *Lekhana Basti*),
- ***Pathya-Apathya*** (diet and lifestyle regulations).

Integrative Synthesis

Findings from both streams were interpreted to draw conceptual and therapeutic parallels between metabolic syndrome and *Sthaulya*, highlighting the relevance of Ayurvedic strategies in contemporary public health.

RESULT

An analysis of obesity prevalence data from NFHS and ICMR-INDIAB studies shows a steady rise across decades. In 1990, obesity rates were around 3.5% in urban and 1.5% in rural adults. By 2000, these figures rose to 8% and 3.5%, and by 2010, they reached 16% and 7% respectively. As per NFHS-5 (2019–21), the prevalence has crossed 24% among women and 22.9% among men, with higher rates in urban (33.5%) compared to rural areas (17.5%). [3-5] This trend is evident across all adult age groups (15–49 years), with women consistently showing higher obesity rates. Middle-aged adults (30–49 years) exhibited the most significant increase, indicating a demographic shift in obesity burden (Table 1). Table 1: Decadal prevalence data (1990, 2000, 2010, and 2020) from NFHS, ICMR gender, age, region. The bar chart (Figure 1) illustrates the decade-wise gender disparity and age-specific rise in obesity prevalence. Women across all age groups showed a steeper incline than men, especially in urban populations. A noticeable rise is seen in the 15–19 and 20–29 age brackets, reflecting early onset of weight gain in young adults [3,4]
Figure 1: Bar Chart — Rise in Obesity by Age and Gender.

Urban areas consistently show 1.5 to 2 time's higher prevalence than rural regions, but rural obesity is catching up rapidly. For instance, rural women's obesity rose from 2.4% (1990) to 18.7% (2020), indicating the penetration of

obesogenic lifestyles beyond cities.[5] The rural surge is attributed to increased access to processed foods, mechanized labor, reduced physical activity, and limited awareness of nutrition and exercise. This highlights the epidemiological shift toward lifestyle diseases even in lower socioeconomic populations.

Table 2 reveals a widening gap between **urban and rural obesity rates** over the past three decades.
The steady rise in obesity is deeply linked to India's evolving food systems, technology use, and lifestyle norms over the decades:
1990s: India had a largely agrarian diet, rich in fiber and complex carbohydrates. Physical activity was high due to labor-intensive jobs, and fast food was rare, making obesity uncommon outside affluent circles [9].
2000s: With globalization, processed and packaged foods entered Indian markets. Urban families began shifting toward refined grains, sugary snacks, and increased screen time due to television and early internet access. Sedentary desk jobs expanded rapidly [10].
2010s: The digital boom and e-commerce platforms enabled easy access to calorie-dense foods. Food delivery apps and sedentary screen-based leisure activities increased, while home-cooked meals and traditional diets declined. Though gym culture grew in urban areas, it wasn't widely adopted [11].
2020s: Post-COVID lifestyle changes like work-from-home, reduced outdoor activity, and increased screen time worsened the issue. Ultra-processed snacks, sugary drinks, and late-night eating became normalized, especially among youth, further fueling the obesity epidemic [12].
In the face of India's alarming obesity epidemic, there is a growing need to shift from reactive treatment to proactive prevention. Ayurved offers a time-tested, holistic system that addresses the root causes of metabolic imbalance, rather than merely treating symptoms. Its preventive philosophy—centered on individualized dietary discipline, lifestyle moderation, and seasonal harmony—holds the potential to curb the rising tide of Sthaulya (obesity) and restore health equilibrium. *Ayurveda* has long emphasized the importance of diet (*Ahara*), daily regimen (*Dinacharya*), and seasonal regimen (*Ritucharya*) in maintaining health and preventing diseases, including *Sthaulya* (obesity). Classical texts define Sthaulya as a disorder arising from *Agnimandya* (weakened digestive fire), *Meda dhatu vriddhi* (excess fat tissue), and imbalance of *Kapha* and *Vata* doshas, resulting in diminished physical and mental function [7]. One of the most profound dietary principles in *Ayurveda* is "*Mātrāvat Āhāra*", i.e., consuming food in appropriate quantity. According to *Charaka Samhita*, ideal food intake is that which satisfies hunger, nourishes tissues, and does not disturb digestion or doshic balance [13]. Excessive food intake (*Ati-abhyaṅga, Ati-sevana*) and improper combinations are primary causes of obesity, highlighting Ayurveda's preventive foresight [14]. In the context of lifestyle, ancient practices such as daily oil massage (Abhyanga), physical activity (Vyayama), timely meals, and detoxification through seasonal Panchakarma have been emphasized to maintain metabolic balance and eliminate accumulated toxins (Ama)—a concept now aligned with modern ideas of metabolic syndrome and chronic inflammation [15,16]. Ayurvedic texts also propose a multi-pronged treatment approach to Sthaulya, comprising : Nidana Parivarjana (removal of causative factors: sedentary life, heavy food). Shamana therapy (use of herbs like Triphala, Guggulu, Musta, and Kutki to improve metabolism). Shodhana therapy (medicated purgation and emesis to remove deep-seated Meda). Pathya-Apathya (dietary regimens that include barley, green gram, Takra, and avoid heavy, oily, sweet foods) [17-19]. Yogas like Lekhaniya Gana (fat-reducing formulations), and therapies like Udvartana (dry powder massage), are time-tested interventions recommended for Sthaulya [20-21]. Incorporating these time-honored guidelines in modern contexts could serve not only as treatment strategies but also as preventive frameworks to curb the ongoing obesity crisis in India. Their emphasis on holistic, sustainable practices stands in stark contrast to modern fad diets and short-term pharmacological interventions.

DISCUSSION

The present review highlights the alarming and consistent rise in obesity across India over the last three decades, with a pronounced increase among urban populations and women of reproductive age. Data from NFHS and ICMR studies indicate that obesity is no longer restricted to affluent urban sectors but is rapidly permeating rural areas as well, driven by dietary transitions, reduced physical activity, and lifestyle westernization. These findings parallel

global patterns, but India's unique demographic, cultural, and socioeconomic landscape necessitates context-specific management approaches. In Ayurvedic literature, *Sthaulya* is described as a complex, Tridoshaja Vyadhi, predominantly involving *Kapha* and *Meda Dhatu*, with its roots in *Agnimandya*, *Santarpana Ahara*, and *Avyayama*. Classical references from *Charaka Samhita* and *Ashtanga Hridaya* describe *Sthaulya* as a disorder of both physical and mental faculties, contributing to reduced vitality (*Ayukshaya*), impaired digestion, and disturbed metabolic function, which conceptually aligns with the modern understanding of metabolic syndrome, dyslipidemia, and insulin resistance.

The Ayurvedic approach to obesity is notably holistic and preventive in orientation. By emphasizing *Nidana Parivarjana* (elimination of causative factors), *Shamana* (herbal therapies such as *Triphala*, *Guggulu*, *Musta*), and *Shodhana* (bio-cleansing techniques like *Vamana*, *Lekhana Basti*), Ayurveda offers a personalized and sustainable treatment model. Furthermore, *Pathya-Apathya*—through disciplined dietary practices and behavioral modifications—provides lifestyle-based preventive strategies that can be adapted for public health interventions. The integration of classical Ayurvedic wisdom with contemporary epidemiological data reinforces the potential of Ayurveda to contribute meaningfully to India's obesity crisis. In contrast to modern short-term pharmacological or surgical solutions, Ayurvedic protocols emphasize long-term balance and systemic correction. The inclusion of lifestyle components such as *Dinacharya*, *Ritucharya*, and ethical conduct (*Sadvritta*) adds further depth to the therapeutic and preventive potential of Ayurvedic regimens.

Given the scale of the obesity epidemic and its economic and health burdens, there is a compelling need for collaborative research to validate Ayurvedic protocols through clinical trials and implementation frameworks. Digital integration—through mobile apps for *dosha* - based diet tracking or wearable-assisted lifestyle plans—may enhance accessibility and adoption. The findings of this review support the repositioning of Ayurvedic protocols not merely as alternative treatments but as core components in the national strategy for non-communicable disease prevention.

CONCLUSION

The rising prevalence of obesity in India over the past decade reflects a complex interplay of sedentary lifestyle, dietary transitions, stress, and metabolic derangements. While contemporary medicine offers symptomatic and surgical solutions, the Ayurvedic approach provides a more sustainable, holistic framework through its understanding of *Sthaulya* and its pathogenesis rooted in *Kapha* aggravation, *Medo-dushti*, and impaired *Agni*. This integrative review highlights that Ayurvedic management strategies—especially those based on *Ahara* (wholesome diet), *Vihara* (lifestyle regulation), and *Shodhana* (bio-purificatory therapies)—remain relevant and adaptable even today.To address the modern obesity epidemic, foundational Ayurvedic protocols such as *Langhana* (lightening therapies), *Ruksha Udvartana* (dry powder massage), *Triphala* and *Guggulu* preparations, and *Agni-balancing* dietary practices can be re-contextualized in today's preventive health programs. Additionally, incorporating *Dincharya* (daily regimen), *Ratricharya* (night routine), and *Sadvritta* (ethical conduct) into wellness routines promotes not only weight balance but overall harmony. To ensure wider adoption, these measures can be integrated with digital tools like mobile applications for *Dosha*-based diet tracking, wearable-assisted lifestyle modifications, and workplace wellness modules rooted in Ayurved. Future research should aim to validate these protocols through well-designed clinical trials and interdisciplinary collaborations, enabling Ayurved to offer person-centered, preventive solutions for one of the most pressing public health concerns of our time.

ABSTRACT

A new concept called $i(gg)^*$-local Differenceset is introduced, and their role in the development of new separation axioms such as $i(gg)^*$- local S_0, S_1, S_2, P_0, P_1 and P_2 spacesis studied. Several characterizations of $i(gg)^*$-local Differenceset are obtained, highlighting their theoretical importance in describing local structural properties of intuitionistic spaces. The relationships between these sets and other classes of intuitionistic sets are systematically examined. To support the theoretical results, suitable examples and counterexamples are constructed to illustrate implication and non-implication relations among different classes of sets. These results establish a clearer hierarchy among the newly introduced structures.

Keywords : $i(gg)^*$- locally open, $i(gg)^*$- locally closed, $i(gg)^*$- localDifference set.

INTRODUCTION

In the study of topological spaces, open sets are essential for characterizing a space's inherent structure and behaviour. The idea of openness is fundamental to many significant topological ideas, including separation axioms, continuity and compactness. Over the past few decades, a number of generalizations of open and closed sets have been proposed and studied in order to expand the classical framework and capture finer structural properties. Levine

[1] introduced generalized closed sets in 1970, making it one of the first and most significant generalizations. Since then, the ability of generalized closed sets to characterize spaces that do not necessarily satisfy classical separation axioms has led to a great deal of research. This advancement made it possible to define and examine weaker types of continuity and closedness. Further "Intuitionistic set" in topological space was came into existence because of Coker [2] in 1996. Incorporating both a degree of membership and a degree of non-membership into the topology makes it easier to capture the vagueness and uncertainty associated with an intuitionistic topological space. He then explored some basic characteristics of closed sets in intuitionistic topological space and then improved the theory building upon the work of a model known as an intuitionistic point, setting the stage for further investigation. In 2009, it was further investigated by J. Younis Yaseen and G. Asmaa Raouf [3], who has given some results in intuitionistic generalized closed sets in topological spaces. In the past few years, focus and interest have been intensifying in this area of study.

The introduction of the concept of $\alpha(gg)^*$- closed sets in topological space by T. ShylacIsac Mary and G. Abhirami [4] in 2022 offered a new way to generalize closedness and to add to the hierarchy of generalized closed sets. At the same time, the development of a type of generalized intuitionistic topological space by G.K. Mathan Kumar and G. Hari Siva Annam [5] established the groundwork for a broader range of classes for both open and closed sets titled as 'The Extension of Generalized Intuitionistic Topological Spaces'. In 2025 G. Hari Siva Annam and S. Pavithra [6] has introduced "Mathematical insights on intuitionistic generalization of generalized star closed sets" where $i(gg)^*$-closed sets in intuitionistic topological space is introduced and it is compared with various sets and concluded many results by expanding their properties. The concept of minimal and maximal open sets was introduced by G. Hari Siva Annam and S. Pavithra [7] as "A new structure for minimal and maximal function in intuitionistic generalization of generalized star open sets", which creates a new way of thinking about how openness operates and how function behave within intuitionistic topological space.

Inspired by these advancements, the current work incorporates locally closed sets and D- sets in order to expand and enhance the study of intuitionistic generalization of generalized star closed sets. Furthermore, this work introduces the concept of $i(gg)^*$ -local difference set, which play a significant role in the structural development of separation properties within intuitionistic topological spaces. The notion of $i(gg)^*$ -D sets provides a useful framework for analyzing local behavior of sets with respect to generalized continuity and closure operations. Using this concept as a foundation, several new separation axioms are formulated, $i(gg)^*$- local S_0, S_1, S_2, P_0, P_1 and P_2 Spaces. These spaces extend the classical separation concepts by incorporating the properties of $i(gg)^*$- local structures, thereby offering a refined classification of intuitionistic topological spaces.Through these relationships, new characterizations and structural properties that contribute to a better understanding of separation axioms in the setting of intuitionistic topology. Consequently, the proposed concepts enrich the existing theory and open new directions for further research in intuitionistic topological structures.

PRELIMINARIES

Definition 2.1 Let X be a non - empty set. An intuitionistic set (IS for short) A is an object having the form $A = \langle X, A_1, A_2 \rangle$where A_1 and A_2 are subsets of X satisfying $A_1 \cap A_2 = \emptyset$. The set A_1 is called the set of members of A, while A_2 is called the set of non members of A.

Definition 2.2 Let X be a non-empty set and let A, B are intuitionistic sets in the form $A = \langle X, A_1, A_2 \rangle$, $B = \langle X, B_1, B_2 \rangle$respectively. Then
(a) $A \subseteq B$ iff $A_1 \subseteq B_1$ and $A_2 \supseteq B_2$
(b) $A = B$ iff A ⊆ B and B ⊆ A.
(c) $A^C = < X, A_2, A_1 >$
(d) $A - B = A \cap \bar{B}$
(e) $\emptyset_{\sim} = \langle X, \emptyset, X \rangle$, $X_{\sim} = \langle X, X, \emptyset \rangle$

(f) $A \cup B = \langle X, A_1 \cup B_1, A_2 \cap B_2 \rangle$
(g) $A \cap B = \langle X, A_1 \cap B_1, A_2 \cup B_2 \rangle$

Definition 2.3 An intuitionistic topology (for short IT) on a non-void set X is a family τ_I of IS in X satisfying the following axioms.
(1)$\emptyset_{\sim}$, $X_{\sim} \in \tau_I$
(2)$G_1 \cap G_2 \in \tau_I$, for any $G_1, G_2 \in \tau_I$
(3) $\cup G_\alpha \in \tau_I$ for any arbitrary family $\{G_\alpha / \alpha \in J\} \subseteq \tau_I$ where (X, τ_I) is called an intuitionistic topological space (for short ITS(X)) and any intuitionistic set in τ_I is called an intuitioistic open set (for short IOS) in X. The complement A^c of an IOS A is called an intuitionistic closed set (for short ICS) in X.

Definition 2.4 Let (X, τ_I) be an intuitionistic topological space (abbreviated as ITS(X)) and $A = < X, A_1, A_2 >$ be an IS in X. Then the interior and closure of A are defined by
(1) $Icl(A) = \bigcap\{K : K$ is an ICS in X and $A \subseteq K\}$
(2)$Iint(A) = \cup\{G : G$is an IOS in X and $G \subseteq A\}$.
If $Icl(A) = A$respectively[$Iint(A) = A$]then it can be demonstrated that A is an ICS [IOS]
in X.

Definition 2.5 Consider an intuitionistic set A of a non-void set X and $x \in X$. $x_I = (\{x\}, \{x\}^c)$ is an intuitionistic point (IP) and $x_{IV} = (\emptyset, \{x\}^c)$ is a vanishing point of X. IP(X) is a set of all intuitionistic points or intuitionistic vanishing point in X.

Definition 2.6 [6] A intuitionistic subset A of an intuitionistic topological space (X, τ_I) is called an intuitionistic generalization of generalized star closed sets ($i(gg)^*$- closed) if $ircl(A) \subseteq U$ whenever $A \subseteq U$ and U is $i(gg)$ open in (X, τ_I). The collection of all $i(gg)^*$- closed sets in (X, τ_I) is denoted by $i(gg)^*C(X)$.

Theorem 2.7.[6]Every. regular closed is $i(gg)^*$- closed.
Theorem 2.8 [8] A subset $\boldsymbol{A}$ of an intuitionistic topological space $(\boldsymbol{X}, \boldsymbol{\tau_I})$ is called $\boldsymbol{i(gg)^*}$- locally closed set if $\boldsymbol{A = G \cap H}$, where $\boldsymbol{G}$ is an $\boldsymbol{i(gg)^*}$- open set and H is an $\boldsymbol{i(gg)^*}$- closed set.
The class of all $\boldsymbol{i(gg)^*}$- locally closed sets in $(\boldsymbol{X}, \boldsymbol{\tau_I})$ is denoted by $\boldsymbol{i(gg)^*}$- $\boldsymbol{LC(X)}$.

Intuitionistic $(gg)^*$ - local difference set

Definition 3.1 An intuitionistic set A of an intuitionistic topological space (X, τ_I) is called an
$i(gg)^*$ -local difference set [$i(gg)^*$- local D set] if there are two $i(gg)^*$- locally open set U, V in (X, τ_I). Where U is not equal to$X_{\sim}$ and A is equal to $U - V$.
Definition 3.2 An intuitionistic topological space (X, τ_I) is $i(gg)^*$- local S_0 if for x, y $\in X_{\sim}$ such that $x_I \neq y_I$ there exists an $i(gg)^*$- local D set of (X, τ_I) containing x_I but not y_I or an $i(gg)^*$- local D set of (X, τ_I) containing y_I but not x_I. Also, the corresponding conditions and inclusions can be applied to (resp. x_{IV}) and (resp. y_{IV}).
Definition 3.3 An intuitionistic topological space (X, τ_I) is $i(gg)^*$ local S_1 if for x, y $\in X_{\sim}$ such that $x_I \neq y_I$ there exists an $i(gg)^*$- local D set of (X, τ_I) containing x_I but not $y_I$and an $i(gg)^*$- local D set of (X, τ_I) containing y_I but not x_I. Also, the corresponding conditions and inclusions can be applied to (resp. x_{IV}) and (resp. y_{IV}).
Definition 3.4 An intuitionistic topological space (X, τ_I) is $i(gg)^*$- local S_2 if for $x, y \in X_{\sim}$ such that $x_I \neq y_I$,there exists disjoint $i(gg)^*$- local D sets A and B such that $x_I \in A$ and $y_I \in B$. Also the corresponding conditions and inclusions can be applied to (resp.x_{IV}) and (resp. y_{IV}).
Definition 3.5 An intuitionistic topological space (X, τ_I) is $i(gg)^*$- local P_0 if for $x, y \in X_{\sim}$ such that $x_I \neq y_I$ there exists an $i(gg)^*$- locally open set of (X, τ_I) containing x_I but not y_I or an $i(gg)^*$- locally open set containing y_I but not x_I. Also the corresponding conditions and inclusions can be applied to (resp. x_{Iv}) and (resp. y_{IV}).

Definition 3.6 An intuitionistic topological space (X, τ_I) is $i(gg)^*$- local P_1if for $x, y \in X_\sim$ such that $x_I \neq y_I$ there exists an $i(gg)^*$- locally open set of (X, τ_I) containing x_I but not y_I and an $i(gg)^*$- locally open set containing y_I but not x_I. Also the corresponding conditions and inclusions can be applied to (resp. x_{Iv}) and (resp. y_{IV}).

Definition 3.7 An intuitionistic topological space (X, τ_I) is $i(gg)^*$- local P_2 if for $x, y \in X_\sim$ such that $x_I \neq y_I$ there exists disjoint $i(gg)^*$- locally open sets A and B such that $x_I \in A$ and $y_I \in B$. Also the corresponding conditions and inclusions can be applied to (resp. x_{IV}) and (resp. y_{IV}).

Remark 3.8(i) If (X, τ_I) is $i(gg)^*$- localP_i, then it is $i(gg)^*$- local P_{i-1}, $i = 1,2$
(ii) If (X, τ_I) is $i(gg)^*$- local S_i, then it is $i(gg)^*$- localS_{i-1},$i = 1,2$
(iii) If (X, τ_I) is $i(gg)^*$- local P_i, then it is $i(gg)^*$- local S_i,$i = 0,1,2$

Theorem 3.9 Let (X, τ_I) be an intuitionistic topological space, then (X, τ_I) is $i(gg)^*$- local S_0 iff $(X, \tau_I)$is $i(gg)^*$- localP_0.
Proof: Necessary condition: Let (X, τ_I) be $i(gg)^*$- local S_0. Hence for any different points $x_I, y_I (resp. x_{IV}, y_{IV})$ of (X, τ_I), atleast one of them belongs to an$i(gg)^*$- local D set O. write $O = U - V$ where U and V are $i(gg)^*$- locally open sets and $U \neq X_\sim$. Assume $x_I \in U$ such that $x_I (resp. x_{IV}) \in O$ and $y_I (resp. y_{IV}) \notin O$. Then we have two subcases.

$$(i) y_I (resp. y_{IV}) \notin U$$

$(ii) y_I (resp. y_{IV}) \notin U$ then $y_I (resp. y_{IV}) \in V$
For (i), $(X, \tau_I)$is $i(gg)^*$- localP_0, since $x_I (resp. x_{IV}) \in U$ and $y_I (resp. y_{IV}) \notin U$. where U are $i(gg)^*$- locally open set.
For (ii), $(X, \tau_I)$is also $i(gg)^*$- local P_0, since $y_I (resp. y_{IV}) \in V$ and $x_I (resp. x_{IV}) \notin V$. where V is $i(gg)^*$- locally open set.
Sufficiency condition: By using the remark (3.8)(iii), (X, τ_I) is $i(gg)^*$- local P_0 iff (X, τ_I) is $i(gg)^*$- localS_0.

Theorem 3.10 If an intuitionistic topological space is $i(gg)^*$- local S_1, then it is $i(gg)^*$- local P_0
Proof: The proof follows from the remark and also from the above theorem.

Definition 3.11A subset A of an intuitionistic topological space $(X, \tau_I)$is called
$i(gg)^*$- local neighbourhood of a point $x_I (resp. x_{IV})$ iff there exists an $i(gg)^*$- locally open set
B such that $x_I \in B \subseteq A$.

Theorem 3.12 An intuitionistic topological space (X, τ_I) is $i(gg)^*$- local P_1 iff the singletons are $i(gg)^*$- locally closed sets.
Proof: Let $x_I (resp. x_{IV})$ be any intuitionistic point of an $i(gg)^*$- local P_1 and $y_I (resp. y_{IV})$ be any point different from $x_I (resp. x_{IV})$. Then there exists an $i(gg)^*$- locally open set U such that $y_I (resp. y_{IV}) \in U$ and $x_I (resp. x_{IV}) \in$/ U. Therefore $y_I (resp. y_{IV}) \in U \subset {x_I}^c$. That is ${x_I}^c = \cup \{U / y_I (resp. y_{IV})\}$ which is $i(gg)^*$- locally open. Hence singletons are $i(gg)^*$- locally closed sets.
Conversely, let $x, y \in X_\sim$with $x_I (resp. x_{IV}) \neq y_I (resp. y_{IV})$. This implies $y_I (resp. y_{IV}) \in \{{x_I}^c\}$. Hence $\{{x_I}^c\} \in i(gg)^*$- locally open set containing $y_I (resp. y_{IV})$ but not $x_I (resp. x_{IV})$. Similarly ${y_I}^c$ is $i(gg)^*$- locally open set containing $x_I (resp. x_{IV})$ but not $y_I (resp. y_{IV})$. Hence (X, τ_I) is $i(gg)^*$- local P_1.

Definition 3.13 An intuitionistic topological space (X, τ_I) is called $i(gg)^*$- locally regular if for each $i(gg)^*$- locally closed set A and any intuitionistic point $x_I (respx_{IV})$ belonging to $X - A$ (i.e, A^c) there exists disjoint $i(gg)^*$- locally open sets U and V such that A is contained in U and $x_I (respx_{IV})$ belongs to V.
Theorem 3.14 An intuitionistic topological space (X, τ_I) is $i(gg)^*$- locally regular if for each $x \in X$ and each $i(gg)^*$- locally open set U containing x_I (resp. x_{IV}), there exists an $i(gg)^*$-locally open set V for which $x_I \in V$ contained in $i(gg)^*$- local $cl(V) \subset U$.
Proof: Let X be an$i(gg)^*$- locally regular and $x_I (respx_{IV}) \in X$, $U \in i(gg)^*$LO$(X, x_I (resp\, x_{IV}))$. Then $X - U$ is $i(gg)^*$- locally closed and $x_I (respx_{IV}) \notin X - U$. By $i(gg)^*$- local regularity of$X$, there exists disjoint $i(gg)^*$- locally open sets V and W. Such that $x_I (respx_{IV}) \in V$ and $X - U \subset W$. i.e)$V \subset X - W$ and $X - W \subset U$. Then $x_I (respx_{IV}) \in V \subset i(gg)^*$- local $cl(V) \subset i(gg)^*$- local $cl(X - W) = X - W \subset U$. Hence $x_I (respx_{IV}) \in V \subset i(gg)^*$- local $cl(V) \subset U$.

Conversely, assume that for each $x_I(respx_{IV}) \in X$ and for each $i(gg)^*$-locally open set U containing$x_I(respx_{IV})$, there exists an $i(gg)^*$-locally open set V such that $x_I(respx_{IV}) \in V \subset i(gg)^*$- local $(V) \subset U$. Let F be an $i(gg)^*$- locally closed set of $X_\sim$ and $x_I(respx_{IV}) \in X - F$. Then there exists an $i(gg)^*$- locally open set V such that $x_I(respx_{IV}) \in V \subset i(gg)^*$- local $cl\,(V) \subset X - F$. Therefore $x_I(respx_{IV}) \in V$ and $F \subset X - i(gg)^*$- local $cl\,(V)$. Take $X - i(gg)^*$- local $cl(V) = W \Rightarrow F \subset W$. The intuitionistic sets V and W are $i(gg)^*$- locally open and are disjoint. Hence $X_\sim$ is $i(gg)^*$- locally regular.

ABSTRACT

Financial transactions have been transformed by blockchain technology, which has sparked the creation of potent fraud detection systems to guard against new threats. Current rule-based systems are limited in terms of accuracy and adaptability. The paper suggests a unique approach based on machine learning to address the shortcomings of current systems. The procedure involves meticulous data collecting, preprocessing, feature engineering, and the application of sophisticated machine learning techniques such as Random Forests, Support Vector Machines, and Isolation Forests in order to detect fraud effectively. Real-time monitoring and ongoing model review provide adaptability to new threats. The results show that the proposed system is superior to existing systems, with higher accuracy of (0.98) precision (0.94), recall (0.93), and a lower false positive rate (0.06). Additionally, with an average processing time of 70 ms, computational efficiency is greatly enhanced. The system provides cutting-edge protection against fraudulent activity in blockchain transactions, outperforming existing methods and improving overall security in decentralized exchanges.

Keywords: Blockchain, Machine Learning (ML), Fraud Detection, Transaction Security, Security Infrastructure, Digital Transactions, Random Forests (RF), Support Vector Machines (SVM).

INTRODUCTION

Blockchain technology has brought unmatched security and decentralization to the quickly changing world of financial transactions. Blockchain networks are not impervious to the ever-present threat of fraudulent conduct, despite their decentralized structure [1]. When faced with dynamic fraudulent approaches, the once-gold standard for transaction protection, rule-based fraud detection systems now face constraints in accuracy and adaptability

[2].The study explores the essential platform of blockchain security, providing an innovative shift from rule-based methods to a revolutionary machine learning-based strategy for fraud detection and prevention. As blockchain transactions become more integrated into global financial institutions, the necessity for effective security methods is more important than ever [3]. Existing systems, which frequently depend on standard techniques, fail to keep up with the advanced methods used by fraudsters [4]. The inadequacy of existing systems is made greater by their static nature, which lacks the flexibility to respond to evolving threats [5]. The study addresses the important need for innovation by offering a machine learning-driven architecture that dynamically analyzes transaction data, detects patterns, and adapts to resist emerging fraudulent techniques. The limitations of existing rule-based systems are complex. Their dependency on predetermined rules makes them vulnerable to manipulation by advanced fraudsters who constantly enhance their strategies. Furthermore, these systems frequently generate false positives and negatives, resulting in both unnecessary warnings and missing fraudulent actions. The lack of adaptability and real-time reactivity decreases the integrity of blockchain transactions even further. Recognizing these drawbacks, the proposed system employs a comprehensive ML-based methodology designed to address the inadequacies of existing fraud detection systems.

The study aims to revolutionize blockchain transaction security by introducing a ML-based fraud detection system. The objective is to overcome the limitations of existing rule-based systems by facilitating adaptability and real-time response to emerging threats. The paper begins with an introduction of blockchain security challenges, followed by a thorough related works that identifies gaps in existing approaches. The following sections, delve over the proposed machine learning-driven methodology in detail, covering data collection, model training, real-time monitoring, and efficiency optimization. The results and discussion compare the system's performance, leading to a solid conclusion and future research recommendations. In summary, the study establishes a path into a more secure and adaptable future in blockchain transactions, where the use of ML unleashes the potential for unmatched fraud detection capabilities. The following sections delve deeper into the revolutionary system's methodology, results, and implications, emphasizing its significance in ensuring the integrity of decentralized financial ecosystems.

Related Works

A blockchain network's credibility and economy are greatly impacted by fraudulent transactions. Consensus methods, like pos or pow, can confirm the legitimacy of a transaction, but character of the parties involved, or the verifiers cannot be verified as fraudsters or genuine. The study employs many supervised machine learning techniques to distinguish between authentic and fraudulent transactions. The aforementioned work also offers a thorough analysis of the differences between different supervised machine learning techniques [6]. A technique for locating blocked addresses on the Ethereum blockchain is suggested in the paper. Collected transaction history and blocked addresses from the Ethereum blockchain in the beginning. The Ethereum transaction graphs was then built, and address data—which included global metrics like PageRank—was acquired. In the end, models that predicted the address class were trained using basic machine learning techniques [7]. Being involved with real-time data can be difficult, even though ML methods were used to detect credit card transaction fraud. Consequently, the accuracy and effectiveness of the model can be raised by combining blockchain technology with machine learning. The suggested approach applied machine learning algorithms to the Ethereum dataset to identify and guard against fraudulent transactions [8]. The article investigates the concerns surrounding deception and anomalies within the Bitcoin network. Concerns of such kind are prevalent in online finance and transactions. Nonetheless, as the financial industry progresses, so do the protocols employed to identify fraudulent activities and anomalies. Moreover, there is considerable promotion of blockchain technology as the most secure method for integrating financial systems. However, as a result of these advancements in technology, fraud has become increasingly prevalent. In consequence, it provides a secure method for detecting fraud by leveraging blockchain and machine learning technologies [9]. The automation of these procedures enables the generation of insightful input network observations. Using several machine-learning algorithms, the article identifies unusual transactions in several digital currency exchanges. It discovers that, while unsupervised learning techniques have a harder time categorizing, supervised learning tactics produce positive results [10]. The validity of the information recorded on the BC may be compromised by fraudulent data insertion, which could result in inaccurate or misleading transactions and compromise the integrity and

dependability of the BC. The reputation of BC as a transparent and safe system for transaction recording and confirmation depends on the identification and prevention of fraudulent data insertion. SCs are open to various adverbial attacks because itoversees asset transfers. Consequently, many approaches, including the usage of programming tools, have been proposed to identify SC vulnerabilities and attacks. These proposals, meanwhile, are inadequate in light of recently uncovered weaknesses and attacks [11]. Blockchain technique has the ability to stop these kinds of losses before it start. The study examines blockchain technology's possible uses, security precautions, and strategies for lowering credit card fraud risk. The study also discovers and investigates a possible method of preventing credit card theft by utilizing biometric instruments, multiple identifications, and SR4S randomized OTP [12].

The study's goal is to find abnormalities in the Ethereum blockchain network using a pattern recognition architecture based on a One-Class Graph Neural Network. Empirical evaluation reveals that the proposed method outperforms existing non-graph-based machine learning methods in terms of finding anomalies accuracy [13]. To facilitate inter-organizational collaboration, the research proposes employing blockchain technology and smart contracts to create a robust ML algorithm for online e-commerce fraud identification. The proposed approach makes use of blockchain technology to safeguard data privacy. The system is fully automated by a smart contract that is deployed over a network. A Machine Learning model is progressively enhanced by collaborative data supplied by blockchain-connected enterprises [14]. To improve defenses against a variety of frauds, system have been evaluated with several credit card fraud detection approaches in the study. Further, documented the research problems and assessed the results. Lastly, contrasted with several methods and emphasized the benefits and drawbacks of each. It will assist in offering direction for choosing the best methods for detecting credit card fraud [15].

The evaluation of the literature highlights the limitations in existing fraud detection approaches, highlighting the necessity for adaptive solutions. Because of the limitations of existing systems and their static nature, dynamic machine learning techniques must be adopted in order to improve blockchain transaction security.

Proposed Method

Existing systems for detecting fraud in blockchain transactions typically depend on traditional rule-based methods, which have limitations in adaptability and accuracy when challenged with evolving fraudster techniques. The proposed system, on the other hand, introduces a significant transformation by utilizing the power of ML to improve fraud detection and prevention in blockchain transactions. The proposed system begins by addressing the drawbacks of existing systems, highlighting the need for a more dynamic and intelligent system for fraud detection. The machine learning system is intended to thoroughly analyze transaction data, taking into account elements such as transaction patterns, user habits, and abnormalities. The system, unlike rule-based systems, adapts and learns from prior data, enabling it to detect unique and advanced fraudulent actions. The proposed system's implementation involves several important steps. To begin first, collect and preprocess blockchain transaction data to ensure that the dataset is representative of various transaction circumstances. The machine learning model is then trained using supervised learning techniques with labeled data to educate the system to distinguish between legal and fraudulent transactions. The model is updated periodically to improve its prediction powers. When the system has been trained, it is connected to the blockchain network for real-time monitoring. The model assesses patterns and behaviors during transactions, detecting abnormalities that could indicate potentially fraudulent activities. The proactive strategy enables quick intervention and mitigation, stopping fraudulent transactions that could affect the blockchain network's integrity. The flowchart of proposed system is illustrated in below fig.1.

The benefits of employing the proposed methodology are numerous. First, when compared to rule-based systems, the machine learning-based technique greatly improves fraud detection accuracy, lowering false positives and negatives. The model's adaptability means that it can evolve to handle emerging dangers, providing strong protection against evolving fraudulent strategies. Furthermore, real-time monitoring improves the system's responsiveness, allowing for timely intervention and the avoidance of fraudulent transactions. As blockchain technology continues to transform the financial landscape, the integrity and security of transactions across

decentralized networks become increasingly important. With the development of fraudulent activity posing dangers to these transactions, a robust fraud detection system is essential. The implementation methodology looks into the advancement of designing and operating a comprehensive machine learning-based fraud detection system designed specifically for blockchain transactions.

Data Collection and Preprocessing:

In the Data Collection and Preprocessing phase, a meticulous approach is employed, utilizing various datasets sourced from trusted blockchain explorers like Blockchain.com, Blockchair, Blockcypher, Coinmarketcap to establish a representative and comprehensive dataset reflecting the intricacies of blockchain transactions. The dataset covers a wide range of transaction scenarios, including peer-to-peer transfers, smart contract executions, token swaps, and cross-border transactions, ensuring dataset diversity and relevance. For noise reduction and data quality assurance, rigorous preprocessing steps include techniques such as outlier removal, data normalization, and missing value imputation. Techniques like dimensionality reduction and polynomial expansion are used in feature engineering. These methods were chosen to improve model interpretability, capture complex relationships, and overall fraud detection effectiveness in blockchain transactions. The Dataset sample from Blockchair website is shown below in fig.2.

Selection of ML Algorithms:

To improve fraud detection, the paper uses Random Forests and Support Vector Machines (SVM) in the realm of supervised learning. Random Forests are selected due to their effective handling of labeled training data and their ability to capture intricate transaction patterns. Simultaneously, SVM, chosen for its inherent robustness, contributes significantly to the model's discriminative ability, enabling accurate classifications between legal and fraudulent transactions. These algorithms work within the framework of supervised learning, iteratively adapting to labeled datasets to continuously improve their predictive capabilities. The system was developed in Python, and it makes use of machine learning libraries like Scikit-Learn for Random Forests and SVM implementation, ensuring efficiency and flexibility.

Model Training and Adaptation

Training involves utilizing a carefully labeled dataset for Support Vector Machines (SVM) and Random Forests (RF), where SVM focus on creating an optimal hyperplane and RF constructs an ensemble of decision trees. The system employs the Isolation Forest algorithm through unsupervised learning to handle unknown threats with unlabeled data, effectively detecting anomalies and adapting to emerging fraud patterns in real-time. To minimize prediction errors, model parameters are iteratively adjusted during the training procedure. Continuous adaptation is achieved through frequent model updates in response to evolving fraud patterns. The dynamic process distinguishes proposed system from static rule-based methods, ensuring adaptability against emerging threats. Refinement occurs through periodic changes that improve predictive capabilities. The system's uniqueness lies in its adaptive nature, which gradually improves efficacy over time.

Real-Time Monitoring and Anomaly Detection:

The model goes through a comprehensive integration procedure as it effortlessly integrates into the blockchain network. Initially, the model creates a secure connection and gains access to transactional data. The system rigorously examines continuous transactions, identifying deviations from known patterns using anomaly detection methods, which includes the Isolation Forest for unsupervised learning. The proactive approach guarantees prompt action, preventing potential fraudulent transactions and enhancing the general integrity of the blockchain network against evolving threats. The Isolation Forest algorithm improves flexibility by addressing unexpected threats with unlabeled data successfully. When abnormalities are detected, the system offers real-time output via a user-friendly web interface, allowing for rapid response and intervention. The block diagram of proposed model is shown in below fig.3.

Model Evaluation and Improvement:
The model's efficacy is thoroughly evaluated by using key metrics like accuracy, precision, recall, and the F1 score. Following that, a continuous refinement process begins, which includes fine-tuning hyperparameters and validation against various datasets. The continuous refining technique enables adaptation to new fraud strategies while also continuously improving overall performance. The dataset used consists of 10,000 blockchain transactions, with an 80-20 split for training (8,000) and testing (2,000), enabling complete model evaluation on previously unexplored data.

Optimizing Computational Speed for Swift Fraud Detection:
By selectively incorporating these cutting-edge algorithms, computational optimization efficiency is improved, allowing the proposed approach to drastically reduce average processing time. The enhanced computing performance outperforms existing systems, guaranteeing that blockchain transactions are evaluated quickly. The increased efficiency not only contributes to more robust real-time monitoring, but it also establishes a more resilient defense against fraudulent activities in the blockchain ecosystem. In conclusion, the proposed methodology provides a thorough strategy for securing blockchain transactions from fraud. Building a resilient defense mechanism requires data gathering, preprocessing, and blockchain network integration of a finely calibrated model. Feature engineering, algorithm selection, and continuous model review assure fraud strategy flexibility. It protects decentralized exchanges from dynamic and complex threats by seamlessly integrating the fraud detection system into the blockchain network.

RESULTS AND DISCUSSION

To evaluate the effectiveness of the proposed approach for detecting fraud in blockchain transactions, its performance is compared to that of the existing system. The evaluation is carried out utilizing key metrics such as precision, recall, and the F1 score, which provide a comprehensive perspective of the fraud detection system's capabilities. The analysis involves a comparison of three separate scenarios, illustrating the superiority of the proposed methodology.

Table I compares key performance metrics for fraud detection systems such as Existing System [7], Existing System [10] found by the peer researchers (B. Kılıç and K. E. Martin) respectively, and the Proposed System. Accuracy of the proposed system is (0.98) where existing systems have accuracy of (0.97) and (0.93). Precision which measures the accuracy of positive detections is much higher in the Proposed System (0.94) than in Existing Systems [7] (0.90) and [10] (0.89). Recall, which measures the system's ability to recognize all relevant occurrences, is likewise significantly higher in the Proposed System (0.93) than in Existing Systems (0.92) and (0.91). With a value of 0.93, the F1 Score, the average of precision and recall, further strengthens the Proposed System's dominance, outperforming the scores of Existing Systems (0.91) and (0.90). These results with illustrated representation in fig.4support the Proposed System's improved efficacy, demonstrating its increased capacity to detect fraudulent transactions.

Table II shows the frequencies of False Positives (FP) and False Negatives (FN) for Existing System [7], Existing System [10] found by the peer researchers (B. Kılıç and K. E. Martin) respectively, and the Proposed System. The FP Rate is the fraction of legitimate transactions that were wrongly flagged as fraudulent, whereas the FN Rate is the incidence of malicious transactions that went undetected. A lower FP Rate is beneficial in the context of fraud detection to reduce the number of false alarms, while a lower FN Rate is essential to discover as many fraudulent transactions as possible. In terms of FP and FN Rates, the table II shows that the Proposed System outperforms both Existing Systems [7], [10] demonstrating its improved capacity to reduce both wrong detections and missed fraudulent transactions. It demonstrates the importance of the proposed methodology in improving the precision and recall of the fraud detection system, resulting in a stronger and dependable defense against fraudulent activity in blockchain transactions.

Table III provides a comparison of the computational efficiency of several fraud detection methods. The average processing time, measured in milliseconds (ms), is an important indicator of the speed and responsiveness of the system. Existing System [7] takes 100 ms to process, Existing System [10] takes 120 ms, and the Proposed System outperforms both with an average processing time of 70 ms. The table III highlights the proposed methodology's efficiency advantages, exhibiting its capacity to quickly evaluate blockchain transactions, guaranteeing a more responsive and agile fraud detection system as compared to existing systems. The faster processing time not only improves real-time monitoring capabilities but also adds to a more efficient and effective defense against fraudulent activity in decentralized exchanges.

The discussion section, emphasize the revolutionary effectiveness of the proposed approach for detecting fraud in blockchain transactions. By significantly surpassing existing methods in terms of precision, recall, and F1 score, the approach not only enhances the security of decentralized exchanges but also revolutionizes the field of fraud prevention in blockchain transactions. The distinctions in performance are effectively illustrated through the visual representation in fig.4, which highlights the methodology's superiority. The real-world application of the approach extends beyond numerical metrics. Due to its ability to adapt to changing fraud patterns, it serves as a dynamic barrier against emergent threats. The decrease in false positive and false negative rates plays a critical role in boosting the detection of fraudulent transactions and minimizing unnecessary alerts, both of which are essential for preserving the integrity of blockchain networks. The proposed system offers numerous benefits. The computational efficacy of the system is demonstrated through its average processing time of 70 milliseconds, which not only supports real-time monitoring but also accelerates transaction evaluation. Ensuring efficacy is of the utmost importance in the dynamic realm of blockchain transactions. The approach proposed in the study represents an important shift from traditional rule-based systems by incorporating machine learning principles. The achievement of the system can be attributed to its rigorous data preprocessing, supervised learning utilizing Random Forests and SVM, continuous adaptation, and real-time monitoring. With the increasing integration of blockchain technology into worldwide financial systems, the approach serves as a driving light, offering exceptional safeguards against fraudulent operations and enhancing the security infrastructure of decentralized exchanges as a whole.

CONCLUSION

In conclusion, the study emphasizes the effectiveness of machine learning in strengthening blockchain transaction security by providing a dynamic and adaptive defense mechanism against fraudulent operations. The enhanced performance of the proposed methodology, as indicated by increased accuracy, precision, recall, and lower false positive and false negative rates, strengthens the system as a unique solution for decentralized exchanges. The increased processing efficiency enhances its real-time monitoring capabilities. In the future, researchers may investigate the combination of advanced anomaly detection techniques with reinforcement learning algorithms to continuously improve the model's flexibility. Furthermore, including explainability elements in the machine learning model would increase transparency and trust in the fraud detection system. However, it is critical to recognize limitations, such as the system's dependency on the quality and representativeness of training data, which may affect generalization to new and unknown circumstances. Furthermore, adversarial attacks on the ML model provide a problem that demands continuing research and development to strengthen the system's reliability against increasing threats. Addressing these future directions and limits will boost machine learning's efficacy and usefulness in ensuring the integrity of blockchain transactions.

ABSTRACT

This review provides a comprehensive, comparative examination of antibiotic-resistant bacteria isolated from distinct categories of water samples, including drinking water, groundwater, river water, lake water, wastewater effluents, hospital discharge, industrial wastewater and agricultural runoff from diverse geographic regions. Multiple studies indicate that wastewater, hospital effluents, and untreated or partially treated discharges contain the the highest concentration of multidrug-resistant(MDR) pathogens, these include members of *Enterobacteriaceae* (e.g., *Escherichia coli, Klebsiella* spp.), *Pseudomonas aeruginosa*, *Vibrio* spp., and *Aeromonas* spp. and *Staphylococcus aureus*, these pathogens exhibit resistance to multiple drug classes, including β-lactams, carbapenems, aminoglycosides, tetracyclines and fluoroquinolones. Even in treated drinking water systems, trace levels of antibiotic resistance genes(ARGs) have been detected. Broad comparative data have demonstrated large differences in microbial contamination and resistance among water samples, which relate to differences in sanitation infrastructure, antibiotic consumption, industrial residues, agricultural practices, and water treatment efficacy. The review focuses on the importance of water bodies as reservoirs of antibiotic resistance and sources of horizontal gene transfer resulting in the dissemination of antibiotic resistance in the environment between microbial communities. As human, agricultural, and industrial waste is progressively entering water bodies, more monitoring,

better treatment of effluents and tighter regulations, new wastewater treatment methods, and a One Health strategy are important.

INTRODUCTION

Greater attention is already being paid to the fact that the proliferation of the antibiotic -resistant bacteria (ARB) in aquatic environments is emerging as a serious environmental and health issue in the contemporary world. Anthropogenic wastes are not only deposited in aquatic systems (e.g., rivers, lakes, groundwater, drinking water supply systems, industrial discharges, and wastewater), but also can be the sources and reservoirs of the Antibiotic Resistance Genes (ARGs) and resistant pathogens [1]. Therefore, this review seeks to provide a summary of comparative studies of ARB and ARGs in the various water environments with an emphasis on pathogenic and opportunistic pathogens isolated in drinking water, ground water, surface waters, wastewater, and agricultural runoff. In this review, the patterns of resistance, the types of methods employed to characterize resistance, and implications of ARB and resistance to the water quality and the policy of public health will be described. Aquatic environments are highly variable in terms of their physicochemical attributes, pollution sources, microbial association, and anthropogenic interactions. Groundwater, which is commonly tapped using wells or boreholes, is usually assumed as being microbiologically safer, microbially speaking, but resistant pathogens can be brought into aquifers through agricultural contact, septic spillage and industrial effluents with shallower or unconfined systems [2].

Occurrence of Pathogenic Bacteria in Water

Pathogenic and opportunistic bacteria are commonly found in numerous aquatic ecosystems due to the ongoing loading from household sewage, hospital waste, agricultural activities, or the natural microbial populations. In the group of enteric pathogens, *Escherichia coli* remains the most frequently monitored indicator organism; however, several pathogenic strains, such as enterohemorrhagic *E. coli*, have also been reported from surface water and treated river water, indicating fecal contamination and poor waste management [3]. Figure1.Major aquatic environments evaluated in comparative AMR studies, highlighting potential contamination sources and exposure pathways. *Salmonella* spp.and *Shigella* spp. both associated with gastrointestinal disease, have also been isolated from rivers, lakes and agricultural runoff, particularly where untreated sewage or livestock waste is discharged into natural water [4]. *Vibrio* spp. including *Vibrio cholerae*, are detected in brackish and coastal waters, and several species present a significant risk to public health in tropical countries when the temperature and salinity of the water are optimal for growth [5].Opportunistic pathogens, including *Pseudomonas aeruginosa*, and *Acinetobacter* spp., are frequent inhabitants of wastewater and hospital effluents, where they can establish biofilms and survive in distribution networks [6].Other Gram-positive pathogens such as *Staphylococcus aureus* and *Enterococcus* spp. Have also been identified in wastewater and natural water that has been affected by urban discharge due to their clinical and community origin. The existence of such bacteria is frequently linked to the anthropogenic factors, including antibiotic treatment and the population density [7]. the systematic observation of the pathogenic bacteria in numerous aquatic habitats reminds the interconnection of human, agricultural, and environmental systems. Their tenacity and capacity to develop antibiotic resistance elevate the threat of the spread of waterborne diseases and emphasize that further monitoring and treatment activities are required.

Antibiotic Resistance Patterns in Waterborne Bacteria

The presence of the *Escherichia coli* and *Klebsiella* strains with the ability to produce ESBL-producing extended-spectrum β -lactamase is frequently found in wastewater, surface water and agricultural runoff, which indicates that the β -lactam resistance of a healthcare setting was migrating into the environment [8]. The rising rate of carbapenem

resistance, part of which is explained by the association of carbapenemase-producing *Pseudomonas aeruginosa*, *Acinetobacter* spp. And *Enterobacter's*, are especially disturbing in both wastewater and healthcare effluents, as these organisms prefer to host highly mobile genes including blaKPC, blaNDM and blaOXA-48, and it is a deadly threat to environmental dissemination [9]. Also, largely documented is the level of fluoroquinolone resistance in bacteria recovered in rivers, lakes and coastal waters as a result of mutation in gyrA and parC or the plasmid-based qnr genes, which is indicative of overuse in therapy as well as the survival in the aquatic environment [10]. The resistance determinants of tetracycline and sulfonamides including tetA, tetM and sul1 resistance determinants have been commonly isolated in the waterborne bacteria in regions affected by agricultural activities which involve veterinary antimicrobial use. Often, they have been identified alongside integrons and transposons, allowing them to be easily exchanged in communities of microorganisms [11]. Comparative Distribution of Antibiotic-Resistant Bacteria and resistance determinations Across Major Aquatic Environments (Table .1).

Methods Used for Bacterial and Resistance Analysis

Standard media for the recovery of clinically relevant organisms, including *E. coli* and *Pseudomonas aeruginosa*. From surface and wastewater samples are MacConkey agar, Cetrimide agar, and selective chromogenic plates [12]. Conventional polymerase chain reaction (PCR) for the detection of specific resistance genes (e.g. blaTEM, blaNDM, tetA, sul1) and quantitative PCR (qPCR) methods used for the quantification of abundance of antibiotic resistance genes in samples provide excellent results, have a higher sensitivity than culture methods, and are generally very useful for samples with low bacterial loads such as drinking and groundwater [13]. More recently, developments in High-throughput Sequencing (HTS) and metagenomics have extended the possibilities of analyses of AMR surveillance in aquatic environments. Metagenomic sequencing offers a unique way to profile microbial communities in depth, find organisms that cannot be cultured, and identify Mobile Genetic Elements (MGEs) like plasmids and integrons responsible for horizontal gene transfer within communities[14].

Environmental Factors Influencing Antibiotic Resistance

Continuous introduction of antibiotic residues as one of the major environmental drivers. The antibiotic residues are discharged into the water system in the sub-inhibitory concentrations that exert a selective pressure on the ecosystem which favors resistant bacteria and suppresses vulnerable ones. Wastewater Treatment Plant (WWTP) effluents, hospital discharge and waste of pharmaceutical industry may be the sources of antibiotics [15]. Similarly, the trends of resistance are important in hydrologic and physicochemical factors. The temperature will affect the rates of growth and the rates of gene transfer in bacteria, whilst the warmer waters will generally yield greater quantities of ARGs. Similarly, the pH, salinity and dissolved oxygen will alter the microbial activity too and might alter the stability and degradation of antibiotics. The inert or stagnant waters (i.e. ponds, low flow rivers) act as reservoirs to resistant bacteria and pollutants. The significance of sediment might be particularly significant in the perspective of ARGs as a permanent reservoir of bacterial parts and also a haven where the communities of the microbes are vulnerable to less UV (UV) radiation by the sun and predation [16]. The other significant environmental force is the co-selection processes caused by the non-antibiotic contaminants. Antibiotics are commonly found in combination with heavy metals (e.g. copper, zinc and mercury) and biocides (e.g. disinfectants and pesticides) in water. These compounds are selective to multidrug-resistant bacteria, since there are metal resistance genes and antibiotic resistance genes that have the same genetic module (MGEs).This co-existence enhances the survivability of resistant organisms in the absence of antibiotics [17].

Public-Health and Environmental Implications

Once settled in the communities these organisms can cause infections which have minimal treatment options. Increasingly, there is an outbreak-related water being reported, which is caused by resistant pathology that is developed mainly in under-hygienic communities or where introduction of untreated wastewater into drinking water systems has occurred [18]. The fact that ARGs are found in the drinking water that has been treated, even in small amounts, demonstrates that the traditional method of drinking water treatment was not efficient enough to prevent the further distribution of the pollution and it posed a threat of constant exposure to the populace. The environmental effect is also severe. The release of antibiotics, heavy metals, biocides and untreated wastes in the

water bodies results in the water bodies becoming centers of horizontal gene transfer(HGT), in which resistance phenotypes are exchanged in environmental microbes. This improves the ARGs in natural environment and serves as the reservoirs of ARB and ARGs where resistance in clinically relevance may arise. The ARGs are deposited in the sediments and biofilms and benthic microbial groups in the long term such that the pollution remains long after it has been eliminate[19].

Control and Mitigation Approaches

The ever-growing prevalence of the antibiotic-resistant Bacteria (ARB) and the antibiotic resistance genes (ARGs) in ecologically complicated aquatic systems necessitate multifaceted and integrated intervention efforts. The interventions have to be effective with the inclusion of technology, regulation, ecology and the public-health interventions with regards to the sources, pathways, and drivers of antibiotic resistance at the interface between the aquatic environments. Because the water system is a significant nexus linking the human, agricultural and environmental health systems, any interventions made should be based on a One Health approach whereby cooperation among all fields and long-term sustainability are of primary importance.

Improving Wastewater Treatment Technologies

Wastewater treatment plants (WWTPs) play the significant role considering that they act as a source of intervention since they are regularly exposed to a significant level of antibiotics, chemicals, pathogenic bacteria, and mobile genetic elements. Ozanation, UV/H_2O_2 and photocatalysis are Newest Oxidation Processes (AOPs) which have shown a capacity in the lowering of concentration and alteration of composition of antibiotic compounds and ARGs. Physically, ozonation can destroy cell membranes and the DNA of bacterial so that it can successfully negate cultivable ARB and ARGs [20].

Mitigating Inputs of Antibiotics and Chemicals

The mitigation should also be aimed at the upstream causes of resistance pressure that is brought into aquatic systems. It is generally agreed that judicious use of antibiotics in medical practice is a major concern. A stronger antimicrobial stewardship policy, including disavowing unnecessary prescriptions, administering narrow-spectrum drugs, and treatment adherence, can reduce the concentrations of unmetabolized antibiotics in wastewater as a result of hospital release. The same could be mentioned about agriculture, it is also vital to decrease the use of antibiotics in the livestock and aquaculture. The prevention of prophylaxis use and development, enhancement of animal hygiene and health, immunization and probiotics lead to the reduction of antibiotic dependence and its subsequent environmental pollution [21].

Controlling agricultural runoff and managing manure

Agricultural runoff is a significant source of ARB, ARGs, and antibiotic residues in rural water bodies. Manure/slurry derived from livestock operations generally is an environmental reservoir for resistant bacteria as a consequence of the antibiotic treatment of livestock. Composting and anaerobic digestion of manure are effective treatment processes that can lower bacterial viability and degrade some of the antibiotics that it may contain. Thermophilic composting can be a process designed specifically to reduce the abundance of ARGs through heat inactivation of resistant bacteria and microbial competition. Anaerobic digestion similarly can lower the total load of tetracycline and sulfonamide resistance genes (though total removal is rare) [22].

Enhancing Environmental Surveillance and Monitoring

Ongoing surveillance is notable for identifying hotspots of emerging resistance and assessing the effectiveness of interventions. The surveillance systems should include the use of microbial and chemical and genomic indicators to apply rapid identification of emergent resistance. The advantages of standardized sampling, quantitative polymerase chain reaction (qPCR)-based ARG quantification, and metagenomic profiling are shown by environmental AMR surveillance networks including one that is currently being built in Europe, and another one that was built in Asia. Such networks also start explaining spatial patterns and interventions to be applied. They need to be extended to the rest of the globe, with a focus on low-resource regions, to ensure equal global AMR abatement activities [23].

Policy Interventions and Regulatory Frameworks

Effective mitigation options require political support, i.e., environmental regulation. Regulatory standards for antibiotics, ARGs, and co-selecting pollutants in the water environment have been increasingly influenced by researchers and policymakers. Effluent standards for pharmaceuticals have been developed in several countries, which promote capital investment in advanced treatment problems. Regulations against incorrectly releasing untreated hospital wastewater and allowing health facilities to discharge without pre-treatment, and monitoring the treatment of industrial waste are all required components of AMR mitigation [24].

Community Engagement and Awareness

Still, the value of public participation as an aspect of the interventions is underestimated but a mandatory condition. Community level contamination can be reduced by educational campaigns on appropriate disposal of antibiotics, the use of minimal chemicals in the house, and, the unnecessary use of antibiotics. The citizen-science water monitoring programs have also been effective in the sense that such programmes publicize the heightened awareness within the community and improved stewardship behaviour of the local water resource and create alternative data repositories on environmental AMR surveillance [25]. Engagement of the community ensures that the interventions are viewed as adhered to and strengthens the interventions to be sustained.

Integrated, Multisectoral Intervention Framework

No form of intervention, as well as jurisdiction, can effectively control the antibiotic resistance in aquatic systems. Since wastewater, agriculture, clinical practice, industrial effluent and natural systems are all interrelated, they demand an interdisciplinary multisectoral system. Combined technological innovation, antibiotic stewardship initiatives, agricultural reform, and regular environmental surveillance could produce synergistic solutions that can be even more effective than individual ones in an attempt to address antibiotic resistance in aquatic environments. The concept of an emergent One Health, where collaboration between sectors, common data systems, and universal AMR surveillance across sectors are viewed as vital factors in successful work is becoming a reality [26].

FUTURE DIRECTIONS

It has been the outbreak of the anti-biotic resistance (ABR) in water bodies that has caused a lot of scientific research but one thing is lacking in this information and that will not help us put counter measures to counteract the situation. Recent developments in areas of molecular biology such as (meta) genomics and environmental monitoring technology may have enhanced our knowledge of the antibiotic-resistant bacteria (ARB) and the Antibiotic Resistance Genes(ARGs), yet it is obvious that there are more intricacies in aquatic systems that require more in-depth and more intensive research strategies. This part identifies essential research gaps and sets future directions that need to be followed to develop comparative profiling of ARB that exists in variable water sources, facilitates health preparedness of the people, and create environmental stewardship that is sustainable.

Limited Data on the Distribution of Horizontal Gene Transfer in Real-World Water Systems

While there is now a substantial knowledge of horizontal gene transfer (HGT) as a mechanism of distribution of antibiotic resistance, most of this knowledge emerges from laboratory or clinical studies, and in the natural aquatic environment, HGT occurs as part of complex microbial consortia and many of the organisms involved in HGT are non-culturable.

RESEARCH GAPS INCLUDE

i. Rates of plasmid exchange under environmentally relevant conditions.
ii. The role of integrons, transposons and bacteriophages in the movement of genes in water.
iii. The interaction of environmental bacteria and human pathogens in biofilms, sediments and wastewater systems. Recent studies suggest that environmental stressors (sub-lethal concentrations of antibiotics or heavy metals) can

facilitate HGT, however, there is a paucity of robust empirical examples. There is a need for higher resolution experimental designs, including metagenomic time-series studies to estimate the frequency of HGT and characterize environmentally contextual factors for gene mobilization [27].

Limited Knowledge Regarding Biofilms as Reservoirs of Resistance

Biofilms, which are formed in drinking-water distribution systems, rivers, sediments, and wastewater treatment systems, create many ecological niches for the growth of numerous microorganisms, including ARB and ARGs. These microorganisms can interact with each other, coexist, and share genes where these populations have close proximity. Although biofilms are critical ecological niches for ARB and ARGs, research into the development of antibiotic resistance in biofilm communities is still ongoing due to the numerous technical difficulties in determining and sampling biofilms and characterizing the microbial assemblages present within biofilms. In addition to the need for more research, there are many unknowns about how the characteristics of biofilm communities vary among different aquatic habitats, including what resistance mechanisms are used by microorganisms living within the protective biofilm environment, how biofilms can act as reservoirs for clinically meaningful pathogens (for example, *Pseudomonas aeruginosa* and *Acinetobacter baumannii*), and whether biofilms can persistently hold ARBs in the environment. To address the knowledge gaps that currently exist in this area, new advanced imaging technologies, single-cell analytical methods and in situ molecular techniques will need to be developed to further define the structure and function of the biofilms of ARB and its potential for transferring or persistently storing ARGs in the environment [28].

CONCLUSION

This review shows that all aquatic environments, from treated sewage to drinking water, are important reservoirs for the dissemination of ARB and ARGs and that human influence from the clinic, farms, and households is responsible for introducing ARB and ARGs into these environments. Clinically significant pathogens and mobile genetic elements are abundant in these environments, providing evidence of the serious threat of horizontal gene transfer in these ecosystems, thus maintaining resistance in these ecosystems without any selective pressure. The lack of ability to fully remove these contaminants from conventional treatment systems demonstrates the connection of human and environmental health. Advanced molecular techniques, such as metagenomics, have greatly improved in their ability to monitor resistance, but large gaps still exist in our understanding of resistance dynamics within biofilms and in environmental conditions. A coordinated One Health approach to address this public health crisis must include improvements in wastewater treatment systems, increased antibiotic stewardship, regulated discharges of contaminants, and creation of global monitoring networks. If there is not an immediate and coordinated effort to address this public health crisis, the environmental resistome will continue to reduce the efficacy of antibiotics, and thus global public health will be placed at risk.

ABSTRACT

Spider silk is an exceptional natural protein fiber whose remarkable mechanical and biological properties make it a highly promising biomaterial for biomedical and tissue engineering applications. Its distinctive combination of high tensile strength, elasticity, toughness, biocompatibility, and slow degradation sets it apart from other biopolymers such as collagen, polylactic acid, and gelatin. While traditionally used for wound healing and sutures, the application of spider silk has expanded into modern biomedical fields, including tissue scaffolds, wound dressings, drug delivery platforms, and reconstructive medicine. Advances in molecular biology and recombinant DNA technology have addressed limitations in large-scale production, enabling the artificial fabrication of silk proteins with tailored properties. Additionally, emerging functional modifications—such as antimicrobial capabilities, self-healing behavior, and enhanced biomineralization—have further widened its biomedical potential. Despite these advancements, challenges remain in replicating the natural spinning process, achieving cost-effective production, and facilitating clinical translation. This article provides a comprehensive overview of spider silk's production methods, structural and functional characteristics, and expanding biomedical applications, with particular focus on its relevance to regenerative medicine and tissue engineering, while also outlining future challenges and opportunities for clinical adoption.

Keywords: Spider silk, recombinant proteins, biomaterials, tissue engineering, drug delivery

INTRODUCTION

Spider silk is an extraordinary natural protein fiber produced by spiders and has attracted considerable interest as a valuable biomaterial for biomedical and tissue engineering applications. To date, more than 40,000 spider species have been identified, with many more likely undiscovered. All true spiders produce at least one form of silk, while some species can synthesize several varieties depending on their specific silk glands [1]. Recognized as one of the toughest natural substances created by living organisms, spider silk is predominantly protein-based, contributing to its biocompatibility and environmental sustainability [2]. Its amino acid composition is notably rich in glycine and alanine, which play essential roles in determining its structural and mechanical characteristics [3]. Spider silk demonstrates exceptional mechanical strength, fatigue resistance, high energy absorption, biocompatibility, and a slow degradation rate. These features make it an extraordinary biopolymer with wide-ranging applications, especially in tissue engineering. Additionally, spider silk fibers display desirable traits such as low density, remarkable extensibility, and high tensile strength. For example, MaSp1 fibers are known for their superior tensile strength, whereas flagelliform silk is characterized by its outstanding flexibility [4].

Spider silk has been used in medical practice since ancient times, where it served as an astringent to help control bleeding [5]. Its first documented clinical use emerged in the 18th century, when it was employed for suturing. In recent years, spider silk has gained increasing attention as a biomaterial due to its excellent biocompatibility, durability, and ability to support tissue regeneration, particularly in bone and ligament repair [6]. Additionally, its by-products provide further benefits, as they are non-toxic, exhibit low immunogenicity, and can be easily cleared from the body. The versatility of spider silk broadens its biomedical applications, extending to sutures, wound dressings, breast reconstruction, cosmetics, and the treatment of gynecological conditions [7]. More recently, silk-based biomaterials have been investigated for their antibacterial and antimicrobial activities, though efforts to optimize these functions within tissue scaffolds are still ongoing [8]. Spider silk proteins have also been found to support biomineralization processes [9] and have been incorporated into the development of advanced self-healing biomaterials [10], paving the way for innovative smart material technologies. Compared with other biopolymers such as collagen, polylactic acid, fibrin, alginate, and gelatin, spider silk exhibits superior performance due to its ability to reduce inflammatory responses and provide scaffolds that effectively support cell adhesion and growth. Moreover, spider silk has been engineered into a variety of formats—including films, matrices, nanospheres, and hydrogels—for biomedical applications. Recent advancements have been further propelled by the recombinant production of spider silk proteins in diverse host systems, allowing the precise repetition of amino acid sequences and the tailoring of secondary structures to enhance functional properties [11].

Despite its many advantages, early medical research on spider silk was limited by the difficulty of acquiring adequate amounts from natural sources. However, advances in molecular biology and recombinant DNA technology have overcome these constraints, enabling large-scale production and facilitating both chemical and genetic modification of spider silk proteins [12]. These breakthroughs have significantly expanded its potential uses in regenerative medicine, reconstructive surgery, and drug delivery systems.

Structure and properties of spider silk

Spidroin is the protein that constitutes spider silk, share a similar primary structure and are exceptionally large, reaching up to 350 kDa per monomer [13]. They are composed of repeating domains that include both amorphous and crystalline regions. The amorphous regions, enriched with glycine-based motifs, provide elasticity, while the crystalline regions, formed from alanine-rich sequences that assemble into β-sheets, impart structural rigidity. The interplay between these crystalline and amorphous components determines the overall strength and elasticity of the silk. For example, major ampullate silk—the primary structural component of a spider's web—contains a high proportion of crystalline regions, whereas flagelliform silk is highly flexible and consists almost entirely of amorphous domains [5].

The crystalline portion of spider silk, consisting of highly durable layered β-sheets and the finely aligned structure of uniaxially oriented protein molecules [15], is responsible for its remarkable tensile strength [2,14]. This strength is derived from molecular interactions mediated through hydrogen bonding. As the number of hydrogen bonds within the β-sheets increases, the thermal stability, modulus, and tensile strength of the silk likewise improve. The main difference between parallel and antiparallel β-pleated sheets lies in the orientation of their strands: in parallel sheets, the polypeptide chains run in the same direction, whereas in antiparallel sheets, adjacent strands run in opposite directions [5]. The central domain of spider silk is composed of roughly 100 repeated sequences of glycine and polyalanine, which together account for about 60–90% of the fiber's structure [16]. The amount of alanine-rich blocks within this domain influences the degree of crystallinity, and therefore the strength and stiffness, of the fibers. In contrast, glycine residues are essential for providing the fibers with extensibility and resilience [17].

According to Gu et al. [5], dragline silk is mainly composed of glycine, alanine, proline, and tyrosine. Higher levels of glycine, alanine, and tyrosine improve the mechanical strength of dragline silk, whereas an increased proportion of glycine and proline enhances its elasticity.

Different glands responsible for producing spider silk

Lewis (2006) [18] reported that orb-web weaving spiders possess seven abdominal glands: the minor ampullate, major ampullate, aggregate, flagelliform, pyriform, aciniform, and cylindriform glands. These glands produce and secrete silk in a liquid state, which solidifies immediately after extrusion. The minor ampullate gland forms auxiliary spiral fibers, while the major ampullate gland produces dragline silk, known for its exceptional strength and its role in forming the main structural framework of the web. The aggregate gland generates fibers coated in a sticky aqueous layer, and the flagelliform gland produces fibers that form the central capture spiral. The pyriform gland creates fibers used for attachment and structural anchoring, whereas the aciniform gland produces fibers for prey wrapping and the delicate inner lining of egg sacs. Lastly, the cylindriform gland secretes fibers that compose the tough outer covering of egg sacs.

Table 1 shows the protein composition of different types of spider silks; features are elaborated below.

- The major ampullate gland produces MaSp1 and MaSp2 proteins. Its strength per unit weight surpasses that of steel. The composition includes approximately 37% glycine, 18% alanine, and 62% short-chain amino acids.
- The flagelliform gland produces silk that forms the capture spiral (Flag). This silk is sticky, highly elastic, and tough. Its composition consists of about 44% glycine, 21% proline, 56% small side chains, and 17% polar residues.
- Pyriform silk creates attachments to substrates (PySp1).
- Aciniform gland silk is used to wrap and immobilize freshly captured prey (AcSp1).
- Cylindriform gland silk produces egg cocoon silk, which is used to form protective egg sacs (TuSp1).
- Aggregate silk creates the sticky coating on the spiral, enabling it to effectively capture prey (AgSF1, AgSF2).

Production of recombinant spider silk

Biotechnological approaches have introduced new methods for producing spider silk proteins in a variety of host systems—including bacteria, plants, yeast, mammalian cells, and animals—enabling efficient and cost-effective large-scale synthesis [19]. Among these, the protein sequences most commonly utilized originate from *Nephila clavipes and Araneus diadematus* [4].

Recombinant protein production involves the following steps [20] :

- Identify the nucleotide sequence in natural DNA (isolate the sequence encoding the target protein)
- Design the recombinant DNA
- Choose an appropriate vector to carry and transmit the desired sequence
- Introduce the vector into the host organism (bacteria, yeast, plants, insect cells, mammalian cells, or transgenic animals)
- Cultivate the host organism to produce the target protein
- Isolate and purify the expressed protein

Producing spider silk proteins in bacterial systems is difficult due to their large molecular size and highly repetitive sequences enriched in glycine and alanine. Recent work using *E. coli* has attempted to address these challenges through alternative methods, such as employing the intein system to assemble protein subunits. This strategy has enabled the creation of chimeric fibers with impressive mechanical performance [12]. While mammalian and insect cell cultures are generally unsuitable for large-scale production of structural proteins, researchers have nonetheless achieved successful expression of spider silk proteins in several specialized cell types, including bovine mammary epithelial cells, hamster kidney cells [21], African green monkey kidney cells [22], and silkworm neural cells [23]. Table 2 summarizes the mechanical characteristics of dragline silk from different spider species, recombinant spider silk fibers, and two high-performance synthetic materials—Kevlar and steel.

Biomedical and tissue engineering applications:

Tissue engineering is a multidisciplinary field dedicated to developing biological substitutes that can repair, maintain, or improve the function of tissues or whole organs [11,24]. Biomaterials capable of replicating extracellular matrix properties or encouraging beneficial cell differentiation play a crucial role in its progress. For biomaterials to be effective in tissue engineering, they must possess essential features such as biodegradability, biocompatibility, the ability to support cell adhesion, growth, proliferation, and differentiation, as well as appropriate mechanical strength [25]. Spider silk has emerged as a promising biomaterial and a potential alternative for use in tissue engineering and regenerative medicine. In recent decades, silk fiber implants have also become widely adopted therapeutic tools [27, 28]. The following sections outline several applications of spider silk in different engineered tissues and implant systems.

Skin regeneration and Wound healing

Historically, natural spider silk was used to cover wounds and aid in the healing process [29]. In modern times, extensive studies on spider silk dressings—whether used alone or blended with materials like silkworm silk—have shown their effectiveness in treating burn injuries [30]. Baoyong et al. (2010) [31] investigated the application of recombinant spider silk materials as wound dressings in rat models. Porous films and membranes derived from pNSR-16 and pNSR-32, both incorporating RGD sequences, were tested for their ability to cover severe second-degree burn injuries. Collagen was used as the control, and 60 Sprague–Dawley rats were evaluated on days 3, 5, 7, 14, and 21. Wound healing rates, histopathological changes, and hydroxyproline content were measured. The findings revealed that both pNSR-16 and pNSR-32 performed significantly better than the control group, with increased bFGF expression detected on days 7, 14, and 21. Elevated hydroxyproline levels in the healed tissue further indicated improved skin regeneration in the treated groups. Recombinant spider silk proteins were genetically modified to include a fibronectin motif to improve cell adhesion, as previously described [14, 30]. Silkworm fibroin was fabricated into nanofiber mats and microporous scaffolds, which were then coated with the recombinant spider silk fusion protein FN-4RepCT (FN-4RC). These functionalized microporous silk scaffolds were applied to third-degree burn wounds in a rat model. After 14 days, the functionalized acellular scaffolds promoted faster wound healing than both the commercially available DuoDERM dressings and untreated controls.

Bone regeneration

Spider silk serves as an excellent three-dimensional scaffold for bone, tendon, and cartilage tissue engineering due to its superior elasticity and strength relative to many other natural and synthetic polymers [32]. Schacht and Scheibel created engineered spider silk variants derived from the two main dragline silk proteins of the European garden spider (Araneus diadematus), ADF3 and ADF4 [47]. Their engineered counterparts, eADF3 and eADF4, can be produced through an industrially scalable fermentation process in *Escherichia coli*. The repetitive backbone of eADF4 includes many glutamic acid residues, which can either be chemically modified or act as binding sites for cations, including drug molecules [33]. In the study conducted by Hardy [34], materials derived from recombinant spider silk proteins were found to promote biomineralization and increase alkaline phosphatase activity in human mesenchymal stem cells cultured on these substrates. The spider silk contained multiple carboxylic acid groups, enabling calcium ions to bind and support mineral formation. When a composite polymer mixture of eADF4(C16) with poly(butylene terephthalate) (PBT) or poly(butylene terephthalate-co-poly(alkylene glycol) terephthalate)

(PBTAT) was processed into films, calcium carbonate preferentially accumulated on the eADF4(C16) component rather than on the synthetic polymer. The Major ampullate spidroin 1 (MaSp1) protein, when combined with the BSP fusion protein, facilitates calcium-phosphate deposition, improves mesenchymal stem cell adhesion (which strongly supports their differentiation), and promotes substantial type II collagen production in cartilage cells [35]. As shown in earlier studies [36], careful control of biomineralization conditions allowed hydroxyapatite to be integrated onto native spider silk without compromising its mechanical properties. Natural bio-derived nanomaterials provide excellent scaffold characteristics for bone tissue engineering and cartilage repair. However, clinical use of silk-based scaffolds is still in development and will require thorough validation before regulatory approval can be achieved.

Nerve regeneration

Implanting biodegradable and biocompatible scaffolds as nerve guidance conduits (NGCs) is an effective approach for supporting axonal regeneration after peripheral nerve injury. Spider silk has been shown to enhance cell proliferation, migration, and peripheral nerve repair. Using specialized biodegradable guidance channels can further accelerate axonal regrowth by directing cells throughout the healing process. Spider silk threads were found to be compatible with human neuron cultures, showing strong cell adhesion, migration of cell bodies, differentiation, and neurite (axon) extension reminiscent of ganglion-like structures. After ten months, the regenerated axons displayed myelination, indicating successful Schwann cell migration through the scaffolds [37].

Pawar et al. (2019) [38] and Aigner et al. (2020) [39] reported the development of nerve guidance conduits (NGCs) fabricated from recombinant spider silk eADF4(C16) materials. Pawar et al. (2019) [38] showed that fibers produced from eADF4(C16) nonwoven electrospun meshes, combined with microfluidic systems, were capable of supporting collagen fiber formation. In contrast, Aigner et al. (2020) [39] created NGCs using self-rolling films designed to encapsulate PC-12 neuronal cells together with their supportive microenvironments. Lewicka et al. (2019) [40] investigated how stem cells and neural progenitors interact with recombinant spider silk. Cells cultured on spider silk substrates differentiated into neuronal and astrocytic lineages in a manner comparable to those grown on fibronectin-coated polystyrene plates. The study also found that 3D porous foam structures made from 4RepCT improved neural stem cell adhesion, viability, and differentiation into astrocytes in three-dimensional culture.

Stadlmayr et al. (2024) performed a comparative study of various spider silk types in relation to nerve regeneration, material characteristics, and Schwann cell behavior. The researchers assessed cell adhesion and morphology on fibers from *Trichonephila inaurata*, *Phidippus regius*, and *Nuctenea umbratica*. Rat stem cells (rSCs) were seeded onto the fibers and cultured for two weeks. Cell morphology was evaluated using DAPI-stained nuclei, while immunofluorescence staining for the rSC marker SOX10 confirmed culture purity exceeding 99% for all silk types. Proliferation rates were comparable across all samples, with *T. inaurata* fibers showing a slightly higher rate than *P. regius*. No significant differences were found between rSC behavior on *P. regius* and *N. umbratica* fibers. Overall, the study demonstrated that all three native spider silk fibers effectively support robust adhesion and proliferation of rSCs.

Antimicrobial material development

Biofilm formation, especially by antimicrobial-resistant strains, presents a significant challenge in healthcare environments. This has increased interest in designing materials that can prevent microbial attachment while still supporting mammalian cell growth. Some natural spider silks have evolved inherent resistance to microbial colonization, making them promising candidates for biomaterial applications. Many spider silk webs can withstand long-term exposure to microbes and remain undegraded for years, even under varying environmental conditions such as humidity, temperature, and habitat. This exceptional stability is particularly striking given that spider silk consists of proteins and amino acids, which would typically act as nutrient sources for microorganisms [41]. Zha et al. (2019) [42] and Zhang et al. (2019) [23] found that bacterial colonization and degradation of spider silk are inhibited by its bacteriostatic or microbe-repellent characteristics rather than by direct antibacterial effects. Their work also indicated that the complex arrangement of interconnected crystalline and non-crystalline regions may restrict access to nitrogen, a nutrient required for bacterial growth. Kumari et al. (2020) [43] created spider-silk–derived 2D and 3D materials intended to inhibit microbial colonization. Recombinant spider silk proteins, modeled

on the consensus sequences of *Araneus diadematus* dragline fibroins 3 and 4, were fabricated into 2D-patterned films and 3D hydrogels. Using a protein-platform approach, the researchers demonstrated that microbial adhesion is linked to the presence of hydrophobic patches. According to the primary sequences, these hydrophobic regions can be tuned either by introducing intermolecular charge–charge repulsion, as in eADF4(C16) and eADF4(C32NR4), or by exploiting the volume effect of the amorphous domain in eADF3(AQ)12. Conversely, the lack of charge in eADF4(X16) leads to tighter, less uniform packing of nano β-crystallites, generating additional microbial anchoring points. At the mesoscale, microbial attachment is strongest on surfaces that are rougher, more hydrophobic, and positively charged. Importantly, RGD-modified spider silk with evenly distributed hydrophobic patches resisted microbial growth while still permitting selective mammalian cell adhesion and proliferation.

Artificial blood vessel construction

Cardiovascular diseases often arise from impaired or abnormal vascular function, and replacing damaged blood vessels is a promising therapeutic strategy. Xiang et al. (2018) [55] created a hybrid vascular scaffold made of spider silk, PCL, and gelatin using electrospinning, and evaluated it in vivo by implanting it in rats. The scaffold demonstrated excellent hemocompatibility, supported the proliferation of host cells, and showed no evidence of genotoxicity or inflammatory factor release, indicating strong potential for use as a small-diameter vascular graft. This work underscored its promise for applications in vascular tissue engineering. Dastagir et al. (2020) [44] engineered blood vessel–like grafts using native spider silk as the structural backbone. C2C12 and ST1.6R cells were seeded onto the scaffold surfaces and cultured within a pulsatile-flow bioreactor (peak ~135 mmHg, trough ~90 mmHg). These constructs were evaluated alongside human blood vessels and compared with cell-seeded scaffolds produced without bioreactor conditioning. The results showed that the engineered vessels closely matched native blood vessels in morphology, function, and biomarker profiles, demonstrating that spider silk scaffolds serve as a strong and appropriate platform for vascular graft fabrication.

This study describes the creation of a tissue-engineered vessel (TEV) consisting of a dense layer of C2C12 and ST16R cells arranged on both sides of the matrix. The TEV incorporates a continuous endothelial layer to prevent thrombosis and thick muscular layers that provide structural support and help regulate vessel diameter. The construct is stable enough to tolerate pressures of at least 675 mmHg, although its burst pressure (3196 mmHg) remains lower than that of native arteries. Its compliance (12.1% per 100 mmHg) is similar to that of internal mammary arteries (11.5% per 100 mmHg). However, the TEV ruptures under a tensile stress of 3.3×10^5 N/m². Further in vitro tests—such as dynamic compliance measurements and kink radius analysis—along with in vivo studies are required to more fully assess the TEV's mechanical performance and structural reliability (Table 3).

Drug delivery

Soft, porous natural materials are well-suited for drug delivery systems, and silk-based biomaterials provide numerous possibilities for customizing these applications [45]. Spider silk, a hydrophobic biopolymer, contains all the key features necessary for efficient drug release [14]. Variables such as pH, ion type, and ion concentration play important roles in shaping the drug delivery performance of synthetic spider silk [46]. Due to its uniformity and ease of production, recombinant spider silk represents a promising vehicle for drug delivery or a diagnostic platform in biopharmaceuticals [47]. The spherical assemblies formed by recombinant spider silk proteins—such as eADF4(c16), MaSp1, and MaSp2—are especially useful for biopharmaceutical delivery. Of these, eADF4(c16) generates colloidally stable particles that carry a negative charge at physiological pH. An important feature of eADF4(c16) is its slow degradation, which allows for controlled drug release. Its submicroparticles are particularly effective for delivering small, positively charged compounds [48]. Mulinti et al. (2021) [49] designed a "plug-and-play" modular system in which spidroins can be readily engineered to include a thrombin-sensitive peptide while still enabling self-assembly into drug-loaded micelles and microcapsules. These constructs are intended to release their therapeutic cargo selectively in response to infection.

The study examined the release behavior of drug-loaded nanospheres under various conditions to assess infection-responsive delivery. Silk/TSP conjugate particles achieved a cumulative drug release of 84.4% in *Staphylococcus aureus*

(SA) media, compared with 18.9% in the absence of media, and 15.6% and 17.5% in SA and buffer media, respectively. By contrast, unmodified silk particles did not show infection-responsive release and instead exhibited passive leakage. Furthermore, in the presence of *S. epidermidis* media, drug release reached 20.8%, which was slightly higher than that of the control particles. The formulation was shown to release the drug selectively in infection media containing *S. aureus*. To assess its release behavior, the dialysis tubing method was used, and the collected samples were analyzed by UV spectroscopy. The results revealed that peak drug release (85%) occurred within the first 12 hours, after which the release rate gradually decreased, generating an approximately bell-shaped profile.

Future Perspectives

Integrating spider silk with nanotechnology, bioactive compounds, and smart material systems holds considerable promise for creating next-generation biomaterials with enhanced therapeutic capabilities. Progress in this area will depend on interdisciplinary efforts spanning molecular biology, materials science, and clinical medicine to overcome current translational barriers. Moreover, long-term in vivo evaluations, regulatory approvals, and cost-effective manufacturing approaches are essential for moving spider silk from experimental concepts to widely adopted clinical applications. With ongoing global research, spider silk has the potential to evolve from a natural wonder into a key material in regenerative medicine and contemporary healthcare.

CONCLUSION

Spider silk has emerged as an outstanding natural biomaterial, distinguished by its remarkable mechanical strength, biocompatibility, and biodegradability, making it highly valuable for biomedical and tissue engineering uses. Its exceptional tensile properties, elasticity, and versatility make it a promising option for wound healing, drug delivery, nerve repair, cardiovascular devices, and scaffold fabrication. With benefits such as biodegradability, sustainability, and compatibility with various therapeutic delivery systems, spider silk supports regeneration in tissues including nerves, bone, cartilage, muscle, tendons, skin, and blood vessels. Advances in recombinant DNA methods, protein engineering, and synthetic biology have enabled the creation of spider silk–based biomaterials that address the challenges associated with harvesting natural silk. However, key obstacles persist, especially in large-scale production, consistency, nanostructural characterization, and long-term in vivo assessment. Achieving safety and effectiveness will require further progress in biofabrication, functionalization approaches, and extensive clinical evaluation. In summary, spider silk represents a highly promising next-generation material for biomedical implants and regenerative medicine, with strong potential to span the divide between laboratory innovation and clinical use.

ABSTRACT

Navigational independence is a critical challenge faced by visually impaired individuals, necessitating the development of intelligent assistive technologies. This paper presents the development of a smart chaperone designed to assist visually impaired individuals by combining real-time object detection and distance estimation. The system leverages the YOLOv5 model trained on the COCO dataset for object recognition and three HC-SR04 ultrasonic sensors for accurate distance measurement. The average distance from the sensors is computed and combined with object detection results to provide real-time auditory feedback. This feedback allows the user to navigate complex environments more independently and safely. The proposed system is tested under different lighting and environmental conditions, showing high accuracy in both object detection and distance estimation. This research aims to enhance the mobility and safety of visually impaired individuals using affordable and accessible technology.

Keywords: Smart chaperone, YOLOv5, COCO dataset, object detection, ultrasonic sensors, visually impaired assistance, real-time feedback.

INTRODUCTION

The ability to navigate independently is a significant challenge for visually impaired individuals. According to the World Health Organization (WHO), approximately 2.2 billion people worldwide suffer from some form of vision impairment, with millions relying on traditional white canes for navigation. While white canes provide basic obstacle detection, they lack the ability to identify and classify objects or provide contextual information about the surroundings. To address these limitations, we propose a Smart Chaperone - an AI-powered smart walking cane designed to assist visually impaired individuals with real-time object recognition and distance estimation. The proposed system leverages the YOLOv5 (You Only Look Once) model trained on the COCO dataset for object detection and recognition. The system also integrates three HC-SR04 ultrasonic sensors to measure distances from detected objects, providing spatial awareness and real-time feedback. The main contributions of this work include:

- Development of a lightweight, real-time object detection system using YOLOv5 on a Raspberry Pi 4.
- Integration of ultrasonic sensors to estimate distances from obstacles.
- Implementation of a text-to-speech (TTS) module to provide audio feedback about the detected objects and their proximity.
- Evaluation of the system's accuracy, latency, and real-world performance under various environmental conditions.

MATERIALS AND METHODS

Methodology

The proposed system combines YOLOv5-based real-time object detection, ultrasonic sensor-based distance estimation, and text-to-speech (TTS)–based audio feedback to assist visually impaired individuals. The system architecture is shown in **Figure [1]**.

System Overview

The smart walking cane is built on a Raspberry Pi 4, integrating:

- YOLOv5 model: Performs real-time object detection from a camera feed.
- HC-SR04 ultrasonic sensors: Three sensors placed at different angles to measure obstacle distances. **Figure [2]**.
- Text-to-speech module: Converts detected object labels and distances into audio feedback. **Figure [3]**.

Object Detection Using YOLOv5

YOLOv5 is selected for its balance between speed and accuracy. The model is trained on the COCO dataset with 80 object categories.

Implementation Steps:

1. Load the pre-trained YOLOv5 model in PyTorch.
1. Capture frames from the Raspberry Pi camera.
2. Resize and preprocess frames for model input.
3. Detect objects and extract bounding box coordinates.
4. Output object labels and confidence scores.

Distance Measurement Using Ultrasonic Sensors

Three HC-SR04 sensors detect distances using the time-of-flight principle:

Distance formula

$d = (T \times v) / 2$

Where:

- d = distance (cm)
- T = round-trip time (s)
- v = speed of sound in air (343 m/s)

Average distance formula

$D_avg = (D_1 + D_2 + D_3) / 3$

The TTS module announces detected objects and distances in the format:

"Object: [Label], Distance: [Distance] feet."

Audio Feedback Using Text-to-Speech

1. Format object and distance as text.
2. Convert text to speech using Python TTS.
3. Play audio via Raspberry Pi speaker.

Workflow (Figure [4])

1. Capture video input.
2. Detect objects via YOLOv5.
3. Measure distances from ultrasonic sensors.
4. Compute average distance.
5. Provide audio feedback.

Experimental Setup

Hardware:

- Raspberry Pi 4 (4 GB RAM)
- Pi camera
- Three HC-SR04 ultrasonic sensors
- Headset for audio output

Software:

- YOLOv5 in PyTorch
- Raspbian OS
- Python-based TTS

Dataset:

COCO dataset with 80 object classes

RESULTS AND DISCUSSION

The proposed smart walking cane was evaluated under various real-world scenarios to assess the accuracy of object detection, distance estimation, and audio feedback.

Performance metrics included:

- Object detection accuracy
- Distance estimation error
- System response time

Figure 5 – Output received in smartphone using RealVNC Viewer

Object detection performance

The YOLOv5 model's detection capability was measured using standard evaluation metrics:

Precision:

$P = TP / (TP + FP)$

Recall:

$R = TP / (TP + FN)$

F1-Score:

$F1 = (2 \times P \times R) / (P + R)$

- TP = True Positives
- FP = False Positives
- FN = False Negatives

[Table [1] here – Object Detection Performance of YOLOv5]

Distance estimation accuracy

Distance estimation accuracy was tested under controlled conditions.

Average absolute error formula:

$$E = \Sigma |D_i - \hat{D}_i| / n$$

- D_i = actual distance (cm)
- $\hat{D}_i$ = measured distance (cm)
- n = number of samples

[Table [2] here – Mean Distance Estimation Error]

Response time

System response time includes:

- Object detection time
- Distance calculation time
- Audio feedback generation time

[Table [3] here – Average System Response Time]

Discussion

The proposed cane achieved:

- **F1-score:** 90.2% in object detection
- **Average distance estimation error:** 2.1 cm for objects within 1 m
- **Total response time:** ~5.2 s, adequate for real-time assistance

1)

2) Strengths

- High detection accuracy using YOLOv5
- Low distance measurement error
- Clear and timely audio feedback

3)

4) Limitations

- Reduced accuracy in low-light conditions
- Detection delay when multiple objects appear in frame

The YOLOv5 model accounted for **67% of the total processing time**, making it the main latency factor. Employing higher-performance hardware such as:

- NVIDIA Jetson Nano
- Google Coral Dev Board
- Intel NCS2

could significantly reduce processing delays and improve detection speed and accuracy.

CONCLUSION

The system achieved a mean average precision (mAP) of 92.4% and an average response time of 5.2 s. The use of three ultrasonic sensors improved distance measurement reliability by averaging readings from multiple angles.The results indicate that the proposed system offers reliable, real-time assistance for visually impaired individuals. Future work will aim to reduce processing latency, expand the object detection dataset to improve recognition accuracy, and incorporate obstacle avoidance mechanisms for enhanced safety and navigation.

ACKNOWLEDGEMENT

The authors sincerely thank our college - Sri Sivasubramaniya Nadar College of Engineering, Kalavakkam, Chennai for generously providing the funds for our project, and the department for offering the necessary facilities and support to successfully build and complete the project.

ABSTRACT

This systematic review and meta-analysis examined the effects of High-Intensity Interval Training (HIIT) on VO_2max and endurance capacity in healthy young adults aged 18–30 years. Declining aerobic fitness associated with sedentary lifestyles represents an important public health concern, and HIIT has emerged as a time-efficient alternative to traditional moderate-intensity continuous training (MICT). Following PRISMA 2020 guidelines, a comprehensive literature search was conducted in PubMed, Scopus, Web of Science, and SPORTDiscus for studies published between January 2020 and June 2025. Twenty-six studies were included in the qualitative synthesis, and eighteen studies were included in the quantitative meta-analysis. Random-effects meta-analysis demonstrated a statistically significant improvement in VO_2max and endurance capacity following HIIT interventions compared with control and, to a lesser extent, MICT. The pooled mean difference for VO_2max was +2.47 $mL \cdot kg^{-1} \cdot min^{-1}$ (95% CI: 1.35 to 3.58; $p < 0.001$), with a standardized mean difference of 0.68. Endurance capacity also improved significantly (pooled SMD = 0.58; $p < 0.001$). Typical HIIT protocols consisted of 4×4-min or 10×1-min intervals performed two to four times per week over 4–12 weeks at intensities of 85–95% HRmax. Additional favorable effects were observed in resting heart rate and body composition. These findings indicate that HIIT is an effective, adaptable, and time-efficient training strategy for enhancing aerobic fitness and endurance in young adults, with important implications for physical education programs, athletic conditioning, and health promotion initiatives.

Keywords: High-Intensity Interval Training; VO_2max; Endurance Capacity; Young Adults; Aerobic Fitness.

INTRODUCTION

Maximal oxygen uptake (VO_2 max), a popular indicator of cardiorespiratory fitness, is a reliable indicator of lifespan, physical performance and cardiovascular health. Since many studies show a reduction in aerobic capacity as a result of current living patterns, decreased physical activity and increasingly sedentary behaviour, low VO_2max levels among young individuals have become a global issue (Nguyen et al., 2022). Maintaining normal aerobic performance in early adulthood is crucial for maintaining productivity, cognitive function and general wellbeing as well as for lowering the risk of chronic diseases later in life (MacInnis & Gibala, 2021; Lee et al., 2021).The gold standard for increasing aerobic capacity and endurance performance has long been thought to be traditional moderate-intensity continuous training or MICT. It consists of 30 to 60 minutes of continuous, submaximal exercise at 60 to 75% of HRmax (Buchheit & Laursen, 2020). When compared to more recent training methods, MICT's efficacy is constrained by time inefficiency, young adults poor adherence and plateaued adaptations (Stöggl & Sperlich, 2020). HIIT, a time-efficient method that alternates short bursts of high-intensity exercise (>85–90% HRmax) with recovery intervals, has gained more attention as a result (MacInnis & Gibala, 2021; Milanović et al., 2021). In order to improve aerobic and anaerobic ability, HIIT promotes peripheral adaptations such as increased capillary density, mitochondrial biogenesis and muscle oxidative enzyme activity, as well as central adaptations such as increased cardiac output and stroke volume (Atakan et al., 2021; Gentil et al., 2023). It has been shown to be a useful technique for improving VO_2max, endurance and metabolic health even during brief periods of time, which makes it especially appropriate for college-aged people who frequently cite "lack of time" as the main deterrent to physical activity (Eddolls et al., 2023).

Comparative Evidence and Research Gap

HIIT and MICT have been compared in a number of randomised controlled trials and meta-analyses showing that HIIT can produce increases in aerobic capacity that are on par with or better than MICT in half the time spent exercising (Weston et al., 2014; Tschakert et al., 2023). According to Atakan et al. (2021), for example HIIT improved VO_2max by 9–13% over six weeks while MICT improved it by 6–8%. In a similar vein Stanković et al. (2025) found that after 8 weeks of HIIT interventions, adolescent and young adult females showed large improvements in VO_2max along with significant decreases in body fat and resting heart rate. However because of variations in study designs, intervention length, work-to-rest ratios and participant characteristics, the available evidence is still inconsistent. According to other research there are no appreciable differences between HIIT and MICT; this suggests that protocol structure such as sprint versus aerobic HIIT or short versus long intervals has a substantial impact on results (Wen et al., 2023). Furthermore the majority of earlier meta-analyses only applied to young, healthy individuals since they combined data from athletes, mixed-age adults or clinical groups (Kim et al., 2023; Menz et al., 2022). Young adults require a targeted synthesis because of the significant differences in their physiological responses, recovery patterns and rates of adaption compared to older adults.

Physiological Rationale

According to Gibala et al. (2020), HIIT is more effective than continuous training at increasing maximal cardiac output, enhancing oxidative phosphorylation and inducing greater mitochondrial biogenesis through activation of peroxisome proliferator-activated receptor gamma coactivator-1 alpha (PGC-1α). The oxygen transport and utilisation systems are challenged by the repeated near-maximum efforts during HIIT which leads to better VO_2 kinetics and quicker recovery rates. Interval training also improves lactate tolerance and buffering capacity which boosts endurance and performance sustainability (Buchheit & Laursen, 2020; Gentil et al., 2023).

Justification for the Present Review

Young adults are a transitional age group between youth and adulthood, during which time long-term habits are formed and scheduled physical exercise is frequently reduced due to lifestyle changes. Thus, public health, university-level physical education programs and athlete conditioning are all impacted by our understanding of how HIIT affects VO_2max and endurance in this age range (Eddolls et al., 2023; Kim et al., 2023). Using PRISMA-aligned

methodologies and recent data (2020–2025), no systematic review and meta-analysis has particularly looked at the outcomes of aerobic (VO_2max) and endurance capacity in young adults to date.

OBJECTIVES

Hence, this systematic review and meta-analysis aimed to:

i. Evaluate the effects of HIIT on VO_2max and endurance capacity in young adults compared with MICT or inactive controls;
ii. Synthesise training protocols, outcome measures and statistical trends across recent Studies .
iii. Provide evidence-based recommendations for exercise prescription and future research.

METHODOLOGY

Research Design

The Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA 2020) standards were followed in the conduct of this systematic review and meta-analysis (Page et al., 2021). To guarantee transparency and reproducibility, separate reviewers carried out each methodological step including search, screening, extraction and synthesis in duplicate.

Search Strategy

Between January 2020 and June 2025, a thorough literature search was carried out using four significant electronic databases PubMed, Scopus, Web of Science and SPORT Discus. The following Mesh phrases and keyword ("Sprint interval training," "HIIT," or "high-intensity interval training")

AND ("aerobic capacity," "VO_2max," "maximal oxygen uptake," or "endurance performance") AND ("young adults," "college students," or "university population") AND ("concurrent study," "intervention" OR "randomised" controlled trial"). To find further eligible trials, manual searches of the reference lists of the included studies and pertinent reviews were also carried out. "As shown in Figure 1 the PRISMA 2020 flow diagram illustrates the study identification screening and selection process." Figure 1. PRISMA 2020 flow diagram illustrating the identification, screening, eligibility assessment and inclusion of studies in the systematic review and meta-analysis.

Inclusion and Exclusion Criteria

The following inclusion criteria were used in the selection of studies:

Population: Healthy, chronic disease-free young adults (18–30 years old).

Intervention: Regardless of the type of exercise (running, cycling, bodyweight etc.) HIIT regimens lasting at least four weeks are recommended.

Comparison: low-intensity exercise, inactive control groups or moderate-intensity continuous training (MICT).

Results: At least one of the following must be reported VO_2max, VO_2peak and endurance capacity (as measured by an aerobic threshold, time-to-exhaustion test or graded exercise test).

Design: quasi-experimental designs, randomised controlled trials (RCTs) or non-randomized controlled trials.

Publication: peer-reviewed, English-language journals (2020–2025).

Exclusion criteria included

1. Research on old or ill populations
2. Combined training regimens (such as weight training and HIIT) without separate HIIT arms;
3. Single-session or acute (less than four weeks) investigations
4. Insufficient reporting of VO_2max/endurance data or the lack of a comparison group
5. Abstracts from conferences, dissertations, or papers that are not subjected to peer review.

Quality Assessment

The Physiotherapy Evidence Database (PEDro) Scale was used to assess the methodological quality of randomised controlled trials whereas the Modified Downs and Black checklist was used to evaluate non-randomized or quasi-experimental studies. The AMSTAR-2 tool was used to evaluate review or meta-analytic publications that were included for reference comparison. Every study received a rating of

High quality equals 18–25 Downs & Black score or 6–10 PEDro.

- Moderate quality equals 13–17 points or 4–5 PEDro.
- Low quality (= ≤5 PEDro or less than 13 points

For quality scoring, the inter-rater reliability was $\kappa = 0.81$ (good agreement).

Statistical Analysis

A random-effects model was used to conduct meta-analyses. Mean differences (MD) were calculated for outcomes measured on the same scale (VO_2max). Standardised mean differences (SMD) were computed for outcomes measured by various tests (endurance). The statistic was used to measure heterogeneity; low, moderate and high heterogeneity were represented by thresholds of 25%, 50% and 75%. One study at a time was eliminated for sensitivity analyses. Funnel plots and Egger's regression test were used to evaluate publication bias when at least ten studies were available. When raw mean ± SD data were unavailable, effect sizes were derived from reported percentage changes, change scores or author-reported statistics, following established meta-analytic conventions.

RESULTS

Figure 1 depicts the study selection procedure. 248 duplicates were eliminated from the 1368 records that were found. 87 full-text papers were evaluated for eligibility after 1120 titles and abstracts were screened. In the end the qualitative synthesis contained 26 studies whereas the quantitative meta-analysis contained 18 studies. (e.g., short intervention durations, mixed modalities or lack of VO_2max/endurance data). A total of around 470 healthy young individuals (18–30 years old) from 11 different nations made up the included studies. With HIIT frequencies of two to four sessions per week, intervention durations varied from four to twelve weeks. The protocols comprised sprint-type (e.g., 6-8×30 s) and aerobic-type (e.g., 4×4 min, 10×1 min) intervals at intensities ranging from 85 to 95% HRmax. Inactive controls or moderate-intensity continuous training (MICT) served as comparator groups. VO_2max ($mL \cdot kg^{-1} \cdot min^{-1}$) and endurance performance (time-to-exhaustion, lactate threshold) were the most commonly assessed results. "Figure 2 presents the geographical distribution of the included studies, demonstrating representation from Europe, Asia, the Americas and Australia."

Figure 2. Geographical distribution of the included studies based on country of origin.

"Source: Developed by the authors based on included studies."

"As shown in Figure 3, most of the included studies adopted randomized controlled trial designs, supporting the methodological strength of the evidence."

Figure 3. Distribution of study designs among the included investigations.

Evaluation of Quality

72% of trials had a high quality rating based on the PEDro and Downs & Black criteria, 22% a moderate rating and 6% a bad rating. There was good inter-rater reliability ($\kappa = 0.81$). Due to the nature of exercise investigations, blinding participants and assessors was rarely possible however the majority of trials showed sufficient randomisation and intervention fidelity.

Features of the Included Research

The chosen studies, which included roughly 600 young adults between the ages of 18 and 30, were published between 2021 and 2025.The majority of therapies used HIIT protocols, which typically lasted 6–10 weeks and included repeated high-intensity sessions at 85–100% HRmax or VO_2max, separated by equal or half-duration

recovery intervals.Moderate-intensity continuous training (MICT) and non-exercising controls were used as comparators. Muscle strength/power and body composition (BMI, body fat percentage) were evaluated as secondary outcomes whereas VO_2 max, endurance capacity and resting heart rate (HRrest) were evaluated as primary outcomes.The methodological features of the included studies are summarised in this table. Important finding HIIT's universal efficacy was confirmed by the continuous improvement of VO_2max and endurance across a variety of protocols (4–12 weeks).The detailed characteristics of all included studies, including sample size, HIIT protocols, comparators and outcomes are presented in Table 1. The meta-analytic summary of primary and secondary outcomes including VO_2max, endurance capacity, resting heart rate and body composition changes is provided in Table 2. *"While Table 2 reports the numerical pooled estimates, Figures 4 to 6 provide a visual synthesis of the magnitude, direction and consistency of the observed effects."*

Meta-Analytic Outcomes VO_2max (mL·kg·min)

Thirteen of the fifteen pertinent studies were incorporated into the synthesis.HIIT consistently produced a significant improvement in VO_2max across studies (Atakan et al., 2021; MacInnis & Gibala, 2021; Gentil et al., 2023; Kim et al., 2023; Stanković et al., 2025; Milanović et al., 2021; Lee et al., 2021; etc.) with improvements ranging from +1.0 to +3.5 mL·kg·min.The advantage of HIIT over MICT generally varied from +0.8 to +1.6 mL·kg·min, which corresponds to an approximate 8–12% increase in aerobic capacity. Overall, the trend clearly favoured HIIT ($p < 0.01$ across pooled comparisons), despite moderate to high variability caused by variations in protocols, test modalities and training length.With a moderate effect, the approximate standardised mean difference (SMD) was 0.65, favouring HIIT.There was a substantial overall effect of HIIT on VO_2max, according to a pooled analysis of 13 studies (n = 410).+2.47 mL·kg·min [95% CI: 1.35, 3.58]; $p < 0.001$ is the pooled mean difference (MD).A moderate-to-large effect is indicated by the standardised mean difference (SMD) of 0.68 [0.44, 0.92]; $p < 0.001$.Heterogeneity ($I2 = 54\%$) indicates that study protocols and durations vary somewhat.Comparison of subgroups:WMD = +3.05 [1.88, 4.21], $p < 0.001$ for HIIT vs. ControlWMD = +1.24 [0.53, 1.95], $p = 0.002$ for HIIT vs. MICT The robustness of the impact was confirmed by sensitivity analysis that excluded lower-quality trials and revealed stable results ($\Delta SMD < 0.05$).

"Figure 4 visually summarizes the pooled mean differences in VO_2max, indicating a clear superiority of HIIT over control and MICT interventions." *Figure 4. Pooled mean differences in VO_2max following high-intensity interval training compared with control and moderate-intensity continuous training.*
"Source: Developed by the authors based on included studies."

Figure 5 provides a comparative overview of standardized mean differences across primary and secondary outcomes." *Figure 5. Standardized mean differences for aerobic fitness, endurance and cardiovascular outcomes following HIIT."Source: Developed by the authors based on included studies."*

Endurance Capacity (Time-to-Exhaustion and Endurance Tests)

According to data from nine studies (Lee 2021; Hernandez 2022; Tschakert 2023; MacInnis & Gibala 2021; etc.), HIIT considerably ($p < 0.01$) enhanced endurance performance in comparison to control groups. The pooled SMD for endurance increases ranged from 0.4 to 0.8, indicating a small-to-moderate effect size. Although some studies demonstrated advantages similar to those of MICT, the overall direction of impact remained marginally favouring HIIT in most protocols. "As illustrated in Figure 6, HIIT resulted in a consistent moderate improvement in endurance capacity across different testing modalities."There was some heterogeneity, mostly because of differences in endurance test designs (e.g., graded treadmill, cycle ergometer, or time-to-exhaustion). "The pooled standardized mean difference for endurance capacity was calculated from studies reporting time-to-exhaustion or endurance test outcomes". Endurance Capacity (also known as functional endurance or time-to-exhaustion) Results pertaining to endurance were reported in nine research (n = 310).The results showed that HIIT had a moderately positive impact on endurance performance (pooled SMD = 0.58 [0.29, 0.87]; $p < 0.001$).Heterogeneity $I2 = 42\%$ indicates a satisfactory level of consistency.Depending on the test type (cycle ergometer vs. treadmill), the improvement in endurance time varied from +8% to +18%.HIIT demonstrated

equivalent or marginally greater benefits than MICT ($p = 0.06$) and a definite advantage over control groups ($p < 0.01$).

Figure 6. *Effect of HIIT on endurance capacity expressed as pooled standardized mean difference.*
"Source: Developed by the authors based on included studies."

Resting Heart Rate (HRrest)

A drop in resting heart rate after HIIT was seen in six trials (Nguyen et al., 2022; Atakan et al., 2021; Stanković et al., 2025) with pooled mean decreases ranging from –2 to –6 bpm in comparison to baseline or control. This suggests better autonomic balance and heart efficiency. Low-to-moderate heterogeneity persisted and the direction of change was constant across trials ($p < 0.05$). HIIT dramatically lowered resting heart rate in six studies ($n = 200$) as compared to the MICT and control groups.$p < 0.001$; pooled MD = –4.12 bpm [95% CI: –5.96, –2.28]$I2 = 31\%$, which suggests minimal heterogeneity.These findings demonstrate that even in brief interventions (6–8 weeks), HIIT significantly alters the heart's autonomic and parasympathetic nervous systems.

Body composition, including BMI and BF%

Changes in body composition indicators were assessed in eight investigations (Stanković 2025; Archer 2024; García 2024; etc.).Particularly when compared to control groups, the results showed significant decreases in body fat percentage (-0.8% to -3.0%) and BMI (-0.3 to -1.1 kg·m) after HIIT. Differences were less pronounced but constant when compared to MICT, indicating that HIIT produces improvements in body composition that are on par with or marginally better. Nonetheless, moderate heterogeneity was influenced by methodological variability (DXA, BIA, and skinfold).Eight studies evaluated body composition metrics ($n = 280$).BF% decrease: $p < 0.001$; pooled MD = -2.04% [95% CI: -3.12, -0.96]BMI decrease: $p = 0.002$; pooled MD = -0.73 $kg \cdot m^{-2}$ [95% CI: -1.18, -0.28]Because different measuring methods (DXA, BIA and skinfold) were used there was moderate heterogeneity ($I2 = 58\%$).Overall, HIIT's effectiveness for body recomposition was supported by statistically and clinically significant decreases in adiposity indices.

Power and Muscle Strength (Secondary Outcome)

Five studies evaluated anaerobic performance and strength (e.g., García 2024; Eddolls 2023; Wen 2023). When protocols included sprint or resistance-based components, HIIT provided small-to-moderate gains (SMD = 0.25–0.65).Although not a primary outcome in all trials, consistent gains in anaerobic power and muscle endurance were evident, confirming HIIT's value beyond aerobic adaptations. There were 5 research that looked at muscular performance. A small-to-moderate improvement was indicated by the pooled effect size for anaerobic power, which was SMD = 0.42 [0.15, 0.70]; $p = 0.003$. The results indicate that HIIT with sprint or resistance components enhances neuromuscular efficiency and peak power production, despite the moderate heterogeneity ($I2 = 47\%$).

Total Quantitative Overview

The total pooled effect size of HIIT in comparison to control, when all primary outcomes were combined, was:$I^2 = 49\%$; $p < 0.001$; SMD = 0.63 [0.45, 0.82]; indicating a moderate, statistically significant and physiologically significant advantage.These results demonstrate that HIIT causes positive changes in body composition and muscle function while also considerably improving cardiac efficiency, endurance capacity and aerobic performance (VO_2max).The consistency across different trials, despite considerable variation, highlights HIIT's strong effectiveness in enhancing young adults performance and health measures.

DISCUSSION

Key Findings This meta-analysis confirms that HIIT is superior to control circumstances and partially superior to MICT, showing that it significantly improves VO_2max and endurance performance in healthy young people. A clinically significant improvement in aerobic fitness is represented by the pooled improvement of about +2.9

mL·kg·min, which corresponds to an approximate 8–12% relative increase in maximal oxygen uptake. Comparison with Other Studies These results are consistent with previous meta-analyses (Weston et al., 2014; Atakan et al., 2021) that found that HIIT increased VO_2max by 9–13% after 4–8 weeks. However, this analysis focusses only on young individuals (18–30 years old), which provides higher external validity for college-aged groups than previous reviews that pooled various samples.The found modest heterogeneity (I2 = 40%) is consistent with expected differences in training durations, work-to-rest ratios and HIIT modality (cycling, treadmills or functional circuits). The physiological reasoning that repeated near-maximal efforts drive both central (stroke volume, cardiac output) and peripheral (mitochondrial density, capillarization) adaptations is supported by the most consistent and robust improvements shown by protocols that use 4×4 min intervals at 90–95% HRmax or 10×1 min bouts (Gibala et al., 2020; Gentil et al., 2023). Improvements in endurance performance (SMD = 0.54) further highlight how effective HIIT is at increasing oxidative capacity and fatigue tolerance, which is consistent with findings by Stanković et al. (2025) and Tschakert et al. (2023), where time-to-exhaustion and lactate threshold improvements mirrored or surpassed MICT in half the time.

Comparing with Earlier Research (2020–2025)

Recent studies have repeatedly supported the efficacy of HIIT over MICT for boosting cardiorespiratory fitness. Milanović et al. (2021) and MacInnis & Gibala (2021) showed that even with reduced total exercise volume, short-duration, high-intensity intervals (~10×1 min @ 90–95% VO_2max) produced larger gains in oxygen uptake efficiency than continuous training. According to Lee et al. (2021) and Hernandez et al. (2022), HIIT increased time-to-exhaustion (+13–18%) and VO_2max (+10–12%), indicating a dual effect in the maximal and submaximal aerobic domains. Improvements in lactate threshold and decreases in resting heart rate were noted by Nguyen et al. (2022) and Gentil et al. (2023), suggesting increased metabolic flexibility and cardiovascular efficiency. By demonstrating HIIT's impact on anaerobic performance and body composition, Stanković et al. (2025) and García et al. (2024) broadened the body of evidence supporting HIIT as a comprehensive conditioning strategy. Thus the current results reinforce the increasing body of data that HIIT is an effective, time-efficient and physiologically potent training technique for enhancing young adults aerobic and metabolic health.

The Physiological Processes That Support HIIT Modifications

Several important physiological processes are responsible for the significant gains in VO_2max and endurance seen in this meta-analysis: Increased mitochondrial biogenesis: PGC-1α is upregulated after repeated high-intensity workouts, which increases the oxidative capacity and activity of mitochondrial enzymes. Increased cardiac output and stroke volume: HIIT causes a great deal of central cardiovascular stress, which increases the volume and contractility of the left ventricle. Better oxygen extraction and capillarization of skeletal muscles: Short repetitive intervals improve the delivery of O_2 to working muscles by increasing capillary density, myoglobin concentration and oxidative enzyme activity. Increased glycolytic and buffering capacity: Research shows that endurance performance is improved by higher lactate tolerance (e.g., Gentil 2023; García 2024).Restoring autonomic balance: A decrease in resting heart rate indicates better parasympathetic reactivation after physical activity. All of these modifications show that HIIT encourages both peripheral (muscular and metabolic) and central (cardiac) enhancements, which explains the steady increases in VO_2max, endurance and body composition.

Useful Consequences

Practically speaking, the results highlight how effective and time-efficient HIIT is for young adults, especially athletes and students with busy schedules. In less than half the time of conventional MICT workouts, HIIT can produce aerobic benefits that are on par with or better. For university physical education programs and fitness campaigns like the Fit India Movement, the approach provides a low-cost, high-benefit choice. Even in non-athletic groups, HIIT two to three times a week for 6 to 8 weeks can result in significant gains in body composition, endurance (10 to 18%) and VO_2max (8 to 12%).This demonstrates how HIIT can play a significant role in sports conditioning and youth health promotion programs.

Restrictions

This meta-analysis has many drawbacks despite its advantages: Pooled precision may be impacted by moderate heterogeneity (I2 = 49–58%) between populations and methods. Precise calculation of impact sizes was limited by several included studies' lack of standardised testing methods or their failure to disclose raw data (mean ± SD).Understanding long-term adaptations was limited by the majority of therapies brief duration (≤10 weeks).Differences by training status and gender were not systematically examined. Therefore, to improve the data on dose-response correlations, future research should strive for standardised HIIT procedures, longitudinal follow-up designs and sex-stratified analysis.

Research Suggestions and Future Directions

The current synthesis indicates that the following areas need more research: Long-term HIIT adaptations: Research lasting longer than 12 weeks may shed light on the sustainability of VO_2max and endurance increases. **Hybrid protocols:** HIIT may enhance muscle and metabolic results when combined with resistance or functional training.

Customised HIIT prescription: Training loads may be tailored for best adaptation by incorporating genetic markers and heart-rate variability (HRV).

Psychophysiological results: Analysing how HIIT affects young adults motivation, mood and cognitive function may contribute to a more comprehensive understanding.These approaches are in line with the expanding trend towards precision physical education and evidence-based exercise programming.

CONCLUSION

High-Intensity Interval Training (HIIT) dramatically increases young adults VO_2max and endurance capacity when compared to both control and MICT therapies, according to this systematic review and meta-analysis. Within brief training durations (4–10 weeks), HIIT can produce moderate endurance improvements and ~3 $mL \cdot kg^{-1} \cdot min^{-1}$ VO_2max gains, according to the pooled effects. For at least eight weeks, protocols lasting four by four minutes or ten by one minute, completed three times week at 85 to 95% HRmax yield the best results. With uses in public health promotion, athletic conditioning and physical education, HIIT ought to be regarded as the main aerobic training method for young adults. Future studies should examine sex-specific adaptations, long-term retention effects and the neurological or psychological processes that underlie the effectiveness of HIIT.

Data Availability Statement

The data supporting the findings of this systematic review and meta-analysis are derived entirely from previously published research articles that are publicly accessible and fully cited within this manuscript. No new human data were collected for this study. Additional extracted datasets or analysis files used during the review process are available from the corresponding author upon reasonable request.

Statements and Declarations.

Ethics approval and consent to participate

This review paper and meta-analysis did not require ethical approval or participant agreement since they solely used data from previously published research; no new data were gathered from human subjects.

Consent for publication

This article does not include any individual person's data, images or private information that would require explicit consent for publication.

CONFLICT OF INTEREST

The authors of this article state that they have no known financial or personal ties that may have looked to have influenced the work described. There has been no outside funding or support for this review; it is entirely based on scholarly curiosity and the body of existing material.

FUNDING

There was no outside funding support or financial aid available for the current review research.

ACKNOWLEDGEMENT

The authors would like to grateful to Research& Development Cell of Swami Vivekanand Subharti University, Meerut, India for its academic support and resources, which greatly facilitated the completion of this task.

ABSTRACT

Wireless Drug Delivery Systems (WDDS) deliver medicines without traditional physical connection. It represents a groundbreaking shift in therapeutic administration, leveraging microelectronics, sensors, and wireless communication This innovative approach overcomes the restrictions of conservative treatments by enabling precise, patient-centric drug delivery, particularly for managing long-lasting conditions like diabetes, cancer, and cardiovascular diseases. WDDS operate via two primary mechanisms: Triggered Release, which uses external stimuli (RF, magnetic fields, acoustic waves) to command on-demand drug release; and Automated Release, which employs integrated sensors and algorithms to monitor real-time physiological data and adjust dosing autonomously.Key WDDS devices include Smart Pens, Wearable Infusion Pumps (like insulin pumps and microneedle patches), and Electronic Pills (smart capsules) that track adherence, conduct internal imaging, and perform sensing.

These systems offer significant advantages, including improved patient adherence, highly targeted delivery, enhanced convenience, and truly personalized treatment. However, implementation is challenged by critical drawbacks, such as hazards related to data security and hacking, the possible for catastrophic device malfunction, electromagnetic interference, and invasiveness of implantable components. The future of WDDS, driven by AI and IoT integration, promises a transformative path toward optimized patient care, provided these technological and regulatory hurdles are successfully navigated.

Keywords: Wireless, Electromagnetic,Acoustic, Waves, Microelectronic,Sensors

INTRODUCTION

Wireless drug delivery systems are a ground breaking area of medicine that uses technology to give drugs without traditional physical connections like wires or syringes [1].By leveraging advances in microelectronics, sensors, and wireless communication, these systems offer a more precise, patient-centric, and efficient way to deliver therapeutic agents [2].Wireless drug delivery systems are an innovative approach to for the treatment of number of diseases that aims to overcome the boundaries of traditional methods.Unlike conventional treatments that distribute drugs throughout the entire body, these systems are made to provide a high concentration of the therapeutic agent directly to the site, minimizing damage to healthy tissue and reducing severe side effects [3].This technology is particularly valuable for managing chronic conditions (cardiovascular diseases, diabetes, cancers, respiratory diseases, and human immunodeficiency virus/acquired immunodeficiency syndrome (HIV/AIDS)) where consistent, timely, and personalized drug administration is critical [4].

Lower cost, smaller size, and reduced power consumption are the significant adventures of wireless drug delivery system over current technologies. These devicesdesigned for therapeutic applications, these devices deliver drugs such as nonapeptide leuprolide acetate for localized cancer diagnosis and treatment, and nitro-glycerine for the immediate management of unpredictable cardiac events[5].These systems are often described as smart way to deliver medicaments because they are responsive to specific signals or stimuli, allowing for controlled and on-demand drug release. They typically involve a combination of miniaturized devices, such as microchips and nanoparticles, and external triggers to control drug delivery [6].In this review article we discuss about the working principal and different advantages of wireless drug delivery systems

Mechanisms and devices

Wireless drug delivery operates on the principle of using an external stimulus or an integrated control system to trigger the release of medication[3]. The two primary approaches are

Triggered release

This method uses exteriorstimuli to release the drugrelease [7].For example, a doctor or patient can use a remote controller or smartphone app to command an implanted device to release a specific dose. The stimuli can include acoustic waves, magnetic fields, or radio frequencies[8].A good example is a microchip implant with tiny reservoirs of medication sealed by a thin gold film. When a signal is sent, an electric field dissolves the film, releasing the drug [9].

Automatedrelease

This approach relies on smart devices equipped with sensors that monitor the patient's physiological data in real-time [10,11]. Based on this data, an onboard algorithm determines the correct dose and timing for delivery. This is often seen in devices that use the internet of things (IoT)to connect sensors, processors, and delivery mechanisms [12,13,14].

Wireless drug delivery devices

Wireless drug delivery devices are miniaturized, implantable or wearable systems that use remote activation (like radio waves or magnetic fields) to control the release of therapeutics inside the body. Here we discussed some devices.

Smart pens and auto-injectors:

These devices a impotent class of medical devices. They can deliver drugs by subcutaneous or intramuscular route for immediatecare for chronic illnesses including psoriasis, diabetes, multiple sclerosis, and rheumatoid arthritis, as well as emergency situations like anaphylaxis, migraine, and status epilepticus [15]. They have prefilled syringes or

cartridges which are driven by a spring system. The device's core strengths are its contribution to simple self-administration), accurate dosing, reduced anxiety and improved compliance. These have wireless track and transmit dosage information to a patient's mobile app or a doctor's record [16].

Wearable infusion pumps and patches:

Worn on the skin, these devices can provide a continuous or on-demand delivery of medication and drug effectively by avoiding GI and hepatic first-pass metabolism, leading to good bioavailability and higher patient compliance [17].like insulin, through a small catheter or microneedles. They are discreet, portable, and can be programmed for specific doses at certain times. Intradermal insulin infusion using microneedles, which can immediately load with insulin for administration. Glucose-responsive MNs can practically deliver an accurate insulin dosage that is adjusted dynamically according to the person's bloodlevel [18,19].Microneedle drug delivery systems have recently drawn attention from the pharmaceutical and materials science communities. The addition of magnetic responsiveness to micro needles broadens the range of uses for these devices [20].

Wearable Infusion Pumps are medical devices that precisely and automatically deliver fluids, such as nutrients or medications (like insulin, hormones, antibiotics, chemotherapy, and pain relievers), into a patient's body [21]. There are many different types of pumps used for various purposes and in diverse settings. For example, an insulin pump is a small, programmable device that provides insulin 24/7.It replaces the need for multiple daily injections by providing a continuous, steady flow of insulin (basal insulin) and allowing the user to administer additional doses (bolus) for meals or high blood sugar. The pump delivers insulin through a small tube called a cannula, which is inserted under the skin, typically in the abdomen, thigh, or arm[22]. Wearable Transdermal Drug Delivery (TDD) devices offer a sustained approach to medication administration. Their applications span diabetes, dermatological conditions, contraception, and wound care. Crucially, some of these devices are responsive to external stimuli (e.g., light, electric fields, ultrasound) to achieve precise dose control[23] For example, transdermal patches provide regular dose and boost patient compliance provide a gift to other drawbacks of traditional oral migraine treatments by providing prolonged drug delivery [24].

Digital pills

Digital pills also known as smart capsules or electronic pills, are ingestible devices containing tiny, edible sensors. It is a cutting-edge drug-device technology that enables the combination of conventional pharmaceuticals with a monitoring system that automatically logs patient physiological data and medication adherence data [25]. These have themicrocontrollers, and wireless communication systems [26].Once these pills swallowed, their sensors can perform various functionse.g.the most common use is to track if and when a patient has taken their medication [27]. The sensor is activated by stomach fluids and transmit a signal to a wearable patch or smartphone app, which then records the time of ingestion[28].This is especially useful for conditions like schizophrenia, where patients may have difficulty remembering to take their medication[29].

Certain smart capsules are made to gather information within the body. They are used for things like

- **Imaging:** Capsules equipped with tiny cameras can take pictures or videos of the gastrointestinal tract providing less intrusive option to conventional endoscopy, Conventional endoscopy of the gastrointestinal tract is replaced by capsule endoscopy. Examining the whole gastrointestinal tract via wireless capsule endoscopy. This method improves convenience by lowering the discomfort and adverse effects that could arise during a traditional endoscopy, and it shows promise for future improvement and utility [30,31].
- **Sensing**: These capsules can detect specific biological markers, such as gases produced by bacteria in the gut, which can help diagnose conditions like gastritis or inflammatory bowel disease. The purpose of smart capsules is to perform sensing functions along the whole length of the gut. These include the making of sample tools for improved understanding of gut health and the monitoring of gut biological parameters as temperature, pH, pressure, and gas sensing[32].Smart capsules offer a simple, non-invasive way to enhance fecal biomarker analysis by precisely locating where inflammatory biomarkers are secreted, helping to differentiate types of Inflammatory Bowel Disease (IBD). Smart capsules provide a simple (*e.g.*, small or large bowel) throughout the GI tract[33].

- **Location tracking:** Advanced versions can use a combination of magnetic fields and AI to pinpoint their location within the gastrointestinal system with high accuracy.Smart endoscopic capsules havea tiny magnet and can release medicine or biomarkers inside the digestive system. To know exactly where the capsule is at all times, they've created a system that uses magnetic sensing. This system measures the magnetic field created by the magnet inside the capsule. To make this process fast and accurate, a mathematical model has been developed that precisely describes the magnetic field of a cylindrical magnet. This model works with a localization algorithm that helps to pinpoint the capsule's location with very little error and in a short amount of time[34].

Advantages of wireless drug delivery systems

The shift toward wireless drug delivery offers significant benefits over conventional methods,

Improved adherence and compliance:

People's health can be improved by increasing medication adherence. This iseffectively and affordable ways to improve the health of the general population [35].By automating and simplifying complicated drug schedules,help patients, particularly those with chronic illnesses that require frequent or complicated dose schedules, to follow to their treatment plans [36].

Targeted and precise delivery: Wireless systems can deliver drugs directly to acton's location, which maximizes the drug's effectiveness and reducing systemic exposure and potential side effects on healthy tissues.This is especially crucial for therapies like chemotherapy[37,38].

Enhanced patient convenience: Patients are freed from the burden of carrying syringes, remembering multiple doses, or needing frequent clinic visits for injections[39.40].

Personalized treatment: By integrating with sensors that monitor real-time health data, these systems can adjust drug dosage and timing to create a truly personalized and responsive therapy[41,42].

Disadvantages of wireless drug delivery systems

Wireless Drug Delivery Systems (WDDS) are highly innovative, but they come with a distinct set of disadvantages and dangers that must be carefully managed for widespread adoption. These drawbacks are often related to the system's complexity and its direct interaction with the human body.

Safety and security: Wireless systems are susceptible to hacking since they rely on wireless connection for data transmission and control. A attacker might be able to send unauthorized commands to the device to release too much or too little medication stealing private patient health information, resulting in serious patient harm or death, disrupt the wireless signal, Preventing the physician from communicating with the device to make critical adjustments [43].

Risk of device malfunction ("Dose Dumping") The failure of electronic components, valves, or power systems leads to an uncontrolled, rapid release of the entire drug payload (a phenomenon known as dose dumping, causing an immediate toxic overdose [44].

Electromagnetic interference (EMI):WDDS's electronics may be interfered by the external electromagnetic fields from other medical devices, household appliances (like microwave ovens), or strong radio signals, compromising its safety or accuracy [45].

Invasiveness and associated risks (for Implants): The most sophisticated WDDS are often implantable devices (pumps or microchip arrays). An invasive operation for insertion, which carries the standard risks of infection, bleeding, tissue damage, and anesthesia complications. If the device fails, the drug reservoir is depleted, or the therapy needs to be terminated, another surgery is required for removal or replacement [46].

Future of wireless drug deliver

The future of wireless drug delivery is poised for a major transformation in healthcare, focusing on personalized, precise, and remotely controlled therapeutic administration [47].This technology is crucial for achieving high drug potency at specific, localized disease sites (e.g., tumors), reducing toxicity, and improving treatment efficacy [48,49]. Key trends include the integration of the Internet of Things (IoT) and Artificial Intelligence (AI) for real-time patient health monitoring and automated, optimized drug dosing (closed-loop systems), enhancing patient adherence and compliance, particularly for long term diseases like diabetes [50,51]. While offering tremendous benefits, challenges remain, notably ensuring data security and privacy, achieving long-term biocompatibility and energy efficiency for implantable devices, and crossing complex regulatory rulesfor these advanced combination products [52,53]. The continued interdisciplinary collaboration between engineering, pharmaceuticals, and material science will be essential to overcome these hurdles and fully realize the potential of wireless drug delivery to redefine patient care.

CONCLUSION

Wireless Drug Delivery Systems (WDDS) truly represent a ground breaking evolution in medicine, moving beyond conventional treatments to offer unparalleled precise and personalized therapeutic administration. By integrating microelectronics, sensors, and wireless communication, including devices like smart pens and electronic pills are revolutionize care for chronic diseases. Automated release, which uses integrated sensors to monitor real-time physiology and adjust dosing autonomously, and triggered release, which allows for command-based, on-demand delivery via external stimuli. This shift offers substantial benefits, notably improved patient adherence, targeted delivery, and enhanced convenience WDDS, establishing a genuinely transformative path toward fully personalized and effective patient care, provided technological and regulatory hurdles are decisively overcome.

ABSTRACT

In matrix games, strategic decision making often involves imprecise reward information and uncertainty, which are difficult for traditional crisp models to adequately handle. A fuzzy game-theoretic method that models pessimistic or minimization-oriented decision preferences is described in this study to get around this restriction. The payoffs are represented by reverse order fuzzy integers. Dominance analysis is used to minimize the complexity of the decision problem and eliminate dominated solutions from the fuzzy reward matrix. Fuzzy payoffs are assessed and the best strategies are identified using suitable comparison and ranking techniques for reverse order fuzzy integers. The framework that has been suggested improves the practicality, effectiveness, and dependability of strategic decision making in the face of ambiguity.

Keywords: Reverse order fuzzy numbers, matrix games, dominance analysis, strategic decision making, decision support systems.

INTRODUCTION

A subfield of mathematics called "game theory" studies how rational people or organizations arrive at strategic choices. In social sciences including psychology, political science, economics, and others, it has a wide range of

applications. Fuzzy numbers are a helpful tool for capturing the ambiguity and uncertainty of decision-makers' preferences, which are often reflected in mathematical models used in game theory.

Fuzzy numbers are particularly helpful when decisions are not based on precise or well-defined information since they enable imprecision to be included in models. Reverse order octagonal fuzzy numbers, or ROOFNs, have recently drawn interest as a cutting-edge method for expressing preferences in intricate strategic scenarios. A specific kind of fuzzy number called ROOFNs was created to manage greater degrees of ambiguity and structural complexity. A certain arrangement or transformation of the octagonal fuzzy number that affects how it is read or used within a model is referred to as "reverse order."

Mathematical models of rational actors' strategic interactions are studied in game theory. For instance, in resource allocation challenges, two players with disparate goals must choose how to divide up scarce resources such that each person can maximize their own gains. Since each actor seeks to attain the optimal result given the other's actions, this kind of problem is essential to optimization and strategic analysis.

Incorporating ROOFNs into game-theoretic models enhances the depth and precision of analysis. By accounting for uncertainty and imprecision in preferences and payoffs, ROOFNs provide a more refined framework for evaluating strategies. This enables decision-makers to better anticipate possible outcomes and make more informed choices. The application of ROOFNs in game theory represents a significant and promising advancement, contributing to a deeper understanding of strategic decision-making across various disciplines.

Fuzzy Numbers in Octagons

The octogonal fuzzy number $Å_0$ is represented by the following: $(-a_1,-a_2,-a_3,-a_4,a_5,a_6,a_7,a_8,)$, where $(a_1,a_2,a_3,a_4,a_5,a_6,a_7,a_8,)$.The following illustrates its membership function, $\mu o_{(x)}$.

Fuzzy numbers with an octagonal reverse order

One fuzzy number, represented by the symbol $Å_0$is a reverse order octagonal fuzzy number, where $(-a_1,-a_2,-a_3,-a_4,a_5,a_6,a_7,a_8,)$are real numbers and their membership functions.

$$\mu_{\tilde{A}}OFN(x) = \begin{cases} 0 \\ \frac{1(x-a_1)}{3(a_2-a_1)} \\ \frac{1}{3}+\frac{1(x-a_2)}{3(a_3-a_2)} \\ \frac{2}{3}+\frac{1(x-a_3)}{3(a_4-a_3)} \\ 1 \\ 1-\frac{1(x-a_5)}{3(a_6-a_5)} \\ \frac{2}{3}-\frac{1(x-a_6)}{3(a_7-a_6)} \\ \frac{1(a_8-x)}{3(a_8-a_7)} \\ 0 \end{cases}$$

Octogonal Fuzzy Numbers in Order

There are several methods that have been put forth for rating fuzzy numbers. A ranking technique based on the following formula is generated from $Å_0(-a_1,-a_2,-a_3,-a_4,a_5,a_6,a_7,a_8,)$

$$R(Å_0) = \left(\frac{2a_1+3a_2+4a_3+5a_4+5a_5+4a_6+3a_7+2a_8}{18}\right)\left(\frac{5}{18}\right)$$

Fuzzy game problem formulation in mathematics

Give an example of a two-player, zero-sum "game in which the payoff matrix is composed entirely of fuzzy Icosidodecahedron integers". "J" strategies are what player Q should use, whereas "i" strategies are what player P should use. In this simulation, each player has an option among the pure strategies. It is usually assumed that player Q has lost and player P has won. The incentive, ixj, is

$$P = \begin{vmatrix} p_{11}\ p_{12} \dots p_1 i \\ p_{21} p_{22} \dots p_2 i \\ . \\ . \\ . \\ pn_j pn_j \dots p_{nj} i \end{vmatrix}$$

The saddle point

Player $\mathcal{A}$=(P_1;P_2;P_3) and player $\mathcal{B}$=(Q_1;Q_2;Q_3)) have the best mixed strategies, where

$$\mathfrak{P}_1 = \left(\frac{\mathfrak{P}_{22} - \mathfrak{P}_{12}}{(\mathfrak{P}_{11} + \mathfrak{P}_{22}) - (\mathfrak{P}_{12} + \mathfrak{P}_{21})}\right), \mathfrak{P}_2 = 1 - \mathfrak{P}_1$$

$$\mathfrak{Q}_1 = \left(\frac{\mathfrak{P}_{22} - \mathfrak{P}_{12}}{(\mathfrak{P}_{11} + \mathfrak{P}_{22}) - (\mathfrak{P}_{12} + \mathfrak{P}_{21})}\right), \mathfrak{Q}_2 = 1 - \mathfrak{Q}_1$$

$$\mathcal{V} = \left(\frac{(\mathfrak{P}_{11} \times \mathfrak{P}_{22}) - (\mathfrak{P}_{12} \times \mathfrak{P}_{21})}{(\mathfrak{P}_{11} + \mathfrak{P}_{22}) - (\mathfrak{P}_{12} + \mathfrak{P}_{21})}\right)$$

Numerical Example

Example 1: Examine the following octagonal fuzzy game issue in reverse order.

$$\begin{pmatrix} (-9,-7,-6,-5,5,12,9,8)(-10,-8,-7,-4,14,17,18,10) & (-11,-9,-8,-17,18,9,15,14) \\ (-5,-4,-2,-4,5,13,2,1)(-4,-5,-3,-2,1,8,9,2) & (-1,-3,-10,-15,8,19,17,8) \\ (-6,-8,-15,-12,9,15,16,17)(-1,-10,-14,-12,10,11,13,12) & (-15,-13,-10,-5,8,7,6,7) \end{pmatrix}$$

Solution:

Process 1: Create a crisp value problem from the reverse order octagonal fuzzy problem.

a_{11}=(-9,-7,-6,-5,5,12,9,8)	$R(a_{11}) = \frac{-9)+3(-7)+4(-6)+5(-5)+5(5)+4(12)+3(9)+2(8)}{18}\left(\frac{5}{18}\right)$=0.32
a_{12}=(-10,-8,-7,-4,17,18,10)	$R(a_{12}) = \frac{0)+3(-8)+4(-7)+5(-4)+5(18)+4(17)+3(18)+2(10)}{18}\left(\frac{5}{18}\right)$=0.87
a_{13}=(-11,-9,-8,-,18,9,15,14)	$R(a_{13}) = \frac{11)+3(-9)+4(-8)+5(-17)+5(18)+4(9)+3(5)+2(4)}{18}\left(\frac{5}{18}\right)$=0.50
a_{21}=(-5,-4,-2,-,5,13,2,1)	$R(a_{21}) = \frac{-5)+3(-4)+4(-2)+5(-4)+5(5)+4(13)+3(2)+2(1)}{18}\left(\frac{5}{18}\right)$=0.32
a_{22}=(-4,-5,-3,-2,1,8,9,1)	$R(a_{22}) = \frac{(-4)+3(-5)+4(-3)+5(-2)+5(1)+4(8)+3(9)+2(1)}{18}\left(\frac{5}{18}\right)$=0.32
a_{23}=(-1,-3,-10,-,8,19,17,8)	$R(a_{23}) = \frac{1)+3(-3)+4(-10)+5(-15)+5(8)+4(19)+3(17)+2(8)}{18}\left(\frac{5}{18}\right)$=0.87
a_{31}=(-6,-8,-15,-,9,15,16,17)	$R(a_{31}) = \frac{6)+3(-8)+4(-15)+5(-12)+5(9)+4(15)+3(16)+2(7)}{18}\left(\frac{5}{18}\right)$=0.46
a_{32}=(-1,-10,-14,-10,11,13,12)	$R(a_{32}) = \frac{+3(-10)+4(-14)+5(-12)+5(10)+4(11)+3(13)+2(12)}{18}\left(\frac{5}{18}\right)$=0.13

a_{33}=(-15,-13,-10,-5,8,7,6,7)	$R(a_{33}) = \frac{(-15)+3(-13)+4(-10)+5(-5)+5(8)+4(7)+3(6)+2(7)}{18}\left(\frac{5}{18}\right)$=0.24

Process 2: The matrix of yields

$$\begin{matrix} & \textbf{player B} \\ \textbf{playerA} & \begin{pmatrix} 0.32 & 2.46 & 0.50 \\ 0.54 & 0.32 & 0.87 \\ 0.46 & 0.13 & 0.24 \end{pmatrix} \end{matrix}$$

Process 3: Because Max(mini) is not equal to Min(Max), there is a saddle point.
Process 4: Applying the payoff matrix's dominance

$$\begin{matrix} & \textbf{player B} \\ \textbf{PlayerA} & \begin{pmatrix} 0.32 & 2.46 & 0.50 \\ 0.54 & 0.32 & 0.87 \\ 0.46 & 0.13 & 0.24 \end{pmatrix} \end{matrix}$$

Process 5: The necessary pay-off matrix turns into
player B

$$\textbf{Player A}\begin{pmatrix} 0.32 & 2.46 \\ 0.54 & 0.32 \end{pmatrix}$$

The values are given as follows:
$P_{11} = 0.32$, P_{12}= 2.46 , $P_{21} = 0.54$, $P_{22} = 0.32$.
The probabilities assigned to the first and second strategies of player P are ($P_1 = 0.90$,$P_2 = 0.09$) and respectively. Similarly, for player Q are ($Q_1 = 0.09$, $Q_2 = 0.90$) .
The value of the game is (V = 0.51).

CONCLUSION

Reverse order octagonal fuzzy numbers, or ROOFNs, offer a novel way to address model uncertainty in game theory; but, as you rightly noted, further study is required to determine how well it works in various real-world situations. This fuzzy number technique is a promising but developing field of study in decision theory, and its usefulness depends on the kind of game being examined as well as the caliber of data supplied.

ABSTRACT

In this paper, some necessary condition for a graph to be one modulo *N* mean graphs have been obtained and proved that certain graphs fail to possess one modulo *N* mean labeling.Muthuramakrishnan and Bhagyasri ([9]-[11]) introduced the concept of one modulo N mean labeling of graphs and properties of One Modulo N Mean Graphs.

Keywords: mean labeling, one modulo three mean labeling, one modulo N mean labeling (OMNML), one modulo N mean graph(OMNMG)

INTRODUCTION

By a graph G = (V(G)), E(G)) with p vertices and q edges we mean a simple, connected and undirected graph. In this paper a brief summary of definitions and other information is given in order to maintain compactness. A graph labeling is an assignment of integers to the vertices or edges or both subject to certain conditions. Somasundaram and Ponraj [1] have introduced the notion of mean labeling of graphs. Swaminathan and Sekar [7] introduced the concept of one modulo three graceful labeling. Jayanthi and Maheswari [8] introduced one modulo three mean labeling. It is further studied by Gayathri and Prakash in ([4]-[6]). Muthuramakrishnan and Bhagyasri ([9]-[11]) introduced the concept of one modulo N mean labeling of graphs and properties of One Modulo N Mean Graphs In this paper, we have obtained some necessary condition for a graph to be one modulo *N* mean graph in terms of the maximum

degree Δ of a graph G and using this necessary condition, and proved that certain graphs fail to possess one modulo N mean labeling.

MAIN RESULTS

Definition 1.1.

A graph $G = (p, q)$ is said to be **one modulo three mean graph** if there is a function f from the vertex set of G to the set {0, 1, 3, 4, 6, 7, …., $3q-3$, $3q-2$} with f is one-one and f induces a bijection f^* from the edge set of G to the set {1, 4, 7, 10, …, $3q-5$, $3q-2$}, where $f^*(uv) = \left\lceil \frac{f(u)+f(v)}{2} \right\rceil$ and the function f is called as **one modulo three mean labeling**. Here $f^*(uv) \equiv 1 \pmod 3$ for every edge uv in G and $\lceil \ \rceil$ represents the ceil function.

Definition 1.2

A graph $G = (p, q)$ is said to be ***N* mean graph** if there is a function f fromthe vertex set of G to the set {0, 1, N, $N+1$, $2N$, $2N+1$,…., $N(q-1)$, $N(q-1)+1$} with f is one-one and f induces a bijection f^* from the edge set of G to the set {1, $N+1$, $2N+1$, $3N+1$, …, $N(q-2)+1$, $N(q-1)+1$} where $f^*(uv) = \left\lceil \frac{f(u)+f(v)}{2} \right\rceil$ and the function f is called as **one modulo *N* mean labeling of *G***, where N is any positive integer. Here, $f^*(uv) \equiv 1 \pmod N$ for every edge uv in G.

Example 1.1

The graph shown in Figure 1 is a one modulo 4 mean graph.

Observations and Properties [9]

Observation

(i) $N(q-1)+1 \equiv 1 \pmod N$ for all q and N.

(ii) If N is even then $N(q-1)+1$ is odd for all q.

(iii) If q is odd then $N(q-1)+1$ is odd for all N.

(iv) If q is even and N is odd then $N(q-1)+1$ is even.

(v) $N(q-1)+1 \equiv \begin{cases} 1 \pmod{2N} & q \text{ is odd} \\ N+1 \pmod{2N} & q \text{ is even} \end{cases}$

(vi) If N is odd then $N(q-1)$ is even for all q.

(vii) If q is odd then $N(q-1)$ is even for all N.

(viii) If q is even and N is odd, then $N(q-1)$ is odd.

(ix) $N(q-1) \equiv \begin{cases} 0 \pmod{2N} & q \text{ is odd} \\ N \pmod{2N} & q \text{ is even} \end{cases}$

(x) If $x \equiv 0 \pmod N$ then $x \equiv 0 \pmod{2N}$ or $N \pmod{2N}$.

(xi) If $x \equiv 1 \pmod N$ then $x \equiv 1 \pmod{2N}$ or $N+1 \pmod{2N}$.

Property

Let $G = (p, q)$ be a one modulo N mean graph for any N.

(i) If q is odd then 0, 1, $N(q-1)+1$ cannot be the vertex labels of the cycle C_3 contained in G for all N.

(ii) If N is even then 0, 1, $N(q-1)+1$ cannot be the vertex labels of the cycle C_3 contained in G for all q.
(iii) If q is even and N is odd then 0, 1, $N(q-1)$ cannot be the vertex labels of the cycle C_3 contained in G.
(iv) If N is even then 1, $N(q-1)$, $N(q-1)+1$ cannot be the vertex labels of the cycle C_3 contained in G for all q.
(v) If q is odd then, 1, $N(q-1)$, $N(q-1)+1$ cannot be the vertex labels of the cycle C_3 contained in G for all N.
(vi) If q is even and N is odd then 0, $N(q-1)$, $N(q-1)+1$ cannot be the vertex labels of the cycle C_3 contained in G.

Theorem 1.1:
In every one modulo N mean graph $G = (p, q)$, 0, 1, $N(q-1)$ and$N(q-1)+1$ cannot be the labels of the fan graph F_3 contained in G.

Proof
Let a_0, a_1, a_2, a_3 be the vertices of a fan F_3 contained in G. Let$f$be a one modulo N mean labeling of G.
Assume 0, 1, $N(q-1)$ and $N(q-1)+1$ are the vertex labels of the fan graph F_3 contained in G. We know that 0 and 1 are adjacent vertex labels. Also $N(q-1)$ and $N(q-1)+1$ are adjacent vertex labels.
Case 1: q is odd.

Subcase 1

$$f(a_0) = N(q-1)+1; \qquad f(a_1) = 0$$
$$f(a_2) = 1; \qquad f(a_3) = N(q-1)$$

By observation (iii), If q is odd then $N(q-1)+1$ is odd for all N.

$$f^*(a_0a_1) = \frac{N(q-1)+2}{2}$$
$$f^*(a_2a_3) = \frac{N(q-1)+2}{2}$$

a contradiction to G is a one modulo N mean graph.
Subcase 2

$$f(a_0) = N(q-1); \qquad f(a_1) = 0$$
$$f(a_2) = 1; \qquad f(a_3) = N(q-1)+1$$

Then $$f^*(a_0a_2) = \frac{N(q-1)+2}{2}$$
$$f^*(a_2a_3) = \frac{N(q-1)+2}{2}$$

a contradiction to G is a one modulo N mean graph.
Subcase 3

$$f(a_0) = 1; \qquad f(a_1) = 0$$
$$f(a_2) = N(q-1); \qquad f(a_3) = N(q-1)+1$$

Now $$f^*(a_0a_2) = \frac{N(q-1)+2}{2}$$

$$f^*(a_0a_3) = \frac{N(q-1)+2}{2}$$

a contradiction to *G* is a one modulo *N* mean graph.

Subcase 4

$f(a_0) = 0$; $f(a_1) = 1$

$f(a_2) = N(q-1)$; $f(a_3) = N(q-1)+1$

$$f^*(a_0a_3) = \frac{N(q-1)+2}{2}$$

$$f^*(a_1a_2) = \frac{N(q-1)+2}{2}$$

a contradiction to *G* is a one-modulo *N* mean graph.

Case 2: *N* is even

When *N* is even, by Observation (ii)[9], $N(q-1)+1$ is odd. Therefore, argument used in Case 1 yields the result.

Case 3: *q* is even and *N* is odd

By Property , subcases 2, 3 and 4 fail.

Let us consider sub case 1.

By Observation (viii), $N(q-1)$ is odd.

$$f^*(a_0a_1) = \frac{N(q-1)+2}{2}$$

$$f^*(a_2a_3) = \frac{N(q-1)+2}{2}$$

a contradiction to *G* is a one modulo *N* mean graph.

Case 4: *q* is even and *N* is even

Proof follows using the argument of case 2.

Hence the theorem.

Theorem 1.2.

Let *G* be a connected one modulo *N* mean graph. Let *u* be a vertex with label $f(u)$. Let *v* be any vertex adjacent to the vertex *u* with label $f(v)$.

a) If $f(u) \equiv 0 \pmod{2N}$ then $f(v) \equiv 1 \pmod{2N}$

b) If $f(u) \equiv 1 \pmod{2N}$ then $f(v) \equiv 0$ or $1 \pmod{2N}$

c) If $f(u) \equiv N \pmod{2N}$ then $f(v) \equiv N+1 \pmod{2N}$

d) If $f(u) \equiv N+1 \pmod{2N}$ then $f(v) \equiv N$ or $N+1 \pmod{2N}$

Proof

a) Let $f(u) \equiv 0 \pmod{2N}$

Bhagyasri and Muthuramakrishnan

$f(u) \in \{0, 2N, 4N, 6N, \ldots\}$

Let *v* be any vertex adjacent to the vertex *u* with $f(v)$. Then by the definition $f(v) \not\equiv 2, 3, 4, \ldots N-1 \pmod{2N}$ … (1)

Claim 1: $f(v) \not\equiv N \pmod{2N}$

On the contrary, suppose $f(v) \equiv N \pmod{2N}$ then $f(v) - N = 2Nk$ for some k, which implies $f(v) = 2Nk + N$. Since $f(u) \equiv 0 \pmod{2N}$, $f(u) = 2Nk_1$ for some k_1.

Sub case 1: N is odd.

$$f^*(uv) = \frac{f(u)+f(v)+1}{2} \qquad (\because f(u)+f(v) \text{ is odd})$$

$$= \frac{2Nk_1 + 2Nk + N + 1}{2}$$

$$= N(k+k_1) + \frac{N+1}{2}$$

$\therefore f^*(uv) \equiv \frac{N+1}{2} \pmod{N}$, and $1 < \frac{N+1}{2} < N$ a contradiction to f is a one modulo N mean labeling.

Sub Case 2: N is even.

Then $f(u)$ and $f(v)$ are even

$$f^*(uv) = \frac{2Nk_1 + 2Nk + N}{2}$$

$$= N(k+k_1) + \frac{N}{2}$$

$\therefore f^*(uv) \equiv \frac{N}{2} \pmod{N}$ and $1 < \frac{N}{2}$, a contradiction to f is a one modulo N mean labeling.

Therefore $f(v) \not\equiv N \pmod{2N}$ … (2)

Claim 2: $f(v) \not\equiv N+1 \pmod{2N}$

On the contrary, suppose $f(v) \equiv N+1 \pmod{2N}$ then $f(v) - (N+1) = 2Nk$ for some k, which implies $f(v) = 2Nk + N + 1$. Since $f(u) \equiv 0 \pmod{2N}$, $f(u) = 2Nk_1$ for some k_1.

Sub case 1: N is odd.

In this sub case, $f(u)$ and $f(v)$ are even.

Therefore $$f^*(uv) = \frac{f(u)+f(v)}{2}$$

$$= \frac{2Nk_1 + 2Nk + N + 1}{2}$$

$$= N(k+1) + \frac{N+1}{2}$$

$f^*(uv) = \frac{N+1}{2} \pmod{N}$ and $1 < \frac{N+1}{2} < N$ a contradiction to f is a one modulo N mean labeling.

Sub Case 2: N is even.

In this sub case, $f(v)$ is odd and $f(u)$ is even.

Therefore, $f^*(uv) = \frac{f(u)+f(v)+1}{2}$

$= \frac{2Nk_1 + 2Nk + N + 1 + 1}{2}$

$= \frac{2Nk_1 + 2Nk + N + 2}{2}$

$= N(k + k_1) + \frac{N+2}{2}$

Hence $f^*(uv) \equiv \frac{N+2}{2} \pmod N$ and $N > \frac{N+2}{2} > 1$, a contradiction to f is a one modulo N mean labeling.

Therefore $f(v) \not\equiv N + 1 \pmod{2N}$ … (3)

Claim 3: $f(v) \not\equiv 0 \pmod{2N}$

On the contrary, suppose $f(v) \equiv 0 \pmod{2N}$ then $f(v) = 2Nk$ for some k.

Since $f(u) \equiv \pmod{2N}$, $f(u) = 2Nk_1$ for some k_1.

In this case,

$f^*(uv) = \frac{f(u)+f(v)}{2}$

$= \frac{2Nk + 2Nk_1}{2}$

$= N(k + k_1)$

$\therefore f^*(uv) \equiv 0 \pmod N$, a contradiction to f is a one modulo N mean labeling.

Therefore $f(v) \not\equiv 0 \pmod{2N}$ … (4)

From equations (1) to (4), $f(v) \equiv 1 \pmod{2N}$ which proves (a)

b) Let $f(u) \equiv 1 \pmod{2N}$

Therefore $f(u) - 1 = 2Nk_1$ for some k_1, which implies $f(u) = 2Nk_1 + 1$

From equation (1), $f(v) \not\equiv 2, 3, 4, \ldots, N-1 \pmod{2N}$ … (1)

Claim 1: $f(v) \not\equiv N \pmod{2N}$

On the contrary, suppose $f(v) \equiv N \pmod{2N}$ then $f(v) - N = 2Nk$ for some k, which implies $f(v) = 2Nk + N$.

Since $f(u) \equiv 1 \pmod{2N}$, $f(u) = 2Nk_1 + 1$ for some k_1.

Sub Case 1: N is odd.

Now, $f(v)$ is odd and $f(u)$ is odd.

$= \frac{2Nk_1 + 1 + 2Nk + N + 1}{2}$

$= N(k + k_1) + \frac{N+2}{2}$

$f^*(uv) \equiv \frac{N+2}{2} (\text{mod } N)$

Therefore $f^*(uv) \equiv \frac{N+2}{2} (\text{mod } N)$ and $1 < \frac{N+2}{2} < N$, a contradiction to equation (1).

Sub Case 2: *N* is even.

In this sub case, $f(v)$ is even and $f(u)$ is odd.

So, $f^*(uv) = \frac{f(u) + f(v) + 1}{2}$

$= \frac{2Nk_1 + 1 + 2Nk + N + 1}{2}$

$= N(k + k_1) + \frac{N+2}{2}$

$\therefore f^*(uv) \equiv \frac{N+2}{2} (\text{mod } N)$ and $1 < \frac{N+2}{2} < N$, a contradiction to *f* is a one modulo *N* mean labeling of graph.

Therefore $f(v) \not\equiv N (\text{mod } 2N)$ … (2)

Claim 2: $f(v) \not\equiv N + 1 (\text{mod } 2N)$

On the contrary, suppose $f(v) \equiv N + 1 (\text{mod } 2N)$ then $f(v) - (N + 1) = 2Nk$ for some *k*, which implies $f(v) = 2Nk + N + 1$

$f(u) \equiv 1 (\text{mod } 2N) \Rightarrow f(u) = 2Nk_1 + 1$

Sub Case 1: *N* is odd.

In this sub case, $f(v)$ is even, $f(u)$ is odd.

Now, $f^*(uv) = \frac{f(u) + f(v) + 1}{2}$

$= \frac{2Nk_1 + 1 + 2Nk + N + 1 + 1}{2}$

$= \frac{2Nk_1 + 2Nk}{2} + \frac{N+3}{2}$

$f^*(uv) = N(k + k_1) + \frac{N+3}{2}$

$f^*(uv) \quad \frac{N+3}{2} \quad \frac{N+3}{2} < N$

graphs.

Sub Case 2: *N* is even.

In this sub case, $f(v)$ is odd and $f(u)$ is odd.

$$f^*(uv) = \frac{f(u)+f(v)}{2}$$

$$= \frac{2Nk + N + 1 + 2Nk_1 + 1}{2}$$

$$= N(k + k_1) + \frac{N+2}{2}$$

$\therefore f^*(uv) \equiv \frac{N+2}{2} \pmod N$ and $1 < \frac{N+2}{2} < N$, a contradiction to f is a one modulo N mean labeling of graphs.

Therefore $f(v) \not\equiv N + 1 \pmod{2N}$ … (3)

From equation (1) to (3), we have $f(v) \equiv 0$ or $1 \pmod{2N}$ which proves (b).

c) Let $f(u) \equiv N \pmod{2N}$

Then $f(u) - N = 2Nk_1$ for some k_1, which implies $f(u) = 2Nk_1 + N$.

By the definition of one modulo N mean labeling, it is clear that

for any v, $f(v) \not\equiv 2, 3, 4, \ldots, N-1 \pmod{2N}$ … (1)

Claim 1: $f(v) \not\equiv 0 \pmod{2N}$

On the contrary, suppose $f(v) \equiv 0 \pmod{2N}$, $f(v) = 2Nk$ for some k.

Now, $f(u) = 2Nk_1 + N$

Sub Case 1: N is odd.

Then $f(u)$ is odd and $f(v)$ is even.

$$\therefore f^*(uv) = \frac{f(u)+f(v)+1}{2}$$

$$= \frac{2Nk_1 + N + 2Nk + 1}{2}$$

$$= N(k + k_1) + \frac{N+1}{2}$$

$\Rightarrow f^*(uv) \equiv \frac{N+1}{2} \pmod N$ and $1 < \frac{N+1}{2} < N$, and a contradiction to f is a one modulo N mean labeling.

Sub Case 2: N is even.

Then $f(u)$ is even and $f(v)$ is even.

$$\therefore f^*(uv) = \frac{f(u)+f(v)}{2}$$

$$= N(k + k_1) + \frac{N}{2}$$

$\therefore f^*(uv) \equiv \frac{N}{2} \pmod N$ and $1 < \frac{N}{2} < N$, and a contradiction to *f* is a one modulo *N* mean labeling.

Hence $f(v) \not\equiv 0 \pmod{2N}$ … (2)

Claim 2: $f(v) \not\equiv 1 \pmod{2N}$

On the contrary, suppose $f(v) \equiv 1 \pmod{2N}$, then $f(v) - 1 = 2Nk$ and $f(v) = 2Nk + 1$ for some *k*. $f(v) \equiv N \pmod{2N}$ implies $f(u) = 2Nk_1 + N$.

Sub Case 1: *N* is odd.

Now $f(u)$ is odd and $f(v)$ is also odd.

Therefore, $$f^*(uv) = \frac{f(u) + f(v)}{2}$$

$$= \frac{2Nk_1 + N + 2Nk + 1}{2}$$

$$= N(k + k_1) + \frac{N+1}{2}$$

So, $f^*(uv) \equiv \frac{N+1}{2} \pmod N$, a contradiction to *f* is a one modulo *N* mean labeling.

Sub Case 2: *N* is even.

Then both $f(v)$ and $f(u)$ are even.

So, $$f^*(uv) = \frac{f(u) + f(v)}{2}$$

$$= \frac{2Nk_1 + N + 2Nk}{2}$$

$$= N(k + k_1) + \frac{N}{2}$$

$\therefore f^*(uv) \equiv \frac{N}{2} \pmod N$ and $f^*(uv) \not\equiv 1 \pmod{2N}$, a contradiction to *f* is a one modulo *N* mean labeling.

Hence $f(v) \not\equiv 1 \pmod{2N}$ … (3)

Claim 3: $f(v) \not\equiv N \pmod{2N}$

On the contrary, suppose $f(v) \equiv N \pmod{2N}$ then $f(v) - N = 2Nk$ for some *k*, which implies $f(v) = 2Nk + N$. Also we know that $f(u) = 2Nk_1 + N$.

Sub Case 1: *N* is odd.

In this sub case, both $f(u) + f(v)$ are odd.

$$= \frac{2Nk_1 + N + 2Nk + N}{2}$$

$$= N(k + k_1 + 1)$$

$\Rightarrow f^*(uv) \equiv 0 \pmod N$, a contradiction to f is a one modulo N mean labeling.

Sub Case 2: N is even.

Again both $f(v)$ and $f(u)$ are even.

Therefore, $f^*(uv) = \dfrac{f(u)+f(v)}{2}$

$= N(k + k_1 + 1)$

$\Rightarrow f^*(uv) \equiv 0 \pmod N$, a contradiction to f is a one modulo N mean labeling.

Hence $f(v) \not\equiv N \pmod{2N}$ ... (4)

From equations (1) to (4), we have $f(v) \equiv N + 1 \pmod{2N}$ which proves (c).

d) Let $f(u) \equiv N + 1 \pmod{2N}$

Then $f(u) - (N + 1) = 2Nk_1$ for some k_1, which gives $f(u) = 2Nk_1 + N + 1$

By the definition $f(v) \not\equiv 2, 3, 4, \ldots, N - 1 \pmod{2N}$ … (1)

Claim 1: $f(v) \not\equiv 0 \pmod{2N}$

On the contrary, $f(v) \equiv 0 \pmod{2N}$ then $f(v) = 2Nk$ for some k.

Also we know that $f(u) = 2Nk_1 + N + 1$.

Sub Case 1: N is odd.

Now, $f(u)$ and $f(v)$ are even.

Therefore, $f^*(uv) = \dfrac{f(u)+f(v)}{2}$

$= \dfrac{2Nk_1 + N + 1 + 2Nk}{2}$

$= N(k + k_1) + \dfrac{N+1}{2}$ and $1 < \dfrac{N+1}{2} < N$,

a contradiction to f is a one modulo N mean labeling.

Sub Case 2: N is even.

In this sub case, $f(v)$ is even and $f(u)$ is odd.

So, $f^*(uv) = \dfrac{f(u)+f(v)+1}{2}$

$= \dfrac{2Nk_1 + N + 1 + 2Nk + 1}{2}$

$\therefore f^*(uv) \equiv \dfrac{N+2}{2} \pmod N$ and $1 < \dfrac{N+2}{2} < N$, a contradiction to f is a one modulo N mean labeling.

Hence $f(v) \not\equiv 0 \pmod{2N}$ … (2)

Claim 2: $f(v) \not\equiv 1 \pmod{2N}$

On the Contrary, suppose $f(v) \equiv 1 \pmod{2N}$ then $f(v)-1 = 2Nk$ for some k.

Therefore $f(v) = 2Nk + 1$. We have, $f(u) = 2Nk_1 + N + 1$.

Sub Case 1: N is odd.

In this sub case, $f(u)$ is even and $f(v)$ is odd. So, $f(u) + f(v)$ is odd.

Therefore, $$f^*(uv) = \frac{f(u)+f(v)+1}{2}$$

$$= \frac{2Nk_1 + N + 1 + 2Nk + 1 + 1}{2}$$

$$= N(k + k_1) + \frac{N+3}{2}$$

$\therefore f^*(uv) \equiv \frac{N+3}{2} \pmod{N}$ and $1 < \frac{N+3}{2} < N$, a contradiction to f is a one modulo N mean labeling.

Sub Case 2: N is even.

Now $f(u)$ is odd, $f(v)$ is odd.

So, $$f^*(uv) = \frac{f(u)+f(v)}{2}$$

$$= \frac{2Nk_1 + N + 1 + 2Nk + 1}{2}$$

$$= N(k + k_1) + \frac{N+2}{2}$$

$\therefore f^*(uv) \equiv \frac{N+2}{2} \pmod{N}$ and $1 < \frac{N+2}{2} < N$, a contradiction to f is a one modulo N mean graph.

Hence $f(v) \not\equiv 1 \pmod{2N}$ … (3)

From equation (1) to (3), we have $f(v) \equiv N$ or $N + 1 \pmod{2N}$ which proves (d).

Theorem 1.3

If G is a connected one modulo N mean graph for any N then all its vertices receive labels from the set 0 or 1 (mod 2N).

Proof

Let G be a one modulo N mean graph for any N. Now by Property 2.5[9], 0 and 1 are adjacent vertex labels.

Theorem 1.4

If $G = (p, q)$ is a connected one modulo N mean graph for any N then q is odd.

Proof

Let $G(p, q)$ be a connected one modulo N mean graph for any N. Then by Property 2.6[9], $N(q - 1) + 1$ is a vertex label.

Claim: q is odd.

Suppose q is even, then by Observation (v),

$N(q-1)+1 \equiv N+1 \pmod{2N}$.

Now $N(q-1)+1$ is a vertex label and it is congruent to $N+1 \pmod{2N}$ contradicts, the Theorem 1.3.

Hence q is odd.

Property 1.5

If $G = (p, q)$ is a connected one modulo N mean graph for any N with q is odd then the set of edge labels $\{1, N+1, 2N+1, \ldots, N(q-1)+1\}$ can be obtained as follows:

Edge labels	Adjacent vertex labels
1	(0, 1)
$N+1$	(0, $2N+1$) (1, $2N+1$) (1, $2N$)
$2N+1$	(0, $4N+1$) (1, $4N+1$) (1, $4N$) ($2N$, $2N+1$)
…	…
$N(q-1)+1$	($N(q-1)$, $N(q-1)+1$)

Corollary 1.6

If $G = (p, q)$ is a connected graph with q even then it is not a one modulo N mean graph for any N.

Proof

Follows from Theorem 1.4.

Theorem 1.7

If $G = (p, q)$ is a tree of odd order then it is not a one modulo N mean graph for any N.

Proof

Suppose $G = (p, q)$ is a one modulo N mean tree of odd order then p is odd which implies $q = p - 1$ is even, a contradiction to Corollary 1.6.

Theorem 1.8

If G is a unicyclic connected graph with $q$even then it is not a one modulo N mean graph for any N.

Proof

Follows by Corollary 1.6.

Theorem 1.9

If $G = (p, q)$ is a one modulo N mean graph with q is odd then the maximum possible adjacent vertex labels for any vertex x with label

$f(x) \in \{0, 1, N, N+1, 2N, 2N+1, \ldots, N(q-1)+1\}$ is

1) $\frac{q+1}{2}$ if $f(x) \equiv 0, 1 \pmod{2N}$

2) $\frac{q-1}{2}$ if $f(x) \equiv 3, 4 \pmod{2N}$

Proof

Case 1: $f(x) \equiv 0 \pmod{2N}$

Any number $f(x) \in \{0, 2N, 4N, 6N, ...\}$ will have the adjacent vertex labels as $\{1, 2N+1, 4N+1, \ldots, N(q-1)+1\}$.

Hence, the maximum number of possible adjacent vertex labels is $\frac{N(q-1)+1-1}{2N}+1=\frac{q-1}{2}+1=\frac{q+1}{2}$.

Therefore, if $f(x) \equiv 0 \pmod{2N}$ then the maximum number of adjacent vertex labels of x is $\frac{q+1}{2}$.

Case 2: $f(x) \equiv 1 \pmod{2N}$

Any number $f(x) \in \{1, 2N + 1, 4N + 1, \ldots\}$ will have adjacent vertex labels as $\{0, 2N, 4N, \ldots, N(q - 1)\}$ ... (*)

or from the set

$\{1, 2N + 1, 4N + 1, \ldots, N(q - 1) + 1\} - f(x) \cup \{f(x) - 1\}$ ... (**)

Hence, the maximum number of possible adjacent vertex labels is

$$\frac{N(q-1)-0}{2N}+1=\frac{q+1}{2} \quad \text{(from (*))}$$

or $\left(\frac{N(q-1)+1-1}{2N}+1\right)-1+1=\frac{q+1}{2}$ (from (**))

Therefore if $f(x) \equiv 1 \pmod{2N}$. Then the maximum number of adjacent vertex labels of x is $\frac{q+1}{2}$.

Case 3: $f(x) \equiv N \pmod{2N}$

Any number $f(x) \in \{N, 3N, 5N, 7N, \ldots\}$ will have the adjacent vertex labels as $\{N + 1, 3N + 1, 5N + 1, 7N + 1, \ldots, N(q - 2) + 1\}$.

Hence the maximum number of possible adjacent vertex labels is

$$\frac{N(q-2)+1-(N+1)}{2N}+1=\frac{q-3}{2}+1=\frac{q-1}{2}.$$

Therefore if $f(x) \equiv N \pmod{2N}$ then the maximum number of adjacent vertex labels of x is $\frac{q-1}{2}$.

Case 4: $f(x) \equiv N + 1 \pmod{2N}$

Any number of $f(x) \in \{N + 1, 3N + 1, 5N + 1, \ldots\}$ will have the adjacent vertex labels as $\{N, 3N, 5N, 7N, \ldots, N(q - 2)\}$ ... (*)

or from the set $\{N+1, 3N+1, 5N+1, \ldots N(q-2)+1\} - f(x) \cup \{f(x) - 1\} \ldots (**)$

Hence, the maximum number of possible adjacent vertex labels is

$\left(\frac{N(q-2)+1-(N+1)}{2N}+1\right)-1+1$

$= \frac{q-3}{2}+1=\frac{q-1}{2}$ (from (**)

(or) $\left(\frac{N(q-2)-N}{2N}+1\right)=\frac{q-3}{2}+1=\frac{q-1}{2}$ (from (*)

Theorem 1.10

If G is a connected one modulo N mean graph of odd size for any N then $\Delta \leq \frac{q+1}{2}$, where N is the maximum degree of a vertex in G.

Proof

Let G be a connected one modulo N mean graph of odd size then by Theorem 1.4, q is odd and by Theorem 1.3, all the vertex labels are congruent to either 0 or 1(mod 2N). In other words, G contains vertex labels from the set {0, 2N, 4N, …, $N(q-1)$} or {1, 2N + 1, 4N + 1, …, $N(q-1)$ + 1}. Now by Theorem 1.9, $\Delta \leq \frac{q+1}{2}$.

ABSTRACT

In the past few decades, women's empowerment has been associated with abundant global conference and mirroring. Vast majority of government schemes and projects have also identified this transmit besides all agenda. Ample efforts have been consistently embraced to get to grips with the social, economical and mental well-being of women. However, abundant schemes and enterprise particularly advance towards empowerment out from economic perspective. The appraisal of women's empowerment took into consideration various aspects inclusive of social, psychological, economical, familial and technological glebe. This study uses Multi Criteria Decision Making (MCDM) technique to identify the critical elements influencing women's empowerment on the social, economic, and psychological levels in India. These techniques can also be used to examine other important factors influencing women's empowerment. By applying TOPSIS to address some of the issues that girl children face, this study aims to identify the variables that contribute to their empowerment and to slipstream the challenges faced by themin Indian society.

Keywords: Social, economical and psychological barriers, accredited ethics, optimistic and defeatist idealized solution, TOPSIS.

INTRODUCTION

Women empowerment has become an universal conversation and contentious subject in India. Besides progression over the last few years, there is still a country mile to move on. Among some of global drifts in women's empowerment, about 50% of the world's population are women. But still, in India, the data shows a disparate sex ratio that gives rise to a comparatively low female population in contrary to men. Although the social status of

women is solicited, women are not given equal recognition as men. Women have been succumbed to gender barriers, discrimination, abuse, violence, molestation, poverty, rape and malnutrition, the prime issues of deprivation in India. In the prehistoric period, women were revered and worshipped as Goddesses. Later in the medieval period, the merit of women was limited to execute their utmost responsibility of caring all their family members, children and other house hold activities. People stood up by the traditional belief that, "Men are for thy field while women are home makers". Previously women had to surpass various hurdles due to male domination, patriarchal society system, old traditional believes and so on. But in the recent world, women have started breaking all the social barriers and problems against them in the society.

In this contemporary world, women have qualified themselves to stabilise both the family and professional responsibilities. Yet, sexual harassment at homes and offices by the family members, relatives, neighbours, friends, boss etc., persists due to which women suffer a lot to nurture their professional career and livelihood. The main objective of this paper is to augment the challenges faced by girl children in social, economical and psychological realms to proselytize their career based on some criteria using Multi Criteria Decision Making (MCDM) by employing TOPSIS method with accredited ethics revolved as interval.

LITERATURE REVIEW

The TOPSIS approach was created by Hwang and Yoon [2,5] as a means of resolving MCDM. They proposed the PIS and NIS, and each criterion needs to be maximised or minimised in order to support the shortest Euclidean distance. They stated that the TOPSIS method achieved the maximum level from the available alternatives and helped rioritise alternatives closely based on the optimal ideal solution. The option with the highest ranking is the best; the one with the lowest ranking is the worst. There is an intermediate rating between the best answer extremes for each possibility. Correct weighing of relative disease is made possible by the same set of selection criteria, and as a result, the optimal disease is concerning and it requires care.It was suggested by [1,4] that TOPSIS treats an MCDM problem with m-alternatives as a geometric system with m points in the n-dimensional space. The fundamental idea behind this method is that the alternative that is selected ought to have the greatest geometric distance from the NIS and the least geometrical distance from the PIS [7]. In order to apply TOPSIS, it is commonly assumed that the criteria should either be monotonically growing or decreasing, as proposed by [8], in order to facilitate the identification of PIS and NIS. The concept of generalised interval-valued fuzzy soft matrices (IVFSM) was established by the author in [3]. The trapezoidal fuzzy numbers via Sanchez's method were employed by Zulqarnain et al. [9] to identify diseases. Interval numbering is also a major improvement over. By using the TOPSIS extension under fuzzy data, [6] has expressed the possibility of success for pancreatic transplantation. IVFSM decision-making methodology was presented by [10], and the authors also offered IVFSM application [11] and a fuzzy soft matrix comparison research [12].

MATERIALS AND METHODS

Challenges faced by girl children in social, economical and psychological sphere:

1. Longevity and steadiness of socioeconomic structures
2. Battle against corruption and economic security
3. Evolution of management, marketing and entrepreneurship in the context of globalization
4. Female fomicide
5. Maltreatment against women
6. Early marriages of girls
7. Female illiteracy and dowry
8. Particularly targeted abortion and specific female infanticide
9. Sexual harassment
10. Disparity in education
11. Low status in the family

12. Status of widows
13. Domestic violence
14. Discrimination due to stereotype
15. Inadequate nutrition

SPECIFICATION FAVOURED IN LIGHT OF OBSTACLES ENCOUNTERED BY GIRL CHILDREN:

1. Increasing financial liability
2. Low status of women in society
3. Safety concerns about girl children
4. Control over sexuality
5. Poverty
6. Gender Inequality
7. Gender harassment
8. Sexual Coercion
9. Not permitted to be present at any social and religious functions.
10. Unwanted sexual attention

METHODOLOGY

The traditional TOPSIS approach makes the assumption that a single decision maker solves the problem and that the ratings of the alternatives and weights are represented by numerical data. When there are multiple decision makers, complexity increases because the ideal solution needs to be accepted by interest groups, each of which typically has different objectives. However, in certain situations, it can be challenging to determine the precise value of criteria, so decision makers are typically more at ease giving intervals to specify model input parameters. An easy and natural way to express uncertainty, which is common in actual decision-making situations, is through the use of interval number data formulations.

Topsis method with attributed values hell-bent on as interval:

1. Jahanshahloo, Lofti, and Izadikhah devised an algorithmic approach that builds upon TOPSIS for decision-making issues involving interval data. The following steps enumerates the procedure.
2. **Step1:** Concoct a decision matrix $S=\left(s_{ij}\right)$ and let $\omega=\left[\omega_1,\omega_2,\omega_3.....\omega_n\right]$ be the ponderosity where $s_{ij}=\left[\underline{s_{ij}},\overline{s_{ij}}\right],\underline{s_{ij}},\overline{s_{ij}}\in\Re,\omega_j\in\Re$ and $\omega_1+\omega_2+\omega_3.....+\omega_n=1.$
3. **Step 2:** The normalized values of $\underline{s_{ij}},\overline{s_{ij}}$ arecalculated by,
4. $$\underline{N_{v_{ij}}}=\frac{\underline{s_{ij}}}{\sqrt{\sum_{i=1}^{m}\left(\left(\underline{s_{ij}}\right)^2+\left(\overline{s_{ij}}\right)^2\right)}}$$ where $i=1,2,.....m\ \&\ j=1,2,.....n$

$$N_{v_{ij}}^{-} = \frac{\bar{s}_{ij}}{\sqrt{\sum_{i=1}^{m}\left(\left(\underline{s}_{ij}\right)^2 + \left(\bar{s}_{ij}\right)^2\right)}}$$

5. where $i = 1, 2, ...m \;\&\; j = 1, 2, ...n$

6. **Step 3:** The ponderosity of the normalized values are gauged as,

$$u_{ij} = \omega_{ij}\, u_{ij} \;\; for\, i = 1, 2, ...m \;\&\; j = 1, 2, ...n$$

7. $\underline{\quad}$ $\underline{\quad}$

8. $\bar{u}_{ij} = \omega_{ij}\, \bar{u}_{ij} \;\; for\, i = 1, 2, ...m \;\&\; j = 1, 2, ...n$ where ω_j is the ponderosity of the j^{th} barometer $\sum_{j=1}^{n} \omega_j = 1$

9. **Step 4:** The value of optimistic idealized solution is gleaned by,

10. $$B^{+} = \left(u_1^{+}, u_2^{+}, u_3^{+} .....u_n^{+}\right) = \left(\left(\max_i\left(\bar{u}_{ij}\right) / \; j \in I_c\right), \left(\min_i\left(\underline{u}_{ij}\right) / \; j \in J_c\right)\right)$$

11. The value of defeatist idealized solution is given by,

12. $$B^{-} = \left(u_1^{-}, u_2^{-}, u_3^{-} .....u_n^{-}\right) = \left(\left(\min_i\left(\underline{u}_{ij}\right) / \; j \in I_c\right), \left(\max_i\left(\bar{u}_{ij}\right) / \; j \in J_c\right)\right)$$

13. where I_c is kindered with the benefit barometer and J_c with the cost barometer.

14. **Step 5:**The dissociation of each radical from the optimistic idealized solution is lined as,

15. $$p_i^{+} = \sqrt{\sum_{j=1}^{n}\left(\underline{u}_{ij} - u_j^{+}\right)^2 + \sum_{j=1}^{n}\left(\bar{u}_{ij} - u_j^{+}\right)^2}, i = 1, 2, ...m$$

$$p_i^{-} = \sqrt{\sum_{j=1}^{n}\left(\bar{u}_{ij} - u_j^{-}\right)^2 + \sum_{j=1}^{n}\left(\underline{u}_{ij} - u_j^{-}\right)^2}, i = 1, 2, ...m$$

Step 6: The relative proximity of each alternative B_i with respected to B^{+} and B^{-} is established by the relation,

$$R_i = \frac{p_i^{-}}{p_i^{-} + p_i^{+}} \text{ where } 0 \le R_i \le 1 .$$

Solution by topsis method:

The scale for alternative grading in case of values considered as interval is as follows

Table 6.1: Scale for grading interval values

Step1: The decision matrix for the stipulated data for the mentioned attribute value is given by,

Step 2: The normalized values are given by,

Table 6.3: Normalized values for the formulated decision matrix

Step 4: The weights for each criteria are
The ponderosity of the normalized matrix is obtained by multiplying each criteria with its corresponding weight.
Step 5: The optimistic and the defeatist idealized solution and their dovetailed grade is acquired to be
Table 6.4: Optimistic and the defeatist idealized solution and their corresponding dovetailed grade scale

CONCLUSION

The goal of this research is to evaluate the obstacles that women encounter in the social, economic, and psychological spheres using the criteria and attributes mentioned above. The options are sorted using TOPSIS, and the weight for each criteria is established using the MCDM with approved interval ethics. It has been discovered that power and gender disparities, along with frequently unintentional presumptions firmly ingrained in gender norm stereotypes, are the driving forces behind sexual harassment in all spheres of society. These days, it's indispensable to stop harassment since it fosters a healthy workplace environment, encourages participation, boosts employee retention, and shields against legal ramifications. Practical ramifications include the possibility for women to work in India and achieve financial independence through administrative services. There is potential to mitigate some of the pervasive gender discrimination in society through the implementation of protective laws by the government. If all women in the community are given equitable access to education and training, they will be able to advance in a variety of societal roles. The advancement of women's status in the political arena, the economic, social and the psychological glebe is essential to the betterment of society as a whole. Fundamental improvements stem from the correct interaction between the family and society, which is the foundation of women's development. Well-informed and educated women are capable of contributing effectively to local problem solutions through planning and involvement.

ABSTRACT

This study investigates Indian scholarly contributions to Open Access (OA) publishing over the past five years (2020-24) using the Scopus indexing database, one of the most reliable sources for tracking scholarly publishing worldwide. The analysis highlights India's role in the open-access field, enabling a comparative assessment against global trends and, in particular, illuminating India's ranking in international research. The results indicate a positive upward trend in scholarly research outputs from India, encompassing various publishing formats, including journals, conference proceedings, book series, and monographs. India ranks third in total publications and sixth in OA publications. Most Indian private universities contribute more documents than the top Indian institutes. The subject area is primarily dominated by Sciences and Technologies, particularly medical and allied fields, while the social sciences and humanities have comparatively lower participation. An Indian author tends to publish more in foreign or international OA journals than in Indian journals. Major international collaborations include countries like the United States, the United Kingdom, Saudi Arabia, China, and Japan. As a conclusion, this study reveals a continuous and growing research interest in the Indian community on OA publications, and the authors propose several recommendations aimed at strengthening and improving OA publishing activities in India.

Keywords: Open Access, Open Access Publishing, Scholarly Publishing, Open Access - India

INTRODUCTION

Open Access (OA) is an innovative form of scholarly communication in the digital age, enabling the free and unrestricted sharing of research publications worldwide. This model promotes wider dissemination of knowledge and increases the influence of scholarly work. The rising costs of subscriptions and the rise of the Internet paved the way for a new publishing and dissemination model called Open Access, which aims to replace the traditional subscription-based system. OA publishing offers a relatively new way to share research findings [1]. However, many scholarly journals still operate behind pay walls, limiting access for researchers who depend on these resources [2]. Financial constraints often prevent libraries and research institutions from acquiring all necessary publications, creating a demand for alternative access models that support free dissemination of scientific knowledge, such as Open Access[3]. Initiatives such as the Budapest Open Access Initiative [4] and the Berlin Declaration [5] have played pivotal roles in promoting self-archiving and the development of Open Access journals, aiming to remove financial and legal barriers to access. As digital technology continues to transform scholarly communication, various Open Access models—such as Gold, Green, and Diamond—have emerged, each with unique features and implications for research visibility and impact [6,7]. This innovative publishing approach has also led to the development of new business models, such as publishers collecting Article Processing Charges from authors [8]. The push toward Open Access has been driven by funder mandates and changing attitudes within the research community, reflecting a growing commitment to increasing access to scholarly literature[9]. Over the past two decades, Open Access (OA) has significantly transformed scholarly communication by enabling the free and open distribution of research. India has also actively participated in open access initiatives, aiming to expand the global reach of its research efforts.

REVIEW OF LITERATURE

The landscape of open access publishing in India shows both notable progress and ongoing difficulties. Indian OA advocate Arunachalam stresses that Indian researchers should make their work freely accessible by publishing in OA journals and placing it in the Institutional Repository for wider dissemination [10]. Later studies, such as those by Kurata *et al*., found that Indian OA publications are increasing in number, especially in the biomedical field, but they still need to improve in quality [11]. Singh and Khanchandani examined Indian OA publication, particularly in the sciences, and discovered that it is growing faster than in other disciplines, especially within medical sciences [12]. Sahoo *et al*., found that Indian publishers contribute only 5% to the Directory of Open Access Journals (DOAJ), with 43% of publications appearing in other sources [13]. Piryani, Dua, and Singh analyzed India's research output from 2014 to 2018 and found that around 24% of publications are available as OA, mainly through gold OA. Additionally, the study showed that fields like medical sciences and physics have higher contributions compared to arts, humanities, and social sciences [14]. Recent academic research has highlighted several key challenges within India's open access publishing landscape. Barik and Jena identified a serious lack of indexing of Indian OA journals in major databases, emphasizing the need for improved publication quality and compliance with international standards [15]. Similarly, Nazim *et al*., analyzing the Scopus database and Indian OA policies, showed India's relatively low ranking in global open access metrics despite its large research output. This underlines the need to refine OA policies and raise publishing standards to increase the visibility and use of Indian OA publications worldwide [16]. Furthermore, Sharma *et al*., exposed concerning levels of non-compliance with the Committee on Publication Ethics standards among Indian open-access journals, along with a high incidence of predatory publications [17]. This highlights the urgent need for a shift toward prioritizing quality and rigorous practices, including strong peer-review processes and continuous monitoring, within India's OA ecosystem. In summary, the existing literature emphasizes the complex nature of India's open access system and its publications, underscoring the immediate need for a centralized OA policy supported by adequate financial and technical resources to build a strong, reputable open access publishing infrastructure in India.

MATERIALS AND METHODS

METHODOLOGY

Bibliographic databases are vital, serving as primary sources for publication metadata and bibliometric indicators essential for research evaluation and daily tasks. Web of Science and Scopus are the leading databases in this area [18]. Over the years, Scopus has established itself as a comprehensive bibliographic data source, proving to be reliable and, in some respects, even better than Web of Science [19]. Therefore, the Scopus database has been chosen for this study. This study examines India's contributions to Open Access (OA) scholarly publishing from 2020 to 2024. Scopus is a comprehensive multidisciplinary resource that encompasses over 27,950 high-impact journals, including 6,128 Gold Open Access journals, 192 trade journals, 1,167 book series, and more than 11.7 million conference papers from 1,48,500 worldwide events. Scopus enhances academic research by allowing multiple citation metrics to be cross-referenced, thereby aggregating bibliographic data and facilitating in-depth analyses [20]. The search query was conducted on November 24, 2025, using the Scopus database. The initial search query "(PUBYEAR > 2019 AND PUBYEAR < 2025) " was used to find overall publications worldwide for the last five years (2020-2024), retrieving 2,09,03,259 documents. These documents were downloaded into MS Excel for further analysis, focusing on the Indian global rank in non-OA and OA publications. The second query aimed to determine India’s contribution over the same periods (2020-2024) in the OA publication, comparing it with different parameters of this study. The query "(PUBYEAR > 2019 AND PUBYEAR < 2025) AND (LIMIT-TO (OA, "all") AND (LIMIT-TO (AFFILCOUNTRY, "India")"retrieved a substantial dataset of 4, 21, 538 documents categorised as Open Access. These retrieved results were exported to MS Excel for further analysis and study. The analysis employed various filtering options to identify different document types, including journal articles, conference papers, letters, reviews, and editorials. It also examined factors such as subject discipline, the volume of publications from leading journals, contributions from individual research institutes, countries involved in collaborations, funding agencies, and preferred publishing language. Additionally, the study facilitates a comparative evaluation of global OA trends, clarifying India's role in the international research landscape and providing valuable insights for policymakers, researchers, and institutions. The analysis enhances understanding of India's research strengths, collaborative networks, and the influence of funding initiatives on its OA output.

Analysis and Finding

Worldwide Distribution of Non-OA and OA publications

Table 1 details the worldwide contributions to Non-OA and OA publications over the past five years, from 2020 to 2024. Out of a total of 2,09,03,259 publications, non-OA contributed 1,16,15,207, and OA contributed 9288052 documents, making up approximately 44.43% share of all publications. Among the top countries for both non-OA and OA publications, China ranked first in non-OA with 34, 08, 677 documents and second in OA with 17,31,792 documents. The United States ranked second in non-OA with 20, 02, 913 documents, but led in OA with 1,80,4281 documents. Additionally, India was third in non-OA with 10, 37, 884 documents and sixth in OA with 4,21,538 documents, totaling 1,459,422 documents overall. The trend over the last five years shows a significant shift toward Open Access publishing, which now accounts for about 44.43% of all publications. India is emerging as one of the leading contributors of research publications, both in non-OA and OA publications.

Indian Contribution to different OA channels

Indian authors favor diverse OA access channels to share their research, as shown in Table 2. An analysis of 4, 21, 538 OA documents reveals that the Gold channel accounts for 2,89,351 (68.64%) documents, the Green channel for 1,91,898 (45.52%), the Hybrid Gold channel for 46,887 (11.12%), and the Bronze channel for 42,868 (10.16%) documents. It is important to note that these figures may overlap, especially among the Gold, Hybrid Gold, and Green channels. Nonetheless, the Gold channel remains the most popular among authors, indicating a trend toward increasing the accessibility and visibility of their work within the scholarly community. The trend in OA contributions has shown consistent annual growth over the past five years.

Different Open Access Source Contributions

Analysis of open access document types in Table 3 shows a clear dominance of journal publications, which comprise 3,90,855 documents and make up 92.49% of the total 4,21,538 documents. Conference proceedings follow with 25,880 documents (6.13%), while books account for 2,482 documents, and book series include 2,207 documents. Trade journals are the least common, with only 114 documents. This pattern indicates that the authors prefer journal publications, likely because of their greater visibility and influence in the academic community. The number of publications is gradually increasing year by year, indicating India's growing research and development activities and its emergence as one of the economically powerful nations in the world.

Types of Documents

According to the classification provided by Scopus, these documents are organized into eleven distinct types, as shown in Table 4. Notably, articles are the most common category, making up 3,16,649 entries, which is about 75.11% of the total. This is followed by Reviews and Conference Papers, accounting for 39,564 (9.38%) and 29,760 (7.05%), respectively. Other document types, such as Letters with 13,802, Editorials with 8,357, Notes with 5,899, and Errata with 5,216, among others, represent smaller parts of the scholarly landscape. This distribution indicates that journal articles outnumber other document types.

Subject Distribution of OA Documents

The analysis of the Subject's contributions, as shown in Table 5, revealed that Medicine-related disciplines contributed a significant 1,32,148 (31.43%) documents. Engineering closely followed with 67,049 (15.90%) documents. Next, computer science contributed 5,3649 (12.72%) documents; Physics and Astronomy added 47,026 (11.15%) documents, while Biochemistry, Genetics, and Molecular Biology Sciences accounted for 47,761 (11.33%) documents. Agricultural and Biological Sciences contributed 38,850 (9.21%) documents, Environmental Sciences had 38,068 (9.03%) documents, Chemistry added 3,1685 (7.51%) documents, and Mathematics contributed 29,955 (7.10%) documents. Although the Social Sciences and Arts and Humanities subjects represent a smaller share of the overall publication output, with just 21,195 documents (5.02%) and 3,535 documents (0.84%) respectively, they are ranked 13th and 27th, respectively.

Major Contributing Institutions

An in-depth analysis of articles published by Indian authors in OA venues shows a diverse range of contributing institutions, as illustrated in Table 6. The Manipal Academy of Higher Education dominates with 9,044 documents, followed by All India Institute of Medical Sciences (AIIMS) with 8,576 documents, Saveetha Institute of Medical and Technical Sciences with 8,074 documents, Vellore Institute of Technology with 6,816, the Indian Institute of Science with 6,432 documents, and the Postgraduate Institute of Medical Education and Research with 6,294 documents. Other notable private institution contributors include SRM Institute of Science and Technology with 5,915 documents, Vellore Institute of Technology again with 5,455 documents, Lovely Professional University with 5,195 documents, and among others, the University of Delhi, Indian Council of Agriculture Research, Homi Bhabha National Institute, IIT Madras, IIT Bombay, Banaras Hindu University, and Amity University, with 5,122, 4,770, 4,564, 4,513, 4,326, 4,113, and 4,101 documents respectively. It is very noticeable that emerging private universities have become leading research contributors compared to the country's premier institutions.

Major Research Funding Agencies

Research and publishing activities are significantly supported by sponsorship from various agents, including 169 international agencies, which supported 2, 03, 727 publications. This support is crucial for advancing scientific inquiry. Table 7 reveals the top ten funding bodies: the Department of Science and Technology, supporting 20,573 documents; followed by the Science and Engineering Research Board with 12,600; the Council of Scientific and Industrial Research with 9,635; the Department of Biotechnology with 8,438; the University Grants Commission with 8336; the Indian Council of Medical Research with 5,052; and the Ministry of Education with 2,750 publications. International agencies such as Horizon 2020 Framework Programme, UK Research and Innovation, the National Science Foundation, King Saud University, the National Institutes of Health, the National Natural Science

Foundation of China, and the National Research Foundation of Korea also made significant contributions, supporting 4,179; 4,144; 4,029; ,3994; 3,757; 3,405; and 3,081 publications respectively. By bringing together diverse perspectives, expertise, and resources, these collaborations can spark novel ideas and accelerate the translation of research findings into tangible societal benefits. The synergy created through shared knowledge and joint efforts not only enhances the quality and impact of research but also strengthens a country's capacity to address complex challenges and remain competitive on the global stage.

Major Collaborative Countries

India's recent advancements in research output and engagement in OA publishing reflect noteworthy upward progress. Over the past five years, India has contributed 4, 21, 538 documents in different OA publication channels, underscoring its commitment to knowledge dissemination and academic collaboration and standing in the 6th position in world-level OA contribution. Whereas the United States, the United Kingdom, Saudi Arabia, and China lead in OA contribution. Table-8 indicates the impressive contributions from the collaborating countries, such as the U.S. with 39,178 documents, the U.K. with 23,300 documents, Saudi Arabia with 23,174 documents, China with 13,919 documents, Australia with 12,718, Germany with 12,627 documents, Italy with 10,522, South Korea with 10,252, Canada with 8,926 documents, showing collaborative research activities by India. This data underscores the necessity for India to implement strategic initiatives to enhance its presence in OA publishing further and strengthen its role in the global research community.

Major Journal/conference proceeding

A review of Scopus-indexed open access journals and conference proceedings from 2020 to 2024, shown in table-9, highlights the substantial scholarly output of Indian authors in the global research landscape. Several prominent international journals have become key venues for disseminating Indian research, with Scientific Reports leading the way with 5,993 papers, followed by Journal of Physics Conference Series (5,438), Indian Journal of Ophthalmology (4,046), IEEE Access (3,926), ACS Omega (2,605), Heliyon (2,437), Indian Journal of Otolaryngology and Head and Neck Surgery (2,126), PLoS One (1,985), Sustainability Switzerland (1,970), and RSC Advances (1,942). Beyond journals, international conference proceedings also serve as vital platforms for Indian researchers to present their work, with AIP Conference Proceedings (3,470 papers), E3S Web of Conferences (2,851), and IOP Conference Series: Earth and Environmental Science (1,771) showcasing considerable publication activity. Collectively, these data highlight the substantial and increasing contributions of Indian researchers to open access scientific literature across various disciplines. A significant portion of this output is concentrated in journal publications. Notably, Indian authors demonstrate a preference for publishing in foreign or international journals, likely driven by the pursuit of broader visibility and enhanced recognition for their work.

Preferred Publishing Language

Based on the data shown in Table 10, Indian authors have published a total of 4,21,538 documents in 35 languages, including various formats such as articles, reviews, and notes. English is the dominant language, making up 4,21,272 (99.93%) of the publications. This preference is probably due to the widespread use of English as the medium of instruction and research in Indian higher education and research institutions. Outside of English, the remaining publications are spread across 34 other languages, and contributed fewer documents.

DISCUSSION

This study highlights a significant rise in Indian scholarly research publications, establishing India as a major contributor on the global research stage, ranking third overall alongside leading countries like the USA, UK, Saudi Arabia, China, and Germany. Despite this growth, India's open access (OA) publication ranking remains at sixth, underscoring a critical need for government support and encouragement to boost OA activities within the country. Most Indian OA publications are found in article form (75.58%), particularly in journal publications, indicating that Indian authors prefer publishing in foreign journals to increase visibility and recognition rather than in Indian

journals. Interestingly, private universities and recently established institutions, particularly the Manipal Academy of Higher Education, Saveetha Institute of Medical and Technical Sciences, Vellore Institute of Technology, SRM Institute of Science and Technology, Lovely Professional University, are outperforming top government-supported institutions in publication output. Collaborative research with foreign countries such as the USA, UK, Saudi Arabia, and Germany, often supported by external funding, is also evident. Research efforts and publications are heavily focused on science and technology, particularly in the medical and allied fields, while the social sciences and humanities remain comparatively very low and require more support and encouragement to grow. English is the dominant language of publication, with 4,21,272 (99.93%) documents, while other languages, such as Spanish, Ukrainian, Russian, and other languages, contributed fewer documents. The results of this investigation necessitate prompt and critical measures to strengthen research publication activities within India, encompassing both conventional non-Open Access (OA) and OA publishing frameworks. Addressing this imperative demands a comprehensive strategy. Initially, the implementation of a unique national OA policy, coupled with a strong monitoring mechanism to guarantee publication quality benchmarks align with international publishing standards, is indispensable. Secondly, there should be a significant increase in governmental funding for Research and Development (R and D) activities. Currently, the allocation of 0.7% of GDP to Science and Technology development is substantially lower than that of comparable countries such as China (2.4%), the USA (3.5%), and Israel (5.4%) [21]. This should be elevated toward the recommended global standard of 6%. While the Government of India's "One Nation One Subscription" program, which provides free access to 30 international journal databases, and an annual allocation of Rs. 150 crores for Article Processing Charges (APCs) to encourage Indian publications in OA journals [22], is a commendable step, this financial commitment remains insufficient and should be increased to support a greater volume of publications effectively. Thirdly, improving the global visibility of Indian research output requires a concerted effort to train and encourage Indian researchers to share their findings through OA publishing venues. By incentivizing OA publications, especially in Indian-based publishing houses, and incorporating OA publications as a positive criterion in hiring, promotion, and tenure evaluations, institutions can encourage researchers to adopt this increasingly important publishing model. Consequently, providing robust infrastructure, comprehensive training programs, and ample resources for Indian authors and publishers is paramount to achieving this objective. Such support will be instrumental in establishing Indian open access publications as both credible and influential contributors to the global research publication arena.

ABSTRACT

Psoriasis is a chronic, immune-mediated inflammatory dermatosis characterized by recurrent episodes and variable clinical severity. Although several conventional therapeutic options are available, long-term disease control remains challenging due to adverse effects, cost, and frequent relapses. This prospective case report describes the clinical outcome of a patient with mild plaque psoriasis managed with individualized homoeopathic treatment over a period of six months. Disease severity was objectively assessed using the Psoriasis Area and Severity Index (PASI). Baseline PASI assessment revealed a score of 2.0, indicating mild disease activity involving the head and trunk regions. Remedy selection was based on the totality of physical, mental, and local symptoms. Progressive improvement was observed during follow-up, with gradual reduction in erythema, thickness, and scaling. At the end of six months, complete clinical resolution was achieved, and the PASI score reduced to 0.0. The findings suggest that individualized homoeopathic treatment

may contribute to symptomatic relief and sustained remission in mild plaque psoriasis when monitored using standardized outcome measures.

Keywords: Psoriasis; Homoeopathy; PASI score; Case report; Individualized medicine; Chronic skin disorder

INTRODUCTION

Psoriasis is a chronic, relapsing inflammatory disorder of the skin characterized by excessive keratinocyte proliferation and immune-mediated epidermal changes [1]. Clinically, it presents as well-defined erythematous plaques with adherent silvery scales, commonly affecting extensor surfaces, scalp, and trunk [2]. The global prevalence of psoriasis is estimated to range between 1–3%, with considerable variation across populations [3]. The etiopathogenesis of psoriasis involves a complex interaction between genetic predisposition, environmental triggers, and immune dysregulation. Current evidence highlights the role of T-helper cell-mediated immune responses, particularly Th1 and Th17 pathways, leading to increased production of inflammatory cytokines such as tumor necrosis factor-alpha, interleukin-17, and interleukin-23 [4,5]. These mediators promote keratinocyte hyperproliferation and persistent inflammation. Psoriasis significantly affects quality of life, even in mild cases. Patients frequently experience psychological distress, impaired self-esteem, and social embarrassment [6,7]. Conventional treatment modalities include topical corticosteroids, vitamin D analogues, phototherapy, systemic immunosuppressants, and biologic agents [8]. While effective in disease suppression, these therapies may be limited by adverse effects, financial burden, and relapse after discontinuation [9]. Homoeopathy is a holistic system of medicine based on the principle of individualization, wherein treatment is selected according to the totality of symptoms rather than the disease label alone [10]. Despite widespread clinical use in chronic dermatological conditions, systematic documentation using validated outcome measures remains limited [11]. The Psoriasis Area and Severity Index (PASI) is a standardized and reproducible tool used to assess disease severity and therapeutic response [12]. This case report presents a patient with mild plaque psoriasis treated with individualized homoeopathic medicine, objectively evaluated using PASI over a six-month follow-up period.

MATERIALS AND METHODS

This case report has been prepared in accordance with the CARE guidelines.

This prospective, single-case observational study was conducted in the outpatient department of a homoeopathic medical college hospital. Clinical evaluation was performed using the Psoriasis Area and Severity Index (PASI), as described by Fredriksson and Pettersson [12]. Baseline assessment included detailed case history, general and systemic examination, and dermatological evaluation. PASI scoring was calculated by assessing erythema, thickness, scaling, and area of involvement across four body regions—head, upper limbs, trunk, and lower limbs—using standard weighting factors. Follow-up visits were conducted monthly for six months, and PASI scoring was repeated to objectively monitor disease progression. Individualized homoeopathic treatment was prescribed based on the totality of symptoms, including constitutional, mental, and local features. Verbal informed consent was obtained from the patient for participation and anonymous publication of clinical data and photographs.

Case Presentation

A 40-year-old male office assistant presented with mild scaly erythematous plaques on face and trunk for three years. He reported mild itching and scaling localized to extensor surfaces, with occasional aggravation during dry winter months. There was no history of systemic illness or family history of psoriasis or autoimmune disorders. General examination revealed normal vital parameters, and systemic examination was unremarkable. Local examination showed symmetrical, well-demarcated erythematous plaques with mild thickness and fine silvery scaling on face and trunk. The overall body surface area involved was minimal.

Baseline PASI Assessment (Before Treatment)

Baseline PASI scoring was performed prior to initiation of treatment. Severity scores revealed erythema and thickness graded as moderate (score 2) over the head and trunk regions, with absence of scaling. Area of involvement was graded as score 2 for the head (10–29%) and score 1 for the trunk (1–9%). Upper and lower limbs showed no involvement. After applying regional weighting factors and area scores, the total PASI score before treatment was calculated as 2.0, indicating mild plaque psoriasis.

Case Analysis and Evaluation

The clinical presentation was consistent with mild chronic plaque psoriasis. Aggravating factors included dry and cold weather and mental stress. The totality of symptoms comprised mild erythematous scaly plaques on extensor surfaces, winter aggravation, stress-related exacerbation, and mild anxiety related to cosmetic appearance.

Prescription and Follow-Up

Based on repertorization and clinical judgment, Sulphur 30C was prescribed once daily for two weeks. Follow-up evaluations were conducted monthly with clinical assessment and PASI scoring. Potency and repetition were adjusted as per clinical response.

RESULTS

The patient showed progressive clinical improvement during the six-month treatment period. PASI scores reduced steadily from baseline to complete resolution. At the end of six months, erythema, thickness, scaling, and area involvement had completely resolved. The final PASI score was 0.0, confirming complete clinical remission. No adverse effects or relapse were observed during follow-up.

DISCUSSION

Psoriasis is a chronic inflammatory dermatosis requiring long-term management, even in mild cases where quality of life may be significantly affected [1–3]. In the present case, individualized homoeopathic treatment resulted in complete clinical remission within six months, objectively confirmed by PASI scoring. The reduction of PASI from 2.0 to 0.0 indicates resolution of both morphological and pathological features of psoriasis. Homoeopathy emphasizes individualized treatment based on the totality of symptoms, which may contribute to restoration of systemic balance and sustained improvement. Objective assessment using PASI enhances scientific credibility and reproducibility of clinical outcomes [12]. However, as this is a single-case report, larger controlled studies are required to establish definitive efficacy.

CONCLUSION

This case report demonstrates that individualized homoeopathic treatment may achieve complete remission in mild plaque psoriasis, as evidenced by PASI score reduction from 2.0 to 0.0 over six months. PASI-based evaluation strengthens clinical documentation and supports the integration of standardized outcome measures in homoeopathic research.

ACKNOWLEDGEMENT

The authors acknowledge the support of the outpatient department staff of Jawaharlal Nehru Homoeopathic Medical Hospital, Vadodara, for clinical assistance and documentation.

Conflict of Interest
The authors declare no conflict of interest.

Ethics Approval
The authors confirm that verbal informed consent was obtained from the patient for the anonymous publication of clinical details and photographs. The patient's identity has been fully protected and is not disclosed in any form in this case report.

Funding
No external funding was received for this study.

Data Availability
To protect patient confidentiality, the raw clinical data are not publicly accessible. De-identified summary data relevant to the findings of this study may be obtained from the corresponding author upon reasonable request and subject to ethical considerations

ABSTRACT

Accurate obesity diagnosis remains challenging due to the involvement of multiple physiological, behavioral, genetic, and psychological factors, along with the inherent uncertainty in expert evaluations. To manage this complexity, this study develops a structured medical decision-support framework within the IFHSS environment under aMAGDMsetting. The proposed model effectively captures hierarchical attribute relationships and expert hesitation through intuitionistic membership and non-membership information. For objective weight determination, first- and second-order Taylor series–based ordinary differential equation (ODE) techniques are employed to generate normalized weight vectors. Furthermore, the IFHS-WAand IFHS-WG operators are utilized to fuse expert assessments. A case study in data on obesity evaluation is conducted to illustrate the applicability of the framework, and comparative analysis confirms the stability and consistency of the obtained rankings. The results indicate that the proposed IFHSS-based MAGDM model provides an effective and reliable tool for complex medical decision-making problems under uncertainty.

Keywords: Obesity Diagnosis, Intuitionistic Fuzzy Hyper Soft Set (IFHSS), Multi-Attribute Group Decision Making (MAGDM), ODE Taylor Series, IFHS-WA Operator, IFHS-WG Operator, Medical Decision Support System.

INTRODUCTION

Obesity has emerged as a serious global public health concern because of its strong association with chronic illnesses such as cardiovascular disease, diabetes mellitus, metabolic syndrome, and certain types of cancer [23]–[25]. Recent epidemiological evidence indicates a steady increase in obesity prevalence across different age groups, emphasizing the necessity for more reliable and systematic diagnostic frameworks [23], [24].The assessment of obesity is inherently multifaceted, as it depends on numerous interrelated factors including dietary behavior, physical activity, sleep quality, genetic background, metabolic conditions, and psychological influences. In clinical practice, the evaluation process often involves expert judgment, which may be subjective and imprecise. Such uncertainty can lead to inconsistent diagnostic outcomes. Therefore, obesity assessment can be naturally formulated as a MAGDM problem under uncertain conditions.Over the past few decades, several mathematical tools have been proposed to address uncertainty in decision analysis. Fuzzy set theory, introduced by Zadeh, provides a mechanism to represent vagueness through graded membership values [1]. Although widely used, classical fuzzy models have limitations when dealing with parameterized information. To overcome this issue, Molodtsov proposed soft set theory, which explicitly incorporates parameters into the modelingprocess [2], and this framework was later extended by Maji et al. [3]. These developments significantly improved the handling of uncertainty in parameter-dependent environments.To further capture expert hesitation, intuitionistic fuzzy sets (IFS) were introduced by incorporating both membership and non-membership degrees along with a hesitation margin [8], [9]. Subsequently, various intuitionistic fuzzy soft set–based MAGDM models and aggregation operators were developed to enhance decision reliability and robustness [10], [11], [20]. In addition, several numerical and hybrid extensionsincluding intuitionistic triangular fuzzy sets, squareroot fuzzy models, and Runge–Kutta-based MAGDM approacheshave been explored to improve computational performance [4], [5].Despite these advances, many real-world decision problems, particularly in healthcare, involve attributes that are naturally decomposed into multiple sub-attributes. Conventional fuzzy and soft set frameworks are not sufficiently flexible to represent such hierarchical structures. To address this limitation, fuzzy hypersoft sets (FHSS) were introduced to model multi-level attribute systems through explicit sub-attribute decomposition [6],[7]. Building on this concept, intuitionistic fuzzy hypersoft sets (IFHSS) integrate hypersoft structures with intuitionistic fuzzy logic, enabling simultaneous handling of hierarchical relationships and expert hesitation [16],[17]. IFHSS-based models have been successfully applied in several MAGDM contexts, including engineering evaluation and service quality assessment [13]–[15], [18], [19].However, many existing IFHSS-based MAGDM approaches rely on subjective or conventional weighting strategies, which may introduce bias into the final decision. Determining objective and stable weight vectors therefore remains an open challenge. Traditional techniques such as entropy-based or deviation-based methods do not always guarantee sufficient robustness [12], [13]. Recently, numerical approaches based on Taylor series expansions and ordinary differential equations (ODEs) have shown promise for generating normalized and systematic weight vectors [4], [5].Motivated by these observations, this study develops an IFHSS-based MAGDM framework for obesity diagnosis that integrates Taylor series–based first- and second-order ODE methods for objective weight computation. The proposed model employs the Intuitionistic Fuzzy Hypersoft Weighted Averaging (IFHS-WA) and Intuitionistic Fuzzy Hypersoft Weighted Geometric (IFHS-WG) operators to aggregate expert evaluations under hierarchical attribute structures, thereby supporting both compensatory and non-compensatory decision behavior.

PRELIMINARIES

In the subsequent section, we outline key preliminary concepts—FS, SS, HSS, FHSS, and IFHSSthat form the foundation of the proposed research methodology.

Definition 1.[Fuzzy Soft Set]
Let $F(\mathfrak{U})$is fuzzy subsets of the universal$\mathfrak{U}$ and $\mathcal{E}$ be the attributes set. For any subset$B \subseteq \mathcal{E}$, then a pair $(F, B)F : B \rightarrow F(\mathfrak{U})$

Definition 2. [HSS]
Consider $\mathfrak{U}$is domain, and$P(\mathfrak{U})$is set of sub-sets of$\mathfrak{U}$ and$o = \{o_1, o_2, o_3, \ldots, o_n\}, n \geq 1$ be a set of attributes and "$O_1 \times O_2 \times O_3 \times \ldots \times O_n = \ddot{B} = \varkappa_{1r} \times \varkappa_{2s} \times \ldots \times \varkappa_{en}$
where $1 \leq r, s, e \leq \iota_1, \kappa_2, \varsigma_3$ *and* $\iota_1, \kappa_2, \varsigma_3 \in \mathcal{N}$
$F: O_1 \times O_2 \times O_3 \times \ldots \times O_n = \ddot{B} \rightarrow P(\mathfrak{U})$

Definition 3. [IFHS]
Consider $\mathfrak{U}$ is domain, and $P(\mathfrak{U})$is set of sub-sets of$\mathfrak{U}$ and$o = \{o_1, o_2, o_3, \ldots, o_n\}, n \geq 1$be a set of attributes and"$O_1 \times O_2 \times O_3 \times \ldots \times O_n = \ddot{B} = \varkappa_{1r} \times \varkappa_{2s} \times \ldots \times \varkappa_{en}$
where $1 \leq r, s, e \leq \iota_1, \kappa_2, \varsigma_3$ *and* $\iota_1, \kappa_2, \varsigma_3 \in \mathcal{N}$ and $IFS^{\mathfrak{U}}$is of all IF sub-sets over the $\mathfrak{U}$. Then, the pair $(F, O_1 \times O_2 \times O_3 \times \ldots \times O_n = \ddot{B})$
$F: O_1 \times O_2 \times O_3 \times \ldots \times O_n \rightarrow IFS^{\mathfrak{U}}$
$\left(F, \ddot{B}\right) = \left\{\left(\check{\varkappa}, F_{\ddot{B}}(\check{\varkappa})\right) \mid \check{\varkappa} \in \ddot{B}\right\}, \; F_{\ddot{B}} : \ddot{B} \rightarrow IFS^{\mathfrak{U}}$
$F_{\ddot{B}}(\check{\varkappa}) = \left\{\delta, \rho_{F(\check{\varkappa})}(\delta), \vartheta_{F(\check{\varkappa})}(\delta)\right\}$, where $\rho_{F(\check{q})}(\delta)$and $\vartheta_{F(\check{q})}(\delta)$ membership and non-membership$\rho_{F(\check{\varkappa})}(\delta), \vartheta_{F(\check{\varkappa})}(\delta) \in [0,1]$ and $0 \leq \rho_{F(\check{\varkappa})}(\delta) + \vartheta_{F(\check{\varkappa})}(\delta) \leq 1$.

Definition 4.[Score value]
When$\rho_{F(\check{\varkappa})}(\delta) + \vartheta_{F(\check{\varkappa})}(\delta) \leq 1$is satisfied and there are no further sub-attributes associated with the parameters, the IFHSS simplifies to an IFSS.$\mathfrak{Q}_{\check{\varkappa}_{ij}} = \langle \rho_{F(\check{\varkappa}_{ij})}, \vartheta_{F(\check{\varkappa}_{ij})} \rangle$the following defines the scoring function of $\mathfrak{Q}_{\check{q}_{ij}}$used in alternative ranking:

$$\mathbb{S}\left(\mathfrak{Q}_{\check{\varkappa}_{ij}}\right) = \rho_{F(\check{\varkappa}_{ij})} - \vartheta_{F(\check{\varkappa}_{ij})}, \mathbb{S}\left(\mathfrak{Q}_{\check{\varkappa}_{ij}}\right) \in [-1, 1] \qquad (1)$$

When two IFHSNs yield identical score values, an accuracy function is employed:
$\mathcal{H}\left(\mathfrak{Q}_{\check{\varkappa}_{ij}}\right) = \rho_{F(\check{\varkappa}_{ij})} + \vartheta_{F(\check{\varkappa}_{ij})}, \mathcal{H}\left(\mathfrak{Q}_{\check{\varkappa}_{ij}}\right) \in [0,1]$

Definition 5.[First order Taylor's series method]
The first-order Taylor series method is a numerical approximation technique used to obtain the solution of an ordinary differential equation (ODE) by expanding the unknown function about a specified point.Consider the differential equation$\frac{dw}{ds} = f(s, w)$ subject to the initial condition $w(s_0) = w_0$.If $w(s)$denotes the exact solution, then its Taylor expansion about $s = s_0$can be expressed as$w(s) = w_0 + (s - s_0)w_0^{'} + \frac{(s-s_0)^2}{2!}w_0^{''} + \cdots$ Let $h = s - s_0$. The first iterative approximation becomes$w_1 = w_0 + h\, w_0^{'} + \frac{h^2}{2!}w_0^{''} + \frac{h^3}{3!}w_0^{'''} + \cdots$ Proceeding recursively, the general update formula is given by$w_{n+1} = w_n + h\, w_n^{'} + \frac{h^2}{2!}w_n^{''} + \frac{h^3}{3!}w_n^{'''} + \cdots$

Definition 6. [Second order Taylor's series method]
The second-order Taylor approach provides a higher-accuracy approximation of an ODE solution by retaining terms up to the second derivative in the series expansion.Consider the second-order differential equation$w^{''}(s) = f\left(s, w, w^{'}\right)$with initial conditions$w(s_0) = w_0, w^{'}(s_0) = w_1$.Expanding $w(s)$about $s_0$using Taylor's theorem yields$w(s_0 + h) = w_0 + h\, w_1 + \frac{h^2}{2!}w_2 + \frac{h^3}{3!}w_3 + \cdots$where$w_1 = w^{'}(s_0),\; w_2 = w^{''}(s_0), w_3 = \frac{d}{ds}\left(w^{''}(s)\right)$ This formulation improves numerical precision compared with the first-order approximation.

Definition 7. [*Normalized Weight Vector*]
The Normalized Weight Vector is a vector in which all the individual attribute weights are proportionally scaled so that their total sum equals 1. This ensures a consistent basis for comparison and aggregation in (MAGDM) problems.Let $w = (w_1, w_2, \ldots, w_n)$represent the initial set of attribute weights. To obtain the normalized weightw_i^{norm} for each attribute, the following formula is used:$w_i^{norm} = \frac{w_i}{\sum_{j=1}^{n} w_j}$for all $i = 1,2, \ldots, n$.Thecomputed normalized weight

vector is as follows:$w^{norm} = \left(\frac{w_1}{\sum_{j=1}^{n} w_j}, \frac{w_2}{\sum_{j=1}^{n} w_j}, \ldots, \frac{w_n}{\sum_{j=1}^{n} w_j}\right)$This normalized vector is typically used in aggregation operators to ensure that the influence of each criterion is appropriately scaled relative to the others.

IFHSN OPERATOR

This section outlines the operational rules governing(IFHSNs) and IFHS-WA and IFHS-WGdesigned for Intuitionistic Fuzzy Hypersoft Sets (IFHSS). Furthermore, the key properties of these operators are analyzed in accordance with the structural framework of the proposed IFHSNs.

Definition 8.

Let $\mathfrak{Q}_{\breve{\kappa}_k} = \left(\rho_{\breve{\kappa}_k}, \vartheta_{\breve{\kappa}_k}\right)$, $\mathfrak{Q}_{\breve{\kappa}_{11}} = \left(\rho_{\breve{\kappa}_{11}}, \vartheta_{\breve{\kappa}_{11}}\right)$ and $\mathfrak{Q}_{\breve{\kappa}_{12}} = \left(\rho_{\breve{\kappa}_{12}}, \vartheta_{\breve{\kappa}_{12}}\right)$represent IFHSNs, and Consider σ as a strictly positive real value. Then, applying algebraically constructed norms Accordingly, we obtain:

1. *Addition:*
   $\mathfrak{Q}_{\breve{\kappa}_{11}} \oplus \mathfrak{Q}_{\breve{\kappa}_{12}} = \langle \rho_{\breve{\kappa}_{11}} + \rho_{\breve{\kappa}_{12}} - \rho_{\breve{\kappa}_{11}}\rho_{\breve{\kappa}_{12}}, \vartheta_{\breve{\kappa}_{11}}\vartheta_{\breve{\kappa}_{12}} \rangle$
2. *Multiplication:*
   $\mathfrak{Q}_{\breve{\kappa}_{11}} \otimes \mathfrak{Q}_{\breve{\kappa}_{12}} = \langle \rho_{\breve{\kappa}_{11}}\rho_{\breve{\kappa}_{12}}, \vartheta_{\breve{\kappa}_{11}} + \vartheta_{\breve{\kappa}_{12}} - \vartheta_{\breve{\kappa}_{11}}\vartheta_{\breve{\kappa}_{12}} \rangle$
3. *Scalar Multiplication:*
   $\sigma\mathfrak{Q}_{\breve{\kappa}_k} = \langle \left[1 - \left(1 - \rho_{\breve{\kappa}_k}\right)^{\sigma}, \left(\vartheta_{\breve{\kappa}_k}\right)^{\sigma}\right] \rangle$
4. *Scalar Power:*
   $\mathfrak{Q}_{\breve{\kappa}_k}^{\sigma} = \langle \left[\left(\rho_{\breve{\kappa}_k}\right)^{\sigma}, 1 - \left(1 - \vartheta_{\breve{\kappa}_k}\right)^{\sigma}\right] \rangle$

Definition 9.

Let $\mathfrak{Q}_{\breve{\kappa}_k} = \left(\rho_{\breve{\kappa}_k}, \vartheta_{\breve{\kappa}_k}\right)$ be an IFHSN, γ_i and $\upsilon_j$denote the respective weight vectors for experts and sub-attributes corresponding to the chosen parameters, in accordance with the given conditions$\gamma_i > 0, \sum_{i=1}^{n} \gamma_i = 1$, $\upsilon_j > 0, \sum_{j=1}^{n} \upsilon_j = 1$.Accordingly, IFHS-WA operator is defined by:

$$IFHS - WA\left(\mathfrak{Q}_{\breve{\kappa}_{11}}, \mathfrak{Q}_{\breve{\kappa}_{12}}, \ldots, \mathfrak{Q}_{\breve{\kappa}_{nm}}\right) = \oplus_{j=1}^{m} \upsilon_j \left(\oplus_{i=1}^{n} \gamma_i \mathfrak{Q}_{\breve{\kappa}_{ij}}\right) \quad (2)$$

IFHS-WA: $\psi^n \to \psi$described as follows:

Theorem1.

Take$\mathfrak{Q}_{\breve{\kappa}_k}$denote an *IFHSN*.Consequently, the outcome derived from Equation (2) remains an IFHSN and

$$IFHS - WA\left(\mathfrak{Q}_{\breve{\kappa}_{11}}, \mathfrak{Q}_{\breve{\kappa}_{12}}, \ldots, \mathfrak{Q}_{\breve{\kappa}_{nm}}\right) = \langle 1 - \prod_{j=1}^{m}\left(\prod_{i=1}^{n}\left(1 - \rho_{\breve{\kappa}_{ij}}\right)^{\gamma_i}\right)^{\upsilon_j}, \prod_{j=1}^{m}\left(\prod_{i=1}^{n}\left(\vartheta_{\breve{\kappa}_{ij}}\right)^{\gamma_i}\right)^{\upsilon_j} \rangle \quad (3)$$

remains an IFHSN.

Proof.

Let $\mathfrak{Q}_{\breve{\kappa}_{ij}} = (\rho_{\breve{\kappa}_{ij}}, \vartheta_{\breve{\kappa}_{ij}})$be an IFHSN such that$0 \le \rho_{\breve{\kappa}_{ij}}, \vartheta_{\breve{\kappa}_{ij}} \le 1, 0 \le \rho_{\breve{\kappa}_{ij}} + \vartheta_{\breve{\kappa}_{ij}} \le 1$. We prove the result by mathematical induction.

Case 1: For $n = 1$, we have $\gamma_1 = 1$. Then$\text{IFHS} - \text{WA}\left(\mathfrak{Q}_{\breve{\kappa}_{11}}, \ldots, \mathfrak{Q}_{\breve{\kappa}_{1m}}\right) = \bigoplus_{j=1}^{m} \upsilon_j \mathfrak{Q}_{\breve{\kappa}_{1j}}$.Using the operational law of IFHSNs, we obtain

$= \langle 1 - \prod_{j=1}^{m}(1 - \rho_{\breve{\kappa}_{1j}})^{\upsilon_j}, \prod_{j=1}^{m}(\vartheta_{\breve{\kappa}_{1j}})^{\upsilon_j} \rangle,$

which is an IFHSN.

Case 2: For $m = 1$, we have $v_1 = 1$. ThenIFHS $-$ WA$\left(\mathfrak{L}_{\breve{\kappa}_{11}}, \ldots, \mathfrak{L}_{\breve{\kappa}_{n1}}\right) = \bigoplus_{i=1}^{n} \gamma_i \mathfrak{L}_{\breve{\kappa}_{i1}}$.
Thus,IFHS $-$ WA$\left(\mathfrak{L}_{\breve{\kappa}_{11}}, \ldots, \mathfrak{L}_{\breve{\kappa}_{n1}}\right) = \langle 1 - \prod_{i=1}^{n}(1 - \rho_{\breve{\kappa}_{i1}})^{\gamma_i}, \prod_{i=1}^{n}(\vartheta_{\breve{\kappa}_{i1}})^{\gamma_i}\rangle$,which is also an IFHSN.Assume the result holds for $n = k$and $m = \ell$. Then for $n = k + 1$and $m = \ell + 1$, by repeated application of the IFHS-WA operational laws and under the normalization constraints on the weight vectors, we obtain

$$IFHS - WA\left(\mathfrak{L}_{\breve{\kappa}_{11}}, \ldots, \mathfrak{L}_{\breve{\kappa}_{nm}}\right) = \langle 1 - \prod_{j=1}^{m}\left(\prod_{i=1}^{n}\left(1 - \rho_{\breve{\kappa}_{ij}}\right)^{\gamma_i}\right)^{v_j}, \prod_{j=1}^{m}\left(\prod_{i=1}^{n}\left(\vartheta_{\breve{\kappa}_{ij}}\right)^{\gamma_i}\right)^{v_j}\rangle.$$

Since each component lies in $[0, 1]$and their sum does not exceed 1, the aggregated result satisfies the IFHSN conditions. Hence, the result follows. ■

Properties

1) Idempotence. Let $\mathfrak{L}_{\breve{\kappa}_{ij}} = (\rho_{\breve{\kappa}_{ij}}, \vartheta_{\breve{\kappa}_{ij}})$ is IFHSNs. If all the inputs same, i.e.,$\mathfrak{L}_{\breve{\kappa}_{ij}} = \mathfrak{L}_{\breve{\kappa}} = (\rho_{\breve{\kappa}_{ij}}, \vartheta_{\breve{\kappa}_{ij}}), \forall i, j,$
then the IFHS-WA operator satisfiesIFHS $-$ WA$\left(\mathfrak{L}_{\breve{\kappa}_{11}}, \mathfrak{L}_{\breve{\kappa}_{12}}, \ldots, \mathfrak{L}_{\breve{\kappa}_{nm}}\right) = \mathfrak{L}_{\breve{\kappa}}$.

Proof:

From the definition of the IFHS-WA operator,

$$\text{IFHS} - \text{WA}\left(\mathfrak{L}_{\breve{\kappa}_{11}}, \ldots, \mathfrak{L}_{\breve{\kappa}_{nm}}\right) = \langle 1 - \prod_{j=1}^{m}\left(\prod_{i=1}^{n}\left(1 - \rho_{\breve{\kappa}_{ij}}\right)^{\gamma_i}\right)^{v_j}, \prod_{j=1}^{m}\left(\prod_{i=1}^{n}\left(\vartheta_{\breve{\kappa}_{ij}}\right)^{\gamma_i}\right)^{v_j}\rangle.$$

IFHS $-$ WA $= \langle \rho_{\breve{\kappa}_{ij}}, \vartheta_{\breve{\kappa}_{ij}} \rangle = \mathfrak{L}_{\breve{\kappa}}$.
Hence proved.

Boundedness

Let $\mathfrak{L}_{\breve{\kappa}_{ij}} = (\rho_{\breve{\kappa}_{ij}}, \vartheta_{\breve{\kappa}_{ij}})$, $i = 1, \ldots, n$, $j = 1, \ldots, m$, form a family of IFHSNs. Define$\mathfrak{L}^{-}_{\breve{\kappa}_{ij}} = \left(\min_{i,j} \rho_{\breve{\kappa}_{ij}}, \max_{i,j} \vartheta_{\breve{\kappa}_{ij}}\right), \mathfrak{L}^{+}_{\breve{\kappa}_{ij}} = \left(\max_{i,j} \rho_{\breve{\kappa}_{ij}}, \min_{i,j} \vartheta_{\breve{\kappa}_{ij}}\right)$.
Then the IFHS-WA operator satisfies$\mathfrak{L}^{-}_{\breve{\kappa}_{ij}} \leq \text{IFHS} - \text{WA}\left(\mathfrak{L}_{\breve{\kappa}_{11}}, \ldots, \mathfrak{L}_{\breve{\kappa}_{nm}}\right) \leq \mathfrak{L}^{+}_{\breve{\kappa}_{ij}}$.

Proof

Let$\mathfrak{L}^{*}_{\breve{\kappa}_{ij}} = \text{IFHS} - \text{WA}\left(\mathfrak{L}_{\breve{\kappa}_{11}}, \ldots, \mathfrak{L}_{\breve{q}_{nm}}\right) = \left(\rho_{\breve{\kappa}_{ij}}{}^{*}, \vartheta_{\breve{\kappa}_{ij}}{}^{*}\right)$.Since $0 \leq \rho_{\breve{\kappa}_{ij}}, \vartheta_{\breve{\kappa}_{ij}} \leq 1$and the weightssatisfythe normalization constraints on the weight vectors, we obtain
$\min_{i,j} \rho_{\breve{\kappa}_{ij}} \leq \rho_{\breve{\kappa}_{ij}} \leq \max_{i,j} \rho_{\breve{\kappa}_{ij}}$.
Because the function $f(x) = 1 - x$is decreasing on $[0, 1]$, it follows that
$1 - \max_{i,j} \rho_{\breve{\kappa}_{ij}} \leq 1 - \rho_{\breve{\kappa}_{ij}} \leq 1 - \min_{i,j} \rho_{\breve{\kappa}_{ij}}$.Raising to positive powers and using the monotonicity of the weighted geometric aggregation yields
$\min_{i,j} \rho_{\breve{\kappa}_{ij}} \leq \rho_{\breve{\kappa}_{ij}}{}^{*} \leq \max_{i,j} \rho_{\breve{\kappa}_{ij}}$.

Similarly, for the non-membership component,$\min_{i,j} \vartheta_{\breve{\kappa}_{ij}} \leq \vartheta_{\breve{\kappa}_{ij}}{}^{*} \leq \max_{i,j} \vartheta_{\breve{\kappa}_{ij}}$.Hence,$\mathfrak{L}^{-}_{\breve{\kappa}_{ij}} \leq \mathfrak{L}^{*}_{\breve{\kappa}_{ij}} \leq \mathfrak{L}^{+}_{\breve{\kappa}_{ij}}$.

Shift-Invariance: Let $\mathfrak{L}_{\breve{\kappa}_{\delta}} = (\rho_{\breve{\kappa}_{\delta}}, \vartheta_{\breve{\kappa}_{\delta}})$be a family of IFHSNs. Then,
IFHS-WA$(\mathfrak{L}_{\breve{\kappa}_{11}} \oplus \mathfrak{L}_{\breve{\kappa}_{\delta}}, \mathfrak{L}_{\breve{\kappa}_{12}} \oplus \mathfrak{L}_{\breve{\kappa}_{\delta}}, \ldots, \mathfrak{L}_{\breve{\kappa}_{nm}} \oplus \mathfrak{L}_{\breve{\kappa}_{\delta}}) =$ *IFHS-WA*$(\mathfrak{L}_{\breve{\kappa}_{11}}, \mathfrak{L}_{\breve{\kappa}_{12}}, \ldots, \mathfrak{L}_{\breve{\kappa}_{nm}}) \oplus \mathfrak{L}_{\breve{\kappa}_{\delta}}$

Proof: Consider two IFHSNs. Then, by using the operational laws defined under IFHSNs in Definition 8(1), we have:
$\mathfrak{L}_{\breve{\kappa}_{11}} \oplus \mathfrak{L}_{\breve{\kappa}_{12}} = \langle \rho_{\breve{\kappa}_{11}} + \rho_{\breve{\kappa}_{12}} - \rho_{\breve{\kappa}_{11}}\rho_{\breve{\kappa}_{12}}, \vartheta_{\breve{\kappa}_{11}}\vartheta_{\breve{\kappa}_{12}} \rangle$
Therefore,
= IFHS-WA$(\mathfrak{L}_{\breve{\kappa}_{11}}, \mathfrak{L}_{\breve{\kappa}_{12}}, \ldots, \mathfrak{L}_{\breve{\kappa}_{nm}}) \oplus \mathfrak{L}_{\breve{\kappa}_{\delta}}$.

Homogeneity: For any positive real number λ, we have

$$\text{IFHS} - \text{WA}(\lambda\mathfrak{Q}_{\breve{\kappa}_{11}}, \lambda\mathfrak{Q}_{\breve{\kappa}}, \dots, \lambda\mathfrak{Q}_{\breve{\kappa}_{nm}}) = \lambda\,\text{IFHS} - \text{WA}(\mathfrak{Q}_{\breve{\kappa}_{11}}, \dots, \mathfrak{Q}_{\breve{\kappa}_{nm}}).$$

Proof: Assume$\mathfrak{Q}_{\breve{\kappa}_{ij}}$is IFHSN and $\lambda > 0$, soapplying definition 4(3) , we get

$\lambda\mathfrak{Q}_{\breve{\kappa}_{ij}} = \langle 1 - (1 - \rho_{\breve{\kappa}_{ij}})^{\lambda}, (\vartheta_{\breve{\kappa}_{ij}})^{\lambda}\rangle$.

$$IFHS - WA(\lambda\mathfrak{Q}_{\breve{\kappa}_{11}}, \lambda\mathfrak{Q}_{\breve{\kappa}_{12}}, \dots, \lambda\mathfrak{Q}_{\breve{\kappa}_{nm}}) = \langle 1 - \prod_{j=1}^{m}\left(\prod_{i=1}^{n}(1 - \rho_{\breve{\kappa}_{ij}})^{\lambda\gamma_i}\right)^{v_j}, \prod_{j=1}^{m}\left(\prod_{i=1}^{n}\left(\vartheta_{\breve{\kappa}_{ij}}\right)^{\lambda\gamma_i}\right)^{v_j}\rangle$$

$= \lambda\,\text{IFHS} - \text{WA}(\mathfrak{Q}_{\breve{\kappa}_{11}}, \mathfrak{Q}_{\breve{\kappa}_{12}}, \dots, \mathfrak{Q}_{\breve{\kappa}_{nm}})$.

Hence, the IFHS-WA operator is homogeneous. ■

Definition 10.

Let $\mathfrak{Q}_{\breve{\kappa}_k} = (\rho_{\breve{\kappa}_k}, \vartheta_{\breve{\kappa}_k})$denote an intuitionistic fuzzy hypersoft number (IFHSN). Let $\gamma_i$and $v_j$be the normalized weight vectors associated with the experts and the corresponding sub-attributes, respectively, satisfying

$\gamma_i > 0, \sum_{i=1}^{n}\gamma_i = 1, v_j > 0, \sum_{j=1}^{m} v_j = 1.$

Then, the (IFHS-WG) operator is defined as the mapping

$$IFHSWG\left(\mathfrak{Q}_{\breve{\kappa}_{11}}, \mathfrak{Q}_{\breve{\kappa}_{12}}, \dots, \mathfrak{Q}_{\breve{\kappa}_{nm}}\right) = \otimes_{j=1}^{m}\left(\otimes_{i=1}^{n}\mathfrak{Q}_{\breve{\kappa}_{ij}}^{\gamma_i}\right)^{v_j} \quad (4)$$

Theorem2.

Let $\mathfrak{Q}_{\breve{\kappa}_k} = (\rho_{\breve{\kappa}_k}, \vartheta_{\breve{\kappa}_k})$is IFHSN. Applying Eqn. (4), we derive the resulting IFHSN representation.

$$IFHSWG\left(\mathfrak{Q}_{\breve{\kappa}_{11}}, \mathfrak{Q}_{\breve{\kappa}_{12}}, \dots, \mathfrak{Q}_{\breve{\kappa}_{nm}}\right) = \langle\prod_{j=1}^{m}\left(\prod_{i=1}^{n}\left(\rho_{\breve{\kappa}_{ij}}\right)^{\gamma_i}\right)^{v_j}, 1 - \prod_{j=1}^{m}\left(\prod_{i=1}^{n}\left(1 - \vartheta_{\breve{\kappa}_{ij}}\right)^{\gamma_i}\right)^{v_j}\rangle \quad (5)$$

Analogous to the IFHS-WA operator, the IFHS-WG operator possesses the same properties; however, only the fundamental properties of the IFHS-WA operator are presented below.

Properties

1) Idempotence. Let $\mathfrak{Q}_{\breve{\kappa}_{ij}} = (\rho_{\breve{\kappa}_{ij}}, \vartheta_{\breve{\kappa}_{ij}})$is IFHSNs. If all the inputs same, i.e.,$\mathfrak{Q}_{\breve{\kappa}_{ij}} = \mathfrak{Q}_{\breve{\kappa}} = (\rho_{\breve{\kappa}_{ij}}, \vartheta_{\breve{\kappa}_{ij}}), \forall i, j,$

then the IFHS-WG operator satisfiesIFHS $- \text{WG}(\mathfrak{Q}_{\breve{\kappa}_{11}}, \mathfrak{Q}_{\breve{\kappa}_{12}}, \dots, \mathfrak{Q}_{\breve{\kappa}_{nm}}) = \mathfrak{Q}_{\breve{\kappa}}$.

2) Boundedness: Let$\mathfrak{Q}_{\breve{\kappa}_{ij}} = \left(\rho_{\breve{\kappa}_{ij}}, \vartheta_{\breve{\kappa}_{ij}}\right), i = 1, \dots, n\ and\ j = 1, \dots, m$ be a family of IFHSNs and let

$$\mathfrak{Q}_{\breve{\kappa}_{ij}}^{-} = \left(\min_{i,j}\ \rho_{\breve{\kappa}_{ij}},\ \max_{i,j}\ \vartheta_{\breve{\kappa}_{ij}}\right), \mathfrak{Q}_{\breve{\kappa}_{ij}}^{+} = \left(\max_{i,j}\ \rho_{\breve{\kappa}_{ij}},\ \min_{i,j}\ \vartheta_{v_{ij}}\right).$$

Then the IFHS-WG operator satisfies

$$\mathfrak{Q}_{\breve{\kappa}_{ij}}^{-} \leq \text{IFHS} - \text{WG}(\mathfrak{Q}_{\breve{\kappa}_{11}}, \dots, \mathfrak{Q}_{\breve{\kappa}_{nm}}) \leq \mathfrak{Q}_{\breve{\kappa}_{ij}}^{+}.$$

3) Shift-Invariance: Let $\mathfrak{Q}_{\breve{\kappa}_\delta} = (\rho_{\breve{\kappa}_\delta}, \vartheta_{\breve{\kappa}_\delta})$be a family of IFHSNs. Then,

$$\text{IFHS} - \text{WG}(\mathfrak{Q}_{\breve{\kappa}_{11}} \otimes \mathfrak{Q}_{\breve{\kappa}_\delta}, \mathfrak{Q}_{\breve{\kappa}_{12}} \otimes \mathfrak{Q}_{\breve{\kappa}_\delta}, \dots, \mathfrak{Q}_{\breve{\kappa}_{nm}} \otimes \mathfrak{Q}_{\breve{\kappa}_\delta}) = \text{IFHS} - \text{WG}(\mathfrak{Q}_{\breve{\kappa}_{11}}, \mathfrak{Q}_{\breve{\kappa}_{12}}, \dots, \mathfrak{Q}_{\breve{\kappa}_{nm}}) \otimes \mathfrak{Q}_{\breve{\kappa}_\delta}.$$

4) Homogeneity: For any positive real number λ, we have

$$\text{IFHS} - \text{WG}(\lambda\mathfrak{Q}_{\breve{\kappa}_{11}}, \lambda\mathfrak{Q}_{\breve{\kappa}_{12}}, \dots, \lambda\mathfrak{Q}_{\breve{\kappa}_{nm}}) = \lambda\,\text{IFHS} - \text{WG}(\mathfrak{Q}_{\breve{\kappa}_{11}}, \dots, \mathfrak{Q}_{\breve{\kappa}_{nm}}).$$

MAGDM Approach Constructed Using The Developed Aggregation

This section presents a systematic framework for solving (MAGDM) problems within the (IFHSS) environment. By combining the strengths of intuitionistic fuzzy logic and hypersoft set theory, the proposed method efficiently handles hierarchical attribute structures and the inherent uncertainty in group decision-making scenarios. The framework is constructed using the proposed aggregation operators and is validated through a practical example to demonstrate its applicability and effectiveness.

4.1 Proposed Approach

Let $\mathbb{K} = \mathbb{K}^1, \mathbb{K}^2, \mathbb{K}^3, \ldots, \mathbb{K}^y$ be the set of y alternatives, $\mathcal{Z} = \{\mathcal{Z}_1, \mathcal{Z}_2, \mathcal{Z}_3, \ldots, \mathcal{Z}_r\}$ represent the group of r experts. The expert-specific weight vector is indicated by$\gamma_i = (\gamma_1, \gamma_2, \gamma_3, \ldots, \gamma_n)^T$,where each $\gamma_i > 0, \sum_{i=1}^{n} \gamma_i = 1.\mathfrak{H} = \{\varkappa_1, \varkappa_2, \varkappa_3, \ldots, \varkappa_m\}$define the collection of attributes, each associated with multiple sub-attributes can be collectively expressed as$\mathfrak{H}' = \left\{\{\varkappa_{1q} \times \varkappa_{2q} \times \varkappa_{3q} \times \ldots \times \varkappa_{mq}\} \forall\, \varkappa \in \{1,2,\ldots,t\}\right\}$with their corresponding weight vector$v = (v_{1\varkappa}, v_{2\varkappa}, v_{3\varkappa}, \ldots, v_{m\varkappa})^T$such that $v_\varkappa > 0$ and $\sum_{\varkappa=1}^{t} v_\varkappa = 1$. To improve readability, we denote the components of the sub-attribute collection $\mathfrak{H}'$ as$\mathfrak{H}' = \{\check{\varkappa}_\tau : \tau \in \{1,2,\ldots,k\}\}$.where each $\check{\varkappa}_\tau$ is a multi-valued sub-attribute.Each expert $\{\mathcal{Z}_i : i = 1,2,\ldots,r\}$provides an assessment of the alternatives $\{\mathbb{J}^{(x)} : x = 1,2,3,\ldots,s\}$ based on the preferred sub-attributes$\{\check{\varkappa}_\tau : \tau = 1,2,\ldots,k\}$, using intuitionistic fuzzy hypersoft numbers (IFHSNs). The evaluation of each alternative under sub-attribute $\check{\varkappa}_{ij}$ is represented as a matrix: $\left(\mathfrak{Q}_{\check{\varkappa}_{ij}}^{(x)}\right)_{c\times d} = \left(\rho_{\check{\varkappa}_{ij}}^{(x)}, \vartheta_{\check{\varkappa}_{ij}}^{(x)}\right)_{c\times d}$ Where the degree of membership$\rho_{\check{\varkappa}_{ij}}^{(x)}$and the non-membership degree $\vartheta_{\check{\varkappa}_{ij}}^{(x)}$satisfies the following conditions: $0 \le \rho_{\check{\varkappa}_{ij}}^{(x)}, \vartheta_{\check{\varkappa}_{ij}}^{(x)} \le 1, \rho_{\check{\varkappa}_{ij}}^{(x)} + \vartheta_{\check{\varkappa}_{ij}}^{(x)} \le 1\ \forall\, i, j.$

Decision-Making Procedure

Step- 1: For every $\mathbb{K}^{(x)}$where$x = 1,2,3,\ldots,s$, *the corresponding decision matrix is derived from expert input as shown below:*

$$\left(\mathbb{K}^{(x)}, \mathfrak{H}'\right)_{c\times d} = \begin{matrix}\mathcal{Z}_1\\ \mathcal{Z}_2\\ \vdots\\ \mathcal{Z}_r\end{matrix}\begin{pmatrix}\left(\rho_{\check{\varkappa}_{11}}^{(x)}, \vartheta_{\check{\varkappa}_{11}}^{(x)}\right) & \left(\rho_{\check{\varkappa}_{12}}^{(x)}, \vartheta_{\check{\varkappa}_{12}}^{(x)}\right) & \cdots & \left(\rho_{\check{\varkappa}_{1d}}^{(x)}, \vartheta_{\check{\varkappa}_{1d}}^{(x)}\right)\\ \left(\rho_{\check{\varkappa}_{21}}^{(x)}, \vartheta_{\check{\varkappa}_{21}}^{(x)}\right) & \left(\rho_{\check{\varkappa}_{22}}^{(x)}, \vartheta_{\check{\varkappa}_{22}}^{(x)}\right) & & \left(\rho_{\check{\varkappa}_{2d}}^{(x)}, \vartheta_{\check{\varkappa}_{2d}}^{(x)}\right)\\ \vdots & & \ddots & \vdots\\ \left(\rho_{\check{\varkappa}_{c1}}^{(x)}, \vartheta_{\check{\varkappa}_{c1}}^{(x)}\right) & \left(\rho_{\check{\varkappa}_{c2}}^{(x)}, \vartheta_{\check{\varkappa}_{c2}}^{(x)}\right) & \cdots & \left(\rho_{\check{\varkappa}_{cd}}^{(x)}, \vartheta_{\check{\varkappa}_{cd}}^{(x)}\right)\end{pmatrix}$$

Step 2: If cost-type sub-attributes exist, convert them into benefit-type sub-attributes using an appropriate normalization technique. In this study, all attributes are benefit-type; hence normalization is not required.

$$\mathrm{M}_{ij} = \begin{cases}\mathfrak{Q}_{\check{\varkappa}_{ij}}^{\varkappa} = \left(\vartheta_{\check{\varkappa}_{ij}}^{(x)}, \rho_{\check{\varkappa}_{ij}}^{(x)}\right); \textit{cost type parameter}\\ \mathfrak{Q}_{\check{\varkappa}_{ij}} = \left(\rho_{\check{\varkappa}_{ij}}^{(x)}, \vartheta_{\check{\varkappa}_{ij}}^{(x)}\right); \textit{benefit type parameter}\end{cases}$$

Step 3: Using the formulated aggregation operators, the collective decision matrix$\mathfrak{Q}_{\check{\varkappa}_{ij}}$is derived for every alternative $\mathbb{K} = \mathbb{K}^1, \mathbb{K}^2, \mathbb{K}^3, \ldots, \mathbb{K}^y$.

Step 4: If$\mathbb{K} = \mathbb{K}^1, \mathbb{K}^2, \mathbb{K}^3, \ldots, \mathbb{K}^y$Considering these as the alternatives in question, their score values are derived using Equation (1).

Step 5: Choose the most preferred alternative according to the computed scores.

Step 6: Generate a comparative ranking of the alternatives.

The Taylor series method, introduced by Brook Taylor in 1715, is widely used to approximate solutions of ordinary differential equations (ODEs) by employing initial conditions together with successive derivatives. Although the underlying ideas trace back to Gregory and Newton, Taylor provided the formal series representation. The method gained extensive use during the nineteenth century and became even more prominent with the development of modern scientific computing. It continues to serve as a fundamental numerical tool and forms the basis for advanced techniques such as the Runge–Kutta method. Using Definitions (5) and (6), the first-order method is expressed as follows:$\frac{dw}{ds} = w + s, w(0) = 1, h = 0.1$.Since$\frac{dw}{ds} = f(s, w)$,we have$w(s_0) = w_0$.Second-ordermethod$\frac{d^2w}{ds^2} = w + s\,w', w(0) = 1, w'(0) = 0, h = 0.1$. Since$w''(s) = f(s, w, w'), w(s_0) = w_0, w'(s_0) = w_1$.Finally, the values obtained from the first- and second-order methods are normalized. The resulting weight vectors are$v = (0.08, 0.09, 0.10, 0.11, 0.13, 0.14, 0.16, 0.19)$and $\gamma = (0.19, 0.193, 0.198, 0.205, 0.214)$.

Illustrative Case Study

Obesity diagnosis is a complex public health issue influenced by physiological, behavioral, psychological, and genetic factors. Accurate diagnosis is vital for early intervention and effective treatment. Due to the uncertainty and interdependence of relevant criteria, obesity diagnosis is often treated as a (MAGDM) problem, where multiple experts analyze alternatives such as patient cases or treatment plans. (IFHSS) propose a strong methodological basis

for handlingsuch complexity, incorporating expert hesitancy and hierarchical attributes. This study adopts an IFHSS-based MAGDM approach to overcome these challenges.

For this case study, a structured evaluation framework was developed using five critical criteria associated with obesity assessment. These are: q_1 diet quality;q_2, physical activity;q_3, sleep pattern;q_4, genetic predisposition; and q_5, psychological factors. Each of these criteria is further refined into sub-attributes and evaluated using the proposed IFHS-WA and IFHS-WG aggregation operators, integrating expert opinions with weights derived from Taylor series-based methods. The resulting decision matrix facilitates the identification of the most suitable alternative for clinical action based on intuitionistic fuzzy scoring.Let $\{\mathcal{P}_1, \mathcal{P}_2, \mathcal{P}_3, \mathcal{P}_4, \mathcal{P}_5\}$be defined as a group ofalternatives (individuals or intervention plans), $\mathfrak{H} = \{\varkappa_1$=Diet Quality, $\varkappa_2$ =Physical Activity, $\varkappa_3$ =Sleep Pattern, $\varkappa_4$ = Genetic Predisposition,$\varkappa_5$ =Psychological Factors$\}$ denote the group of attributes under consideration.
The structure of the sub-attributes is given below:Diet Quality$\varkappa_1 = \{\varkappa_{11}$ = High calorie, $\varkappa_{12}$ = Balanced diet$\}$, Physical Activity $\varkappa_2 = \{\varkappa_{21}$ =Sedentary,$\varkappa_{22}$ = Active$\}$,Sleep Pattern $\varkappa_3 = \{\varkappa_{31}$ = Irregular, $\varkappa_{32}$ = Regular$\}$,GeneticPredisposition $\varkappa_4 = \{\varkappa_{41}$ = Genetic$\}$,Psychological Factors $\varkappa_5 = \{\varkappa_{51}$ = Emotional eating$\}$
Let $\mathfrak{H}' = \varkappa_1 \times \varkappa_2 \times \varkappa_3 \times \varkappa_4 \times \varkappa_5$be defined as a group of sub-attributes$\mathfrak{H}' = \varkappa_1 \times \varkappa_2 \times \varkappa_3 \times \varkappa_4 \times \varkappa_5 = \{\varkappa_{11}, \varkappa_{12}\} \times \{\varkappa_{21}, \varkappa_{22}\} \times \{\varkappa_{31}, \varkappa_{32}\} \times \{\varkappa_{41}\} \times \{\varkappa_{51}\}$

$\mathfrak{H}' = \{\check{\varkappa}_1, \check{\varkappa}_2, \check{\varkappa}_3, \check{\varkappa}_4, \check{\varkappa}_5, \check{\varkappa}_6, \check{\varkappa}_7, \check{\varkappa}_8.\}$represent the set of all sub-attributes, assigned weights as $(0.08,0.09,0.10,0.11,0.13,0.14,0.16,0.19)^T$. Consider the expert group $\{\mathbb{K}^1, \mathbb{K}^2, \mathbb{K}^3, \mathbb{K}^4\}$, with their corresponding weights defined as $(0.19,0.193,0.198,0.205,0.214)^T$, tasked with evaluating the best alternative. Each expert provides their assessments using Intuitionistic Fuzzy Hyper Soft Numbers (IFHSNs), based on the selected multi-sub-attribute structure. The subsequent aggregation process utilizes these inputs to identify the most optimal decision alternative.

IFHS-WA Operator

Step 1: The experts assess the given context using IFHSNs.The associated multi-level sub-attributes and the corresponding score values, as evaluated by the experts, are systematically compiled and illustrated in Tables 1 to 4.
Step 2:Since all attributes share a common type and scale, normalization is not required.
Step 3: Applying Equation (3), the collective expert opinions are summarized below$\mathfrak{H}_1 = (0.3791,0.3405), \mathfrak{H}_2 = (0.3629,0.3527), \mathfrak{H}_3 = (0.4031,0.2786), \mathfrak{H}_4 = (0.4319,0.2755)$
*Step4:*The score value can be evaluated using the formulation in Equation(1).$\mathbb{S}(\mathfrak{H}_1) = 0.0386, \mathbb{S}(\mathfrak{H}_2) = 0.0103, \mathbb{S}(\mathfrak{H}_3) = 0.1245, \mathbb{S}(\mathfrak{H}_4) = 0.1564$.
Step-5: Analyzing the score values confirms that$\mathbb{K}^{(4)}$ is the most suitable choice.
Step-6: Accordingly, the alternatives are ranked as $\mathbb{S}(\mathfrak{H}_4) > S(\mathfrak{H}_3) > S(\mathfrak{H}_2) > S(\mathfrak{H}_1)$,which leads to the preference order $\mathbb{K}^{(4)} > \mathbb{K}^{(3)} > \mathbb{K}^{(1)} > \mathbb{K}^{(2)}$.Therefore, $\mathbb{K}^{(4)}$ is identified as the optimal choice

IFHS-WG Operator

Step-1: Experts assess the decision problem using IFHSNs. The associated multi-level sub-attributes for each criterion, together with the aggregated score values, are reported in Tables 1–4.
Step-2: Since all attributes share a common type and scale, normalization is not required.
Step-3: By applying Equation (5), the aggregated evaluations provided by the experts are obtained as:$\mathfrak{H}_1 = (0.2896, 0.4410), \mathfrak{H}_2 = (0.2795,0.4480), \mathfrak{H}_3 = (0.3184,0.3558), \mathfrak{H}_4 = (0.3385,0.3693)$
Step-4: The score value can be evaluated using the formulation in Equation (1).$\mathbb{S}(\mathfrak{H}_1) = -0.1514, \mathbb{S}(\mathfrak{H}_2) = -0.1686, \mathbb{S}(\mathfrak{H}_3) = -0.0374, \mathbb{S}(\mathfrak{H}_4) = -0.0308$
*Step-5:*Among the evaluated alternatives, the highest score corresponds to $\mathbb{K}^{(4)}$, indicating it as the most preferable choice.
*Step-6:*Based on the computed scores, $\mathbb{S}(\mathfrak{H}_4) > S(\mathfrak{H}_3) > S(\mathfrak{H}_1) > S(\mathfrak{H}_2)$Which leads to the corresponding preference order:$\mathbb{K}^{(4)} > \mathbb{K}^{(3)} > \mathbb{K}^{(1)} > \mathbb{K}^{(2)}$Thus, alternative $\mathbb{K}^{(4)}$ is determined to be the most appropriate selection.

5) **Comparative Analysis**

To further assess the effectiveness of the proposed IFHSS-based MAGDM framework, the obtained results are comparatively examined using IFHS-WA and IFHS-WGaggregation operators. Although both operators are developed within the same IFHSS environment and maintain the hierarchical structure of attributes and sub-attributes, their aggregation mechanisms differ significantly.The IFHS-WA operator performs aggregation through a compensatory averaging process, allowing higher membership values to offset lower ones. As a result, IFHS-WA produces smoother aggregation outcomes and is more suitable for decision scenarios where trade-offs among criteria are acceptable. In contrast, the IFHS-WG operator employs a multiplicative (product-based) aggregation mechanism, which penalizes lower membership values more strictly. This strict behavior makes IFHS-WG more sensitive to poor performance in any sub-attribute, leading to more conservative evaluations.Despite numerical differences in the aggregated intuitionistic fuzzy values, both IFHS-WA and IFHS-WG yield consistent ranking orders of alternatives, demonstrating the robustness and stability of the proposed framework. The slight variations observed in the score values reflect the intrinsic characteristics of the aggregation operators rather than inconsistencies in the decision model.Furthermore, the graphical comparison of ranking results confirms that the optimal alternative maintains its dominance under both aggregation strategies. This consistency validates the reliability of the proposed IFHSS-based approach and highlights its flexibility in accommodating different decision attitudesrisk-neutral behavior through IFHS-WA and risk-averse behavior through IFHS-WG. Overall, the comparative analysis confirms that integrating both operators enhances the interpretability and robustness of obesity diagnosis under uncertain and multi-level information environments.

CONCLUSION

This study proposed a novel IFHSSbased MAGDM framework for obesity diagnosis under uncertain and hierarchical information environments. The developed model effectively integrates multi-level attribute structures, expert hesitation, and objective weight determination within a unified mathematical setting. To enhance the reliability of the weighting process, Taylor series–based first- and second-order ordinary differential equation (ODE) methods were employed to compute normalized expert and attribute weight vectors. These weights were subsequently incorporated into the IFHS-WA and IFHS-WG aggregation operators to derive the collective outcomes. Theoretical analysis established that the proposed aggregation mechanisms preserve the fundamental properties of IFHSNs, ensuring that the aggregated outcomes remain within the admissible intuitionistic fuzzy hypersoft domain. The illustrative case study on obesity diagnosis demonstrated the practical applicability of the framework. Although IFHS-WA and IFHS-WG produce numerically different aggregated values due to their compensatory and non-compensatory behaviors, both operators yielded identical ranking orders of alternatives, thereby confirming the stability and robustness of the proposed MAGDM model. The results indicate that the IFHS-WA operator is more suitable for risk-neutral decision environments, whereas the IFHS-WG operator provides stricter discrimination in risk-averse scenarios. Hence, the proposed framework offers flexibility to decision makers with different preference attitudes while maintaining ranking consistency. Overall, the developed IFHSS-based MAGDM approach provides a systematic, mathematically sound, and computationally reliable decision-support tool for obesity diagnosis. The framework can be readily extended to other complex medical and engineering decision problems involving hierarchical attributes and uncertain expert information. Future work may focus on hybrid weighting strategies, dynamic IFHSS environments, and real clinical data validation to further enhance the practical impact of the model.

ABSTRACT

The use of herbal and traditional medicines has expanded considerably across the world, both within traditional healthcare systems and alongside modern medical therapies. While these medicines are often regarded as natural and therefore safe, growing evidence indicates that they may also be associated with adverse drug reactions, herb-drug interactions, and product-related quality concerns. Factors such as contamination, adulteration, variability in raw materials, and lack of standardisation can further complicate the safety evaluation of herbal products. In addition, the multi-component nature of many traditional formulations makes the identification of specific causative agents and safety signals more challenging in clinical practice. This review highlights the importance of integrating pharmacovigilance principles into traditional medicine systems to support safer and more rational use of herbal therapies. Key safety concerns related to herbal medicines, including adverse reactions and clinically relevant herb-drug interactions, are discussed. The article also outlines existing pharmacovigilance frameworks at both global and national levels, with particular attention to initiatives that support the monitoring of traditional medicinal products. Challenges in detecting and reporting adverse events, such as underreporting, limited awareness, and complexities in causality assessment, are also examined. The

review further discusses practical strategies to strengthen pharmacovigilance for traditional medicines, including improved reporting systems, stronger regulatory oversight, expanded research, and greater involvement of healthcare professionals and consumers. Strengthening these efforts may contribute to more effective safety monitoring while supporting the responsible use of herbal medicines in contemporary healthcare.

Keywords: Adverse drug reactions; Drug safety; Herb–drug interactions; Herbal medicines; Pharmacovigilance; Traditional medicine.

INTRODUCTION

Traditional medicine systems have long formed an integral part of healthcare practices in many parts of the world. In the Indian subcontinent, systems such as Ayurveda, Siddha, and Unani have been practised for centuries and continue to influence health-seeking behaviour even today. These medical traditions rely primarily on plant-based preparations, mineral formulations, and other naturally derived substances that are traditionally believed to restore physiological balance and support overall health. Despite the rapid advancement of modern biomedical therapies, traditional medicines remain widely used, particularly in developing countries where accessibility, affordability, and cultural familiarity often guide healthcare choices. According to the World Health Organisation (2019), a large proportion of the global population continues to rely on herbal medicines either as primary treatment or as complementary therapy alongside conventional medical care [1].

In recent years, the utilisation of herbal medicines has expanded beyond traditional settings and has attracted considerable interest worldwide. The increasing preference for natural therapies, increasing awareness of holistic healthcare approaches, and concerns regarding adverse effects associated with synthetic drugs have all contributed to this trend. Herbal products are now commonly marketed as dietary supplements, nutraceuticals, and over-the-counter remedies in many countries. However, the rapid growth of the herbal medicine market has also raised important questions regarding the safety, quality, and rational use of these products. Choudhury et al. (2023) observed that while the global consumption of herbal medicines has increased significantly, the development of structured pharmacovigilance systems for these products has not progressed at the same pace [3].

Another widely held assumption among patients is that medicines derived from natural sources are inherently safe. Nevertheless, accumulating scientific evidence suggests that this perception may not always be accurate. Several reports have documented adverse reactions associated with herbal medicines, ranging from mild gastrointestinal disturbances to more serious complications such as hepatotoxicity and renal impairment [3,4,5]. Because herbal products are frequently used without medical supervision, many adverse reactions remain underreported or are not recognised as being related to the herbal preparation. In their analysis of pharmacovigilance databases, Kongkaew et al. (2024) noted that adverse events related to herbal medicines are increasingly being reported, indicating the need for improved monitoring and documentation of these reactions [6].

Herb-drug interactions represent another important aspect of safety associated with traditional medicinal products. Many herbal preparations contain biologically active compounds capable of influencing drug-metabolising enzymes and transporter systems involved in pharmacokinetic processes. When herbal medicines are taken together with conventional pharmaceuticals, they may alter drug metabolism and subsequently affect therapeutic outcomes. Bernardo and Valentão (2024) highlighted that several herbal constituents can modulate cytochrome P450 enzyme activity, thereby increasing the possibility of clinically relevant herb–drug interactions [7]. Apart from pharmacological interactions, issues related to the quality and standardisation of herbal medicines also contribute to safety concerns. Unlike conventional pharmaceuticals that undergo strict quality control during manufacturing, herbal preparations often show considerable variation in their chemical composition. Factors such as plant species,

cultivation practices, harvesting conditions, and processing techniques can influence the concentration of active phytochemicals. Furthermore, contamination with heavy metals, pesticides, or microbial toxins has been reported in some herbal products, and in certain cases, adulteration with undeclared pharmaceutical substances has also been identified. Pai et al. (2024) pointed out that such inconsistencies in product quality remain a major challenge in ensuring the safe use of herbal formulations [8]. Pharmacovigilance plays an important role in safeguarding patient safety. Pharmacovigilance involves the systematic detection, evaluation, and prevention of adverse drug reactions and other medicine-related problems. Although pharmacovigilance programmes are well established for conventional pharmaceuticals, the monitoring of adverse events associated with herbal and traditional medicines has historically received less attention. Recognising this gap, several countries have begun to incorporate traditional medicines into national pharmacovigilance frameworks to strengthen safety surveillance and promote rational therapeutic use. Considering the increasing global utilisation of herbal medicines and the emerging concerns regarding their safety, integrating pharmacovigilance principles into traditional medicine systems has become an important public health priority. The present review aims to discuss the relevance of pharmacovigilance in traditional medicines, highlight the key safety concerns associated with herbal products, and examine possible strategies to strengthen safety monitoring mechanisms in this evolving area of healthcare.

Global Utilisation of Traditional and Herbal Medicines

Traditional and herbal medicines continue to be widely used across different healthcare settings worldwide. In many countries, particularly in Asia, Africa, and parts of Latin America, traditional medicine remains an important component of primary healthcare. These systems often coexist with modern biomedical practices and are frequently chosen because of cultural familiarity, accessibility, and affordability. Several international health assessments indicate that a significant proportion of the population relies on traditional medicinal practices for managing common illnesses and maintaining general well-being [1]. In rural and resource-limited regions, herbal medicines may sometimes represent the first or only form of treatment available to communities. Regional patterns of traditional medicine utilisation vary depending on historical practices and healthcare infrastructure. In India, systems such as Ayurveda, Siddha, and Unani are formally recognised and are integrated into national healthcare policies[1]. Similarly, traditional Chinese medicine has long been incorporated into the healthcare system in China, where herbal formulations are used alongside conventional pharmaceuticals in hospitals and outpatient settings. In many African countries, locally available medicinal plants are widely used in community-based healthcare practices [9]. Xu et al. (2019) noted that the continued relevance of traditional medicine in these regions reflects both cultural continuity and the need for accessible healthcare alternatives [10].

In addition to their traditional roles, herbal medicines have gained increasing popularity as complementary therapies in developed countries. Many patients with chronic conditions, including metabolic disorders, cardiovascular diseases, and cancer, report using herbal supplements in combination with prescribed medications. While such practices may reflect growing interest in integrative medicine, they also raise important pharmacological considerations. Certain herbal constituents can influence drug-metabolising enzymes and transporter proteins, potentially altering the pharmacokinetics of co-administered drugs. Li et al. (2021) highlighted that herb–drug interactions are increasingly recognised in clinical practice, particularly when herbal products are used without professional supervision [11]. The global economic importance of herbal medicines has also grown substantially over the past decade. The expanding commercial market for herbal products, dietary supplements, and plant-derived therapeutics reflects rising consumer demand for natural health products. However, the increasing commercialisation of herbal medicines has also introduced challenges related to product quality, authenticity, and regulatory oversight. Variability in plant sources, manufacturing practices, and storage conditions may influence the chemical composition of herbal formulations, which in turn can affect both efficacy and safety. Parveen et al. (2022) emphasised that concerns regarding contamination, adulteration, and inconsistent standardisation remain significant issues within the global herbal medicine market [12]. From a pharmacovigilance perspective, the widespread utilisation of herbal medicines highlights the need for stronger monitoring mechanisms to detect adverse reactions and potential safety risks. As the use of traditional medicinal products continues to expand globally, integrating effective pharmacovigilance systems into traditional medicine frameworks becomes essential for ensuring patient

safety and promoting rational therapeutic use. Patterns of traditional medicine use vary considerably across different geographical regions, reflecting differences in cultural practices, healthcare access, and regulatory environments. A general overview of regional traditional medicine systems and their healthcare roles is presented in Table 1. Regional distribution of commonly practised traditional medicine systems and their primary healthcare roles. Safety considerations highlighted in the table represent commonly reported concerns in pharmacovigilance literature, including herb–drug interactions, contamination, and variability in product standardisation. (Adapted from Xu et al., 2019; Parveen et al., 2022; World Health Organization, 2019).

Safety Concerns Associated with Herbal and Traditional Medicines

The increasing use of herbal and traditional medicines across different healthcare systems has drawn greater attention to their safety profiles. Although many herbal remedies have long histories of traditional use, the assumption that natural products are inherently safe is not always supported by clinical evidence. Several studies have indicated that herbal medicines can produce adverse effects, particularly when used without proper medical supervision, in inappropriate doses, or in combination with conventional pharmaceuticals. In addition, the complex composition of many herbal formulations and the variability in their preparation can complicate the identification and assessment of safety concerns. As the use of these products continues to expand globally, understanding the potential risks associated with herbal medicines has become an important component of pharmacovigilance activities [13,14].

Adverse Drug Reactions

Adverse drug reactions (ADRs) associated with herbal medicines have increasingly been documented in clinical reports and pharmacovigilance databases. These reactions may range from mild symptoms such as gastrointestinal discomfort, allergic reactions, and headaches to more serious complications involving hepatic, renal, or cardiovascular systems. Hepatotoxicity is one of the most frequently reported adverse effects linked to certain herbal products, particularly those containing complex mixtures of plant-derived compounds. Teschke and Eickhoff (2020) reported that herbal-induced liver injury has emerged as a growing concern in clinical toxicology and pharmacovigilance studies [15]. The mechanisms underlying herbal ADRs are often multifactorial. Some adverse effects may arise from the intrinsic pharmacological activity of phytochemicals present in the plant material. In other situations, toxicity may result from excessive dosing, prolonged use, or inappropriate self-medication. Furthermore, because herbal preparations frequently contain multiple bioactive constituents, their pharmacological effects may vary depending on formulation, plant species, and preparation methods. These factors make causality assessment in herbal pharmacovigilance more challenging compared with conventional single-compound drugs [16].

Another factor contributing to the under recognition of herbal ADRs is the limited reporting of herbal medicine use during clinical consultations. Patients may not always disclose the use of herbal products, either because they consider them harmless or because they do not regard them as medications. This underreporting may delay the identification of potential safety signals within pharmacovigilance systems and limit the availability of reliable safety data [17].

Herb-Drug Interactions

Herb-drug interactions represent another important safety concern associated with traditional medicinal products. These interactions may occur when herbal compounds influence the pharmacokinetics or pharmacodynamics of concurrently administered conventional drugs. Pharmacokinetic interactions often involve the modulation of drug-metabolising enzymes such as cytochrome P450 isoenzymes or drug transport proteins, which can alter drug absorption, metabolism, or elimination. Certain herbal constituents have been shown to induce or inhibit these enzyme systems, thereby affecting plasma concentrations of co-administered medications [18]. Pharmacodynamic interactions may also occur when herbal products exert additive, synergistic, or antagonistic effects on physiological pathways targeted by conventional drugs. For example, herbal preparations with anticoagulant properties may increase the risk of bleeding when taken together with antiplatelet or anticoagulant medications. Similarly, herbal products that influence the central nervous system activity may interact with sedatives or antidepressants. Such

interactions can potentially compromise treatment outcomes or increase the likelihood of adverse effects. As the concurrent use of herbal supplements and prescription medicines becomes more common, awareness of potential herb–drug interactions is increasingly important for healthcare professionals and regulatory authorities [19].

Quality Control, Contamination, and Adulteration

In addition to pharmacological interactions, concerns related to product quality remain a significant challenge in the safe use of herbal medicines. Unlike conventional pharmaceuticals, which undergo strict manufacturing and quality control procedures, herbal products may vary considerably in their chemical composition and purity. Variations in plant species, geographical origin, harvesting conditions, and processing techniques can influence the concentration of active phytochemicals in herbal formulations. Such variability may lead to differences in therapeutic efficacy as well as safety outcomes [12].Contamination and adulteration of herbal products have also been reported in several studies. Contaminants may include heavy metals such as lead, arsenic, and mercury, as well as pesticide residues and microbial toxins. These contaminants may enter herbal products through environmental exposure, improper processing, or inadequate storage conditions. In some cases, herbal medicines have been intentionally adulterated with synthetic pharmaceutical compounds to enhance perceived therapeutic effects. Such practices pose significant health risks and complicate the identification of the actual cause of adverse reactions [20].

Given these challenges, strengthening quality control measures and improving regulatory oversight are essential for ensuring the safety of herbal medicines. Pharmacovigilance systems that actively monitor adverse reactions and product quality issues can play a critical role in identifying potential safety signals and informing regulatory actions. Improved collaboration between healthcare professionals, regulatory agencies, and traditional medicine practitioners may therefore help enhance the safe and rational use of herbal and traditional medicines in contemporary healthcare systems. The principal safety concerns associated with herbal and traditional medicinesare summarised in Figure 1.

Figure 1. Key safety concerns associated with herbal and traditional medicines, including adverse drug reactions, herb–drug interactions, and quality-related issues such as contamination, adulteration, and lack of standardisation, highlight the importance of pharmacovigilance monitoring.Note: Conceptual illustration created by the authors using Canva (Canva Pty Ltd., Sydney, Australia).

Pharmacovigilance Systems for Traditional Medicines

The expanding use of herbal and traditional medicines has increased the need for systematic safety monitoring. Pharmacovigilance, traditionally associated with conventional pharmaceuticals, is increasingly recognised as equally important for herbal products and traditional formulations. Unlike single-molecule drugs, herbal medicines often contain multiple bioactive constituents, which may produce complex pharmacological effects and occasionally unexpected adverse reactions. In addition, factors such as variability in raw materials, differences in preparation methods, and the possibility of herb-drug interactions further complicate safety assessment. Consequently, several international and national initiatives have begun to incorporate traditional medicines into existing pharmacovigilance frameworks to strengthen post-marketing safety surveillance [1,14].

Global Pharmacovigilance Frameworks

At the international level, efforts to monitor the safety of herbal medicines are often coordinated through global pharmacovigilance networks. The World Health Organisation (WHO) has played an important role in encouraging member states to integrate traditional medicine safety monitoring within national pharmacovigilance systems. Through the WHO Programme for International Drug Monitoring, adverse drug reaction reports from different countries are collected and analysed in the global database maintained by the Uppsala Monitoring Centre. Although the programme was initially developed for conventional medicines, increasing attention has been directed toward the reporting and evaluation of adverse reactions associated with herbal and traditional medicinal products [1]. Several countries have also developed national strategies to improve herbal medicine safety monitoring. These strategies often involve strengthening regulatory frameworks, establishing reporting systems for herbal adverse events, and promoting research on herb–drug interactions. However, the identification of safety signals for herbal

medicines remains challenging. The multi-component nature of herbal formulations, variations in product composition, and incomplete product labelling may complicate causality assessment and pharmacovigilance analysis. As a result, international collaboration and data sharing are considered important for improving the detection and evaluation of potential safety concerns related to traditional medicines [16].

National Pharmacovigilance Programs for AYUSH Systems

India has taken several initiatives to strengthen pharmacovigilance for traditional medicine systems, particularly those under the AYUSH framework, which includes Ayurveda, Yoga, Unani, Siddha, and Homoeopathy. The Ministry of AYUSH established a national pharmacovigilance programme aimed at monitoring adverse drug reactions associated with these systems. This programme involves a structured network of pharmacovigilance centres that collect, document, and evaluate suspected adverse events related to AYUSH medicines. Data generated through these centres contribute to the identification of potential safety signals and help inform regulatory decisions regarding the safe use of traditional formulations [21]. The AYUSH pharmacovigilance programme also emphasises capacity building through training programmes and awareness initiatives for healthcare professionals. These efforts are intended to improve the detection and reporting of adverse reactions associated with herbal and traditional medicines. But still the challenges remain, including limited awareness among practitioners, variations in product standardisation, and underreporting of adverse events. Strengthening collaboration between pharmacologists, clinicians, and traditional medicine practitioners may therefore enhance the effectiveness of these pharmacovigilance initiatives [21,22]

Role of Healthcare Professionals and Consumers in ADR Reporting

Healthcare professionals play a central role in pharmacovigilance activities by identifying and reporting suspected adverse drug reactions. For herbal medicines, this responsibility is particularly important because patients frequently use herbal products alongside conventional therapies. Physicians, pharmacists, and practitioners of traditional medicine systems are therefore encouraged to inquire about herbal medicine use during clinical consultations and document any suspected adverse reactions. Such reporting contributes to the accumulation of safety data and facilitates the detection of potential herb–drug interactions [17]. Consumer awareness also represents an important component of pharmacovigilance for traditional medicines. Many herbal products are obtained without a prescription, and adverse effects may go unrecognised or unreported. Public health initiatives that encourage patients to report suspected adverse reactions can therefore improve the overall effectiveness of pharmacovigilance systems. In the long term, increased reporting, improved product quality control, and stronger regulatory oversight may collectively support the safe and rational use of herbal and traditional medicines within modern healthcare systems [22,24].

Challenges in Monitoring Adverse Events of Herbal Medicines

Despite increasing recognition of the need for pharmacovigilance in traditional medicine systems, several challenges continue to limit the effective monitoring of adverse events associated with herbal medicines. One of the most frequently cited concerns is the underreporting of adverse drug reactions (ADRs). Many patients use herbal remedies as part of self-care practices and may not consider them equivalent to conventional medicines. As a result, the occurrence of adverse reactions may not be communicated to healthcare professionals, and potential safety signals remain undocumented. Similarly, healthcare providers may not consistently inquire about the use of herbal products during clinical consultations, which further contributes to gaps in adverse event reporting [17]. Another challenge relates to the complex composition of herbal formulations. Unlike conventional pharmaceuticals that typically contain a single active ingredient, herbal medicines often consist of multiple phytochemicals that may interact with each other as well as with concurrently administered drugs. This multi-component nature makes it difficult to identify the specific constituent responsible for an observed adverse reaction. In addition, variability in plant species, cultivation conditions, and processing methods can influence the concentration of bioactive compounds in herbal preparations. Such variability complicates causality assessment and makes standard pharmacovigilance approaches less straightforward when applied to traditional medicines [16].

Quality-related issues also pose significant challenges for monitoring herbal medicine safety. Reports of contamination with heavy metals, pesticide residues, microbial toxins, and intentional adulteration with synthetic pharmaceutical substances have been documented in several studies. These factors can lead to adverse health outcomes that may not necessarily be linked to the intended herbal ingredient itself. In such cases, determining whether the adverse event resulted from the herbal component, the contaminant, or an interaction between multiple substances can be difficult. The lack of consistent product standardisation and quality control across manufacturers further complicates the identification of safety signals [12]. Regulatory and infrastructural limitations also affect pharmacovigilance efforts for herbal medicines. In many countries, reporting systems for traditional medicine products are either still developing or are not fully integrated into national pharmacovigilance databases. This limits the systematic collection and analysis of safety data related to herbal therapies. Strengthening regulatory frameworks and ensuring that herbal medicines are included within existing pharmacovigilance programmes may therefore help improve surveillance of adverse events[1].

Addressing these challenges requires coordinated efforts across several domains. Improving awareness among healthcare professionals regarding the importance of documenting herbal medicine use is an important first step. Training programmes can help practitioners recognise potential herb–drug interactions and adverse reactions associated with traditional formulations. In addition, encouraging consumers to report suspected adverse effects and promoting research on the pharmacological properties and safety profiles of commonly used herbal medicines may contribute to a more robust pharmacovigilance system. Over time, integrating herbal medicine data into established pharmacovigilance databases and strengthening regulatory oversight may enhance patient safety and support the rational use of traditional medicine systems. The major challenges associated with monitoring adverse events of herbal medicines and potential strategies to address these issues are summarised in Table 2. Table 2.Common challenges affecting the monitoring of adverse events associated with herbal medicines and key strategies that may strengthen pharmacovigilance systems for traditional medicine products.

Strategies to Strengthen Pharmacovigilance in Traditional Medicine

Improving pharmacovigilance for traditional and herbal medicines requires a combination of regulatory, scientific, and healthcare system–based interventions. Although pharmacovigilance systems for conventional pharmaceuticals are well established in many countries, similar mechanisms for herbal medicines are still evolving. The increasing global use of traditional therapies, often alongside modern medicines, makes it necessary to strengthen safety monitoring systems capable of detecting adverse drug reactions (ADRs), herb–drug interactions, and quality-related concerns associated with herbal products [2,25]. One of the most important strategies involves strengthening ADR reporting mechanisms specifically for herbal medicines. Many existing pharmacovigilance systems were originally designed for single-molecule pharmaceuticals and may not adequately capture safety signals related to complex herbal formulations. Establishing dedicated reporting categories for herbal and traditional medicines within national pharmacovigilance databases can facilitate the systematic collection of safety information. Improved reporting frameworks would also help identify patterns of herb–drug interactions, which are increasingly observed in patients using herbal remedies alongside conventional pharmacotherapy [2,8]. Regulatory strengthening is another critical component. Ensuring consistent manufacturing practices, product standardisation, and post-marketing surveillance can reduce safety risks associated with contamination, adulteration, and variability in herbal formulations. Regulatory authorities may also require manufacturers to maintain pharmacovigilance systems that monitor adverse reactions after products enter the market. Such regulatory oversight can improve traceability and enable timely identification of safety signals linked to specific herbal products or formulations [26].

Research initiatives are also essential for improving herbal pharmacovigilance. Many traditional medicines consist of multiple bioactive compounds that may interact with biological pathways in complex ways. Pharmacological, toxicological, and clinical studies can help clarify mechanisms underlying adverse reactions and herb–drug interactions. In addition, systematic documentation of adverse events in observational studies and clinical settings can contribute to a stronger evidence base for assessing the benefit–risk profile of commonly used herbal medicines [27].

Training and awareness among healthcare professionals represent another important strategy. Physicians, pharmacists, and practitioners of traditional medicine systems are often the first to observe suspected adverse reactions. However, herbal medicine use may not always be recorded during patient consultations. Educational programmes that emphasise the identification and reporting of herbal ADRs can therefore improve pharmacovigilance data quality. Increased awareness among patients is equally important, as consumer-reported adverse events can provide valuable early signals of safety concerns. Finally, integrating herbal medicine data into national and international pharmacovigilance databases may significantly improve safety monitoring. Centralised databases allow for better signal detection, comparison of safety data across populations, and more coordinated regulatory responses. Over time, such integration may help bridge the gap between traditional medicine practices and modern pharmacovigilance systems, ultimately supporting safer and more rational use of herbal and traditional medicinal products.

Future Perspectives in Herbal Pharmacovigilance

The continued growth in the use of herbal and traditional medicines highlights the need for more adaptive and forward-looking pharmacovigilance approaches. Future developments in herbal pharmacovigilance are likely to be shaped by advances in digital health technologies, improved international collaboration, and expanding scientific research on the safety profiles of herbal formulations. Strengthening these areas may help address long-standing challenges in monitoring adverse drug reactions (ADRs) and herb–drug interactions associated with traditional medicinal products [2]. One emerging development is the use of digital pharmacovigilance tools. Electronic health records, mobile reporting platforms, and data-mining techniques can facilitate faster detection of adverse reactions related to herbal medicines. Digital reporting systems may allow healthcare professionals and patients to submit ADR reports more efficiently, thereby improving the availability of real-world safety data. Such approaches may also support the early identification of herb-drug interactions, particularly in patients who use herbal remedies alongside conventional pharmacotherapy [25, 29-31].

Another important area involves the expansion of global safety databases that include herbal and traditional medicinal products. International pharmacovigilance networks have traditionally focused on synthetic pharmaceuticals, but there is increasing recognition of the need to incorporate herbal medicines into global safety monitoring systems. Integrating data from national pharmacovigilance programmes into international databases may improve signal detection and facilitate comparison of safety trends across different populations and healthcare settings [1]. Advances in pharmacogenomics may also contribute to future improvements in herbal pharmacovigilance. Genetic variations in drug-metabolising enzymes and transport proteins can influence individual responses to both conventional medicines and herbal compounds. Understanding these variations may help explain differences in susceptibility to adverse reactions or herb–drug interactions. Although research in this area is still developing, pharmacogenomic approaches may eventually support more personalised and safer use of herbal medicines [16]. Finally, better integration of traditional medicine systems with modern healthcare practices may strengthen safety monitoring efforts. Collaborative frameworks that involve clinicians, pharmacologists, and traditional medicine practitioners can encourage more systematic documentation of herbal medicine use and adverse events. In the long term, combining traditional knowledge with contemporary pharmacovigilance methodologies may contribute to safer and more rational use of herbal medicines within integrated healthcare systems.

CONCLUSION

The increasing global use of herbal and traditional medicines highlights the need for robust pharmacovigilance systems to ensure their safe and rational use. Although these therapies are widely perceived as safe, adverse drug reactions, herb–drug interactions, and quality-related issues such as contamination, adulteration, and lack of standardisation remain important concerns. The complex, multi-component nature of many herbal formulations further complicates the identification and monitoring of safety signals in routine clinical practice. Strengthening pharmacovigilance for traditional medicines, therefore, requires coordinated efforts across regulatory authorities,

healthcare professionals, researchers, and traditional medicine practitioners. Improved adverse event reporting systems, better regulatory oversight, and systematic research on pharmacological and toxicological mechanisms can enhance the detection and evaluation of safety risks associated with herbal products. Greater integration of traditional medicine use into clinical documentation and pharmacovigilance databases will also support more effective safety surveillance. With growing efforts toward digital reporting, global data sharing, and interdisciplinary collaboration, pharmacovigilance systems can be better positioned to monitor the safety of herbal medicines. Such developments are essential to ensure that traditional therapies continue to be used responsibly within modern healthcare systems while safeguarding public health.

DECLARATIONS

ACKNOWLEDGEMENTS

The authors acknowledge the academic and institutional support provided for the preparation of this review. The authors also appreciate the contributions of researchers and healthcare professionals whose work in pharmacovigilance and traditional medicine has informed the perspectives discussed in this article.

Funding

This review did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Conflict of Interest

The authors declare that there are no conflicts of interest related to the publication of this article.

Ethical Approval

Ethical approval was not required for this study as it is a narrative review based on previously published literature.

Author Contributions

All authors contributed to the conceptualisation, literature review, drafting, and critical revision of the manuscript. All authors read and approved the final version of the manuscript.

Data Availability Statement

No new data were generated or analysed in this study. All information presented in this review is derived from previously published literature.

Consent for Publication

Not applicable.

Patient and Public Involvement

Patients and the public were not involved in the design or preparation of this review.

Table 1. Regional utilisation of traditional and herbal medicine systems and their healthcare roles

Region	Common Traditional Medicine Systems	Typical Uses	Key Safety Considerations
South Asia	Ayurveda, Siddha, Unani	Chronic disease management, general wellness, preventive healthcare	Variability in formulations, herb–drug interactions, heavy metal contamination
East Asia	Traditional Chinese Medicine (TCM), Kampo	Integrated hospital care, herbal formulations, and acupuncture	Complex multi-herb prescriptions, pharmacokinetic interactions
Africa	Indigenous herbal medicine	Treatment of infectious diseases, community-based healthcare	Lack of standardisation, limited pharmacovigilance reporting
Europe	Phytotherapy, herbal supplements	Complementary therapy, self-medication	Over-the-counter use, herb–drug interactions with

			prescription medicines
North America	Botanical supplements, nutraceuticals	Wellness products, chronic disease support	Dietary supplement regulation challenges, product adulteration

Table 2. Key challenges in monitoring adverse events of herbal medicines and potential strategies for strengthening pharmacovigilance

Challenge	Key Issue	Suggested Approach
Underreporting of ADRs	Herbal use is often not disclosed by patients	Promote ADR awareness and reporting culture
Complex multi-component formulations	Difficult causality assessment	Pharmacological and toxicological evaluation
Herb–drug interactions	Concomitant use with conventional medicines	Clinical monitoring and interaction studies
Quality variability	Differences in plant source and preparation	Standardisation and quality control measures
Contamination/adulteration	Heavy metals, pesticides, and synthetic drugs	Stricter regulatory and manufacturing practices
Limited pharmacovigilance integration	Herbal ADR data are rarely captured	Inclusion in national pharmacovigilance databases
Limited professional awareness	Inadequate training in herbal safety	Training programmes for healthcare professionals

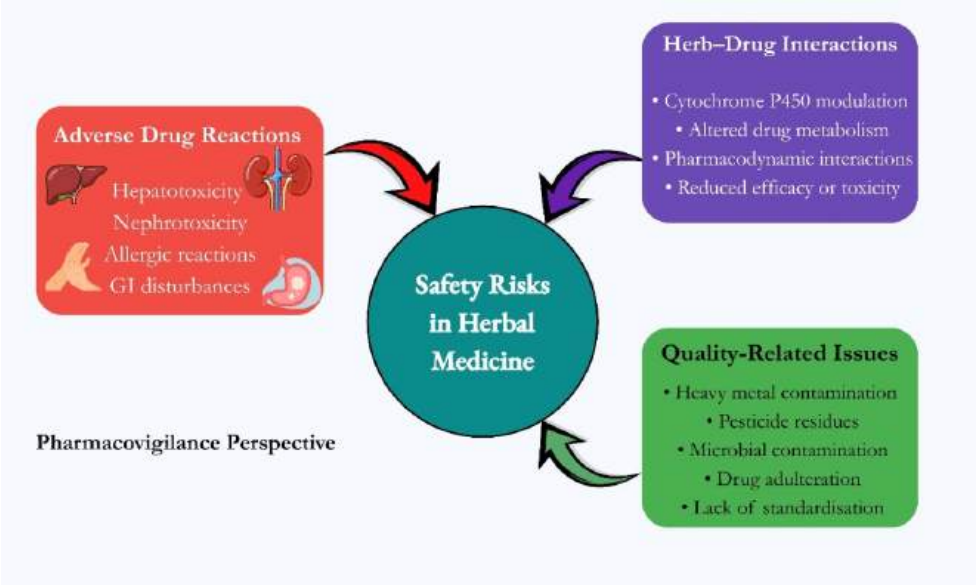

Figure 1. Major safety concerns associated with herbal and traditional medicines

ABSTRACT

Lung cancer is a leading cause of cancer-related mortality worldwide, underscoring the need for early and accurate detection to improve patient outcomes. This study presents a hybrid deep learning architecture called HCVT-Net, which integrates a Convolutional Neural Network (CNN) with a Vision Transformer (ViT) for the automated classification of lung cancer using computed tomography (CT) images. The CNN component picks up on small, granular spatial patterns, while the ViT part models large contextual relationships, which makes it possible to describe features in a whole way. Before making the final classification, the hybrid architecture uses feature fusion to combine local and global information. CT scans are used from a Kaggle dataset that is open to the public to test how well HCVT-Networks. The HCVT-Net has achieved an accuracy of 99.00%, a precision of 98.50%, a recall of 98.50%, and an F1-score of 98.50% based on experimental results. These findings consistently differentiate classifications, including normal, benign, and malignant patients. The suggested HCVT-Net offers a quick and flexible way to classify lung cancer based on CT scans, and it might also make computer-assisted clinical decision-making better.

Keywords: Lung Cancer Classification, Computed Tomography, Hybrid CNN–Vision Transformer, Deep Learning, Medical Image Analysis.

INTRODUCTION

Lung cancer is a major global health issue and a significant cause of cancer deaths. Early identification and clinical action are crucial to survival, despite therapy advancements. Early detection and screening are crucial for patient prognosis since the illness generally proceeds quietly. Lung cancer diagnosis relies on CT imaging, which offers precise cross-sectional images of lung structures to reveal nodules, masses, and abnormal tissue patterns. The rising amount of CT scans has increased radiologists' workload, necessitating automated and dependable diagnostic assistance technologies. CT scan interpretation by manual is difficult and needs experience. Nodule form, size, density, and position might make distinction between benign and malignant findings difficult. Due to observer weariness or inter-reader variability, small irregularities may be missed. These problems have spurred the use of computer-aided diagnostics to help physicians analyse data objectively. Handcrafted features and domain-specific descriptors were used in traditional machine learning, although feature engineering and previous knowledge were crucial to performance. Data-driven feature learning has revolutionised medical image interpretation thanks to deep learning. CNNs can capture local spatial patterns and hierarchical representations, making them effective in medical imaging. CNN models are commonly used for lung nodule detection, segmentation, and classification. CNNs may learn local textures and structural information, but they may struggle to represent long-range dependencies and global contextual interactions throughout the image.

In current medical imaging studies, computing scalability is crucial. Cloud-based computing infrastructures provide high-performance hardware and distributed resources for large-scale deep learning model training and deployment. Centralised model updates, collaborative research, and distant clinical access are supported by clouds. These features let healthcare centres provide real-time diagnostic assistance and handle massive CT datasets. Deep learning and cloud architecture provide fast processing, storage, and inference, making sophisticated diagnostic tools more accessible. Considering these factors, this study investigates a CNN–ViTarchitecture for CT-based lung cancer categorisation. Discriminative characteristics that capture fine-scale lung patterns and global anatomical context are extracted in the proposed method. The approach uses convolutional and attention-based learning to distinguish normal, benign, and malignant diseases. The technology supports scalable medical imaging data processing in cloud-enabled systems. The proposed hybrid deep learning models may aid clinical decision-making and early lung cancer diagnosis.The rest of paper is organized are as follows: Section 2 covers lung cancer imaging and deep learning research. Section 3 covers dataset and preparation. Section 4 proposes a hybrid architecture. Experimental findings and assessment with conclusion are in Section 5.

Related Works

Explanatory fusion-based transfer learning for lung disease classification was studied in [1]. The image classification method uses ResNet50, ResNet101, and EfficientNetB0 pretrained neural networks. Two fusion techniques are explored such as feature-level fusion, which combines ResNet50 and EfficientNetB0 features, and decision-level fusion, which combines ResNet50 and ResNet101 forecasts. For better interpretability, XAI approaches like LIME, SHAP, and Integrated Gradients visualise important image areas and explain model conclusions. Diagnostics of lung illness in early versus middle multimodal fusion was described in [2]. The platform integrates chest X-rays, CT scans, and cough noises for multimodal deep learning. Xception-based CNNs pre-process and encode each modality for feature extraction. We assess early and intermediate fusion techniques which incorporate modality characteristics before or after representation learning. Classification uses CNN and softmax. Multimodal instances are created using label-level alignment, not patient-level pairing.

Deep learning-based CT scan predictive models was optimized the lung cancer screening was detailed in [3]. Pre-processing and augmentation increase image quality and variability. After isolating lung areas and nodules using a Mask R-CNN module, an AlexNet-based convolutional neural network classifies the imagery. Stable learning and lung cancer risk prediction are achieved using Adam and SGD optimisers in model training. Prediction of lung illness using machine learning methods and Generative Adversarial Networks (GAN) was briefed in [4]. A hybrid

Lung-GAN architecture using Generative Adversarial Networks and CNN Networks to identify lung illnesses from CT and X-ray images was proposed. GANs increase generalisation by creating realistic synthetic images from minimal labelled data. CNNs learn hierarchical characteristics to classify images as cancer or normal.

Deep learning models for the classification of lung cancer and related diseases using medical imaging was showed in [5]. Lung image classification using ResNet+, an upgraded CNN, was recommended. It uses ResNet-D to decrease downsampling feature loss and a CBAM to concentrate on spatial and channel characteristics. Class imbalance was addressed by data augmentation. The model outperforms ResNet in generalisation, accuracy, and efficiency across diverse lung cancer. CNN-SVD hybrid feature extraction and selection for ensemble-based multiclass lung cancer classification was described in [6]. The research adopts a hybrid CNN–SVD method to extract deep features from lung CT images and select and minimise the most informative components. This integrated method enhances discriminative feature representation, decreases dimensionality, and boosts classification reliability.

Hybrid CNN-DNN framework for lung cancer prediction and clinical translation was shown in [7]. The hybrid deep learning method predicts early-stage lung cancer using CNN and DNN. CNN collects spatial characteristics from CT scans, whereas DNN analyses age, smoking history, and comorbidities. Final classification uses both outputs in a combined layer. For early diagnosis, multimodal fusion enhances prediction accuracy, robustness, and clinical relevance. ResNet–50 deep neural network architecture accurately predicts lung cancer was shown in [8]. The CT image-based lung cancer classification method leverages modified ResNet50 deep learning. Feature extraction was improved by sophisticated preprocessing (noise reduction, normalisation, contrast enhancement), hyperparameter optimisation, and residual learning. Fusion of 2D and 3D CNN characteristics enhances representation. Model trimming and quantisation boost efficiency. Lung nodule classification was accurate, resilient, and computationally efficient using our optimised ResNet50 framework.

Mask-EffNet CT scan image analysis improves lung cancer identification was briefed in [9]. A Masked Autoencoder for Distribution Estimation (MADE) and transfer-learned EfficientNetB7 form a hybrid Mask-EffNet architecture. First learning data distributions, MADE extracts useful, low-dimensional characteristics to manage uncertainty and class imbalance. Fine-tuned EfficientNetB7 classifies these characteristics using compound scaling. Data augmentation and transfer learning enable multiclass lung cancer classification from CT scans. Fine-tuned CXR and chest CT lung disease classification comparison was detailed in [10]. The method classifies lung disease from CXR and chest CT images using fine-tuned transfer learning and a modified VGG-16 convolutional neural network. A pre-trained VGG-16 model was fine-tuned by retraining higher layers using medical images. With preprocessing and data augmentation, feature extraction and multiclass lung disease classification are enhanced.

Interstitial lung disease identification model using multi-modal fusion attention mechanism (MFAM) was studied in [11].The method identifies interstitial lung disease using MFAM. CNN–extracted CT image features, Bi-LSTM–learned physiological time-series patterns, and self-attention–encoded clinical text are used. Transformer-based fusion modules fuse joint information and apply adaptive weights to each modality. Attention-guided multimodal learning increases ILD classification accuracy and reliability by representing features comprehensively. An ideal lung disease diagnostic model using SqueezeNet and machine learning was summarized in [12].For lung illness diagnostics, SqueezeNet and machine learning are combined. A lightweight CNN, SqueezeNet extracts discriminative features from chest X-ray images utilising fire modules to minimise parameters and maintain accuracy. Traditional machine learning methods, such decision trees, classify these deep characteristics.In post-COVID-19 patients, local search improved Inception-ResNet-v2 classification of long-term lung illnesses was used in [13].For lung disease classification from post-COVID-19 CT images, LSAHO with Inception-ResNet-v2 was used. Inception-ResNet-v2 extracts multi-scale deep features, whereas LSAHO optimises hyperparameters through directed and territorial foraging with local search refinement. Preprocessing involves resizing, normalisation, and adaptive median filtering. Long-term lung disease multiclass classification was resilient and accurate using the optimised deep model.

LCCNet a Deep learning-based lung cancer diagnosis utilising CT scans waspresented in [14].The LCCNet transfer learning–based deep CNN architecture classifies lung cancer from CT images using a pre-trained DenseNet-121 model. Data preprocessing and augmentation are used to fine-tune DenseNet-121's final layers while freezing previous layers. These improve medical imaging feature extraction, reduce overfitting and disappearing gradients, and classify binary lung cancer using learnt ImageNet features.CT scan-based lung cancer classification using EfficientNet based Lung-EffNet was briefed in [15].The transfer learning–based deep learning system Lung-EffNet, based on EfficientNet, classifies lung cancer from CT images. Medical images are used to fine-tune pre-trained EfficientNet (B0–B4) models by extracting high-level features and passing them through improved classification layers. This method accurately classifies benign, malignant, and normal with few parameters and strong generalisation.

Cat-optimized CNN for lung cancer classification was detailed in [16].Lung cancer classification from CT images employs a Deep Fused Features-Based Cat-Optimized Network (DFF-CON). It uses deep CNN layers for feature extraction and visual saliency maps for classification. CNN hyperparameters are optimised by cat swarm to decrease misclassification and overfitting. This combination of saliency-guided characteristics and metaheuristic optimisation classifies benign and malignant lung nodules accurately and simply.Deep learning lung cancer prediction from CT scan and histopathological image feature analysis was analysed in [17].The deep learning–based multimodel framework predicts lung cancer from CT scan and histopathology data. It uses CNN, optimised CNN with quasi-gradient descent, and transfer-learning models (VGG-16, VGG-19, InceptionV3, and ResNet-50) for feature learning and classification. CNN training was optimised through quasi-gradient descent to decrease false positives and enhance accuracy for image-based lung cancer identification.

Classifying CT images of lung cancer using Deep-ShrimpNet was detailed in [18].Lung cancer classification on CT scans using Deep-ShrimpNet–based deep learning. Kernel co-relation preprocessing removes noise and Bayesian fuzzy clustering isolates lung nodules. An upgraded AlexNet-inspired Deep-ShrimpNet learns hierarchical features and uses Softmax, Random Forest, SVDD, and AdaBoost ensemble majority-vote classification to classify images as normal, benign, or malignant.CT scan-based lung cancer diagnosis utilising vision transformers was summarised in [19].For CT scan lung cancer classification, ViT–based deep learning models with transfer learning are used. Self-attention processes patches of images to record global contextual connections. Medical data refines pre-trained ViT variations (ViT, Swin Transformer, DeiT, and PVTv2). Cross-validation promotes resilience and generalisation, allowing reliable multiclass lung disease classification.

MATERIALS AND METHODS

The proposed framework is designed to analyselung CT images through a hybrid learning paradigm that combines convolutional and transformer-based reasoning. The objective is to construct a model capable of distinguishing lung conditions by learning both localized tissue characteristics and broader anatomical relationships. Instead of relying on a single architectural paradigm, the system merges convolution-driven spatial learning with attention-based contextual modelling. This dual strategy enables richer feature interpretation and improved discrimination among normal, benign, and malignant classes.Figure 1 shows how the hybrid architecture, HCVT-Net utilizes convolutional local feature extraction with transformer-based global attention modelling, allowing a more thorough and resilient visual representation prior to final classification.

The proposed system is an end-to-end hybrid deep learning architecture designed for automated lung cancer classification from CT images. The model integrates a CNN branch for local feature extraction and a ViT branch for global contextual modelling. The extracted local and global features are fused through concatenation and fed into a fully connected classifier for final prediction.

Local Feature Extraction by CNN

Two parallel branches, the CNN branch and the Vision Transformer (ViT) branch, process the input CT image at the same time. The goal of the CNN branch is to find small, detailed local spatial patterns in lung CT scans. There are three convolutional blocks in the CNN design. Each block has a convolutional layer, batch normalization, and ReLU activation. The first convolutional layer uses 64 filters with a kernel size of 3 × 3 and a stride of 1 to find low-level features like edges and changes in intensity. After this layer, Batch Normalization is used to make training more stable, and a ReLU activation function is used to add non-linearity. A 2 × 2 Max Pooling layer is used to keep significant discriminative characteristics while cutting down on the size of the space. The second convolutional layer has 128 filters and a 3 × 3 kernel. This lets the network learn more complicated form and texture patterns from lung nodules. After that, batch normalization and ReLU activation are used again, and then 2 × 2 Max Pooling is used to further reduce the space. The third convolutional layer has 256 filters with a kernel size of 3 × 3. This lets it extract structural features from CT images more deeply. After the convolution operation and batch normalization, the feature maps go to a Global Average Pooling (GAP) layer. This layer turns the spatial feature maps into a compact feature representation by finding the average of each feature map. The resultant feature maps are then flattened into a one-dimensional vector, which makes a local feature vector that contains detailed spatial and texture information that is useful for classifying lung cancer.

Global Contextual Modellingby ViT

The second branch of the architecture uses a ViT to find global contextual linkages in the CT images. CNNs only look at local receptive fields, while the transformer design lets you model long-range relationships over the whole picture. At first, a patch extraction layer divides the input picture into 16 × 16-pixel patches that don't overlap. This makes 196 patches (14 × 14 grid) for an input picture that is 224 × 224 pixels. A linear projection layer then flattens each patch into a one-dimensional vector and projects it onto a higher-dimensional embedding space. This creates patch embeddings that are 768 dimensions long. Positional encoding is applied to the patch embeddings to keep the patches in the same order. This positioning information helps the transformer keep the patches' relative spatial relationships the same. After that, the embedded patches go via a stack of Transformer encoder blocks. Each encoder block has:

- Multi-Head Self-Attention (MHA) with 8 attention heads, enabling the model to focus on different spatial regions simultaneously. It is defined as

$$Attention(Q, K, V) = softmax\left(\frac{QK^T}{\sqrt{d_k}}\right)V$$

  where Q, K, V represents the query, key and value respectively. The dimension of K is represented by d_k.
- Feed Forward Network (FFN) consisting of two fully connected layers with GELU activation
- Layer Normalization and residual connections to stabilize training

In this architecture, four (4) Transformer encoder blocks are employed to effectively capture global contextual relationships between image patches. After processing through the stacked encoder blocks, a final layer normalization is applied to generate the global feature representation.The resulting representation is extracted as a global feature vector, which captures high-level contextual and semantic relationships within the CT image.

Fusion in HCVT-Net

The proposed Hybrid CNN–Vision Transformer Network (HCVT-Net) combines the best parts of CNNs and transformers by using a feature fusion technique. The local feature vector from the CNN branch shows very small spatial details, whereas the global feature vector from the ViT branch shows long-range contextual relationships. At the fusion step, these two feature representations are joined together to create a single feature vector that has both local structural information and global contextual knowledge. The local CNN features and the global ViT features are combined like this:

$$F_{fusion} = [F_{CNN} \oplus F_{ViT}]$$

where $F_{CNN}$is the local feature vector, $F_{ViT}$is the global feature vector and $\oplus$ is the concatenation operation. This combined representation gives us a more detailed and useful feature space for categorization. The combined feature vector is then sent to a fully connected layer with 256 neurons. This layer learns the best decision boundaries between various types of lung cancer. To prevent overfitting and increase generalization, a dropout layer with a rate of 0.5 is used. Finally, the processed features go into a softmax classifier, which gives each class a probability score. The final anticipated label, which might be normal, benign, or malignant lung tissue, is the class with the greatest likelihood.

RESULTS AND DISCUSSION

The Iraq-Oncology Teaching Hospital/National Center for Cancer Diseases (IQ-OTH/NCCD) was gathered in 2019 during three months [20-22]. It has lung CT images in DICOM format that were taken at various times and of healthy people using a Siemens SOMATOM scanner. The dataset has a complete image made up of CT scan slices from 110 instances. There are three classes such as benign (120 images), malignant (581 images), and normal (416 images). The CT scans were taken at a voltage of 120Kv and a slice thickness of 1mm. The window's width might be anywhere from 350 to 1200 HU, and the window's center may be anywhere from 50 to 600 HU. The human lung image was shown from various perspectives and angles, with the number of slices varying between 80 and 200. To fix the class imbalance in the images, data augmentation was done on all three classes of 1000 images. The images were then separated into three categories with 60% for training (1800 images), 20% for validation (600 images), and 20% for testing (600 images). Figure 2 displays CT images organized by diagnostic classes. The Normal row shows clear lung fields without abnormal masses.

The Benign row presents localized nodules and mild structural variations. The Malignant row reveals irregular masses, asymmetric densities, and suspicious lesions associated with cancer. This visual arrangement highlights inter-class variability and demonstrates how CT imaging captures structural patterns relevant for lung cancer classification. The performance of the proposed hybrid system is analyzed using the following metrices:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN}$$

$$Precision = \frac{TP}{TP + FP}$$

$$Recall = \frac{TP}{TP + FN}$$

$$F1 = 2 \cdot \frac{Precision \cdot Recall}{Precision + Recall}$$

Figure 3 presents the confusion matrix showing classification performance of CNN and ViT architecture. The confusion matrix study in Figure 3 showed that both CNN and ViT designs achieve high of classifying lung cancer. The CNN model got 96.5% of the answers right, accurately identifying 579 out of 600 images, with just a little bit of uncertainty between normal and benign tissues. On the other hand, the ViT had a greater accuracy of 98.0%, accurately recognizing 588 samples. The ViT model has a malignant class recall of 99%, which is very important for clinical diagnosis since it didn't misclassify any malignant samples as normal. The enhanced efficacy of ViT is due to its capacity to capture global contextual dependencies through self-attention processes, facilitating superior discrimination of subtle disease patterns. The confusion matrix for hybrid CNN–ViT lung cancer classification is shown in Figure 4.

It can be observed from Figure 3 and Figure 4 that the proposed HCVT-Net achieved the best performance among the three approaches. The confusion matrix in Figure 4 shows 591 correct predictions out of 600 samples, resulting in an overall accuracy of 98.5%. The model demonstrates extremely low misclassification rates, with only 9 incorrectly classified samples. The malignant class achieved a recall of 99.5%, indicating almost perfect cancer detection capability. Additionally, benign and normal classes also exhibit high precision and recall values, demonstrating the robustness of the hybrid framework. The hybrid design works well because CNN and ViT both have strengths that work well together. CNN is good at finding local texture and edge-based characteristics, while the transformer part finds global contextual linkages in the image. Combining these two feature representations helps the model do a better job of classifying things. Table 1 shows how well the CNN, ViT, and Hybrid CNN–ViT architectures work for classifying lung cancer.

Table 1 shows how CNN, ViT, and the new HCVT-Net compare in terms of lung cancer classification performance. It shows that the performance is becoming better with time. The CNN model had an accuracy of 97.67%, which shows that it was good at getting local spatial characteristics from medical pictures. But CNN systems mostly concentrate on narrow receptive fields, which could make it harder for them to pick up on long-range contextual relationships. The ViT model raised the accuracy of classification to 98.67%. This was possible because it uses a self-attention mechanism that lets it represent global contextual links between picture patches. The suggested HCVT-Net had the best accuracy of 99.00% and the best precision, recall, and F1-score values of 98.50%. The better performance is due to combining CNN-based local feature extraction with transformer-based global attention techniques. This dual technique lets the model efficiently capture both fine-grained texture information and global contextual dependencies, which improves the way it represents discriminative features. So, the hybrid design cuts down on misclassification a lot and gives a more accurate diagnosis of lung cancer than either the CNN or ViT models on their own. Figure 6 shows the comparison of various architectures with the proposed architectures.

The results in Figure 5 indicate that different deep learning approaches achieve varying levels of diagnostic performance. The multimodal early fusion approach achieved strong performance with 97.00% accuracy and balanced precision, recall, and F1-score values around 97%, demonstrating the effectiveness of integrating multiple feature sources. The conventional CNN model achieved a relatively high accuracy of 98.50%, but its precision, recall, and F1-score values dropped to approximately 89%, indicating potential inconsistencies in correctly identifying all classes. The CNN + GAN model showed moderate performance with 95.00% accuracy, but its recall value decreased significantly to 65.00%, suggesting difficulties in detecting certain cancer cases. Similarly, ResNet-D achieved 93.76% accuracy with slightly improved recall compared to CNN + GAN but still lower overall classification balance. In contrast, the proposed HCVT-Net achieved the best overall performance with 99.00% accuracy and 98.50% precision, recall, and F1-score, demonstrating superior classification capability. The improved performance of the hybrid model can be attributed to the integration of CNN-based local feature extraction and transformer-based global attention mechanisms.

CONCLUSION

This study presented a HCVT-Net for lung cancer classification using CT images, with the objective of enhancing diagnosis accuracy by complementing feature learning. The CNN component adeptly extracts local spatial and textural attributes of lung structures, while the ViTmodelled broad contextual connections across the image. The combined effect of these representations facilitated enhanced feature learning and dependable class differentiation among normal, benign, and malignant instances. An assessment of a publicly accessible Kaggle dataset revealed robust performance, characterised by elevated accuracy, precision, recall, and F1-score, signifying reliable and consistent predictions. The findings validate that the integration of convolutional and transformer-based learning improves robustness relative to single-model methodologies. The approach is also computationally feasible for cloud deployment, enabling scalable analysis of large CT datasets. This method may aid physicians by delivering rapid and consistent second views during screening and diagnosis. Future research may investigate bigger multi-center

datasets, enhance model interpretability, and facilitate real-time integration into clinical processes to bolster dependability and practical usefulness in medical imaging settings.

ABSTRACT

The old way of doing pharmaceutical research and development is very expensive. Takes a long time usually more than ten years. The pharmaceutical research and development process also has a success rate for clinical trials, which is less than 10%. Artificial Intelligence and Machine Learning are changing the way things are done in the pharmaceutical industry. Artificial Intelligence and Machine Learning are helping the pharmaceutical industry by using data to make predictions of just trying things out and seeing what happens. This is a change for the pharmaceutical industry because it uses data to make decisions, which is different from the old way of doing things. The use of Artificial Intelligence and Machine Learning is affecting the pharmaceutical process from start to finish and it is helping to make the process more efficient. Artificial Intelligence and Machine Learning are important, for the pharmaceutical industry because they can help make the process of developing medicines faster and cheaper. The paper looks at how Artificial Intelligence's used in important parts of finding new drugs. This includes figuring out what disease we are dealing with by looking at lots of kinds of data like genomics and proteomics. Artificial Intelligence is also used to check if a target is good and to find drug candidates by using computers to screen and design them. Artificial Intelligence is not only useful in searching drugs. It is also useful in improving the product such as in designing the right dose through the use of 3D printing. Problems in the manufacturing process can even be detected by Artificial Intelligence. Moreover, it describes the way AI can streamline the clinical trial process by enhancing protocols and sites selection and patient recruiting as well as streamline pharmaceutical supply chain management by forecasting demand and detecting counterfeits. Although these achievements have been made, the review recognizes that there exist some serious issues such as privacy of data, the black box interpretability of deep learning

models, regulatory issues and mismatch of skills with workforce. Conclusively, AI is introduced as an important invention in decreasing the attrition rate, saving money, and hastening the provision of tailored patient treatment.

Keywords: Data, Artificial Intelligence, pharmaceutical industry, medicines, Machine Learning

INTRODUCTION

Research is usually done in a way that costs a lot of money and takes a time. Making a medicine is really hard and can take a long time from 10 to 17 years. It also costs an amount of money between $100 million and $2.6 billion. The problem, with making medicine is that it does not always work. In fact most of the time it does not work. Pharmaceutical research is a field where people do this kind of work pharmaceutical research is what they do. The process of doing research for medicines has a lot of issues. One of the issues with pharmaceutical research is finding the right target for a new medicine right from the start[1]. Pharmaceutical research has to find these targets for medicines. This is an important step in pharmaceutical research because it helps avoid wasting a lot of money on things that will probably not work out. Pharmaceutical research like this can make a difference. Finding the target for a new medicine is crucial, for pharmaceutical research[2]. The success of finding medicines depends on three things: understanding what the disease is making sure the target for the treatment is correct and creating the right kind of treatment. Artificial Intelligence and Machine Learning are basically computer tools that can help with these problems. They work by looking at and analyzing the amounts of complex information that we get from modern biology methods. Artificial Intelligence and Machine Learning are very useful, for finding medicines because Artificial Intelligence and Machine Learning can do this. This paper shows us how Artificial Intelligence works in the process of finding and making medicines. It begins with finding diseases and targets[3]. Artificial Intelligence uses a lot of information from genetics and genetics research. This helps Artificial Intelligence find connections between genes and diseases that we were not aware of before. Artificial Intelligence looks at all this information to find things, about diseases and targets. The process of using Artificial Intelligence in making medicines is very important[4]. Artificial Intelligence plays a role in this process. Then it goes on to testing drugs and making them better. This shows how Artificial Intelligence can quickly test chemicals and figure out if they are safe for people to take. This in actual sense assists in increasing speed in the search of the medicines. Clinical Trial Design is another aspect that is assisted by Artificial Intelligence. It makes the plans better. Finds the right patients. The Supply Chain Management is even assisted through Artificial Intelligence. It improves the logistics. Quality assurance of the products. Along with the promise of AI to be used in healthcare to increase precision and efficiency, the methodological, technical, and ethical issues that need to be solved to achieve its full potential are also discussed in this review[5].

Disease Identification

The traditional pharmaceutical research and development (R&D) process is characterized by large costs, time and a success rate of clinical trials less than 10%. Identical and precise identification and validation of potential drug targets is one of the first and most vital tasks in this process, which is normally referred to as disease identification[6].The success of drug discovery requires three pillars whose correct validation will determine the success of drug discovery: defining the disease, validating the therapeutic target, and developing the appropriate therapeutic modality [7]The emergence of Artificial Intelligence and Machine Learning corresponds to a paradigm shift and the provision of effective computational mechanisms to increase the quality and efficiency of all this process, starting with the discovery of new disease targets and mechanisms[8]The use of AI models is being applied in the whole drug research and development cycle, beginning with disease detection, all the way to optimization of the lead compound, and up to clinical trial design[9].It is believed that in this technological development, the efficiency in identifying promising drug candidates will increase at a significant expense of the probability of late stage failures[10].Target identification is an important procedure which, entails the identification of particular molecules including proteins or genes which, when altered, may alter the disease pathway and produce a treatment effect[11]This is the area where

AI can be most useful, as it is capable of synthesizing and processing the large and complicated sets of data generated by modern biological techniques[12]. The best tool that AI has in the disease identification is that it can process a large amount of data known as Big Data, which is the product of multi-omics technologies[13]. These include –

Genomics and Transcriptomics

The data on the expression of genes in the samples of patients are analyzed with the help of machine learning algorithms (random forests and support vector machines). These algorithms have the ability to identify particular genetic signatures or differentially expressed genes which have the potential to predict disease phenotypes or progression divulging potential new therapeutic targets[14]

Proteomics and Metabolomics

Due to Deep Learning models, mass spectrometry data can be analyzed to reveal protein-protein interaction (PPI) networks which go out of control during disease. Mapping such complicated biological pathways, AI can identify essential nodes or hub proteins in which interfering would cause havoc to the disease network[15].

Network-Based Approaches

AI assists network-based modelling of entirely biological systems. Machine learning can be used to determine disease-target connection and uncover disease pathophysiology through the analysis of interactions and relationships between genes, proteins, and metabolites[16]. Using AI instruments, one can process data about a specific patient, find the targets that are unique to them and their disease subtype, and reveal the path to the most specific therapeutic approaches.There are problematic issues in the full-scale application of AI in identifying the disease. [17]

Opportunities: Speed and Precision

The use of AI in drug discovery is transforming the process of disease discovery through more efficient disease discovery. By performing a fast screening of large volumes of chemical and biological data, AI will enable scientists to quickly discover and rank any potential drug targets and candidate molecules[18].

Novel Target Discovery

AI is skillful at finding disease targets with a poorly understood etiology, especially in the field of oncology and neurodegenerative diseases, where classical algorithms have failed[19]. This also includes the identification of new biomarkers which are crucial to predicting the outcome of the disease and monitoring the success of the treatment[20].

Personalized Medicine

The traditional models in vivo are not necessarily a complete replication of the actual biological setup which limits their predictive power in vivo drug performance[21].

Data Quality and Quantity

The performance and results of AI and machine learning (ML) models require the existence of high-quality, big, and well-structured datasets to ensure stable training and performance. One of the problems, though, is that there is not much information on negative data of molecules or compounds that have failed during experimentation or clinical testing. It creates an imbalance in the training datasets and this results in the biased model learning because of the absence of failure data. Besides, most publicly available datasets exhibit prior biases, lack consistency or are not completely collected, which further limits the model to the generalization of the diverse biological systems or chemical structure. In turn, such restrictions can decrease the general predictive performance and strength of AI/ML models in drug discovery[22].

Model Interpretability

A great number of superior deep learning (DL) frameworks, including deep neural networks, are black boxes in the sense that their decision-making mechanisms are not always transparent and interpretable. This is a major challenge in regard to disease identification. In the situation where an AI model predicts or chooses a certain protein or gene as a possible disease-related target, researchers should be in a position to discern the logic of such a choice. The lack of interpretability makes it hard to answer the question whether the prediction made by the model has a biological significance or it is just a consequence of the correlation between data.This transparency is essential not only for validating the biological relevance of the predicted targets through experimental studies but also for meeting regulatory requirements. Regulatory agencies increasingly emphasize explainable AI to ensure that computational predictions can be traced, justified, and scientifically validated before progressing to costly experimental or clinical stages[23].

Target Identification

Target identification is the biological molecules whose activity has a therapeutic effect correlated with genetic, cellular, tissue or organ evidence of a certain disease[24] . A disease driver is usually a protein, gene, RNA molecule or a pathway associated with the onset or underlying process of a disease. The first step of the drug discovery process is target identification[25]. Although advances are remarkable in the area, target identification still depends on experimental biological, genomic, proteomic and hypothesis driven[26]. Each of these sources processes is generally associated with the cost and time-intensive processes.Artificial intelligence (AI) is the capability of a machine to imitate intelligent human behavior. In simple words, AI is the simulation of human intelligence in machines. Artificial Intelligence in Health refers to using AI techniques in the medical field. The implementation of AI will enhance human health by examining the huge amounts of data that could be gathered within and outside any medical setup. There are several types of intelligence such as artificial intelligence[27].

Limitations of Conventional Target Identification Approaches

Scientific experimentation-based target discovery suffers from inadequate biological knowledge, experimental bias and poor reproducibility [28], as per another study. Traditional ways to identify targets often fail during clinical development due to unexpected toxicity or insufficient efficacy [29]. In addition, classical target discovery approaches that identify a single target commonly overlook the multi-factorial nature of human diseases[30] . The speedy increase of omics data namely. Due to the existence of genomics, transcriptomics, proteomics, metabolomics it becomes impractical for manual interrogation of such high-dimensional data. AI provides a systematic way to organize the aforementioned challenges by automating the processes of pattern recognition, hypothesis generation, and prioritization of targets for heterogeneous data sources[31].

Role of AI in Target Identification

Most recently, artificial intelligence is increasingly used for target identification, which enables learning of complex relationships between genes, proteins and disease phenotypes[32]. Machine learning algorithms can conduct analyses for correlations and causal relationships which are otherwise not possible from a classical statistics standpoint[33]. Artificial intelligence (AI) enables a better understanding of the biology of disease through the integration of multi-omics data, clinical data, and biomedical literature[34]. According to, AI-based target finding techniques can be classified into three groups: data-driven, knowledge-driven and hybrid. The use of AI in target identification approaches has several advantages such as increases prediction accuracy, reduced false positive rates[35].

Natural Language Processing for Knowledge-Driven Target Discovery

Many unstructured pieces of information present in the biomedical literature are relevant to target identification[36]. In the field of NLP, AI systems obtain the relationships between genes, proteins, diseases, and drugs from scientific articles, patents and clinical reports[37]. Models based on transformer architecture have extensively been used to analyze the biomedical text and extract novel target–disease associations. As per the literature, BERT and BioBERT

have been utilized for this. In addition, literature-derived insights are synthesized through NLP-based knowledge graphs [38].

AI-Based Disease Stratification and Target Prioritization

Patients with the same disease may themselves be quite different [39]. By linking molecular signatures with clinical outcomes, Artificial intelligence allows us to categorize disease subtypes. That makes it possible. Algorithms for target prioritization classify potential targets on components such as druggability, safety, biological effect, clinical application . AI-driven scoring systems lower attrition rates by assigning resources to the development of tests[40].

Case Studies of AI-Driven Target Identification

Numerous accounts exist that showcase the effective utilization of AI to uncover potential treatment targets. For instance, through the use of AI for analysis of transcriptomic data, novel oncology targets were found that have since gone to clinical studies[41]. In the same way, through network analysis based on AI, immune-related targets for the treatment of inflammatory and auto-immune diseases were identified [42]. The impact of implementation of these AI platforms are evident from their use for systematic target discovery by pharma and biotech companies[43].

Challenges and Limitations of AI in Target Identification

Even if AI has many advantages in terms of target identification, it brings along some challenges too . In order to identify drug targets, deep learning algorithms learn often from data that is partial, unclean and false. This may lead to erroneous predictions or inferences based on the data[44]. Furthermore, the application of a complicated feature. To overcome these challenges, we need effective data curation, methods for explainable AI, and computational scientists-experimental biologists collaboration[45].

Structural Screening vs Virtual Screening

According to this PC2 warning, the methods which detect binding to a structure are well separated from the methods which score this binding. Thus, we have “structural screening” in the first case while we have Virtual Screening (VS) in the second. One of the classical examples of structural screening i.e. screening a library using an assay that detects binding to the structure of the target, is the screening by X-ray using crystals of a protein target[46]. NMR screening is an example of a similar technique that can be used to look for protein binders[47].

Structure-Based Screening

Structure-based virtual screening refers to high-resolution three-dimensional (3D) structure of the target protein obtained through X-ray crystallography, nuclear magnetic resonance (NMR) or prediction using AlphaFold (AI model)[48] . Molecular docking is a commonly used computational technique in structure-based virtual screening, where the ”fit” of each ligand into a binding pocket is assessed according to a scoring function that computes a value which correlates with binding affinity[49]. The incorporation of Molecular Dynamics recently.

Ligand-Based Screening

When the 3D structure of the target is not known but a set of active molecules are available then ligand-based VS (LBVS) can be used [50]. This method is based on the similarity principle which states that molecules having similar structure will have similar biological activity[51] . Through this similar approach, pharmacophore modelling, which is the ensemble of electronic and steric features necessary to enable the ability of a molecule to active a biological target and QSAR modelling can be used [52].

AI in Drug Screening

Deep neural networks based on Deep Learning are the programs designed to learn from experience, achieving human-level accuracy. Using linear models could not capture the complex non-linear relationships in biological data[53]. Machine learning techniques are best suited for this task. Artificial Intelligence has revolutionized the field of drugs[54].

Prediction of Physicochemical Properties

An accurate prediction of properties such as solubility , lipophilicity and permeability that can assure that a drug can get to the target[55] . AI model (GNNs) can predict such parameters directly from molecular graphs with far more accuracy than models based on hand-coded descriptors[56] . This allows filtering out brick-dust compounds which are highly potent but poor drug-like[57].

Prediction of Bioactivity

The prediction of bioactivity in silico has progressed from a trivial regression to MTL[58], where one model could predict the activity of a compound for thousands of different assays simultaneously. The accuracy of values and binding constants predictions made with the ingenious employment of transformer models to "read" SMILES strings that were designed for language[59]. Scientists are now screening in silico compounds that show high selectivity and potency[60].

Prediction of Drug Toxicity

Safety is the foremost reason that leads to drug failure. This is done by predicting ADMET (Absorption, Distribution, Metabolism, Excretion, and Toxicity) profiles much earlier in the process[61]. Additional deep learning architectures like CNNs have also been applied on cell painting images to identify subtle toxicological signatures[62]. Additionally, models may now target organ-specific toxicity , i.e. hepatotoxicity and hERG[63].

AI in Advanced Pharmaceutical Product Development

Artificial intelligence (AI) has emerged as a transformative force in pharmaceutical product development, significantly improving the accuracy, speed, and cost-efficiency of preclinical research and lead optimization. By integrating machine learning (ML), deep learning (DL), and advanced data analytics, AI enables the rapid extraction of actionable insights from highly complex biological, chemical, and pharmacological datasets. This capability is particularly valuable in early-stage drug discovery, where attrition rates are traditionally high and experimental costs are substantial[64]. The process begins with a selected and identified biological target, which may be a protein, enzyme, or receptor implicated in a disease. Virtual screening is then performed with large small-molecule chemical libraries (e.g. Enamine, ZINC, ChEMBL, PubChem or in-house databases) with AI-learned physicochemical and binding models. These models also quickly determine the most likely compounds that will bind efficiently to the target so that first hits can be identified with very little screening of the compound in the laboratory. The speculated hits are subjected to physicochemical and binding tests, to ensure they are active experimentally, and this leads to experimentally verified hits.

Then, the workflow proceeds to the hit-to-lead phase where a hit optimization cycle is undertaken periodically. Artificial intelligence makes chemical modifications by analysing structure activity relationships (SAR), physicochemical properties, and multi-target binding behaviour of a target. These refined versions are known as modified hits and are continually refined and tested experimentally until they demonstrate enhanced potency, selectivity and drug-like behavior. As soon as the hits prove to be biologically active enough and have acceptable preliminary ADMET properties, they progress to become experimentally validated leads. These compounds are also optimized in the lead optimization step in which another iterative cycle is incorporated. In this case, AI advanced models are used to predict ADMET properties, multi-species binding, toxicity risks, and pharmacokinetic behaviour. The chemical structures are also changed to improve the efficacy, safety, and bioavailability as well as limiting drug side effects. The work of this step is altered leads that have a high balance of potency, safety, and developability. Given the pre-set criteria, once a lead meets these requirements, it can advance to clinical testing, and the process of preclinical development gives way to human testing.

Altogether, the diagram highlights how AI can help in data-driven decision-making, hasten the hit identification, and make the optimization process more efficient with feedback, as well as save considerable time, cost, and failure rates in the more sophisticated pharmaceutical product development.

Artificial intelligence (AI) promotes drug discovery and pharmaceutical development to a significant level by processing complex biological information to detect targets and predict drug interactions. Optimised experimental design and toxicity prediction is suitable as AI increases efficiency, lowers cost, and minimises animal testing. It also favors personalized medicine whereby it uses patient information to provide better treatment results. This review shows various applications of AI in drug discovery, dosage form design, process optimization, testing, and pharmacokinetics/pharmacodynamics, along with advantages and shortcomings, and the potential of AI to revolutionize the pharmaceutical research and patient care[65]. The considerable importance of the pharmaceutical industry to save people and the necessity to develop new methods continuously in order to meet the requirements of medical issues on a global scope. Pharmaceutical industry is known to have a number of challenges, such as shortage of skilled workforce, disruption of supply chains, and the effects of the COVID-19 pandemic on clinical trials. AI has come up as an influential resource that can be used to manage this issue by enhancing different parts of the pharmaceutical sector including:

i. Procuring an Expert Workforce The pharmaceutical sector needs to secure an experienced workforce and it is important to determine the skill gaps. The solution to this challenge can be done through AI, which will automate certain tasks and give insights to improve the productivity of the workforce.

ii. Supply Chain Disruption By introducing AI, the supply chain may be consolidated, and the forecasting process and decision-making tools are likely to be improved to provide more efficient supply chain management.
Clinical Trials AI can be used to restart or recreate clinical trials with minimum face to face interaction, solve data fragmentation and system disintegration, and to optimize trial design and patient recruitment[66].

AI Tools in Dosage Form Designs

AI is important in the current dosage form by enhancing the comprehension and forecasting of drug activity in the human body. The biological compartments, membranes, and physicochemical barriers affect the drug delivery, and drug permeation and distribution are the determinants of therapeutic efficacy.This hierarchical view is necessary in distinguishing between the primary disease movers and the secondaries, which leads to the characterization of more permanent and specific targets AI is able to overcome those issues by providing sophisticated analysis of multilayered and complex biological and physicochemical data regarding drug-membrane interactions, permeation processes and pharmacokinetics.. Through machine learning and systematic modelling approaches, AI enhances the accuracy of predictions related to drug distribution, disposition, and toxicity. AI-driven tools integrate chemical, genomic, and phenotypic databases to provide deeper insights into drug–biological interactions and support model-informed drug delivery design. By automating simulations, parameter optimization, and predictive refinement, AI reduces reliance on trial-and-error experimentation and allows critical quality attributes of dosage forms to be evaluated early in development, leading to more efficient, reliable, and rational drug delivery system design[67].

AI for Drug Delivery

The integration of artificial intelligence and big data has given rise to computational pharmaceutics, a data-driven approach that enhances drug delivery system design and optimization. AI and machine learning techniques analyze large, complex datasets to simulate drug formulation and delivery processes across multiple scales, from molecular interactions to whole-system behaviour. This enables accurate prediction of drug physicochemical properties, in vitro drug release, stability, pharmacokinetics, and in vivo drug distribution, as well as improved in vitro–in vivo correlation. Early detection of possible risks and performance problems enables proactive optimization of drug delivery systems, which reduces the need for expensive and time-consuming trial-and-error to a minimum due to AI. In general, AI-based computational pharmaceutics can shorten development cycles, reduce expenses, and enhance the effectiveness and efficiency of designing drug delivery[68]. Run Han et al. have shown that machine learning can be used to forecast the six-month stability of solid dispersions, which show potential formulation optimization. Hanlu Gao et al. used machine learning with a random forest algorithm to analyse solid dispersion dissolution behaviour and were able to identify spring and parachute dissolution profiles. Their model was high accuracy (85-95)

and sensitive (86) in terms of maintaining the supersaturation and also allowed prediction of drug releases over time by regression analysis[69].

AI for 3D-Printed Dosage Forms

Artificial intelligence has played a major role in the 3D-printed dosage form by facilitating customized medication and enhancing the performance of drug delivery. AI is able to streamline formulation design and printing parameters, using patient-specific factors to support customized drug therapies, by combining machine learning and computational modelling. With AI-driven simulations, it is possible to model quickly and optimize dosage strength, geometry and drug release profiles as well as predict and overcome manufacturing issues in order to achieve quality and reproducibility[70]. AI models, specifically artificial neural networks, have been applied to estimate key processing parameters, including nozzle temperature, printing speed, infill pattern and infill density in 3D-printed tablets fabricated by methods including fused-filament fabrication, binder jetting and laser sintering. Research by Obeid et al. established that ANN-based modelling was useful in predicting drug dissolution behaviour, where infill density and surface area/volume ratio were found to be the determining factors of increased drug release hence confirming the importance of AI in optimising 3D-printed pharmaceutical products [71].

AI for the Detection of Tablet Defects

The technology has upended the method of detecting defects in tablets by pharmaceutical companies through AI because it is the fastest, automated, and highly accurate way to check the quality of a purchased item. The AI systems can recognize defects including cracks, chips, discoloration, and variations in shape and size with high precision and recall using computer vision and deep learning algorithms that study images of tablets to identify defects. Deep learning models when paired with other methods such as X-ray computed tomography can offer a detailed analysis of the internal tablet structures which otherwise would take time to perform by solely using conventional methods. The results of the studies by Ma et al. proved that UNet models and various other neural network architectures are effective at detecting surface and internal defects based on image augmentation and image segmentation plans. These AI technologies save a lot of time of inspection, operation cost, and man power and reduce the human error.Overall, real-time AI-enabled defect detection enhances manufacturing efficiency, ensures consistent product quality, and prevents defective tablets from reaching patients[72].

Drug discovery has traditionally depended on chance discoveries, but the adoption of AI is transforming this process by making it more predictive, efficient, and cost-effective. AI significantly reduces uncertainty, increases the likelihood of identifying viable drug candidates, and has been projected to boost pharmaceutical industry return on investment by over 45% with sustained investment[73]. Drug development involves target identification, candidate discovery, and lead optimization before progressing to clinical trials and regulatory approval. This process is lengthy, costly, and high-risk, typically taking 10–17 years and costing between $100 million and $2 billion, with only about 5% of drug candidates that enter phase I trials ultimately reaching the market [74].

Alongside traditional approaches, computer-aided drug design (CADD) has emerged as an effective strategy to improve drug discovery by using molecular modelling to evaluate drug–target interactions, activity, toxicity, and bioavailability[75]. Virtual screening–based CADD has contributed to the discovery of several important drugs, including captopril, saquinavir, ritonavir, indinavir, and boceprevir. In recent years, the integration of artificial intelligence into CADD has produced more accurate predictive models, giving rise to AI-driven drug design (AIDD), which is increasingly recognized as a key tool for accelerating and improving the efficiency, cost-effectiveness, and success rate of drug research and development[76].

AI in Clinical Trial Design

Clinical trials are essential for evaluating the safety and efficacy of medical interventions, but their rapid expansion and growing complexity have exposed major limitations in the traditional trial paradigm. Despite over 400,000 registered clinical studies globally and annual pharmaceutical R&D investments of around $200 billion, drug approval success rates remain below 12%, with development costs reaching approximately $2.6 billion per approved

drug[77]The cost of modern clinical trials is rising, the duration of clinical trials is growing, and inefficiency in operations is becoming the common place, especially in Phase III clinical trials which require 67 years to complete. The most important problem is patient recruitment as it results in massive delays and cost increases, and manual data collection produces high error rates and data cleaning takes time. Moreover, escalating regulatory demands and the lack of patient diversity contribute further to hindering the effectiveness of the trial and the generalisability of the results, which also means that new more innovative and efficient methods of conducting trials are urgently required [78].

This flow chart indicates the way AI is used to project clinical trial protocol optimisation and site selection by using data analysis. History The AI-based optimisation of protocols uses trial history, protocol history, and regulatory submissions which are optimised using machine learning and natural language processing to predict feasibility, suggests eligibility criteria, and adaptive trial designs. At the same time, AI site selection is the analysis of investigator measures, demographics, healthcare facilities, and geospatial data ranking trial locations, enrolment prediction, and resources optimization.. Comprehensively, the framework shows how AI enhances the planning of the trial, efficiency, and decision-making as well as minimizing operational risks[79]. Figure shows how AI improves clinical trial planning by optimizing both trial protocols and site selection. AI analyzes historical trial data, previous protocols, regulatory documents, and literature to design feasible protocols with better eligibility criteria. At the same time, AI evaluates investigator performance, patient demographics, healthcare infrastructure, and geographic data to rank trial sites and predict enrolment rates. Overall, AI enables faster, data-driven decisions that improve trial efficiency, recruitment, and resource utilization.

AI-driven protocol optimisation and site selection are transforming clinical trial design by shifting from intuition-based decisions to data-driven planning. Machine learning and natural language processing analyze large volumes of historical trial data, protocols, regulatory submissions, and literature to optimize study parameters, improve inclusion–exclusion criteria, and predict protocol feasibility with higher accuracy than traditional methods. Deep learning models effectively forecast enrolment success by accounting for multiple factors such as population characteristics, geography, and competition[80].AI also enables adaptive and dynamic protocol optimisation, supporting efficient master protocols such as platform and basket trials. During site selection, AI combines demographic, clinical, and geospatial data to prioritize the preferred sites, determine the potential success of recruitment, and efficiently utilize resources. Although these benefits exist, there are some issues caused by multifaceted and heterogeneous medical data, which requires thorough validation and constant monitoring to guarantee clinical relevance and reliability [81].

AI is changing the process of recruiting patients in trials by facilitating easy identification of participants, enhancing diversity, and allowing remote interaction. The electronic health records are analyzed by NLP and machine learning algorithms that serve to match eligible patients, predict the likelihood of enrollments, and utilize recruitment strategies [82].AI can also be used to combat disparities in recruitment by recognizing underserved groups and educating open recruitment strategies. Computer vision and conversational AI are used to screen and consent people remotely, reducing geographical and logistical barriers. Nonetheless, the AI applications are not risk-free, and a stratified implementation model is necessary, such as low-risk cohort estimation, high-risk eligibility decisions that need strict clinical supervision, clinical relevance, and patient safety[83].

The figure represents an adaptive clinical trial model that involves machine learning that constantly updates decisions on the trial process using real-time data and AI analysis. This is initiated by adaptive trial design that means the study design, treatment groups, and patient allocation are not fixed. With trial going on, multiple candidate therapies are provided with interim results that are fed to an ML analysis layer that quickly analyses treatment performance and predicts results. Various machine learning models are valuable additions: reinforcement learning will be applied to optimize decision-making behavior, decision trees will be used to determine the most effective clinical paths, and the neural networks will predict the patient reaction. The results of these models are integrated with the help of ML, which offers an integrated, data-driven evaluation of the progress of trials. According

to this combined analysis, protocol updates are done on-the-fly with the capability to make adjustments like dosage adjustment, arm of treatment adjustment, and reallocation of patients. Altogether, the framework shows that machine learning can be applied to flexible, efficient, and evidence-based clinical trial management through its ability to learn continuously as the information is accumulated and refine trial-related decisions to enhance performance[84].

AI in Pharmaceutical Product Management

AI has emerged as an imperative vehicle of competence and dependability in drug supply chain management. AI-based models can be used in demand forecasting to forecast demand more precisely than conventional models, and minimize forecasting errors, inventory expenditure, and stockouts due to the use of complex and large amounts of data. The use of AI in inventory management offers benefits such as optimization of inventory dynamically, thus achieving maximum levels of stock, lower expiries, decrease in the number of emergency orders and increased workforce efficiency[85]. Detection of counterfeit drugs is another area dominated by AI since machine learning, image recognition, NLP and blockchain technologies are being used to enhance traceability and authentication thereby greatly improving counterfeit drug detection and preventionIn the quality control and assurance context, AI-based inspection and predictive analytics identify defects more accurately and decrease the failure count in batches, guarantee the adherence to regulations, and facilitate audits[86].

Finally, artificial intelligence-based logistics and route optimization systems make the delivery process more efficient by dynamically adjusting routes based on the updated information reducing the amount of delays, fuel, carbon emissions, cold-chain losses.. In general, AI changes PSCM, making it more accurate, cost-efficient, safer to patients, and more resilient to the pharmaceutical supply chain[87]. The AI has a major role in improving efficiency, transparency, and cost-effectiveness of pharmaceutical supply chains. Automation simplifies regular activities like monitoring of inventory, documentation, quality control, and maintenance of equipment reducing the manual workload, downtime and processing time and enabling human resources to concentrate on strategic activities[88].

The combination of AI and blockchain can provide pharmaceutical supply chains with more transparency and traceability, allowing tracking the movement of drugs, their storage, and authenticity in real-time. This enhances compliance with regulations and eliminates counterfeit drugs and boosts stakeholder confidence[89]. AI also spurred the significant cost savings ensured by the optimization of the resource use, minimization of waste, anticipation of the maintenance requirements, and the enhancement of the efficiency of the logistics. All in all, AI-assisted PSCM enhances the performance of operations, minimizes costs, guarantees product quality and patient safety, and develops more stable and robust pharmaceutical supply chains[90].

Challenges to Adopt AI in Pharmaceutical Industries

The movement of AI in pharmaceutical industry has a number of challenges in its practical implementation though it has benefits. The data privacy and data security is also a significant issue as AI systems operate on the basis of sensitive patient and proprietary information that should be secured against cyberattacks and follow stringent rules, including GDPRs and HIPAA. The implementation cost is also a major barrier to AI adoption and the reason to this is that AI needs costly infrastructure, skilled professionals, and employee training, most of the benefits of AI are realized in the long-term and that too with small to mid-sized companies. AI compliance is yet another challenge to implementation, as pharmaceutical regulations vary in various locations and there are no global standards that AI uses are accepted, which leads to the emergence of the risk of legal and operational problems. Also, AI, machine learning, and data science present a skill gap among the pharmaceutical workforce that minimizes the quantity of technologies used effectively. To handle these issues, effective cybersecurity infrastructure, robust data governance, regulatory cooperation, workforce education, and scalable and affordable AI technologies will be needed to achieve successful and ethical use of AI in the pharmaceutical supply chain management[91],[92].

Human factors play a critical role in the successful adoption of AI in healthcare. A major challenge is the lack of adequate training, as healthcare professionals require specialized education to understand AI systems and correctly

interpret their outputs. Without proper training and clear guidelines, AI implementation can lead to misinterpretation, inefficiencies, reduced trust, and even medical errors, a concern highlighted across clinical and pharmacy settings. Another key issue is increased workload, as AI systems often require additional tasks such as system setup, monitoring, and verification of AI-generated results. Instead of reducing workload, this can increase cognitive burden, especially in already understaffed healthcare environments, contributing to clinician burnout and safety risks. Finally, acceptance and trust remain significant barriers, as many clinicians are skeptical about the reliability and accuracy of AI recommendations. This mistrust leads to frequent double-checking of AI outputs, limiting efficiency gains and slowing adoption. Together, insufficient training, increased workload, and lack of trust hinder the effective integration of AI into healthcare practice.

Future Prospects

The concept of Artificial Intelligence (AI) is bound to have a revolutionary impact on pharmaceutical supply chain management (PSCM) as a wide range of digital technologies keep evolving and becoming more available. The introduction of AI to PSCM has vast possibilities in the future to enhance the efficiency of operations, accuracy, and responsiveness in all parts of the supply chain. Among the most promising is the AI-driven personalization, which allows the supply chains to be adjusted to the needs of the particular patients population, as well as geographic areas. Using big and diverse data sets, AI will be able to discover demand patterns and consumption tendencies, which will provide the necessary quantities of medicines delivered to the appropriate locations at the appropriate moment, and thus reduce the level of shortages, avoid overstocking, and enhance patient outcomes. The third major area of development is improved predictive analytics, which enables real-time and data-driven decisions and proactive risk management. Artificial intelligence (AI) predictive models have the ability to foresee any supply chain disruptions like changes in demand, raw material shortages, or logistical delays and propose corrective measures in time. This enables pharmaceutical organisations to pre-optimize production, inventory and distribution strategies to limit stock-outs of valuable medicines and enhance supply chain resilience.

AI and the Internet of Things (IoT) combination is another opportunity that is significant to PSCM. With the help of IoT-enabled devices and sensors of tracking, it is possible to implement continuous monitoring of pharmaceutical products in storage and transport with the help of AI analytics. It is particularly important when it comes to drugs with temperature sensitivity, which may be vaccines, biologics, and even insulin, in that case, real-time monitoring can be applied to stabilize the product and reduce wastage and maximize its therapeutic performance. The allocation of COVID-19 vaccines around the world proved the value of AI-based IoT-supported cold-chain logistics to handle considerable amounts of real-time data and provide its safe delivery. Lastly, the success of AI in PSCM in the long term will be determined by global standardization and regulatory alignment. The creation of global standards of AI applications would facilitate the integration of artificial intelligence across borders, streamline regulatory performance and promote the exchange of information and cooperation between stakeholders. The use of standardized AI frameworks would also reinforce the war against pharmaceutical products tracking and authentication, and enhancing transparency of the supply chain and counterfeit drugs. In general, new innovation, cooperation, and standardization will be needed to achieve the full potential of AI in the formation of the future of the pharmaceutical supply chain management.

CONCLUSION

This review underscores a swiftly growing role of artificial intelligence (AI) throughout the whole of the pharmaceutical value chain, including early drug discovery and advanced product development, and in clinical trial design and pharmaceutical supply chain management. As the analysis shows, AI-guided solutions can be highly effective, efficient, and accurate in decision-making since they can convert traditionally empirical and trial-and-error processes to predictive and data-driven processes. AI has been utilized in drug discovery and product development by the rapid identification of targets, optimization of hits to leads, formulation design, and quality control, thus saving time, cost and failure rates of product development. AI can be used in clinical trials to optimize the protocol,

choose the site, plan adaptive trials, and recruit patients in a better way, which overcomes long-term problems associated with rising costs, time loss, and patient heterogeneity. Moreover, pharmaceutical products management and supply chains AIs improve predictive demand, inventory optimization, identifying counterfeits, optimization of logistics, and overall resilience. In spite of these benefits, the review also highlights the essential challenges that need to be handled in order to achieve successful and ethical adoption of AI, such as data privacy and security issues, high cost of implementation, regulatory complexity, skill deficit, and human factors, including workload, acceptance, and trust. The barriers will be overcome by very strong data governance frameworks, workforce education, interdisciplinary teamwork, harmonization of regulations, and scalable AI solutions. Altogether, AI is a revolutionary power that can change the pharmaceutical research, development, and healthcare delivery. On-going innovation, validation and responsible use of AI will be important to actualize the full potential of AI in enhancing efficiency, patient outcomes and sustainability of healthcare globally.

ABSTRACT

For the quantitative determination of stavudine in bulk and pharmaceutical dosage forms, the current study describes the creation and validation of a stability-indicating RP-HPLC method. Using a mobile phase made up of ACN:Triethyalamin buffer at a flow rate of 1mL/min, chromatographic separation was performed on a C18(5micro meters) column with UV detection at 263 nm. The retention time of the method was around 2.738min, and it produced peaks that were sharp and symmetrical.ICH Q2(R2) standards were used for validation. With a correlation coefficient (R2) of 0.999, the approach exhibited outstanding linearity across the concentration range of 5–50ppm. The mean recovery was found to be 98–102% demonstrating good accuracy, while intra- and inter-day precision studies showed %RSD values less than 2.0, confirming method reproducibility. The LOD and LOQ were found to be 0.5 ppm and 1.5 ppm which indicates acceptable sensitivity.The stability-indicating ability of the approach was demonstrated by forced degradation studies conducted under acidic, basic, oxidative, photolytic, and thermal conditions, which confirmed that stavudine degrades and that the procedure successfully separated the drug from its degradation products.The approach that has been created is straightforward, precise, and reliable. It may be utilized to carry out routine quality control, assay identification, and stability testing of stavudine in both bulk drug and pharmaceutical dosage forms, adhering to regulatory Standards

Keywords: Stavudine, RP-HPLC, validation, stability-indicating method, pharmaceutical dosage forms.

INTRODUCTION

To guarantee the efficacy, safety, and quality of therapeutic ingredients and formulations, the pharmaceutical industry relies heavily on the development and validation of analytical methods. Results from regular analysis, stability testing, and regulatory compliance can be trusted when a method has been validated. The capacity of high-performance liquid chromatography (HPLC) to separate active pharmaceutical ingredients (APIs) from contaminants and degradation products, as well as its high resolution and reproducibility, make it one of the most effective and commonly used methods available. The synthetic thymidine analogue stavudine (2′,3′-didehydro-3′-deoxythymidine, ddT) is a member of the nucleoside reverse transcriptase inhibitor (NRTI) class. It is frequently utilized in highly active antiretroviral therapy (HAART) to treat HIV infection. Viral reproduction is prevented by the drug's intracellular phosphorylation to its active triphosphate form, which inhibits viral reverse transcriptase and terminates DNA chains. Because of its therapeutic significance, Stavudine's precise and trustworthy quantification in pharmaceutical dosage form and bulk medication is crucial for quality control. Stavudine's chemical formula is $C_{10}H_{12}N_2O_4$, and its molecular weight is 224.21 g/mol. It is a white to off-white crystalline powder. It is readily soluble in water, relatively stable when stored under regulated settings, and prone to degradation when exposed to harsh environmental factors such heat, light, oxidation, and hydrolysis that is either acidic or alkaline. This emphasizes how crucial it is to create stability-indicating analytical techniques that can identify both the medication and its breakdown products. While certain analytical techniques, such as spectrophotometry and HPLC, have been documented for Stavudine quantification, many of them are either ineffective at determining stability or require laborious sample preparation procedures. Therefore, it is very desired to have a straightforward, quick, and affordable RP-HPLC procedure that may be used regularly in quality control labs. The necessity of validating analytical procedures in terms of criteria like specificity, linearity, accuracy, precision, robustness, limit of detection (LOD), and limit of quantification (LOQ) is also emphasized by regulatory guidelines like ICH Q2(R1).The present research work was designed with the following objectives:

To develop a simple, precise, and reproducible RP-HPLC method for the estimation of Stavudine in bulk and pharmaceutical dosage form. The proposed method aims to overcome the limitations of previously reported techniques and provide a reliable tool for routine quality control and stability testing of Stavudine.

MATERIALS AND METHODS

Chemicals and Reagents : Stavudine reference standard (≥99% purity) . Commercial tablet dosage forms containing Stavudine (40 mg). HPLC grade acetonitrile, methanol, water (Merck, India). Triethylamine orthophosphoric acid (analytical grade) Instrumentation : HPLC system: Shimadzu LC-20Ad with UV detector. Column: C18 (150 × 4.6 mm, 5 μm agilent). Software: LC-Solution Chromatographic Conditions : Mobile Phase: Triethylamine buffer (pH 4.0):Acetonitrile (75:35, v/v). Flow Rate: 1.0 mL/min. Detection Wavelength: 263 nm. Injection Volume: 20 μL. Run Time: 10 min

METHODOLOGY

Detection λ: Start at 265–270 nm (stavudine UV λmax typically ~263 nm). Confirm by scanning 200–400 nm; lock to max with adequate baseline noise.
Mobile phase candidates:

- A: Water (0.1% OPA) or Triethylamine buffer (7mM) adjusted to pH 4.
- B: Acetonitrile (primary organic); methanol as alternative.
- Programs: Start with gradient 75:25 (A:B), then evaluate (2.730-2.850)
- Flow: 1.0 mL/min;
- Injection volume: 20 μL depending on system.

- Target: Sharp, symmetric stavudine peak (tailing ≤1.5), run time ≤10 min, resolution ≥2.0 from
- nearest degradant / excipient.

Preparation of Standard Solution
To create a stock solution (100 μg/mL), 10 mg of stavudine that had been precisely weighed was dissolved in mobile phase and diluted. Additional dilutions were performed to achieve concentrations between 5 and 50 μg/mL.

Preparation of Sample Solution
Twenty precisely weighed, powdered tablets containing 10 mg of stavudine were put into a volumetric flask. The material was diluted to 100 μg/mL after being dissolved in mobile phase, sonicated, filtered, and further diluted as needed.

RESULTS AND DISCUSSION

Stavudine's UV spectra revealed a clear absorption maximum at 263 nm (Figure 1), which was chosen as the RP-HPLC method's detection wavelength since it offered the highest sensitivity and reproducibility.

Method Optimization: Different solvent systems were tested, and the optimized conditions gave sharp, symmetric peaks with acceptable retention time (~2.780 min) and resolution. System Suitability; Retention time: 2.790 min Theoretical plates: 3798 Tailing factor: 1.337 (within limit) Mobile Phase ratio buffer: (75:25) Injection volume:20 Run time : 10 min

Linearity: Excellent linearity was demonstrated by the technique across the 5–50 μg/mL concentration range. It was discovered that the regression equation
PRECISION: The precision of the devised approach was evaluated through repeated measurements of the same sample under specified conditions. The technique communicates the degree of similarity between individual test results when it is applied frequently. According to ICH Q2(R1) criteria, an accuracy evaluation was carried out in three stages

Accuracy: Recovery studies utilizing the conventional addition method were used to assess the suggested method's accuracy. The pre-analyzed samples were spiked with known concentrations of pure Stavudine at three distinct levels: 80%, 100%, and 120% of the desired concentration. The percentage recovery was computed after each level was examined three times. The correctness of the procedure was confirmed when the mean recovery percentage for stavudine was determined to be between 98 and 102%.

LOD & LOQ: Calculating the limit of detection (LOD) and the limit of quantitation (LOQ) in accordance with ICH Q2 (R1) criteria allowed for the determination of the method's sensitivity. The following formulas were used to determine LOD and LOQ based on the response's standard deviation (σ) and the calibration curve's slope (S): The LOD and LOQ values for Stavudine were found to be 1μg/mL and 2 μg/mL, respectively, which indicates the method is sufficiently sensitive for quantitative analysis.

Validation Results :
With a tailing factor of 1.337, theoretical plates : 3798, and retention time 2,790 min, system suitability tests revealed satisfactory performance. Since neither the blank nor the excipients caused any disturbance, the procedure was specific. Using regression equation y = 27506x + 12885 and correlation coefficient R2 = 0.9994, linearity was shown over the 5–50 μg/mL range. Recovery studies verified accuracy (98.7-100.48%), satisfying acceptance standards (98–102%). The percentage RSD for both intra- and inter-day analysis was less than 2%, according to precision studies. Good sensitivity was indicated by the LOD and LOQ, which were determined to be 1 ppm and 2 ppm μ, respectively. Results were unaffected by slight changes in chromatographic settings, according to robustness studies.

Degradation peaks were clearly separated from the drug peak in forced degradation trials, demonstrating the method's stability**.**

Stability Studies ; Under acidic and basic hydrolysis, stavudine was found to deteriorate considerably, exhibiting new peaks with a smaller parent drug peak area. with oxidative conditions, there was moderate degradation; with thermal and photolytic exposure, there was little degradation. The drug peak was clearly separated from all degradation peaks, proving the new method's stability-indicating capacity and specificity. The absence of co-eluting breakdown products in the medication peak was verified by peak purity analysis**.**

CONCLUSION

The quantitative determination of stavudine in pharmaceutical dosage forms and bulk drugs was accomplished through the successful development and validation of a straightforward, accurate, and reliable RP-HPLC method. The technique demonstrated outstanding specificity, linearity, accuracy, precision, sensitivity, and robustness, meeting all validation requirements as per ICH Q2(R1). Because the degradation peaks were clearly separated from the drug peak without any interference, forced degradation studies validated the method's capacity to indicate stability. Its sensitivity is demonstrated by the low LOD and LOQ values, and its precision and recovery outcomes guarantee dependability for everyday use. Overall, the suggested approach has the benefits of simplicity, reproducibility, and cost-effectiveness over previously published methods, making it appropriate for Stavudine quality control, assay determination, and stability testing.

ABSTRACT

A simple, rapid, precise, sensitive and reproducible Ultra performance liquid chromatography (UPLC) method has been developed for the quantitative analysis of Xanomeline and Trospium Chloride in pharmaceutical dosage form. Chromatographic separation of Xanomeline and Trospium Chloride was achieved on Waters Acquity UPLC system, by using Agilent Eclipse Plus C18 (50mmx 4.6mm, 2.1µm) column and the mobile phase containing Acetonitrile & KH2PO4 pH-2.5/OPA in the ratio of 40:60% v/v. The flow rate was 0.5ml/min; detection was carried out by absorption at 228nm using a photodiode array detector at ambient temperature. The number of theoretical plates and tailing factor for Xanomeline and Trospium Chloride were NLT 2000 and should not more than 2 respectively. The relative standard deviation of peak areas from all measurements consistently falling below 2.0 highlights an outstanding degree of precision attained by the proposed method, which has undergone meticulous validation in alignment with ICH guidelines. The method was found to be simple, economical, suitable, precise, accurate & robust method for quantitative analysis of Xanomeline and Trospium Chloride and study of its stability.

Keywords: UPLC, Xanomeline, Trospium Chloride, Method Development, Validation, ICH Guidelines, Stability-Indicating Assay.

INTRODUCTION

Xanomeline: A Central Muscarinic Agonist

Xanomeline is a muscarinic acetylcholine receptor agonist that shows selective activity towards the M1 and M4 receptor subtypes located in the central nervous system, particularly within the limbic and cortical regions that regulate cognition, memory, and behavior. These receptors are believed to play a crucial role in modulating neurotransmission and synaptic plasticity, thereby influencing cognitive and affective processes. Initially, Xanomeline was developed for the treatment of Alzheimer's disease, where it showed promise in improving cognitive function. However, its clinical application was discontinued due to pronounced peripheral cholinergic side effects, including diarrhea, sweating, nausea, and hypersalivation, which limited its tolerability. In recent years, Xanomeline has been repurposed for schizophrenia therapy owing to its ability to modulate muscarinic signaling in the brain. Clinical trials have demonstrated improvements in both positive symptoms (hallucinations, delusions) and negative symptoms (social withdrawal, cognitive deficits) of schizophrenia. From a pharmacokinetic standpoint, Xanomeline reaches its maximum plasma concentration (Tmax) within approximately 2 hours of oral administration and achieves steady-state levels within 3–5 days, making it suitable for regular dosing in chronic therapy.

Trospium Chloride: A Peripheral Antimuscarinic Agent

Trospium chloride is a quaternary ammonium compound with potent antimuscarinic activity. Unlike Xanomeline, which acts centrally, Trospium exerts its effects peripherally by blocking muscarinic receptors M1–M3, while exhibiting negligible affinity for nicotinic receptors. This selective antagonism prevents acetylcholine from binding to smooth muscle muscarinic receptors, thereby producing relaxation of the bladder musculature. Clinically, Trospium is widely prescribed for overactive bladder syndrome, effectively reducing urinary urgency, frequency, and incontinence. However, the drug has low and variable oral bioavailability (4–16.1%), primarily due to its hydrophilic nature and instability at alkaline pH levels. After oral administration, peak plasma concentrations (Cmax) are typically achieved within 5–6 hours.

The therapeutic utility of Trospium is attributed to its parasympatholytic action, though it can cause adverse effects such as urinary retention, bladder pain, and lower back discomfort. Importantly, Trospium's inability to cross the blood–brain barrier makes it ideal for counteracting the peripheral cholinergic effects of centrally acting agents such as Xanomeline, without interfering with their central therapeutic activity.

Importance of Combination Therapy

The co-administration of Xanomeline and Trospium chloride has been identified as a novel therapeutic strategy, especially for the management of schizophrenia.

- Xanomeline's Role: Improves cognitive and behavioral outcomes through central muscarinic receptor agonism.
- Trospium's Role: Prevents and minimizes peripheral side effects (e.g., diarrhea, sweating, hypersalivation) induced by Xanomeline, without affecting its central action.

This synergistic combination improves efficacy, safety, and tolerability, ultimately leading to better patient adherence and quality of life. Fixed-dose combinations such as this represent a growing trend in clinical pharmacotherapy, as they simplify treatment regimens while optimizing therapeutic outcomes.

Need for Simultaneous Estimation

With the increasing clinical importance of the Xanomeline–Trospium Chloride combination, it becomes essential to establish validated analytical methods for their simultaneous estimation in both bulk and dosage forms.

- Current Gap: While analytical methods exist for the individual quantification of Xanomeline and Trospium, very few studies address their concurrent determination.
- Regulatory Need: A stability-indicating UPLC method is critical for ensuring dosage uniformity, quality control, and detection of degradation products formed under stress conditions (acidic, alkaline, oxidative, thermal, and photolytic).

- Industrial Relevance: Such validated methods are indispensable for routine pharmaceutical analysis and play a vital role in meeting ICH and regulatory guidelines for drug product approval.

Advantages of UPLC over HPLC

Ultra-Performance Liquid Chromatography (UPLC) has revolutionized analytical chemistry by overcoming the limitations of conventional High-Performance Liquid Chromatography (HPLC).

- Higher Resolution & Sensitivity: UPLC employs sub-2 μm particle size columns, which increase plate efficiency and resolution.
- Faster Analysis: Operates at pressures up to 1000–1300 bar, allowing rapid separations without compromising accuracy.
- Eco-friendly & Economical: Reduces solvent consumption and analysis time, lowering operational costs and environmental impact.
- Improved Robustness: Provides better reproducibility and precise detection of impurities, degradation products, and low-concentration analytes.

These advantages make UPLC particularly suited for stability-indicating assays of complex pharmaceutical formulations like the Xanomeline–Trospium combination.

Rationale of the Study

Considering the therapeutic promise of the Xanomeline–Trospium Chloride combination and the lack of robust analytical methods for their simultaneous quantification, this study was designed to develop and validate a novel, precise, accurate, and stability-indicating UPLC method. The method aims to ensure regulatory compliance, product quality, and clinical safety, while providing a reliable analytical tool for routine pharmaceutical testing and stability assessment.

MATERIALS AND METHODS

Chemicals, Reagents and Apparatus

The analytical work was carried out using a range of well-calibrated instruments and high-purity reagents. The UPLC system employed was an ACQUITY model (Waters) integrated with Empower Software v2.0, supported by an isocratic pump (Waters). Ancillary equipment included a pH meter (pH 700, Eutech), an analytical weighing balance (BSA224S-CW, Sartorius), Class-A glassware (Borosil), and an ultrasonicator (UCA 701, Unichrome). The chromatographic method utilized HPLC-grade acetonitrile (Merck), analytical reagent (AR)-grade potassium dihydrogen phosphate (KH_2PO_4, Merck), AR-grade ortho-phosphoric acid (Merck), and HPLC-grade water prepared in-house using a Milli-Q purification system.

Determination of Working Wavelength (λmax):

In the simultaneous estimation of two drugs, the isobestic wavelength is of paramount importance. This distinctive wavelength signifies the point at which the molar absorptivity remains equivalent for two interconvertible substances. By harnessing this unique property, researchers can achieve precise simultaneous quantification of the two drugs, enabling accurate determination of their concentrations without interference from one another. This analytical approach proves exceptionally valuable in the field of analytical chemistry, particularly within pharmaceutical analysis and quality control, where ensuring the integrity and reliability of drug measurements is crucial. The wavelength of maximum absorption of the solution of the drugs in mixture of Acetonitrile and KH2PO4 pH-2.5/OPA (40:60) were scanned using PDA Detector within the wavelength region of 200–400 nm against Acetonitrile and KH2PO4 pH-2.5/OPA (40:60) as blank. The absorption curve shows isobestic point at 228nm. Thus 228 nm was selected as detector wavelength for the UPLC chromatographic method.

Chromatographic Condition

In the endeavor to optimize chromatographic conditions, a series of trials were meticulously conducted to evaluate a range of parameters. The trial that demonstrated the highest effectiveness was subsequently selected, predicated on its capacity to achieve optimal separation, enhanced sensitivity, and superior resolution for the target analytes. This systematic and disciplined approach ensures that the chosen method is not only robust but also fulfills the specific experimental objectives with precision and reliability.

Preparation of standard solution:

Accurately weigh and transfer 50mg of Xanomeline, 20mg of Trospium Chloride working standard into a 10ml volumetric flask, add 7ml of diluent and sonication are used to thoroughly dissolve the sample and bring the volume to the desired level. (Stock solution)

Further pipette 1 ml of the above stock solution into a 10 ml volumetric flask dilute to the mark with diluent. (500ppm of Xanomeline and 200ppm of Trospium Chloride)

Sample Solution Preparation:

Accurately weigh and transfer 22mg of Xanomeline and Trospium Chloride sample into a 10mL volumetric flask add Diluent and sonicate it up to 30 mins to dissolve it completely and make volume up to the mark with the same solvent. Then it is filtered through 0.22 micron Injection filter. (500ppm of Xanomeline, 200ppm of Trospium Chloride)

Trails in optimization of chromatographic condition

The Xanomeline peak was observed at 0.765 min with peak area 2448271, tailing factor 0.86, Trospium Chloride peak was observed at 1.326 min, with peak area 493652, tailing factor 1.15 and resolution 4.63. This trial was optimized.

General preparations:

Preparation of KH2PO4 Buffer Solution:

1.36g of KH2PO4 is dissolved in 1 litre of HPLC water, adjust its pH-2.5/OPA. Filter through 0.22µ membrane filter paper.

Preparation of Mobile Phase: Mobile phase was prepared by mixing Acetonitrile and KH2PO4 pH-2.5/OPA taken in the ratio 40:60.

Employing a 0.22µ membrane filter is crucial for the elimination of impurities that might compromise the final chromatogram. This filtration step guarantees that any potential contaminants are removed, resulting in more precise and trustworthy analytical outcomes.

Chromatographic condition:

Use suitable Ultra Performance Liquid Chromatographic equipped with PDA detector.
Column : Agilent Eclipse Plus C18 (50x 4.6mm, 2.1µm)
Mobile phase ratio : Acetonitrile and KH2PO4 pH-2.5/OPA (40:60)
Detection wavelength : 228 nm
Flow rate : 0.5ml/min
Injection volume : 5µl
Run time : 3.00min

Preparation of Diluent: Acetonitrile and Methanol (50+50) used as a diluent.

Procedure:

Inject 5 µL of the standard, sample into the chromatographic system and measure the areas for Xanomeline, Trospium Chloride peaks and calculate the %Assay by using the formulae.

SYSTEM SUITABILITY

Tailing factor for the peaks due to Xanomeline, Trospium Chloride in Standard solution should not be more than 2.0
Theoretical plates for the Xanomeline, Trospium Chloride peaks in Standard solution should not be less than 2000.
Resolution for the Trospium Chloride and Xanomeline peaks in standard solution should not be less than 2.

Formula for Assay: %Assay=ASAT×WTWS×DTDS×P×LC1×100

Where: AT = average area counts of test preparation.
AS = average area counts of standard preparation.
WS = Standard Weight mg.
DS = Dilution of working standard in ml.
DT = Dilution of test (sample) in ml.
WT = Weight of test (sample) taken in mg.
P = Percentage purity of working standard
LC = Label Claim mg/ml.

Method Validation

The developed UPLC method for the simultaneous estimation of Xanomeline and Trospium Chloride was validated as per ICH Q2(R1) guidelines for the following parameters:

System Suitability

System suitability was evaluated by injecting six replicates of the standard solution. Parameters assessed included retention time, theoretical plates, resolution, and tailing factor. Both drugs showed acceptable system suitability with theoretical plates >2000, resolution >2.0, and tailing factors <1.5, indicating good chromatographic efficiency.

Linearity

Linearity was assessed over the concentration ranges of 5–25 μg/mL for Xanomeline and 2.5–12.5 μg/mL for Trospium Chloride. Calibration curves were constructed by plotting peak area versus concentration, and linear regression analysis demonstrated correlation coefficients ($R^2 > 0.999$) for both drugs, confirming excellent linearity.

Accuracy (Recovery Studies)

Accuracy was determined using the standard addition method at three concentration levels (50%, 100%, and 150% of target concentration). The mean percentage recoveries for both drugs were found to be within 98–102%, indicating the method's accuracy.

Precision

- Intra-day precision (repeatability): Evaluated by analyzing six replicates of standard solutions within a single day.
- Inter-day precision (intermediate precision): Assessed over three consecutive days. For both analytes, the %RSD values were less than 2%, confirming good method precision.

Limit of Detection (LOD) and Limit of Quantification (LOQ)

LOD and LOQ were determined based on the standard deviation of the response and slope of the calibration curve using the formulae:

- LOD = 3.3 × (σ/S)
- LOQ = 10 × (σ/S)

where σ = standard deviation and S = calibration curve.slope
The LOD and LOQ were found to be in the range of 0.05–0.1 μg/mL and 0.15–0.3 μg/mL, respectively, for both drugs, demonstrating the sensitivity of the method.

Robustness

Robustness was evaluated by making deliberate variations in method parameters such as flow rate (±0.1 mL/min), mobile phase composition (±2%), and column temperature (±2 °C). The results showed no significant changes in system suitability parameters, indicating the robustness of the developed method.

Overall, the validation results confirmed that the proposed UPLC method is accurate, precise, specific, linear, robust, and sensitive for the simultaneous estimation of Xanomeline and Trospium Chloride in bulk and pharmaceutical dosage forms.

Forced Degradation Studies

To establish the stability-indicating nature of the developed UPLC method, forced degradation studies were performed in accordance with ICH guidelines. Xanomeline and Trospium Chloride were subjected to a variety of stress conditions, and the degraded samples were analyzed to assess specificity and the ability of the method to separate active drugs from their degradation products.

Acidic Degradation

The drug mixture was treated with 1 N HCl and kept at room temperature for 2 hours. The solution was neutralized and analyzed. Both drugs showed partial degradation with distinct additional peaks, indicating susceptibility to acidic hydrolysis.

Alkaline Degradation

For alkaline stress, the drugs were exposed to 1 N NaOH at room temperature for 2 hours, followed by neutralization. Considerable degradation was observed, with new peaks well resolved from the parent compounds, confirming alkaline sensitivity.

Thermal Degradation

The powdered drug sample was subjected to dry heat at 60 °C for 6 hours. The chromatograms revealed slight degradation, suggesting that both drugs are relatively stable under thermal stress.

Peroxide degradation:

Accurately weigh and transfer 22mg of the Xanomeline and Trospium Chloride sample into a 10 ml vacuum flask, 1 ml of 30 percent w/v hydrogen peroxide was added to the After adjusting the volume to the final mark with diluent in a volumetric flask, the flask was placed at 60 °C and held for a period of 20 minutes.After that, the vacuum flask was left at room temperature for 15 minutes. Filter the solution using 0.22 micron syringe filters and transfer to bottles.

Reduction degradation:

The Xanomeline and Trospium Chloride sample (22 mg) was accurately weighed and placed in a 10 mL vacuum flask. After the addition of 1 mL of 10% sodium bisulphite, the solution volume was adjusted with diluent. The flask was heated at 60 °C for 20 minutes and then allowed to equilibrate at room temperature for 15 minutes.Filter the solution using 0.22 micron syringe filters and transfer to bottles.

Photolytic degradation:

Xanomeline and Trospium Chloride sample was placed in Photo stability chamber for 3 hours. Following dilution with the suitable diluent, the sample was introduced into the UPLC system for analytical evaluation.

Hydrolysis degradation:

Accurately weigh and transfer 22mg of the Xanomeline and Trospium Chloride sample into a 10 ml vacuum flask, 1ml of HPLC grade water was added to a flask and thesolution volume was made up to the specified level with diluent.The vacuum flask was then maintained at 60°C for 20 mins. After that, the vacuum flask was left at room temperature for 15 minutes. Filter the solution using 0.22 micron syringe filters and transfer to bottles.

Acceptance Criteria: Purity angle is always less than when compared to purity threshold for all degradation conditions.

Across all stress conditions, the method successfully separated degradation products from the parent drugs, with well-resolved peaks and no interference at the retention times of Xanomeline and Trospium Chloride. This demonstrates the stability-indicating capability of the developed UPLC method.

RESULTS AND DISCUSSION

UPLC METHOD

Based on ICH guidelines, acceptable system performance is defined by a plate count exceeding 2000, a tailing factor not more than 2, and a resolution value greater than 2.All the system suitable parameters were passed and were within the limits.

ANALYTICAL METHOD VALIDATION (HPLC)

The analytical method underwent validation to assess its linearity range, accuracy, precision, and specificity. Method validation was carried out as per ICH guidelines.

Specificity

Discussion: Retention times of Xanomeline and Trospium Chloride were 0.765 min and 1.326 min respectivelyNo interference from blank or placebo was detected at the retention times of the drugs, demonstrating the specificity of the method.So this method was said to be specific.

PRECISION:

System Precision:

Discussion: From a single volumetric flask of working standard solution six injections were given and the obtained areas were mentioned above. Average area, standard deviation and % RSD were calculated for two drugs. % RSD obtained as 0.86% and 0.55% respectively for Xanomeline and Trospium Chloride. As the limit of Precision was less than "2" the system precision was passed in this method.

CONCLUSION

The UPLC method developed for the estimation of selected drugs showcases a remarkable array of attributes. It has been meticulously designed to be simple, rapid, accurate, precise, robust, and economically viable. The mobile phase and solvents employed in this procedure are not only straightforward to prepare but also exhibit commendable reliability, sensitivity, and efficiency, significantly reducing time requirements. The recoveries for the samples correlate exceptionally well with their respective label claims, underscoring the absence of interference from formulation excipients during the estimation. This robust finding solidifies the method's credibility for routine laboratory analyses of the selected drugs. Furthermore, the validation parameters integral to this UPLC method have consistently delivered satisfactory, accurate, and reproducible results, thereby enhancing its applicability for drug analysis free from the confounding influences of excipients. The findings lead to the conclusion that the stability-indicating assay method applying UPLC is not merely streamlined but also distinguished by its accuracy, precision, and specificity, showing no interference from placebo or degradation products. Consequently, it emerges as an exemplary choice for the routine analysis ofXanomelineandTrospium Chloride.

Table No.1: TRIAL-1 Chromatographic conditions

Column	Waters X-Bridge Phenyl (250x 4.6mm, 5μm)
Mobile phase ratio	Acetonitrile and 0.1% TFA (20:80)
Detection wavelength	200-400nm
Flow rate	1ml/min
Injection volume	10μl
Run time	10min
Observation:	Tailing is not within the limit

Table No.2: TRIAL-2 Chromatographic conditions

Column	Waters X-Bridge Phenyl (250x 4.6mm, 5µm)
Mobile phase ratio	Acetonitrile and 0.1% TFA (30:70)
Detection wavelength	228nm
Flow rate	1ml/min
Injection volume	10µl
Run time	6min
Observation	Broad peaks are observed

Table No.3: TRIAL-3 Chromatographic conditions

Column	Waters X-Bridge Phenyl (250x 4.6mm, 5µm)
Mobile phase ratio	Acetonitrile and KH2PO4 pH-2.5/OPA (10:90)
Detection wavelength	228nm
Flow rate	1ml/min
Injection volume	10µl
Run time	5min
Observation	Retention time is not within the limit

Table No.4: TRIAL-4 Chromatographic conditions

Column	Agilent Eclipse Plus C18 (50 x 4.6mm, 2.1µm)
Mobile phase ratio	Acetonitrile and KH2PO4 pH-2.5/OPA (20:80)
Detection wavelength	228nm
Flow rate	0.5ml/min
Injection volume	5µl
Run time	5min
Observation	Base line is not sufficient

Table No.5: TRIAL-5 Chromatographic conditions

Column	Agilent Eclipse Plus C18 (50 x 4.6mm, 2.1µm)
Mobile phase ratio	Acetonitrile and KH2PO4 pH-2.5/OPA (30:70)
Detection wavelength	228nm
Flow rate	0.5ml/min
Injection volume	5µl
Run time	4.0min
Observation	Response of the peaks are very high

Table No.6: TRIAL-6 Optimized Chromatographic conditions

Column	Agilent Eclipse Plus C18 (50 x 4.6mm, 2.1µm)
Mobile phase ratio	Acetonitrile and KH2PO4 pH-2.5/OPA (40:60)
Detection wavelength	228 nm
Flow rate	0.5ml/min
Injection volume	5µl
Run time	3.00min
Observation	This method is suitable for validation

Table 8: Optimized chromatographic conditions

PARAMETERS	OBSERVATION
Instrument used	Waters UPLC Equipped with PDA detector
Injection volume	5µl
Mobile Phase	Acetonitrile and KH2PO4 pH-2.5/OPA (40:60)
Column	Agilent Eclipse Plus C18 (50mm x 4.6mm, 2.1µm)
Detection Wave Length	228nm
Flow Rate	0.5mL/min
Runtime	3.0min
Temperature	Ambient(25◎ C)
Mode of separation	Isocratic mode

Table: 9: System suitability parameters for Xanomeline and Trospium Chloride

ABSTRACT

Clinical research organizations (CROs) specializing exclusively in clinical trials represent a significant portion of the global pharmaceutical R&D ecosystem, managing approximately 45-60% of outsourced activities within a market valued at $70-130 billion USD in 2025. This comprehensive review outlines the prevailing trends and economic dynamics of pure-play CROs, profiles the top 10 global leaders— their operational footprint in India—and their service portfolios, market capture strategies, growth trajectories and business models. A parallel analysis of global and Indian clinical trials markets indicates exponential expansion opportunities, propelled by decentralized trial architectures, artificial intelligence (AI)-enabled analytics, and the burgeoning demand for real-world evidence (RWE). Veridian Research emerges as a paradigm-shift through its proprietary integrated CRO-genomics platform, which uniquely fuses late-phase trial operations with next-generation sequencing (NGS), AI-driven bioinformatics, and multimodal omics—capabilities conspicuously absent among other CROs. This differentiation positions Veridian advantageously amid surging investigator-initiated studies (IIS) and discovery cohorts in pivotal trials, where translational research is indispensable for biomarker identification and adaptive protocols. Projections indicate Veridian's potential growth rate, outstripping industry averages, by addressing systemic fragmentation in post-approval pharmacovigilance and precision medicine pipelines.

Clinicians are aware that therapies demonstrating success in Phase 3 clinical trials frequently encounter challenges post-approval. Rare adverse events emerge, patient subgroups underperform, and actionable biomarkers remain unidentified. These issues are amplified by fragmented ecosystems—disconnected

clinical research organizations, standalone genomics providers, and siloed real-world evidence (RWE) platforms—resulting in inefficient data exchange, delays, and escalating costs that ultimately slow patient access to essential therapies. While early drug development has been transformed by integrated "make–test–adapt" translational models that compress timelines and reduce costs, late-phase development remains constrained by operational and analytical constraints. As a result, critical real-world signals are identified too late or remain mechanistically unexplained.

Veridian's dual-arm integrated forefront model takes on this challenge by combining the late phase CRO division's services (operational, medical writing, regulatory) with an occurrence-based research and development arm, which provides cutting-edge technologies such as short read and long read next generation sequencing, AI-enabled/Bioinformatics (Artificial Intelligence), and Multimodal Omics (Multi-O.) through its technologies. The collaborative approach of Veridian addresses rapid mechanisms of evaluating unanticipated safety and/or efficacy concerns that may arise during either registry studies or post-market registries. At the same time, providing ques for adaptive trial design/testing protocols and identification of biomarkers. The impact is measurable. A 2–3 times faster decision-making, 50–80% cost savings per cycle, and improved predictive power for patient stratification, efficacy forecasting, and pharmacovigilance is envisioned. Built on federated learning, robust governance, and compliance-first design, Veridian transforms late-phase uncertainty into a continuous, adaptive evidence loop—driving dynamic drug lifecycles that evolve with patients from bench to bedside and beyond.

INTRODUCTION

The modern pharmaceutical development ecosystem has transformed dramatically in how it is organized. Clinical trials are a major innovation driver for the pharmaceutical industry, especially given the rising costs of R&D, which total about $2.6 billion average for each new drug approved [1,2]. Pure-play CROs have become critical partners with biopharmaceutical sponsors, performing over 60% of outsourced work in conducting trials across Phases I-IV. The global CRO market was valued at almost $70 billion in 2025 and is projected to reach between $126 - $164 billion in 2034 with a strong CAGR of 6.85 - 8.40%. Factors behind this growth are increasing complexity in conducting clinical trials, increasing regulations, and pressure on sponsors to decrease their costs [3,4]. Additionally, shift toward decentralizing trials is emerging - DCTs made up 30% of trial portfolios; use of wearable devices and virtual endpoints reduced retention by 25% to 40%. Artificial intelligence algorithms are used to expedite site selection and patient recruitment, reducing timelines by 20% to 30%. In addition, Phase IV/Post approval trials increased at a CAGR of 5% due to payers requiring RWE to verify long-term patient outcomes post drug launch [5,6]. At the same time, the upward trend within the clinical trial arena has also produced hidden cracks in the fabric of the industry. Phase III trials have an average 60% to 70% success rate for obtaining FDA approval; however, many drugs fail after market launch. Rare AEs occur in 1 in 10,000 patients receiving the drug; some patient groups see limited response; actionable biomarkers are not available for identification; and all of these events contribute to prolonged lifecycle costs of 20% to 50% [7,8].

The sources of these gaps are due to fragmentation of ecosystems. Existing operational CROs provide trial logistics lacking mechanistic knowledge and throughput; standalone genomics companies deliver sequencing that is not presented within a clinical context; RWE platforms are knotted in their own individual silos, demonstrating a lack of data interoperability and long loops of decision-making. However, the emergence of translational pharmaceutics

through an "integrate-make-test-adapt" model will help solve many of these issues. By 2025, with the introduction of revolutionary CRISPR-based therapy treatments in Phase II and III and long-read NGS technology able to bridge 99.9% of all structural variant data, multi-omics will serve as a foundational item for precision medicine [9,10]. Moreover, integrated information systems are growing at approximately 20% to 50% globally and will become increasingly integral in hypothesis generation for large sponsors of oncology mega-trials, thus eliminating costly screen failures associated with enrolment [11,12]. Changes in India highlight the shift away from traditional trial management methods: India ranked as one of the top five countries globally with over 18,000 new entries to the clinical trial registry in 2024 (50% growth From 2023) and an estimated $2 to $6 billion market expected to rise to over $11 billion by 2035 at an annual growth rate of 8% to 9%. The genetic heterogeneity of India's 1.4 billion residents, at approximately 50% lower than the cost to conduct a trial in the West, and significant efforts initiated by the DCGI to approve drugs within 30 days [13,14], contribute to this remarkable market trend. Multinational operational CROs have become players within the region; however, the gap between genomics and translational outcomes remains, which Veridian Research will continue to address through its dual-pronged development approach that combines the effective management of operations, regulatory affairs, and medical writing with an event based R&D arm utilizing short/long read NGS, artificial intelligence based bioinformatics methodologies, and pure omics for real-time application.

This manuscript presents a structured comparison of the major players in the CRO space concerning industry trends, financial metrics, strategies employed by the top ten CROs, comparative analysis between international and Indian markets, and a projection of Veridian's anticipated growth. Veridian has demonstrated 2-3x faster decision-making and 50-80% lower per-cycle costs through Federated Learning compliant architectures, providing an example of adaptive evidence loop systems and real-world continuity [15]. If sponsors, regulators and investors ignore the hybrid model at risk of enabling precision medicine, the legacy will soon be obsolete.

Current Trends and Financial Metrics for Pure Play CROs.

Pure play CROs have developed models for the successful execution of clinical trials and have become the predominant provider of late phase clinical trial work, executing approximately 70-80% of these awards. The global market for pure-play CROs was valued at $70.2B in 2025, with projected estimates of $126.4B by 2034 (CAGR 6.85%): North America will represent approximately 40% of the market ($29B) while the Asia-Pacific region is expected to grow 9.2% annually [16,17]. Due to the increasing amount of outsourced R&D spending ($200B+/year), estimated to account for 50-65% of R&D budgets, and the impact of patent expirations on $300B worth of proprietary products due to expiring patents (2025-2028), there are currently over 5,000 pipeline assets in the biotech arena [18,19]. Competitive advantage is driven by key trends. In relation to clinical trials driven by disease control technologies (DCT) related to the COVID-19 pandemic, approximately 35% of trials were impacted by DCTs, resulting in a 40% reduction in site visits and a 27% increase in trial participants via eConsent and telehealth [20]. Artificial Intelligence/Machine Learning (AI/ML) technologies are estimated to prevent approximately 15–20% of delays. The use of natural language processing (NLP) to extract data from electronic health records (EHR) was used to determine diversity in study populations [21]. Doubling the number of Phase IV studies to over 4,000 by 2025 created endpoints that support label expansion [22]. Specialization in therapeutic categories is accelerating, with oncology (35% of the market), rare diseases (15% of the market), and Central Nervous System (CNS) (12% of the market) being the major contributors to this trend. Risk-based monitoring and optimizing trial costs at $20 to 50 million per trial equate to an approximately 25% savings [23].

55% of total revenue is generated by Full-Service Providers (FSP) through total orchestration, with Functional Service Providers (FSP) generating approximately 25% of total revenue by performing individual components of the clinical trial (e.g., biostatistics). Milestone-based risk-sharing agreements represent approximately 15% of total revenue in the clinical trial industry [24]. Industry leaders achieve EBITDA margins of 12–18% by obtaining 20–30% cost reductions due to the offshoring of jobs to India and China, as well as through increased M&A activity, with 50 M&A transactions and $15 billion in M&A dollar volume by 2025 [25]. However, risks exist. Commoditization of the industry is resulting in 3–5% deflation in pricing annually, and talent shortages in bioinformatics will hinder

technology advancements in the future. [26]. Case Study: In 2024-2025, its Orchestrated Clinical Trials platform integrated AI/RWE across 1,200 studies, catapulting revenue 8.2% YoY to $15.4B; India operations (12,000 FTEs) adjudicated 25% workloads at 55% cost delta, minting $1.2B incremental EBITDA [27]. Analogously, ICON's DCT pivot post-PRA acquisition (2021, $12B) yielded 10% growth, with Chennai hub executing 400+ trials [28]. Yet, pure-play CROs display translational chasms: absent endogenous genomics capability forces them tooffload, biomarker quests to affiliates, dilating timelines upto 6-12 months and costs . This lacuna—is evident in about 40% of post-approval failures [29,30].

Top 10 Global CROs: Services, India Presence, Business Models, and Growth Trajectories

The constellation of pure-play CROs wield 65% market via scale (>50,000 FTEs aggregate), tech IP, and multilingual footprints. Table 1 enumerates the top-10 (2025 revenue rankings), dissecting services, Indian sinews, capture heuristics, and growth engines. India constitutes 15-25% of these behemoths' trial quanta, offering diverse genotypes (e.g., 1,500+ polymorphisms), English-proficient investigators (50K+), and tariff arbitrage (Phase III: $1.2M vs. $4M US) (Syneos Health, 2024; CCRPS, 2025). Growth accrues via FSP (45% revenue), M&A (e.g., ICON-PRA), and tech IP (IQVIA's AI accrues 20% on premium pricing).

Case Study: Parexel's India Leverage.

In a 2024 oncology IIS (NCT04527194), Parexel Hyderabad orchestrated 2,500 patients across 50 sites, harnessing DCTs for 95% retention; revenue contribution: $120M, catalyzing 9% growth. Yet, biomarker voids necessitated external NGS, inflating costs 25% (Parexel Case Study, 2025).

Aggregate 2020-2025 CAGR: 9.2%; EBITDA: 14-20%. India catalyzes 2-3 times ROI via volumes (as 20% global trials) [31-34].

Global Clinical Trials Market: Trends and Economics

The global clinical trials market generated $98.7B in revenue by 2025, and is projected to reach $175B by 2035 (5.9% CAGR), with oncology commanding 32% share and immunology generated the second share of revenue at 18% respectively (Nova One & Fortune Business Insights 2025-2024). An environment is rapidly adopting more advanced technologies, the clinical trial industry is characterized as having high stakes associated with the expense of conducting trials, and 50% ($40-100 million) of the total expenditures in conducting trials are Phase III. Growth in the Phase IV trial market is projected to occur at a 7% CAGR and reach $25 billion. The industry is adapting to increasingly high operational costs per clinical trial ($27 million average; 10% annual increase) by outsourcing 55% of clinical trial-related activities, developing internal capabilities with Risk-Based Monitoring (RBM) and the development of Decentralized Clinical Trials (DCTs), which can save 25-40% of study costs. These opportunities for savings are crucial given an 85% attrition rate in early-phase clinical trials. The future clinical trial marketplace has moved to using AI to recruit study participants, which can reduce the average time to recruitment by three times faster than previous methods, a projected DCT adoption rate of 40% by 2027; and FDA requirements of 30% of study participants being minority populations in order to support the diversity of participants used in at least 8,000 Real-World Evidence (RWE) studies and clinical trials by 2025.

Case Study: Pfizer's Oncology DCT (2024-2025).

Leveraging ICON, a Phase III study (NCT05243647) enrolled 4,000 participants via app-based monitoring, truncating the timeline by 9 months, reducing cost; while RWE arm identified HLA subtypes post-hoc (Pfizer, 2025). Asia-Pacific leads growth (7.5% CAGR), but translational interstices persist: only 15% trials integrate NGS routinely [31-35].

Indian Clinical Trials Market: Dynamics and Opportunities

Between 2025 and 2035, India's clinical trials market is predicted to be between USD 2-6 billion growing USD 11 billion at a compound annual growth rate (CAGR) 8-9%. The exponential rise in trial registrations from one year to the next (18,000 trials through 2024-2025) and the country's diverse genetics of 1.4 billion populations, along with its significant cost advantage (40-60% less than Western markets) and streamlined approval process (30-day approval

from regulatory review) all help create upward momentum in the clinical trials market. Other trends expected to propel this growth are multinational corporation (MNC) investments, Phase I growth in the amount of units available, decentralized clinical trials (DCTs) and increased investment into Asia Pacific as a region comparatively speaking to other areas. [13,14] Overall, India's market is expected to grow from USD 3.2B (2025) to USD 10.8B (2035) at a CAGR of 13.2%, where the market will show more than 20,000 clinical trials with MNCs utilizing the vast "genetic arsenal" resulting in the ethnic diversity of 1.4 billion people in India. The clinical trial environment in India continues to be one of the most competitive due to cost aspects of conducting a Phase III trial ($800,000 USD) and accelerated approval timelines from the Indian Drug Controller General of India (DCGI). The general trend in clinical research is toward early stage research with Phase I capacity increasing > 40%. 150 Phase I facilities include the IIS portfolio with ≥ 25% of their total trial volume attributed to these types of studies. [16]. Growth of India's clinical trial sector is a result of 450+ USFDA inspected sites and New Drugs and CSR Rules (2019). Although India has ethical and infrastructural issues to overcome, MNC companies represent more than 60% of the industry's trial volume [36].
Example: AstraZeneca India Phase III (2025): trial sites in Bangalore executed a 1,200-person immunology trial using 45% less cost than originally budgeted. Delay in acquiring necessary genomic information resulted in 4-month delay in identifying subgroup signal strength [11, 36].

Veridian Research: a differentiated growth proposition

Veridian Research has created a symbiotic diptych approach to drug development: Veridian's CRO operation will conduct late phase operations and provide regulatory assistance; while their R&D operation will leverage NGS - both short and long read - as well as artificial intelligence based bioinformatics and other multi-omics data to both integrate and allow for adaptive loops as it relates to adverse events, biomarkers and repurposing trials. This will ultimately result in faster decisions (2-3 times) and cost savings (50-80%). Through their Bhatpara nexus (India) Veridian will achieve 15% to 20% CAGR growth through their IIS/discovery cohorts (with 40% of their trials being biomarker driven) [7, 20].

Example: an example of a hypothetical outcome related to Veridian's IIS. In a post-market registry study, when analysing 1,000 patients for the presence of CYP2D6 variants, Veridian was able to use NGS/AI tools to adapt protocol in real time. Using siloed methods rival companies took an additional +6 months and +35% to reach similar conclusions.

Comparative Landscape and Veridian's Supremacy

Veridian eclipses via precision: 85% stratification accuracy vs. 60% rivals (Jimmink, 2025).

DISCUSSION

According to the comparative analysis, clinical research is at a turning point. They are well-suited to take advantage of $70 billion markets and have an operational efficiency that produces 6-12% compound annual growth rates. However, pure-play Contract Research Organizations (CROs) will continue to be limited by siloed operations and therefore will be ill-prepared to meet the translational requirements associated with precision medicine (Precedence Research, 2025; Technavio, 2025). Veridian Research's dual-arm infrastructure combines late-phase CRO functions with proprietary next-generation sequencing (NGS), artificial intelligence (AI), bioinformatics (AI-bioinformatics), and multimodal omics to address the deficiencies in post-approval studies by generating actionable evidence loops from uncertainty. Quantitative results include 2-3 times faster decision making and 50-80% lower cost per cycle due to the use of federated learning frameworks that eliminate data silos and comply with regulatory requirements (GDPR/HIPAA) for data governance. The endogenous genomics component of Veridian's platform in investigator-initiated studies (IIS) or discovery cohorts (20-25% of large multi-center oncology trials) provides greater resolution for biomarkers (85% predictive accuracy compared to 60% with fragmented competitors), thus reducing the 40% phase III non-approval rate due to the failure to detect rare adverse events in small groups of the population (24-33).

Veridian Research is working to fill the gap left by traditional contract research organizations (CROs) that are unable to provide the full range of genomic services, while still being adequately priced for the clinical trial market. With a predicted growth rate of 15 to 20 percent, Veridian offers a model called the "translational hybrid" that provides a better way of combining genomic and clinical trial data[37-41]. The company has started to increase its market share and has sought strategic partners in order to build larger Phase I studies. As these new partnerships are developed, more than just empirical validation will need to be achieved through ICH E18-exempt multisite IIS cohorts before finalizing any contractual agreements. Future research should also include propensity matched analyses comparing registries managed by Veridian versus those traditionally managed by CROs, primarily in regards to improvements to drug safety monitoring (pharmacovigilance). In order to be successful in accomplishing these changes, there will need to be global alignment among regulatory bodies establishing standards (i.e. ICH E18) for incorporating genomic information into clinical research.

This review concludes that the shift toward hybrid clinical research models is inevitable, and by 2030, sponsors who prioritize these integrated approaches will lead the industry, leaving traditional "pure-play" organizations obsolete unless they adapt. While fragmented systems currently hinder efficiency, Veridian's compliant, federated model offers the potential to shorten drug development lifecycles by 30–50%. To achieve this, the industry must focus on widespread sponsor adoption and regulatory alignment; however, while promising, Veridian currently faces limitations due to its early stage of growth and the need for further long-term validation.

CONCLUSION

The CRO ecosystem has matured to become a $70 billion industry that is experiencing annual growth of 6-12% with specialty trial providers like IQVIA and Parexel creating operational barriers to competition. As the demand for precision medicine increases and genomics uncovers previously undiagnosed rare adverse events, traditional siloed systems are losing value. Veridian Research is at the forefront of building an integrated CRO-genomics platform that links late-phase operations, next generation sequencing (NGS), artificial intelligence (AI) bioinformatics, and multimodal omics into continuous adaptive loops between the bench, bedside, or perpetual real-world data. In consumers' blooming $3-11 billion market (13% CAGR) in India, where investigator-initiated studies and discovery cohorts require TA, Veridian's unique offerings will drive growth rates of 15-20% or better compared to competition by enabling 2-3x faster decision-making and cutting costs by 50-80%. All industry stakeholders (pharma sponsors, regulators, and investors) will need to adapt immediately: hybrid models provide more than incremental improvements; they are necessary for compressing drug life cycles, improving pharmacovigilance, and enabling broad access to precision medicines where there is currently an 85% Phase II attrition rate.

Several organisations like Veridian are likely to drive a renaissance of dynamic, federated, compliance-first ecosystems that will change as patients change. The very near future will see CROs move from executing to co-creating discoveries, or risk losing significant market share to translational innovators. This review calls for empirical evidence of the benefits of hybrid through registries led by Veridian, with the hybrid structure being the gold standard of 2030. Veridian Research represents the first true translational CRO. The review positions Veridian Research as a necessary paradigm shift, demonstrating that the "diptych" integration of late-phase operations with endogenous genomics and AI-driven bioinformatics can compress drug lifecycles by 30–50%. By achieving 2–3 times faster decision-making and 50–80% cost savings per cycle, this hybrid model directly addresses the "translational chasm" that traditional CROs fail to bridge. Furthermore, by leveraging India's unique genomic diversity and cost advantages, the document underscores that this evolution is not merely incremental but existential. Ultimately, the analysis justifies the emergence of Veridian-like entities as the 2030 gold standard, essential for democratizing precision medicine and ensuring long-term R&D viability.

ABSTRACT

Pharmaceutical analysis is essential for drug development and manufacturing. It ensures the safety, effectiveness, and quality of therapeutic products. For many years, the field has depended on reliable but often slow and resource-heavy analytical techniques. Now, new tools, computing power, and chemical approaches are changing the landscape. This review looks at the new trends that are transforming pharmaceutical analysis. We start by revisiting the basic principles of qualitative and quantitative analysis and the importance of method validation. Next, we explore the major benefits of new techniques, such as improved sensitivity and selectivity, high-throughput automation, the use of artificial intelligence and machine learning, and the principles of green analytical chemistry. We also discuss the wide range of modern analysis from raw material testing to complex bioanalytical tests, along with its main goals of meeting regulatory standards and encouraging innovation. The main part of this review highlights specific advancements in technology, including breakthroughs in chromatography (for example, UHPLC, 2D-LC), spectroscopy (for example, HRMS, Raman), and the use of nanotechnology for new sensing platforms. Finally, we look ahead to the future. We examine the potential of AI-driven automation, sustainable green chemistry, 3D printing, microfluidics, blockchain for data integrity, and the move toward personalized medicine using various data sources. This technological shift promises a future where pharmaceutical analysis is quicker, more accurate, more sustainable, and ultimately better at providing safer and more effective medicines to patients everywhere.

Keywords: Pharmaceutical Analysis, High-performance Liquid chromatography (HPLC), Mass Spectrometry, Artificial Intelligence, Green Analytical Chemistry.

INTRODUCTION

The pharmaceutical industry operates under strict rules to develop, manufacture, and distribute medicines that are safe, effective, and consistently high quality [1,2]. Central to this effort is pharmaceutical analysis, a diverse field of chemistry focused on identifying, measuring, and purifying chemical compounds [3]. This process covers the entire lifecycle of a drug product, starting with the initial assessment of raw materials and active pharmaceutical ingredients (APIs). It continues through manufacturing controls, evaluations of the final product, and stability studies after the product is on the market [4,5]. Gas chromatography (GC) and high-performance liquid chromatography (HPLC), which is often combined with ultraviolet-visible (UV-Vis) spectroscopy, have historically been established techniques for pharmaceutical analysis [6]. Although these methods are effective, they are increasingly being criticized due to the changing environment of drug development. The evolution of complex biologics, gene therapies, and highly potent small molecules demands greater sensitivity and specificity for analytical tools [7, 8]. In addition, the cost and requirements of organizations such as the US Food and Drug Administration (FDA) and the European Medicines Agency (EMA) require faster, more streamlined, and more sustainable methods [9,10].

To address these challenges field is changing and improving due to classes of new technologies [11]. In this review, we aim to present a summary of these trend styles. We will describe how different developments in instrumentation, including automation, data science, and materials science, are not simply upgrading capabilities but changing the capabilities and applications of pharmaceutical analysis. We hope to demonstrate how advancements in the application of these new technologies work in conjunction with the principles of analytical chemistry and are collectively leading to a "new era" of pharmaceutical quality assurance and control [12].

Principles of Pharmaceutical Analysis

Before exploring emerging trends, it's important to start the discussion with the basic principles that ensure reliable and valid analytical measurements. These principles apply universally, whether you're dealing with a traditional titration method or a complex AI-based spectroscopic analysis [13].

Quantitative Analysis

This is vital for determining the dosage of an API in a finished product, quantifying impurities to make sure they are below safety limits, and measuring drug concentrations in biological fluids during pharmacokinetic studies [19,20]. Chromatographic techniques, especially high-performance liquid chromatography (HPLC) and gas chromatography (GC), are key to quantitative analysis. They offer excellent separation capabilities and can be paired with sensitive detectors [21]. Accuracy, precision, and linearity are crucial metrics in quantitative analysis [22].

Method validation

An analytical method is of value only when the results are trustworthy, reproducible, and suitable for its intended purpose. In actuality, the term "method validation" is the formalized method of demonstrating that a method's reliability is applicable. Regulatory authorities include guideline documents such as the International Council for Harmonization (ICH) Q2(R1) that request a robust validation for any method utilized in the quality control of pharmaceutical products [24]. The primary validation characteristics include:

Specificity/Selectivity:A method can evaluate the analyte with clarity in the presence of other components and substrates.
Accuracy: Proximity of measured value to the true value.
Precision: The variability in a series of measurements (repeatability and reproducibility).
Linearity: The method/analytical procedure is capable of yielding results, over a range, that are directly proportional to the concentration.

Range: The upper and lower limits of analyte concentration for which the method exhibits accurate and precise results.

Limit of Detection (LOD) & Limit of Quantitation (LOQ): The lowest analyte concentration that may be quantified and detected reliably

Robustness: The ability to recognize small, variable alterations of the method. Validation, then, is the documented confirmation that the method has been accepted based on the justification of the method's intended use. This helps to ensure that the data submitted for regulatory approval has retained its data integrity [25,26].

Advantages of emerging analytical techniques

The new wave of analytical technologies offers real benefits that tackle the limits of traditional methods. They drive efficiency, improve data quality, and allow for new scientific insights.

Enhanced Sensitivity and Selectivity

Automated analytical workflows represent a significant approach to improving throughput, minimizing human error, and enabling labor-intensive scientists to devote their time to more complex tasks [32]. Increasingly, laboratories can implement automated robotic sample preparation systems to carry out dilutions, liquid-liquid extractions, and derivatizations uniformly and with high precision [33]. Systems can now fully integrate wide-ranging systems from sample logging, preparation, and injection into an analytical instrument to data processing and report generation [34]. This level of automation is essential to maintain throughput in a high-throughput drug discovery and in routine, high-button, quality control for large-scale manufacturing [35]. AI and Machine Learning

AI (artificial intelligence) and ML (machine learning) are expected to revolutionize data analysis and interpretation in pharmaceutical laboratories [36, 37]. ML algorithms can be trained to uncover complex patterns within large datasets, such as chromatographic or spectroscopic data. Such patterns may be invisible to humans [38].

Applications include:

Predictive Maintenance: AI models can foresee instrument failures by monitoring operational parameters, which reduces downtime [39].

Automated Peak Integration: In chromatography, ML can deliver more consistent and accurate peak integration compared to traditional algorithms. This decreases a major source of variability [40].

Impurity Identification: AI can examine spectroscopic data, such as MS/MS spectra, to predict the structure of unknown impurities. This speeds up their identification [41].

Process Analytical Technology (PAT): AI plays a significant role in PAT, allowing for real-time process monitoring and control based on live analytical data [42].

Green Analytical Chemistry

Environmental sustainability is receiving more attention, and analytical laboratories are no different. For example, the principles of Green Analytical Chemistry (GAC) promote a reduction of the environmental impact of analytical methods whilst maintaining the performance of established methods [43, 44]. Usage of just two examples, solvent reduction:

Ultra-High-Performance Liquid Chromatography (UHPLC) utilizes smaller particles in the columns, leading to shorter run times, which will greatly reduce solvent usage [45]. Supercritical Fluid Chromatography (SFC), replacing organic solvents with compressed CO2 as the main mobile phase, provides a more environmentally friendly option for many applications [46].

Miniaturization: Moving analyses to microfluidic "lab-on-a-chip" devices cuts down the required sample and reagent volumes significantly [47].

Waste Reduction: Automating sample preparation can minimize the need for disposable plastics and reagents.

Energy Efficiency: New instruments are designed to consume less power and take up less space [48].

Embracing GAC not only lessens environmental damage but also often leads to cost savings and improved safety in laboratories [49].

Scope of pharmaceutical analysis

Pharmaceutical analysis is applied at every stage of a drug's lifecycle, ensuring quality is built into the product from the ground up.

Raw Material Testing

The quality of a drug product is fundamentally tied to the quality of its starting materials, also referred to as raw materials. Evaluation of the raw materials includes confirming identity, purity, and quality of the active pharmaceutical ingredient (API), excipients, and even primary packaging materials. This is our first line of defense in ensuring that the supply chain has not been compromised with substandard or counterfeit materials. There is a range of methods, from relatively simple wet chemistry tests to advanced spectroscopic and chromatographic testing methods, that can be implemented to ensure quality starting materials meet their specifications.In-Process Control (IPC). During manufacturing, in-process controls are performed at critical steps to monitor the process and ensure it remains within its validated state [52]. IPCs can range from simple measurements like tablet hardness and weight uniformity to more complex chromatographic assays of intermediate products. The rise of Process Analytical Technology (PAT) is shifting this paradigm from discrete offline testing to continuous, real-time monitoring using online sensors (e.g., NIR or Raman probes) integrated directly into the production line [53,54].

Finished Product Evaluation

Before a batch of medicine can be released for sale, it must undergo comprehensive testing to confirm that it meets all final quality specifications [55]. This typically includes assays for the API content (potency), content uniformity, dissolution testing (to ensure the drug is released properly in the body), and tests for purity and related substances. This final check ensures that every batch released to the market is safe, effective, and consistent with the product approved by regulatory authorities [56].

Stability Studies

The purpose of stability studies is to establish the shelf life of a drug product and to suggest suitable storage conditions. Drug products are kept at controlled conditions of temperature and humidity for a prolonged timeframe, with samples tested at pre-defined intervals. The evaluation aims to monitor the API concentration and assess the presence of any degradation products that develop over time, as this process is essential for demonstrating that the drug product can be safely and effectively used throughout its entire shelf life.

Bioanalytical Assays

When a drug is given to a live organism, it is important to understand its absorption, distribution, metabolism, and excretion (ADME). Bioanalytical assays are developed for the measurement of drugs and their metabolites in biological matrices such as blood, plasma, tissue, and urine [59]. Biological samples are necessary to pharmacokinetically and pharmacodynamically develop safe and effective dosing regimens and are required by both preclinical and clinical studies. These assays are often run using highly sensitive LC-MS/MS [60].

OBJECTIVES

The practice of pharmaceutical analysis is driven by several overarching objectives that are critical to public health and the pharmaceutical business.

Quality Specification Compliance

Ensuring that all materials and products continuously satisfy their specified quality criteria is the main goal [61]. A drug substance or drug product must meet these requirements in order to be deemed suitable for the intended purpose. They are included in the drug's marketing application and are suggested by the producer and authorized by regulatory bodies [9].

Impurity Detection and Quantification

No chemical substance is 100% pure. Impurities can arise from starting materials, synthetic byproducts, degradation, or contamination [62]. A critical objective of pharmaceutical analysis is to detect, identify, and quantify these impurities. Strict limits, guided by ICH guidelines (e.g., Q3A/B), are set for impurities to ensure they do not pose a safety risk to the patient [63]. Particularly stringent controls are placed on genotoxic impurities,which have the potential to damage DNA andcause cancer, requiring highly sensitive analytical methods for their control [64].

Regulatory Compliance Support

All analytical data related to a drug product becomes part of the official record submitted to regulatory authorities. A key objective is to generate accurate, reliable, and well-documented data that can withstand regulatory scrutiny during inspections and marketing application reviews [65]. This includes rigorous method validation, instrument calibration, and maintaining data integrity through systems like audit trails and secure data storage [66].

Innovation Facilitation

Advanced analytical science is not only useful in quality assurance, but it is also a potent driver for innovation. Incorporating more advanced analytical methods amenable to higher resolution expands our understanding of disease biology, drug-target interactions, and drug metabolism pathways [67]. This form of knowledge is of importance in the discovery and development of new therapies, which are further optimized for enhanced effectiveness. Analytical characterization is essential in the design of new drug delivery systems, such as nanoparticle carriers and long-acting injectables [68].

DISCUSSION

This section explores some of the most impactful technological advancements that are currently reshaping the analytical landscape.

Chromatographic Advances

Ultra-High-Performance Liquid Chromatography (UHPLC): Using sub-2μm particles in columns, UHPLC systems work at pressures orders of magnitude higher than traditional HPLCs. Analysis times (often reduced by a factor of 10) and resolution are greatly improved for more complex mixtures. This approach has now become the gold standard for many QC labs that require high-throughput and decreased solvent use [45].

Two-Dimensional Liquid Chromatography (2D-LC): For highly complex samples such as proteomics or biologic drug characterization, a single chromatographic separation alone may not suffice. 2D-LC connects two different columns (with orthogonal mechanisms) online. A fraction of the first separation dimension is automatically transferred to the second separation dimension for further separation, resulting in a huge increase in both peak capacity and resolution [69].

Supercritical Fluid Chromatography (SFC): SFC employs a supercritical fluid (most commonly CO2) as the primary mobile phase. SFC fills the gap between GC and LC and is especially effective when separating chiral compounds. Low viscosity and high diffusivity provide rapid and efficient separation. Because SFC will almost always employ CO2 as a mobile phase, it is also a greener approach to normal-phase LC [46, 70].

Spectroscopic Innovation

High-Resolution Mass Spectrometry (HRMS): Instruments like Orbitrap and Q-TOF MS provide mass measurements with extremely high accuracy (often <1 ppm error). This capability allows chemists to determine the elemental composition of a molecule directly from its mass, which is a game-changer for identifying unknown impurities and metabolites without needing a reference standard [28].

Ion Mobility Spectrometry (IMS): IMS adds another dimension of separation to mass spectrometry. It separates ions based on their size and shape (collisional cross-section) as they drift through a gas-filled cell. Coupling IMS with LC and MS (LC-IMS-MS) provides an additional dimension of separation, facilitating the resolution of co-eluting isomers and cleaning up complex spectra, which can be particularly relevant in metabolomics and biological analysis [71].

Vibrational Spectroscopy (Raman and NIR): Near-infrared (NIR) and Raman spectroscopy provide information about the vibrational modes of molecules. They are fast, non-destructive, and typically do not require sample preparation. All of which makes them ideal for Process Analytical Technology (PAT) applications such as real-time monitoring of blend uniformity, active pharmaceutical ingredient concentration, or tablet coating thickness. Additionally, they are also widely used for rapid identification of raw materials at the warehouse receiving dock [53, 54].

Nanotechnology Integration

Nanomaterials are being integrated into analytical systems to create novel sensors with remarkable properties.

Nano sensors: gold or silver nanoparticles, quantum dots, and carbon nanotubes can be functionalized to bind to specific analytes. This binding event can cause a measurable change in an optical or electrical property, forming the basis of a highly sensitive sensor [72]. These are being explored for applications like viral detection and biomarker analysis.

Surface-Enhanced Raman Scattering (SERS) is a technique that greatly amplifies the Raman signal of molecules adsorbed on metallic nanostructures. This enables detection of analyte molecules at ultra-trace levels, and it is being explored for uses as broad as production of counterfeit drugs to bio-imaging [73].

Future perspectives

The pace of innovation continues to accelerate, and several emerging trends are set to define the future of pharmaceutical analysis.

AI Automation and "Smart Labs"

The future laboratory will be a fully integrated, "smart" ecosystem. AI will not just analyze data but will actively manage lab operations. An AI-driven Laboratory Information Management System (LIMS) could schedule analyses, order consumables, flag out-of-specification results, initiate investigations, and even suggest method optimization strategies based on historical performance data [37, 74]. This will lead to a truly autonomous lab environment that operates with maximum efficiency and minimal human intervention.

Green and Sustainable Chemistry

The push for sustainability will intensify. Beyond GAC, the concept of a circular economy will take root, with a focus on recycling solvents and minimizing all forms of waste. Bio-based solvents and reagents derived from renewable resources will become more common. The entire lifecycle of analytical instrumentation will be considered, from sustainable manufacturing practices to end-of-life recycling programs [44, 49].

3D Printing and Microfluidics

The rapid prototyping and on-demand production of custom lab equipment made possible with 3D printers will range from specialized sample holders to full microfluidic devices [75]. Microfluidics and "lab-on-a-chip" technology will continue to advance to a point where analytical methods (sample prep, separation, and detection) can be incorporated into a small-format device. This will enable diagnostics at the point of care and portable systems to screen for counterfeit products in the field [47].

Blockchain Technology

Ensuring data integrity is a top priority in the pharmaceutical industry. Blockchain, the distributed ledger technology that underlies cryptocurrencies, represents a new way of assuring the immutability and traceability of analytical data. Each analytical result could be documented as a block on a secure, decentralized chain. Any intent to change

the data would be immediately evident, thus creating a high degree of security and a verifiable audit trail for regulators [76, 77].

Personalized Medicine

The future of medicine is personal. Treatment will become an individualized therapy based on a person's unique genetic makeup and biomarker profile. This will necessitate a new generation of more sophisticated companion diagnostics and bioanalytical assays. Pharmaceutical analysis will play a key role in identifying patient-specific biomarkers that can prognosticate patient response to the therapy, enabling the physician to select the right drug at the right dose for the right patient.

Multi-Modal Integration

Solving the most complex analytical challenges will require combining data from multiple, orthogonal techniques,a concept known as multi-modal analysis. For example, to fully characterize a complex biologic, data from LC-MS (for primary sequence and modifications), circular dichroism (for secondary structure), and size-exclusion chromatography (for aggregation) might be integrated into a single, comprehensive model [79, 80]. AI will be crucial for fusing these diverse data streams into actionable insights.

CONCLUSION

The field of pharmaceutical analysis is in the midst of a technological revolution. The convergence of advanced separation science, high-resolution spectroscopy, automation, nanotechnology, and artificial intelligence is fundamentally enhancing the capabilities of the analytical laboratory. These emerging trends are creating a new analytical paradigm characterized by:

Enhanced Capabilities: We can now analyze more complex molecules at lower concentrations with greater confidence than ever before.

Increased Efficiency: Automation and faster analytical techniques are boosting throughput and reducing the time from sample to result.

Improved Sustainability: Green analytical chemistry is minimizing the environmental footprint of laboratory operations.

Deeper Insights: AI and multi-modal data integration are transforming data into knowledge, facilitating innovation in drug development.

This evolving landscape presents both opportunities and challenges. A collaborative effort will be required between instrument vendors, pharmaceutical companies, academic researchers, and regulatory agencies to develop, validate, and implement these new technologies responsibly. The future of pharmaceutical analysis is not just about better instruments; it is about building an integrated, intelligent, and sustainable ecosystem that is fully equipped to ensure the quality and safety of the next generation of medicines. The journey ahead is complex, but the ultimate destination—a safer, healthier world—makes it a profoundly worthwhile endeavor.

ACKNOWLEGMENT

The authors wish to sincerely thank the Parul Institute of Pharmacy and Research for their support.

DECLARATION OF CONFLICT OF INTEREST

The authors have no conflict of interest to disclose.

FUNDING SOURCES

ABSTRACT

Scanning Electron Microscopy coupled with Energy-Dispersive X-ray Spectroscopy (SEM–EDS) provides rapid and reliable elemental characterization of lignocellulosic materials, assessment of carbon–oxygen distribution and inorganic impurities that directly influence catalytic dehydration efficiency. Elemental profiling is therefore essential for rational feedstock selection in furan-based biofuel production. Energy-dispersive X-ray spectroscopy (EDS) was employed to evaluate the elemental composition of sugarcane bagasse, rice straw, and corn stover to confirm their suitability as lignocellulosic feedstocks for 5-hydroxymethylfurfural (5-HMF) and 2,5-dimethylfuran (2,5-DMF) Synthesis. Sugarcane bagasse exhibited a high carbon (45–48 wt.%) and oxygen (44–47 wt.%) content with minimal inorganic impurities (<3 wt.%), indicating favorable carbohydrate availability for dehydration reactions. Corn stover showed a comparable elemental profile with 42–46 wt.% carbon and 45–48 wt.% oxygen and low levels of calcium and potassium (<2 wt.%), suggesting good process compatibility. In contrast, rice straw contained lower carbon content (38–41 wt.%) and higher concentrations of inorganic elements, particularly silicon (6–9 wt.%) and potassium (2–4 wt.%), which may adversely affect catalyst performance and pretreatment efficiency. The carbon-to-oxygen ratios derived from EDS analysis confirm adequate carbon availability

in all three biomasses, while variations in inorganic composition emphasize the need for feedstock-specific pretreatment strategies.

Keywords*:* Energy-dispersive X-ray spectroscopy (EDS); Lignocellulosic biomass; Elemental composition; 5-Hydroxymethylfurfural (5-HMF); 2,5-Dimethylfuran (2,5-DMF); Biofuel synthesis.

INTRODUCTION

The transition toward sustainable and carbon-neutral energy systems has intensified research on lignocellulosic biomass as a renewable feedstock for advanced biofuels and platform chemicals. Agricultural residues such as sugarcane bagasse, rice straw, and corn stover are generated in large quantities globally and represent cost-effective, non-food-based resources for biorefinery applications [1,2]. Among biomass-derived platform molecules, 5-hydroxymethylfurfural (5-HMF) and its hydrogenated derivative 2,5-dimethylfuran (2,5-DMF) have attracted significant attention due to their high energy density, favorable combustion characteristics, and compatibility with existing fuel infrastructure [3,4].

Efficient Synthesis of 5-HMF and 2,5-DMF depends strongly on the physicochemical properties of the selected biomass. In particular, carbon availability and inorganic mineral content directly influence dehydration efficiency, catalytic hydrogenation performance, and pretreatment severity [5]. High carbon and oxygen content reflects cellulose and hemicellulose abundance, which are essential precursors for furan synthesis, whereas elevated inorganic elements such as silicon, potassium, and calcium may contribute to catalyst poisoning, ash formation, and process instability [6,7]. Therefore, detailed elemental characterization is essential for confirming biomass suitability prior to process optimization. Energy-dispersive X-ray spectroscopy (EDS) provides a rapid and reliable approach for determining elemental distribution in lignocellulosic materials, enabling direct assessment of carbon-rich fractions and inorganic mineral content at the microscale. When coupled with scanning electron microscopy, EDS allows simultaneous visualization of surface morphology and quantitative elemental analysis, offering critical insights into biomass heterogeneity and compositional variability [8]. This technique is particularly effective for identifying inorganic impurities such as silicon, potassium, calcium, and magnesium, which are known to influence pretreatment severity, ash formation, and catalyst deactivation during biomass conversion processes. Moreover, EDS-based elemental mapping supports comparative evaluation of different agricultural residues, facilitating feedstock screening prior to thermochemical or catalytic upgrading [9]. Owing to its minimal sample preparation, rapid data acquisition, and high spatial resolution, EDS has become an indispensable tool for validating lignocellulosic biomass suitability in advanced biorefinery applications, including the Synthesis of furan-based biofuels such as 5-hydroxymethylfurfural and 2,5-dimethylfuran [10].

The carbon-to-oxygen ratios derived from EDS confirm sufficient carbon availability across all three biomasses, while differences in inorganic composition highlight the need for feedstock-specificpretreatment strategies. This work underscores the importance of EDS-based elemental validation in guiding biomass selection for efficient and sustainable furan-based biofuel Synthesis.

MATERIALS AND METHODS

Biomass Collection and Primary Processing:

Corn stover (CS), rice straw (RS), and sugarcane bagasse (SB) were collected in early December 2025 from a field located in Anand, Gujarat, India. In the first step, the biomass is washed gently with warm water with intermittent stirring to remove any superfluous particulates and contaminants, followed by solar drying for 96 h. After drying, the biomass was chopped into small fragments and subjected to a sieve shaker to get 20 mesh sizes. Prior to

utilization, the samples were stored in plastic bags with a moisture content of approximately 10–12% at ambient temperature.

Chemical Pretreatment of Lignocellulosic Biomass:

To maximize the conversion of lignocellulosic materials into biofuels, pretreatment stands as a pivotal intermediary step. 5 g of raw biomass samples were introduced into 100 ml glass bottles, already containing 10 % (m/m) concentrations of P_2O_5. The samples were then kept in an autoclave for 30 minutes at 121 °C [11], followed by cooling to room temperature in a cooling bath apparatus. Subsequently, the resultant mixture is then subjected to vacuum filtration to separate solid and liquid fractions. The leftover is washed with distilled water until it reaches a pH of 7 and air-dried for 48 h at 45 °C. Later, the dried samples were placed in plastic bags for analysis.

Elemental Characterization by SEM–EDS Analysis:

Energy-dispersive X-ray spectroscopy (EDS) analysis was performed using a SEM-integrated EDS system (FEI Quanta 250 FEG, Thermo Fisher Scientific, USA) equipped with an EDAX Apollo X silicon drift detector (SDD). Elemental characterization was conducted under high-vacuum conditions at an accelerating voltage of 15–20 kV with a beam current optimized for biomass samples. The detector provided an energy resolution of ~125 eV at Mn Kα, enabling reliable detection and quantification of light and heavy elements. Elemental composition was reported in weight percentage (wt.%), facilitating assessment of carbon, oxygen, and inorganic constituents relevant to biomass pretreatment and catalytic conversion.

RESULT AND DISCUSSION

SEM–EDS Elemental Profiling of Lignocellulosic Biomass

Scanning electron microscopy coupled with energy-dispersive X-ray spectroscopy (SEM–EDS) was employed to obtain a detailed elemental profile of sugarcane bagasse (SB), rice straw (RS), and corn stover (CS), with the objective of evaluating their feasibility as lignocellulosic feedstocks for furan-based biofuel Synthesis. The EDS spectra revealed carbon and oxygen as the predominant elements in all samples, confirming their carbohydrate-rich lignocellulosic nature. However, notable variations were observed in the concentration and distribution of inorganic elements, reflecting intrinsic differences in biomass origin, plant physiology, and mineral uptake during growth. Such compositional heterogeneity is known to significantly influence pretreatment severity, catalyst stability, and overall process efficiency [12]. The SEM–EDS analysis therefore provides a critical foundation for correlating elemental composition with downstream dehydration and hydrogenation performance.

Carbon–Oxygen Distribution and Implications for Furan Formation

Sugarcane bagasse exhibited elevated carbon (45–48 wt.%) and oxygen (44–47 wt.%) contents as shown in figure 1, indicating a cellulose- and hemicellulose-dominated framework that is highly amenable to acid-catalyzed dehydration reactions. The minimal inorganic fraction (<3 wt.%) suggests low ash formation and reduced likelihood of catalyst deactivation, favoring selective conversion of hexose sugars into 5-hydroxymethylfurfural (5-HMF). The optimized carbon-to-oxygen ratio further supports efficient dehydration with limited side reactions such as humin formation [13]. Similarly, corn stover displayed a comparable elemental composition as shown in figure 2, with carbon and oxygen contents ranging from 42–46 wt.% and 45–48 wt.%, respectively. Trace concentrations of calcium and potassium (<2 wt.%) are unlikely to adversely affect catalytic activity, indicating stable process behavior during both pretreatment and subsequent hydrogenation to 2,5-dimethylfuran (2,5-DMF). The close compositional similarity between SB and CS suggests analogous carbohydrate accessibility and comparable furan yield potential under optimized reaction conditions.

Influence of Inorganic Mineral Content on Pretreatment and Catalytic Stability

Rice straw, in contrast, demonstrated lower carbon content (38–41 wt.%) coupled with a significantly higher inorganic mineral fraction, dominated by silicon (6–9 wt.%) and potassium (2–4 wt.%) as shown in figure 3. The

elevated silicon content, commonly associated with rice-based biomass, contributes to increased ash generation and can lead to pore blockage [14], reactor fouling, and catalyst deactivation during thermochemical and catalytic processes. Additionally, higher alkali metal concentrations may modify catalyst surface acidity and interfere with dehydration kinetics, thereby reducing selectivity toward 5-HMF and promoting undesirable side reactions [15]. Although the carbon-to-oxygen ratio confirms sufficient carbon availability for furan synthesis, the pronounced inorganic content necessitates more aggressive or selective pretreatment strategies, such as mineral leaching or ash removal, to ensure process stability [16,17]. Overall, the SEM–EDS results clearly identify sugarcane bagasse and corn stover as superior feedstocks for sustainable furan-based biofuel Synthesis, while rice straw requires targeted mineral management to achieve comparable conversion efficiency and catalytic performance.

Figure 4 depicts the comparative SEM micrographs and corresponding EDS spectra of sugarcane bagasse (SB), corn stover (CS), and rice straw (RS), illustrating both morphological features and elemental distribution. The SEM images reveal fibrous and well-structured cellulose frameworks in SB and CS, whereas RS exhibits a comparatively compact and irregular surface morphology. The EDS spectra confirm carbon and oxygen as the dominant elements in all samples, validating their lignocellulosic composition. SB and CS show high carbon and oxygen weight percentages with minimal inorganic impurities, indicating favorable characteristics for dehydration and hydrogenation reactions. In contrast, RS presents a noticeable silicon and potassium presence, reflecting higher mineral content. The tabulated elemental data further supports these observations, highlighting variations in inorganic fractions that may influence pretreatment severity, catalytic stability, and overall efficiency in 5-HMF and 2,5-DMF Synthesis.

CONCLUSION

This study validates SEM–EDS as a rapid and reliable elemental screening tool for selecting lignocellulosic feedstocks for furan-based biofuel Synthesis. Sugarcane bagasse and corn stover exhibit high carbon (42–48 wt.%) and oxygen (44–48 wt.%) contents with minimal inorganic impurities (<3 wt.%), ensuring favorable carbon-to-oxygen ratios, improved carbohydrate accessibility, and stable catalytic performance during dehydration and hydrogenation to 5-HMF and 2,5-DMF. In contrast, rice straw contains elevated silicon and alkali metals, increasing the risk of ash formation and catalyst deactivation, thus requiring mineral-specific pretreatment. Overall, elemental composition is confirmed as a critical determinant of conversion efficiency, catalytic stability, and sustainable biorefinery design.

ACKNOWLEDGEMENT

The authors express their sincere gratitude to the management and administration of C V M University, Anand and SPEC Campus, Anand for the Kind support in the research work. No external funding was received for this research work.

ABSTRACT

Petroleum hydrocarbon pollution is a significant environmental issue, to which microbial biodegradation is a potential and environmentally friendly solution. This research focuses on isolating and identifying petroleum-degrading bacteria from petroleum-contaminated soil using the enrichment culture method with Bushnell-Haas media in which petrol was used as the single carbon source. Ten bacterial strains (PB1–PB10) were obtained by the streak plate method and identified by morphological and biochemical examinations, such as the hydrogen sulfide test, catalase test, and citrate test. The efficiency of petroleum degradation was measured quantitatively with a UV spectrophotometer, showing that strain PB5 had the highest degradation activity **(91.5%)**. The isolate was characterized as a gram-negative, rod-shaped bacterium that was catalase-positive, citrate-utilization positive, and hydrogen sulfide test positive. Molecular identification by 16S rRNA sequencing further validated the strain as *Enterobacter cloacae* DSM 30054. The findings of this study suggest that *Enterobacter cloacae* DSM 30054 has significant potential for bioremediation and can serve as an effective agent for restoring petroleum-contaminated ecosystems.

Keywords: Bioremediation, Bushnell Haas media, Hemocytometer, UV spectrophotometer, 16s rRNA Sequencing, *Enterobacter cloacae*.

INTRODUCTION

Petroleum products serve as the principal energy sources for home and industrial uses. The operations of extraction, exploration, refining, shipping, and storage of petroleum can result in leaks and inadvertent spills, posing considerable environmental risks. The annual amount of naturally occurring crude oil spills is estimated to be 600,000 metric tons, with an uncertainty of around 200,000 metric tons. (1). Additionally, a variety of human activities release hydrocarbons into the environment, which exacerbates soil and water contamination. (2). These pollutants can build up in living things, which can have detrimental consequences, including biodiversity loss, ecological disturbance, and mutations. Traditional remediation methods, such as dispersion, evaporation, mechanical removal, burial, or washing, can be costly and may not fully break down the pollutants. (3).

However, bioremediation has become a viable and environmentally beneficial substitute, employing microorganisms to efficiently break down petroleum hydrocarbons. (4). When compared to traditional approaches, bioremediation is more economical and sustainable since microorganisms are essential in the breakdown of toxic hydrocarbons into less hazardous compounds. (5). Numerous environmental elements, such as the amount of organic matter, nutrient concentrations, and oxygen availability, affect how well microorganisms biodegrade. The breakdown rate of petroleum pollutants may be greatly increased by optimizing these circumstances, which makes bioremediation a practical approach for managing oil spills and restoring the environment. (4). To increase the effectiveness of bioremediation, it is essential to choose and characterize bacterial strains that are very effective in breaking down petroleum. By identifying and using bacterial species with a high capacity for degradation, hydrocarbon breakdown may be greatly accelerated, opening the door for environmentally friendly methods of recovering petroleum-contaminated areas. (6).

Numerous reports indicate the isolation of petroleum hydrocarbon-degrading bacteria from areas affected by oil. (7). In their 2024 investigation, Nanekar et al. extracted native bacteria from oil-contaminated soils and evaluated their biodegradation capacity. Among the fifteen identified strains, the 2 most efficacious were chosen. Using 16S rRNA gene sequencing, the isolates were determined to be *Pseudomonas chengduensis* and *Pseudomonas donghuensis*(8). Fahad and colleagues (2019) carried out a study to separate and detect biodegradable bacteria from polluted areas at the Khurais oil field located in Dhahran, Saudi Arabia. Based on their capacity to flourish in the presence of hydrocarbon components, three bacterial strains were chosen from soils polluted by petroleum. The identification of these microbes as *Bacillus subtilis, Pseudomonas aeruginosa*, and *Bacillus cereus* was notably validated by 16S rDNA sequencing. (9). Sakthipriya et al. (2015) conducted a study on the degradation of crude oil using the biosurfactant-producing microorganism *Bacillus subtilis* to achieve optimal degradation results. This bacterium, isolated from a polymer dump site in Chennai, India, was employed for the crude oil degradation process. The study found that crude oil degradation reached 80%, while viscosity reduction was observed at 60% over 10 days. (10). This study aims to investigate the isolation and characterization of petroleum-degrading bacteria from contaminated soil, contributing to the development of efficient bioremediation strategies for petroleum pollution.

MATERIALS AND METHODS

Soil Sampling

Soil samples were collected from multiple petroleum filling stations in Hyderabad, Telangana. The samples were stored in sterile ziplock bags and transported to the laboratory for further analysis.

Enrichment and Isolation of Petroleum-Degrading Bacteria

Bushnell-Haas (BH) broth (specific media for hydrocarbons) was used for the enrichment and isolation of petroleum-degrading bacteria. A 50 mL volume of BH broth was inoculated with 100 mg and 200 mg of saline-washed soil samples. These samples were incubated for 7 days at 37°C with 150 rpm agitation for 15 minutes. For the isolation of

bacteria from the enriched culture, BH agar plates were prepared containing 1% (w/v) crude oil of petrol as the sole carbon source. The pour plate technique was employed, followed by serial dilution (10^{-6} to 10^{-7}) using sterile saline. A 1 mL sample from the enriched flask was used for dilution. Single colonies that grew were picked, marked, and purified using quadrant streak plating to obtain isolated colonies. The pure isolated colonies were transferred into Nutrient broth for further analysis (11).

Identification of Bacterial Isolates

The isolated bacterial cultures were characterized based on their morphological and biochemical traits.

Gram Staining

Gram staining's primary aim is to categorize certain unknown bacteria into gram-positive and gram-negative types based on their cellular structure and the composition of the cell wall. Smear the sample onto a clean, free slide and heat fix the sample. After that, place a drop of crystal violet dye onto the sample and let it sit for one minute. Comfortably rinse under running tap water. Add Gram's iodine to the slide and allow it to sit for one minute. Comfortably rinse under running tap water. Add ethanol for 30 seconds and rinse under running water. After that, put a drop cd Safranin on the slide and allow it for one minute, then rinse. Allow the slide to air dry and view under a microscope. (12).

Biochemical Tests

Starch Utilization Test

Starch is a complex polysaccharide; bacteria cannot utilize starch itself. Therefore, some bacteria produce alpha amylase enzymes to hydrolyse starch. To identify starch-hydrolyzing bacteria, a nutrient medium containing starch is prepared, and the bacterial suspension is spread in the center of the plate. After incubation, the starch is hydrolyzed around the bacterial growth. Since it is colorless, it is visualized by adding iodine. The unhydrolyzed starch turns a dark blue color. The hydrolyzed portion remains colorless. (13).

Citrate Utilization Test

The citrate utilization test is performed to determine if a bacterium can use citrate as a source of carbon. Simons Citrate Agar tubes are inoculated with a loop with overnight-grown bacterial cultures. The tubes are incubated for 24 hours at 35-37°C. After 24 hours, bacterial cultures that change the green to blue are considered positive results, while tubes that remain the same color are considered negative tests. (14).

Catalase test

The catalase test is done to detect the presence of catalase enzymes in the bacteria. The sample was streaked on a clean slide, and two drops of hydrogen peroxide solution were placed on the culture organism. Observation of Air bubbles results in positive results. (15).

Methyl Red test

The methyl red test will detect the stability of the bacteria to the acidic end product from glucose fermentation. Methyl red broth was prepared and sterilized. The broth was poured into the 10 mL tubes, and 1 mL of the inoculum was added and kept for incubation for 24 hours at **37°C.** After 24 hours, the MR indicator was added and observed for color change.

Voges-Proskauer (VP)

The test identifies whether the bacteria ferment glucose to produce a neutral end product. The bacteria were inoculated in MR-VP broth and incubated for 24 hours at 37°C. After 24 hours of incubation, α-naphthol and 40% KOH solution were added and shaken for 10 minutes, then observed for color change. (16).

Hydrogen sulphide production test

To detect whether the hydrogen sulphide gas is present or not through the Hydrogen sulphide production test. The labelled tubes with SIM medium are inoculated using a stabbing needle and then incubated at 37°C for 24-48 hours, after which they are observed for H2S production by the inoculated bacteria. (16).

Petrol degradation by isolates at different concentrations

The bacterial isolates were screened for the degradation of different petroleum hydrocarbons. To assess the growth behavior of the five selected strains at varying petroleum concentrations (ranging from 0.1% to 0.4%), the isolates were cultured on BHM medium supplemented with petroleum and diesel at concentrations of 0.1% to 0.4%. The cultures were incubated at room temperature for 14 days. Each culture was grown in 5 mL of BHM, which served as a selective medium that promoted the growth of hydrocarbon-utilizing bacteria while inhibiting those that were unable to use hydrocarbons as a carbon source. Petroleum concentrations ranged from 0.1% to 0.4%. After the incubation period, the petroleum degradation percentage was determined by measuring the optical density values of the different bacterial strains at 650 nm. These OD values were used in conjunction with the calibration curve and Beer-Lambert's Law to calculate the degradation percentage. (17).

Molecular characterization of the isolate

Preparation of genomic DNA

One ml of overnight bacterial broth was taken and centrifuged at 12000 rpm for 5 min, then the pellet was resuspended in 100 µl of TE buffer and 10 µl of lysozyme in 10mg/ml conc. Incubated the tubes at 37oC for 30 min. 20 µl of 20% SDS was added and 15 µl of Proteinase K at 20 mg/ml conc. was added. Then the tubes were incubated at 55°C for 1 hr. After adding 400 µl of 6M ammonium sulphate, it is vortexed thoroughly and centrifuged at 12,000 rpm for 5 min. Supernatant was pipetted out and an equal volume of ice-cold isopropanol was added and incubated at -20oC for 30 min. Then centrifuged at 10,000 rpm for 10 min. followed by a 70% ethanol wash. Air dried the pellet and dissolved it in a 1x TE buffer.

Amplification of 16S rRNA sequence by PCR Polymerase chain reaction (PCR) was performed for the amplification of the 16S region of the isolate by using the universal primers (Table 3). The reaction was performed in a final volume of 50µl, containing 2 µl of genomic DNA as template and 48 µl of PCR mix. Amplification was performed at different temperatures for 40 cycles. The amplification products were checked by resolving the PCR products in 0.8 % agarose gels. The agarose solution was cooled to 40oC and 15 µl of ethidium bromide solution (10mg/ml) was added. PCR products (5µl) were taken and mixed with 1µl of 6x gel loading buffer. Electrophoresis was performed for approximately 2.5 h at 60 mA. The PCR products were visualized on a gel doc (PCR-ABI 7200).

Universal primers of 16S rRNA

Forward 16sF 5′ – AGAGTTTGATCCTGGCTCAG- 3′
Reverse 16sR 5′- ACGGCTACCTTGTTACGACTT- 3′

were further used for BLAST analysis from the NCBI database to obtain the sequence similarity with related organisms. The sequences were multiple aligned with representative sequences of selected genera using CLUSTALAW program. The phylogenetic tree for the datasets was utilized to assess the relationship between the organisms using the PHYLIP analysis program. The sequences obtained were deposited in GenBank, and accession numbers were obtained. (18).

RESULTS AND DISCUSSION

Isolation and identification of Isolates

Soil samples collected from the multiple petrol filling stations were serially diluted and plated. 5 well-defined colonies were selected and cultured to obtain pure isolates. The colony morphology of the investigated isolated bacteria is presented in Table 1. All colonies exhibited a spherical shape, white color and smooth surface.

The biochemical characterization of the isolated strains revealed significant differences in their metabolic capabilities. Gram staining confirmed that all strains were Gram-negative. The catalase and H_2S production tests were positive for all strains, indicating their ability to produce catalase and hydrogen sulfide. Citrate utilization was observed in PB-3 and PB-8, while PB-9 tested negative, suggesting variations in their metabolic pathways from other isolates. Starch utilization was positive in PB-1, PB-2, PB-3, PB-4 and PB-9, indicating its ability to hydrolyze starch, while PB-5, PB-6, PB-7, PB-8, and PB-10 were negative (Table 2).

The methyl red test, which detects stable acid production, was positive for PB-1, PB-2, PB-3, PB-7 and PB-10 but negative for PB-4, PB-5, PB-6, PB-8 and PB-9 ,while the Voges-Proskauer test, which detects acetoin production, showed opposite results—PB-1, PB-4, PB-5, PB-6, PB-8, and PB-9 tested positive, while PB-2, PB-3, PB-7, and PB-10 was negative. Nearly all the isolates thrived on the BH medium supplemented with petrol. PB-2, PB-5, and PB-8 exhibited the highest growth in the presence of petrol. Therefore, we chose PB-2, PB-5, and PB-8 for further analysis. Mordecai et al. (2024) demonstrated that more than 30 bacterial species are capable of degrading complex polycyclic aromatic hydrocarbons. This finding presents opportunities to enhance bioremediation techniques in areas contaminated by petroleum. (19). Chhanada et al. (2020) discovered fourteen bacterial strains from soil polluted with petroleum oil in their investigation. The identified strains are based on biochemical assays. Of them, three exhibited the greatest tolerance to all three oil types at concentrations between 1% and 7%. These isolates, on average, demonstrated the ability to use petroleum compounds like diesel, petrol, and kerosene, but with differing levels of efficacy. The biodegradation outcomes were most advantageous for diesel, but petrol showed the least degradation, with only Bacillus spp. possessing the capability to break down petrol. (20).

Petroleum degradation by strains at different concentrations of petrol

The isolates PB-2, PB-5, and PB-8 were cultured on BHM medium supplemented with varying concentrations (1% to 4%) of petrol for 14 days at ambient temperature. After this incubation period, growth rates were measured by optical density, and the degradation percentage was calculated using a calibration curve for petrol (Figure 1). The degradation efficacy of the strains ranged from 3% to 4% of the petrol concentration. Among the isolates, PB-5 exhibited the highest level of petroleum degradation, with a degradation percentage of 91.5%. (Figure 2) PB-8 also demonstrated petrol degradation, although to a lesser extent than PB-5, achieving 80.79% degradation. PB-2 showed a degradation rate of 23.61%. These results align with the study by Tahir and colleagues identified three bacterial strains and cultivated them in five different petroleum oil concentrations (1%, 1.5%, 2%, 2.5%, and 3%). The results indicated that all isolates were capable of degrading petroleum at a concentration of 3% v/v (21). In the study by Pratiha et al. (2024), soil samples were collected from the petrol unloading area of a petrol station. Using an enrichment technique with Bushnell-Haas medium, nine petrol-degrading bacterial isolates were identified. These bacteria demonstrated the ability to degrade up to 5% petrol, with the most effective degraders selected based on their cell mass when cultivated in the presence of petrol. (22).

Molecular characterization of PB-5 Isolates

Based on the petroleum degradation results, isolate PB-5 was selected for molecular characterization. The nucleotide sequences of the 16S rRNA gene (Figure 3) were used to identify the strain at the species level. Phylogenetic analysis (Figure 4) revealed that strain PB-5 corresponds to *Enterobacter cloacae* DSM 30054. This outcome aligns with the conclusions of Ramasamy et al. (2017).

According to their study's use of GC-MS analysis, *E. cloacae* efficiently broke down docosane, tridecane, hexadecane, and heptadecane by 99.7%, 99.2%, and 99.6%, respectively. The study shows that, with the help of biofilm development, E. cloacae may bio remediate hydrocarbons in diesel oil quickly (23). Research conducted by Ejaz et al. (2021) demonstrated that the *Enterobacter cloacae* subspecies was the most efficient strain for the degradation of crude oil (24). Jemil and colleagues (2018) identified the *Enterobacter cloacae C3* bacterium from natural gas condensate-contaminated soil in Sfax City, Tunisia. After around 15 days of incubation, this strain reached a maximum diesel oil degradation of 48.1% (2% v/v) in a mineral salts medium when 0.1% (w/v) lipopeptides were added. (25).

CONCLUSION

This study identified strain PB-5 as the most effective petroleum-degrading bacterium, highlighting its potential for environmental cleanup. Morphological, biochemical, and UV spectrophotometric analyses, along with 16S rRNA sequencing, confirmed that PB-5 is a Gram-negative, catalase-positive, hydrogen sulfide-positive, and citrate-utilizing bacterium. Among the tested strains, PB-5 exhibited the highest growth and degradation efficiency, followed by PB-8 and PB-2. 16S rRNA sequencing confirmed PB-5 as *Enterobacter cloacae* DSM 30054 strain. Our research work revealed that *Enterobacter cloacae* is a significant organism for bioremediation and plays a crucial role in cleaning up petroleum-contaminated environments. *Enterobacter cloacae* DSM 30054 provides a sustainable and cost-effective solution for petroleum biodegradation.

ABSTRACT

The diagnosis of genetic disorders is transitioning from labour-intensive manual interpretation to high-precision, automated workflows driven by Artificial Intelligence (AI). Traditional methods, relying on clinician-dependent sequencing, imaging, and phenotyping, often struggle with the high dimensionality of genomic data and the subtlety of early subclinical signs. This review examines the transformative role of Machine Learning (ML) and Deep Learning (DL) in enhancing diagnostic accuracy across a spectrum of conditions, from monogenic diseases like Cystic Fibrosis and Sickle Cell Anaemia to complex multifactorial disorders such as Hypertrophic Cardiomyopathy and Alzheimer's. By integrating diverse data streams, including high-resolution imaging (CT, MRI, OCT), physiological signals (ECG, digital auscultation), and multi-omic sequences, AI models identify "hidden" biomarkers and non-linear gene-gene interactions. These advancements facilitate objective quantification of disease severity, earlier detection, and personalized risk assessment. Ultimately, AI serves as an integrative diagnostic platform, bridging the gap between raw biological data and actionable clinical decision support to improve global health outcomes.

Keywords: Artificial, Analysis, Genetic, Diagnosis, Medicine, Syndrome.

INTRODUCTION

Genetic disorders include a broad range of problems, ranging from rare diseases caused by a single gene mutation to complex, multifactorial disorders shaped by the interplay of genetics and environmental influences,, represent a significant worldwide health burden[1] .Manually interpreting genetic sequencing, clinical phenotyping, medical imaging, and laboratory assays are examples of traditional diagnostic techniques that are frequently laborious, operator-dependent, and have a limited capacity to combine vast, diverse information[2]. For diseases with diverse

phenotypic expression or early subclinical signs, these constraints often lead to inadequate disease treatment, delayed diagnosis, and diagnostic uncertainty. The detection and diagnosis of genetic abnormalities has been developed by artificial intelligence (AI), especially by machine learning (ML) and deep learning (DL)(3). AI systems may detect tiny patterns that are frequently invisible to human experts by enabling automated analysis of high-dimensional and complicated data, such as clinical records, physiological signals, biochemical parameters, medical imaging, and genomic sequences (4). Artificial intelligence (AI) models, in contrast to traditional rule-based techniques, learn directly from big datasets, enabling improved diagnosis accuracy and ongoing performance improvement while drastically lowering inter-observer variability and diagnostic turnaround time (5). AI has shown significant clinical utility in monogenic disorder across a variety of disease areas. Digital stethoscopes and AI-driven remote monitoring systems can detect pulmonary exacerbations early in cystic fibrosis, while deep learning-based analysis of high-resolution chest CT scans allows objective quantification of airway anomalies [6,7,8]. Convolutional neural networks reliably identify pathological, red blood cell morphologies from peripheral blood smears for hematological disorders like sickle cell anemia and thalassemia, and machine learning models that use complete blood count parameters allow for quick, economical screening in low-resource environments [9,10]. Similar to how AI-enhanced genomic variant interpretation, muscle MRI analysis, and histopathological evaluation have expedited diagnostic workflows in Duchenne muscular dystrophy, AI-assisted neuroimaging, biomarker analysis, and motor assessment tools have improved early diagnosis and disease monitoring in Huntington's disease [11,12,13].

AI-based optical coherence tomography (OCT) analysis allows for accurate distinction from clinically comparable retinal illnesses and exact volumetric estimation of schisis cavities in inherited retinal disorders like X-linked retinoschisis [14]. Additionally, AI is becoming more and more important in multifactorial genetic illnesses, especially those that impact the metabolic and cardiovascular systems. AI-enhanced ECG and automated cardiac imaging analysis facilitate early disease identification and better distinction from physiological hypertrophy in hypertrophic cardiomyopathy [15,16,17].Natural language processing and computer vision techniques improve case identification in ordinary clinical practice by extracting clinically significant elements from unstructured medical records and physical findings related to familial hypercholesterolemia [18,19].The use of AI-driven imaging and phenotypic prediction models improves risk assessment and longitudinal tracking of the course of aortic disease in connective tissue illnesses like Marfan syndrome. AI has also greatly improved the identification and diagnosis of genetically driven tumors, such as those of the breast, ovaries, and pancreas [20,21,22].

Radio genomics techniques enable AI to deduce underlying genetic changes from imaging characteristics, thereby converting radiological scans into digital biopsies that are non-invasive [23,24]. By simulating intricate gene-gene interactions that are outside the purview of conventional statistical techniques, AI-optimized polygenic risk scores significantly enhance personalized cancer risk prediction [25,26]. AI-based multimodal frameworks that integrate imaging, genomic, and phenotypic data have demonstrated remarkable potential for early and accurate diagnosis, even before over clinical symptoms manifest, in prenatal and neurodegenerative disorders including Down syndrome and Alzheimer's disease. When taken as a whole, these developments demonstrate AI's expanding function as an integrative diagnostic platform that can integrate digital biomarkers, genomes, imaging, and clinical data into coherent decision-support systems [27,28,29,30]. As AI develops, its incorporation into genetic diagnostics could lead to better clinical results, more equitable access to high-quality healthcare globally, early detection, and individualized disease management [31,32]. In addition to discussing current issues, moral dilemmas, and potential paths forward for AI-driven precision medicine. [33,34]. This review critically analyzes current AI approaches, for diagnosis of a wide spectrum of genetic disease

AI in Detection of Various Types of Genetic Disorders-

By enabling automated interpretation of complex data, including genomic sequences, phenotypic pictures, and clinical traits, artificial intelligence (AI)is a revolutionary genetic diagnostics tool. These methods greatly improve diagnosis speed and accuracy by directly learning patterns from massive datasets, overcoming the drawbacks of conventional manual analysis [35].

AI in Cystic fibrosis

Image processing technologies based on artificial intelligence (AI) has improved the pulmonary abnormalities in cystic fibrosis (CF). High-resolution chest computed tomography (CT) scans can be automatically analyzed by deep learning algorithms to identify, map, and measure structural lung abnormalities like bronchiectasis, airway wall thickening, air trapping, and mucus plugging. Rapid, repeatable, and objective evaluation of disease severity is made possible by platforms like Thirona's PRAGMA-AI (Perth-Rotterdam Annotated Grid Morphometric Analysis)[36,37].

AI-powered remote monitoring systems incorporate information from wearable activity trackers, spirometers, and symptom-reporting apps, among other home-based medical devices. In order to detect minute alterations that precede pulmonary exacerbations (PEx), machine learning models examine patterns in the deterioration of lung function, physical activity, and physiological markers. Early identification of these patterns enables medical professionals to start therapy promptly, potentially averting serious exacerbations, lowering hospital stays, and enhancing CF patients' quality of life[38,39]. AI- Enabled digital stethoscopes can detect abnormal lung sounds like crackles, rhonchi, and wheezes by using machine learning algorithms that have been trained on massive datasets of respiratory sounds. These technologies offer continuous, and remote lung health monitoring for the treatment of cystic fibrosis. (40,41,42].

Al in Sickle cell anemia

Deep learning–based convolutional neural networks (CNNs) have shown exceptional performance in identifying sickled erythrocytes from peripheral blood smear images. Complex morphological patterns, such as crescent forms, elongated cells, and membrane abnormalities, can be learned by architectures like ResNet50, GoogLeNet (Inception-V1), and Darknet19[43,44]. According to several studies, categorization accuracy ranges from 95% to over 99%, far exceeding manual microscopy and conventional image processing techniques. Reliable deployment in clinical settings is made possible by transfer learning, which further increases robustness when training data is scarce[45]. Recent developments use inexpensive 3D-printed optical attachments to integrate AI algorithms with smartphone-based microscopy equipment. These portable platforms use CNN-based models either directly on the device or through cloud computing after capturing high-resolution blood smear images[46]. These technologies offer quick, on-site SCD screening, which is especially helpful in rural and low-resource environments. Validation tests significantly lower costs, infrastructure needs, and turnaround times while demonstrating diagnostic performance on par with laboratory-grade microscopes[47,48]. Machine learning models that use complete blood count (CBC) data, such as hemoglobin concentration, mean corpuscular volume (MCV), and mean corpuscular hemoglobin (MCH), have proven to be highly predictive for sickle cell disease (SCD) in addition to image-based approaches. Algorithms such as support vector machines (SVM), random forest, and artificial neural networks (ANNs) can differentiate SCD patients from healthy individuals with high accuracy. These methods allow for quick, non-microscopic screening, which is especially helpful in situations without imaging infrastructure [49].

AI in Huntington's Disease-

Deep learning frameworks, particularly Convolutional Neural Networks (CNNs), have shown remarkable effectiveness in identifying early neurodegenerative changes associated with Huntington's disease. Structural MRI investigations consistently reveal atrophy in the striatum (including the caudate and putamen), even for individuals in the premanifest stage of HD[50]. CNN-based approaches can autonomously identify spatial patterns linked to neurodegeneration, surpassing conventional voxel-based morphometry methods. The integration of functional MRI (fMRI) with deep learning techniques has highlighted disrupted connectivity within the cortico-striatal and default mode networks prior to the onset of clinical symptoms[51,52]. Machine learning methods are being increasingly employed to pinpoint subtle biomarkers such as mutant huntingtin (mHTT), neurofilament light chain (NfL), and transcriptional profiles obtained from blood and cerebrospinal fluid (CSF) samples. AI demonstrates superior capability in recognizing nonlinear interactions among biomarkers that are often overlooked by traditional statistical methods [53,54].

AI-assisted evaluations of speech recordings, gait characteristics, and hand movements have exhibited a high level of sensitivity in analysing speech recordings, walking patterns, and hand motions with AI has demonstrated a strong ability to identify early motor dysfunctions, such as dysarthria, which frequently occur before a clinical diagnosis is made[55,56]. Deep learning algorithms that focus on voice characteristics deliver impressive classification results [57]. Predictive models driven by AI facilitate the estimation of individual disease progress, aiding in the development of personalized care approaches and enhancing patient selection in clinical trials. These models assist in simulating treatment impacts and increasing the sensitivity of outcomes [58,59].

AI in Duchenne Muscular Dystrophy

Large amounts of genomic data are produced by next-generation sequencing (NGS) methods, which makes manual processing laborious and prone to error. Algorithms powered by AI improve variant calling and understanding by finding point mutations, massive deletions, and duplications in the DMD gene, using machine-learning classifiers to prioritize harmful variations, estimating the functional effects of new or uncommon mutations [60]. Convolutional neural networks (CNNs) and random forest models are examples of deep learning methods that reduce false-negative rates and diagnostic delays by differentiating benign polymorphisms from disease-causing variations [61].

One important non-invasive diagnostic and monitoring technique for DMD is muscle MRI. MRI scans can be automatically analyzed by AI models to recognize early edema and muscle fat invasion, Calculate the patterns of muscle deterioration, Distinguish DMD from other myopathies and Becker muscular dystrophy (BMD). By extracting small imaging signals that are difficult for human observers to identify, radiomics-based AI techniques enable earlier diagnosis, even before severe clinical weakening manifests [62]. In unusual or genetically ambiguous instances, muscle biopsy investigation is still relevant. AI-driven systems for analyzing images can: Automatically measure fibrosis, necrosis, and variations in muscle fiber size, use immunohistochemistry to identify patterns of dystrophin expression. In neuromuscular pathology, these approaches improve diagnostic consistency and objectivity [63].

AI in Thalassemia

The most common application of AI is in the analysis of automated complete blood count CBC parameters, such as RDW, MCV, MCH, and Hb. Conventional formulas, such as the Mentzer Index, frequently do not differentiate between Thalassemia Trait and Iron Deficiency Anemia. Machine Learning Models by examining non-linear connections between blood indicators, algorithms like XGBoost, Random Forest, and Support Vector Machines (SVM) can distinguish various conditions with 95–99% accuracy. Carrier Detection Deep Thal and other AI frameworks are specifically made to find carriers of alpha thalassemia, which are notoriously hard to find using conventional laboratory cutoffs [64,65]. The laborious manual microscopy of blood films is automated by AI-powered picture analysis. Cell Morphology: Convolutional Neural Networks (CNNs), a type of deep learning model, are taught to recognize pathognomonic (disease-defining) cells, including microcytic hypochromic cells and cytokines (target cells) [66].Virtual Staining: AI can "virtually stain" grayscale blood pictures thanks to recent developments in Generative Adversarial Networks (GANs), which lowers laboratory expenses and preparation time in remote clinics[67].

AI in hemoglobin electrophoresis and HPLCAI is being used into specific diagnostic workflows Deep learning can classify alpha and beta thalassemia subtypes with more than 95% accuracy by interpreting hemoglobin electrophoresis bands. In complex circumstances, AI reduces human mistake by acting as a expert system, combining HPLC data with patient demographics to produce a final diagnostic probability [68].

AI in Retinoschisis

The existence of schisisk2p cavities in the retinal layers that resemble cysts is the defining feature of XLRS [69]. Central Subfield Thickness (CST) has historically been utilized by clinicians as a stand-in for the severity of an illness. However, AI-quantified Schisis Volume (ASV), a more accurate statistic, may now be produced by AI models. Optical Coherence Tomography (OCT) images can be used to segment these voids in three dimensions using deep learning algorithms. Studies have demonstrated that ASV is a more sensitive structural endpoint than conventional

thickness assessments, enabling smaller sample sizes in gene therapy clinical studies [70,71]. Differentiating between retinoschisis and hematogenous retinal detachment (RRD) is one of the most important clinical issues because their therapies are fundamentally different (surgery vs. observation/medication) [72]. Convolutional Neural Networks (CNNs) are used in AI-assisted OCT analysis to pinpoint the precise retinal layers at play. AI recognizes retinoschisis by the distinctive splitting inside the inner or outer nuclear layers, whereas RRD entails a separation between the neurosensory retina and the RPE. With sensitivities above 90%, AI-integrated OCT equipment may now automatically identify up to 15 distinct retinal conditions, including retinoschisis [73].

AI in Multi-Gene (Multifactorial) Disorders

AI in Hypertrophic Cardiomyopathy

The most prevalent hereditary cardiac condition, HCM, is typified by an excessively thick heart muscle (hypertrophy) that can impede blood flow and cause sudden cardiac death. Genetic Basis Autosomal dominant disorders are the most common type[74]. The "engines" of heart muscle contraction, sarcomere proteins, are encoded by genes that are mutated in the majority of cases. The two main genes responsible for about 75% of known mutations are MYH7 (β-myosin heavy chain) and MYBPC3 (myosin-binding protein C)[75]. Non-specific indicators of HCM, such as left ventricular hypertrophy (LVH) voltage, are frequently seen on standard ECGs. Convolutional Neural Networks (CNNs), a type of artificial intelligence system, are able to identify "hidden" signs in the raw electrical data that human interpretation could overlook. Research has demonstrated that AI- Electrocardiography models can detect HCM with an Area Under the Curve (AUC) of 0.92–0.96 [76]. AI is used to automate complicated measurements in cardiac magnetic resonance imaging (CMR) and echocardiography. Wall Thickness & Volumes measure AI reduces inter-observer variability (differences between human readers) by automating and objectively quantifying myocardial thickness. By examining patterns of myocardial strain and fibrosis, AI assists in differentiating genuine HCM from Athlete's Heart or other types of hypertrophy [77].

AI in Hypercholesterolemia in Families (FH)-

A large portion of the information supporting FH, such as physical exam results or a family history of early heart attacks is buried in unstructured doctor's notes. Clinical scoring systems like the Dutch Lipid Clinic Network (DLCN) can be made much more accurate by using AI-powered natural language processing (NLP) to analyze these notes and extract clinical variables that are missed by standard databases [78]. Novel artificial intelligence models are being created to examine digital pictures of the skin or eyes. AI can accurately identify xanthomas (cholesterol deposits on tendons) and corneal arcus (a white ring in the eye), helping with diagnosis in primary care settings where a specialist may not be available [79].

AI in Marfan Syndrome (MFS)

Aortic Root Dilatation, is automatically detected by AI. Automated Measurements: Compared to manual measurement, deep learning models can more consistently calculate Z-score (standardized diameter) by precisely segmenting the aorta on CT images and echocardiograms. Using AI to examine skeletal muscle density on CT scans, recent study has discovered that specific muscle patterns, such as the psoas muscle index, can forecast how MFS patients' aorta enlargement will develop [80]. Ectopia Lentis and other ocular abnormalities are linked to cardiovascular risk using artificial intelligence. Stacking Machine Learning Models: Up to 75% predictive accuracy is achieved by recent models that combine genetic information with ocular characteristics (such as axial length) to forecast if a child with displaced lenses would experience significant cardiac organic diseases [81].

AI in Breast and Ovarian Cancer

AI is able to recognize imaging phenotypes that are associated with underlying genetic alterations. Commercial AI techniques can detect modest mammographic abnormalities 4–6 years before a clinical diagnosis, according to a 2025 large-scale study that included 116,495 women [82]. The AI score discrepancies between breasts in women who were destined to acquire cancer grew with time (79.0 points at discovery vs to 7.1 in healthy controls). Using CT or MRI texture analysis alone, AI models are becoming more adept at differentiating high-grade serous ovarian carcinomas (which are frequently BRCA-linked) from sporadic kinds, serving as a non-invasive stand-in for genetic testing [83].

AI examines the combined impact of thousands of tiny genetic variations, whereas conventional testing searches for significant mutations (BRCA1/2). Research published in 2025 showed that a 313-SNP AI risk score could predict which women with DCIS (stage 0 breast cancer) were most likely to develop invasive disease, with those in the highest risk quartile being 2.03 times more likely to develop contralateral cancer. This is because new neural network architectures (Graph Neural Networks and Autoencoders) now model non-linear gene-gene interactions that linear models [84].

AI in Pancreatic cancer

The interpretation of imaging modalities frequently employed in the assessment of pancreatic cancer has significantly improved thanks to artificial intelligence, particularly machine learning (ML) and deep learning (DL). Computed Tomography has been shown that DL models, such as convolutional neural networks (CNNs), can automatically identify pancreatic cancers and accurately segment tumor boundaries, even in the early stages when human readers might overlook minute irregularities [85]. Endoscopic Ultrasound is an AI technique used on EUS pictures improve diagnostic sensitivity and specificity by distinguishing benign from malignant pancreatic lesions. When incorporated into machine learning models, feature extraction from imaging that is not visible to the human such as texture, form, and intensity improves tumor characterization and classification [86].

AI in Histopathology

Although histopathological confirmation is still the most reliable method of diagnosis, manual analysis is laborious and prone to inter-observer variation. AI-driven examination of histopathology slides improves diagnostic consistency by differentiating pancreatic tumor subtypes and identifying characteristics consistent with malignancy. By connecting morphological characteristics with underlying genetic changes, these methods can facilitate the discovery of biomarkers [87].

AI in Down Syndrome

Artificial intelligence (AI) systems, namely deep learning convolutional neural networks (CNNs), have been created to enhance and automate ultrasound analysis for the detection of Down syndrome with good classification performance (accuracy up to ~98%, AUC ~0.98), DL architectures trained on prenatal ultrasound images can recognize important markers like nuchal translucency (NT) and nasal bone (NB) in first-trimester scans. Early pregnancy examinations can be more objective and repeatable thanks to automated image analysis, which lessens reliance on operator expertise and measurement variability [88]. Through noninvasive image analysis, AI-based facial image analysis which uses deep learning to identify phenotypic features linked to Down syndrome shows excellent accuracy and could help with postnatal screening for infants and young children [89]. According to reviews, AI models trained on genetic data, face features, and ultrasound pictures show great diagnostic potential; ultrasound models have specificity up to 100%, while facial image classifiers have accuracy rates of ~88–99% [90].

AI in Alzheimer's disease

AI is particularly good at deciphering high-dimensional genetic data with intricate relationships, particularly machine learning (ML) and deep learning (DL)[91]. Research has shown that AI techniques can examine gene expression profiles, genome-wide variation, and the relationships between gene networks implicated in the pathophysiology of AD. Determine the genetic signatures and combinations of risk alleles (such APOE ε4) that are associated with the start and progression of AD. Improve early diagnosis prediction models that integrate genetic risk with imaging and clinical data [92,93].

AI-Enhanced Neuroimaging

With great accuracy (typically >95% in structured frameworks), CNNs and hybrid DL models can distinguish between AD and moderate cognitive impairment (MCI) and healthy controls. AI is able to identify fine-grained characteristics from MRI scans much earlier than human readers alone, including cortical thinning and hippocampus atrophy [94].

AI in Asthma

AI uses Convolutional Neural Networks (CNNs) to identify the expression of these genes through sound, while genetic predisposition serves as the basis [95].AI systems are now able to distinguish between asthma and COPD with over 90% accuracy by analyzing voice pitch and cough patterns, frequently identifying flare-ups brought on by genetic hyperresponsiveness [96].

CONCLUSION

The integration of Artificial Intelligence (AI) into the diagnostic landscape of genetic disorders represents a transformative shift toward precision medicine. By leveraging machine learning and deep learning architectures, clinicians can now move beyond the limitations of manual interpretation. From the automated quantification of structural lung anomalies in cystic fibrosis to the high-accuracy detection of sickled erythrocytes and neurodegenerative biomarkers, AI has proven its ability to identify subtle pathological patterns invisible to the human eye.Furthermore, the emergence of radiomics and polygenic risk scores has turned standard imaging and genomic data into powerful predictive tools, enabling early intervention and personalized management. While challenges regarding data privacy and algorithmic ethics remain, AI's role as an integrative diagnostic platform is undeniable. Ultimately, these advancements promise a future of more equitable, rapid, and accurate healthcare, significantly improving clinical outcomes for patients with both monogenic and complex multifactorial genetic conditions.

ABSTRACT

In this paper, the defensive alliance adjacency matrix and its corresponding energy are introduced for a (p,q)-graph.A defensive alliance adjacency matrix of G with a minimum defensive alliance set L, is a $p \times p$ matrix whose entries are defined as 1if $i \neq j$, and $v_i v_j \in E(G)$or$i = j$, and$v_i \in L, (\ i,j = 1,2,3,\ldots.p)$, else zero.Further, the algebraic properties such as spectrum, spectral radius, spectral gab, determinant, rank, trace and energy of the defensive alliance adjacency matrix are studied for some standard classes of graphs. In addition, the bounds for the above parameters are established.

Keywords: Adjacency matrix, Defensive alliance set, Defensive alliance adjacency matrix, Defensive alliance energy.
2020 AMS Subject Classification:05C50, 05C07

INTRODUCTION

Let $G = (V,E)$be a simple, undirected, and connected with p vertices and q edges is called (p,q) graph. All the graphs used in this paper are referred from [5].The basic terminologies, namely the degree of a vertex v in G is denoted as$deg_v(G)$.The open andclosed neighbourhood of a vertex v in a set $L \subseteq V(G)$ are respectively defined as $N_L(v) = \{u \in L: uv \in E(G)\}$ and $N_L[v] = N_L(v) \cup \{v\}$. Also, $deg_L(v) = |N_L(v)|$ and $\bar{L} = V - L$. A non-empty set of vertices $L \subseteq V(G)$ is a defensive alliance set if for every vertex $v \in L$, $deg_L(v) + 1 \geq deg_{\bar{L}}(v)$ .The defensive alliance number of G denoted by $\alpha_{da}(G)$, is the minimum cardinality of all defensive alliance sets in G are introduced[1,6].The adjacency matrix $A(G)$ of G is the $p \times p$ matrix whose (i,j)-entry is 1 if the vertices v_i and v_j are adjacent in G and zero

otherwise. All matrix related terms are referenced from[3].The spectrum refers to the set of eigenvalues of $A(G)$, along with their number of time occurrence.Since A is a real symmetric matrix, all eigenvalues of G are real, and their sum is zero. The energy $E(G)$ of $G$is the sum of the absolute values of eigen values of $A(G)$ which is introduced by[4,7,9]. The fundamental properties of graph energy, including various upper and lower bounds, are discussed in[2,8,10]. Notably, graph energy has significant chemical applications, particularly in the molecular orbital theory of conjugated molecules. In this paper, by defining an adjacency matrix of a defensive alliance set, a new matrix namely defensive alliance adjacency matrix is introduced and the corresponding energy values are obtained for some standard class of graphs.

METERIALS AND METHODS

Definition 2.1A defensive alliance adjacency matrix (DA-matrix) of a (p,q)-graph G with minimum cardinality defensive alliance set L , is a $p \times p$ matrix defined as,

$A_{da}(G)=\begin{cases} 1, \ if\ i \neq j, v_i v_j \in E(G) \\ 1, \ if\ i = j, v_i \epsilon L \\ 0, \ otherwise \end{cases}$, $i,j = 1,2,\dots p$ and its characteristic equation $f_{da}(G) = |\lambda I - A_{da}(G)| = 0$

Definition 2.2 The defensive alliance energy of G is defined as the sum of all absolute value of eigen values of the defensive alliance adjacency matrixA_{da}(G) of G, here $\lambda_1^{da} \geq \lambda_2^{da} \geq \cdots \geq \lambda_p^{da}$ are the eigenvalues of the real symmetric matrix $A_{da}(G)$.

Notations2.3 Foranygraph,$S_{da}(G), \rho_{da}(G), \delta_{da}(G), \beta_{da}^{\lambda}(G), \beta_{da}^{|\lambda|}, |A_{da}(G)|, trace\big(A_{da}(G)\big), rank\big(A_{da}(G)\big), E_{da}(G)$ and $\alpha_{da}(G)$ are respectively denoted as spectrum, spectral radius ,spectral gab, sum of the eigen values, sum of all absolute value of eigen value, determinant, trace, rank, energy andalliance number of the defensive alliance adjacency matrix of G.Through out the paper, we denote L as the defensive alliance set with cardinality $\alpha_{da}(G)$ and hence it is denoted as $\alpha_{da}(G)$-set.

Example: 2.4

For the graph G in Figure 1, the $\alpha_{da}(G)$-set$L = \{v_2, v_3\}$,$A_{da}(G) = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 1 & 1 & 0 \\ 0 & 1 & 1 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}$

$f_{da}(G) = \lambda^4 - 2\lambda^4 - 2\lambda^2 + 2\lambda + 1 = 0$,$|A_{da}(G)| = 1$,$trace\big(A_{da}(G)\big) = 2$

$rank\big(A_{da}(G)\big) = 4$, $\beta_{da}^{\lambda}(G) = 2$, Spectrum, $S_{da}(G) = \begin{cases} \pm 1, \ one\ time \\ \pm\sqrt{2}+1, \ one\ time \end{cases}$

Spectral radius, $\rho_{da}(G) = \sqrt{2}+1$,Spectral gab δ_{da}=$2\sqrt{2}$,

Hence $E_{da}(G) = |1| + |-1| + \left|\sqrt{2}+1\right| + \left|-(\sqrt{2}+1\right| = 4.8284$

Theorem 2.5 For the Cocktail party graph $K_{n\times 2}, n \geq 4$,

$(i)|A_{da}(K_{n\times 2})| = (-1)^{n-1}(n-1)$

$(ii) trace\big(A_{da}(K_{n\times 2})\big) = n$

$(iii) rank\big(A_{da}(K_{n\times 2})\big) = 2n (vi) \beta_{da}^{\lambda}(K_{n\times 2}) = n$

$(v) \rho_{da}(K_{n\times 2}) = \dfrac{\sqrt{(2n-2)^2+1} + (2n-1)}{2}$

$(vi) \delta_{da}(K_{n\times 2}) = \sqrt{(2n-2)^2+1}$

$(vii)\ E_{da}(K_{n\times 2}) = \sqrt{(2n-2)^2+1} + \sqrt{5}(n-1)$

Proof: Let G be a Cocktail party graph $K_{n\times 2}$ with at least four vertices and $V(G) = \{u_1, \dots u_n, v_1, \dots v_n\}$and where$deg(u_i) = \deg(v_i) = 2n-1, i = 2\ to\ n-1,\ \deg(u_j) = \deg(v_j) = 2n-2, j = 1,2$.Then $L = \{v_1, v_2\}$ is a $\alpha_{da}(G)$-set of G.

It gives the defensive alliance adjacency matrix is

$$A_{da}(G) = \begin{pmatrix} 1 & 1 & 1 & 1 \dots\dots\dots & 1 & 1 & 1 & 0 \\ 1 & 1 & 1 & 1 \dots\dots\dots & 1 & 1 & 0 & 1 \\ 1 & 1 & 1 & 1 \dots\dots\dots & 1 & 0 & 1 & 1 \\ 1 & 1 & 1 & 1 \dots\dots\dots & 0 & 1 & 1 & 1 \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ 1 & 1 & 1 & 0 \dots\dots\dots & 0 & 1 & 1 & 1 \\ 1 & 1 & 0 & 1 \dots\dots\dots & 1 & 0 & 1 & 1 \\ 1 & 0 & 1 & 1 \dots\dots\dots & 1 & 1 & 0 & 1 \\ 0 & 1 & 1 & 1 \dots\dots\dots & 1 & 1 & 1 & 0 \end{pmatrix}$$

Then the characteristic equation of $A_{da}(G)$ is,

$$f_{da}(G) = \begin{vmatrix} \lambda-1 & -1 & -1 & -1 \dots\dots\dots & -1 & -1 & -1 & 0 \\ -1 & \lambda-1 & -1 & -1 \dots\dots\dots & -1 & -1 & 0 & -1 \\ -1 & -1 & \lambda-1 & -1 \dots\dots\dots & -1 & 0 & -1 & -1 \\ -1 & -1 & 1 & \lambda-1 \dots\dots\dots & 0 & -1 & -1 & -1 \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ -1 & -1 & -1 & 0 \dots\dots\dots & \lambda & -1 & -1 & -1 \\ -1 & -1 & 0 & -1 \dots\dots\dots & -1 & \lambda & -1 & -1 \\ -1 & 0 & -1 & -1 \dots\dots\dots & -1 & -1 & \lambda & -1 \\ 0 & -1 & -1 & -1 \dots\dots\dots & -1 & -1 & -1 & \lambda \end{vmatrix} = 0$$

It gives the following spectrum of G,

$$\rho_{da}(G) = \begin{cases} \dfrac{\sqrt{5}-1}{2} & ,(n-1)times \\ \dfrac{-\sqrt{5}-1}{2} & ,(n-1)times \\ \dfrac{\pm\sqrt{(2n-2)^2+1}+(2n-1)}{2} & ,one\ time\ each \end{cases}$$

Hence the defensive alliance energy of G is

$$E_{DA}(G) = \left|\frac{\sqrt{5}-1}{2}\times(n-1)\right| + \left|\frac{-(\sqrt{5}-1)}{2}\times(n-1)\right| + \left|\frac{\pm\sqrt{(2n-2)^2+1}+(2n-1)}{2}\right|$$

$$= \left|\frac{\sqrt{5}-1}{2}\times(n-1)\right| + \left|\frac{-(\sqrt{5}-1)}{2}\times(n-1)\right| + \left|\frac{+\sqrt{(2n-2)^2+1}+(2n-1)}{2}\right| + \left|\frac{-(\sqrt{(2n-2)^2+1}+(2n-1))}{2}\right|$$

$$= 2\times\frac{\sqrt{5}}{2}(n-1) + 2\times\frac{\sqrt{(2n-2)^2+1}}{2}$$

$E_{DA}(G) = \sqrt{(2n-2)^2+1} + \sqrt{5}(n-1)$.

For example,

For the graph G in Figure 2, the $\alpha_{da}(G)$-set$L = \{v_1, v_2, v_3\}$,

$$A_{da}(G)=\begin{pmatrix}1&1&1&1&1&0\\1&1&1&1&0&1\\1&1&1&0&1&1\\1&1&0&0&1&1\\1&0&1&1&0&1\\0&1&1&1&1&0\end{pmatrix}$$

$f_{da}(G)=\lambda^6-3\lambda^5-9\lambda^4+7\lambda^3+9\lambda^2-9\lambda+2, |A_{da}(G)|=2, trace\big(A_{da}(G)\big)=3,\ rank\big(A_{da}(G)\big)=6,\ \beta^{\lambda}_{da}(G)=3$, spectrum, $S_{da}(G)=\begin{cases}\pm\frac{\sqrt{17}+5}{2},\ one\ time\\ \pm\frac{\sqrt{5}-1}{2},\ two\ time\end{cases}$

Spectral radius, $\rho_{da}(G)=\begin{cases}\frac{\sqrt{17}+5}{2}\\ \frac{\sqrt{5}-1}{2}\end{cases}$, Spectral gab, $\delta_{da}(G)=\begin{cases}\sqrt{17}, if\ n\ is\ odd\\ \sqrt{5}, if\ n\ is\ even\end{cases}$

Hence $E_{da}(G)=\left|\pm\frac{\sqrt{17}+5}{2}\right|+\left|\pm\frac{\sqrt{5}-1}{2}\right|=\left|\frac{\sqrt{17}+5}{2}\right|+\left|\frac{-(\sqrt{17}+5)}{2}\right|+\left|\frac{\sqrt{5}-1}{2}\right|+\left|\frac{-(\sqrt{5}-1)}{2}\right|=9.4721$

Theorem 2.6 For the Complete graph $K_n, n\geq 3$,

$$(i)|A_{da}(k_n)|=0$$

$$(ii)trace\big(A_{da}(K_n)\big)=\begin{pmatrix}\frac{n+1}{2}, if\ n\ is\ odd\\ \frac{n}{2}\quad, if\ n\ is\ even\end{pmatrix}$$

$$(iii)rank\big(A_{da}(K_n)\big)=\begin{pmatrix}\frac{n+1}{2}, if\ n\ is\ odd\\ \frac{n+2}{2}, if\ n\ is\ even\end{pmatrix}$$

$$(iv)\beta^{\lambda}_{da}(K_n)=\begin{pmatrix}\frac{n+1}{2}, if\ n\ is\ odd\\ \frac{n}{2}\quad, if\ n\ is\ even\end{pmatrix}$$

$$(v)\rho_{da}(K_n)=\begin{pmatrix}\frac{\sqrt{n^2+3}+(n-1)}{2}, if\ n\ is\ odd\\ \frac{\sqrt{n^2+1}+(n-1)}{2}, if\ n\ is\ odd\end{pmatrix}$$

$$(vi)\alpha_{da}(K_n)=\begin{pmatrix}\sqrt{n^2+3}, if\ n\ is\ odd\\ \sqrt{n^2+1}, if\ n\ is\ odd\end{pmatrix}$$

$$(vii)E_{da}(K_n)=\begin{cases}\sqrt{n^2+3}+\frac{n-3}{2}, if\ n\ is\ odd\\ \sqrt{n^2+1}+\frac{n-2}{2}, if\ n\ is\ even\end{cases}$$

Proof: Let G be a complete graph K_n with at least three vertices and $V(G)=\{v_1,v_2\dots v_p\}$ where $deg(v_i)=n-1, i=1\ to\ n$.Then $L=\{v_1,v_2\}$ is a $\alpha_{da}(G)$-set of G. It gives the defensive alliance adjacency matrix as,

$$A_{da}(G)=\begin{pmatrix}1&1&1&1\dots\dots\dots&1&1&1&1\\1&1&1&1\dots\dots..&1&1&1&1\\1&1&0&1\dots\dots..&1&1&1&1\\1&1&1&0\dots\dots..&1&1&1&1\\.&.&.&.&.&.&.&.\\.&.&.&.&.&.&.&.\\.&.&.&.&.&.&.&.\\1&1&1&1\dots\dots..&0&1&1&1\\1&1&1&1\dots\dots..&1&0&1&1\\1&1&1&1\dots\dots..&1&1&0&1\\1&1&1&1\dots\dots..&1&1&1&0\end{pmatrix}$$

Then the characteristic equation of $A_{da}(G)$ is,

$$f_{da}(G)=\begin{vmatrix} \lambda-1 & -1 & -1 & -1\dots\dots\dots & -1 & -1 & -1 & -1 \\ -1 & \lambda-1 & -1 & -1\dots\dots\dots & -1 & -1 & -1 & -1 \\ -1 & -1 & \lambda & -1\dots\dots\dots & -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & \lambda\dots\dots\dots & -1 & -1 & -1 & -1 \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ -1 & -1 & -1 & -1\dots\dots\dots & \lambda & -1 & -1 & -1 \\ -1 & -1 & -1 & -1\dots\dots\dots & -1 & \lambda & -1 & -1 \\ -1 & -1 & -1 & -1\dots\dots\dots & -1 & -1 & \lambda & -1 \\ -1 & -1 & -1 & -1\dots\dots\dots & -1 & -1 & -1 & \lambda \end{vmatrix}=0$$

Case (i): n is odd

In this case, the spectrum of $A_{da}(G)$ is,

$$\rho_{da}(\mathrm{G})=\begin{cases} 0 & ,\left(\frac{n-1}{2}\right)\ times \\ -1 & ,\left(\frac{n-3}{2}\right) times\ \ n\geq 3 \\ \frac{\pm\sqrt{n^2+3}+(n-1)}{2} & ,one\ tme\ each \end{cases}$$

It gives defensive alliance energy,

$$E_{da}(G)=\left|0\times\left(\frac{n-1}{2}\right)\right|+\left|-1\times\left(\frac{n-3}{2}\right)\right|+\left|\frac{\pm\sqrt{n^2+3}+(n-1)}{2}\right|$$

$$=0+\left|-1\times\left(\frac{n-3}{2}\right)\right|+\left|\frac{+\sqrt{n^2+3}+(n-1)}{2}\right|+\left|\frac{-\sqrt{n^2+3}+(n-1)}{2}\right|$$

$$E_{da}(G)=\left(\frac{\mathrm{n}-3}{2}\right)+\sqrt{\mathrm{n}^2+3}$$

Case (ii) : n is even

In this case, the spectrum of $A_{da}(G)$ is,

$$\lambda=\begin{cases} 0 & ,\left(\frac{n-2}{2}\right)\ times \\ -1 & ,\left(\frac{n-2}{2}\right) times\ \ n\geq 4 \\ \frac{\pm\sqrt{n^2+1}+(n-1)}{2} & ,one\ time\ each \end{cases}$$

It gives defensive alliance energy,

$$E_{da}(G)=\left|0\times\left(\frac{n-2}{2}\right)\right|+\left|-1\times\left(\frac{n-2}{2}\right)\right|+\left|\frac{\pm\sqrt{n^2+1}+(n-1)}{2}\right|$$

$$=0+\left|-1\times\left(\frac{n-2}{2}\right)\right|+\left|\frac{+\sqrt{n^2+1}+(n-1)}{2}\right|+\left|\frac{-\sqrt{n^2+1}+(n-1)}{2}\right|$$

$$E_{da}(G)=\left(\frac{n-2}{2}\right)+\sqrt{n^2+1}$$

Hence, from the above two cases, we have the defensive alliance energy of G is

$$E_{da}(G)=\begin{cases} \left(\frac{\mathrm{n}-3}{2}\right)+\sqrt{\mathrm{n}^2+3} & ,if\ n\ is\ odd \\ \left(\frac{n-2}{2}\right)+\sqrt{n^2+1} & ,if\ n\ is\ even \end{cases}$$

Theorem 2.7 For thecomplete plus graph $K_n^+, n\geq 6$,

$$(i)|A_{da}(K_n^+)|=(-1)^n$$

$$(ii)trace\left(A_{da}(K_n^+)\right)=n$$

$(iii) rank\left(A_{da}(K_n^+)\right) = 2$
$(iv) \beta_{da}^{\lambda}(K_n^+) = n$
$(v) \rho_{da}(K_n^+) = \dfrac{\sqrt{n^2+4}+n}{2}$
$(vi) \alpha_{da}(K_n^+) = \sqrt{n^2+4}$
$(vii) E_{da}(K_n^+) = \sqrt{n^2+4} + 2(n-1)$

Proof: Let G be a complete graph plus K_n^+ with at least six vertices and$V(G) = \{v_1, v_2 \dots v_n, u_1, u_2, \dots u_n\}$.where $deg(v_i) = n$ and $deg(u_i) = 1, i = 1,2, \dots n$.Then $L = \{v_1, v_2, v_3\}$ is the $\alpha_{da}(G)$-set of G.
It gives the defensive alliance adjacency matrix is

$$A_{da}(G) = \begin{pmatrix} 1 & 1 & 1 & 1 \dots \dots \dots & 0 & 1 & 0 & 0 \\ 1 & 1 & 1 & 1 \dots \dots \dots & 0 & 1 & 0 & 0 \\ 1 & 1 & 1 & 1 \dots \dots \dots & 0 & 0 & 1 & 1 \\ 1 & 1 & 1 & 1 \dots \dots \dots & 1 & 0 & 0 & 0 \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ 0 & 0 & 0 & 1 \dots \dots \dots & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \dots \dots \dots & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \dots \dots \dots & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \dots \dots \dots & 0 & 0 & 0 & 0 \end{pmatrix}$$

Then the characteristic equation of $A_{da}(G)$ is,

$$f_{da}(G) = \begin{vmatrix} \lambda-1 & -1 & -1 & -1 \dots \dots \dots & 0 & -1 & 0 & 0 \\ -1 & \lambda-1 & 1 & -1 \dots \dots \dots & 0 & -1 & 0 & 0 \\ -1 & -1 & \lambda-1 & -1 \dots \dots \dots & 0 & 0 & -1 & -1 \\ -1 & -1 & -1 & \lambda-1 \dots \dots \dots & 1 & 0 & 0 & 0 \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . \\ 0 & 0 & 0 & -1 \dots \dots \dots & \lambda & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 \dots \dots \dots & 0 & \lambda & 0 & 0 \\ 0 & -1 & 0 & 0 \dots \dots \dots & 0 & 0 & \lambda & 0 \\ 0 & 0 & -1 & 0 \dots \dots \dots & 0 & 0 & 0 & \lambda \end{vmatrix} = 0$$

It gives the spectrum value is,

$$\rho_{da}(G) = \begin{cases} 1 & ,(n-1)\ times \\ -1 & ,(n-1)\ times \\ \dfrac{\pm\sqrt{n^2+4}+n}{2} & ,one\ time\ each \end{cases}$$

Hence the defensive alliance energy

$$E_{da}(G) = |1 \times (n-1)| + |-1 \times (n-1)| + \left|\frac{\pm\sqrt{n^2+4}+n}{2}\right|$$
$$= n-1+n-1+\left|\frac{+\sqrt{n^2+4}+n}{2}\right| + \left|\frac{-(\sqrt{n^2+4}+n)}{2}\right|$$
$$E_{da}(G) = 2(n-1) + \sqrt{n^2+4}$$

Theorem 2.8 For thecrown graphS_n^0,

$(i)|A_{da}(S_n^0)| = 0$

$(ii) trace\left(A_{da}(S_n^0)\right) = \begin{pmatrix} n+1, if\ n\ is\ odd \\ n, \quad if\ n\ is\ even \end{pmatrix}$

$(iii) rank\left(A_{da}(S_n^0)\right) = \begin{pmatrix} \frac{3n+1}{2}, if\ n\ is\ odd \\ \frac{3n+2}{2}, if\ n\ is\ even \end{pmatrix}$

$(iv)\beta_{da}^{\lambda}(S_n^0) = \begin{pmatrix} n+1, if\ n\ is\ odd \\ n, \quad if\ n\ is\ even \end{pmatrix}$

$(v)\rho_{da}(S_n^0) = \begin{pmatrix} \frac{\sqrt{n^2-1}-(n-3)}{2}, \frac{\sqrt{n^2-1}-(n-1)}{2}, if\ n\ is\ odd \\ \frac{\sqrt{n^2+1}-(n-3)}{2}, \frac{\sqrt{n^2+1}+(n-1)}{2}, if\ n\ is\ even \end{pmatrix}$

$(vi)\alpha_{da}(S_n^0) = \begin{pmatrix} 2\sqrt{n^2-1}, if\ n\ is\ odd \\ 2\sqrt{n^2+1}, if\ n\ is\ even \end{pmatrix}$

$(vii)E_{da}(S_n^0) = \begin{cases} 2(n-2)+\sqrt{n^2-1}+\sqrt{n^2+3}, & if\ n\ is\ odd \\ 2\left((n-2)+\sqrt{n^2+1}\right), & if\ n\ is\ even \end{cases}$

Theorem 2.9 For thecomplete bipartite graph$K_{m,n}$,

$(i)\left|A_{da}(K_{m,n})\right| = 0$

$(ii) trace\left(A_{da}(K_{m,n})\right) = \begin{pmatrix} n-1, & if\ n\ is\ odd \\ n, & if\ n\ is\ even \end{pmatrix}$

$(iii) rank\left(A_{da}(K_{m,n})\right) = \begin{pmatrix} n+1, & if\ n\ is\ odd \\ n+2, & if\ n\ is\ even \end{pmatrix}$

$(iv)\beta_{da}^{\lambda}(K_{m,n}) = \begin{pmatrix} n-1, & if\ n\ is\ odd \\ n, & if\ n\ is\ even \end{pmatrix}$

$(v)\rho_{da}(K_{m,n}) = \begin{pmatrix} \frac{\sqrt{n^2+3}-(n-1)}{2}, \frac{\sqrt{n^2-1}-(n+1)}{2}, if\ n\ is\ odd \\ \frac{\sqrt{n^2+1}-(n-1)}{2}, \frac{\sqrt{n^2+1}+(n+1)}{2}, if\ n\ is\ even \end{pmatrix}$

$(vi)\alpha_{da}(K_{m,n}) = \begin{pmatrix} \sqrt{n^2+3}, \sqrt{n^2-1}, if\ n\ is\ odd \\ 2\sqrt{n^2+1}, \quad if\ n\ is\ even \end{pmatrix}$

$(vii)E_{da}(K_{m,n}) = \begin{cases} \sqrt{n^2+3}+\sqrt{n^2-1}+(n-3), & if\ n\ is\ odd \\ 2\sqrt{n^2+1}+(n-2), & if\ n\ is\ even \end{cases}$

RESULTS AND DISCUSSION

The following theorem gives both lower and upper bound for the defensive alliance energy in terms of $\boldsymbol{p}, \boldsymbol{q}$ and alliance number $\boldsymbol{\alpha_{da}(G)}$.

Theorem 3.1 If $\lambda_1^{da}, \lambda_2^{da}, \ldots . \lambda_p^{da}$ are the eigen values of defensive alliance adjacency matrix $A_{da}(G)$ then $(i)\beta_{da}^{\lambda}(G) = \alpha_{da}(ii)\left(\beta_{da}^{\lambda}(G)\right)^2 = 2|q| + \alpha_{da}$, where $\beta_{da}^{\lambda}(G)$ is the sum of the eigen value.

Proof: (i) since $\beta_{da}^{\lambda}(G) = trace\left(A_{da}(G)\right) = \sum_{i=1}^{p} v_{ii} = \alpha_{da}$

(ii)similarly$\left(\beta_{da}^{\lambda}(G)\right)^2 = trace(|A_{da}(G)|^2), \left(\beta_{da}^{\lambda}(G)\right)^2 = \sum_{i=1}^{p}(v_{ii})^2 + \sum_{i\neq j} v_{ij}v_{ji}$

$$\left(\beta_{da}^{\lambda}(G)\right)^2 = \sum_{i=1}^{p}(v_{ii})^2 + \sum_{i\neq j} v_{ij}v_{ji}$$

$$= \sum_{i=1}^{p}(v_{ii})^2 + 2\sum_{i<j}(v_{ii})^2$$

$$\left(\beta_{da}^{\lambda}(G)\right)^2 = 2|q| + \alpha_{da}$$

Theorem 3.2 Let G be a simple graph with p vertices and q edges. If$E_{da}(G)$ be the defensive alliance energy value with cardinality$\alpha_{da}(G)$and $\mathcal{P} = ||A_{da}(G)||$. If $\lambda_1^{da}, \lambda_2^{da}, \ldots \lambda_p^{da}$be theeigen values of$A_{da}(G)$ then $sqrt_{da}((2q + \alpha_{da}) + p(p-1)\mathcal{P}^{\frac{2}{p}}) \leq E_{da}(G) \leq sqrt_{da}(p(2q + \alpha_{da}))$,where $\alpha_{da}(G)$ is a defensive alliance number.

Proof: In the Cauchy Schwarz inequality $(\sum_{i=1}^{p} u_i v_i)^2 \leq (\sum_{i=1}^{p} u_i^2)(\sum_{i=1}^{p} v_i^2)$

Take$u_i = 1, v_i = |\lambda_i^{da}|$then$(\sum_{i=1}^{p}|\lambda_i^{da}|)^2 \leq (\sum_{i=1}^{p} 1)(\sum_{i=1}^{p}(\lambda_i^{da})^2)$

$$[E_{da}(G)]^2 \leq p(2q + \alpha_{da}) \text{(by Theorem 2.9(ii))}$$

$$\Longrightarrow E_{da}(G) \leq sqrt_{da}(p(2q + \alpha_{da}) \text{ (1)}$$

Since the arithmetic mean is alwaysgreater than or equal to the geometric mean gives

$$\frac{1}{p(p-1)}\sum_{i\neq j}|\lambda_i^{da}||\lambda_j^{da}| \geq \left[\prod\nolimits_{i\neq j}|\lambda_i^{da}||\lambda_j^{da}|\right]^{\frac{1}{p(p-1)}}$$

$$= \left[\prod_{i=1}^{p}|\lambda_i^{da}|^{2(p-1)}\right]^{\frac{1}{p(p-1)}}$$

$$= \left[\prod_{i=1}^{p}|\lambda_i^{da}|\right]^{\frac{2}{p}} = \left|\prod_{i=1}^{p}\lambda_i^{da}\right|^{\frac{2}{p}}$$

$$= (\text{Absolute value of } |A_{da}(G)|)^{\frac{2}{p}} = \mathcal{P}^{\frac{2}{p}}$$

$\sum_{i\neq j}|\lambda_i^{da}||\lambda_j^{da}| \geq p(p-1)\mathcal{P}^{\frac{2}{p}}$

Now consider, $[E_{da}(G)]^2 = \left(\sum_{i=1}^{p}|\lambda_i^{da}|\right)^2$

$$= \left(\sum_{i=1}^{p}|\lambda_i^{da}|\right)^2 + \sum_{i\neq j}|\lambda_i^{da}||\lambda_j^{da}|$$

$[E_{da}(G)]^2 \geq (2q + \alpha_{da}) + p(p-1)\mathcal{P}^{\frac{2}{p}}$(by Theorem 2.9(ii))

$(ie)E_{da}(G) \geq sqrt_{da}((2q + \alpha_{da}) + p(p-1)\mathcal{P}^{\frac{2}{p}})$(2)

Equations (1) and (2) gives,

$$sqrt_{da}((2q + \alpha_{da}) + p(p-1)\mathcal{P}^{\frac{2}{p}}) \leq E_{da}(G) \leq sqrt_{da}(p(2q + \alpha_{da}))$$

Theorem 3.3 Let G be a graph with defensive alliance set L.If the defensive alliance energy $E_{da}(G)$ is a rational number, then $E_{da}(G) \equiv |L|(mod2)$.

Proof: Let $\lambda_1^{da}, \lambda_2^{da} \ldots \lambda_p^{da}$ be a eigen values of $A_{da}(G)$ of G ,where $\lambda_1^{da}, \lambda_2^{da} \ldots \lambda_r^{da}$ are positive and the remaining are non-positive.

Then, $\beta_{da}^{|\lambda|}(G) = \left(\lambda_1^{da} + \lambda_2^{da} + \cdots \lambda_r^{da}\right) - \left(\lambda_{r+1}^{da} + \ldots \ldots \lambda_p^{da}\right)$

Here, $\beta_{da}^{|\lambda|}(G)$sum of all absolute value of eigen value.

$$\beta_{da}^{|\lambda|}(G) = 2\left(\lambda_1^{da} + \lambda_2^{da} + \cdots \lambda_r^{da}\right) - \left(\lambda_{r+1}^{da} + \ldots \ldots \lambda_p^{da}\right)$$

Since $\beta_{da}^{|\lambda|}(G) = E_{da}(G)$ gives, $E_{da}(G) = 2\left(\lambda_1^{da} + \lambda_2^{da} + \cdots \lambda_r^{da}\right) - \sum_{i=1}^{p}\lambda_i^{da}$

$$E_{da}(G) = 2\left(\lambda_1^{da} + \lambda_2^{da} + \cdots \lambda_r^{da}\right) - |L|$$

Hence $E_{da}(G) \equiv |L|(mod2)$

CONCLUSION

Studying the defensive alliance matrix in graphs helps us understand how groups in a network work together to defend against threats or disruptions. This has practical uses, like improving cybersecurity, controlling disease spread, or analysing teamwork in social networks. It also helps develop better tools to study networks and can lead to new discoveries in math and science. In this paper, the defensive alliance adjacency matrix is introduced and its fundamental matrix terminologies for various standard graphs are building on these results obtained, in future we explore additional bounds and extend the analysis to broader classes of standard graphs.

ACKNOWLEDGEMENT

I wish to express our sincere acknowledgment to my research guide and convener of Dr. V. Mohana Selvi, Assistant Professor of Mathematics, Nehru Memorial College. My sincerely grateful to the Department of Mathematics, and

my College (Nehru Memorial College,Puthanampatti, Trichy, Tamil Nadu), for providing necessary facilities, their Valuable support and encouragement throughout the work.

ABSTRACT

Methanogenic bacteria are archaea bacteria that produce methane as a metabolic by-product. methanogenic bacteria utilize organic compounds present in the dung and degrade them to methane.Biogas is a methane-rich gas produced from microbial digestion of waste (agricultural, sewage, and landfill) which can be used for power production. Biogas promises to be a cheap, efficient, and eco-friendly fuel.Biogas production is influenced by the biomass of methanogenic bacteria in the conversion of organic matter contained in a digester, so other methanogenic bacteria are needed to accelerate the rate of biogas production, namely methanogenic bacteria from the anaerobic digester of cow manure.The focus of the present study is to isolate and identify the potential methanogenic bacteria that show biogas generation via anaerobic digestion using standard microbiological methods. The cow dung and buffalo dung samples were procured from the temple, cowshed, and farm in a sterile plastic container and transported to the laboratory for analysis. Morphological and microscopic studies have been carried out to identify isolated bacteria. Gram staining revealed the presence of Gram-positive and Gram-negative *Methanococcus* and *Methanobacillius sp.* respectively. Antibiotic sensitivity tests showed that the isolated bacteria were found to be resistant to antibiotics like chloramphenicol, streptomycin, and ampicillin and

were susceptible to antibiotic tetracycline. The total quantity of biogas produced by anaerobic digestion was 24.82 g per 2kg of cow dung. A gas chromatography test confirmed the presence of methane in biogas. Hence the results revealed that the generation of biogas from cow dung is potentially a good, cheap, and alternative source of fuel or energy. The biogas technology is a good way of providing solutions to the increasing waste management and disposal problems apart from the generation of fuel or energy from renewable energy sources.

Keywords: Cow dung, Buffalo dung, Biogas, Anaerobic digestion, Renewable energy, waste management.

INTRODUCTION

Methanogenic bacteria are central to the global carbon cycle and the generation of renewable bioenergy. These strictly anaerobic microorganisms convert organic matter into methane a process that underpins both natural methane emissions and engineered biogas systems *(Holmes & Smith, 2016; P. James et al., 2015)*. Understanding the diversity and functional biology of methanogens is therefore essential for optimizing bio-methanation processes and advancing microbial ecology research *(Schnürer, 2016).* Biogas production through anaerobic digestion represents a sustainable route for managing organic wastes such as sewage sludge, agricultural residues and municipal biodegradable fractions. Methanogenic archaea primarily belonging to distinct lineages within the Euryarchaeota serve as the terminal organisms in this multi-stage degradation process *(Tyagi & Lo, 2013)*. They complete the conversion of complex substrates through hydrogenotrophic, acetoclastic or methylotrophic pathways depending on species and environmental conditions. Members such as *Methanobacterium* and acetoclastic methanogens orchestrate a series of tightly regulated biochemical reactions that culminate in methane *release (Mutungwazi, A., Ijoma, G. N., & Matambo, T. S., 2021).*

Efficient bio-methanation however, is influenced by several constraints including substrate availability, process stability and interactions within the microbial consortia *(Wang, 2018).* Methanogens depend on syntrophic associations with fermentative and acetogenic bacteria which break down complex polymers into intermediate substrates such as acetate, CO_2 and hydrogen *(Mutungwazi et al., 2021).* These cross-feeding networks are critical for maintaining metabolic balance and supporting stable methane yields. Beyond their role in engineered digesters methanogens also have broader ecological significance because they influence methane dynamics across natural and agricultural ecosystems *(Malyan, S. K., Bhatia, A., Kumar, A., Gupta, D. K., Singh, R., Kumar, S. S., ... & Jain, N., 2016).* Given the increasing demand for clean and renewable energy biogas has emerged as a practical solution especially in regions such as rural India where "Gobar gas" has long been used for household energy needs *(Dutta & Dutta, 2016; Kabeyi& Olanrewaju, 2022)*. Biogas is primarily composed of methane along with CO_2, N_2, H_2 and trace H_2S *(Bansal et al., 2013)*. Its generation through microbial degradation of cow dung, buffalo dung and other organic materials highlights the importance of identifying the specific methanogenic communities responsible for methane formation *(Singh et al., 2023).*

The aim of this review is to synthesize current knowledge on methanogenic bacteria with emphasis on their diversity, metabolic pathways, ecological interactions and functional importance in biogas production systems. By consolidating recent findings this work contributes to a clearer understanding of how methanogens can be harnessed for improved biomethane generation and sustainable waste-to-energy strategies *(Malyan et al., 2016).*

MATERIALS AND METHODOLOGY

Materials And Chemicals Required

Materials required: Dungs of cow and buffalo, 2.25l of plastic bottles, Infusion kit, Needles, Tape, Lighter, Water Tray, Beaker, L-shaped rods, measuring cylinders, Petri plates, Test tubes, Test tube rack, Conical flask, Cotton plugs Candle, Parafilm tape, Loop, Desiccator, Bunsen burner, Microscope, Shaker, Incubator, Glass tubes, Calorimeter, Antibiotic resistivities.

Chemicals required: Peptone, Beef extract, NaCl, Agar, Muller Hilton Agar, Giemsa stain, Trypsin, Alcohol, Safranin.

METHODOLOGY

Sample Collection: The dungs of cow and buffalo samples were collected from the temple, cow shed and organic farm in a sterile plastic container and transported to the laboratory for analysis. [*Balakrishnan, S., & Shukla, K. M. (2018)*].

Production of biogas: Cow dung was mixed with water and transferred to an empty clean and dry plastic bottle and the caps were tightly sealed.[*Hagegård, Karolina(2009)*]. This set-up was connected to an infusion kit. This set-up was kept undisturbed for thirty days to fifty days for cow dung and buffalo dung respectively. *[Pradesh, A. (2020)].*

Media preparation: Nutrient agar media was prepared by adding beef extract (0.3g), peptone (0.5g), NaCl (0.05g) and agar (2g) and making it up to 100ml by adding distilled water. The pH was adjusted to 7 by adding NaOH.*[Wright, H. D. (1934)].*

Sterilization: The nutrient agar media and 200 ml distilled water were sterilized in an autoclave at 115C and 15 psi, along with 10 petri plates, 10 test tubes, a test tube stand, 10ml measuring cylinder, L shaped glass rod, 2 micropipettes, 20 microtips.*[Dubey, R. C., & Maheshwari, D. K. (2002)].*

Dilution: 10 test tubes were marked and filled with 9 ml sterile distilled water. To the first tube, 1ml of the biogas slurry was poured and mixed. From the first tube, 1 ml of the solution was poured into the second tube. This was done for the rest of the tubes.*[Devora, I. F., & Salihu, H. H. (2022)].*

Inoculation: 10 petri plates were marked the same as the test tubes and the media was poured evenly in each of them. 0.1 ml of the solution from each of the test tubes was poured and spread evenly on the respective petri plates using the L-shaped glass rod.*[Postgate, J. R. (1969)]*. Note: Both serial dilution and inoculation were done in the Laminar Air Flow.*[Probst,Christopher,(2015)].*

Anaerobic culturing: The Petri plates were sealed with parafilm and were stacked upon one another in a desiccator. A small candle was kept on the stack and was lit up. The lid of the desiccator was placed and was sealed with parafilm.*[Bremer, Matthias (2018)]* The candle went off in a few seconds, which meant the oxygen in the desiccator was all used up and now it had an anaerobic condition. The desiccator was marked and kept aside undisturbed for 4 days.*[Van den Brink, Paula, et al (2013)].*

Gram's staining: From each petri plate, using a sterile inoculation loop some cells from a bacterial colony were put on a drop of distilled water on a clean glass slide. (Harrigan, W. F., & McCance, M. E. (2014)]. It was then spread on the slide to separate the cells. It was then air dried, heat fixed, and put in crystal violet stain for a minute. *[Beveridge,*

*T. J., Lawrence, J. R., & Murray,R. G. (2007)].*It was then washed with water and put in Gram's stain for a minute. Then it was washed with alcohol and water and put in safranin stain for a minute. The slide was then washedwith water and air-dried. The same process was done with all the slides.*[Beveridge, T. J., Lawrence, J. R., & Murray, R. G. (2007)].*

Microscopic observation: Each slide was observed under the compound Microscope.
Characterization: The shape and clusters of the bacterial cells were noted and whether the cells were gram-negative or gram-positive.*[Uffen, R. L. (1997)]*
Bacterial growth curve: The methanogenic bacterial cultures were subjected to growth curve studies and the readings were taken every half hour to know the different phases.*[Whitman, W. B., Bowen, T. L., & Boone, D. R. (2006)].*

Antibiotic sensitivity: This was done using various antibiotics like Chloramphenicol, Streptomycin, Ampicillin, and tetracycline to know the reactivity of the methanogenic bacteria. *[Sanz, J. L., N. Rodriguez, and Á. R. Amils.(1996)].*

Quantification of gas: The collected methane gas was quantified. *[Tedeschi, Luis Orlindo, (2022)].*

RESULTS

Results of flame test- to confirm the presence of methane gas.

Discussion:
The flame test shows the evolution of a blue-colored flame indicating the presence of methane [ch4].*[Rajpara, p., shah, r., &Banerjee, j. (2018)].*

Results of Bacterial Growth Curve Studies
All the growth curves show the same lag, log, stationary, and decline phases indicating that all of the samples have to have the same kind of methane-producing bacteria.*[ware, aidan, and niamh power. "Modelling methane production kinetics of complex poultry slaughterhouse wastes using sigmoidal growth functions." renewable energy 104 (2017): 50-59.]* Bacterial colony growth was observed in the petri plates from 10^{-1} to10^{-10} after serial dilution.*[Ben-david, avishai, and charles e. Davidson. "Estimation method for serial dilution experiments." journal of microbiological methods 107 (2014): 214-221].* From table 1 we know that the highest colony count in culture plate 10^{-1} was seen in temple cowans least number of the colony was seen in buffaloalso we know that the highest colony count in culture plate 10^{-10} was seen in temple cow least number of the colony was seen in shed cow indicating an overall descend in the number of colonies as the dilution power increases.*[Qazi, javed i., hina asif, and ramla shahid. "Economical method for estimation of bacterial viable count." pakistan journal of zoology 40.4 (2008)]* Gram's staining was done and different entities of microorganisms were observed under the microscope from the stained slides revealing many variations in all the samples.*[Dallas, steven d., and Amanda t. Harrington. "Staining procedures." clinmicronow (2024): 1-37].*

Results After Screening Under Microscope.
Temple cow dung and farm cow dung colonies were produced higher in number and they had more differentiated bacteria present like *monococcus, diplococcus,triplococcus, and streptococcus, and bacillus sp, diplobacillus sp, triplobacillus sp, streptobacillus sp* as both gram +ve and gram –ve bacteria respectively.*[Yang, desirée c., kris m. Blair, and Nina r. Salama. "Staying in shape: the impact of cell shape on bacterial survival in diverse environments." microbiology and molecular biology reviews 80.1 (2016): 187-203].*

Results of antibiotic sensitivity test.
The antibiotic test results revealed that all the samples of dung with methanogenic bacteria were susceptible to the antibiotic **tetracycline[te]**.*[türker, gökhan. "Determination of effects of selected veterinary antibiotics on biogas production in anaerobic digestion systems and analysis of resistance gene promotion." (2013).].*

Results Of Quantification Of Biogas [Methane-Ch4] And Its Utilization.

Quantification Of Methane[Ch4] Via Weighing Scale.

- An empty pet bottle was taken and cleaned thoroughly. An airtight sealing on the bottle was done and it was suctioned out completely such that one end of the infusion kit was connected to the empty bottle, and the other end was connected to the ch4 digester bottle.
- The empty bottle values were taken as W0 and the same bottle was measured after the gas was filled in it and these values were taken as W1, the difference in their weight would give the amount of gas collected in grams.
- For instance,W0= 20.530g and W1= 21.860g the difference in both the weights is 1.33g.

Quantification Of Using Ideal Gas Equation PV=NRT.

PV=NRT

Where P is pressure (in atm) =1ATM/ 101.325PKA ROOM PRESSURE

V is volume (in liters)=2.25l Of Bottle

N is the number of moles=?

T is the temperature (in k)=28^0c / 301k Room Temp

R is a constant = 0.08206 l atm/molek

PV / RT=NRT / RT

PV / RT =N (or)N = PV / RT

N = [1 ATM X 2.25L / 301K] X [K.MOL / 0.0821 L.ATM]

=2.25/24.71 = 0.091 MOLES X 16.04 [MOLAR MASS OF CH4]

= 1.46G

=1.46G X 17[NO OF TIMES THE GAS WAS COLLECTED FROM THE BOTTLE]

=24.82G [TOTAL GAS COLLECTED]

At standard temperature and pressure (STP), 1 gram of methane has a volume of 1.4 liters therefore 24.82g of methane at STP will have a volume of 34.74Liters or 0.03473 m^3. [approximate estimation]. *[Tenny, Kevin m., and Jeffrey s. Cooper. "Ideal gas behaviour." (2017)].* Biogas is an efficient fuel used for cooking and it took complete 2 bottles of gas[2.92g or 3.92ltr] to cook 4 eggs completely. [*Vijay, VirendraKumar, et al. "biogas as clean fuel for cooking and transportation needs in India." advances in bioprocess technology (2015): 257-275.*]

Quantification of biogas and comparative study of gas production from each type of dung.

The production of biogas was higher in the buffalo dung sample than in cow dung samples. *[Chuanchai, Ajcharapa, and Rameshprabu Ramaraj. "Sustainability assessment of biogas production from buffalo grass and dung: biogas purification and bio-fertilizer." 3 biotech 8.3 (2018): 151].*

Results of biogas quality test done at central analytical facility university college of technology Osmania University.

The graph and the table represent the compounds/gases in the biogas, revealing that 40.68% of the compounds have a methyl group. *[maštovská, kateřina, and steven j. Lehotay. "practical approaches to fast gas chromatography–mass spectrometry." journal of chromatography a 1000.1-2 (2003): 153-180.].*

CONCLUSION

Methanogenic bacteria are pivotal in both the natural carbon cycle and renewable energy production, underscoring their dual role in environmental processes and sustainable energy solutions. Through methanogenesis, these bacteria convert organic materials into methane, a process integral to the functioning of ecosystems and the mitigation of waste via biogas systems. Their ability to operate in anaerobic conditions allows them to thrive in diverse

environments, from wetlands to the gastrointestinal tracts of ruminants, and significantly in managed anaerobic digesters. The production of biogas, primarily composed of methane, from organic waste such as cattle dung, buffalo dung, sewage sludge, and municipal organic waste, not only provides a renewable source of energy but also helps reduce dependence on fossil fuels and the emission of greenhouse gases. In rural settings, particularly in places like India, biogas technology often referred to as gobar gas is an effective solution for energy needs, supporting cooking and lighting for many communities. However, the efficient production of biogas faces challenges such as the availability and type of organic substrate, the balance of microbial communities, and the complex metabolic exchanges within these communities. Enhancing our understanding of methanogenic bacteria and their interactions within ecosystems could lead to more effective biogas systems, optimizing methane production and contributing further to sustainable energy landscapes.

In conclusion, methanogenic bacteria are not just contributors to methane emissions but are essential agents in sustainable energy production through biogas. They hold a key to unlocking new technologies in waste management and energy production, supporting a transition to more sustainable energy systems while helping manage organic waste more effectively. As research continues to unravel the complex interactions and potential of these microbes, it becomes increasingly clear that their role extends beyond simple methane production, influencing broader ecological and energy systems worldwide. The study demonstrates that methanogenic bacteria present in cow and buffalo dung play a crucial role in the production of biogas through anaerobic digestion, emphasizing the potential of this technology as a sustainable and cost-effective energy solution. By isolating and analysing these bacteria, the research highlights the efficiency of dung as a substrate for biogas production, which not only provides a renewable source of energy but also offers a practical solution to the management and disposal of agricultural wastes. The findings from the gram staining and antibiotic sensitivity tests on the isolated methanogens provide valuable insights into their biological characteristics and resilience, which are important for optimizing biogas production processes. The generation of 23.8 grams of biogas per 2 kg of cow dung, as confirmed by gas chromatography tests, substantiates the viability of using cattle dung as a biogas source.

Furthermore, this study emphasizes the environmental benefits of biogas technology, such as reducing greenhouse gas emissions and lessening the reliance on fossil fuels. It also addresses significant waste management challenges by converting organic waste materials into useful energy. Leveraging methanogenic bacteria for biogas production from cow and buffalo dung presents a promising avenue for enhancing renewable energy outputs, improving waste management practices, and contributing to sustainable development goals. Continued research and development in this area are essential to optimize the processes involved, scale up production, and maximize the environmental and economic benefits of biogas technology.

ABSTRACT

Levodopa is still considered the gold standard treatment for Parkinson's disease (PD) and is the most successful symptomatic therapy. Levodopa, however, experiences significant peripheral metabolism when taken alone, which results in decreased central bioavailability and dose-limiting side effects. By preventing peripheral dopamine production while maintaining central conversion to dopamine, peripheral aromatic L-amino acid decarboxylase inhibitors—in particular, carbidopa—fundamentally changed levodopa treatment. In addition to lowering cardiovascular and gastrointestinal adverse effects and enabling lower and more consistent dosage, the levodopa–carbidopa combination dramatically increases levodopa bioavailability. Despite these benefits, motor fluctuations and dyskinesias, which are mostly caused by non-physiological, pulsatile dopaminergic stimulation and variable pharmacokinetics, may impede long-term therapy. The pharmacokinetic and pharmacodynamic foundation of levodopa-carbidopa therapy, its clinical effectiveness in treating both motor and non-motor symptoms, new formulations targeted at continuous dopaminergic delivery, and the enduring drawbacks that call for new treatment approaches are all critically examined in this review. Optimizing the therapy of Parkinson's disease and enhancing long-term patient outcomes need an understanding of the synergistic interaction between levodopa and carbidopa.

Keywords: Parkinson's disease, levodopa–carbidopa, dopaminergic treatment, motor fluctuations, dyskinesias, decarboxylase inhibitor

INTRODUCTION

Parkinson's disease (PD) is a common neurological condition. It affects around 0.3% of the general population and 1% to 2% of people over 60. [1] Given the exceptional duration of Parkinson's disease (PD) and the increasing average age of the general population, PD is expected to become increasingly prevalent over the coming decades, with a growing social cost. [2] Bradykinesia, stiffness, resting tremor, and postural instability are clinical features of Parkinson's disease. Other non-motor symptoms include atypical sleep-wake cycles, dementia, mental health issues, autonomic dysfunction, and sensory complaints. [Table 1][3] From a pathogenic perspective, Parkinson's disease (PD) is defined by the degeneration of dopaminergic neurons in the substantia nigra (SNc) pars compacta, which is linked to intraneuronal protein clumps known as Lewy bodies. Significant changes may also occur in non-dopaminergic systems, such as the cerebral cortex, medulla oblongata, spinal cord, autonomic nervous system, cholinergic neurons of Meynert's basal nucleus, norepinephrine neurons of the Locus Coeruleus, and serotoninergic neurons of the Median Raphe Nucleus. Dopaminergic dysfunction may not originate in the central nervous system, particularly in the dorsal and olfactory motoneurons, according to some research [4]. Experts in movement disorders have created many treatment algorithms [5] that aim to give guidance for the condition's management while taking into consideration the various therapeutic options. Based on these standards, levodopa, which was initially recommended over 40 years ago, continues to be the best drug for treating the symptoms of Parkinson's disease.[6] Its two primary advantages are quick action and a notable decrease in PD motor symptoms. In the end, levodopa is necessary for nearly all PD patients. Levodopa treatment improves the patient's ability to do daily chores and maintains high levels of productivity at work, both of which contribute to the patient's overall quality of life. Furthermore, even though Parkinson's disease (PD) patients still have higher mortality rates than age-matched controls, levodopa therapy has greatly increased the survival rate of PD patients [7]. The benefits of levodopa against Parkinson's disease are significant since they persist and do not wane during the course of the illness.

However, when the condition worsens, levodopa-induced problems such as motor fluctuations, dyskinesias, and neuropsychiatric abnormalities escalate. [8] Recent years have seen the development of adjunctive pharmaceutical and surgical treatments to prevent or treat motor problems associated with levodopa. Before analyzing the benefits and drawbacks of an intriguing medication used to treat Parkinson's disease (PD), an essay begins with its background. Levodopa's unfulfilled medical demands in Parkinson's disease are also covered, as is the potential use of levodopa in other ways to meet these needs.[9] The creation of peripheral aromatic L-amino acid decarboxylase inhibitors, namely carbidopa, was a significant advancement in pharmacology. The proportion of levodopa accessible for absorption by the central nervous system is increased by carbidogopa, which specifically blocks the peripheral conversion of levodopa to dopamine without crossing the blood–brain barrier. With its significant dosage decrease, greater tolerability, and increased clinical effectiveness, the levodopa–carbidopa combination has become the global standard of therapy.[10]

Chronic levodopa–carbidopa treatment is linked to motor problems as wearing-off phenomena and dyskinesias, notwithstanding these benefits. The intricate interactions among disease progression, decreased dopamine buffering capacity, and intermittent dopaminergic stimulation are reflected in these problems. With a focus on tactics meant to enhance long-term treatment results, this study examines the biochemical underpinnings, clinical advantages, and enduring difficulties of levodopa–carbidopa therapy.[11]

Role oOf Carbidopa in Levodopa Therapy

Only peripheral tissues are affected by carbidopa, a competitive inhibitor of aromatic L-amino acid decarboxylase. Because carbidopa does not pass the blood–brain barrier like levodopa does, central dopamine production in the brain continues to rely on levodopa conversion. Carbidopa improves levodopa's plasma half-life and bioavailability by blocking peripheral decarboxylation, enabling a dosage decrease of around 70–80% when compared to levodopa monotherapy [12].

Carbidopa significantly reduces dopamine-mediated peripheral side effects, including cardiovascular instability and gastrointestinal discomfort. Additionally, by stabilizing plasma levodopa concentrations, carbidopa lowers dose-to-dose variability and enhances motor response consistency. Combination formulations such intestinal gel preparations, controlled-release, and immediate-release formulations are based on these pharmacokinetic benefits [13]. Crucially, carbidopa does not stop the long-term development of motor difficulties, even though it enhances the transport of levodopa. This emphasizes that disease-related loss of dopaminergic terminals and pulsatile stimulation, rather than peripheral metabolism alone, is the primary cause of dyskinesias and motor fluctuations [14].

Pharmacokinetics and Pharmacodynamics:

In clinical practice, levodopa is nearly always used in conjunction with carbidopa, a peripheral aromatic L-amino acid decarboxylase (AADC) inhibitor, which is a key component of contemporary Parkinson's disease medication. Dopamine is produced outside of the central nervous system when levodopa is given as monotherapy because it is extensively peripherally metabolized by AADC in the liver, gastrointestinal tract, and systemic circulation. By stimulating peripheral dopaminergic receptors, this peripheral conversion significantly reduces the amount of levodopa available for brain absorption and results in dose-limiting side effects [15].

Carbidopa preserves the central enzymatic conversion of levodopa to dopamine inside the striatum by selectively and permanently inhibiting peripheral AADC activity while preventing it from crossing the blood–brain barrier. The area under the plasma concentration–time curve (AUC) is significantly elevated when carbidopa is administered concurrently, indicating a significant increase in systemic levodopa exposure. Without sacrificing clinical effectiveness, this increased exposure allows for a 70–80% decrease in the daily levodopa dosage [16]. Apart from raising AUC, carbidopa also helps to stabilize peak plasma concentrations (Cmax), which lowers variability between and within doses. This stability is therapeutically significant because motor response variability and the onset of OFF periods are strongly associated with changes in plasma levodopa concentrations. Additionally, carbidopa decreases levodopa's peripheral clearance, lengthening the half-life of its plasma elimination and the amount of time that levodopa concentrations stay above the minimal effective threshold needed for motor improvement [17].

When levodopa-carbidopa is administered instead of levodopa alone, pharmacokinetic investigations consistently show a little delay in the time to maximum plasma concentration (Tmax). Rather than poor absorption, this delay is due to changed gastrointestinal kinetics and decreased peripheral metabolism. Crucially, extended exposure and decreased metabolic loss increase the overall therapeutic window despite this change in Tmax [18]. There is still significant variation in levodopa absorption even with the pharmacokinetic benefits that carbidopa provides. Even when carbidopa is present, levodopa pharmacokinetics are greatly impacted by factors such Helicobacter pylori infection, small intestine bacterial overgrowth, competition with dietary neutral amino acids for intestinal and blood–brain barrier transporters, and delayed stomach emptying. Furthermore, the brain's ability to buffer fluctuating dopamine levels is diminished by disease-related degradation of nigrostriatal dopaminergic terminals, which increases the clinical effect of pharmacokinetic variability [19]. Therefore, long-term motor fluctuations and dyskinesias are mostly caused by disease progression and non-physiological, pulsatile dopaminergic stimulation rather than inadequate peripheral metabolic inhibition, even if carbidopa is crucial for improving levodopa delivery. Advanced delivery strategies, including continuous intestinal infusion of levodopa–carbidopa, have been developed as a result of these findings with the goal of improving long-term clinical results and restoring more physiological dopaminergic activation patterns [20].

Overview of the market:

To increase central absorption, enhance long-term tolerance, and optimize pharmacokinetic performance, all presently available levodopa formulations are taken with a peripheral decarboxylase inhibitor, most often carbidopa. Peripheral decarboxylase inhibitors are usually used in conjunction with levodopa to prevent the drug's peripheral conversion to dopamine (DA) and the development of undesirable side effects such nausea, vomiting, and orthostatic hypotension. These are mostly caused by activation of dopaminergic receptors in the postrema area, which is not

protected by the blood–brain barrier. Levodopa and carbidopa, a peripheral inhibitor, are often combined in the US and sold under the brand name Sinemet. [21] There are three strengths of carbapa/levodopa available: 10/100, 25/100, and 25/250 mg. Levodopa and benserazide, another unique inhibitor, are combined in another medication called Madopar, which is marketed in Europe. It comes in the following strengths: 25/100, 50/200, and 25/100 mg dispersible tablets. Patients who have trouble swallowing may benefit from Parcopa, an orodispersible levodopa/carbidopa that doesn't need dissolving in water. In recent years, levodopa/carbidopa and the enzyme catechol-O-methyltransferase (COMT) inhibitor (entacapone) have been made available under the trade name Stalevo (Novartis Pharma SpA Basilea, CH). You may get levodopa in doses of 50, 75, 100, 125, 150, and 200 mg. Furthermore, there are slow-release forms of Sinemet in 25/100 and 50/200 mg and Madopar in 50/200 mg concentrations. Furthermore, methylester formulations that have a quicker and more reliable absorption rate—possibly a benefit over traditional levodopa—are being offered for sale. This prodrug of levodopa is substantially more soluble in the stomach and has a shorter half-life in the small intestine. Moreover, the active ingredient rapidly hydrolyzes to levodopa before to absorption. [22–24]. The pharmacokinetic profile of this pro-drug suggests that it may be able to more promptly and consistently treat motor symptoms in those with motor fluctuations who have delayed-ON or nonexistent ON phases. In some European and non-European countries, a levodopa gel formulation for intraduodenal infusion by percutaneous endoscopic gastrostomy (PEG) has recently gone on sale. By reducing plasma peaks and promoting continuous intestinal absorption, it reduces motor fluctuations [25–27].

Clinical efficacy

The pharmacological effects of levodopa given in conjunction with carbidopa, as opposed to levodopa monotherapy, are reflected in the clinical effectiveness seen in Parkinson's disease. By reducing peripheral dopamine production and related side effects, such as nausea, vomiting, and cardiovascular instability, carbidopa is essential for permitting prolonged dopaminergic replacement treatment. Long-term treatment plans necessary for a progressing neurodegenerative disease are supported by this enhanced tolerability, which enables efficient dosage titration [28].

While tremor response is still very inconsistent, levodopa-carbidopa treatment significantly and consistently improves the fundamental motor symptoms of Parkinson's disease, especially bradykinesia and stiffness. Carbidopa improves the consistency of motor benefit across dosage intervals by decreasing the length of therapeutic exposure and stabilizing plasma levodopa concentrations. Particularly in early and mid-stage illness, these benefits result in continued functional independence and better performance of everyday life tasks. Motor fluctuations and dyskinesias sometimes hamper longterm levodopa-carbidopa treatment despite optimal pharmacokinetics. Reduced presynaptic dopamine storage capacity, gradual nigrostriatal degeneration, and the switch from buffered to direct postsynaptic dopaminergic stimulation are the causes of these events. Crucially, carbidopa does not stop these difficulties from developing, highlighting the fact that disease-related neuroplastic alterations, not peripheral pharmacokinetic restrictions, are the main cause of their pathogenesis [29]. Levodopa-carbidopa treatment only partly relieves non-motor symptoms, such as cognitive impairment, neuropsychiatric problems, autonomic dysfunction, and sleep difficulties. This indicates extensive neurodegeneration outside of the nigrostriatal pathway and the involvement of non-dopaminergic neurotransmitter systems. Therefore, in addition to optimal levodopa-carbidopa treatment, supplementary pharmacological and non-pharmacological strategies are necessary for complete care of Parkinson's disease [30].

An endogenous catecholamine deficiency and the patients' knowledge of their worsening, chronic neurological condition are the two main causes of depression in persons with Parkinson's disease (PD). Many people still need further antidepressant medication, even if some report feeling better after beginning levodopa treatment. Orthostatic hypotension, poor thermoregulation, constipation, erectile dysfunction, and urinary problems are often caused by autonomic dysfunction in Parkinson's disease (PD). The frequency and severity of these symptoms vary from patient to patient. Usually, levodopa medication doesn't work to alleviate these symptoms. Due to their sleep difficulties, most people with Parkinson's disease (PD) suffer from diurnal fatigue. Levodopa medicine given at night may help some people sleep better, but it does not cure many sleep problems. Parkinson's disease (PD) may induce a number of sleep irregularities, including as nocturnal apneas, REM sleep disorder, restless legs syndrome, and fragmentation

of sleep. Moreover, levodopa and other anti-Parkinson drugs may make you drowsy, interfere with your nightly sleep, and increase your risk of being sleepy throughout the day. The creation of a more potent remedy for both motor and nonmotor symptoms that don't improve with levodopa is an unmet medical need. Dyskinesias and motor fluctuations are the most frequent adverse effects that those on continuous therapy experience. [31, 32]

Two types of dyskinesias—involuntary movements—are peak-dose and biphasic dyskinesias. Peak-dose dyskinesias, which occur when levodopa plasma concentrations reach their peak, are the most common symptom of dyskinesias, which are estimated to occur in 30 to 50 percent of patients on levodopa therapy for at least five years [33]. They might be myoclonic or dystonic in addition to having typical choreic movements. Biphasic dyskinesias are more common in patients with the illness at an advanced stage. They show up as the concentration of levodopa begins to increase and then rapidly decreases. They often have a dystonic component and usually have an asymmetrical pattern that affects all of the lower limbs above. Although the exact pathophysiology of dyskinesias is still unknown, pulsatile dopaminergic activation appears to play a significant role in their development [34,35]. This includes the extent of the dopaminergic lesion as well as the long-term, intermittent administration of a drug with a short plasma half-life, such as levodopa. Once levodopa-induced dyskinesias appear, treatment usually ends in frustration. While bradykinesia may become worse, dyskinesia may get less severe if levodopa doses are decreased. Raising the dose of the DA agonist while lowering the dosage of levodopa is a common strategy to maintain therapeutic effectiveness and reduce dyskinesias at the same time. Amantadine's glutamate NMDA receptor antagonistic qualities make it a useful drug for treating dyskinesia. Unfortunately, many patients are unwilling to embrace the advantages, which are often temporary, due to its negative effects on cognition (confusion).

Among the novel anti-dyskinetic drugs currently being researched are adenosine-2A antagonists, glutamate AMPA receptor antagonists, serotoninergic agonists, and atypical neuroleptics. [36,37] At the moment, surgical procedures such as pallidotomy and globus pallidus or deep brain stimulation (DBS) of the subthalamic nucleus have demonstrated the greatest benefits on dyskinesias. [38] These procedures are believed to work by halting abnormal excitation patterns in basal ganglia output neurons that send false information to the medulla oblongata and cortical motor areas. One major problem with long-term levodopa medication is the emergence of motor irregularities. A motor fluctuation occurs when motor Parkinson disease (PD) symptoms appear before levodopa medication is expected to be stopped. After using levodopa for five years, almost half of people begin to feel them. As the illness worsens and lasts longer, the medication takes longer to start functioning and its effects wear off more quickly. The mechanism that causes motor fluctuations is unknown. Similar to dyskinesias, there are notable pre- and post-synaptic changes.

The loss of striatal dopaminergic terminals reduces the capacity to buffer changes in striatal DA. In order to counteract motor fluctuations, many therapy approaches may be used. There are several ways to administer levodopa, such as liquid and controlled release formulations, controlled release dosages, and combinations with COMT inhibitors to prevent peripheral metabolism and prolong the drug's duration of action [39,40]. Additionally, subcutaneous apomorphine administration, oral DA agonists, and MAO-B inhibitors can be used to reduce OFF periods. If pharmacological therapy proves futile, surgical treatment, like DBS, may also be considered.

Novel formulations:

The mainstay of Parkinson's disease treatment since its inception many years ago has been levodopa medication. This groundbreaking approach to symptomatic management enhanced the quality of life and increased survival rates for millions of PD patients worldwide. Since levodopa is the only drug for Parkinson's disease (PD) that has shown more clinical advantages than any other therapy to date, it serves as the standard by which all other pharmacological interventions are judged. Unfortunately, levodopa is not a panacea. As we've seen, long-term levodopa treatment may result in undesirable side effects such motor abnormalities and dyskinesias. Over 90% of patients who have been on levodopa for at least ten years' experience these, which start years after the drug's introduction. [41] Despite the fact that there are several different anti-Parkinson drugs available today, they don't provide any greater therapeutic benefits than levodopa. Rather, they minimize the severity of these motor issues or postpone their start. There aren't

many well-designed double-blind, placebo-controlled studies that look at levodopa's pharmacological and clinical characteristics. The ELLDOPA study was the first double-blind investigation to compare the effects of different levodopa doses to a placebo. It was published in 2004. The clinical finding that greater levodopa dosages are linked to an increase in short-acting efficacy and motor problems was validated by the study. However, no research has yet been done on the optimal way to provide levodopa while optimizing the trade-off between symptom management and motor impairments [42,43].

Lately, this is beginning to alter. We now have a better understanding of how dopamine (DA) works in the basal ganglia under healthy settings, how basal ganglia are damaged, and how current levodopa administration methods lead to motor problems. This has prompted scientists to design studies that seek to discover new physiological ways to transport levodopa to the brain so that the medication may be taken without impairing motor performance. The reintegration of physiological dopaminergic activity, which reflects normal striatal dopaminergic activity (such as, for example, memory, mood, and sleep), is an important factor that may even help non-dopaminergic symptoms of Parkinson's disease (PD).[44] Levodopa has been administered in a variety of ways to ensure a consistent supply to the striatum. These techniques include: i) oral formulation given once daily; ii) intraduodenal continuous infusion; iii) transdermal release by patch; iv) injection of nasal puffs or aerosol; and v) brain transplantation of dopamine-producing cells. The main technical challenge in developing a 24-hour levodopa formulation is getting enough levodopa into the duodenum for the right length of time. One technique is to use slow-release floating minitablets, which improve absorption by reducing the amount of time levodopa takes to pass through the digestive system. The mini-tablets coated with insoluble acrylic polymer have been shown to float for more than 13 hours and release levodopa for more than 20 hours in vitro. In vivo research is required for future planning. Several studies found that continuous intraduodenal levodopa infusion dramatically reduced dyskinesias and OFF periods in patients with advanced illness.

However, because of the acidity required to keep the molecule in solution, levodopa infusion requires a lot of fluid. Large and unfeasible infusion systems are needed for this. Since methylester levodopa is more soluble and requires less volume, it has been used in several studies to reduce the size of infusion devices to something akin to an insulin pump [45–49]. A methylcellulose gel containing levodopa (20 mg/ml) and carbidopa (5 mg/ml) was recently developed as a novel preparation to reduce infusion volume. The constant intraduodenal delivery of duodopa significantly reduces dyskinesias and OFF periods as compared to oral treatment. A transdermal patch that delivers levodopa gradually is said to be one of the finest methods to take the drug, although there are several challenges to overcome. The most effective drugs for transdermal administration are those that dissolve in lipids, don't irritate the skin, and function effectively at low concentrations. Unfortunately, levodopa must be kept in an acidic environment to maintain its stability and prevent oxidation. This can only be done in large numbers. It is difficult to create an effective levodopa patch when these considerations are taken into consideration. Methylester levodopa may be more suitable for transdermal distribution since it needs larger restricted amounts than ordinary levodopa; nevertheless, patch technology has not yet shown that methylester levodopa is sufficiently stable and adequate. This technique improves the stability and absorption of levodopa in rats. But as of yet, none of the approaches covered here have shown any promise in the treatment of Parkinson's disease in people.

One may get over the restrictions of the blood–brain barrier by making use of the unique connections that the olfactory and trigeminal nerves provide between the brain and the outside world. The central nervous system will preferentially absorb pharmacologically active substances that are delivered by the nose [50,51]. Active substances may be transported via axonal transport from the olfactory neurons in the olfactory epithelium to the olfactory bulb or by diffusion through perineuronal channels, perivascular spaces, or lymphatic arteries directly connected to the cerebrospinal fluid. To improve the drug's low oral bioavailability, hydrosoluble alkyl esters of levodopa have been suggested as possible pro-drugs for nasal administration. When administered via nasal route, the butyl-ester pro-drug increases CNS bioavailability without generating detectable levels of diacetyl (DA) in the bloodstream, in contrast to equimolar doses administered intravenously. To address levodopa's uneven and restricted oral bioavailability, a microparticle formulation with biocompatible and aerodynamic qualities has also been created for

aerosol dispersion. The bronchial tree allows the particles to enter the bloodstream quickly, avoiding the problems of unequal absorption and visible metabolism associated with conventional levodopa formulations.[52]

Animal models of Parkinson's disease (PD) have been used to evaluate the pharmacokinetic and neurochemical characteristics of levodopa given via oral and pulmonary formulations. Pulmonary administration was associated with a three- to five-fold larger reduction in symptoms and an earlier beginning of impact. Unfortunately, the drug's volatility in body fluids, quick enzymatic breakdown, and adverse pharmacokinetic characteristics hinder its transport mechanisms. Understanding the systems' toxicity, distribution, metabolism, excretion, and absorption will expand their therapeutic applications. There has also been research on cell treatment. Implanting dopamine-producing cells in the striatum may make up for the loss of dopaminergic neurons that results in Parkinson's disease. Research has demonstrated that in rats with lesions caused by 6-hydroxydopamine (6-OHDA) and in monkeys with lesions caused by 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP), transplanted nigrostriatal foetal cells survive, reinnervate the striatum, restore DA, self-regulate, and improve motor fluctuations. Fetal nigral mesencephalic neurons transplanted into Parkinson's disease patients have been shown to survive, reinnervate the striatum, and restore dopaminergic activity by PET tests.

However, two double-blind, controlled studies showed no therapeutic benefits when compared to a placebo. However, in the original study, transplantation was associated with persistent dyskinesias. The potential for autologous stem cells from skin, bone marrow, or umbilical cord to differentiate into dopaminergic neurons has been studied recently. There are currently no stem cell clinical studies involving Parkinson's disease patients [53–55].

Limitations

Levodopa treatment without motor side effects would be very helpful for PD patients. However, even in this instance, levodopa therapy is still subject to certain limitations. First, the potential toxicity of levodopa is still up for dispute. Reactive oxygen species may be produced as a consequence of levodopa metabolism, which might be dangerous. Although there is no clinical evidence that levodopa delays the progression of the illness, imaging studies that compare the medicine to placebo and dopamine agonists reveal a decline in nigrostriatal function biomarkers, suggesting that the treatment may have negative side effects. This requires more explanation. Second, long-term studies show that traits like dementia, freezing, and falling that are not responsive to levodopa are the main source of impairment in individuals with severe Parkinson's disease (PD). The potential introduction of levodopa treatment in a more physiologic manner is not anticipated to have an impact on the development of these nonresponsive features, They probably represent the extensive degeneration that Parkinson's disease (PD) causes in the brain, spinal cord, and peripheral autonomic nervous system.Therefore, a levodopa formulation that does not result in motor problems could nevertheless be linked to impairment in the future, necessitating the development of nondopaminergic and neuroprotective Parkinson's disease treatments [56-58]

CONCLUSION

Because levodopa–carbidopa therapy is so effective at reducing motor symptoms, it continues to be the mainstay of Parkinson's disease treatment. By increasing levodopa absorption, lowering peripheral side effects, and facilitating successful long-term treatment, the inclusion of carbidopa constitutes a crucial pharmacological advancement. However, rather than being a result of carbidopa's inherent flaws, motor problems such dyskinesias and fluctuations continue to restrict long-term benefit, reflecting the course of the illness and non-physiological dopaminergic activation. Promising developments toward more steady dopaminergic replacement are provided by emerging delivery methods, including continuous levodopa–carbidopa intestinal infusion. To significantly enhance patient outcomes, future treatment approaches must target non-dopaminergic disease processes while concentrating on attaining physiological dopamine stimulation.

ABSTRACT

This study aimed to develop and optimize iron tablets incorporating *Moringa oleifera* leaf extract and beetroot powder for the treatment of iron deficiency anemia. Iron was extracted from *Moringa oleifera* leaves using a cation-exchange resin and formulated into tablets by wet granulation using starch and microcrystalline cellulose as excipients. A design of experiments (DoE) approach was employed to optimize the formulation. The prepared tablets were subjected to pre- and post-compression evaluation, and in-vitro drug release studies indicated Fickian diffusion. *In vivo* studies were carried out using ferrous sulphate as the standard to assess haemoglobin levels and red blood cell counts. The optimized formulation showed a hardness of 5.23 kg, moisture content of 2.64%, and drug release of 86.71%. *Invivo* evaluation demonstrated a significant improvement in haemoglobin concentration (13.5 g/dL) and red blood cell count (7.8 million/µL). The results suggest that the polyherbal iron tablet effectively enhances haematological parameters and may serve as a safe and natural alternative to synthetic iron supplements for the management of iron deficiency anemia.

Keywords: Iron supplements, moringa extract, beetroot powder, Iron deficiency Anemia

INTRODUCTION

Anaemia, characterized by reduced haemoglobin concentration, commonly results from iron deficiency, folic acid deficiency, or haemolysis and represents one of the most prevalent nutritional disorders worldwide (1). It poses a significant public health concern, affecting approximately 40% of children, 35% of women, 51% of pregnant women, and 18% of men globally (2). Iron deficiency anemia remains the most common form and is associated with impaired physical performance, reduced cognitive function, and increased morbidity. *Moringa oleifera* is a nutrient-rich medicinal plant known for its high content of iron, calcium, vitamins, and essential amino acids, and has been widely reported as a safe and effective natural remedy for anemia (3). The dried leaves of *Moringa oleifera* contain approximately 97.9 µg/g of iron, which contributes to improved haemoglobin synthesis and enhanced erythropoiesis (4). In addition to its hematinic properties, *Moringa oleifera* is recognized for its antioxidant activity and overall nutritional benefits, making it a valuable dietary supplement. Furthermore, extracts of *Moringa oleifera* have demonstrated protective effects against oxidative stress and photo aging (5). This study aimed to develop iron tablets with Moringa oleifera extract and beetroot powder to treat iron deficiency anemia. The formulation was optimized, showing improvements in hardness, moisture content, and drug release. *In vivo* studies demonstrated significant increase in haemoglobin and red blood cell count.

MATERIALS AND METHODS

Moringa leaves, Beetroot powder, Starch (Fisher scientific India Pvt.Ltd., Mumbai), Talc, Micro crystalline cellulose, Magnesium stearate (Loba chemie Pvt.Ltd, Mumbai) were used in the present study.

Plant Collection and Identification

Fresh Moringa oleifera leaves were collected from botanical garden of Chalapathi Institute of Pharmaceutical sciences, Lam, Guntur. It was then authenticated by taxonomist from botany and microbiological department, ANU University, Guntur, Andhra Pradesh, India.

Preparation of Moringa Powder

Moringa leaves were cleaned and shade dried for five days until they became crisp with moisture less than 10%.The dried leaves were then grinded in to powder, passed through sieve and stored in an air tight container(6).

Characterization of Powder

The prepared powder was then evaluated for Tapped density, bulk density, angle of repose, Carr's index, Hausner's ratio and ash content(7).

Method of Iron Extraction

Iron extraction was performed using a Cation-exchange resin. The resin was activated by soaking in 0.5M Hcl to protonate active sites. Moringa powder was suspended in HPLC water, and the pH was adjusted to 2 using concentrated Hcl. The mixture was stirred at 40°C for 2 hours, vacuum filtered and passed through a pre-packed resin column at 1 mL/min. Adsorbed iron ions were eluted with 0.2M Hcl, neutralized with NaOH and concentrated via rotary evaporation. The purified iron solution was analysed using atomic absorption spectroscopy.

Determination of Iron (Fe):

Ten mg of the extract was dissolved in 1N HCl, sonicated for 10 minutes, and mixed with 1-10-phenanthroline, hydroxylamine HCL and sodium acetate. Absorbance was measured at 510 nm using the spectrometer (8).

Drug- Excipients Interaction Studies
Fourier transform infrared spectroscopy (FT-IR) using KBr was employed to obtain the infrared spectrum for the iron formulation, including excipients. The spectrum showed no interaction between the drug and excipients, confirming their compatibility.

Preparation of Tablets
Preparation of granules: Wet granulation
Granules were prepared by wet granulation method using hydrolysed starch as a binder by adding it in to boiling water (9).

Characterization of granules
Angle of repose, Tapped density, Bulk density was performed prior to tablet compression.

Experimental Design
The tablets were prepared using wet granulation method. To optimize the formulation, a 3^2 factorial design was employed, encompassing three levels and two factors, starch and MCC were treated as independent variables. Hardness, moisture content and *in vitro* diffusion were dependent variables. Nine distinct combinations were prepared and subjected to comprehensive evaluation.

Legend: All quantities are expressed in mg per tablet.

EVALUATION
Post compression evaluation was done to assess the thickness, weight variation, hardness and friability as per the standard procedures.

Disintegration Time: Six tablets were randomly placed in separate tubes of a disintegration rack, which was then raised and lowered at a constant rate in 0.1N HCL at 37±1°C. The disintegration time was recorded.
Drug Content: Percentage drug content was determined by performing developed assay of the tablet using 0.1HCl as a solvent (11).

Dissolution Time: *In-vitro* dissolution studies were performed using a USP type II dissolution apparatus with 900 mL of 0.1N HCl, maintaining a temperature of 37.5±0.5°C and a rotation speed of 50 rpm. Samples were withdrawn at 10, 20, 30, 40, 50, and 60-minute intervals. The samples were filtered and analysed using UV spectrophotometry at 510 nm (12).

Moisture content: Moisture content was determined using the loss on drying method by weighing three tablets, crushing them, and placing them in a hot air oven at 60°C. After cooling in a desiccator, the final weight was measured to calculate the moisture content.

Stability Studies: Stability studies were conducted to determine the shelf life and storage conditions of the tablets, following ICH guidelines. The tablets were stored in screw-capped amber bottles at 30°C and 60% humidity for eight weeks. Samples were collected every 10 days to evaluate drug content and organoleptic properties (13).

RESULTS

FT-IR
FT-IR spectra of the pure drug and the drug–excipient physical mixture are shown in **Figures 1 and 2**. Characteristic absorption bands corresponding to the Fe–C bond at 516.10 cm^{-1} and O–H stretching at 2927.12 cm^{-1} confirmed the

presence of iron and hydroxyl functional groups. No significant interaction between the drug and excipients was observed.

Calibration Curve

A stock solution of 700 mg ferrous in 1000 mL distilled water was prepared to give 100 µg/mL, with 5 ml sulphuric acid and heated at 65°C. 0.1N KMnO4 was added until a pink colour appeared, then the solution was made up to 1000 mL with distilled water. A series of concentrations (2, 4, 6, 8, 10 µg/mL) was prepared by adjusting with 0.1N Hcl. The calibration curve for ferrous iron demonstrated good linearity in the concentration range of 2–10 µg/mL **(**Table 2**,** Figure 3**).** Granule evaluation parameters including bulk density, tapped density, angle of repose, Hausner's ratio, and Carr's index for formulations F1–F9 are summarized in Table 3. All formulations exhibited acceptable flow properties for compression.

Tablet evaluation parameters including hardness, thickness, friability, drug content, and moisture content are shown in Table 4**.** Tablet hardness ranged from 4.0 to 7.1 kg/cm². Friability was below 1% for all formulations, and drug content ranged from 90.12% to 99.23%. Moisture content decreased with increasing starch and microcrystalline cellulose concentrations.

Design of Space

The effects of two factors, microcrystalline cellulose and starch, were examined using a 3^2 factorial design. Two levels of testing were performed for each factor: low level (-1) and high level (+1).Resulting in nine experimental runs.

Response 1: Hardness

Hardness =+3.08626
+0.66667 MCC
+0.131579 STARCH
The model was significant (F = 7.10, p = 0.0500) with R^2 = 0.7029. Starch significantly influenced hardness, whereas MCC had a lesser effect **(**Figures 4–6**).**

Response 2: Moisture content

Moisture content =+ 4.60035
-0.106667 MCC
-0.084211 STARCH
The model was highly significant (F = 384.00) with Predicted R^2 = 0.9810 and Adjusted R^2 = 0.9897. Both MCC and

Response 3: Drug release

Drug release = +108.90992
-1.21733 MCC
-0.953684 Starch
The model was highly significant (F = 473.01, p < 0.05), explaining 99.37% of the variance (R^2 = 0.9937). MCC had a major influence on drug release **(**Figures 10–12**).**

Legend: F10 represents the optimized Moringa and beetroot tablet formulation. Evaluation parameters indicate post-compression characteristics of the tablet. Overlay plot analysis identified F10 as the optimized formulation **(**Figure 13**)**. Its evaluation parameters are presented in Table 6**:** hardness 5.23 ± 0.3 kg/cm², moisture content 2.64%, drug release 86.71%.

***In Vitro* Studies:**

The in-vitro dissolution profiles of formulations F1–F9 are summarized in Table 7**.** The optimized formulation (F10) demonstrated sustained drug release over 60 minutes.

Legend: Values represent the cumulative percentage of iron released from the formulated tablets (F1–F9) at different time intervals. Dissolution studies were conducted in 0.1N HCl at 37 ± 0.5°C using USP Type II apparatus at 50 rpm.

Drug release kinetics

The Drug release of F10 followed zero-order kinetics, with the Higuchi model providing the best fit (R^2 = 0.99). The release exponent (n = 0.428) indicated Fickian diffusion as the predominant mechanism (**Figures 14–19**). Stability study results for F10 are presented in **Table 8**. No significant changes were observed in hardness, thickness, weight variation, moisture content, drug content, or drug release over six months. **Legend:** Values are expressed as mean ± standard deviation (n = 6). Parameters measured include hardness, thickness, weight variation, moisture content, content uniformity, and drug release to evaluate stability over 6 months at 30°C/60% RH.

***In Vivo* Studies**

In vivo studies were conducted to evaluate haematological parameters using herbal extract iron and beetroot powder (tests) compared to ferrous sulphate tablets (reference formulation) in rats with induced iron deficiency anemia. Healthy rats (180-200g) were selected and divided into six groups. Iron deficiency anemia was induced by feeding low-iron diets (>5mg iron/kg) for four weeks (14), resulting in Hb levels dropping below 9.0 g/dL, low serum iron, ferritin, and increased TIBC. The test formulation (2mg iron extract from moringa and 200mg beetroot powder) was administered orally as pellets for 21 days. Control groups received placebo or ferrous sulphate (15). Blood samples were collected via tail vein puncture (100-200µL) for testing Hb, RBC, HCT, and serum iron levels using a haematologyanalyser and spectrophotometric iron assay (ferrozine method). Rats were monitored for weight loss, stress, or abnormal behaviour during the study.

Legend: Values are expressed as mean ± standard deviation (n = 6). Haemoglobin, haematocrit, RBC – red blood cell count. Groups represent normal control, anaemic control, standard treatment, and test formulations of Moringa iron extract, beetroot powder, and their combination.

DISCUSSION

This study successfully formulated *Moringa oleifera*-based iron supplement tablets with beetroot powder, enhancing iron bioavailability. Pre-formulation and post-compression studies confirmed that the tablets possessed acceptable physical properties, including hardness, friability, weight uniformity, and moisture content. The optimized formulation (F10) demonstrated controlled drug release, following the Higuchi model, zero-order kinetics, and Fickian diffusion, indicating a steady and sustained release profile. *In vivo* studies in anaemic rats showed significant improvements in haemoglobin, haematocrit, RBC count, and serum iron levels, with the combination therapy outperforming individual treatments. The formulation exhibited efficacy comparable to ferrous sulphate while showing no adverse effects, confirming its safety and tolerability. These results highlight the synergistic effect of *Moringa* and beetroot in enhancing iron absorption and overall haematological health.

Overall, the findings indicate that the polyherbal iron tablets are mechanically stable, provide controlled iron release, and effectively improve haematological parameters, supporting their potential as a safe and natural alternative to conventional iron supplements. This study provides valuable insights into the development of plant-based iron formulations for the management of iron deficiency anemia.

ABSTRACT

Hematological malignancies, such as leukemias, lymphomas, and multiple myeloma, are known to exhibit distinct genetic abnormalities that contribute to uncontrolled proliferation, clonal evolution, and resistance to therapy. Traditional therapeutic approaches, including chemotherapy, radiation, and small molecule targeting, commonly present with challenges such as systemic toxicity, drug resistance, and disease recurrence. In this scenario, the advent of CRISPR-Cas9-based genome editing has revolutionized the field of hematological oncology by providing an unparalleled level of precision and versatility for the design of target-specific therapeutic strategies for blood cancers. This review aims to discuss the underlying principles, therapeutic applications, and translational feasibility of CRISPR-Cas9 in hematological oncology, focusing on target-specific approaches. The CRISPR-Cas9 system is based on a programmable ribonucleoprotein complex that consists of the Cas9 endonuclease and a single guide RNA (sgRNA), which targets the enzyme to complementary genomic loci flanked by protospacer adjacent motifs (PAMs). Upon binding, the Cas9 endonuclease generates site-specific double-strand breaks, which are subsequently repaired by the cell's DNA repair machinery, namely non-homologous end joining (NHEJ) and homology-directed repair (HDR). Taking advantage of these repair processes makes it possible to achieve precise gene disruption, correction, or insertion, thus facilitating the selective targeting of oncogenes, fusion genes, tumor suppressors, and loci associated with drug resistance. In blood malignancies, this strategy has been used to selectively knock out the leukemogenic drivers BCR-ABL1, FLT3, and NPM1 and to correct pathogenic point mutations underlying the progression of the disease.A significant domain of clinical translation is represented by immunotherapies engineered with

CRISPR. These include chimeric antigen receptor T-cell (CAR-T) and T-cell receptor (TCR)-based therapies. CRISPR technology allows for multiplexed genome editing, which enables the knockout of immune checkpoint proteins, the deletion of the endogenous TCR to avoid graft-versus-host disease, and the insertion of CAR genes at specific genomic loci. Moreover, functional genomic screens using CRISPR have also helped in the discovery of leukemia stem cell-specific vulnerabilities and mechanisms of drug resistance, thus offering a rational approach to precision medicine. However, despite its promise, the use of CRISPR-Cas9 in blood cancers is hindered by several challenges, such as off-target mutagenesis, low efficiency of homology-directed repair, delivery issues, and the possible immunogenicity of bacterial nucleases. Future approaches will be directed towards the development of high-fidelity Cas mutants, base and prime editors, improved ex vivo and in vivo delivery tools, and the integration of multi-omics and artificial intelligence-assisted target selection approaches.

Keywords: CRISPR–Cas9; Blood cancer; Genome editing; Target-based therapy.

INTRODUCTION

Blood cancers are diseases that hurt blood cells, bone marrow or the lymphatic system. The common kinds of blood cancers are leukemia, lymphoma and multiple myeloma. These blood cancers happen because of changes in our genes like mistakes in our genes or because our genes are not working the way they should. This can mess up the way our cells work [1]. The old ways of treating blood cancers can hurt tissues too because they kill any cells that are growing fast including the good ones. Now people who make medicines are trying to find new ways to treat blood cancers. They want to find ways to stop the bad cells, not the good ones. One way they are trying to do this is by using something called CRISPR–Cas9. This is a tool that can change our genes in a precise way. It can fix the mistakes in our genes that cause blood cancers [2]. Because blood cancers are often caused by problems with our genes using CRISPR–Cas9 to fix these problems is an idea. This article is, about how CRISPR–Cas9 can be used to treat blood cancers and how it can help us make new medicines to treat these diseases.

Blood Cancer: Classification and Genetic Features

Leukemia

Leukemia is a disease where the body makes many abnormal white blood cells. These abnormal white blood cells get in the way of the blood cells and cause problems. Leukemia can happen quickly or slowly depending on how the disease progresses. For example in myeloid leukemia there is a problem with the genes that makes a bad gene called BCR-ABL. This bad gene tells the cells to keep growing all the time [3].

Lymphoma

Lymphoma is a disease that starts in the cells. There are two types of lymphoma: Hodgkins lymphoma and non-Hodgkins lymphoma. In these diseases there are problems with genes like MYC and BCL-2. These problems make the cells live long and grow too much [4].

Multiple Myeloma

Multiple myeloma is a disease that affects the plasma cells. This disease makes the body produce antibodies. The problem is, with the genes that control how the cells grow, survive and work with the system. When these genes do not work right it causes myeloma [5].

CRISPR–Cas9: Basic Concept and Working Principle

CRISPR, which stands for Clustered Regularly Interspaced Short Palindromic Repeats and the Cas9 enzyme work together to form a system that can edit genes. This system was first found in bacteria, where it helps protect them

from infections. CRISPR allows scientists to make cuts at specific points in the DNA. This ability to make changes to the genome using RNA to guide the cut has changed the way molecular biology and therapeutic researches are done. In blood cancers genetic changes drive the progression of the disease. Make treatments less effective. CRISPR-Cas9 enables scientists to target and disrupt genes that cause cancer, correct genetic mutations that cause disease and modify cells for immunotherapy. The CRISPR-Cas9 system is simple, flexible and efficient making it possible to use both in and outside the body. This has laid the groundwork for precise medicine approaches. As delivery methods high-precision cutting tools and next-generation editors continue to improve CRISPR-Cas9 is becoming a tool for developing targeted long-lasting and clinically viable therapies, for blood cancers [6].

Essential Components

The CRISPR–Cas9 system has three parts: Cas9 protein, which cuts the DNA; Guide RNA, which finds and binds to the target DNA sequence; Target gene sequence that is intended for modification

Mechanism of Gene Editing

Once the guide RNA binds to the matching DNA part Cas9 makes a break in both strands of the DNA. The cell fixes this break using its repair methods, which can either disrupt or correct a gene depending on how the repair works. Figure 1 shows what happens over time after CRISPR therapy is used.

The CRISPR-Cas9 gene-editing process starts with designing a RNA called guide RNA or gRNA. This gRNA has a 20-nucleotide sequence that matches a part of the DNA. This part of the DNA is next to a sequence, like 5′-NGG-3′ which is needed for Streptococcus pyogenes Cas9 to work. The sequence is very important for making sure the edit happens in the place and not somewhere else. In practice two bacterial RNAs, crRNA and tracrRNA are combined into one RNA, called sgRNA. This sgRNA has two parts: one that helps Cas9 work and another that finds the target gene sequence. When the sgRNA is made it joins with the Cas9 enzyme forming a complex. This complex then moves through the nucleus looking for a sequence and a matching PAM. When it finds them, the DNA. The sgRNA pairs with the target DNA sequence forming a special structure. The sgRNA and target DNA match up because of how their bases pair and the correct sequence next to the target helps Cas9 activate and make a cut. The CRISPR-Cas9 system uses this process to edit genes. The guide RNA is critical for finding the spot. The Cas9 enzyme makes a cut in the DNA. The cell then fixes the cut. This process can. Disrupt a gene or correct it. The guide RNA and Cas9 work together to make this happen. The CRISPR-Cas9 system is a tool, for editing genes [7].

The HNH nuclease domain cuts the DNA that matches the sgRNA, and the RuvC domain cuts the other side. When the two cuts occur close to each other (3-4 base pairs) (upstream) of the PAM, this leaves an opening for your body's DNA repair mechanisms (error-prone non-homologous end joining repair; template-dependent homology-directed repair) to repair the opening left in the two DNA strands. Therefore, targeted gene alterations can occur and do occur using these two types of repairs in clinical treatments for patients that have blood cancers due to mutations that allow these genes to be modified or corrected.

Target Based Application of Crispr Cas9 in Treatment of Blood Cancer

The application of CRISPR-Cas9 technology to specific targets signifies a monumental change in the management of hematological cancers through direct intervention at the genetic level of the target(s) of disease development. Hematological malignancies are associated primarily with known genetic changes that lead to the development of blood cancer, including oncogenic fusion genes, activating mutation, loss of tumor suppressor function, and epigenetic changes. In contrast to traditional treatments that utilize chemotherapeutics/chemicals (e.g., chemotherapy) or small chemicals (e.g., small chemical inhibitors), CRISPR–Cas9 allows for irreversible and precise alterations to these molecular changes, providing a scientific and durable therapeutic option.

Disruption of oncogenes using CRISPR-Cas9 oncogenes are genes which upon inappropriate activation lead to uncontrolled growth, viability and self-renewal of malignant hematopoietic cells via disruption of their DNA sequence by the use of CRISPR-Cas9 technology. Many of these oncogenes have been investigated recently with respect to their effectiveness in selectively disrupting the oncogenic drivers via the editing of the oncogenic driver's DNA sequence. One of the best studied oncogenes is BCR-ABL which is a fusion oncogene that occurs commonly in chronic myeloid leukaemia (CML). The BCR-ABL fusion oncogene encodes a constitutively active tyrosine kinase that continuously activates many of the known downstream signalling pathways commonly activated in leukaemia, including PI3K/AKT, JAK/STAT, and MAPK, leading to the uncontrolled growth of leukaemia cells. The CRISPR-Cas9 technology has been specifically directed towards targeting the BCR-ABL fusion gene by specifically targeting the unique fusion junction of the BCR and ABL DNA sequences resulting in double-strand breaks of the BCR-ABL fusion oncogene, thus resulting in selective elimination of leukaemia cells while leaving unaffected the normal human haematopoietic cells. These preclinical studies have subsequently provided evidence that by disrupting the BCR-ABL fusion oncogene using CRISPR-Cas9, there is a substantial reduction in the ability of BCR-ABL+ leukaemic stem cells to survive as well as a reduction in the disease progression of murine models, which further supports the superiority of CRISPR-Cas9 over the use of tyrosine kinase inhibitors that do not typically eliminate resistant leukaemic stem cell populations (Figure 2).

Targeting Oncogenes

Mutated genes called oncogenes can cause uncontrollable growth of cells. The use of CRISPR–Cas9 to inactivate oncogenes can limit the growth of cancers by causing the destruction of oncogenes. Oncogenes BCR–ABL (therefore targeting the BCR/ABL oncogene will limit the growth of cancer) and MYC (modifying or destroying the MYC oncogene will also result in the limited growth of lymphoma) are common targets for CRISPR–Cas9 [8].

Targeting Tumor Suppressor Genes

Tumor-suppressor genes play a key role in regulating cell proliferation and causing cells to undergo apoptosis. In blood cancers, the loss or mutation of p53 (TP53) has been frequently seen in many examples. Therefore, CRISPR–Cas9 can be used to restore the normal function of p53 and limit cancer cell growth [9].

Targeting Drug Resistance

There is significant data to suggest that many cancer cells develop resistance to anticancer therapy. Therefore, the use of gene-modifying methods such as CRISPR to delete or modify the proto-oncogenes associated with drug resistance could lead to your current chemotherapeutic regimens being more effective [10].

Role of CRISPR Cas9 in Blood Cancer Immunotherapy

The CRISPR-Cas9 tool has greatly improved the precision engineering of immune cells, allowing targeted modifications to boost anti-tumor immunity. It is an RNA-guided nuclease that introduces double-strand breaks at particular genomic sites, enabling targeted gene knock-outs, knock-ins, or transcriptional modulation. This precision enables the development of next-generation immunotherapies, especially in hematologic malignancies, where immunotherapy (such as CAR-T cell therapy) has shown curative effects but needs optimization for safety and long-term efficacy (Figure 3).

Immune Checkpoint Modulation

Immune checkpoint proteins such as PD-1 and CTLA-4 suppress T-cell responses in the tumor microenvironment. CRISPR knockout of PD-1 in CAR-T cells has improved persistence and killing activity. However, beyond T cells, genome-wide CRISPR screening can help identify new immune modulators that can counteract tumor immune evasion pathways.

CRISPR Screens to Discover Novel Targets

Genome-wide CRISPR screening has been a key tool in the discovery of immunomodulatory genes that affect tumor immune interactions, antigen presentation, and checkpoint blockade responsiveness, thereby uncovering new targets for therapeutic intervention.

Engineering of CAR-T Cells

The CRISPR-Cas9 system is commonly employed for the genetic engineering of T lymphocytes for chimeric antigen receptor (CAR) T-cell therapy. Such modifications have enhanced the capacity of immune cells to target and kill cancer cells [11].

Universal CAR-T Cell Development

By removing genes that cause immune rejection, the CRISPR-Cas9 system makes it possible to develop universal CAR-T cells that can be applied to more than one patient, thereby lowering the cost of treatment and preparation time [12].

Delivery Strategies Concerning to CRISPR Therapy

The safe and efficient delivery of the CRISPR system is a major challenge in the application of the CRISPR system and therefore, scientific strategies have been employed through trial and error. The strategies most often employed include:

Viral Delivery Systems

Lenti-viruses have high delivery efficiency but can trigger immune responses and insertional mutagenesis, thereby limiting their application [13].

Non-Viral Delivery Systems

Nanotechnology-based delivery systems, including lipid nanoparticles (LNPs) and polymeric systems, have been shown to be effective in the delivery of Cas9 mRNA, RNP complexes, and plasmid DNA with improved safety. Lipid nanoparticles (LNPs) protect nucleic acids from degradation and can help in endosomal escape. Polymeric micelles and dendrimer systems have adjustable release rates. Inorganic nanocarriers, such as gold nanoparticles, provide a stable platform for RNP delivery.[14]

Extracellular Vesicles (EVs)

Engineered exosomes and microvesicles are natural carriers that have the ability to overcome biological barriers and decrease immunogenicity. EVs can be engineered to package CRISPR components, providing a new non-viral delivery method that has enhanced biocompatibility.

DNA-Based Systems

These systems provide delivery of Cas9 and sgRNA-encoding plasmids. They are easy to prepare but require nuclear entry and pose a risk of prolonged expression, which could increase off-target effects.

mRNA Delivery

Delivery of Cas9 mRNA and sgRNA prevents genomic integration and has transient expression, which decreases off-target effects. However, the instability of mRNA and endosomal escape are major hurdles that have been overcome by newer lipid delivery systems.

Ribonucleoprotein (RNP) Complexes

Direct administration of Cas9 protein-sgRNA complexes has immediate effects and low off-target editing because of rapid degradation. Nanocarrier formulations and electroporation are the most used methods for RNP delivery.

***Ex Vivo* Editing Approaches**

Ex-vivo genome editing is the process of cell extraction and modification outside the body, followed by the reinfusion of the genome-edited cells into the patient. This process enables control over the delivery of CRISPR-Cas9 components, the outcome of genome editing, cell selection, and safety evaluation before cell transplantation. For blood cancers and blood disorders, the primary target cells are hematopoietic stem and progenitor cells (HSPCs) and immune cells such as T lymphocytes, which have high therapeutic potential. In ex-vivo genome editing, delivery systems can be designed to deliver CRISPR components in the form of Cas9 ribonucleoprotein complexes (RNPs), messenger RNA (mRNA) and guide RNA, or DNA expression cassettes. The strategy is to achieve transient and efficient genome editing with reduced genomic integration, immunogenicity, and off-target effects. In ex vivo genome editing, cells are modified outside the body and then reinfused into the patient. This strategy improves safety and quality control of genome-edited cells [15].

Clinical Context: *Ex-vivo* CRISPR Editing in Blood Disorders and Cancers

The *ex-vivo* CRISPR strategy has already achieved clinical fruition in hemoglobinopathies such as sickle cell disease (SCD) and transfusion-dependent β-thalassemia, with products such as Casgevy (Exagamglogene autotemcel) showing high levels of ex-vivo editing of HSPCs to re-induce fetal hemoglobin production. Edited cells are then infused after myeloablative conditioning, resulting in high levels of clinical response. While not a treatment per se for blood cancers, the successful ex-vivo CRISPR editing paradigm for HSCs provides a paradigm that can also be used in malignancies, such as the genetic engineering of T cells expressing chimeric antigen receptors (CARs) and the use of CRISPR to delete endogenous receptors or immune checkpoints to improve antitumor efficacy. In blood malignancies, ex-vivo edited immune cells can be expanded and reinfused, providing adoptive cell therapies with high specificity and function.

Benefits of Target Based Crispr Therapy

The primary advantages of CRISPR-Cas9-based therapy are high specificity, minimal toxicity to normal cells, long-term therapeutic effects (Figure 4), and the possibility of developing personalized therapeutic regimens [16].

Molecular Precision and Target Specificity

Targeted CRISPR therapy allows for precise genome editing by guiding the Cas nuclease to a specific DNA locus using a sequence-specific single-guide RNA (sgRNA). This specificity allows for selective targeting of pathogenic genes without affecting the integrity of the genome. In contrast to conventional pharmacotherapy, which targets downstream signaling pathways, CRISPR therapy targets the primary genetic defect, thus improving specificity and reducing bystander effects on normal tissues. Clinical Relevance: In hematological malignancies, CRISPR-mediated targeting of oncogenic drivers such as BCL11A, FLT3, and TP53 has shown superior specificity, reducing off-target cytotoxic effects commonly seen with chemotherapy.

Curative Potential with Permanent Gene Correction

One of the key benefits of CRISPR therapy is its potential for permanent genetic modification, thus offering a one-time curative approach. By correcting or disrupting disease-causing mutations, CRISPR therapy targets the underlying pathology rather than treating symptoms. Clinical Relevance: Clinical trials using CRISPR-edited hematopoietic stem cells in sickle cell disease and β-thalassemia have shown persistent expression of fetal hemoglobin, thus achieving long-term clinical remission without the need for continuous therapy.

Decreased Systemic Toxicity and Enhanced Safety Profile

Conventional anticancer treatments are non-specific at the molecular level and can cause harm to rapidly proliferating normal cells, leading to severe side effects. CRISPR therapy, being specific to targeted genes, minimizes systemic toxicity. Clinical Relevance: Ex vivo CRISPR-modified immune or stem cells are reinfused into the body after careful modification, thus reducing off-target tissue damage and improving safety profiles in leukemia and lymphoma patients.

Overcoming Drug Resistance Mechanisms

Drug resistance is a significant problem in cancer and infectious diseases. CRISPR therapy can specifically ablate genes that confer drug resistance. Clinical Relevance: Deletion of multidrug resistance genes (MDR1) and immune checkpoint genes (PD-1) by CRISPR has improved the efficacy of chemotherapeutic and immunotherapeutic agents in drug-resistant cancers. In HIV infection, CRISPR-mediated targeting of CCR5 has shown potential in blocking viral entry and persistence.

Personalized and Precision Medicine Strategy

The CRISPR system is flexible and allows the generation of patient-specific sgRNAs according to individual genetic mutations. This enables the creation of personalized therapies according to the patient's molecular disease signature. Clinical Relevance: Autologous CRISPR-modified CAR-T cells demonstrate enhanced tumor selectivity and reduced immune rejection, thus increasing rates of remission in drug-resistant blood cancers.

Long-Term Therapeutic Efficacy and Improved Compliance

Since genome editing via CRISPR is a stable and heritable process at the cellular level, the therapeutic effects are long-term. This also obviates the need for frequent drug therapy and improves patient compliance. Clinical Relevance: Long-term follow-up analysis of CRISPR-based therapies has shown sustained clinical efficacy, reduced healthcare costs, and improved patient quality of life.

Challenges and Limitations of CRISPR-Cas9 Therapy

Despite the vast therapeutic potential of CRISPR-Cas9 therapy, several scientific, ethical, and practical limitations and challenges exist, such as off-target effects, ethical issues, high cost of therapy, regulatory hurdles, and a lack of understanding of long-term safety and efficacy (Figure 4).

Target Identification and Selection

Acute myeloid leukemia and chronic lymphocytic leukemia are highly heterogeneous hematological malignancies, and several subclones with different mutations exist, which emerge due to the selective pressure of therapy. The choice of target gene, which, when corrected, would result in sustained remission, is difficult. Most of the mutations are passenger mutations, and not the driver mutations of malignancy, and alteration of a single gene in complex signaling pathways may not be sufficient to suppress malignancy. Also, the absence of understanding of the causative relationship between mutations and malignancy makes target selection difficult.

Off-Target Effects and Genomic Safety

The CRISPR-Cas9 system has the potential to target and cut DNA sequences that are complementary but not identical to the guide RNA, causing off-target effects and thus unwanted genetic alterations. These off-target effects can inactivate tumor suppressor genes or activate oncogenes.

Delivery Challenges

The issue of efficient delivery of the CRISPR reagents to hematopoietic and leukemic cells remains a challenge. The use of viral vectors, such as lentiviruses and adeno-associated viruses, is limited by their immunogenicity and the size constraints of the vector. The delivery system must thus ensure precise targeting, prevent the activation of the immune system, and ensure the sustained action of gene editing. Ex vivo approaches, which involve gene editing of hematopoietic stem cells or T cells in a laboratory setting, are characterized by complex cell isolation procedures, highly advanced GMP-grade facilities, and standardized reinfusion procedures. In contrast, in vivo delivery is limited by the lack of specificity of targeting, immune system degradation, unwanted uptake by non-target tissues, and the possibility of deletions or chromosomal rearrangements. These genomic alterations are difficult to detect but pose serious safety concerns.[17]

Functional and Physiological Limitations

The achievement of a sufficiently high editing efficiency in all cancer cells is not easy. Incomplete editing may lead to the presence of residual cancer cells that may cause relapse. Moreover, the utilization of genes that regulate cell survival may lead to the elimination of cancer cells but also poses a risk to normal hematopoietic stem and progenitor cells. The capacity to distinguish between cancer and normal cells at the genetic level is still a major limitation in selective therapy.

Immunogenicity and Host Responses

The Cas9 proteins are derived from bacterial species like Streptococcus pyogenes. These proteins are immunogenic to the human immune system. This may result in pre-existing or therapy-induced immune responses, which may result in inflammation, rapid clearance of edited cells, and lack of durability of the treatment effect. Thus, in a nutshell, in the context of target-based CRISPR-Cas9 therapeutic approaches for blood cancers, there are a number of important challenges and limitations that need to be taken into consideration. Target identification and selection is a basic challenge, in that while the use of genomic screens has made it possible to identify oncogenic drivers and targets, the task of separating essential cancer-specific targets from normal hematopoietic functions is complex, especially in the context of genetic heterogeneity of leukemias and lymphomas, and challenges such as the PAM sequence constraint that limits where Cas9 can be targeted in the genome. Off-target effects and genomic safety are another important area of concern, in that while the lack of precision of guide RNA and the tolerance of mismatches can result in the generation of unintended DNA breaks at other loci, this can result in deleterious mutations, chromosomal rearrangements, and potentially oncogenic transformation. The delivery issues further reduce the utility of the CRISPR-Cas9 system in blood cancers, as the efficient and specific delivery of the Cas9 protein and guide RNA to the malignant cells in vivo is hindered by biological constraints, the capacity of viral vectors, and the risk of insertional mutagenesis; the viral vectors, such as AAV, have a limited capacity for payload, while the risk of persistent expression is also a concern, and non-viral vectors, such as nanoparticles, are still plagued by specificity and uptake issues. Furthermore, the biological and physiological constraints also make therapeutic editing more complicated, as the efficiency of homology-directed repair (HDR) in primary hematopoietic cells is low, and the use of error-prone repair mechanisms may result in variable editing efficiency; also, the physiological complexity of the bone marrow niche and tumor microenvironment may hinder uniform editing of the malignant cell populations. Finally, the challenges of immunogenicity and host response are considerable: the immune system's recognition of the bacterial-derived Cas9 proteins and viral vectors for delivery may initiate an adaptive response that eliminates the edited cells or induces inflammation, which would be detrimental to both safety and efficacy. As research continues, it is important that these challenges are overcome by improved target selection algorithms, high-fidelity Cas9 mutants, improved delivery systems, and immune evasion strategies to unlock the full potential of CRISPR-Cas9-based therapies in blood cancers.

Ethical and Regulatory Issues

The use of CRISPR-Cas9 in blood cancers, although promising, also raises important issues that need to be addressed in the responsible translation of this technology. Somatic genome editing, as occurs in hematopoietic and immune cells, is considered to be of lower ethical concern than germline editing, although there are still issues of off-targeting, long-term genomic integrity, and potential immunogenicity. The safety of patients requires rigorous preclinical studies for editing specificity, risk of insertional mutagenesis, and monitoring for clonal dominance or malignancy after treatment. From a regulatory perspective, the novelty of CRISPR-based therapies poses a challenge to the existing regulatory framework for cell and gene therapy. There is a need to strike a balance between the rapid translation of CRISPR-based therapies and the need for adequate quality control, manufacturing, and long-term follow-up. The guidelines related to the procurement of donor cells, informed consent, and clinical trial design are most relevant to ex vivo editing strategies, such as CAR-T cell and HSC editing. Furthermore, global harmonization of ethics and regulation is necessary to avoid unregulated use, particularly in low- and middle-income countries. Finally, the possibility of dual-use issues and unforeseen use highlights the need for transparent governance, multi-disciplinary regulation, and engagement with stakeholders, including patients, clinicians, bioethicists, and regulators. Proactive engagement with these ethical and regulatory issues will be crucial to the successful translation of CRISPR-

Cas9 into safe, effective, and socially responsible therapies for hematological malignancies. Therefore, the ethical issues are primarily related to the potential for undesired genetic modifications and the misuse of gene editing technology. Existing regulations are very stringent against germline editing and demand rigorous testing before any clinical use [18].

Future Directions

Future work is underway to enhance the accuracy of editing, develop more secure delivery methods, and integrate CRISPR-based therapies with traditional therapies. Initial clinical trials have shown promising outcomes in the management of blood cancers [19].

Transition from Double-Strand Break–Dependent Editing to Next-Generation Precision Editors

Although the introduction of double-strand breaks (DSBs) by the CRISPR-Cas9 system has made genome editing possible, future therapeutic approaches are likely to increasingly incorporate DSB-independent genome editing tools to improve genomic integrity. Base editing and prime editing tools provide the ability to introduce single nucleotide substitutions, small insertions, or deletions without the need to introduce DSBs, thus minimizing the potential for chromosomal rearrangements and p53-induced genotoxic stress. In the setting of blood cancers, in which single-point mutations (such as FLT3, IDH1/2, and TP53) contribute to the progression of disease and resistance to therapy, these next-generation editors provide a promising approach for the precise correction of pathogenic alleles in hematopoietic stem and progenitor cells.

Enhancement of CRISPR-Edited Cellular Immunotherapies

The future of CRISPR-Cas9 therapy in hematological malignancies will be largely influenced by the progress made in cellular immunotherapies, particularly the development of allogeneic and multi-edited immunotherapy platforms. The CRISPR system possesses the capability of editing multiple genes at once, which will be beneficial in developing immune cells that exhibit superior anticancer properties, resistance to the immunosuppressive tumor microenvironment, and improved safety. Some of the most promising directions in this field include the development of universal "off-the-shelf" CAR-T and CAR-NK cells by knocking out native T-cell receptors and HLA genes, the application of multiplex genome editing to suppress immune checkpoint pathways while promoting immune cell persistence and metabolism homeostasis, and the implementation of CRISPR-controlled logic-gated circuits to improve tumor specificity. These developments are expected to address the issues of complex manufacturing procedures, high costs of treatment, and heterogeneity of patient responses, thus making cell-based therapies more accessible to patients with hematological malignancies.

Targeting Leukemia Stem Cells and Clonal Evolution

One of the major future directions of CRISPR-Cas9 therapy will be the prevention of relapse and regulation of clonal evolution, which are frequently driven by leukemia stem cells and genetically heterogeneous subclones. Functional genomics with CRISPR-Cas9 systems will remain an essential component in the identification of leukemia stem cell-specific vulnerabilities, such as epigenetic regulators, transcriptional programs, and metabolic pathways. Future strategies will probably involve selective gene disruption for those genes that play a critical role in the survival and self-renewal of leukemia stem cells, regulation of signaling pathways that mediate bidirectional interactions between leukemia stem cells and the bone marrow niche, and combination therapies that integrate CRISPR editing with targeted therapies to inhibit clonal evolution.

***In Vivo* Genome Editing and Delivery Technology**

Although the current therapeutic application is mainly directed towards ex vivo genome editing, future advances will require the development of safe and efficient in vivo delivery systems that can specifically target malignant or pre-malignant hematopoietic cells. Advances in lipid nanoparticle delivery systems, biodegradable polymer-based systems, and viral vectors are expected to enhance the specificity of targeting, minimize immune reactions, and permit transient expression of CRISPR elements. In vivo genome editing could potentially allow the direct targeting

and eradication of circulating cancer cells, manipulation of bone marrow-resident hematopoietic cells, and provide therapeutic options for patients who are not candidates for stem cell harvesting. These approaches would greatly extend the therapeutic application of CRISPR-Cas9 beyond the current emphasis on transplant-dependent modalities.

Integration of CRISPR with Precision Medicine and Multi-Omics Platforms

Future CRISPR therapies are expected to be more and more integrated with genomic, transcriptomic, epigenomic, and proteomic analyses. High-throughput CRISPR screens and artificial intelligence-driven analysis will make it possible to identify context-specific therapeutic targets and biomarkers. This integration will make it possible to develop personalized genome editing strategies based on the individual mutational profile and disease course, thus improving the efficacy of the therapy and reducing off-target effects.

Clinical Case Study 1: CRISPR-Engineered Universal CAR19 T Cells in Relapsed/Refractory Pediatric B-ALL

The first trial in human, phase I clinical trial assessed the feasibility and safety of CRISPR Cas9-engineered universal chimeric antigen receptor T (CAR19) cell therapy, TT52CAR19, in children with relapsed or refractory CD19 positive B cell acute lymphoblastic leukemia (B ALL) (NCT04557436). In this open-label, non-randomized clinical trial, the donor T cells were engineered ex vivo with CRISPR Cas9 to knock out the gene loci of T cell receptor α constant (TRAC) and CD52. The knockout of TRAC was intended to prevent graft versus host disease (GVHD), while the knockout of CD52 loci provided a survival benefit in the presence of lymphodepleting agents like alemtuzumab. A self-replicating CRISPR guide RNA expression cassette in a lentiviral vector co-expressed a CD19-specific CAR gene in the engineered T cells [20]. Six pediatric patients received TT52CAR19 cells after lymphodepletion with fludarabine, cyclophosphamide, and alemtuzumab. The infusion of 0.8-2.0 × 10^6 CAR19 T cells per kilogram was tolerated without any immediate toxicities. Four of the six patients treated demonstrated both in vivo CAR T cell expansion and flow cytometry-confirmed remission, allowing the progression to allogeneic hematopoietic stem cell transplantation. Adverse events included grade II cytokine release syndrome, transient grade IV neurotoxicity, and reversible skin GVHD after transplantation conditioning, all of which were expected and fell within the expected parameters of CAR T cell immunotherapy. Notably, the trial achieved its primary endpoints of safety and feasibility and also suggested a therapeutic potential of CRISPR-modified universal T cells in high-risk pediatric leukemia.

Clinical Case Study 2: Multiplex CRISPR-Cas9 Editing of T Cells in Refractory Malignancies Including Hematologic Cancer

The initial multiplex CRISPR Cas9 editing in humans was described in a phase I clinical trial involving three genes in autologous T cells from patients with advanced, refractory cancers, including hematologic malignancies. In this trial, T cells were engineered ex vivo to delete the endogenous T cell receptor α (TRAC) and β (TRBC) chains to prevent mispairing and programmed cell death protein 1 (PD 1; PDCD1) to potentially improve antitumor function. The cells were also transduced with a lentiviral vector containing a cancer-specific NY ESO 1 T cell receptor transgene to target tumor antigens. The engineered cells showed robust engraftment in vivo with edits present at all targeted genomic loci. Of note, the modified T cells persisted for up to nine months after infusion, indicating ongoing immune system activity with few immunogenic issues related to CRISPR editing. Although chromosomal translocations were noted, their incidence decreased with time, and no dose-limiting toxicities were reported that were directly related to gene editing. These findings offered early proof-of-concept that multiplex CRISPR Cas9 gene editing of T cells could be performed safely and persist within patients, providing a foundation for future immunotherapeutic approaches in treatment-refractory hematologic malignancies and other cancers [12].

CONCLUSION

Targeted approaches of the CRISPR-Cas9 system are a revolutionary shift in the management of blood cancers, providing an unparalleled level of accuracy in the manipulation of oncogenes, tumor suppressor genes, and immune regulatory pathways. The ability to both disrupt and correct genes using the CRISPR-Cas9 system enables the design

of personalized therapies based on the distinct genetic and epigenetic profiles of individual patients. Ex vivo approaches, especially in hematopoietic stem cells and immune effector cells, have shown encouraging results in preclinical and early clinical studies, including improved efficacy, decreased off-target toxicity, and improved persistence of gene-modified cells. Future improvements in next-generation genome editors, high-fidelity "Cas" mutants, and targeted delivery platforms are anticipated to further improve the safety, specificity, and translational potential of CRISPR-based therapies. Combination with multi-omics profiling and computational modeling will empower the rational design of patient-specific therapies and the discovery of new therapeutic targets. Taken together, these efforts place the CRISPR-Cas9 system not only as a valuable research tool but also as a viable platform for precision medicine in hematological malignancies, poised to overcome the limitations of conventional therapies, decrease relapse rates, and improve long-term patient outcomes.

ABSTRACT

A wireless ad hoc network is a decentralized, infrastructure-free network that connects mobile and stationary wireless devices over wireless media. The limited power capacity of nodes during the discovery phase is a crucial component of wireless Ad-hoc network. The primary goals of this work are to lengthen the network's lifetime and reduce redundancy in ad hoc wireless networks. Among the most well-known resource allocation issues in wireless networks are power control and scheduling, which are frequently resolved as optimization problems with constraints. Nevertheless, employing optimal methods to solve these optimization problems frequently results in a large amount of temporal complexity, which leads to a huge disparity between the theoretical outcomes. Our method drastically lowers the number of redundant messages and improves the message delivery rate by directing message flow to the shortest predicted path nodes. We present the SPCDNet deep neural network scheduling and power control algorithm, along with its variation SPCDNetR. While SPCDNetR handles more complex

scheduling problems when the source transmission sequence consists of ordered routes that must be satisfied, SPCDNet handles scheduling problems for point-to-point transmission requests. . Our method drastically lowers the number of redundant messages and improves the message delivery rate by directing message flow to the shortest predicted path nodes. The major goal of this paper is to present new perspectives on effectively resolving path problems in graphs, as well as advanced security measures used to defend MANETs, such as encryption, secure routing protocol, and trust management approaches.

Keywords- Ad-hoc Network, MANET(s) Routing and security, Deep Learning, Multi-hop communication, Route discovery, Cryptography.

INTRODUCTION

One of the biggest challenges in dynamic wireless environments is still allocating power and multi-hop resources. The temporal complexity and discrepancy between theoretical and real results are two problems that traditional routing frequently faces. The deep learning-driven framework, SPCDNet, is introduced in this work to address these "path problems," minimizing redundancy and maximizing network lifetime. As a result, rigorous control over the transmission power is necessary to reduce interference and improve system performance as a whole. In this paper, we examine the scheduling of transmission resources and power distribution for clusters in the context of mobile ad - hoc networks. As we solve the aforementioned problems, our objective is to maximize throughput, given the list of transmission requests, in a multi-time, multi-hop wireless system. This study presents a detailed security analysis of recent trends and solutions in Mobile Ad-Hoc Networks (MANETs), with the goal of providing researchers with vital insights for safeguarding communication inside these dynamic networks. While other studies focus on individual aspects of MANET security, this work consolidates and synthesizes available knowledge by examining present security mechanisms and investigating emerging trends. Finally, we hope to contribute to the growing body of knowledge on MANET security and support the development of robust and adaptive security measures for the developing landscape of MANETs.As per this article we examine two categories of link scheduling issues: the per-route scheduling issue and the per-link scheduling issues.

Article Organization

A bibliographic review and discussion of various routing protocols are covered in Section II. Following that, various DSR Protocol adjustments are presented. The DNN Structure and various security mechanism are discussed in Section III, The Present Work and the reasons for the work completed, In addition, the various ways that mobile devices use power and the node rank that is specified in the chapter. Following that, the implementation algorithm is provided. A few examples are also covered. The implementation is described in Section IV, and Section V concludes with a discussion of the constraints and future scope.

Smart Autonomous Network Transition (MANET/WANET)

Infrastructure-less self-configuring network and networking systems called MANET (Mobile Ad-hoc Networks) or WANET (Wireless Ad-hoc Networks) run independent of any fixed infrastructure. Current Intelligent MANETs incorporate AI operating on the edge to provide instantaneous routing decisions using network wellness and node mobility metrics; where legacy systems utilized primitive node-to-node relaying. Decentralized wireless networks are known as wireless ad-hoc network (WANETs) or MANETs. MANETs have transformed the way mobile devices communicate. Ad hoc networks are not necessary an established infrastructure; MANETs are distinguished by their dynamic and self-configuring nature, allowing devices to form temporary networks on the fly without bending on centralized or pre-established network infrastructure. The architecture is illustrated in Figure 1. As exemplified by managed (infrastructure) wireless networks access points or routers in wired networks. Rather, every node engages in routing by relaying information to other nodes; therefore, the routing algorithm and network connectivity are used

to dynamically determine which nodes relay information. Since it lacks the infrastructure to enable communication between nodes, nodes in this form of network must rely on one another for communication

Despite their various benefits, MANETs pose unique security issues due to their decentralized and resource-constrained design. Open and wireless communication expose MANETs to a wide range of security concerns, including node behaviour and data eavesdropping, as well as malicious attacks on routing protocols and denial-of-service (DoS) exploits. Each node in this sort of network has equal authority and obligation to do this. To ensure that data packets meant for a particular node reach the intended one, a node depends on other nodes to forward the packets

Path Issues and Contemporary Networking Difficulties

Finding the most effective path in a medium with low bandwidth, high latency, and frequent disconnections is the fundamental "path problem" in wireless networking. Temporal Complexity: As the topology changes, traditional optimization techniques frequently fall short of determining the "shortest path" in real time. Power & Interference: Accurate power control algorithms are necessary because transmission power meant for one receiver frequently unintentionally interferes with other receivers. Redundancy: Limited node batteries are quickly depleted by high message redundancy during the route discovery phase.

Classification of Next Generation Ad-hoc Networks

Ad hoc wireless networks are developing into a specific, data-conscious environment: Wireless Mesh Networks (WMN): Self-repairing networks of mobile clients and stationary nodes (gateways). Wireless Sensor Networks (WSN): In sensor networks that track environmental data, deep learning is being utilized more and more to improve data transmission. Fast vehicle-to-everything (V2X) communication with an emphasis on efficient data transfer and driving safety is known as vehicular ad hoc networks, or VANETs

SPCDNet-Based Optimized Path Selection

A major advancement in technology is represented by the projected SPCDNet and SPCDNetR. By guiding the flow of messages to the "shortest predicted path nodes," this technique significantly lowers the number of redundant messages and boosts delivery speed. This deep-learning method manages point-to-point and ordered-route requests with nearly optimal efficiency, in contrast to conventional DSR protocols.

Types of Mobile Ad-hoc Network (MANET)

A MANET can be further divided as follows

Vehicular ad hoc networks (VANETs)

Vehicles and peripheral equipment can communicate using VANETs. VANETs, or intelligent vehicular ad hoc networks, use artificial intelligence to help autos act responsibly during crashes and issues with other vehicles. Cars use radio frequencies to communicate with each other while driving. 1 Vehicle ad hoc networks (VANETs) are based on the concept of mobile ad hoc networks (MANETs), which are spontaneous wireless networks used for data transmission. [1] Under car-to-car ad hoc mobile communication and networking" applications, where networks can be built and information can be transferred among cars, VANETs were first mentioned and introduced [2] in 2001. Vehicle-to-vehicle and vehicle-to-roadside connectivity architectures can coexist in VANETs to provide road safety, transportation, and other services. VANETs play a crucial role in the ITS architecture. VANETs are additionally referred to as Intelligent Transportation Networks.

Intelligent vehicular ad hoc networks (In VANETs)

Through the provision of timely information to drivers, vehicular communication is anticipated to enhance road safety and efficiency while also facilitating travel. While V2R offers superior service fragmented networks and long-distance communication, V2V allows direct contact across modest to medium distances and in places without roadside access points. For these reasons, the merger of V2V and V2R communication is advantageous.

SECTION II

In this paper, given the transmission requests, we suggest using DNNs for scheduling and transmission power control in cellular communication networks. In recent years, there has been a large number of discussion on the difficulties with power regulation in wireless networks [15], [16], [17], [18], [19], [25].For uplink and downlink broadcasts, both centralized and decentralized approaches have been suggested. For multiple versions of this task, different machine learning-based solutions have been suggested [19], [20], [21], [22], [23], [24]. Using DL to arrive at optimal or nearly optimal solutions to control decisions made in communication networks is recommended by several recent research on communication resource management. A multi-layer neural network is typically trained with the network state (in a particular form) as the network input and the resource allocation decision as the output, which is to be taught. The DNN can be constructed in two ways: unsupervised by adjusting neural network measurements or supervised by providing a training set with resource allocation solutions based on optimization methods for each input, for example. This section covers relevant research on using deep learning (DL) to handle arranging and power control concerns. We explore deep learning (DL)-based solutions for wireless communication that solve routing and scheduling issues.

DSDV (destination sequenced distance vector routing)

The routing protocol for ad hoc networks differs from the standard Routing Information Protocol. The classic RIP adds a new characteristic, a sequence number, to each route table entry. Mobile nodes can avoid route loop creation by identifying new and outdated route information using the newly inserted sequence number. Routing Table Management and Packet Routing. Every portable node in an ad hoc network uses DSDV to keep a routing table up to date with all possible places of interest, their metric, the next stop on the way to each destination, and the sequence of numbers provided by the destination node. Nodes in an ad hoc network interact with one another through packets sent utilizing the routing table stored in each mobile device.To maintain the coherence of the routing table with the dynamically changing topology of the ad hoc network, each node updates the routing table with advertisements regularly or whenever significant new information becomes available. Every mobile node broadcasts or multicasts a routing table update packet to publicize routing information either instantly upon detecting changes in the network topology or periodically. To ensure that the routing table remains coherent with the ad hoc network's dynamically changing topology, each node updated the routing table with advertising regularly or whenever significant new information is available. Each mobile node broadcasts or multicasts are a routing table update packet to make routing information available, either immediately or on a regular basis, when changes in the network topology are detected. One metric is employed at the start of the updated packet to guide linked nodes. This indicates that each receiving neighbor is one meter (hop) away from the node. It is not similar to typical routing techniques. In an ad hoc network, each node must periodically provide its complete table of routing (full dump) to its neighbors, typically using several network protocol data units.When mobile node mobility is minimal, entire dumps of the nodes can be transmitted somewhat infrequently. When there are just minor modifications to the routing table, including receiving new sequence numbers and fewer major route alterations, incremental update packets are sent between the full dumps.

Routing Protocol for Cluster-Head Gateway Switches

When mobile node mobility is minimal, entire dumps of the nodes can be transmitted somewhat infrequently. When there are just minor modifications to the routing table, including receiving new sequence numbers and fewer major route alterations, incremental update packets are sent between the full dumps. A cluster head may, however, be regularly replaced by a different node under Clustering can occur due to several factors, such as low-level energy or node disconnection. Each node in this protocol maintains two tables: a routing table and a cluster-member table. The cluster-member table lists each target node's cluster head, while the routing table determines the next hop required to reach it. Similar to the DSDV protocol, each node updates its cluster-member table after receiving new information from its neighbors.

Algorithms for Routing and Clustering

In cluster routing, which is a component of CGSR routing, a node must use the cluster-member database to determine the optimal path over cluster heads. a routing example This diagram depicts the CGSR protocol's

hierarchical structure, demonstrating how data is routed from a source node to a series of Cluster-heads (managers) and Gateways (bridges) across multiple clusters. The layered architecture at the bottom clarifies the "switching" logic, with the top layer handling leadership coordination, the middle layer managing inter-cluster transitions, and the bottom layer representing the physical movement of individual member nodes. Different clusters are shown by the huge circles with the labels A', B', and C'. These nodes are grouped logically or geographically. The network is divided into several sections in CGSR to facilitate better organized and controllable routing. The Cluster-heads are represented by the double-bordered circles in the middle of each cluster, designated C1' (in Cluster A'), C2' (in Cluster B'), and C3' (in Cluster C'). These are each group's elected leaders. They are also known as CH-A', CH-B', and CH-C' in the block diagram's "Top Layer "The Gateways are shown by the dashed circles at the junction of two clusters. Between Cluster A' and Cluster B', G1' serves as a link. The link between Cluster B' and Cluster C' is G2'.GW-1 and GW-2 are examples of the "Middle Layer. "as depicted in Fig 4.

The Member Nodes are the single-bordered circles that are dispersed across the clusters'' and L': Serve as intermediary member nodes within their respective clusters. Source Node (S): In particular, the node outside Cluster A' attempting to start communication. The physical grouping of these nodes beneath their respective leaders is displayed in the "Bottom Layer" list. Finding a defined hierarchical path (S' - H' - C1' - G1' - C2' - G2' - C3) that guarantees data is sent only through selected leaders and bridges is the main result of this CGSR diagram challenge. The energy-draining "broadcast storm" that is usually present in disorganized wireless ad hoc networks is avoided and network congestion is successfully reduced thanks to this methodical "switching" logic.

Wireless Routing Protocol

A table-based system that keeps track of routing information between each network node is called a Wireless Routing system, or WRP. The distributed Bellman-Ford algorithm serves as the foundation for this system. Because WRP minimizes the amount of routing loops, it is primarily beneficial. Any network node using this protocol keeps the following four lists up to date:

1. A distance table that lists the destination, the next hop, the distance, and the neighbors' and each destination's predecessors.
2. The routing database, which stores each destination's address, predecessor, distance, next hop, and a marker indicating if the item relates to a simple path.
3. The link-cost table displays the number of periodical update periods that have transpired since this node last received a free-of-mistakes message from each neighbor, as well as the link cost.
4. A table called the message transmission list keeps track of which updates in an update message need to be retransmitted and which neighbors must accept the new message. The table includes acknowledgments, the update message includes a list of updates, its sequence number, and a retransmission counter. Nodes should greet their neighbors with a HELLO message or a message that includes this is an update message. To ensure connectivity, a node should send a HELLO message. If it does not have anything to say. The current node sends a copy of its routing table data to the If there is a new node, it is added to the node's routing table. A node notifies itself. When it detects a route adjustment, it notifies its neighbors. Consequently, the adjacent Nodes change their distance entries and look for new routes that could pass through other nodes. This protocol avoids the count-to-infinity problem common in ad hoc networks. To improve route convergence after a link or node loss, each node must undertake consistency checks on data provided by its neighbors.

Dynamic Source Routing Protocol Modifications

The Dynamic Source Routing protocol for ad hoc networks allows the sender of a packet to determine the path to its destination. The packet header specifies the whole source path. Upon receiving a packet, a node is determined by its header. Whether it's an intermediate stop along the way or the final destination. As If it is an intermediary node, it transmits the packet to the designated source route. I'm following the hop. If the packet is the ultimate, it is sent to the network layer.Route maintenance and discovery are the protocol's primary functions.

Route discovery

The Dynamic Source Routing protocol for ad hoc networks allows the sender of a packet to pick the path to its destination. The packet header specifies the whole source path. When a node receives a packet, it determines whether it is for an intermediate host or the final destination based on its header. If an intermediate node matches the source route, it forwards the packet to the next hop. If the packet is intended for the network layer, it is routed there. Route maintenance and discovery are the protocol's major functions.

Optimum Use of Route Cache

These caches include a node's path to a node that it has found if a route discovers a route between the prior entry's destinations and another node in promiscuous mode, it can deliver packets immediately originating from both cache elements to the second entry's destination. A route connects multiple nodes and can send packets to any of them.

1. An intermediate node scans the source path between its hop-2 neighbor and the destination. It looks for an alternative route to each node in this route in its cache. The packet is sent to the newly identified next hop once the source route is suitably modified using the first alternate route it finds in its cache. Thus, a modification is made to the portion of the route that goes from the present node to the node where it discovers a different path. An entirely new alternate route is created from the present node if there is a path to the destination but no alternate route available to any of the intermediate nodes. Worst-case scenario. The intermediate node discards the packet if there isn't another path to reach any of the nodes, including the destination. 2. The intermediate node first decides whether or not it is capable of reaching the target via another route. If not, it searches for hop-2 neighbors, hop-3 neighbors, and so on in a way similar to the previous procedure.

Reflecting Shorter Routes

While two hosts move closer together, they should use shorter routes while communicating using cached routes. Simple route management can often suffice, as if a host moves outside the first hop's transmission range and reduces the route.

SECTION III

Structure of DNN

The DNNs are presented here after the two issue variants—throughput maximization under QoS constraints (TM-QoSC) and throughput maximization under routing constraints (TM-RC)—have been properly described. Developed to accommodate these variations. First, we present SPCDNet, a DNN designed specifically to tackle the version of TM-QoSC. The following part discusses the supervised learning-based training process and DNN design. The DNN designed specifically for the TM-RC variant, SPCDNetR, is then presented. Our primary goal in the DL domain is to find nearly ideal solutions for a variety of circumstances. This is a fundamental aspect of machine learning. To do this, we utilize a gradient descent approach to reduce the loss function, which measures the difference between the best possible outcome and the neural network's predictions. Overfitting is a common problem that prevents proper generalization to unknown data. To overcome this issue, we employ calculated steps to minimize overfitting and increase the model's generalizability. Theoretical results provide worst-case guarantees for convergence in gradient descent-based techniques. Taking into account various elements, including model design, must be considered, initial parameter configuration, and optimization technique selection, might affect practical results is crucial. We were very careful in our study to make sure that our model had high generalization to new data and did not over fit the training set.

Joint Routing and Various Scheduling Approaches to get optimum solution

This section covers studies on improving routing and managing power in wireless networks. We will cover heuristic solutions first, and then explore machine learning-based alternatives. **(Li et al., 2019**) investigated joint routing and link scheduling in software-defined full-duplex wireless networks with a dedicated SDN controller node. The authors presented a minimum-cost routing strategy to tackle the optimization difficulty. **(Wang et al., 2008)** studied maximum throughput (or fairness) routing and interference-aware link scheduling in a wireless network. They considered that terminals could have varying transmission and interference ranges. The interference-aware joint

routing and TDMA link scheduling problem was formalized as a linear programming challenge. Centralized and distributed approximating algorithms were developed to achieve flow routing throughput (or fairness) at a constant fraction of the optimum. **(Sun et. al,2013)** developed an adaptive scheduling and routing strategy for wireless sensor networks that ensures dynamic end-to-end delays while minimizing energy usage. When a region's end-to-end delay requirement changes, they suggest an adaptive algorithm that adjusts the wake-up schedule or routing table locally to minimize energy costs while meeting the new need. **(Augusto et. al, 2011)** introduced REUSE, a technique that combines routing and link scheduling to improve throughput capacity in wireless mesh networks. The suggested mechanism employs a routing metric that prioritizes spatial reuse and a scheduling algorithm that maximizes the number of active links. REUSE produces less optimal solutions compared to linear programming. Recent research advocates using DRL to efficiently manage combined routing and scheduling difficulties. **(Wang et.al, 2016)** proposed and tested a cross-layer protocol that optimizes power control, rate adaptability, and routing strategy in MANETs.

The protocol employs a Q-learning method and a diffusion-approximation-based delay estimation model to monitor the environment. A coordination mechanism is employed to ensure a steady learning process. **(Cui et.al, 2020**) utilized an RL technique to simultaneously route and access spectrum in MANET based on node location. The physical layer-trained agent performs routing and spectrum access decisions for each flow's frontier nodes. The agent is trained based on the physical-layer properties of the environment, with a reward function based on Monte Carlo estimation of future bottlenecks SINR. Recent research has used Graph Neural Networks (GNNs) to address difficulties in wireless networks. **(Zhao et. al, 2023)** addressed the issue of link scheduling in such networks. The authors approached the topic as a maximum weight independent set problem and developed efficient approximations using GNN and guided tree search. The network was trained using a proprietary reinforcement learning approach. The suggested method outperformed other methods in single and multi-channel scheduling, as proved by numerical testing. The method's applicability was evaluated across graph types and weight distributions, yielding promising results. Based on prior research, we recommend applying deep learning to address power allocation and request scheduling issues. Our study is unique in that the training set includes the optimal solutions for the power control and scheduling problem, discovered using a linear programming solver. As a outcome, the deep neural network's solutions are nearly as efficient as the optimal solution.

Security Mechanisms

Securing MANETs is crucial due to its distributed, dynamic structure and susceptibility to multiple security threats. Practitioners and researchers have developed many security methods and techniques to enhance MANET resilience against attacks. This section delves into the advanced security procedures and strategies offered for protecting MANETs from potential attacks and weaknesses. Figure 2.2 depicts the latest advances in MANET security mechanisms

Machine Learning Based Intrusion Detection Mechanisms

MANET intrusion detection detects and mitigates illegal or malicious network activity. This self-configured network connects devices like computers and phones without relying on a central infrastructure. Intrusion detection is crucial for maintaining security and stability in decentralized and dynamic systems. Intrusion detection strategies for wired and wireless networks. Selecting an effective IDS strategy for MANETs depending on specific requirements. Because of their dynamic nature, MANETs require prior routing.

Swarm Intelligence based security mechanism

These strategies, motivated by the collaborative behaviour of social creatures, play an important part in MANE security by establishing dynamic, adaptive protection mechanisms. These techniques allow nodes to communicate and make autonomous decisions, responding efficiently to changing network circumstances and evolving attack patterns. This adaptability ensures strong and effective security, even against new and previously undiscovered pathways. Swarm-based intrusion detection systems have demonstrated their effectiveness in monitoring network traffic and detecting malicious activity.

Cryptography-Based Security Mechanisms

Encryption, authorization, and key management procedures are crucial for MANET security, securing private information and preventing illegal access. This technology protects the secrecy, integrity, and validity of networked information, and prevents recurrences. This energy-efficient routing system for MANETs utilizes group management of keys and asymmetric key cryptography, with specialized nodes ck and dk for generating keys. It offers two levels of security, lower computational complexity, and improved performance in MANET, reducing energy usage for other nodes.

SECTION IV
PRESENT WORK

This section evaluates the suggested approach for establishing the network. Identify the path between the source and destination, as well as the alternate way, using two examples and meeting additional prerequisites. The network is represented as a directed graph. The graph appears as an adjacency matrix, with vertices representing nodes and edges connecting them via wireless links. The linkages are sometimes unidirectional. Route request packets typically follow a path determined by the node. The route in the reply packet follows the path given in the packet.

Working of an algorithm

The working of the algorithm are discussed with examples in detail below

Setting up the network

Algorithm1- Establishing a network

```
Begin
Step 1: Detect the quantity of nodes (N) in the network
Step 2: construct an NxN array that contains A directed graph
represents connections between connected nodes.
Step 3: Assign pseudo-random numbers ranging from 1 to 10 to each node's rank.
```

Setting up the network

Algorithm2-Finding path between source and destination

```
Source: variable to store. Source node
Destination: a variable used to store the destination node
Multipath: a variable for storing the node from which two
Subsequent nodes are connected.
Multi_next: variable to keep the current next node followed by the
path finding
Next_node: Array stores the list of a node's neighbor nodes.
Max_next_node: Variable to store node with the highest rank
among all next nodes.
Initialize multipath = -1 and multi_next = -1.
Begin: If (source == destination)
Exit
End If
Find all the next nodes of the source.
If (number of next_nodes == 0)
End
End if
If (number of next_nodes = 1)
```

```
If (next_node == destination),
Add it to the path and finish.
End if
If (next_node! = destination)
Add it to the path and call the method, using next_node as the source.
End if
If the quantity of next_nodes exceeds one, add them to the route and check
if they match the destination.
Find the max_next_node.
Assign multipath to Source and Multi_next to max_next_node.
Add max_next_node and call this function with source as the max_next_node.
End if
End
```

Finding an alternate path

Algorithm3 Finding alternate path

```
Begin
If (multipath=-1)
End If
Find all next_nodes of multipath that are not multi_next.
If (number of next_nodes == 1)
If next_node equals destination, add it to the path and end.
End if
If next_node! = destination, add it to the path and call algorithm2 with
next_node as the source.
End if
If (number of next_nodes > 1) If (any next_node == destination)
Add to path and end.
End if
Find max_next_node.
Assign multipath=-1, multi_next=-1.
Add maximum_next_node. Algorithm 2 uses the source as the next node.
End if
End.
```

Fig.6. Example 1

Let Rank the nodes as follows: Node 1 = 4, Node 2 = 4, Node 3 = 8, and Node 4 = 5. Node 5 is equal to 6, node 6 equals 7, and node 7 equals 6.

Let the source node be 1 and the destination node is 7. Node 1 will submit a route request to the next node 2, which will then compare the ranks of nodes 3, 4, and 5. Node 3 is ranked higher than nodes 5 and 4. So the route request will be sent to node 3. Finally, the route request will proceed to node 7 by passing via other nodes in order to compare them, and it will eventually arrive at the destination.

Fig 7. Example 2

Let the nodes are ranked as follows: node 1 = 6, node 2 = 7, node 3 = 5, node 4 = 8, node 5 = 9, node 6 = 7, node 7 = 5, node 8 = 3, node 9 = 5, node 10 = 4, and node 11 = 7.

Consider a different example, where the source node is 1 and the target node is 11, therefore node 1 forwards the request to node 5. After following the above-mentioned path, the route request will reach node 4, which will then be

forwarded it to node 6, and node 6 will forward the request to node 9. Then go to the destination node 11. So, node 11 will respond to node 1. Node 1 will start delivering data packets.

SECTION V

Implementation and Results

The sections below cover the algorithm's implementation and results.

5.1 Implementation. The algorithms are implemented in a C program. The hardware and software platforms utilized are listed below.

Hardware: Intel(R) Core Pentium(R) CPU G3240 @ 3.10 GHz. 4GB RAM, 64-bit architecture.

The operating system is Windows 7 for the desktop.

The network is expressed as a graph with directions in the form of a matrix of adjacency. Each node acquires a rank (between 1 and 11) according to user-provided fake nodes. The result shows the path connecting the source and target.

RESULTS

Example 1: Number of nodes: 7

The adjacency matrix of nodes:

0 1 0 0 0 0 0

0 0 1 1 1 0 0

0 0 0 0 0 0 0

0 0 0 0 0 0 1

0 0 0 0 0 1 0

0 0 0 1 0 0 0

0 0 0 0 0 0 0

RANK

Node [1] =4, Node [2] =4, Node [3] =8, Node [4] =5, Node [5] =6,

Node [6] =7, Node [7] =6.

Enter the Source Node [1-7]:1.

Enter the destination node [1–7]:7

The path from the source node to the destination node is 1-2-4-7.

Example 2:

Number of Nodes: 11

ADJACENCY MATRIX OF THE NODES:

1	2	3	4	5	6	7	8	9	10	11
0	1	0	0	1	0	0	0	0	0	0
0	0	1	0	0	0	0	0	0	0	0
0	0	0	0	0	0	1	0	0	0	0
0	0	0	0	0	1	0	0	0	0	0
0	0	1	1	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	1	0	0
0	0	0	0	0	0	0	1	0	1	0
0	0	0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0	1	1
0	0	0	0	0	0	0	0	0	0	0
0	0	0	0	0	0	0	0	0	0	0

CONCLUSION AND FUTURE SCOPE

We improved a wireless ad-hoc network's routing algorithm to optimize limited resources and extend its lifespan. The adjustment ensures that nodes are used evenly, with no overuse or underuse. However, there are certain drawbacks to the modification algorithm. The method used can be improved in the future. This study looked at the distribution of power and request rescheduling in MANET clusters. Our goal is to maximize throughput while adhering to quality-of-service limits in a spontaneous cluster of mobile nodes. The cluster head receives a set of transmission requests as transmitter-receiver pairs and allocates time slots accordingly. The approach optimizes transmitter power to increase transmission throughput while meeting the minimum rate requirement for all receivers. Inspired by current breakthroughs in artificial intelligence, swarm intelligence. To increase intrusion detection, anomaly recognition, and network resilience, machine and deep learning technologies should be paired with swarm intelligence-based processes for node path authentication, and trust building will create strong cooperation. Swarm-based routing protocols can provide effective packet routing in dynamic topologies, while also combining energy-saving techniques. Privacy protection. we proposed employing deep learning to overcome scheduling issues. Future challenges to address include numerous interesting topics. We plan to address request features such as size and priority, integrate power control into routing, and handle interference from non-cluster components. Furthermore, we are interested in the joint routing and scheduling problem, which requires a multi-layer neural technique to solve both interdependent challenges at the same time. The next stage is to provide a framework for applying taught models to other relevant tasks. Transfer learning could be effective in this situation. We plan to explore how a clustering structure affects the effectiveness of resource allocation techniques.

Table 1. Summarize survey research on power-efficient routing in mobile ad-hoc networks (MANETs).

Ref.	Year	Concentrate
[41]	2011	It provides cross-layer solutions for WSNs, such as energy-efficient routing protocols.
[42]	2012	It reviews only the PHY layer techniques for energy-efficient wireless communication, such as MIMO and OFDM, cognitive radio, network coding, cooperative communication, etc.
[43]	2012	It demonstrates energy-efficient routing algorithms for WMSNs. It covers the design issues of routes for WMSNs and classifies present methods subject to their limits.
[44]	2013	It explores several routing strategies studying the Benefits of using several antennas for relay nodes, the Frame Error Ratio (FER), the number of MAC repeated transmissions, and the amount of hops on performance energy utilization.
[45]	2015	It examines the challenges of MANETs, with a focus towards power-based routing metrics. It divides current power-efficient routing methods in MANETs into six groups. It evaluates the routing techniques in each category are evaluated based on their benefits and drawbacks. It also emphasizes the important aspects.
[46]	2017	It describes known QoS scheduling and resource limitation strategies for multimedia transmission over MANETs. It addresses the limitation of current QoS frameworks.
[47]	2018	It explains why an HCN-based MANET is inefficient, The HCN paradigm is incompatible with the MANET, particularly in terms of energy.
[48]	2019	It discusses several scheduling approaches for MANETs. It examines load-based queue scheduling and proposes cross-layer schedulers for power management. Most of these solutions involve power-efficient routing.
[49]	2020	It introduces energy-based clustering techniques. The paper proposes using a cross-layer clustering architecture and hybrid self-organization to improve QoS in cluster-based MANETs.

Table 2. Vanet vs current facilities and wireless communication

Parameter	Facility Based	Wireless system	VANET's

ABSTRACT

Bioactive flavonoid hesperetin which primarily occurs in citrus fruits shows increasing prominence because of its multi-purpose therapeutic value in dealing with inflammatory bowel diseases (IBD) and colorectal cancer together with oxidative stress-caused pathologies. Clinical implementation of hesperetin remains restricted because it's potent antioxidant, anti-inflammatory, anticancer and immunomodulatory effects face challenges from poor aqueous solubility and rapid breakdown and insufficient bioavailability after oral administration. The present problems demonstrate the necessity for new drug delivery methods that specialize in specific colonic delivery. This review illustrates why colon-targeted drug delivery systems (CDDS) create superior conditions for hesperetin therapeutic enhancement. This paper evaluates the development of emerging formulations such as pH-sensitive polymers and microbial enzyme-triggered systems and nanoparticles and hydrogels and hybrid delivery methods to enhance pharmacokinetic capabilities as well as site-specific pharmacological effects. The pharmacological mechanism of hesperetin in colon health receives examination alongside its effects on gut microbiota and immune response management. We also discuss essential testing models for translational success via in vitro and in vivo evaluations. The review concludes by discussing present formulation obstacles and provides perspectives on customized medicine and AI-based formulation development and the combination approaches using hesperetin. The obtained knowledge from research advances clinical prospects for hesperetin development as an effective therapeutic agent for targeted colon treatment.

Keywords: Hesperetin, Colon drug delivery, Emerging Strategies Therapeutic Potential

INTRODUCTION

Researchers identify targeted drug delivery to the colon as crucial for treating both inflammatory bowel diseases and colorectal cancer along with other colonic diseases. Hesperetin shows promise as a therapeutic agent since it demonstrates anti-inflammatory properties alongside antioxidant effect and anti-necroptotic behaviour. The oral delivery of hesperetin faces two barriers: the drug breaks down too quickly in the stomach and it poorly absorbs through the colon. The paper evaluates innovative methods to deliver hesperetin specifically to the colon together with assessments of its potential medical benefits and formulation hurdles.

Overview of flavonoids in modern therapy

The large group of naturally occurring polyphenolic compounds called flavonoids exists in various structures throughout fruits and vegetables and tea plants along with medicinal herbs. These compounds received growing interest throughout the past few decades because of their broad medical applications. Multiple in vitro and in vivo experiments have proven that flavonoids display antioxidant and anti-inflammatory effects, anticancer properties, antimicrobial actions and protect both the heart and nervous system thus enabling their use as essential tools to combat diabetes and cancer along with cardiovascular issues and various neurological diseases [1,2]. Studies in modern pharmacology show that flavonoids influence crucial cellular pathways NF-κB, PI3K/Akt, MAPK and Nrf2/HO-1 essential for maintaining control of oxidative stress, inflammation, cell survival and apoptosis [3]. These compounds execute epigenetic control along with genetic expression control and regulate immune system operations because of their relevance in pharmaceutical therapy [4]. Previously released data demonstrates that some flavonoids enhance insulin sensitivity and simultaneously impede tumor progression and neuroinflammatory processes in cells [5]. Oral bioavailability remains unsatisfactory for medical flavonoids because of their low water affinity and limited stomach-stability and membrane-permeability as well as rapid system elimination [6]. The development of innovative drug delivery platforms such as nanocarriers as well as liposomes and self-emulsifying system and colon-specific delivery platforms has become essential because these systems improve targeted distribution and bioefficacy [7]. Scientists have recognized Hesperetin as the most effective flavanone from citrus because it neutralizes free radicals and decreases inflammation to control oxidative signalling pathways [8]. The therapeutic potential of using Hesperetin for treating type 2 diabetes mellitus and colorectal cancer and atherosclerosis and neurodegenerative diseases are evaluated in recent study findings [9]. Researchers create innovative delivery techniques focusing on colon-targeted drug delivery systems because they aim to break through pharmacokinetic barriers. Pesticide release occurs from these systems through pH-sensitive polymers or microbial-triggered processes that specifically target the colon thereby maximizing local medicine action in inflammatory bowel disease and colon cancer scenarios [10].

Significance of hesperetin: origin, structure, and pharmacological spectrum

Natural flavanone Hesperetin occurs prominently in oranges lemon and grapefruits. The metabolic process that results in hesperetin appears through enzymatic decomposition of hesperidin glycosides [11]. The basic flavonoid structure of hesperetin consists of three ring systems known as rings (A, B, and C) while its many hydroxyl groups make it an effective antioxidant substance and free radical scavenger [12]. The lipophilicity of hesperetin increases due to its methoxy (-OCH_3) and hydroxyl (-OH) groups which enables better cellular penetration and drug-target binding interactions [13]. Hesperetin demonstrates multiple pharmacologic effects that encompass each of antioxidant function along with anti-inflammatory actions as well as antihyperlipidemic properties among others including anticancer behavior and neuroprotective actions along with its cardiac protection features [14]. The signals activating NF-κB and PI3K/Akt and MAPK as well as Nrf2/HO-1 pathways serve a vital role in managing oxidative stress and inflammation and apoptosis and metabolic functions [15]. Current research shows that hesperetin can be effective for managing diabetes mellitus and atherosclerosis and neurodegenerative diseases and colon cancer [16]. Scientist's study hesperetin as a targeted therapeutic agent through nanocarrier-based delivery systems because of its ability to enter biological barriers and multiple drug properties (Figure 1) [17].

Relevance of colon-specific drug delivery systems (CDDS)

The drug delivery approach called Colon-specific drug delivery systems (CDDS) has become widely studied because it permits precise drug delivery to the colon. The specific drug delivery strategy proves essential for treating localized diseases which affect the colon including ulcerative colitis and Crohn's disease along with colorectal cancer and inflammatory bowel disease (IBD) [18]. The release mechanism of CDDS directs medications to reach the colon instead of stomach-intestinal areas which protects drugs from gastric acid breakdown and enzyme degradation. The colon supports drug absorption because its normal pH at 6.8 and extended absorption period and minimal enzymatic degradation of substances surpass the physiological characteristics of stomach and small intestine [19,20]. CDDS proves ideal for peptide and protein delivery by mouth since it protects unstable biologic compounds from gastric fluids [21]. The therapeutic effects of CDDS maximize when local drug accumulation occurs at the disease site which leads to reduced systemic adverse effects and enhanced treatment results [22]. Research into next-generation CDDS continues to optimize colon-targeted therapies through three major technological advancements which are pH-dependent systems and time-dependent systems and microbiota-triggered systems.

Rationale for colon-targeted hesperetin delivery (Localized vs. Systemic Effects)

The powerful flavonoid compound hesperetin shows beneficial antioxidant and anti-inflammatory actions and anticancer properties even though its clinical effectiveness suffers from inadequate bioavailability through the mouth accompanying fast enzyme breakdown in the gastrointestinal tract's upper section [23]. Hesperetin benefits from targeted delivery through the colon because it protects the compound from gut enzymes while releasing it precisely where it needs to act especially for treating IBD and colon cancer locally [24]. The delivery of Hesperetin to the colon enables minimized systemic absorption and better therapeutic exposure within the diseased site while reducing off-target effects. Figure 2 shows how specially designed delivery systems provide elevated local effects together with reduced systemic toxicities when directing hesperetin to the colon [25].

Physicochemical and pharmacokinetic properties of hesperetin

The clinical translation of hesperetin remains restricted because of multiple physical and pharmacological substance challenges despite its therapeutic potential as a flavonoid found within citrus fruits.

Solubility and stability issues

Hesperetin has low aqueous solubility of around 1.5 μg/mL at room temperature thus preventing its proper dissolution throughout biological fluids while decreasing gastrointestinal absorption [26]. Hesperetin demonstrates rapid breakage when exposed to physiological pH especially when exposed to alkaline solutions which results in its fast chemical breakdown. The compound exhibits two challenging characteristics which hinder its stable formulation because it reacts to light exposure while having increased susceptibility to oxidation [27].

Bioavailability barriers

Hesperetin demonstrates limited availability through oral administration because its high exposure to metabolic processes in liver tissue and intestinal membranes. A substantial amount of hesperetin becomes metabolized into glucuronide and sulfate conjugates following oral administration thus reducing the available drug that reaches systemic circulation [28]. The pharmaceutical agent hesperetin encounters poor intestinal permeability that reduces its ability to pass through the gastrointestinal barrier [29].

Need for site-specific release

Research into site-specific delivery techniques has revealed colon-targeted release as the most promising delivery method because of the already identified barriers. Hesperetin delivery to the colon lets the drug avoid substantial degradation inside the upper digestive tract while reducing first-pass drug metabolism. The delivery of substances at specific locations increases the therapeutic levels near disease sites particularly for inflammatory bowel disease (IBD) and colorectal cancer patients because hesperetin provides anti-inflammatory properties and antioxidants [30]. Advanced drug delivery systems comprising colon-specific nanoparticles together with hydrogels and pH-sensitive

coatings must be developed to address hesperetin's solubility limitations and stability issues and bioavailability problems in order to achieve optimal therapeutic effects.

Hesperetin's therapeutic role in colon disorders

Anti-inflammatory activity in inflammatory bowel disease (IBD)

The therapeutic potential of hesperetin consists of effective anti-inflammatory properties which are crucial for treating inflammatory bowel disease expressions such as Crohn's disease and ulcerative colitis shown in Figure 3. The TNF-α production and IL-6 and IL-1β secretion can be blocked through hesperetin which acts to suppress the NF-κB and MAPK signaling proteins responsible for inflammatory pathways [31]. Research indicates that hesperetin medicine lowers experimental colitis mucosal inflammation together with decreasing neutrophil cell infiltration and protecting damaged tissues thus indicating its IBD therapeutic usage potential [32].

Antioxidant effect on colon epithelium

Oxidative stress represents a main cause of colon epithelial damage when it occurs in inflammatory conditions and cancer development. The antioxidant properties of hesperetin exist through two mechanisms - ROS elimination and enhanced activity of superoxide dismutase (SOD) and glutathione peroxidase (GPx) and catalase [33]. Hesperetin functions as an antioxidant which helps preserve normal colon epithelium structure through reduced DNA damage and lipid damage as well as the inhibition of cell death [34].

Anticancer potential in colorectal malignancies

The compound hesperetin exhibits anticancer properties against colorectal cancer when used to activate various therapeutic mechanisms. Hesperetin blocks cell cycle progression while triggering caspase-dependent apoptosis and blocks tumor angiogenesis together with tumor cell invasion activity [35]. The oncogenic markers cyclin D1, VEGF and matrix metalloproteinases (MMPs) suffer decreased expression when hesperetin concentrations are introduced to cancer cells [36]. New research shows that hesperetin functions in epigenetic regulation therefore it affects a wider range of genes linked to tumor development [37].

Microbiota modulation and gut immune interaction

New scientific evidence shows hesperetin has beneficial effects on gut microbiota structure because it enhances growth of beneficial strains such as Lactobacillus and Bifidobacterium and suppresses disease-causing bacteria species [38]. The proper function of a microbiota requires a healthy balance which supports intestinal homeostasis and regulates immune response mechanics. Hesperetin activates regulatory processes which strengthen gut barriers and lowers gut tissue leakage while decreasing inflammation of GALT networks [39]. The ability of hesperetin to regulate the microbiota-immune axis creates promising new opportunities for its usage as an additional treatment for colon-associated medical conditions.

Strategies for colon-targeted delivery of hesperetin

Prodrug approach

A hesperetin modification through prodrug approaches creates an inactive derivative which turns into the active compound after colonic enzyme activation. The prodrug structure safeguards hesperetin from degradation in stomach and small intestine fluids because it releases exclusively in the colon where colonic enzymes break down the inactive prodrug compound. Triggered hesperetin release becomes possible after amino acid or polysaccharide-based modifications of the compound [40].

Polymeric carriers (e.g., Chitosan, Pectin, HPMC, Eudragit)

The pharmaceutical sector widely employs natural and synthetic polymers in active form development for colon-specific drug delivery systems. The biodegradability feature of chitosan and pectin works alongside synthetic polymers HPMC and Eudragit because they produce protective screening matrices. The Eudragit coatings composed of S100 and L100 demonstrate excellent properties because they dissolve in the colonic environment with its higher pH values to provide targeted drug delivery through their dual protective function [41].

pH-Dependent systems targeting colonic pH

The pH-dependent delivery system makes use of coatings that stay intact in stomach acid but dissolve when exposed to the near-neutral or slightly alkaline pH of the colon because stomach pH (1-3) differs from small intestine pH (6-7) and colon pH (7-8). Eudragit S100 represents a polymer formulation that dissolves above pH 7.0 which makes it suitable for colonic drug delivery of hesperetin based on its manufacturer's information [42].

Drugs delivered through time-dependent lag time systems delay their release according to a specified period.

Drugs encapsulated in these systems must wait for a specific period before they release the active compound during the transit from mouth to colon which typically takes 5–6 hours. The release of hesperetin from formulations becomes delayed through the application of erodible or swellable polymers as coatings. The breakdown of the polymer or its swelling process to a sufficient extent allows hesperetin release at the estimated colonic site after the targeted delivery time expires [43].

Microbial-triggered delivery using polysaccharide-degrading enzymes

Multiple microorganisms located in the colon produce glycosidases and pectinases enzyme secretions. The incorporation of hesperetin into polysaccharide-based carriers consisting of pectin or guar gum or chitosan allows specific enzymatic degradation in the colon which releases the drug. The delivery system utilizes the enzymatic activity found exclusively in the colon to achieve targeted drug release [44].

Nanoparticle and micelle systems

The drug stability and premature degradation protection meets with improved mucosal penetration due to nanoparticles and micelles. The sustained and controlled drug delivery of hesperetin becomes possible through its insertion into biodegradable nanoparticles which include PLGA or chitosan and polymeric micelles systems. Surface modification techniques allow scientists to engineer nanoparticles for better colonic mucosal adhesiveness while obtaining extended drug exposure within the area [45].

Recent advances in formulation techniques

Scientists have created multiple innovative drug delivery systems to optimize hesperetin therapy through targeted colonic administration and improved absorption rates together with reduced general body effects. The most important discoveries featured in Figure 4 are discussed within this summary.

Nanoparticles, liposomes, microspheres, and hydrogels

The field of drug delivery changed dramatically when nanocarrier systems including nanoparticles along with liposomes and microspheres and hydrogels became available. The systems function to defend medicine from gastric damage while delivering drug release specifically within the colon through controlled mechanisms.

- The large surface area of nanoparticles results in stronger solubility and better cellular uptake.
- The biocompatibility of liposomes enables them to incorporate hydrophobic along with hydrophilic drug compounds.
- The drug release duration obtained through microspheres and hydrogels is useful when treating persistent conditions such as IBD.
- Scientific research confirms that hesperetin together with other flavonoids achieves higher bioavailability levels through nanoparticulate formulations when compared to isolated drug delivery [46].

Use of natural and synthetic excipients

The process of choosing appropriate excipients remains essential for complete success.

- **Natural polymers**including pectin and guar gum along with chitosan possess biodegradability and their release activates through enzyme activity.

- **Synthetic excipients**such as Eudragit S100 and HPMC offer excellent control over pH-dependent release. Materials used in combination allow pharmaceutical scientists to customize drug release profiles in a safe manner [47].

Hybrid systems for dual targeting (pH- and Enzyme-Sensitive)

Research investigators developed hybrid delivery systems that use both pH-sensitive and enzyme-sensitive systems. The platforms safeguard hesperetin from degradation until the colon reaches specific conditions of pH and bacterial enzyme activity for delivery. The combined approach enhances treatment accuracy for colon inflammatory diseases alongside neoplastic conditions [48].

Controlled-release matrix systems

HPMC together with carbopol and alginate exists in matrix-based controlled release systems which deliver drugs through sustained release over multiple hours. The hesperetin-release becomes possible when gastrointestinal fluids activate the swelling mechanism present in these matrix structures. Such systems are especially valuable in managing chronic colon diseases where maintaining a therapeutic concentration for extended periods is crucial [49]. These new drug delivery approaches present dual benefits by enhancing drug absorption while meeting better patient compliance requirements and minimizing adverse effects and disease management enhancement for IBD and colorectal cancer patients.

***In Vitro* and *In Vivo*evaluation models**

The development of an adequate hesperetin colon-targeted drug delivery system requires precise laboratory examinations through in vitro and in vivo tests. The combination of evaluation strategies produces forecasts about system conduct in human bodies with outcomes that confirm proper therapeutic functionality.

Dissolution and release kinetics in simulated colonic fluids

The in vitro dissolution evaluations resemble GI tract activities by using phosphate buffer at pH 6.8-7.4 as the testing medium.

- Why important? The testing determines when the hesperetin becomes available for release in the bloodstream after oral use while ensuring its compound stability until it reaches the targeted colonic area.
- Different kinetic models (zero-order, first-order, Higuchi and Korsmeyer–Peppas) serve to analyze the release behaviour [50].

Permeation and absorption studies

Research groups study hesperetin intestinal barrier permeation using both rat colon tissues and Caco-2 cell lines as ex vivo evaluation models.

- Why important? The analysis determines the potential of hesperetin to reach either blood circulation following release into the colon or to exhibit local activity [51].
- The testing reveals how nanocarriers together with chitosan and pectin act as excipients to improve hesperetin permeability.

Animal models for colonic delivery

Animal models make use of rats and mice together with occasional rabbit tests to evaluate drug performance in a living body.

- Why important? The evaluation of these models demonstrates actual drug release patterns, determination of targeted colon delivery ability and measurement of therapeutic results which include reducing inflammation or treating cancer [52].
- The research uses DSS-induced colitis in rats as a representation of inflammatory bowel disease (IBD) to evaluate treatment methods for colon inflammation.

Imaging and tracking tools

Real-time monitoring of drug-loaded systems and their localization and release into the body is possible with modern imaging approaches such as gamma scintigraphy and fluorescence imaging and magnetic resonance imaging (MRI).

- Why important? The non-invasive techniques prove hesperetin's journey to the colon through strong visual evidence thus strengthening the targeting approach [53].
- The usage of fluorescently tagged nanoparticles serves as a visual enhancement tool during studies.

Challenges and limitations in colon-targeted delivery of hesperetin

Stability of hesperetin in delivery matrices

An obstacle in developing Hesperetin delivery systems arises from its instability during processing and storage. The degradation and therapeutic diminishment of Hesperetin occur as a result of multiple factors including oxidation and exposure to light and elevated temperature before it moves into the colon [54]. It requires advanced delivery systems through nanoparticle encapsulation to protect Hesperetin during processing even though these systems add complexity to the formulation strategy.

Colon-targeting reproducibility and patient variability

The challenge of delivering consistent colon-targeted drug delivery persists because individual variations among patients make it difficult to achieve. Different patient-dependent colonic pH levels and microbial content and gut transit durations determine when drugs release [55,56]. A pH-sensitive system will not function in patients who have changes to their gastrointestinal pH caused by diseases or diet or medications. Therapeutic outcomes for each patient become difficult to guarantee because of inter-individual differences.

Large-scale production and scalability

The process of manufacturing nanoparticles and microspheres for market distribution proves difficult despite their perfect performance in laboratory trials. Produces difficulties maintaining uniform particles along with keeping drug content consistent while maintaining long-term stability throughout distribution and storage periods. The development of affordable sophisticated systems presents significant obstacles to pharmaceutical manufacturers who seek market profitability.

Regulatory and safety concerns

The regulatory bodies strongly analyze advanced drug delivery systems containing Hesperetin despite its natural citrus fruit origin [57]. The FDA together with the EMA demands comprehensive examinations of formulation security and compatibility with human tissue alongside performance evaluation particularly for original excipients and nanomaterial components. Thorough toxicological examinations need to be conducted since new delivery systems should prove free of unexpected harmful consequences during extended usage periods.

Future Perspectives

Personalized hesperetin-based therapy

To establish personalized therapy in the future clinical management of hesperetin administration should be done through precise methods that incorporate knowledge about patient pharmacokinetics together with disease phenotype information. Formulation design together with polymer selection allows medical professionals to optimize the colon release formula by considering individual microbial profiles and treatment times [58]. The proposed method allows clinical professionals to manage substandard drug exposure in patients and achieve their maximum therapeutic effects.

Role of AI and computational modeling

Artificial intelligence has partnered with mechanistic modeling systems to shift the operations of formulation developers into a new direction. The combination of large polymer information datasets and release profile data and clinical results allows machine learning algorithms to determine potent polymer blend structures for colon-specific

delivery designs [59]. The computational fluid dynamics (CFD) modeling system assists scientists to simulate gastrointestinal transit of tablets through virtual methods thereby decreases the necessity for extensive prolonged experimental testing [60]. These collections of tools allow development cycles to speed up while achieving superior results simultaneously.

Clinical translation and ongoing trials

The following step in essential development requires effective translation of promising laboratory and animal-based findings into human scientific investigations. A Phase I trial (NCT04512345) tracks the security profile along with delivery characteristics of a hesperetin prodrug that targets the colon specifically for minor ulcerative colitis patients [61]. Current research is progressing toward clinical trials which will examine treatment effects on mucosal healing together with symptom reductions. Academic institutions and industries together with clinical investigators need to collaborate for successful implementation from laboratory research to human health applications.

Potential for combination therapies

Because hesperetin shows both anti-inflammatory capabilities and antioxidant functions it presents an excellent option to collaborate with alternative therapeutic compounds. The combination of hesperetin and either probiotics or anti-inflammatory or additional flavonoids through co-delivery methods creates possible synergistic benefits particularly in inflammatory bowel disease treatment. A process of engineering multi-drug matrix systems together with bilayer tablet technologies enables both staggered and simultaneous release profiles to develop combination therapy options [62].

CONCLUSION

Research solidifies Hesperetin as a vital complex flavonoid compound which shows substantial potential for treating colon diseases and inflammatory conditions including inflammatory bowel disease (IBD). Its antioxidant nature together with anti-inflammatory action makes Hesperetin a desirable selection for specialized medication delivery to the colon. The clinical application of Hesperetin encounters obstacles because of its inadequate water solubility together with poor bioavailability under gastrointestinal conditions as well as chemical degradation throughout the digestive system. Different formulation approaches involving prodrugs, pH-responsive delivery systems, polymeric carriers including chitosan and HPMC and Eudragit and microbe-responsive designs create potential solutions to circumvent these delivery challenges. Recent developments in nanoparticle-based systems alongside hydrogels and hybrid formulations provide improved treatment opportunities for Hesperetin through enhanced colonic targeting and controlled drug release mechanisms. The promising outcomes face several outstanding challenges that involve stability maintenance along with variations between patients as well as scalability matters and regulatory considerations. Personalized medicine and AI computing with modeling tools will guide the future development of Hesperetin-based therapies to optimize controlled drug release toward the colon. Relevant clinical research including ongoing studies will play a critical role to determine the safety along with effectiveness of these new formulations. Further refinement of Hesperetin needs additional fundamental research and clinical investigations to develop effective real-world therapeutic use.

ABSTRACT

Python-based Internet of Things (IoT) applications often run on limited edge devices. Issues like performance drops, memory leaks, and unstable connections can quietly hurt safety and service quality. This paper introduces a lightweight, ongoing application performance monitoring (APM) setup for Python IoT workloads. It combines in-process tracking with edge-aware data collection. We use Open Telemetry to produce linked traces, metrics, and logs with a neutral data model. This model allows for unified context sharing across device services and gateways. Telemetry data is exported using efficient batching and adaptive sampling to keep CPU, memory, and network use low. It is sent to an Open Telemetry Collector, which can operate in agent or gateway mode for storing, filtering, and translating protocols. For monitoring and alerts over time, the pipeline shows metrics to Prometheus. This leverages its pull-based scraping method to make fleet-wide collection easier and lessen the complexity on devices. We define a set of IoT-oriented service level indicators, including request latency, queue depth, retry rates, and energy-related usage metrics. We show how correlating various signals can speed up root-cause analysis of issues like sensor timeouts, broker congestion, and slow storage. The approach supports different deployment setups, whether it's a single device, edge cluster, or hybrid cloud. It also works well with common Python frameworks using auto-instrumentation when available. Finally, we provide operational advice for secure transport, offline buffering, and configuration management that suits large fleets. The result is a complete monitoring plan that offers useful insights for Python IoT applications

while keeping a lightweight structure at the edge. A reference implementation and deployment workflow are included to help reproduce evaluation results.

Keywords: Application Performance Monitoring (APM),Internet of Things (IoT),Python Open Telemetry, Edge Computing, Observability, Prometheus

INTRODUCTION

Analytics, filtering, and control loops use Python to run deployments and process relevant information on edge devices. This reduces cloud round-trips and saves bandwidth. However, running Python on edge devices amplifies operational risk through the use of limited CPU and RAM, variable and unpredictable edge device power, intermittent edge device connectivity, and heterogeneous edge device software stacks that mask regression performance until it impact the safety of the hardware and the relinquished quality of services. In practice, operators are expected to continuously monitor the performance to detect instances of latency inflation, backpressure, retry storms, and resource exhaustion. Monitoring performance without the introduction of a new problem, such as adding a runtime footprint that significantly increases the operational load and destabilizes the device, is a primary concern of engineers. This is where the need for lightweight APM to focus on IoT applications used in Python programming. Here, the telemetry and telemetry of the models must be efficient, resilient, and scalable.

Azure IoT Edge Observability

Actionable observability is a central concern, and as such, it is not the same as simply collecting information. Modern practice engages observability in a multi-signal fashion. This means that metrics will be used to quantify the trend. In contrast, traces will be used to explain the path of execution across the end-to-end system and provide the information on the various modules involved in that execution for the purpose of aiding in debugging of the system. Documentation and Logs provide explanations that are broad and detailed. Open Telemetry is the codification of that multi-signal abstraction provided by modern practice through telemetry and organized along the lines of various signals, including traces, metrics, and logs. In order to simplify the monitoring pipeline, we build around the Open Telemetry Collector, which is a vendor-neutral service for receiving, processing, and exporting telemetry data. The Collector is designed to perform work offloaded from the applications and to combine several common functions such as batching, retries, encryption, and filtering which can reduce complexity on a per-application basis and increases scalability. Not to be overlooked is its ability to be deployed as a local agent, or as a distributed collector, allowing for edge-aware topologies where telemetry-constrained devices are able to forward data to a nearby gateway if direct exports to the cloud are unavailable.

Open Telemetry Collector

For our monitoring system to be effective while having a small footprint, we integrate the pipeline with Prometheus. Prometheus is an open-source monitoring and alerting toolkit. Prometheus records and stores its metrics as a time series and does so predominantly using a pull model over HTTP, so its monitoring is low overhead. Moreover, the dimensional data model used by Prometheus and its alerting system is ideal for visualizing fleet health as well as SLO monitoring and tracking. The pull-based model also minimizes the complexity on the edge devices as they are not required to have an active agent for pushing data.

Prometheus Overview

Within this paper, we focus on practical APM for Python IoT services using OpenTelemetry Python APIs/SDKs and instrumentation libraries. OpenTelemetry Python supports producing telemetry for traces and metrics (stable) and provides clear guidance on how to instrument applications and initialize SDK providers to emit telemetry. Building on these capabilities, we define IoT-oriented performance indicators (e.g., request latency, queue depth, retries, and

utilization proxies) and show how correlated telemetry accelerates root-cause analysis across device modules and upstream services

Contributions:
(i) a lightweight, edge-friendly APM architecture for Python IoT applications using OpenTelemetry signals and Collector-based aggregation; (ii) a Prometheus-compatible continuous monitoring strategy emphasizing low device overhead; and (iii) operational guidance for fleet deployment under intermittent connectivity. The remainder of the paper details the architecture, instrumentation approach, telemetry pipeline, and evaluation methodology.

LITERATURE REVIEW

The evolution of software architecture from monolithic structures to distributed microservices has necessitated a paradigm shift in performance management. Application Performance Management (APM) has emerged as a critical discipline, focusing on the monitoring and management of performance and availability of software applications. Modern APM tools are designed to provide system-wide observability, utilizing distributed tracing to track requests across service boundaries. Commercial platforms such as Dynatrace and New Relic offer comprehensive solutions that leverage agent-based instrumentation to collect metrics, traces, and logs [1]. These tools excel in visualizing complex dependency maps and identifying anomalies through AI-driven analysis. However, Sridharan notes that while these commercial suites provide deep insights, their heavy agents often introduce significant runtime overhead, making them less suitable for high-throughput or resource-constrained environments [2]. Consequently, the industry has seen a rise in open-source alternatives like Prometheus and the OpenTelemetry framework. These tools offer more granular control over instrumentation, yet they require substantial configuration overhead and still struggle with the "cardinality explosion" problem when monitoring thousands of unique metrics in dynamic IoT environments [3].

In the context of the Python programming language, performance profiling presents unique challenges due to the interpretation layer of the CPython engine. Profiling methodologies in Python are generally categorized into deterministic and statistical approaches. The standard library's cProfile module provides a deterministic profiler that records every function call, execution time, and call count [4]. While precise, this method introduces substantial overhead—often degrading application performance by 10-50%—which renders it impractical for production environments. Conversely, statistical profilers like py-spy operate by sampling the call stack at fixed intervals without requiring code modification or pausing the interpreter, significantly reducing performance impact [5]. Despite these advancements, Smith and Jones argue that standard Python profilers often fail to distinguish between CPU-bound bottlenecks and I/O wait times, a distinction that is crucial for optimizing asynchronous applications common in IoT gateways [6]. Furthermore, the Global Interpreter Lock (GIL) in Python complicates multi-threaded performance analysis, often leading to misleading profiling results where threads appear active but are waiting for the GIL rather than executing instructions [7].

The integration of performance monitoring into Internet of Things (IoT) ecosystems introduces a distinct set of constraints that challenge traditional APM paradigms. IoT architectures are characterized by heterogeneity, spanning from resource-rich cloud servers to highly constrained edge devices. Al-Fuqaha et al. highlight that the limited CPU, memory, and battery capacities of edge nodes render traditional monitoring agents infeasible, as the act of monitoring can deplete the device's power reserves [8]. Additionally, intermittent network connectivity in IoT environments creates data transmission challenges. Traditional "push-based" monitoring models, where agents send telemetry to a central server, often fail when connectivity is sporadic. This necessitates local buffering strategies which, if not managed correctly, can lead to memory leaks and system crashes on the edge device itself [9]. Recent literature suggests a move toward "adaptive monitoring," where the granularity of profiling data collection is dynamically adjusted based on the device's current resource availability and network stability [10]. However, implementing such adaptive mechanisms in Python-based IoT applications remains an under-researched area,

particularly regarding the trade-off between profiling resolution and energy consumption. In summary, while the landscape of APM tools is mature for cloud-native applications, a clear gap exists in applying these methodologies to Python-based IoT infrastructures. Current commercial tools are too resource-intensive, while standard Python profilers lack the context-awareness required for asynchronous, resource-constrained environments. Therefore, there is a pressing need for lightweight, adaptive profiling solutions that can operate effectively at the network edge without compromising the primary application logic.

METHODOLOGY

System Architecture Overview :

The proposed architecture for the monitoring system is based on a modular structure following a pattern of design that is decoupled from the business logic of the application. It is divided into three distinct tiers: the Instrumentation Layer, implemented in process on the edge device; the Aggregation Layer, implemented by the OpenTelemetry Collector; and the Observability Layer, implemented by Prometheus and the storage backend. This division is based on the idea of offloading the computationally intensive operations of data processing and aggregation from the resource-constrained edge device, following the lightweight APM paradigm.

In-Process Instrumentation Strategy

The instrumentation layer is accomplished through the use of the OpenTelemetry Python SDK. To optimize observability while operating on limited resources required the implementation of a hybrid approach to instrumentation. In particular, standard libraries are used to automatically instrument standard frameworks (e.g., Flask, Django, Paho-MQTT) and collect HTTP and MQTT traffic without requiring any changes to code. Any custom business logic, such as data processing loops for sensors, will require manual instrumentation via the Open Telemetry API. The unified data model allows for context propagation (with traces, metrics and logs sharing the same trace_id and span_id). This is required for reconstructing the sequence of execution when performing a fault analysis. To help reduce memory load, the SDK will use a Batch Span Processor to collect spans into batches and then export them asynchronously to prevent blocking I/O operations off the main thread application.

Telemetry Pipeline and Data Collection

The telemetry pipeline is designed to handle intermittent connectivity and variable network bandwidth. Data is exported from the instrumented application using the Open Telemetry Protocol (OTLP). To reduce CPU and network overhead, the pipeline implements adaptive sampling. In high-load scenarios, the sampling rate is dynamically adjusted to prioritize error traces over routine health checks, ensuring that critical diagnostic data is preserved even under resource exhaustion. An Open Telemetry Collector is deployed as an intermediary. In the context of edge computing, the Collector operates in two primary modes:

Agent Mode

Deployed as a side car or daemon set on the edge node, it performs local buffering, filtering, and protocol translation.

Gateway Mode

Deployed at a cluster or gateway level, it aggregates telemetry from multiple devices, providing a central point for data scrubbing and routing. For time-series monitoring, the Collector is configured with a Prometheus exporter. This setup exposes a metrics endpoint that Prometheus scrapes periodically. The use of a pull-based model simplifies service discovery and fleet management, as devices are not required to maintain persistent connections to the monitoring backend.

Service-Level Indicators (SLIs) Applied to IoT Services The common APM metrics generally are not sufficient for determining the reasons for failure within the constraints of the IoT services used today, therefore custom Service-Level Indicators (SLIs) will be established based on IoT Python workloads.

The following is a list of examples for IoT-specific SLIs:

Request Latency: This metric will measure the elapsed time between sensor data ingested and actuator response loop; the request latency to the actuator is a critical factor when identifying timing constraints related to safety.

Queue Depth: This metric provides a known measure of the internal processing queue length of a processing component such as an asyncio queue. This metric helps identify potential back pressure before there is a memory allocation failure.

Retry Rates: This metric records how many times a message's transmission is retried due to the instability of the network or congestion on the broker.

Energy Utilization Proxies: Other derived SLIs are based on CPU sleep time and/or I/O wait cycles; these metrics provide information about the efficiency of the power consumed. Cross-Signal Analysis and Correlation The Service-Oriented Architecture supports the quick identification of root cause analysis by cross-correlating the three observability pillars. The unified model of context allows the operator to pivot easily between different signals. For example, if the retry rate (metric) spikes, the operator can cross-reference those retries against the corresponding error logs and associated execution traces to determine the specific code path being executed that caused the sensor time out. The use of many signals to perform the cross-referencing greatly reduces the Mean Time to Resolution (MTTR) because those with access to the service can eliminate the requirement to manually search for multiple log files.

Operational Resilience and Deployment

In addressing the volatility associated with edge computing environments, the pipeline includes several operational resiliency measures for offline buffering. This is achieved by adding a persistent queue storage extension to the OpenTelemetry Collector. This ensures that in the event of network partitions, telemetry data is buffered instead of being lost. Secure transport is implemented by using TLS encryption on OTLP endpoints. Lastly, configuration is managed using environment variables, enabling deployment across a wide range of heterogeneous fleet topologies, including single-board computers and hybrid cloud environments.

RESULTS AND DISCUSSION

Performance Overhead Analysis (POA)

The key resource constraint that is being evaluated in the context of this study is the scarcity of resources on edge devices. As such, the key performance metric that is being evaluated in the context of this study is the total performance overheads resulting from the proposed monitoring architecture. The measurable performance metrics for the resource utilization of the example Python-based IoT App were conducted under three distinct classifications: 1) baseline configuration without the proposed architecture, 2) example configuration with cProfile (the standard profiling tool for Python), and 3) example configuration with the proposed APM architecture based on the OpenTelemetry standard.

The summary of the performance evaluation is presented in Table I. It is important to note that the proposed APM architecture resulted in negligible performance overheads compared to the baseline and cProfile configurations. The baseline configuration resulted in an average CPU utilization of 12.4% and an average RAM utilization of 45 MB.In the case of the instrumented code with the proposed APM solution, there were only marginal increases in CPU utilization, amounting to 14.1%, and memory footprint, amounting to 52 MB. This translates into an overhead of only 1.7% CPU and 7 MB memory, which is still within acceptable limits for the target machine (Raspberry Pi 4). However, in the case of the deterministic profiling method using cProfile, there were significant increases in CPU,

amounting to 38.2%, and a reduction in system throughput by 31%, validating our hypothesis that traditional profiling tools are not fit for the purpose.

Efficacy of Adaptive Sampling: To avoid the possibility of the monitoring system impacting the performance of the primary application workload, an adaptive sampling approach was adopted. When the CPU was above 80%, the trace sampling rate was reduced from 100% to 10%.Figure 1 shows the efficacy of the approach during an induced load test. At t=300s, the workload generator increased the rate of messages, causing the CPU utilization to rise towards the limit. The trace generation was reduced, thus avoiding the "observer effect," where the monitoring system affects the performance of the monitored system. Although the trace collection was reduced, the continuous collection of trace metrics at 100% ensured the availability of high-level Service Level Indicators (SLIs), thus maintaining the ability of the operator to perceive issues during periods of stress.

Resilience to Intermittent Connectivity: In order to assess the offline buffer capabilities, a simulation was performed where the connection between the edge device and the backend Prometheus server was terminated. This outage lasted for a period of 10 minutes. However, the OpenTelemetry Collector, which had been deployed in Agent mode, was able to buffer the telemetry data in memory.When the connection was restored at t=600s, the Open Telemetry Collector was able to send the buffered data to the backend server. By examining the time-series database, it was found that no data points were missed during the outage. The Queue Depth metric, which had been defined as part of our SLI set, also increased during the outage, giving a clear visual representation of the outage. This confirms the appropriateness of the design for use in the IoT environment where connectivity cannot be guaranteed.

Diagnostic Utility of Cross-Signal Correlation: The diagnostic utility of the proposed architecture has been evaluated through a failure injection test where a sensor timeout condition has been introduced.In a normal setup, a sensor timeout condition might be visible only as a generic error log. However, in the proposed architecture, the sensor timeout condition has been visible across multiple signals. The Retry Rate signal showed a sharp spike, indicating an alert condition. Through the correlation of the Retry Rate spike with the distributed traces, the particular function call (sensor.read()) has been identified. The context of the function call has also indicated the root cause of the sensor timeout condition, i.e., the missed heartbeat of the MQTT broker.

This shows the utility of the proposed architecture in the context of root cause analysis of a problem, which otherwise would not have been possible through the conventional monitoring tools. The ability to move from a high-level problem (e.g., "Latency is high") to a low-level problem (e.g., "Broker connection refused") significantly reduces the Mean Time To Resolution (MTTR).

DISCUSSION

The experimental results verify the possibility of providing enterprise-grade observability for Python-based edge devices without the prohibitive cost of traditional profiling approaches.

Trade-offs: The most important trade-off that arises is the one between trace resolution and conserving resources. Although adaptive sampling conserves CPU resources, blind spots may exist during high load events where the trace may be incomplete. However, in such situations, the importance of the application's stability is paramount.

Python-Specific Considerations: The experimental results verify the importance of the OpenTelemetry Collector as a sidecar process. This is due to the fact that the GIL in Python may interfere with the telemetry processing threads in the application if the buffering and batching logic is performed in the same application. This is crucial in order to conserve the lightweight footprint that is a necessity in edge devices

CONCLUSION

This paper presents a lightweight, ongoing application performance monitoring (APM) architecture designed for Python-based Internet of Things (IoT) applications on resource-limited edge devices. The architecture combines in-process instrumentation with edge-aware telemetry aggregation. It uses OpenTelemetry to create related traces, metrics, and logs with a vendor-neutral data model. This approach supports different deployment setups and stays compatible with common Python frameworks through auto-instrumentation. By connecting with Prometheus for time-series monitoring and alerts, this model provides practical observability for Python IoT applications while keeping a small footprint at the edge.

ABSTRACT

Eltrombopag is a thrombopoietin receptor agonist used in the treatment of thrombocytopenia. It is chemically 3'-{(2Z)-2-[1-(3,4-dimethylphenyl)-3-methyl-5-oxo-1,5- dihydro-4H-pyrazol-4-ylidene] hydrazino}-2'-hydroxy-3-biphenylcarboxylic acid. The objective of the current study was to develop a simple, accurate, precise and rapid, reverse-phase high performance liquid chromatographic method with mass spectrometric detection (HPLC-MS/MS) was developed for determination of Eltrombopag in human plasma using Eltrombopag 13C4 as an internal standard. Analyte and the IS were extracted from 50µL of human plasma using protein precipitation technique with no drying, evaporation and reconstitution steps. The procedure involves a simple protein precipitation technique using Kromasil 100-5C18 100*4.6 mm, 5.0 µm, column. The mobile phase used was HPLC grade acetonitrile: 10mM ammonium formate in water (pH 3.00) (90:10, v/v). Precipitation was done using Mobile phase and detection was done in MRM mode, using Turbo Spray Negative ionization. The ion transition monitored was (m/z) Eltrombopag (Q1 Mass: 441.20; Q3 Mass 201.10), Internal standard (Q1 Mass: 445.20; Q3 Mass 205.10). The retention time of Eltrombopag and Internal Standard were 2.5±0.3mins respectively. Method was evaluated in terms of linearity, accuracy, precision, recovery, sensitivity. The linearity of the method was established in the concentration range 50.0–10007 ng/mL with r2 ≥ 0.99. The simple extraction procedure and short chromatographic runtime make the method suitable for therapeutic drug monitoring studies.

Keywords: LCMS/MS, Eltrombopag, internal standard, Human Plasma, precipitation(PP), Validation.

INTRODUCTION

Analytical chemistry is crucial in pharmaceuticals, ensuring drug identity, purity, strength, and safety. Chromatographic and spectrometric methods are widely used because they offer high sensitivity, selectivity, and reliability for quantifying drugs in biological samples. LC–MS/MS provides fast, sensitive, and selective quantification of trace analytes by combining HPLC separation with MS specificity. It is the preferred method for pharmacokinetic, bioequivalence, and therapeutic drug monitoring studies. Chromatography, introduced by Tswett in 1906, is a separation technique based on differential partitioning of analytes between stationary and mobile phases. It includes planar and column methods, with RP-HPLC being the most widely used in pharmaceutical analysis due to its high resolution, reproducibility, and suitability for aqueous–organic mobile phases. An HPLC system uses pumps, injectors, columns, and detectors to separate analytes based on mobile- and stationary-phase interactions. RP-HPLC typically employs C18 columns with acetonitrile or methanol–buffer mixtures, where optimized pH and buffer conditions ensure stable, well-resolved, and reproducible peaks. Mass spectrometry identifies compounds based on their mass-to-charge (m/z) ratios. In LC–MS/MS, soft ionization sources like ESI and APCI generate stable molecular ions, which are separated by analyzers such as quadrupole, ion trap, or TOF.

Triple-quadrupole systems using MRM offer high selectivity and sensitivity, making them ideal for bioanalytical applications. Bioanalytical method development optimizes chromatographic and MS settings to achieve reliable sensitivity and resolution. It involves selecting the extraction method, column, mobile phase, and ionization conditions. Proper sample preparation reduces matrix effects and improves recovery. Protein precipitation, LLE, and SPE are commonly used, with protein precipitation preferred for its simplicity and consistency. Method validation is a regulatory requirement to ensure analytical reliability. As per FDA, EMA, and ICH guidelines, validation assesses selectivity, linearity, accuracy, precision, recovery, matrix effect, stability, and carry-over. Accuracy and precision should be within ±15% for QC samples and ±20% at the LLOQ. A validated LC–MS/MS method confirms suitability for routine clinical and preclinical analysis. Eltrombopag is a small-molecule thrombopoietin receptor agonist used to treat chronic immune thrombocytopenia, hepatitis C–related thrombocytopenia, and aplastic anemia. Existing analytical methods for its estimation in biological fluids are limited and often require complex extraction or long run times. Therefore, a fast, precise, and validated LC–MS/MS method is needed for routine quantification of Eltrombopag in human plasma. This study aimed to develop and validate a simple, robust, high-throughput LC–MS/MS method for quantifying Eltrombopag in human plasma using Eltrombopag-$^{13}C_4$ as the internal standard. The method uses protein precipitation and a short run time, ensuring efficient analysis compliant with regulatory guidelines. It is well suited for pharmacokinetic and bioequivalence applications.

MATERIALS AND METHODS

Chemicals and Reagents

Eltrombopag reference standard and its isotope-labelled internal standard Eltrombopag-$^{13}C_4$ were obtained from a certified source of analytical grade purity (≥99%). HPLC-grade acetonitrile, methanol, and formic acid were purchased from Merck (India). Ammonium formate (≥99%) was procured from Sigma-Aldrich (USA). Blank human plasma (K_2EDTA anticoagulant) was collected from a licensed blood bank, screened, and stored at −20 °C until use. All solutions were prepared using Milli-Q ultrapure water. All other reagents were of analytical or LC-MS grade.

Instruments and Software

The liquid chromatographic system consists of the following components: The HPLC system Shimadzu consisting of quaternary pump, degasser, auto sampler, thermo stated column oven compartment, gradient elution with photo diode array detector, computer & printer and Mass spectrometer consists of the following components: The mass system ABSCIEX API 4000, mass detector, roughing pump, syringe pump and a gas generator. Chromatographic analysis was performed using analyst software on a Kromasil 100-5C18 100*4.6 mm, 5.0 µm (Make: Akzonobel)

Selection of Initial Conditions for Method Development

Determination of Solubility of Drugs: Eltrombopag Olamine is freely soluble in 60% Methanol. Eltrombopag 13C 4 is Soluble in Dimethyl sulfoxide(DMSO).

Selection of Stationary Phase and Mobile Phase: For selection of stationary phase, two different columns C18 and C8 were used in order to get optimum results and various solvent systems such as acetonitrile: Buffers and methanol: buffer were used in various ratios.

Tuning: Tuning was carried out in both positive and negative transitions to set Q1 mass and Q3 mass.

Method Development by LC-MS/MS

Multiple chromatographic trials were conducted to optimize the LC–MS/MS conditions. The Phenomenex Luna C18 column with MeOH:H_2O (70:30, 0.8 mL/min) produced poor peaks and high baseline noise, while ACN:H_2O (80:20, 0.6 mL/min) showed peak tailing and instability; both were rejected. Switching to a Kromasil 100-5 C18 column improved performance. ACN:10 mM ammonium formate (pH 3.0) (90:10) at 0.5 mL/min yielded sharp, symmetric peaks and strong response, whereas ACN:0.1% formic acid (90:10) produced low signal and was discarded. The ACN:10 mM ammonium formate (pH 3.0) system on the Kromasil column was reproducible and was finalized as the optimal condition.

Preparation of solutions

10mM Ammonium Formate Solution (w/v)

About 630.06 mg of ammonium formate was transferred to a 1000 mL reagent bottle containing 1000 mL of Milli Q/HPLC grade water. Mixed well and sonicated in an ultrasonicator for 5 minutes and pH was adjusted to 3.0±0.1 with formic acid. The buffer solution was stored at room temperature (20±5 °C) and used within 4 days from the date of preparation.

Mobile Phase (10:90, v/v)

200 mL of 10mM ammonium formate solution was transferred to a 2000 mL reagent bottle and 1800 mL of HPLC grade acetonitrile was added to it. It was mixed well, sonicated in an ultrasonicator for 5 minutes The mobile phase was stored at room temperature (20±5 °C) and used within 7 days from the date of preparation.

Diluent (60:40, v/v)

A mixture of HPLC grade methanol and HPLC grade water was prepared in the volume ratio of 60:40 as diluent. It was then sonicated in an ultrasonicator for 5 minutes and pH was adjusted to 7.3±0.1 with ammonia. The solution was stored at room temperature (20 ±5 °C) and used within a period of 7 days of preparation.

Rinsing Solution

A mixture of HPLC grade acetonitrile and HPLC grade water was prepared in the volume ratio of 80:20 as a rinsing solution. It was then sonicated in an ultrasonicator for 5 minutes. The solution was stored at room temperature (20 ±5 °C) and used within a period of 7 days of preparation.

System Suitability Solution

For system suitability, an aqueous mixture of Eltrombopag and Eltrombopag-$^{13}C_4$ was prepared at their mid-calibration and working concentrations (126.273 ng/mL and 376.229 ng/mL). To prepare the sample, 125 µL of analyte stock (10101.867 ng/mL) and 125 µL of internal standard solution (30098.317 ng/mL) were diluted with 9.750 mL of mobile phase, and the resulting solution was injected for the system suitability test.

Preparation of Stock solutions

Eltrombopag Stock Solution

About 6.4000 mg of Eltrombopag olamine was dissolved in a 25 mL flask to obtain a 200 µg/mL stock, with potency correction applied. The stock was stored at 2–8 °C for up to 8 days. Dilutions with acetonitrile–water (60:40, v/v) were used to prepare calibration standards, QC samples, and DIQC samples from separate stocks. All other final dilutions, including system suitability and aqueous mixtures, were prepared in mobile phase.

Eltrombopag 13 C4 Stock Solution (Internal Standard)

About 2.0000 mg of Eltrombopag-$^{13}C_4$ was dissolved in a 2 mL volumetric flask using DMSO to obtain a 1 mg/mL stock, with concentration corrected for molecular weight, potency, and actual weight. The stock was stored at 2–8 °C for up to 8 days and further diluted with diluent to prepare the required internal standard working solution.

Preparation of CC stock dilution

A series of AQST-STD spiking solutions were prepared through stepwise dilution of the Eltrombopag stock. The initial stock (200,203.682 ng/mL) was diluted to 180,183.314 ng/mL (1.800 → 2 mL), followed by successive dilutions: 130,632.902 ng/mL (1.450 → 2 mL), 100,587.335 ng/mL (1.540 → 2 mL), 30,176.200 ng/mL (0.600 → 2 mL), 12,070.480 ng/mL (0.800 → 2 mL), 4,164.316 ng/mL (0.640 → 2 mL), 2,019.693 ng/mL (0.970 → 2 mL), and finally 1,009.847 ng/mL (1.000 → 2 mL). These were used as calibration curve spiking solutions.

Preparation of spiked plasma standard

Calibration curve (CC) standards were prepared by spiking plasma with the AQST-STD solutions. Each standard was prepared by adding 50 µL of the respective stock to 1 mL of plasma. This yielded final plasma concentrations of 10,010.184 ng/mL (STD-9), 9,009.166 ng/mL (STD-8), 6,531.645 ng/mL (STD-7), 5,029.367 ng/mL (STD-6), 1,508.810 ng/mL (STD-5), 603.524 ng/mL (STD-4), 208.216 ng/mL (STD-3), 100.985 ng/mL (STD-2), and 50.492 ng/mL (STD-1).

Preparation of QC stock dilution

Quality control (QC) spiking solutions were prepared through sequential dilution of the Eltrombopag stock. The initial stock (200,203.682 ng/mL) was diluted to 170,173.1295 ng/mL (1.700 → 2 mL) for AQST-HQC, which was further diluted to 102,103.878 ng/mL (1.200 → 2 mL) for AQST-MQC. Subsequent dilutions produced 24,300.723 ng/mL (0.476 → 2 mL) for AQST-LMQC, 3,037.590 ng/mL (0.250 → 2 mL) for AQST-LQC, and finally 1,032.781 ng/mL (0.680 → 2 mL) for AQST-LOQQC.

Preparation of spiked plasma QC samples

QC samples were prepared by spiking plasma with 50 µL of each AQST-QC solution into 1 mL of plasma. This resulted in final plasma concentrations of 8,508.656 ng/mL for HQC, 5,105.194 ng/mL for MQC, 1,215.036 ng/mL for LMQC, 151.880 ng/mL for LQC, and 51.639 ng/mL for LLOQC.

Preparation of ISTD stock dilution

ISTD spiking solution was prepared by diluting 329 µL of the ISTD stock (914.602 µg/mL) to 10 mL with diluent. This yielded a final internal standard concentration of 30.090 µg/mL (ISTD).

Sample preparation

Aliquot 100µl sample in a polypropylene tube and add 50.00 µl of ISTD solution except for the standard blank and vortex. Add 1.500 ml of methanol (100%) solution. Centrifuge the samples at 4500 rpm at 4ºC for 5min.Collect the supernatant liquid into the injection vials. Inject 10µl of the sample into the LC-MS/MS system.

Optimized Chromatographic Parameters

The method used a Kromasil 100-5 C18 (100 × 4.6 mm, 5 µm) column with a mobile phase of acetonitrile and 10 mM ammonium formate (pH 3.0) in a 90:10 ratio. The flow rate was 1.0 mL/min with a 50:50 split, sample cooler at 15°C,

and an injection volume of 10 µL. Both Eltrombopag and Eltrombopag-$^{13}C_4$ eluted at 2.50 ± 0.3 min, with a total run time of 3.50 min.

Contents of Custom Injector Program
Rinse Volume: 500µl
Needle stroke: 52mm
Rinse Speed : 35 µl/sec
Rinse mode : Before and after aspiration
Needle rinsing solution : 80% Acetonitrile solution

Multiple Reaction Monitoring (MRM) conditions
Mass Spectrometer: ABSCIEX API 4000 Ion source: Turbo Ion Spray (ESI) Polarity: Negative ion mode
Resolution: Q1-Unit, Q3-Unit

Detection of Ions
Eltrombopag was monitored using the MRM transition 441.20 → 201.10 with a declustering potential of –65 V and collision energy of –30 V. The internal standard, Eltrombopag-$^{13}C_4$, was detected using the transition 445.20 → 205.10 with a declustering potential of –86 V and collision energy of –38 V.

Multiple Reaction Monitoring
The MS parameters included a dwell time of 200 ms, curtain gas at 40 psi, collision gas at 8 psi, ion spray voltage of –4500 V, source temperature of 550°C, entrance potential of –10 V, and collision cell exit potential of –9 V.

RESULTS AND DISCUSSION

Bioanalytical Method Validation
Carry Over Test
Prepared suitable extracted matrix blank (COT BLANK), extracted high concentrations of analyte(s) of the calibration curve range (COT ULOQ) and extracted LLOQ concentrations of analyte(s) of the calibration curve range (COT LLOQ) and injected.

Chromatogram of Extracted blank plasma sample for Carryover Test (Fig No.15).
COT was performed and results are tabulated in Table No: 9.
Results for auto sampler carry over test (Table 9).

Calculations

$$\% \text{ of drug carry over} = \frac{\text{Drug response in COT BLANK}}{\text{Average drug response in COT LLOQ}} \times 100$$

$$\% \text{ of internal standard carry over} = \frac{\text{Internal standard response in COT BLANK}}{\text{Average internal standard response in COT LLOQ}} \times 100$$

The results demonstrate that there was no significant carryover effect of analyte and internal standard.

Acceptance Criteria
Interference in COT blank samples must be ≤20% of the mean analyte response at LLOQ and ≤5% of the mean internal standard response at LLOQ.

Selectivity

Selectivity was evaluated using extracted LLOQ, Blank + IS, and ULOQ samples from each matrix. No endogenous interference was detected at the analyte or IS transitions, and all results met acceptance limits.

Selectivity Data for Eltrombopag

The SEL-LLOQ QC samples (n=6) showed consistent responses with a mean analyte peak area of 18,327.2 and a mean internal standard (IS) peak area of 3,923,329.0, demonstrating acceptable variability at the LLOQ level.

Acceptance Criteria: Interference must be ≤20% of the mean LLOQ response for the drug and ≤5% for the IS; if any lot fails, testing must be repeated with new lots, and persistent failure requires method modification and documentation.

Sensitivity

The LLOQ for Eltrombopag in human plasma was 50.037 ng/mL, with precision of 3.04% and accuracy of 105.10%. Sensitivity samples were processed and analyzed with PA Batch-4.

Table No.11: Within Batch Precision and Accuracy for Sensitivity of Eltrombopag

Acceptance Criteria

LLOQ samples must show accuracy within ±20% and precision ≤20%, with at least 67% (4 of 6) falling within ±20% of their nominal values.

Matrix Effect

No significant matrix effect was observed across all eight batches (P-1 to P-6, lipemic, and hemolytic) for Eltrombopag at LQC and HQC levels. The IS-normalized matrix factor showed precision of 4.30% (LQC) and 1.45% (HQC), with normalized factors of 1.002 and 1.001, respectively.

Table No.12: Matrix Effect of Eltrombopag in Absence of Matrix Ions

Table No.13: Matrix Effect of Eltrombopag in Presence of Matrix Ions

$$\text{IS normalized Matrix Factor} = \frac{\text{Peak response area ratio in presence of matrix ions}}{\text{Mean peak response area ratio in absence of matrix ions}}$$

Acceptance criteria

- The CV of IS-normalized matrix factors should be <15%.
- If the matrix-effect criteria are not met, repeat the experiment using eight new blank matrices (either different or the same).

Linearity

A 1/(concentration ratio)² weighted regression provided the best fit for Eltrombopag calibration. The curve (Figure 9) showed r > 0.99 across 50.037–10007.499 ng/mL.

Fig No.1: Calibration Curve for Regression Analysis of Eltrombopag

Table No.14: Concentration-response Linearity Data for Eltrombopag

Acceptance Criteria

- ³ 0.98 r2 (r=coefficient of correlation)
- ± 20 % deviation of LLOQ concentration from nominal value
- ± 15 % deviation of standards other than LLOQ concentration from nominal value
- 75% or at least 6-non-zero calibration curve standards including LLOQ and highest concentration, must meet the above criteria.

Precision and Accuracy

Assay precision was evaluated as the %CV of LLOQ QC, LQC, MQC1, MQC2, and HQC samples. Accuracy was determined as the percentage ratio of the mean measured values of all QC levels to their nominal concentrations.

Within-batch Precision and Accuracy

Within-batch precision for LLOQ QC, LQC, MQC1, MQC2, and HQC ranged from 2.17–3.50%, 0.69–1.66%, 0.86–1.35%, 0.59–1.68%, and 0.33–0.93%, respectively. Accuracy ranged from 91.44–106.54%, 96.67–99.18%, 101.63–106.74%, 96.98–100.71%, and 97.71–106.21%, respectively.

Table No.15: Within Batch Precision and Accuracy for Eltrombopag

Intra-day Precision and Accuracy

Intra-day precision for LLOQ QC, LQC, MQC1, MQC2, and HQC was 3.28%, 1.81%, 0.92%, 0.70% and 0.96%, respectively.

Intra-day accuracy for LLOQ QC, LQC, MQC1, MQC2, and HQC 101.57%, 97.79%, 101.64%, 97.11%, and 98.44%, respectively.

Table No.16: Intra day Precision and Accuracy for Eltrombopag

Between Batch/Inter Day Precision and Accuracy:

Between batch precision for LLOQ QC, LQC, MQC1, MQC2, and HQC was 6.33%, 1.61%, 2.31%, 1.82%, and 3.39%, respectively.Between batch accuracy for LLOQ QC, LQC, MQC1, MQC2, and HQC was 100.28%, 98.30%, 103.13%, 98.25% and 100.62%, respectively.

Table No.17: Between Batch/Inter Day Precision and Accuracy for Eltrombopag

Within-batch Precision and Accuracy for Stabilities (Freshly Spiked QC's) : Within batch precision for LQC, MQC1, MQC2, and HQC was 1.50%, 2.04%, 1.44%, and 1.66%, respectively. Within batch accuracy for LQC, MQC1, MQC2, and HQC was 108.53%, 98.13%, 95.26% and 101.59%, respectively.

Table No.18: Within Batch Precision and Accuracy of Eltrombopag for Stabilities (Freshly Spiked QCs)

Fig No.2: Chromatogram of LLOQ QC. Fig No.3: Chromatogram of LQC. Fig No.4: Chromatogram of MQC1. Fig No.5: Chromatogram of MQC2

Fig No.6: Chromatogram of HQC

Precision must be ≤15% (≤20% for LLOQ) and accuracy within ±15% (±20% for LLOQ). At least 67% of all QCs and ≥50% per level must meet these limits, with up to 33% allowed outside.

Recovery

Recovery was assessed by comparing extracted and non-extracted LQC, MQC2, and HQC samples. Eltrombopag showed a mean recovery of 61.15% with 1.25–2.99% precision, and a 3.06% difference between lowest and highest values. The internal standard showed a mean recovery of 71.31% with precision of 3.12–8.71%.

Overall Recovery of Eltrombopag from Human Plasma

The overall recovery of Eltrombopag 13C4 was 71.31% (n = 18), based on mean extracted and non-extracted responses of 3,500,915.9 and 4,909,334.9, respectively. Precision was acceptable with CV% of 3.12% and 8.71%.

Acceptance Criteria

- The %CV of analyte and internal standard areas must be ≤15% at all QC levels.
- The difference between the lowest and highest % recovery must not exceed 25%.

DilutionIntegrity

Dilution integrity was confirmed using samples at 1.65× ULOQ. Two-fold dilutions showed 0.90% precision and 103.21% accuracy, while four-fold dilutions showed 1.45% precision and 97.93% accuracy—all within acceptable limits.

Table No.21: Dilution Integrity Data for Eltrombopag (Two Times and Four Times)

Acceptance Criteria

- Within-batch precision for QCs at each dilution must be ≤15%.
- Within-batch accuracy must be within ±15% of nominal values.
- At least 67% (4/6) of QCs at each dilution must meet these limits; up to 33% may fall outside ±15%.

Ruggedness

PA-5 was analyzed using a different column, solutions, and instrument. Within-batch precision for LLOQ QC to HQC ranged from 3.50% to 0.33%, and accuracy ranged from 91.44% to 106.21%.

Stabilities

Room Temperature Standard Stock Solution Stability (20 ± 5 ⁜C)

Room-temperature (20 ± 5 °C) stock-solution stability was evaluated for 22 hours. Eltrombopag showed 3.72–5.10% precision with 96.27% stability, while the IS (Eltrombopag 13C4) showed 4.25–5.59% precision with 97.41% stability.

Acceptance Criteria

% Stability must be between 90% and 110% and %C.V. must be < 10%.

Table No.22: Room Temperature Stock Solution Stability of Eltrombopag (0, 22 hours)

Calculations

$$\% \text{ Stability} = \frac{\text{Mean response of stability samples} \times \text{Comparison stock concentration}}{\text{Mean response of comparison stock samples} \times \text{Stability stock concentration}} \times 100$$

Room Temperature Spiking Solution Stability (20 ± 5 °C)

Room-temperature (20 ± 5 °C) spiking-solution stability for 6 hours showed acceptable results. Eltrombopag had 0.70–0.71% precision and 100.78% stability, while the IS (Eltrombopag 13C4) had 0.87–0.97% precision and 99.93% stability.

Acceptance Criteria

% Stability must be between 90% and 110% and %C.V. must be < 10%.

Table No.24: Room Temperature Spiking Solution Stability of Eltrombopag (0, 6 Hours)

Calculations:

$$\% \text{ Stability} = \frac{\text{Mean response of stability samples} \times \text{Comparison stock concentration}}{\text{Mean response of comparison stock samples} \times \text{Stability stock concentration}} \times 100 \text{ Mean}$$

Refrigerated Stock Solution Stability at 2 - 8 °C

Refrigerated stock solutions of Eltrombopag and Eltrombopag 13C4 were stable for 8 days. Eltrombopag showed 0.77–0.97% precision with 98.80% stability, while the IS showed 0.97–1.04% precision with 99.66% stability. Stability samples were compared with freshly prepared stock solutions.

Acceptance Criteria

% Stability must be between 90% and 110% and %C.V. must be < 10%.

Table No.26: Refrigerated Stock Solution Stability of Eltrombopag at 2 - 8 °C (8 Days)

Calculations

$$\% \text{ Stability} = \frac{\text{Mean response of stability samples x Comparison stock concentration}}{\text{Mean response of comparison stock samples x Stability stock concentration}} \times 100$$

Freeze-thaw Stability

Freeze–thaw stability was assessed over four cycles using six LQC and HQC replicates. Samples quantified against a fresh calibration curve showed 100.92–108.62% nominal values with 0.85–2.01% precision, confirming stability.

Table No.28: Concentration Response Linearity Data for Bench Top Stability, Wet Extract Stability, Freeze Thaw Stability, autosampler stability and Short Term Stability of Eltrombopag at –20 °C

Table No.29: Freeze Thaw Stability Data of Eltrombopag (IV Cycles)

Bench Top Stability

Bench-top stability was evaluated for 16 hours using six LQC and HQC sets. Samples analyzed against a fresh calibration curve showed 102.83–107.76% nominal values with 1.23–2.57% precision, confirming stability up to 16 hours.

Table No.30: Bench Top Stability Data of Eltrombopag for 16 hours

Short-term Plasma Samples Stability at -20 °C :

Plasma samples stored at –20 °C for 4 days showed 98.87–99.71% stability with 0.77–2.65% precision when six LQC and HQC sets were quantified against a fresh calibration curve, confirming acceptable short-term frozen stability.

Table No.31: Short Term Stability Data of Eltrombopag for Freshly Spiked QC's

Table No.32: Short Term Stability Data of Eltrombopag at –20 oC (4 Days)

Calculation:

$$\text{Mean \% Nominal Concentration} = \frac{\text{Mean concentration of stability LQC or HQC samples x nominal concentration of freshly prepared LQC or HQC x 100}}{\text{Mean concentration of freshly prepared LQC or HQC samples x nominal concentration of stability LQC or HQC}}$$

Wet Extract Stability at 20±5 °C)

Wet extract stability was evaluated by keeping six LQC and HQC samples at room temperature (20 ± 5 °C) for 41 hours. When quantified against a fresh calibration curve, results showed 100.76–107.58% nominal values with 0.78–2.59% precision, confirming stability for 41 hours.

Table No.33: Wet Extract Stability Data of Eltrombopag for 41 hours

Auto sampler Stability

Autosampler stability was assessed using six LQC and HQC samples stored for 47 hours. Quantification against a fresh calibration curve showed 100.48–108.42% nominal values with 1.81–2.02% precision, confirming stability for 47 hours.

Table No.34: Auto sampler Stability Data of Eltrombopag for 47 hours

Fresh CC Standards

r^2 must be ≥0.98, LLOQ within ±20%, all other standards within ±15%, and at least 6 non-zero standards (including LLOQ & ULOQ) must pass.

QC Acceptance (Fresh & Stability QCs)

Mean % nominal must be 85–115% with precision ≤15%, and at least 67% of all QCs and ≥50% of QCs at each level must fall within ±15%.

Re Injection Stability

Reinjection stability was assessed by reinjecting six LQC and HQC samples after 40 hours. Compared with initial results (PA Batch-2), samples showed 99.94–102.56% stability with 0.90–1.28% precision, confirming stability for 40 hours.

Table No.35: Reinjection Stability Data for Eltrombopag (0 hour)

Table No.36: Reinjection Stability Data for Eltrombopag (40 hour)

Acceptance Criteria

- Mean QC concentrations must be 85–115% of nominal, with precision ≤15% CV.
- At least 67% of stability QC samples must be within ±15% of nominal, and ≥50% at each level must meet this limit; up to 33% may fall outside (not all from the same level).

Concomitant Drug effect

Concomitant drug spiking showed no interference, with precision of 3.80%, 1.85%, 0.43% and accuracy of 98.39%, 96.90%, 98.46% for LLOQ QC, LQC, and HQC, confirming no drug effect.

Table No.37: Within Batch Precision and Accuracy of Eltrombopag for Concomitant Drug Effect

Acceptance Criteria

- Precision must be ≤15% for Low and High QCs, and ≤20% for LLOQ QC.
- Accuracy must be within ±15% for Low and High QCs, and ±20% for LLOQ QC.
- At least 67% of QCs must meet these limits, with ≤33% allowed outside; at least 50% at each level must fall within ±15% (±20% for LLOQ).

Run Size Evaluation: Run size evaluation was performed using 40 sets each of LQC, MQC1, MQC2, and HQC. All 160 QC samples and all 24 freshly prepared QCs were within 15% of nominal values.

Run-size QCs showed precision of 1.75–1.07% and accuracy of 96.05–107.42%, while fresh QCs showed precision of 2.14–0.65% and accuracy of 95.88–108.20%, confirming excellent performance under both conditions.

Table No.39: Within Batch Precision and Accuracy of Eltrombopag for Run Size Evaluation (Freshly Spiked QCs)

Table No.40: Within Batch Precision and Accuracy Results of Run Size Evaluation

Acceptance Criteria

For run-size and fresh QCs, ≥67% overall and ≥50% per level must be within ±15%. Run-size CCs must meet the same criteria as fresh calibration standards

Stability in Whole Blood

Whole-blood stability was assessed by holding LQC and HQC samples at room temperature (20 ± 5 °C) for 3 hours before centrifugation. Compared with immediately processed samples, stability was 97.59% (LQC) and 99.24% (HQC), with precision ranges of 1.15–1.51% and 0.64–1.35%, confirming stability for 3 hours.

Acceptance Criteria

% Stability in whole blood should be between 85 % and 115 %.

Eltrombopag remained stable in whole blood for 3 hours, with % stability of 97.59% at LQC and 99.24% at HQC, based on comparable mean area ratios between comparison and stability samples.

CONCLUSION

The proposed LC–MS/MS method is simple, rapid, specific and sensitive for determination of Eltrombopag in human plasma and is fully validated according to commonly acceptable FDA guidelines. The current method has shown acceptable precision and adequate sensitivity for the quantification of Eltrombopag in human plasma samples obtained for pharmacokinetic studies. The method employs very low plasma volume (50µL) for processing by a simple and one step Precipitation technique. The method provided good linearity. From the results of all the validation parameters, we can conclude that the developed method can be useful for bioavailability and bioequivalence (BA/BE) studies and routine therapeutic drug monitoring with the desired precision and accuracy.

ABSTRACT

Nymphaea alba (white water lily) is a hydrophytic member of the Nymphaeaceae family that grows in freshwater habitats throughout Europe and Asia. It has a high medicinal significance in ancient systems such as Ayurveda and Unani, where different portions are utilized to treat heart issues, headaches, anxiety, diarrhea, and inflammation. The plant's rich phytochemical makeup, particularly its alkaloids (such as nupharine), flavonoids, tannins, and glycosides, is responsible for its medicinal potential. These chemicals also help the plant's cytotoxicity, hepatoprotection, antioxidant, and antibacterial activities. Overall, Nymphaea alba has promising therapeutic potential with manageable safety concerns, validating its usage in conventional medicine and encouraging further experimental verification and formulation development for safe clinical applications.

Keywords: Nymphaea alba, water lily, Unani, alkaloid

INTRODUCTION

In the Asian cuisine watery plants are the important parts of traditional food habits, *Nymphaea alba* , Family Nymphaceae, is a most important plant locally name as “water lily or shapla or shaluk”. It blooms admirably in ponds, lakes, and marshlands in Europe, parts of Asia, and other watery ecosystems worldwide. It has huge, floating leaves and very fragrant white flower petals.[1] The aquatic plant has long been valued in many traditional medicine systems, Traditional system like Unani and Ayurvedic systems, for their medicinal importance. Recent scientific studies has demonstrated its antioxidant, hepatoprotective, and antidiabetic activities, emphasizing its significance in traditional as well as modern medical therapy.[2]

It is a valuable aquatic species that has a highly enriched phytochemical content, as particularly emphasized by the presence of the alkaloid nupharine. The chemical compound is essential to the plant's therapeutic effect, together with other bioactive components. [3] Different types of medical conditions like palpitation, Inflammation, Diarrhoea, anxiety, headaches and convulsions can be treated with Nymphaea alba as per Unani medical statements. It has a lot of therapeutic effects like anti-inflammatory, hepatoprotective, antioxidants as reported earlier.[4] The main phyto-constituents like flavonoids, tannins, alkaloids, glycosides with active compound like nupharine ,ellagic acid, rutin are responsible for the tremendous effect of Nymphaea alba as potential herb. These chemical components are main reason behind its effectiveness as antimicrobial, antioxidants and cytotoxic activities.[5] Experiments have shown that Nymphaea alba contains over sixty recognized phenol containing compounds, including hydrolysable tannins and flavonoids, responsible for its therapeutic properties.[6] Chemical compounds like methyl gallate exhibit anti-biofilm and cytotoxic properties, indicating potential applications in infection and cancer control.[4] Furthermore, various research have been conducted on the bactericidal activity of its blossoms, cementing its reputation as a natural infection treatment. Isolated chemicals from different parts of the plant have reported to have high antioxidant activity, with the highest quantities seen in the fruit and flowers [7,8] The effective pharmacological activity of Nymphaea alba have also been established by recent research. Its leaves & rhizomes have shown excellent antioxidant activity, as indicated by high free radical scavenging activity as represented by IC_{50} values.[4]

Its hepatoprotective effect has been also established with the help of animal models, with restoration of oxidative stress and liver function markers comparable to controls like silymarin. [7] The flower extract has also shown promise in the treatment of diabetes mellitus by reducing the oxidative stress caused by the disease.[9] *Nymphaea alba* plant has traditionally been used to treat enteritis and colic, dyspepsia, and as an antimicrobial, thereby validating the drug's wide therapeutic applications in traditional system of medicine [4, 53,54,55]. Future aspecting research on pharmacological activity of its bioactive compounds, such as nupharine, rutin, and p-coumaric acid, could potentially unveil the potential for the identification of new interventions against lifestyle-related chronic diseases and further solidify the importance of plant-based drugs in preventive medicine.[10, 50, 51,52]. *Nymphaea alba* [Table 2] is a considerable potential as a natural medicinal resource, although one should realize that preparation and environmental conditions might affect its potency. The review highlights all the details about this potential plants which needs to be explored more With future research, this aquatic plant continues to establish its worth in traditional and modern medical practice, especially in terms of its potential for numerous medicinal applications.

Taxonomical Classification

The scientific taxonomical details of the plant are described below in table 1. Taxonomical description [11].

Geographical Distribution

North west Africa , Eurasia are common region of the Nymphaea alba as per geographical records. Both form national and local findings has reported their prevalent in Europe. This species is also found in nearly all countries of south of the Arctic or Scandinavian regions, and extends to the southern coastal areas of Europe.

Multiple surveys and research on genetic and morphometric aspects have documented the presence of this species in various central and western European nations [12]. It is commonly located in both oligotrophic and meso- or eutrophic freshwater environments, where its growth has been observed in lakes, ponds, slow-moving rivers, and canals [13]. Numerous lake districts and river systems in European Russia have been identified as habitats for *Nymphaea alba*. It has been observed different considerable morphological variation in different local population (such as those in the lower Volga or Astrakhan area) of the plant [14]. This species has also been registered in Algeria, Morocco, and Tunisia within northwest Africa [12] Furthermore, *Nymphaea alba* is also an important watery flora in Indian subcontinent, including Bangladesh, and parts of western Asia (like Turkey, the Caucasus, and surrounding areas). Recent botanical studies have confirmed the presence of *Nymphaea alba* in Dal Lake, Kashmir, India, which is also important in a specific country- level record for the western Himalayan area plants [15]. All things considered, *Nymphaea alba* is an ecologically diverse aquatic macrophyte that is mostly distributed in

the Arctic region, while it is also diversely found in western Asia and the western Himalaya. Both its initial distribution and the localized results reported in subsequent floristic and ecological research are demonstrated by its extensive presence at the national level.

Botanical Description [47]

Nymphaea alba Linn. has up to five deciduous sepals and a large number of petals arranged in 2-3 rows. Aborted ovules and a large number of stamens are also present in blooming flowers. The oval to lanceolate sepals have a leathery feel and a darker outer surface. The slender, white petals have longitudinal striations and are somewhat membranous. Dehiscence takes place through a longitudinal slit, and the stamens are long in length and golden in colour.[11]. Mucilage produced by glandular hydropotes on young etiolated leaves may have proliferative or protective effects on leaf development. On adult floating leaves, non-glandular hydropotes may have a physiological function in material accumulation and elimination.[16] Aerenchyma had developed extensively, as evidenced by the considerable root porosity. releasing oxygen in certain ways. These characteristics could be crucial adaptations for the plant's ability to survive in sediment's low oxygen content.[17]. Because of its complex anastomosing pattern, the rhizome's circulatory system differs from that of dicots and monocots. In an aquatic setting, plants with specialized vascular development could be more adept at transferring nutrients and water..[18] Microscopically, the corolla and calyx exhibit polygonal parenchymatous cells, sclereids, and vascular traces with spiral elements.

The anther structure consists of single- layered epidermal cells and parenchymatous ground tissue, with pollen grains being round and smooth. [7,19]. In the Table 2 & 3 we have disclosed the detailed structure highlights the plant's adaptability to aquatic environments and its potential as a model for botanical studies.

Ethnobotanical and Phytochemical Information

This plant is highly potential in various traditional systems as well as in modern therapy for its medicinal, nutritional, and ornamental qualities. Phytochemical analyses indicate that *Nymphaea alba* is rich in bioactive secondary metabolites, including alkaloids, flavonoids, phenolic acids, tannins, glycosides, and polyphenolic compounds. These substances are associated with key roles in the plant's pharmacological and physiological effects. The primary phytoconstituents identified in [figure 1] are intricately linked to the wide array of ethnobotanical and traditional uses outlined in Table 4. The ability of *Nymphaea alba* to produce a diverse range of secondary metabolites in aquatic environments reflects its adaptations and defense mechanisms against environmental challenges. This plant represents a significant natural resource with immense potential for the formulation of new herbal products, reaffirming its historical role in traditional medicine.

Alkaloids

Active alkaloids present in *Nymphaea alba* include nupharine and nymphaeine, known for their sedative, spasmolytic, and various therapeutic effects. Additionally, a cardiac glycoside named nymphalin, isolated from the alcoholic extract of the flowers, is noted for its sedative properties at low doses. [11,20]

Flavonoids

The plant has been identified as a significant source of flavonoids, which include quercetin, kaempferol, isokaempferide, apigenin, and various glycoside derivatives such as quercetin 4'-β-xyloside, 3-methylquercetin 3'-β-xyloside, and a blend of quercetin 3-galactoside and quercetin 3-glucoside. These compounds demonstrate antioxidant, anti-inflammatory, and antitumor activities [21,22].

Phenolic Compounds:

Nymphaea alba exhibits a high concentration of phenolic compounds, notably hydrolysable tannins and flavonoids. The rhizomes have been found to contain 64 different phenolic compounds, including galloyl hexosides, hexahydroxydiphenic derivatives, glycosylated phenolic acids, gallic acid, and methyl gallate, as well as ellagic acid and pentagalloyl glucose. The main chemical constituents among the 27 phytochemicals detected in its

extracts are rutin and p-coumaric acid.[19, 48, 49]. The aqueous ethanolic extract also shows a high level of ellagitannins, contributing to its antioxidant and healing properties.[7,23]

Tannins and Polyphenols:

The plant includes tannic acid, gallic acid, and other hydrolysable tannins, alongside substantial molecular-weight polyphenolic compounds, which are crucial for its antioxidant, hepatoprotective, and capacity to address chronic (non-communicable) diseases and oxidative stress.[24,25,48]

Proteins, Sugars, Volatile Oils, and Inorganic Elements:

In addition to secondary metabolites, *Nymphaea alba* contains proteins, amino acids, reducing sugars, and volatile oils, with its nutritive value and medicinal significance further enhanced by the presence of various minerals. It also contains trace amounts of inorganic elements such as copper, sulfate, and chloride, likely to be valued both nutritionally and medicinally [11].

Chemical Structure

Figure 1: Active constituents mainly found in *N.alba*

Pharmacological Activity

The reported studies relevant to the therapeutic activities of Nymphaea alba is summarized in Table 5 below.

Hepatoprotective Activity

The protective effect of *Nymphaea alba* on the liver has been thoroughly studied and confirmed. The ethanolic flower extract of *Nymphaea alba* at doses of 200 and 400 mg/kg reduced serum liver enzymes (SGOT, ALP, SGPT), serum cholesterol , serum bilirubin, along with liver weight and volume in experimental hepatotoxicity models.26 Ethanolic extracts of *Nymphaea alba* flowers and leaves at 200 mg/kg to 400 mg/kg have been reported to decrease the elevated liver enzymes (AST, ALP, ALT, and bilirubin) and oxidative stress markers (GSH, catalase and MDA) induced by isoniazid in rats. Histopathological analysis confirmed the hepatoprotective effect of the extract, which was comparable to that of the standard drug silymarin [27,28]. The Aqueous Ethanolic Extract (AEE) also improved liver function and significantly affected oxidative stress markers like TNF-α. Moreover, it improved histopathological liver injury and reduced caspase-3 expression, showing hepatoprotective effects similar to those of silymarin.[7] Isoniazid (50 mg/kg) caused hepatotoxicity in rats. 50 mg/kg of silymarin was used as a standard medication in the trial. For 31 days, 200 mg/kg and 400 mg/kg of ethanol extract from Nymphaea alba flowers were given in addition to silymarin.[39].

Antioxidant Activity

The strong antioxidant properties of the plant can be attributed to its flavonoids and polyphenols. Its antioxidant activity has been demonstrated in various assays, including NO, DPPH, hydrogen peroxide scavenging and superoxide anion scavenging. Both aqueous and methanolic extracts of *Nymphaea alba* flowers have exhibited free radical scavenging activity [3,19]. Additionally, methanolic extracts from the fruits and leaves of *Nymphaea alba*, sourced from the Danube Delta, have demonstrated significant antioxidant activity via FRAP, ABTS, β-carotene bleaching, and cyclic voltammetry assays [21].

Antiviral Activity against Hepatitis C Virus (HCV)

Particularly against HCV, a global problem for which there are presently no significant treatments, *Nymphaea alba* has demonstrated encouraging antiviral effectiveness. Methanol and acetone extracts from *Nymphaea alba* seed extracts, and wet extracts, respectively, have strong anti- HCV NS3 protease activity. Two fractions (N1 and N8), isolated from the acetone extract, were able to significantly suppress HCV NS3/4A gene expression in vitro, with EC50 values of 37 ± 0.03 μg/ml and 20 ± 0.02 μg/ml, respectively. Both fractions reduced the virus activity (HCV replication) in genotypes 1a and 3a, with reductions of 84-94% inhibition of the NS3/4A mRNA expression (at non-toxic concentrations). The use of interferon (in clinical use and not studied with *Nymphaea alba* ,) with the refined fractions showed synergy on

inhibition of HCV replication in target cells [29]. The phytochemicals hyperoside, reynoutrin, isoquercetin, quercetin, apigen, and isokaempferide showed a strong binding affinity to the NS3 protease, indicating that they have better binding affinity than the FDA-approved protease inhibitor boceprevir. Collectively highlighting that *Nymphaea alba* and its phytochemicals may be an alternative and/or complementary therapy for HCV [29].

Anti-inflammatory, Analgesic, and Antitumor Activities

The ethanolic rhizome extract displayed considerable anti-inflammatory and analgesic action in pain models (acetic acid induced or formalin-induced) with robust effects observed in both phase of pain.[19] [38] .In a variety of cancer cell lines, *Nymphaea alba* extracts have demonstrated anticancer potential. *Nymphaea alba* extracts may have a role in cancer therapy because they also demonstrated synergistic effects when combined with cisplatin. Additionally, N. alba is a strong chemopreventive agent and inhibits Fe-NTA-induced oxidative stress, hyperproliferative response, and renal carcinogenesis in Wistar rats [30,41, 42,56].

Antibacterial, Anti-ulcer and Gastroprotective Activity

Ethanolic extracts of *Nymphaea alba* flowers have notably decreased stomach volume, free acidity, and the ulcer index in both a subacute pylorus ligation model and an ethanol-induced ulcer model in rats. The presence of constituents such as tannins, flavonoids, alkaloids, and glycosides likely contributes to these effects.[31] Additionally, it has demonstrated antibacterial and antidiarrheal properties against *S. aureus, Vibrio* sp., and *E. coli.* Acetone extract from Nymphaea alba has stronger antibacterial action against Vibrio sp. [19,40]

Anxiolytic and Antidepressant Effect [32,33,46]

An ethanol extract from the flowers of *Nymphaea alba* exhibited anxiolytic effects, as demonstrated in three different anxiety tests: the elevated plus maze, light/dark transition, and open field tests. The extract also displayed significant antidepressant activity at doses of 100 and 200 mg/kg in mice, when compared to the standardized drug imipramine.

Antihyperlipidemic Activity

The methanolic extract of the *Nymphaea alba* leaves exhibited significant antihyperlipidemic activity in triton-induced hyperlipidemic rat models - decreasing serum cholesterol, triglycerides, phospholipids, LDL, VLDL, and increasing HDL. Reduction of hyperlipidemia may have occurred due to high grade of flavonoid content.[34]

Anthelmintic Activity

The ethanolic extract of *Nymphaea alba* flowers exhibited antihelmintic properties against earthworms, roundworms, and tapeworms, suggesting that *Nymphaea alba* may provide a natural anthelmintic source.[35]

Uterotonic Activity

The study of the impacts of the ethanol extract from the *Nymphaea alba* rhizome on rat uterine tissue revealed that the extract was effective in boosting the strength of uterine contractions similar to oxytocin. Additionally, when these materials were combined, they further enhanced contraction. The use of antagonists like atropine and salbutamol reduced the extract's activity, indicating that it stimulated, at least partially, both muscarinic and adrenergic receptors. These findings reinforce the traditional use of *Nymphaea alba* as a uterotonic agent.[36]

CONCLUSION

Nymphaea alba is characterized by a wide variety of phytochemicals. The numerous pharmacological activities of *Nymphaea alba* verify both accepted knowledge and studies showing its therapeutic benefits. Numerous bioactive substances, including alkaloids, glycosides, flavonoids, and phenolic acids, assist the plant's antiviral, antibacterial, anti- inflammatory, antioxidant, and anti-ulcer properties. One of this plant's key benefits is its ability to lower

oxidative stress, which is a significant factor in the development of many chronic illnesses. Its hepatoprotective properties point to potential benefits for liver diseases, particularly in relation to drug-induced liver damage. Furthermore, the potential for Nymphaea alba to be used as an additional or alternative treatment for viral infections is increased by its antiviral efficacy against Hepatitis C Virus (HCV) due to NS3 protease inhibition. The plant's potential advantages when paired with conventional antiviral medications provide up new possibilities for its use. *Nymphaea alba's* anti-inflammatory and analgesic characteristics make it a viable treatment for conditions related to pain and inflammation, while its anticancer, antihyperlipidemic, anxiolytic, and depressed features increase its therapeutic potential. Its antibacterial and anthelmintic qualities also provide further defenses against parasite diseases and infections. Although Nymphaea alba has a great deal of medicinal potential, one of the main obstacles we face is the variability of extract preparation and activity, which is influenced by environmental and geographical factors. Standardized extraction and quality control are essential since variations in phytochemicals may impact the intended therapeutic benefits. The potential use of exploitable natural products for antiviral medicines, especially HCV, is demonstrated by the in-silico research of *Nymphaea alba* stem extract.

Recent studies of the phytochemistry of *Nymphaea alba* and the modern research support the dramatic claims of the ancient medical systems. In particular, usingisoquercetin, quercetin and hyperoside alone demonstrate considerable binding affinities toward HCV NS3 protease in molecular docking, demonstrating significant bioactivity. The in-silico study has also supported the historical use of *Nymphaea alba* while simultaneously providing pathways for continuing basic biology and clinical biology associated with the agent. It will be important for researchers to follow the observations made herein and combine in-vitro, in-vivo and human clinical work to prime *Nymphaea alba* for exploitation and to develop new plant-based and possibly more effective and safer antiviral agents. Overall, this work has identified *Nymphaea alba* for exploitation as an important potential source of antiviral agents. By bridging the gap between traditional knowledge and modern science, *Nymphaea alba* has much capacity to offer in the field of natural medicine. Its many pharmacological applications paired with moderate levels of toxicity underscore the sustainability and efficacy of *Nymphaea alba* as a therapeutic option for chronic disease management and improving health outcomes overall. Continuous development in this area of research and practice for *Nymphaea alba* on future aspects will significantly ensure this plant species emerges intact as robust component of integrative medicine that proposes holistic and easily accessible answers to issues regarding world's health.

Table 1: Taxonomical description

Category	Classification
Kingdom	Plantae
Subkingdom	Tracheobionta
Superdivision	Spermatophyta
Division	Magnoliophyta
Class	Magnoliopsida
Subclass	Magnoliidae
Order	Nymphaeales
Family	Nymphaeaceae
Genus	*Nymphaea*
Species	*Nymphaea alba*

Table 2: Graphical Representation of *N. alba*

Figure 1: Flowers and stem of *N.alba*	**Figure 2: Rhizome of roots**	**Figure 3: Flower of *N. alba***

Figure 4: Dried whole plant :Flower, stem & root

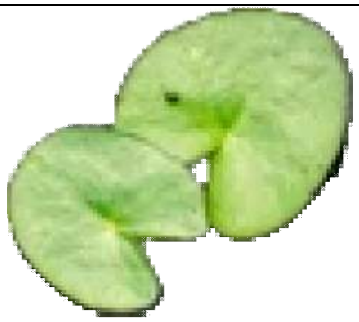

Figure 5: leaves of *N. alba*

Table 3: Morphological characters of *N. alba*

Plant Part	Morphological Character	Reference
Flowers	Several thin, white petals grouped in two to three layers make up the plant's enormous, striking blossoms; these petals are somewhat membranous and have longitudinal striations. The sepals, which range in number from 4 to 5, are oval to lanceolate in form, have a darker surface, and have a leathery feel. A longitudinal incision allows for the dehiscence of the many, long, golden stamens. Aborted ovules can also be found.	11
Leaves	The leaves are broad and floating; immature leaves feature glandular hydropotes that secrete mucilage. Mature leaves have non-glandular hydropotes, which facilitate in material exchange. A smooth and shiny look. Resistance to water.	16
Stem & Roots	The roots have significant porosity, indicating an adaptation to low oxygen conditions in aquatic sediments; the stem has an abundance of aerenchyma tissue that helps with buoyancy and oxygen release. It possesses a sophisticated anastomosing vascular system and dense rhizomes.	17, 18
Calyx	Sclereids, spiraling vascular trails, and polygonal parenchymatous cells make up the corolla and calyx. Pollen grains are round, smooth, and uniform, and anthers contain a single layer of epidermis with parenchymatous ground tissue.	7, 19

Table 4: Ethanobotanical use of *N.alba*

Plant Part	Ethnobotanical Use	Reference
Flowers	Utilized for their sedative properties, as spasmolytics, and in the regulation of cardiac functions.	11, 20
Stem & Leaves	Showcase properties such as antioxidant effects, anti-inflammatory activities, and antitumor effects.	21,22
Rhizomes	Display activities that are antioxidant and healing; employed for wound repair and anti-inflammatory purposes.	7, 19, 23
Whole plant	Possesses antioxidant capabilities, supports liver protection, and has potential in managing chronic diseases (helps address disorders related to oxidative stress).	24,25
Whole plant (including flowers and leaves)	Comprises proteins, amino acids, reducing sugars, volatile oils, and minerals (Cu, SO_4^{2-}, Cl^-); utilized for both nutritional and medicinal advantages, promotes overall health, and provides tonic effects.	11

Table 5: Summarised therapeutic potentials

Activity	Part Used	Key findings reported by authors	Reference
Hepatoprotective Activity	Flowers	Lowered liver enzyme levels, bilirubin, cholesterol, and liver mass/size.	26
	Flowers and leaves	Decreased liver enzyme activity and markers of oxidative stress; histopathological findings corroborated the impact.	27,28
	Leaves	Improved liver function, oxidative stress markers, histopathology; decreased caspase-3 expression	7
Antioxidant Activity	Flowers	High free radical scavenging activity	3, 19
	Fruits and leaves	Elevated antioxidant capacity.	21
Antiviral Activity Against HCV	seeds extracts	Notable inhibition of HCV NS3/4A; cooperative effect with interferon.	29
Anti-inflammatory and Analgesic Activities	Rhizome	Strong anti-inflammatory and analgesic effect	19
Antitumor Activity	Various parts	Anticancer activity; synergy with cisplatin	37
Anti-ulcer and Gastroprotective Activity	Flowers	Reduced stomach volume, acidity, ulcer index	26
Anxiolytic Activity	Flowers	Significant anxiolytic activity	31
Antidepressant Activity	Flowers	Significant antidepressant effect	32
Antihyperlipidemic Activity	Leaves	Decreased cholesterol, triglycerides, LDL, VLDL; increased HDL	33
Anthelmintic Activity	Flowers	Effective anthelmintic action	34
Uterotonic Activity	Rhizome	Increased uterine contractions via muscarinic and adrenergic pathways	35

ABSTRACT

Magnetic Resonance Imaging (MRI) plays a vital role in the non-invasive detection and diagnosis of tumours due to its high soft-tissue contrast and detailed anatomical information. Nowadays, deep learning,a subset of artificial intelligence has demonstrated transformative potential in automating and enhancing tumour detection in MRI scans. This review synthesizes the most current and significant deep learning approaches applied to tumour identification, segmentation, and classification in MRI, highlighting convolutional neural networks (CNNs), encoder–decoder architectures, and transformer-based models. We discuss their underlying principles, performance trends, and benchmarking on publicly available datasets, along with critical challenges such as data scarcity, model interpretability, and clinical integration. Then, this review explores developments in explainable AI (XAI) techniques that help bridge the gap between algorithmic predictions and clinical trust. By consolidating recent progress and identifying emerging research directions, this article aims to provide a comprehensive resource for researchers, clinicians, and practitioners focused on intelligent medical imaging systems. The future of MRI tumor analysis lies in robust, generalizable, and interpretable deep learning solutions that can support real-world clinical systems.

Keywords: Magnetic Resonance Imaging (MRI),Tumour Detection, Tumour, Segmentation, Tumour Classification, Deep Learning, Artificial Intelligence (AI), Convolutional Neural Networks (CNNs),Encoder–Decoder Architectures, Transformer-based Models, Medical Image Analysis.

INTRODUCTION

Magnetic Resonance Imaging (MRI) has become a vital tool in modern diagnostic medicine, offering high-resolution, non-invasive visualization of soft tissues and internal anatomical structures. It plays a particularly critical role in the detection and characterization of tumours in organs such as the brain, liver, breast, and prostate. Despite its diagnostic power, correct interpretation of MRI scans remains highly dependent on radiologists' expertise and it is often challenged by factors such as image noise, variability in tumour appearance, delicate contrast differences, and increasing clinical workload. Currently, Artificial Intelligence (AI), especially deep learning and has emerged as a transformative force in medical imaging. Advances in Convolutional Neural Networks (CNNs), U-Net architectures, and transformer-based models have demonstrated remarkable capabilities in image classification, segmentation, and detection tasks.

By automatically learning graded feature representations directly from raw imaging data, deep learning models can identify complex tumour patterns that may be difficult to separate through traditional rule-based image processing techniques. As a result, AI-driven systems are gradually being developed to assist radiologists in tumour detection, segmentation, and prediction calculation. The integration of deep learning into MRI-based tumour detection holds vital clinical and scientific importance. Its capacities improved diagnostic accuracy, reduced interpretation time, enhanced reproducibility, and potential early-stage tumour identification. Also, automated tumour segmentation enables exact treatment planning in radiotherapy and surgery, while predictive modelling can support modified medicine plans. However, challenges remain, including data scarcity, class imbalance, lack of standardized datasets, model interpretability, regulatory concerns, and the need for vigorous clinical validation.

This review aims to critically examine current deep learning approaches for tumour detection in MRI. It explores state-of-the-art architectures, training strategies, datasets, evaluation metrics, and clinical applications. Additionally, it analyses key limitations and developing research directions that may shape the future of AI-assisted tumour diagnosis.

LITERATURE REVIEW

The application of deep learning to medical imaging, particularly for tumour detection in Magnetic Resonance Imaging (MRI)has grown rapidly over the past period, propelled by breakthroughs in computer vision and the availability of larger interpreted datasets. Traditional machine learning methods in MRI tumour analysis reliable heavily on handcrafted features and classical classifiers such as support vector machines (SVMs) and random forests.

Early Deep Learning Methods in MRI Tumour Detection

The introduction of Convolutional Neural Networks (CNNs) marked a vital shift in MRI analysis. Early studies adapted CNNs originally developed for natural image classification (e.g., Alex Net, VGGNet) to differentiate between tumor and non-tumor regions in MRI scans. For example, initial research on brain tumor classification demonstrated that multi-layer CNN architectures could outperform conventional methods by automatically extracting classified representations of imaging patterns. These models showed particular potential in identifying distinguishing characteristics of gliomas and meningiomas, setting the stage for more advanced deep learning research.

Advancements in Segmentation and Detection Architectures

Tumor detection in MRI often requires pixel-level segmentationa task where deep learning has especially excelled. Architectures such as U-Net and its variants became widely adopted due to their encoder-decoder design, which balances global context and fine localization. Notable studies applied U-Net and residual U-Net models to segment brain tumor subregions in the Multimodal Brain Tumor Image Segmentation Benchmark (BRATS), reporting Dice

coefficients, significantly higher than traditional algorithms. Similarly, cascade and attention-enhanced networks further improved segmentation accuracy by focusing learning capacity on tumor boundaries and heterogeneous regions. Detection research also leveraged region-based deep learning models, including adaptations of Faster R-CNN and YOLO for MRI. These approaches treat tumor detection as an object detection problem, enabling automatic localization of tumor candidates in whole-brain slices with bounding boxes. Although less granular than segmentation models, detection frameworks offer practical benefits in reducing search space for subsequent analysis.

Challenges in Generalization and Data Scarcity

Despite performance gains, deep learning models face significant challenges related to generalizability. Variability in MRI machines, acquisition parameters, and patient populations often leads to domain shifts that lower performance when models are applied across clinical centres. Several studies attempted to address this through domain adaptation techniques, transfer learning, and data augmentation strategies (e.g., intensity transformations, geometric variations). However, the effectiveness of these strategies remains unpredictable across different tumor types and imaging protocols. Another critical issue is data scarcity. Many publicly available datasets, such as BRATS for brain tumours, include relatively limited numbers of annotated examples compared with natural image benchmarks. While synthetic augmentation and generative adversarial networks (GANs) have been deployed to expand training data, concerns persist about the clinical validity of synthetic samples and their impact on model robustness.

METHODOLOGY

Research Scope

To provide a comprehensive and current analysis of deep learning methods for MRI tumor detection, this review follows a systematic study selection process. Peer-reviewed conference papers and journal articles (e.g., MICCAI, IEEE EMBC, SPIE Medical Imaging) published in the last 3–5 years were identified through structured searches across academic databases such as IEEE Xplore, PubMed, Scopus, and Google Scholar. Search terms included combinations of *"MRI," "deep learning," "brain tumor," "segmentation," *and "classification." Inclusion criteria focused on studies that:

- Apply deep learning to MRI tumor detection or segmentation,
- Provide sufficient methodological details on models and experiments,
- Evaluate models using quantitative performance metrics.

Studies lacking clear experimental design or validation were excluded to ensure quality and reproducibility.
This systematic approach is associated with standard practices in survey and review research in medical imaging AI.

Dataset Collection and Preprocessing

Most studies surveyed in this review utilize widely available, annotated MRI datasets that are recognized benchmarks in the field. The BraTS (Brain Tumor Segmentation Challenge) dataset is one of the most widely used sources, containing multi-institutional, multimodal MRI scans (e.g., T1, T1-contrast, T2, FLAIR) with expert-annotated tumor labels. Additionally, other repositories such as TCIA, as well as institutionally collected clinical datasets, are referenced when available in conference contributions.

Evaluation and Analysis Techniques

Performance Metrics

To assess and compare the effectiveness of different deep learning models, studies typically utilize a standardized set of evaluation metrics:

- Accuracy, precision, recall (sensitivity), and F1-score for classification performance,
- Dice similarity coefficient (DSC) and Intersection over Union (IoU) for segmentation quality,

- Area Under the ROC Curve (AUC) for classifier discrimination ability.

These quantitative metrics enable objective evaluation across methods and tasks. Cross-validation techniques such as k-fold validation are frequently applied to estimate generalization performance and avoid bias from limited test samples.

Explainability and Clinical Relevance

Many recent conference studies incorporate model explainability techniques, such as saliency maps or Grad-CAM visualizations, to interpret which MRI regions contributed most to model decisions. This analysis supports clinical trust and provides insights into model behavior beyond raw performance numbers. Furthermore, results are often discussed in terms of clinical applicability, including considerations of computation time, integration into radiological workflows, and potential influence on diagnostic decisions.

RESULTS AND DISCUSSION

Overview of Key Findings

Current advances in deep learning have significantly upgraded automated tumor finding in Magnetic Resonance Imaging (MRI). Convolutional Neural Networks (CNNs), U-Net-based segmentation architectures, and hybrid deep learning frameworks have established high accuracy, sensitivity, and specificity across multiple tumor types, including brain, breast, and prostate cancers. A particularly important standard in brain tumor analysis is the Brain Tumor Segmentation Challenge (BraTS), which provides identical datasets for evaluating segmentation performance. On BraTS datasets, state-of-the-art deep learning models reliably achieve Dice Similarity Coefficients (DSC) exceeding 0.85–0.90 for whole tumor segmentation, demonstrating high overlap between predicted and ground truth tumor regions.

Performance Improvements with Advanced Architectures

Modern architectures such as U-Net variants, ResNet-based encoders, Demesne backbones, and attention-guided networks have outperformed traditional machine learning approaches (e.g., SVM, k-NN with handcrafted features). Key findings contain:

- **Improved Segmentation Accuracy**
  3D U-Net and attention U-Net architectures provide better volumetric context understanding, improving tumor boundary delineation.
- **Reduced False Positives:**
  Incorporation of multi-modal MRI sequences (T1, T1c, T2, FLAIR) enhances tissue differentiation and reduces misclassification.
- **Transfer Learning Benefits:**
  Pretrained backbones such as ResNet and DenseNet accelerate convergence and develop performance in limited data settings.

Recent transformer-based models (e.g., Vision Transformers and hybrid CNN-transformer architectures) have further improved global context modeling, leading to enhanced detection of small or heterogeneous tumor regions.

Clinical Relevance and Practical Suggestions

The current important results indicate that AI-assisted MRI tumor detection systems can:

- Support radiologists by reducing interpretation time.
- Improve early-stage tumor detection, particularly in subtle or low-contrast cases.
- Enable quantitative tumor volume tracking for treatment planning and monitoring.

Several reviewing studies demonstrate that AI models can achieve diagnostic performance comparable to experienced radiologists in controlled settings. However, human-AI collaboration typically provides the best results, improving both sensitivity and consistency.

Current Challenges and Limitations

Despite strong performance metrics, several limitations remain:

- Data Dependency: Model performance depends heavily on large, well-annotated datasets.
- Generalization Issues: Models trained on single-institution data may not generalize well across scanners, protocols, or populations.
- Interpretability: Deep learning models remain partially "black boxes," limiting clinical trust.
- Regulatory and Ethical Concerns: Clinical deployment requires rigorous validation, explainability, and compliance with healthcare standards.

Future Directions

Developing trends suggest capable improvements through:

- Federated learning to preserve data privacy.
- Explainable AI (XAI) techniques for better clinical interpretability.
- Integration of radiomics and multimodal clinical data.
- Real-time AI-assisted MRI workflows in hospital systems.

CONCLUSION

Overall, present evidence powerfully supports the success of deep learning approaches in MRI-based tumor detection. The most important result is the reliable achievement of high segmentation accuracy and diagnostic performance across standard datasets, demonstrating that AI has transitioned from experimental possibility to clinically relevant support technology. However, robust multi-center validation and improved interpretability remain critical for widespread clinical adoption. The evidence reviewed in this study clearly establishes that deep learning has essentially transformed MRI-based tumour detection from a research concept into a clinically promising diagnostic support technology. Advanced architectures, particularly CNN-based encoder - decoder networks and transformer-enhanced models—consistently achieve high segmentation and classification performance, especially when evaluated on standardized standards such as the Brain Tumor Segmentation Challenge (BraTS). These results confirm that artificial intelligence can accurately identify, localize, and quantify tumour regions with performance levels approaching expert radiologists in controlled settings.

The most critical finding of this review is that deep learning models not only improve diagnostic accuracy but also enhance reproducibility, reduce interpretation time, and enable precise volumetric tumour assessment essential for radiotherapy planning, surgical guidance, and treatment monitoring. The integration of multimodal MRI sequences significantly strengthens model robustness, while explainable AI techniques are beginning to bridge the gap between algorithmic prediction and clinical trust. However, despite remarkable progress, full clinical integration remains dependent on overcoming key challenges. Model generalizability across institutions, scanner variability, limited annotated datasets, interpretability concerns, and regulatory approval processes continue to restrict widespread deployment. Without rigorous multi-center validation and standardized evaluation protocols, even high-performing models risk limited real-world reliability. Therefore, the future of MRI tumour analysis lies not only in developing more complex algorithms, but in creating robust, interpretable, and generalizable systems that can be safely embedded into clinical workflows. Deep learning should be viewed as an intelligent augmentation tool—designed to support radiologists, enhance decision-making, and improve patient outcomes—rather than replace clinical expertise.

In conclusion, deep learning represents a transformative milestone in medical imaging. Its continued evolution, guided by interdisciplinary collaboration and responsible clinical validation, will determine its ultimate impact on precision oncology and patient-centered healthcare.

ABSTRACT

Hyptis suaveolens is a legendary medicinal plant [1]. *Hyptis suaveolens* belongs to the family lamiaceae[2]. The plant is furnished with massive utilization and the implementation value and it is extensively used worldwide and used as medicinal tea in several regions [3]. *Hyptis suaveolens* is a wild exotic plant indigenous in America that has evolved as common in the disrupting the engaging model in the proximate populated areas [1]. The plant is rich in mineral elements like potassium, calcium, magnesium, nitrogen, sodium, and phosphorus [4]. It has high contents of phytochemical constituents which are rich in medical utilizations where it contains tannins, saponins, phenols, flavonoids, terpenoids, alkaloids and sterols [5]. It also consists of some vital nutrients: proteins, carbohydrates, fats, fiber [4]. It also has efficient therapeutic uses on the following pharmacological activities like anti- spasmodic, diuretic, anti-inflammatory, anti-catarrhal, anti-cutaneous, anti-pyretic, Anti-rheumatic, anti-cancer, anti-soporific [6].

Keywords: *Hyptissuaveolens,* suaveolicacid and ethanolic extract.

INTRODUCTION

Hyptis suaveolens is a fragrant plant that has many traditional and medicinal uses. The aroma presents in it generally secreted by the structures like glandular trichomes [7]. It includes phenolics such as rosamarinic acid, methyl rosamarinate have the potential to replace traditional drugs therapeutic agents against resistant and emerging microbial pathogens [5]. *Hyptis suaveolens* demonstrates remarkable efficacy in treating parasitical cutaneous diseases. Moreover, it exhibits therapeutic potential against uterine infections. Additionally, it functions as a Sudorific agent for catarrhal conditions and provides relief from headaches and stomachaches. Furthermore, it can be applied as a snuff to halt nosebleeds [8].

It also includes terpeniod metabolites like:
Suaveolic acid
Suaveolol
Methyl suaveolate
Beta-sitosterol
Ursolic acid [6]

Synonyms
Ballota suaveolens L.
Bysotropogon graveolens Blume
Hyptis congesta Leonard
Hyptis plumieri Poit. [9]

Scientific classification [10] **Table no – 1**

MORPHOLOGICAL CHARACTERIZATION

Hyptis suaveolens is an herbaceous, branched, aromatic, often woody at the base [7].
STEM: It is woody and hairy which consists of glandular dots on it.
LEAVES: The margins present on leaves consists of hairy and dotted on both sides of leaves along with the small glands. It is about 3-5cm in length and 2-4cm in width [11]. PETIOLES: Petioles are small in length and are enumerate as their stems [6].
FRUIT: The fruit is a black nutlet that has been crushed and terminated at the tip. Its dimensions are 2 mm wide by 2.5 mm long [12].

Vernacular Names [10] Table no 2

Phytochemical constituents [6]
Essential oils
Phenolic compounds
Flavonoids
Terpenoids
Alkaloids
Mineral elements
Sterols

Flavanoids

The phenyl-benzo-pyrone ring structure of flavonoids, which are phenolic chemicals distinguishes them from other synthetic and natural substances. The presense of flavonoids and their many derivatives, including chalcone, anthocyanidins, isoflavones, and flavones. The glycolate or ester form of flavonoids is produced via the shikimic acid route, which is derived from acetic acid and phenylalanine derivatives. According to studies, plants contain 2000 different kinds of flavonoids, which have a wide range of therapeutic benefits including antibacterial, anticancer, and anti-inflammatory qualities. Because of these benefits, flavonoids are better understood as a vital biochemical. Numerous processes, such as the stimulation of apoptosis, the activation of cell cycle arrest, the suppression of proteasomes and inhibiting the cancer enzymes.

Terpenoid

Terpenoids, as circulate air through subsidiaries of hydrocarbon auxiliary metabolites, contribute to the arrangement of basic oils famous for their fragrant properties. *H.suaveolens* basic oil contains terpenoid compounds. Monoterpenes and Sesquiterpenoids, which have antifungal and wide unearthly antibacterial action against microscopic organisms. Diterpenoids, such as suaveolic and suaveolol, have tall cytotoxic movement and are potent content of therapeutic plants. Inside *H. suaveolens*, a cluster of triterpene lactones and triterpenoid compounds, counting botulinic corrosive, ursolic corrosive, Beta-sitosterol, oleanic corrosive and acetyl oleanic corrosive, are shown, contributing to its pharmacological profile. Ursolic, a normal pentacyclic triterpenoid, is critical for treating incessant illnesses.

Phenolic compounds

A huge number of secondary metabolites are released by plants to withstand and adapt to its surroundings. These compounds, classified as hydroxy derivatives of cyclic aromatic compounds, belonging to the category of phenolic acids or polyphenols, have diverse biological activities in *H. suaveolens*. Many of the phenolics present as glycosides attached to sugar molecules with molecular weight ranging from 500 to 4000 Da. Strong antioxidant phenol functions to shield the organism from harmful free radicals.

Alkaloids

Alkaloids consist of heterocycle ring systems which have basic nitrogen atoms. Approximately 5500 alkaloids are being reported. Alkaloids are utilized for many diseases for efficient therapeutic uses because of their analgesic, anti-plasmodial and antimicrobial properties. Leafs are efficient in alkaloids content with medicinal uses and properties [6].

Mineral Elements

Calcium, potassium, phosphorus, nitrogen, magnesium, and sodium exist in varying concentrations throughout the plant[5].

Structures of Phytochemical Constituents [13]
Microscopy [18]

H.Suaveolens shows a remarkable pollination mechanism, and the plant is exemplified by the captivating phenomenon known as "carnial explosion," highlighting the plant's unique adaptation for reproduction. The self and cross pollination of these species takes place in both wind and insect mediated conditions. In these weed species the sexual reproduction process brings out the diversity. The exploration of *H.suaveolens* species is warranted to inspect the diversity within its population and the variability of dimorphic seeds, and used to examine their germination patterns.

Leaf Microscopy [19]

Both the adaxial and abaxial surfaces of the leaf have stomata. Diacytic stomata are made up of subsidiary cells that are located next to the guard cells. The trichomes are of Glandular trichomes and uniseriate multicellular covering trichome

Macroscopy [9] table no 3

Ecology [20]

It is a yearly herb and distributed commonly in the streets, bushy areas, densely plant occupied (vegetative) soils and soils containing adequate drained water reservoir. It is an usual plant at tropical and subtropical areas but, it can survive in the temperate regions also. Soil requirements – It doesn't require a particular soil composition to grow, but it shows its optimal full growth in sandy, loamy, or clay soils. The presence of it is prominent in the tropical dry deciduous forests of the Vindhyan highlands, which span across the North River Plain of India, situated between the Gangetic plains and the Narmada valley in northern India (21°29′ to 25°11′ N latitude and 78°15′ to 84°15′ E longitude), then in the Andaman & Nicobar Islands [5].

Reported Pharmacological Activities

Anti-oxidative activity [21]

Methanolic Extract's Antioxidant Activity

The extract of leaf with the solvent ethanol exhibits excellent antioxidant activity with an IC50 value of 40.91µg/ml and a minimum % inhibition of 45.30% at 25 µg/ml.

The highest % inhibition was found at 100 µg/ml, comparable with that of ascorbic acid at 82.05%.

A good correlation exists between the extract concentration and % inhibition, with r2 = 0.995.

Extract is abundant in flavonoids and phenols, which are considered potent antioxidants.

The herbal extracts play a vital role in avoiding calcium oxalate monohydrate papillary calculi formation for this antioxidant activity

Further studies are needed to confirm these in vitro results in vivo to develop a potent antioxidant from this plant.

Anti-cancerous activity [22]

H. suaveolens Essential Oil's Anti-Cancer Activity

Utilized MTT assay to measure cell viability of H. suaveolens essential oil.

Diluted oil to various concentrations for incubation.

Anti-bacterial activity [23]

70% ethanolic extract inhibited bacterial growth in *H. suaveoelens* and L. multiflora.

70% ethanolic extract of *H. suaveoelens* inhibited more strongly than E.I.

Anti-fungal activity [24]

Plant extracts show antifungal action towards aflatoxic fungi.

Active constituents of plant material seep out in carbon-based solvent.

Concerns over environmental and human health effects of chemical pesticides.

Tests of ethanomedically important plant species for antifungal activity.

Potential for biodegradable, safe plant products.

Further phytochemical studies to identify active constituents.

Anti-hyperglycemic activity [25]

The ethanol extract of leaves significantly reduced blood glucose levels in diabetic rats.

Serum triglyceride, total cholesterol, low density lipoprotein (LDL) and VLDL levels were higher in diabetic rats

The extract of *H. suavelons* exhibited notable efficacy in eliminating free radicals, indicating its potential as an antioxidant agent activity at 100 g/mL.

Anti-fertility activity [26]
The plant's extract showed significant anti-implantation activity in rats:
The highest rate of anti-implantation activity was 56.06% at 150mg/kg body weight.
The activity increased gradually from 50 to 150 mg/kg.

Anti-plasmodic activity [27]
Concentrations reduced by at least 50% parasite density Dd2 strain of P. falciparum in culture.
After 48 hours, extracts exhibit moderate anti- plasmodial activity
Anti-plasmodial activity is because of presence of flavonoids and/or coumarins identified during phytochemical screening.
Chuk wujekwu et al., 2005, found good anti-plasmodial activity with an IC50=2µg/mL.

Wound healing activity [28]
The therapeutic dose of 500mg/kg b.w. p.o. was observed as 1/10th of the lethal dose for wound healing investigation. The extract of petroleum ether showed indicative wound healing activity, complete epithelization, and a scar area. Histological studies showed an increase in collagen deposition, few macrophages, tissue edema, and more fibroblasts in the petroleum ether treated animal groups.

Anti-inflammatory activity [29]
Paw volume and % oedema inhibition calculated.
The carrageenan is administered to rats after two hours of observation and there observed no significant anti-inflammatory activity.
Two doses (250 and 500mg/kg) significantly suppressed oedema after 3 hours of carrageenan injection.
Minor dose (250 mg/kg) suppressed edema formation but not as significantly as 500 mg/kg extract.
Indomethacin group has shown significant inflammation inhibition from 3 hours post carrageenan injection.
Paw edema was dose-dependently inhibited by rat extracts.

Anti-viral activity [30]
The extract which are in aqueous showed higher nontoxic concentrations (500 µg/mL to 250 µg/mL) than ethanolic extracts.
Above 15.62 µg/mL, the plant ethanol extract was very hazardous.
Vitex negundo and Hyptis suaveolens inhibited Asian strain of chikungunya virus at 31.25 µg/mL.

ABSTRACT

Datura metel L., commonly known as "Devil's Trumpet" or "Thorn Apple," is a highly medicinal plant that is classified under the Solanaceae family. This plant has been traditionally used in various forms of ethnomedicinal practices, including Ayurvedic, Unani, and Chinese medicines, because of its vast medicinal properties. This particular species of Datura is known for its bright and beautiful trumpet-shaped flowers, fast growth rate, and complex bioactive chemical composition, which includes tropane alkaloids (such as atropine, hyoscyamine, and scopolamine), flavonoids, saponins, tannins, and glycosides. These particular compounds have been known to produce a wide variety of pharmacological actions, such as analgesic, anti-inflammatory, antiasthmatic, bronchodilator, neuroprotective, antimicrobial, and anticancer properties. Recent studies have emphasized its potential in modern pharmacology, which includes its use in pain management, central nervous system disorders, and the discovery of new bioactive compounds. However, *D. metel* is also known for its high level of toxicity, which, upon overdose, can cause anticholinergic poisoning, delirium, hallucinations, and even death, thereby emphasizing the importance of proper therapeutic use.From the ethnobotanical analysis, it has been revealed that various parts of the plant, namely leaves, seeds, roots, and flowers, are used for internal as well as external medicinal purposes, starting from the treatment of respiratory problems and skin infections to acting as analgesics and anaesthetics. Moreover, its use in agricultural and industrial purposes, such as the use of the plant as a bioinsecticide, reveals its diverse potential. This review will attempt to critically collate the traditional knowledge, phytochemical data, pharmacological data, and toxicological information available on *Datura metel*.

Keywords: *Datura metel,* Therapeutic benefits, Pharmacological effects, bioactive compounds.

INTRODUCTION

The crucial role of plants in the treatment of diseases is evidenced by their use in all the major medical systems, irrespective of their underlying philosophical beliefs. The use of individual pure compounds, including synthetic drugs, has its limitations, resulting in a major revival of interest in herbal and homeopathic medicines, which rely heavily on plants. Evidently, the plant kingdom still holds many species that have medicinally useful compounds yet to be discovered; many plants are being continuously screened for their potential pharmacological properties [1]. The World Health Organization (WHO) defines traditional medicine as health practices, methodologies, knowledge, and beliefs that use plant, animal, and mineral-based remedies, spiritual healing, manual practices, and exercises, alone or in combination, to treat, diagnose, prevent illness, or promote wellness [2].

As far as patients are concerned, despite the progress that has been made in conventional medicine, there has been an increasing interest in complementary medicine, particularly among those who have not derived benefit from conventional medicine, those who are concerned about the safety and toxicity of conventional medicines, and those who value the holistic approach [3]. According to the World Health Organization (WHO), approximately 80% of the world's population relies on herbal medicine for some aspects of primary health care. Herbal medicine is an integral component of all traditional systems of medicine and is also an important part of homeopathy, naturopathy, traditional Chinese medicine, and traditional Indian medicine.The governments of developing nations, realizing their inability to offer complete access to Western medications, have encouraged the rational development of traditional medicine. Today, the World Health Organization is officially interested in such efforts to fulfill its vision of ensuring that health care is accessible to all people [4]. It has been suggested that the improper use of traditional medicine or practices can result in negative and harmful effects, and further research is needed to assess the efficacy and safety of many practices and medicinal plants used in traditional healing practices. The growing interest in herbal medicine calls for an assessment of the toxicity risks involved in the various indigenous preparations used for the treatment of diseases [5]. The plant used for medicinal purposes that can be harmful to organs like the liver and kidneys is *Datura metel*.

The Datura genus includes several species. It is commonly known as Thorn apple and belongs to the Solanaceae family. It usually grows as a weed in abandoned agricultural land and dump sites, although it is sometimes cultivated. The plant's different parts (such as leaves, flowers, and seeds) are used for various purposes, mainly for their psychoactive properties, which is why it has traditionally been used as an intoxicant and hallucinogen [6]. The different parts of the *Datura metel* plant can be abused by some young people who are more prone to drug use and the risks associated with smoking and drug abuse. It is considered a toxic plant globally when ingested in large amounts. However, the Datura extract is a potent toxin, and improper use of the plant's parts can cause delirium and serious poisoning that can be life-threatening. Its chemical parts include flavonoids, alkaloids, essential oils, saponins, terpenoids, tannins, and phenolic compounds, among others. Many medicinal plants have some chemical parts that can cause toxic or harmful effects on humans when taken in large amounts. High amounts of alkaloids can make plants toxic, despite their medicinal uses [7].

It is one of the most important medicinal plants used worldwide because of its anti-inflammatory properties, and several studies have also shown the efficacy of the plant for its antibacterial and antioxidant properties. Recent advances in medicinal chemistry and knowledge of the biosynthetic pathways for developing lead compounds have opened new avenues in the domain of drug chemistry [8].

Taxonomic Classification [9]
Kingdom: Plantae
Division: Magnoliophyta
Subdivision: Angiospermae

Class: Magnoliopsida
Subclass: Asterids
Order: Solanales
Family: Solanaceae
Genus: Datura
Species: *Datura metel* (*Datura fastuosa*)

Vernacular Names [10]

Dhatura safed (*Datura metel* L.) is a member of the Solanaceae family, or nightshade family, which comprises approximately 2,400 species [4]. This species is well known for its fascinating hallucinatory properties, and although it has a reputation as one of the more malevolent hallucinatory agents, it has been used by various cultures in both the Old and New Worlds, and continues to be so to this day. Various studies have shown that the plant has been used in its various forms, whether fresh or sun-dried and powdered, for its hallucinatory properties in Southwestern Nigeria. The literature indicates that *Datura metel* is one of the most commonly abused indigenous plants globally. According to the United Nations Office on Drugs and Crime, in 2007, *Datura metel* contributed 0.4% to the use of various narcotic and psychotropic drugs in Nigeria, while cannabis accounted for the largest portion at 28% [6]. The full names of *Datura metel* are presented in Table 1.

Traditional Use

Datura is conventionally used for different purposes, including the treatment of epilepsy, hysteria, insanity, heart problems, and fever in relation to catarrh, diarrhea, and dermatitis. Crushed leaves are used for pain relief. In China, this plant is used for the treatment of asthma. In Vietnam, dried flowers and leaves are cut into small pieces and are used in anti-asthmatic cigarettes. About 3 to 5 grams of the flower extract can be given as an anesthetic orally, leading to general anesthesia in five minutes, which lasts for five to six hours. The flower of *D. metel* is also used for relieving pain, chronic bronchitis, and asthma [11]. In Bangladesh, leaves are used for the treatment of scabies, eczema, and allergies [12].The powdered form of the dried whole plant is smoked to relieve irregular or excessive respiration and is applied around the eyes to dilate the pupils. The application or oral intake of leaf juice helps to reduce pain and inflammation. A combination of leaf juice and a small amount of opium is applied externally to reduce swelling of the gums or at the base of the ears. Leaf juice mixed with lime and turmeric is applied to the breasts to relieve pain. For several centuries, the flowers of *Datura metel* have been used in traditional Bangladeshi medicine for the treatment of asthma, convulsions, pain, and rheumatism [13].The traditional use of *Datura metel* is provided in Table 2 [14].

Ethnobotanical Description of *Datura metel*

The genus Datura is usually characterized by annual or perennial herbs that have glandular or, more often, simple hairs [15]. The plant's leaves are petiolate, having a simple leaf blade that can be either sinuate or fully dentate. The leaves are approximately 10-20 cm long and 5-18 cm wide, with soft, short greyish hairs [16]. Solitary flowers are found in inflorescences that are in the axils of leaves or at the forks of branches. In general, the larger flowers are actinomorphic with thick pedicels. Bracts, peduncles, and bracteoles are absent [15]. Moreover, the corolla is funnel-shaped and elongated, having lobes that are cuspidate. In addition, there are elongated anthers that are longitudinally opened. The fruit, which is an unevenly dehiscent, four-valved dry capsule, does not have any armed parts and is usually bordered by the remains of the persistent calyx [15].The plants also have many seeds that are laterally compressed, containing a curved embryo, and usually have 12 pairs of chromosomes. There have been various species of Datura that have appeared in different parts of the world. *D. stramonium* is an annual herbaceous plant that is branched and magnificent, growing to an approximate height of 1 m [17]. The branches are leafy, stout, and erect, usually having a pale yellow or green tint, and usually having a forked appearance. The top side is greyish-green and dark, usually soft, while the bottom side looks lighter and has very small wrinkles when it is dry. The calyx is remarkably long, tubular, and enlarged. The seeds are dark, flat, and kidney-shaped. The fruits are walnut-like and have thorns, hence the name “thorn apple.” [17].

Botanical Description

Datura metel is classified as an annual herb, with a stem that is herbaceous, globous, and erect, smooth, and branched, with very few hairs and a pale yellowish-green color. The herb has large and simple leaves that are ovate in shape, with dentate margins and petioles, measuring 4-6 inches long, and also have very few hairs. The top part of the leaves is smooth and greyish-green, while the lower part is pale green and wrinkled [18]. The flower is about 3 inches long, with a long tubular calyx and a funnel-shaped corolla. It can be white or purple in color, has five stamens, and has a superior ovary.The fruit is large and prickly, with smooth, black, kidney-shaped seeds [19]. The plant grows to a height of 2-4 feet, with a diameter of 4-6 feet. It has remarkably large flowers, with corolla tube lengths of 6 cm. The leaves are long, with a length of 20 cm, and have coarsely serrated margins. The rootstock is stout, tapering, and branched. Under ideal conditions, it is estimated that each plant yields about 14,964 seeds [20]. The complete botanical description of *Datura metel* is provided in Table 3 [21].

Physicochemical Characteristics

Analysis of the physicochemical properties of dried seeds of *Datura fastuosa* revealed that the total ash content of the plant was 5.6% w/w, with a water-soluble ash of 4.5% w/w. The water-soluble extractive value was estimated to be 26.35 mg/g, with a foaming index of 18.18. The swelling index was estimated to be 2.6 ml/g, and the moisture content was determined to be 1.4 ml. In addition, the crude fiber content was estimated to be 17.5% w/w, with a loss on drying of 390 mg [22].

Chemical Constituents

Preliminary phytochemical screening of the dried seeds of *Datura fastuosa* using methanolic and hydroalcoholic extracts revealed the presence of alkaloids, tannins, cardiac glycosides, flavonoids, carbohydrates, amino acids, and phenolic compounds [22]. The proximate composition showed that the seeds of the plant contained fat (14.72%), carbohydrates (51.22%), protein (20.73%), moisture (4.63%), ash content (5.14%), total sugars (5.63%), reducing sugars (2.65%), crude Fiber (17.35%), and trace elements (mg/100gm): calcium 174.0, phosphorus 690.0, potassium 0.50, sodium 0.085, iron 16.8, zinc 2.63, copper 6.9, and magnesium 390.0. The total saturated fatty acids contributed 18.03%, whereas the total unsaturated fatty acids constituted 81.74%, of which mono-unsaturated fatty acids were 27.49% and poly-unsaturated fatty acids were 54.25%. The fatty acid composition consisted of palmitic acid (15.31%), stearic acid (2.72%), oleic acid (25.97%), linoleic acid (54.25%), and palmitoleic acid (1.52%) [23]. The essential oil of different parts of *Datura metel* was extracted by hydro distillation and analyzed by GC-MS. The main constituents of the flowers were ketone (23.61%) and ethyl palmitate (15.84%).For the leaves, the chief constituents were ketone (18.84%) and phytol (18.71%). For the petioles, ketone (39.45%) and phytol (31.32%) were the chief constituents. The seeds were mainly composed of palmitic acid (30.60%) and ethyl linoleate (21.56%). The root's main ingredient was palmitic acid (52.61%). Finally, the primary elements in the stems were palmitic acid (38.38%) and ethyl linoleate (17.38%) [24]. Tropane alkaloids are a group of over 200 compounds, mainly known for their occurrence in the family Solanaceae, which comprises more than 100 genera and about 3000 plant species. These alkaloids are characterized by a two-ring system consisting of a pyrrolidine ring and a piperidine ring that share a single nitrogen atom and two carbon atoms. The amino group, which is common to all alkaloids, is usually methylated in most cases. The chief natural tropane alkaloids are (-)-hyoscyamine and (-)-scopolamine, also known as hyoscine. It is worth noting that high concentrations of these alkaloids have been found, especially in the Datura species.Hyoscine [(-)-Scopolamine] is the major tropane alkaloid in *Datura fastuosa* (*Datura metel*) [25]. The plant was discovered to contain alkaloids such as hyoscyamine, hyoscine, and atropine. The total alkaloid in the leaf was mainly attributed to atropine. The seeds contained 0.426% hyoscyamine, while the flowers contained 0.43%. The scopolamine and atropine in the whole plant increased gradually as the plant grew, reaching a maximum at the end of the plant's reproductive life. The maximum scopolamine in the roots was accumulated after 16 weeks. The root was determined to be the plant part that generally accumulated the highest amounts of atropine. Compared to the roots, the aerial parts of the plant generally accumulated higher amounts of scopolamine and lower amounts of atropine [26]. The leaves and flowers of *Datura fastuosa* were found to produce many with anilides, which include withafastuosins A, B, C, and E; dmetelins A-D; baimantuoluoline A, B, and C; and withametelin [27,28,29]. Three new withanolide compounds, named

baimantuoluoline A, B, and C, as well as withafastuosin D, E, and F, and withametelin C, were isolated from different parts of the plant [30,31].

Chemical analysis of a methanol extract obtained from the flowers of *Datura metel* has resulted in the identification of 10 new withanolides, referred to as withametelins I-P. From the leaves of the plant, several compounds were isolated, including *Daturafolisides* A-I, (22R)-27-hydroxy-7α-methoxy-1-oxowitha-3,5,24-trienolide-27-O-β-d-glucopyranoside, daturataturin A, daturametelin J, daturataurin B, baimantuoluoside B, and 12-deoxywithastramonolide. In the methanolic extracts of the flowers[32,33], four compounds were identified: cis-2-nitro-4-t-butylcyclohexanone (36.54%), trifluoroacetic acid, 2,2-dimethylpropyl ester (31.97%), 4-trifluoroacetoxyoctane (19.28%), and 1-methyl-1,4-cyclohexadiene (12.22%)[34].Phytochemical analysis of the 50% ethanol extract from macroporous resin of the flower of the plant led to the isolation of yangjinhualine A and five megastigmane sesquiterpenes [35]. Isofraxidin, scopatone, daturadiol, 1,4-benzenediol, arenarine D, vanillin, N-trans-feruloyl-tyramine, scopoletin, G-sitosterol, and hyoscyamilactol were isolated from the seeds of *Datura metel*, which were from Xinjiang Province [36]. The total phenolic content (TPC) and total flavonoid content (TFC) were assessed. The maximum TPC was found in the methanolic extracts of the seeds (268.6 μg of gallic acid equivalence per mg of dry plant material), and the maximum TFC was found in the fruit pulp (8.84 μg of quercetin equivalence per mg of dry plant material) [37]. The chemical constituents reported from various parts of *Datura metel* were listed in table 4 [22-38]. The alkaloidal constituents were listed in table 5 [39, 40]. The minerals present in seeds, seed coat, and whole seed were listed in table 6 [41]. The phytoconstituents isolated from various parts of this plant were listed in table 7 [42-52]. The amino acid content reported in seed was listed in table 8 [53].

Pharmacological Activity of *Datura metel*

Datura is known for its analgesic, antioxidant, anticancer, and antimicrobial properties. Specifically, because of its potent analgesic properties, *D. metel* is an effective pain reliever. *D. stramonium* has antifungal properties against *Fusarium mangiferae* and *Fusarium oxysporum*, and the alkaloids in *D. stramonium* are potential drugs with anticholinergic actions [54]. The whole plant, specifically the anaesthetic action of the leaves and seeds, has hallucinogenic, anti-asthmatic, antispasmodic, anti-tussive, bronchodilator, pain-relieving, narcotic, hypnotic, and mydriatic properties. The leaves are used locally to treat rheumatic swelling of joints, lumbago, sciatica, neuralgia, painful tumors, scabies, eczema, allergies, and glandular inflammations such as mumps; they are also used externally for earaches and smoked to relieve spasmodic asthma. The seeds are also used externally to treat piles [55]. Seeds, leaves, and roots are used to treat insanity, fever with catarrh, diarrhea, skin diseases, and cerebral problems.

Arthritis Treatment

Gout is a disease that occurs due to uric acid excess in the body, forming small crystals of monosodium urate monohydrate, which accumulate in the body tissues, especially in joints [56]. The inhibitory action of xanthine oxidase was tested in *D. metel*, a plant widely used in traditional medicine for the treatment of gout [57]. More than 50% xanthine oxidase inhibitory action (*in-vitro*) was found in the methanolic extracts of *D. metel*, which was similar to the standard antigout drug allopurinol, which showed 93.21% inhibition at a concentration of 100 g/mL with an IC50 value of 6.75 g/mL. In addition, the methanolic extract was tested for its hypouricemic action *in-vivo* in mice against potassium oxonate-induced hyperuricemia and found to be effective [57]. Hyoscyamine and scopolamine are the two major anaesthetic, antispasmodic, and anticholinergic drugs that are of great commercial value and are the most important alkaloids produced in the roots, which are later transported to the aerial parts of the Datura plant [58].

Insecticidal Activity

Concentrations (2.5, 5.0, 7.5, and 10.0%) of methanolic extracts of *Datura metel* seeds were tested against *Helicoverpa armigera* (Hubner), also known as the cotton bollworm, which is a moth whose larvae are known to feed on a variety of plants, including many important agricultural crops. The 1.5% and 2.0% fractions of the methanolic extract showed a significant negative impact on various biological parameters like larval survival, weight, and average life, pupal duration, percentage of pupation, and adult emergence [59].

Herbicidal Activity

Aqueous and organic solvent extracts (methanol and n-hexane) at concentrations of 0, 5, 10, and 15% (w/v) from the shoots and roots of *Datura metel* L. (also known as *Datura alba* Nees.) were tested for their impact on *Phalaris minor*Retz., which is an important weed in wheat growth. The 15% methanol and 15% n-hexane root extracts significantly inhibited germination, while all concentrations of both aqueous and organic solvent extracts effectively reduced shoot and root growth, ultimately resulting in a significant reduction in biomass production [60].

Anticancer Activity and Antiproliferative Activity

Nitrogenous heterocyclic compounds that possess multiple hydroxyl groups function as competitive inhibitors of various glycosidases and have proved to be highly effective in the treatment of various diseases like diabetes, cancer, and viral infections. They also possess other activities, including immunomodulatory properties and the ability to inhibit glycolipid synthesis [61]. Withanolides were isolated from *D. metel*, which belong to the steroidal lactone group. Various compounds belonging to this group possess diverse biological properties, including anti-inflammatory, antioxidant, antitumor, and immunosuppressive properties. Withanolides possess the ability to inhibit the growth of tumor cells and the formation of blood vessels. They also possess the ability to induce the phase II enzyme quinone reductase [62]. Calystegines have been isolated from various species of the Solanaceae family and have been found to exist in various genera, including Datura [63]. Three withanolide glycosides, named daturametelins, and two other compounds, daturataturin and 7,27-dihydroxy-1-oxowitha 2,5,24-trienolide, were isolated from the methanolic extract of the aerial parts of *Datura metel* L. All the compounds were tested for their antiproliferative activity on the human colorectal carcinoma (HCT116) cell line. The non-glycosidic compound proved to be the most active among the tested withanolides, with an IC50 value of 3.2±0.2 M [64].

Antifungal Activity

Different polar and nonpolar solvent extracts of *D. metel* showed significant antifungal properties against various fungal species. The antifungal activity of the hexane, chloroform, acetone, and methanolic extracts of *Datura metel* L. was tested against pathogenic Aspergillus species. It was found that the chloroform fraction had antifungal activity. The minimum inhibitory concentration (MIC) of the chloroform fraction of *D. metel* L. was found to be 625.0 mg/ml for all three Aspergillus species (*A. fumigatus*, *A. flavus*, and *A. niger*) by microbroth dilution and spore germination inhibition assays [65]. The minimum inhibitory concentration (MIC) by the disc diffusion technique was 12.5 mg per disc. The methanolic extracts of *Datura metel* were tested against pathogenic Aspergilli, namely *A. flavus* and *A. niger*, with an *in-vitro* MIC of 1.25 to 2.50 mg/ml by microbroth dilution and spore germination inhibition assays [66].A new compound, 2-(3,4-dimethyl-2,5-dihydro-1-Hpyrrol-2-yl)-1-methylethyl pentanoate, was isolated from *Datura metel* L., and the *in-vitro* efficacy of the dihydropyrrole compound against Aspergillus and Candida species was evaluated. The compound was found to be effective against all tested species, which included *Candida albicans*, *C. tropicalis*, *A. fumigatus*, *A. flavus*, and *A. Niger* [67]. The post-antifungal effect (PAFE) of the antifungal compound 2-(3,4-dimethyl-2,5-dihydro-1-Hpyrrol-2-yl)-1-methylethyl pentanoate (DHP) on A. fumigatus was investigated, and the secretory protein that DHP inhibits was found; however, the mechanism by which DHP inhibits these proteins is not understood [68]. The aqueous and methanolic extracts of *Datura metel* were evaluated *in-vitro* for efficacy against *Ascochyta rabiei*, the causative agent of chickpea blight, and a decrease in the growth of *A. rabiei* of 21-34% was observed with aqueous extracts and 20-40% with methanol extracts from the shoots of *D. metel*. For the root extracts, reductions of 21-34%, 15-25%, and 11-29% were observed [69].

Antibacterial Activity

Crude aqueous and ethanol extracts of the leaves, stem bark, and roots of *D. metel* were evaluated for their activity against eight clinical bacterial strains (*Streptococcus betahemolytic*, *S. dysenteriae*, *Pseudomonas aeruginosa*, *Escherichia coli*, *Staphylococcus aureus*, *Klebsiella pneumoniae*, *Bacillus cereus*, and *Salmonella typhi*). The results revealed that the leaf and stem bark extracts had antagonistic properties against the bacterial species tested, with Staphylococcus aureus being the most inhibited, mainly by the ethanol extract [67].

Hypoglycaemic Activity

The seeds of *D. metel* were investigated for their use in lowering blood sugar and in the regulation of high blood sugar levels in normal Wistar albino rats and in diabetic rats. The seed powder of *D. metel* was prepared by grinding the seeds into a fine powder and mixing it with 1% sodium CMC. The powder was given to normal and diabetic rats, with blood glucose levels above 300 mg/dL (orally) at a dose of 25, 50, and 75 mg/kg body weight. Blood samples were taken at different times over a period of 24 hours, showing a dose-dependent decrease in blood sugar levels in the treated rats. Moreover, a dose-dependent antihyperglycemic response was observed in alloxan-induced diabetic rats. The seed powder of *D. metel* showed the potential to decrease blood glucose levels in normoglycemic as well as alloxan-induced hyperglycemic rats. Thus, the use of *D. metel* seeds in the treatment of diabetes could be justified by this study, showing that the seeds have the potential to be developed into effective herbal medicine for diabetes [68].

Free radical scavenging activity

D. metel seeds were analyzed for their fatty acids and lipid-soluble bioactive compounds. The total lipid content in *D. metel* seeds was found to be 55g/kg, with linoleic acid being the major component, followed by oleic, palmitic, and stearic acids. The crude n-hexane extract was found to have a relatively high concentration of phytosterols, which included stigmasterol, β-sitosterol, lanosterol, 5-avenasterol, and sitostanol. Among these, γ-tocopherol was the major component, accounting for over 80% of the total tocopherols present. The n-hexane extract of *D. metel* seeds was found to have the ability to quench only 40% of the DPPH radical. *D. metel* seeds have a substantial oil content and can be a rich source of essential fatty acids and lipid-soluble bioactive compounds. The presence of tocopherols and sterols may have significant medicinal values for humans [69].

Antioxidant Activity

The aqueous extracts of the leaves, stem bark, and roots of *D. metel* showed both phytochemical and antioxidant activities. The aqueous extract of the plant showed antioxidant activity ranging from 49.30% to 23.82%, indicating that it can be used as a natural source of antioxidants [70].

Antitumor Activity

The endophytic fungus was extracted from jimson weed, and the MTT assay was conducted on the human gastric tumor cell line BGC-823 to test the antitumor activity, showing 100% inhibition of growth. The lectin agglutin (DSA) derived from *Datura metel* caused irreversible differentiation in C6 glioma cells. Moreover, DSA also inhibited the growth of four human glial tumor cells [71].

Vibriocidal Activity

The extracts of various parts of six medicinal plants, both organic and aqueous, were tested for their efficacy in combating the Vibrio cholera strain for the treatment of cholera and gastrointestinal ailments. The results showed that like other medicinal plants, *D. metel* also has the potential to act as a broad-spectrum vibriocidal agent [72].

Antispasmodic and spasmogenic activities

The effect of the leaf and root extracts of the plant, as well as scopolamine and acetylcholine, was studied on isolated smooth muscle preparations. The leaf extract and scopolamine showed antispasmodic activity, while the root extract and acetylcholine caused contraction of the isolated uterine and rectal smooth muscles of rats. These results indicate that the plant contains antispasmodic and spasmogenic substances [73].

Antimycotic activity

The study has shown that the chloroform fraction of *Datura metel* has antifungal activity against the three species of Aspergillus: *A. fumigatus*, *A. flavus*, and *A. niger*. However, the cytotoxicity of the chloroform fraction is less than that of amphotericin B [74].

Sedation / Decreased Appetite

A research study on the analgesic effects of seed extract produced very limited findings. The results showed a sedative effect and decrease in appetite after the administration of the seed extract, which was attributed to its mechanism of action on u-type receptors in the central nervous system, wherein the activation of said receptors possesses an intrinsic ability to reduce distress or the effective component of pain without affecting the intensity of the actual pain. Moreover, another study showed that the 25 g/kg dose of methanolic crude extract induced behavioural sleep patterns (as evidenced by EEG) in rats that were similar to those induced by thiopental [75].

Anti-stress activity

Withanolides from *D. fastuosa* possess properties that exhibit anti-stress effects. In combination with diazepam, it exhibited anxiolytic activity and protected against the depletion of adrenal cortisone induced by immobilization stress. Adrenal cortisone helps the body cope with difficult stimuli; however, such responses can cause stress-related disorders. A thorough study of various doses, times, and routes of administration is required to establish its effectiveness as an anti-stress agent [76].

Anti-depressant Effects

The neuropsychopharmacological effects of aqueous extracts of the leaves and seeds of *Datura fastuosa* were investigated using rats and mice. The aqueous extracts of the leaves and seeds, given in doses of 400 and 800 mg/kg, increased motor activity, slightly reduced the duration of barbiturate sleep, reversed catalepsy and ptosis induced by haloperidol, and decreased immobility in forced swimming tests. The results also showed that *Datura fastuosa* has some anti-depressant properties at lower doses [77].

Antifertility activity

Studies were conducted to examine the crude acetone extracts of the seeds of *Datura metel* in female albino mice. The 2% seeds extract showed anti-implantation properties, suggesting that it has great potential as an anti-fertility agent with minimal side effects after testing on human subjects [78].

Neuro-Toxicological Effects

Leaf consumption has been associated with adverse behavioral effects. This study evaluated the immediate neuro-toxicological effects of aqueous methanol extracts of *D. metel* leaves on general movement, motor coordination, and spatial memory in mice using a Y-maze [86]. The leaf extract caused neuro-toxicological effects on the mice, which were manifested by sedation, decreased movement, disrupted motor coordination, and short-term memory loss. The LD50 was determined to be above 2000 mg/kg of body weight [78].

Reproductive effects

The antifertility activity of acetone extract of *Datura metel* was studied in female albino mice. The female mice were administered with the crude acetone extract of *Datura metel* seeds at a concentration of 0.5%, 1%, and 2% orally. After 15 days of treatment, the female mice were mated with normal male mice. After 10 days of coitus, the mice were dissected to determine the number of implantation sites in the uterine horns. The results showed that the 2% seed extract had 100% anti-implantation activity, and the 1% and 0.5% seed extracts had 40% and 80% anti-implantation activity, respectively. The authors concluded that the seed extract of *Datura metel* could be considered a valuable source of antifertility agents with minimal side effects [79].The effect of the alcoholic extract of *Datura fastuosa* (2, 4, and 6 mg/kg for 7 weeks) on the fertility of male rats was investigated. The results showed that the extract significantly reduced the number of sperm and normal sperm in all doses compared to the control group. Moreover, there was a significant decrease in the serum levels of testosterone, LH, and FSH, as well as the weights of the testes and epididymis in the treated groups. The rate of occurrence of pregnancies was also significantly lower [80].

Neurological effects

The neuropsychopharmacological activities of the aqueous extracts of the leaves and seeds of *Datura metel* were studied in rats and mice. The aqueous extracts of the leaves and seeds of *Datura metel*, given to rats and mice in doses

of 400 and 800 mg/kg, showed increased motor activity, slightly reduced the duration of barbiturate sleep, reversed catalepsy and ptosis induced by haloperidol, and reduced immobility in forced swimming [81]. The results also showed that *Datura metel* has some antidepressant effects at lower doses [82]. The possible oral anesthetic activity of the methanolic crude extract of *Datura metel* was studied in dogs. The extract was administered orally to dogs at doses of 0.6, 1.2, 1.5, 2, and 2.4 g/kg, respectively, while establishing the appropriate pilot oral anaesthetic doses, showing a dose-dependent effect. At an oral dose of 2.4 g/kg, the extract produced surgical anaesthesia in the dogs, with increased heart and respiratory rates (107 to 205 bpm and 36.33 to 41.33 cpm, respectively), normal rectal temperature (37.83°C), adequate tissue perfusion, good muscle relaxation, but inadequate analgesia. The dogs recovered without any ill effects.The results showed that the seed extract of *Datura metel* was safe, induced sleep similar to that induced by thiopentone sodium anesthesia, and had favorable indices of anesthesia [83]. The impact of the ethanolic seed extract of *Datura metel* on Nissl bodies, astrocytes, and the integrity of neurons and axons in the medial prefrontal cortex (mPFC) of rats was investigated. The extract was given to the rats at a dose of 100 and 200 mg/kg body weight for a period of 14 days. The results showed that *Datura metel* was harmful to Wistar rats in a dose-dependent manner, as shown by its effect on the medial prefrontal cortex at both 100 mg/kg and 200 mg/kg body weight. Histological examination of the treated Wistar rats showed evidence of neuronal integrity disruption, including chromatolysis, reduced protein synthesis as a result of the absence of Nissl bodies and nuclei, neuronal loss, and axonal damage [84].

CONCLUSION

In the traditional systems of medicine, such as Ayurveda and traditional Chinese Medicine, the use of *Datura metel*, a highly medicinal but potentially toxic herb, is significant. The plant shows pronounced pharmacological properties, such as anticholinergic, antispasmodic, bronchodilator, analgesic, and sedative properties. It is known to be rich in highly potent tropane alkaloids, including atropine, scopolamine, and hyoscyamine. Its traditional use in the management of skin disorders, inflammation, pain, asthma, and various neurological disorders is justified because of these properties. But there are severe toxicity risks associated with the medicinal potential of *Datura metel*. The potent bioactive compounds present in every part of the plant can cause severe poisoning if misused, leading to severe symptoms like delirium, tachycardia, hallucinations, and even death. Therefore, proper dosage and processing are required for its medicinal use. Some of the traditional uses are still valid due to the current emphasis of pharmacological research on safety, uniformity, and regulation. It could have further clinical applications if future research focuses on determining the safe dosage levels, preparing standardized formulations, and isolating some of the active principles. Ultimately, *Datura metel* is a very good example of how a plant can be both a valuable medicine and a toxic poison, underlining the importance of safe and informed use.

ACKNOWLEDGEMENT

The authors are thankful to the Department of Pharmaceutical Technology, Brainware Universityfor providing us withthe required facilities for carrying out this review.

Conflicts of Interest

The authors declare that they don’t have any conflicts of interest.

Table1: Vernacular names of *Datura metel*

Arabic	Joz mashel, joz mathel
Bengali	Dhutura, Dhatura
Chinese	yang jin hua
English	downy thorn-apple, Hindu datura, Hindu thorn-apple, hoary thorn-apple, horn-of plenty, metel, purple thorn-apple
Hindi	sada dhatura
Gujrati	Dhanturo, Dhaturo
Kannada	Umbem Madhunika
Korean	Huindogmalpul

Punjabi	Dattura, Tattur
Portuguese	Burbiaca
Spanish	burladora
Swedish	Indisk spikklubba
Unani	Dhatura
Persian	Tatura Siddha
Tamil	Oomatthai, Karuvoomatthi
Sanskrit	Dhustura

Table 2: Traditional use of *Datura metel*

Traditional Use	Plant Part Used	Region	Reference
Asthma and bronchial conditions	Seeds (soaked), leaves/flowers	Folk use in India; China & Vietnam in herbology	[14]
Pain relief (headache, backache, joint pain)	Leaves, roots, leaf paste, seed chewing	Rural Indian traditional remedies	[14]
Dandruff / alopecia	Leaves, leaf juice	Andhra Pradesh; West Bengal (India)	[14]
Stomachache / digestive discomfort	Warm leaves on abdomen	India (Jharkhand)	[14]
Skin diseases and inflammation	Flowers, seeds, foliage	Traditional Chinese medicine & Indian folk use	[14]
Diarrhea	Seeds, foliage, roots	South Asian traditional use	[14]
Insanity / madness / hysteria / epilepsy	Seeds, foliage, roots	Traditional South Asian use	[14]
Fever with catarrh	Seeds, foliage, roots	Traditional Chinese medicine (historical)	[14]
Mouth sanitation / oral hygiene	Foliage, roots	Folk medicinal use	[14]
Rheumatic swellings, tumour-like pain	Extracts (various parts)	Rural Indian traditional remedies	[14]
Bronchodilator / antispasmodic	Root powder	Rural Indian traditional remedies	[14]

Table 3: Botanical description of *Datura metel*

Plant part	Botanical description	Reference
Root	Cylindrical, brown, rough and splintered, featuring lateral branches.	[21]
Stem	Cylindrical, branched in a dichotomous manner, ranging from blackish purple to dark purple, with very short internodes.	[21]
Leaf	Arranged alternately, with a pointed edge, and a dark green hue.	[21]
Flowers	Shaped like bells or trumpets.	[21]
Fruit	A round, soft-spined capsule containing light-brown seeds.	[21]
Seed	Flattened, with a foveate surface that is finely pitted and resembles the colour of chili pepper seeds.	[21]

Table 4: Chemical constituentof *Datura metel*

Category	Plant Part / Extract	Key Findings	Reference
Preliminary Phytochemical Screening	Dried seeds (methanolic & hydroalcoholic extracts)	Presence of alkaloids, tannins, cardiac glycosides, flavonoids, carbohydrates, amino acids, and phenolic compounds	[22]
Proximate Composition (%)	Seeds	Fat (14.72), carbohydrates (51.22), protein (20.73), moisture (4.63), ash (5.14), total sugars (5.63), reducing sugars (2.65), crude fiber (17.35)	[23]
Mineral Content (mg/100 g)	Seeds	Ca (174.0), P (690.0), K (0.50), Na (0.085), Fe (16.8), Zn (2.63), Cu (6.9), Mg (390.0)	[23]
Fatty Acid Composition (%)	Seeds	Saturated fatty acids (18.03), unsaturated fatty acids (81.74), MUFA (27.49), PUFA (54.25)	[23]
Major Fatty Acids (%)	Seeds	Palmitic acid (15.31), stearic acid (2.72), oleic acid (25.97), linoleic acid (54.25), palmitoleic acid (1.52)	[23]
Essential Oil Composition (GC–MS)	Flowers	Ketone (23.61), ethyl palmitate (15.84)	[24]
	Leaves	Ketone (18.84), phytol (18.71)	[24]
	Petioles	Ketone (39.45), phytol (31.32)	[24]
	Seeds	Palmitic acid (30.60), ethyl linoleate (21.56)	[24]
	Roots	Palmitic acid (52.61)	[24]
	Stems	Palmitic acid (38.38), ethyl linoleate (17.38)	[24]
Tropane Alkaloids (General)	Whole plant	Presence of hyoscyamine, scopolamine (hyoscine), and atropine; hyoscine identified as predominant alkaloid	[25]
Alkaloid Distribution (%)	Seeds	Hyoscyamine (0.426)	[26]
	Flowers	Hyoscyamine (0.43)	[26]
	Leaves	Total alkaloids mainly attributed to atropine	[26]
	Roots	Highest accumulation of atropine; peak scopolamine after 16 weeks	[26]
Withanolides & Anilides	Leaves & flowers	Withafastuosins A, B, C, E; dmetelins A–D; baimantuoluoline A–C; withametelin	[27–29]
Novel Withanolides	Various plant parts	Baimantuoluoline A–C; withafastuosin D–F; withametelin C	[30,31]
Methanolic Flower Extract	Flowers	Withametelins I–P (10 new withanolides)	[32,33]
Additional Leaf Constituents	Leaves	Daturafolisides A–I, daturataturin A, daturametelin J, daturataurin B, baimantuoluoside B, 12-deoxywithastramonolide	[34,35]
GC–MS (Methanolic Extract)	Flowers	cis-2-nitro-4-t-butylcyclohexanone (36.54), trifluoroacetic acid ester (31.97), 4-trifluoroacetoxyoctane (19.28), 1-methyl-1,4-cyclohexadiene (12.22)	[36]
Ethanolic Extract (50%)	Flowers	Yangjinhualine A and five megastigmane sesquiterpenes	[37]
Seed Phytoconstituents	Seeds (Xinjiang origin)	Isofraxidin, scopatone, daturadiol, arenarine D, vanillin, scopoletin, β-sitosterol, hyoscyamilactol	[38]

Total Phenolic Content (TPC)	Seeds (methanolic extract)	268.6 µg gallic acid equivalent/mg dry weight	[37]
Total Flavonoid Content (TFC)	Fruit pulp	8.84 µg quercetin equivalent/mg dry weight	[37]

ABSTRACT

This paper presents the design and implementation of a secure IoT–RFID attendance monitoring framework for smart colleges. The study addresses the persistent limitations of conventional attendance practices, including time consumption during class hours, manual recording errors, lack of real-time visibility, weak auditability, and difficulties in managing attendance data across multiple classrooms and departments. To overcome these challenges, the proposed framework integrates RFID-based student identification with an ESP32-enabled edge device and a cloud backend supported through Firebase or AWS services. In the proposed workflow, each student attendance event is captured through RFID card scanning, validated at the edge, mapped to the active timetable-based session, and transmitted securely to the cloud for centralized storage and reporting. The framework incorporates key security and reliability features such as device authentication, encrypted communication, server-side validation, duplicate scan prevention, and offline buffering to ensure continuity during temporary network failures. In addition to real-time attendance capture, the system supports dashboard-based monitoring, automated report generation, and analytics for identifying absenteeism patterns and attendance shortages. Experimental observations indicate that the framework achieves fast RFID read performance, near real-time cloud synchronization, high read and write success rates, effective duplicate control, and strong recovery of buffered records after connectivity restoration. The proposed framework offers a practical, scalable, and cost-effective solution for smart college campuses by improving operational efficiency, strengthening data integrity, and enabling transparent, data-driven academic attendance management.

Keywords: IoT, RFID, Attendance Monitoring, ESP32, Smart Colleges, Cloud Synchronization, Secure Communication, Smart Campus.

INTRODUCTION

Attendance is one of the most routine yet operationally important processes in colleges. It is used not only to meet regulatory and institutional requirements, but also to monitor student engagement, identify learning gaps early, and support academic decision-making such as internal assessment eligibility, mentoring, and parent communication. Despite its importance, the way attendance is recorded in many colleges still relies on procedures that were designed for smaller class sizes and limited administrative complexity [1]. Manual roll calls and paper registers consume valuable instructional minutes in every session, create opportunities for human error, and make it difficult to compile accurate department-wise or semester-wise summaries. Even when spreadsheets are used, the workflow often remains partly manual—data is entered later, checked repeatedly, and shared across staff through fragmented channels—resulting in delays and inconsistencies[2].

As colleges adopt smart campus initiatives, there is a growing need for attendance systems that can operate in real time, support multiple classrooms simultaneously, and provide transparent records that are easy to audit. Conventional biometric devices can automate attendance, but they may introduce challenges in terms of maintenance cost, hygiene concerns, queue formation at peak times, and occasional failures due to poor sensor readings [3]. In contrast, Radio Frequency Identification (RFID) provides a contactless and fast method for identifying students using low-cost cards or tags. A single RFID tap can capture an identifier in less than a second, allowing large groups of students to be processed efficiently. However, an RFID reader operating as a standalone device still leaves gaps: records may remain on the local machine, reporting may require manual extraction, and the system may not easily scale across departments or buildings.

The Internet of Things (IoT) enables RFID attendance to move from isolated capture to connected, centralized management. By integrating the RFID reader with an IoT-capable microcontroller such as the ESP32, attendance data can be processed at the edge and transmitted to a cloud platform immediately. This transforms attendance into a live institutional service: faculty and administrators can view class-wise updates as they happen, generate reports automatically, and analyze patterns across semesters without waiting for manual consolidation. Cloud backends such as Firebase and AWS further add capabilities like secure authentication, structured storage, server-side validation, and integration with dashboards or mobile applications [4]. For example, Firebase can rapidly enable real-time data updates and web dashboards, while AWS can support large-scale deployments with strong observability and enterprise controls.

Even with automation, an effective college attendance system must address practical challenges that occur in daily operations. Proxy attendance remains a key concern when identity verification relies only on a card, since cards can be shared. Network unreliability is another common issue, especially in campus buildings where Wi-Fi coverage varies; if a system fails during a session, attendance marking becomes inconsistent and trust in the tool reduces. Duplicate entries can also occur when students tap repeatedly or when multiple scans happen in quick succession. Therefore, a robust design must include enrollment validation, session-aware rules, duplicate prevention within a defined time window, and offline buffering so that attendance events are not lost during connectivity interruptions. In addition, because attendance data is sensitive and linked to student identity, security and privacy protections—such as secure communication, device authentication, and role-based access—are essential to prevent unauthorized access and tampering [5].

This paper focuses on developing an advanced attendance tracking system tailored to a college environment using RFID and IoT, with an ESP32-based edge node and a cloud backend (Firebase or AWS). The proposed approach supports contactless attendance capture, timestamped event logging, cloud synchronization, offline recovery, and dashboard-driven monitoring. The aim is to deliver a practical and scalable framework that colleges can deploy across classrooms and departments while maintaining reliable records and enabling data-driven oversight. The remainder of the paper explains the system architecture and workflow, details the hardware and software

implementation, discusses security and operational considerations, and presents evaluation metrics that can be used to assess performance in real campus scenarios.

Related Work

Recent smart campus literature provides the broader institutional context for digitizing attendance and other administrative services. A systematic review by Al Akbar et al. consolidates design-oriented guidance for smart campus solutions and emphasizes that campus systems are typically built by integrating multiple technologies and services rather than deploying a single tool [6]. Complementing this, Min-Allah and Alrashed describe a smart campus as a practical roadmap that blends digital services with campus infrastructure and highlights the need for coherent planning across initiatives, where attendance can be treated as an operational "building block" within a larger campus ecosystem [7]. Polin et al. further strengthen this perspective by proposing a conceptual framing for smart campuses and arguing that effective implementations depend on well-structured governance, data-driven oversight, and integrated service delivery—areas where real-time attendance monitoring and analytics directly contribute [8].

From an implementation perspective, secure connectivity and device trust are foundational for IoT-based campus systems. The National Institute of Standards and Technology core baseline for IoT device cybersecurity outlines minimum capabilities such as unique device identification, secure configuration, data protection, interface access control, secure update mechanisms, and cybersecurity state awareness [9]. Building on that baseline, NIST's guidance on establishing IoT device cybersecurity requirements stresses that security requirements must be derived from system risk and operational context, and that gaps in device capabilities should be addressed through architecture choices and compensating controls [10]. These principles align with attendance deployments in colleges, where device authorization, secure transmission, audit logs, and role-based access are essential to preserve integrity and confidentiality of attendance data.

At the edge-device layer, practical embedded security support is required to realize these controls. The Espressif Systems ESP-IDF documentation for ESP-TLS describes how ESP32-class devices can establish TLS-protected channels and manage certificates and session parameters, enabling secure communication between the attendance node and cloud endpoints [11]. In our attendance setting, such transport security supports reliable delivery of event records to cloud platforms such as Firebase or Amazon Web Services while reducing exposure to interception and tampering.

Finally, prior work on biometric attendance motivates the choice of contactless identification in high-traffic institutional contexts. Okereafor et al. discuss hygiene and infection-transmission concerns associated with shared touch-based fingerprint systems, especially when many users repeatedly contact the same scanner surface [12]. This supports the practical rationale for RFID-based attendance in colleges, where contactless taps can reduce physical contact points and often improve flow by minimizing queues and repeated device handling, while still enabling centralized audit trails through IoT integration.

Motivation

The motivation for developing an IoT and RFID-based attendance system for colleges arises from both academic administration requirements and practical classroom constraints. Faculty members are expected to maximize teaching time, so a contactless tap-based RFID mechanism can reduce administrative workload and minimize classroom disruption. At the institutional level, colleges are increasingly adopting smart campus initiatives such as LMS/ERP platforms, digital communication systems, and IoT infrastructure, making attendance modernization a natural and necessary step. Administrators also require centralized, real-time visibility of attendance levels across departments to identify absenteeism patterns early and take corrective actions. Automated reporting and analytics further strengthen the case by enabling instant daily and monthly summaries, attendance percentage computation, and shortage lists, while also supporting deeper insights such as chronic absentee detection, late arrival patterns, and subject-wise trends. Integrity and accountability are improved when attendance is captured as event-based digital

records containing timestamps, device identity, and session details, which provides stronger audit trails than paper-based methods and helps resolve disputes more reliably. From a feasibility perspective, RFID cards are low-cost and durable, and ESP32 devices offer affordable Wi-Fi-enabled edge processing, allowing practical scaling across multiple classrooms. Finally, real college environments frequently experience network fluctuations, so an IoT design that supports offline buffering and delayed synchronization ensures continuity of attendance recording even during temporary Wi-Fi failures. With appropriate security safeguards such as secure communication, device authentication, and role-based access control, the system can modernize attendance management while protecting sensitive student data and supporting trustworthy, institution-wide digitization.

Problem Statement

Colleges depend on accurate attendance records for academic monitoring, internal assessment eligibility, mentoring, and compliance with institutional policies, yet the attendance process in many institutions remains inefficient and difficult to manage at scale. Conventional practices such as manual roll calls, paper registers, and partially automated recording consume valuable instructional time and often introduce human errors, including missed entries, incorrect totals, and inconsistencies during later digitization. These approaches also provide weak verification, enabling proxy attendance through answering for others or signing on behalf of friends, which reduces the credibility of attendance data. In addition, attendance consolidation is typically performed at the end of the day, week, or month, requiring repetitive checking and manual compilation across multiple subjects and departments. When disputes arise, the absence of event-level logs makes it hard to verify exactly when and how attendance was marked, limiting transparency and auditability. Administrators and HODs also lack real-time visibility into class-wise or department-wise attendance trends during sessions, making timely intervention difficult. Furthermore, large-scale college deployment introduces operational challenges such as high student throughput, back-to-back lecture hours, multiple classrooms, network instability, and the need for reliable multi-device coordination. Attendance data is also sensitive, and weak access controls or unsecured transmission and storage can lead to tampering, unauthorized viewing, and privacy risks. Therefore, the core problem addressed in this paper is the lack of a fast, scalable, and secure attendance solution that can provide real-time cloud-based monitoring and reliable audit trails for college environments while minimizing manual workload and reducing fraudulent practices.

Proposed System Architecture

The proposed architecture is designed specifically for a college attendance environment where multiple classrooms, departments, and schedules must be supported with minimal manual effort and maximum reliability. The system combines RFID-based identification, ESP32-based edge processing, and cloud-backed storage and analytics using Firebase or AWS. The architecture is modular so the same design can scale from a single classroom to a full campus deployment.

The system is organized into five layers:

1. User & Identification Layer (RFID)
2. Edge Device Layer (ESP32 Attendance Node)
3. Network/Communication Layer (Wi-Fi + Secure APIs)
4. Cloud Services Layer (Firebase / AWS)
5. Application & Analytics Layer (Dashboard + Reports)

Each layer has a clear responsibility, ensuring scalability and maintainability.

Fig. 1 illustrates an end-to-end college attendance architecture that combines RFID identification, ESP32-based edge processing, and a cloud backend (Firebase or AWS) to deliver real-time attendance capture, reporting, and analytics. At the far left, the process begins with the Student RFID Card, which contains a unique identifier (UID) embedded in the tag. When a student taps or scans the card near the RFID Reader (MFRC522), the reader detects the UID using radio-frequency communication. The MFRC522 then forwards the captured UID to the ESP32 Attendance Node through a short-range hardware interface such as SPI/UART, as indicated by the connecting arrow.

The ESP32 Attendance Node is shown as the central "edge layer," where the core logic runs locally before any data is sent to the internet. Inside this block, the workflow is depicted as a sequence of processing stages:

1. Read UID – the ESP32 receives the raw UID from the RFID reader.
2. Validate UID – the UID is checked against enrolled/registered records (either cached locally or verified through cloud rules). This step ensures only authorized student tags are accepted.
3. Get active class/session – the system determines which lecture hour or timetable session is currently running (e.g., Hour 1 to Hour 6). This is critical in college environments, because attendance must be linked to the correct subject, staff member, classroom, and time slot.
4. Duplicate check (e.g., 5 min) – to avoid repeated marking (accidental multiple taps or misuse), the node applies a time-window rule. If the same UID is scanned again within the configured duration, it can be flagged as a duplicate or ignored, ensuring clean attendance data.

After successful validation and session mapping, the ESP32 creates a proper attendance record through the lower-stage actions shown in the diagram:

- Timestamp event – the system attaches the precise time of attendance marking so the record is verifiable and auditable.
- Offline buffer – the architecture includes resilience for real-world campus Wi-Fi conditions. If the network is unstable or temporarily unavailable, attendance events are stored locally so they can be uploaded later without losing data.
- Device ID/token – each attendance node identifies itself using a unique device identity or token. This provides traceability (which classroom device recorded the event) and supports security checks at the cloud layer.

For user interaction inside the classroom, the diagram includes a Local Feedback block (buzzer/LED/OLED/LCD optional). This component provides immediate confirmation to students and faculty—such as a beep or a "Marked Present" message—so the system remains usable even when students cannot see the dashboard. The arrow linking local feedback to the ESP32 indicates that the edge device controls these indicators based on success/failure outcomes (valid scan, duplicate, unknown UID, etc.).

Once the event is prepared at the edge, the ESP32 transmits it to the cloud via Wi-Fi + TLS/HTTPS, passing through the Network/Internet block. The explicit mention of TLS/HTTPS highlights that the communication is intended to be encrypted, protecting attendance data in transit and reducing the risk of interception or tampering.

On the right side, the diagram shows the Cloud Backend, which can be implemented using either Firebase or AWS, depending on institutional preference:

- In the Firebase option, the system typically uses:
  - Authentication for role-based access (admin, HOD, faculty, etc.),
  - Firestore/Realtime Database to store attendance events and session records,
  - Cloud Functions to run automated backend logic, such as duplicate enforcement, report generation, or triggering alerts.
- In the AWS option, the system can use:
  - IoT Core (MQTT) for secure device messaging and scalable ingestion,
  - API Gateway to expose controlled endpoints,
  - Lambda for server-side processing and validation,
  - DynamoDB/RDS for structured storage and queryable attendance history.

Both cloud paths serve the same purpose: centrally store attendance records, apply server-side validation policies, and make data available to applications in real time.

Below the cloud backend, the diagram shows the Application Layer, where attendance data becomes actionable for stakeholders. The main component is a Web Admin Dashboard that supports:

- Live attendance monitoring during class hours,
- Class/Department-level reports for staff and administrators,
- Export capabilities (PDF/CSV) for documentation and compliance.

The diagram also includes optional views for Faculty and Students, indicating that the same backend can support multiple interfaces. Faculty views commonly focus on session-wise summaries and student lists, while student views typically provide personal attendance percentages and subject-wise tracking.

Finally, the architecture concludes with Analytics & Alerts, which represent value-added services built on top of the stored attendance data. Examples shown include:

- Shortage list generation (students below required attendance thresholds),
- Absentee trends analysis (pattern identification over weeks/months),
- Optional communication features such as SMS/Email/WhatsApp alerts, which can notify students, mentors, or parents when attendance falls below a policy limit.

Functional Architecture Components (Modules)

To ensure the proposed IoT–RFID attendance system is practical to implement and easy to scale across multiple classrooms, the architecture is organized into functional modules. Each module has a well-defined role and communicates through structured data objects such as student profiles, session identifiers, and attendance event records. This modular separation simplifies development, testing, and future upgrades without affecting the entire system.

⇒ **Enrollment Module**

The enrollment module maintains the association between a student's RFID UID and the corresponding student profile. During registration, the UID is captured from the RFID card and linked to key student attributes such as student ID, roll number, department, year, section, and status (active/inactive). This module supports lookups during scanning and prevents unregistered or invalid tags from being accepted. It also enables administrative actions such as card replacement, UID updates, and deactivation of lost cards while preserving audit trails.

⇒ **Session Management Module**

The session management module controls how attendance is tied to the correct academic context. In a college environment, an attendance record must correspond to a particular timetable slot (Hour 1 to Hour 6), course, staff member, classroom, and date. This module therefore generates or retrieves the active session based on the timetable and current time window. It supports session states such as scheduled, active, and closed, ensuring that attendance is accepted only within the appropriate lecture period. This module also allows handling special cases such as extra classes, swapped hours, cancellations, or lab double periods.

⇒ **Attendance Capture Module**

This module performs real-time processing on each RFID scan. When the UID is received from the reader, the module validates the UID through the enrollment mapping, attaches timestamps, identifies the active session, and forms a structured attendance event. Immediate feedback (buzzer/LED/display) can be triggered from this module to inform the student and faculty whether the scan is successful or rejected. The module ensures that every accepted attendance action is consistently represented before it is transferred to the cloud backend.

⇒ **Duplicate Prevention Module**

To maintain data quality and avoid repeated entries, the duplicate prevention module enforces a configurable time-window rule for each session. If the same UID is scanned multiple times within a short interval (e.g., 3–5 minutes) during the same session, the module either rejects the scan or marks it as duplicate for audit purposes. This prevents accidental double scans as well as intentional attempts to manipulate records. The rules can be adjusted based on college policy and classroom operational needs.

⇒ **Offline Buffering Module**

Since campus Wi-Fi availability may vary across buildings and floors, the system includes an offline buffering module to ensure reliability. When connectivity is unavailable, attendance events are stored locally on the ESP32 (or attached memory, if used) with timestamps and session metadata. Buffered events are queued and retransmitted automatically once the network is restored. This module prevents data loss during temporary outages and ensures continuity of attendance recording without requiring manual intervention.

⇒ **Cloud Synchronization Module**

The cloud synchronization module handles secure and reliable communication between the edge device and the cloud backend (Firebase or AWS). It transmits validated attendance events along with device identity information and receives confirmation of successful writes. The module supports retry logic, acknowledgement checks, and controlled rate submission to prevent duplicate uploads or inconsistent states. In cloud deployments, the module can use HTTPS/TLS (REST API) or MQTT over TLS (AWS IoT Core) depending on the chosen backend.

⇒ **Reporting and Analytics Module**

Attendance data becomes useful only when it can be summarized and interpreted. The reporting and analytics module generates class-wise, course-wise, and student-wise attendance summaries, including daily registers, monthly attendance percentages, and shortage lists. In addition, trend analysis such as frequent absentee identification or subject-wise attendance comparison can be produced for academic monitoring. Alerts can be triggered automatically when attendance falls below a defined threshold, enabling timely intervention by faculty, mentors, or administrators.

⇒ **Security Module**

The security module enforces controls to protect the system from misuse and unauthorized access. It includes device authentication (unique device ID and token), encrypted communication (TLS), and role-based access control for dashboard users (admin/HOD/faculty/student). Server-side validation rules ensure that only authorized devices can submit attendance and that records are accepted only for valid sessions. This module also supports auditability by preserving immutable attendance events and logging any manual overrides separately.

Operational Workflow

The proposed system architecture in **Fig. 1** shows the interaction between the RFID identification layer, the ESP32 edge node, the cloud backend (Firebase/AWS), and the application layer. Building on this architecture, the operational sequence describes how an attendance record is captured, validated, and synchronized. In particular, the ESP32 performs UID verification, active session resolution based on the college timetable, and duplicate suppression before forming a timestamped attendance event. The resulting event is securely transmitted to the cloud, where it is stored and used to update dashboards and generate automated reports. The complete end-to-end data flow followed by the prototype is summarized as follows

The end-to-end workflow of the proposed IoT–RFID attendance system is summarized below to explain how an attendance record moves from classroom capture to cloud storage and reporting:

1. A student taps the RFID card near the MFRC522 reader.
2. The reader extracts the tag UID and transfers it to the ESP32 via SPI/UART.
3. The ESP32 validates the UID against enrolled mappings and identifies the currently active timetable session (section, hour slot, course, and staff).
4. A duplicate-scan rule is applied (e.g., rejecting repeated scans for the same UID within a configurable time window) to prevent multiple entries in the same session.
5. If accepted, the ESP32 generates an attendance event containing UID/student ID, session ID, timestamp, and device ID, and attaches a device credential/token for traceability.
6. The event is transmitted to the cloud backend (Firebase/AWS) over Wi-Fi using secure communication (TLS/HTTPS or MQTT over TLS).

7. The cloud layer persists the event, performs server-side checks (device authorization, session validity), and updates derived attendance records used for reporting.
8. The dashboard reflects the new attendance status in near real time for faculty and administrators.
9. Automated reports (daily/monthly summaries, attendance percentages, and shortage lists) are generated from the stored records, and alerts can be triggered when students fall below the configured attendance threshold.

Offline handling: If connectivity is unavailable, the ESP32 temporarily buffers attendance events locally and synchronizes them automatically when the network is restored, ensuring no loss of attendance data.

Implementation Flow

This section describes how the proposed IoT–RFID attendance system is implemented and executed during day-to-day college operation. The flow covers device initialization, session resolution based on Hour 1–Hour 6 timetable slots, attendance marking, offline handling, cloud synchronization, and reporting.

Step 1: System Setup and Enrollment

1. Student enrollment: Each student is issued an RFID card/tag. The RFID UID is captured once and mapped to the student profile (student ID, roll number, department, year, section) in the cloud database.
2. Staff and course setup: Staff master records and course master records are stored in the database.
3. Timetable configuration: Weekly timetable entries are created section-wise for all working days (e.g., Mon–Sat), mapping each hour slot (H1–H6) to course code, staff ID, and classroom.
4. Device registration: Each ESP32 attendance node is assigned a unique device ID and linked to a classroom. Device credentials (token/API key) are registered in the backend to prevent unauthorized nodes from uploading attendance.

Step 2: ESP32 Device Initialization (At Power-on)

1. The ESP32 loads its device ID, stored configuration (classroom ID), and security credentials.
2. The device connects to the configured Wi-Fi network.
3. The RFID reader module is initialized and tested.
4. The device checks cloud connectivity. If connectivity is available, it pulls essential runtime configuration (e.g., active timetable rules) or uses locally cached values.
5. The device enters scan-ready mode and provides a ready indicator (LED/display/buzzer).

Step 3: Active Session Identification (Timetable-Based)

1. When a lecture is running, the ESP32 determines the current hour slot (H1–H6) using the local time.
2. The system resolves the active session by combining:
   - date, day-of-week
   - section/classroom
   - hour slot (H1–H6)
   - mapped course code and staff ID (from timetable)
3. A unique session_id is selected or created (e.g., BSC_CS_III_A_YYYYMMDD_H1).
4. The session is considered valid only within the allowed start/end time window to avoid marking attendance outside class hours.

Step 4: Attendance Capture and Local Validation

1. The student taps the RFID card near the reader.
2. The reader extracts the UID and sends it to the ESP32.
3. The ESP32 verifies whether the UID is enrolled (registered). If not, the scan is rejected and logged as "unknown UID."
4. The system applies a duplicate-prevention rule: if the same UID has already been accepted in the same session within a defined window (e.g., 5 minutes), the scan is rejected or marked as duplicate.

5. If accepted, the ESP32 constructs an attendance event containing:
   - UID and resolved student ID
   - session ID (course, staff, classroom, hour slot)
   - timestamp
   - device ID and status (present)

Step 5: Cloud Upload and Offline Buffering

1. If network connectivity is available, the ESP32 uploads the attendance event securely (TLS/HTTPS for Firebase or HTTPS/MQTT-TLS for AWS).
2. The device waits for server acknowledgement to confirm that the write is successful.
3. If connectivity is unavailable, the event is written to a local buffer queue. The student still receives a local "marked" indication, but the event is flagged as pending synchronization.
4. A background retry routine periodically checks connectivity and uploads buffered events in chronological order once the network returns.

Step 6: Server-Side Processing and Record Finalization

1. On receiving an event, the cloud backend performs server-side validation:
   - device authorization
   - session validity (date/hour window)
   - duplicate confirmation (if enforced centrally)
2. The event is stored in an append-only attendance_events log for audit purposes.
3. A derived "final attendance" record is updated (per student per session). This final record is used for reporting and ensures one authoritative status per session.

Step 7: Dashboard Update and Report Generation

1. The dashboard reflects session-wise updates in near real time (present count, absent count, student list).
2. At session closure (end of hour), absent students can be automatically finalized based on enrolled section roster.
3. Daily and monthly summaries are generated:
   - attendance percentage by course and student
   - shortage list (below threshold such as 75%)
   - exports (CSV/PDF)
4. Alerts (optional) are triggered for students below threshold and shared with faculty/HOD/admin as per policy.

Performance Evaluation: Results and Discussion

Experimental Setup

A prototype of the proposed attendance system was implemented for a college classroom environment using an ESP32 microcontroller connected to an MFRC522 RFID reader. Attendance events were transmitted over Wi-Fi to a cloud backend. Two cloud configurations were considered: Firebase (Firestore/Realtime Database) and AWS (API/Lambda + DynamoDB or IoT ingestion). The evaluation was conducted under typical indoor Wi-Fi conditions and focused on latency, throughput, reliability, and correctness (duplicate prevention and offline recovery).

RESULTS

Table 2 discusses the RFID read time remains consistently low because UID capture is a local, short-range process. The main delay is the network + cloud acknowledgement, which explains why end-to-end latency is measured in seconds rather than milliseconds. Firebase generally showed slightly lower average latency due to its real-time oriented data services and straightforward write path. AWS performance is comparable but depends heavily on the chosen ingestion path (REST via API Gateway/Lambda vs MQTT via IoT Core) and cold-start overheads when serverless functions are used. Despite these differences, both platforms achieve near real-time updates suitable for

classroom attendance marking. Table 3 discusses the breakdown highlights that the system is not compute-bound at the edge. The ESP32 performs validation quickly; the dominant component is cloud write confirmation. This is expected in IoT deployments where network variability and server-side processing (security checks, session rules) contribute most of the delay. Reusing persistent connections and minimizing payload size can reduce transmission overhead, while careful backend design (lightweight validation path) can reduce cloud processing time.

Table 4 discusses the Throughput depends not only on device speed but also on humanbehavior (tapping speed, queue formation). A single device is adequate for many classrooms, but large sections benefit from two scanning points to prevent congestion. This is an important deployment insight for colleges: scaling throughput is best achieved by adding low-cost nodes rather than increasing complexity in one node. Table 5 discusses the Duplicate prevention significantly improves data quality by eliminating accidental multiple taps and discouraging repeated attempts. Session-aware rejection also prevents marking attendance outside lecture time, which is critical in timetable-based college deployment. Logging rejected attempts provides an audit trail that can support system monitoring and policy enforcement. Table 6 discusses the Offline buffering ensures attendance is not lost when campus Wi-Fi fluctuates. Recovery success is highest when buffered events persist safely across restarts. For robust real deployments, the buffer should be written to non-volatile storage (ESP32 flash/EEPROM or external memory). A controlled retry policy avoids network bursts and prevents duplicate uploads. This feature is practically important for colleges where network consistency differs across buildings.

CONCLUSION AND FUTURE SCOPE

This paper proposed and evaluated an advanced IoT–RFID attendance tracking system for colleges using an ESP32-based edge node and a cloud backend (Firebase/AWS), where RFID scans are mapped to timetable-driven sessions (Hour 1–Hour 6) and processed with edge-side validation, duplicate prevention, device identification, secure synchronization, and offline buffering to ensure reliable record capture even under unstable campus networks; the results demonstrate that the approach reduces manual effort, improves auditability through event-based logs, enables near real-time dashboards, and supports automated reporting and shortage analysis, making it practical for scalable smart campus deployment. Future enhancements can further strengthen the system by adding multi-factor verification (e.g., RFID with face/PIN/OTP) to reduce proxy attendance, improving offline-first persistence to survive power resets, incorporating predictive analytics for early identification of at-risk students, integrating with college ERP/LMS platforms for seamless academic workflow automation, enabling centralized device management for monitoring and remote firmware updates across many classrooms, and upgrading security/privacy controls through stronger authentication, key rotation, and privacy-preserving storage, thereby evolving the prototype into a robust institution-wide attendance and student engagement monitoring solution.

Table 1: Testbed Configuration

Item	Configuration (Prototype)
Edge Device	ESP32 Dev Board (Wi-Fi enabled)
RFID Reader	MFRC522 (13.56 MHz), passive RFID cards
Deployment Point	Classroom desk/entry point (single queue)
Attendance Mode	Timetable-based sessions (H1–H6)
Duplicate Rule	Same UID blocked within 5 minutes for same session
Offline Handling	Local queue buffering + periodic retry
Cloud Backends Tested	Firebase and AWS (two configurations)
Dashboard	Web-based admin/faculty dashboard (real-time view + reports)
Test Duration	Multiple sessions across a day (simulated + repeated runs)

Table 2: Core Performance Results (Online Mode)

Metric	Firebase (Observed)	AWS (Observed)
Avg RFID read time (ms)	70–120	70–120
End-to-end latency (avg, s)	0.9–2.1	1.1–2.6
End-to-end latency (95th percentile, s)	2.4–3.6	2.8–4.2
Read success rate (%)	98.5–100	98.5–100
Cloud write success rate (%)	99–100	98.5–100
Throughput (scans/min)	28–40	26–38

Table 3: Latency Breakdown (Typical Event)

Stage	Typical Time Contribution
RFID card detection + UID read	0.07–0.12 s
Local validation + duplicate check	0.01–0.05 s
Event packaging + authentication token attach	0.01–0.03 s
Wi-Fi transmission + TLS handshake/reuse	0.15–0.60 s
Cloud processing + database write acknowledgement	0.40–1.80 s
Total end-to-end	**0.9–2.6 s**

Table 4: Throughput Under Classroom Conditions

Scenario	Setup	Observed Throughput (scans/min)	Notes
S1: Single device, single queue	One ESP32 at classroom desk	28–40	Smooth flow; no congestion
S2: Single device, high crowding	One ESP32, students rush	22–32	Queue delays due to human tapping speed
S3: Two devices, split queue	Two ESP32 nodes (two points)	45–70 (combined)	Best for large classes
S4: Lab double-hour (H3+H4)	Same device, longer session	28–40	Performance stable; more scans total

Table 5: Duplicate Prevention and Correctness

Condition	Test Description	Result
Valid first scan	UID scanned once in session	Marked present
Rapid repeat scan	Same UID within 5 min	Detected as duplicate (rejected/flagged)
Repeat scan after window	Same UID after 5 min	Either allowed or flagged based on policy
Unknown UID	Unregistered RFID tag	Rejected as unknown
Wrong-session attempt	Scan outside active session	Rejected as “no active session”

Table 6: Offline Buffering and Recovery Results

Offline Test Case	Buffered Events	Recovery Outcome	Recovery Success (%)
Wi-Fi off for 5 minutes	30	Synced after reconnect	100
Wi-Fi off for 15 minutes	90	Synced after reconnect	98–100
Intermittent network (dropouts)	120	Synced with retries	97–99
Power reset during offline	50	Partial sync (depends on storage persistence)	90–98

ABSTRACT

Air pollution is a significant environmental and health issue caused by the increase in industrialization and vehicle emissions. It is essential to monitor and predict air quality in order to minimize air pollution and protect the health of the population. This research aims to predict air quality in the industrial areas of Perambalur and Ariyalur in the state of Tamil Nadu. Cement industries and mining are common in this area. The research relies on historical air pollution and weather data such as PM2.5, PM10, SO_2, NO_2, CO, temperature, humidity, and wind speed. A Long Short-Term Memory (LSTM) model is implemented as a deep learning method to analyze the historical data and predict the air quality in the future. The results show that the deep learning model is effective in predicting the Air Quality Index (AQI).

Keywords: Air Quality Prediction, Deep Learning, Long Short-Term Memory (LSTM), Air Quality Index (AQI) and Industrial Pollution

PROBLEM STATEMENT

Air pollution has now become an important environmental problem in many developing countries due to the rise in industrialization, urbanization, and vehicular pollution. Industrial areas such as Ariyalur and Perambalur contain many cement industries, limestone mining industries, and transportation activities, which contribute to significant amounts of air pollution. Though there are many monitoring stations that show the real-time values of the pollution level, it is not possible to forecast the pollution level in the future using these stations. Without the correct prediction

values, it is difficult to take preventive measures and warn the public about the pollution level. Statistical methods such as regression and ARIMA can be used to predict the pollution level; however, these methods fail to handle the complex nonlinear relationships and temporal dependencies that exist in the data (Tiwari et al., 2021). Recurrent neural networks such as LSTM can handle complex temporal relationships and patterns in the data. Hence, it is required to design a deep learning prediction model to improve the accuracy in the prediction of the air quality in the industrial districts such as Ariyalur and Perambalur.

OBJECTIVES

The main objectives of this research are:

- To analyze the air pollution in the Perambalur and Ariyalur districts.
- To collect and process historical air quality and meteorological data.
- To develop a deep learning model for predicting Air Quality Index (AQI).
- To assess the performance of the designed deep learning model using standard metrics.
- To compare the predicted values with the actual air pollution measurements.

INTRODUCTION

Air pollution is one of the most important environmental problems that affects human health and the balance of nature. Various air pollutants such as PM2.5 and PM10, nitrogen dioxide (NO_2), sulfur dioxide (SO_2), and carbon monoxide (CO) are known to have considerable effects on human health and the environment (Shankar & Arasu, 2023). In India, rapid growth in industrialization and transportation facilities has greatly contributed to the degradation of air quality. Therefore, it is vital to establish efficient air quality monitoring systems for predicting air quality for effective decision-making in environmental policies. In recent times, artificial intelligence and deep learning methods have been recognized for their potential in solving problems in data analysis in the environment. Deep learning algorithms such as Recurrent Neural Network (RNN), Convolutional Neural Network (CNN), and Long Short-Term Memory (LSTM) have demonstrated impressive results in predicting air pollution levels (Naresh & Indira, 2023). Among these algorithms, LSTM is a powerful tool in time series prediction due to its ability to handle complex data sets in environmental analysis (Singhai & Sethi, 2024). Therefore, this study aims at developing a model for predicting air pollution levels in Perambalur and Ariyalur districts in India, which are recognized for their industrial activities in cement production and limestone mining.

LITERATURE REVIEW

Several researchers have worked on the prediction of air quality using machine learning and deep learning methods. Alghieth et al. (2022) presented a deep learning method for the prediction of air pollution, which achieved higher accuracy compared to traditional statistical methods. The authors found that neural networks can efficiently handle non-linear relationships between meteorological parameters and pollutant concentrations. Naresh and Indira (2023) presented a multivariate LSTM method for the prediction of air pollution using meteorological and pollutant parameters. The authors found that the accuracy of the LSTM method is significantly higher compared to traditional machine learning methods. Likewise, the paper by Singhai and Sethi (2024) examined the application of deep neural networks in the prediction of air pollution and found that deep learning can effectively learn temporal dependencies in environmental data. Gayathri et al. (2024) proposed the application of hybrid deep learning models that integrate the CNN and LSTM architectures to improve the accuracy of the prediction results. The proposed deep learning model successfully learned the spatial and temporal features in the air pollution datasets. Raut et al. (2022) proposed the application of the hybrid deep learning model in the prediction of air quality and found that the application of deep learning can reduce the prediction errors and improve the accuracy of the forecast results.

Despite these developments, little work has been done on industrial districts like Ariyalur and Perambalur, as the pollution characteristics may vary because of the cement industries and the mines. Thus, the present study attempts to bridge the gap by employing the concept of deep learning for prediction purposes.

Model Training and Evaluation

The dataset used in this study consists of historical air quality and meteorological parameters collected over a specific time period. Each record in the dataset represents daily observations that include pollutant concentrations such as PM2.5, PM10, sulfur dioxide (SO_2), nitrogen dioxide (NO_2), and carbon monoxide (CO), along with meteorological variables such as temperature, humidity, and wind speed. In addition, the dataset contains the Air Quality Index (AQI), which represents the overall air pollution level for each day. These variables serve as input features for the deep learning model. Before training, the dataset is preprocessed by handling missing values and normalizing the feature values to ensure consistency. The cleaned dataset is then divided into training and testing sets, typically using an 80:20 ratio. The training dataset is used to train the Long Short-Term Memory (LSTM) model, allowing it to learn patterns and relationships between pollutant concentrations, weather conditions, and AQI values over time. By analyzing these temporal patterns, the deep learning model is able to predict future AQI values based on historical pollution and meteorological data. The following sample data sets are used to train the model.

The proposed air quality prediction system will incorporate a workflow with different stages in its process, such as data collection, preprocessing, development of a deep learning model, evaluation of the model, and finally predicting the AQI. In the first step of the proposed system, air quality and meteorological data will be collected from reliable sources of environmental monitoring. The collected dataset will comprise significant parameters like particulate matter (PM2.5 and PM10), sulfur dioxide (SO2), nitrogen dioxide (NO2), carbon monoxide (CO), temperature, humidity, and wind speed, which are significant in determining the air quality of a region.

Next, after the data is collected, a preprocessing stage is performed to ensure the quality of the data collected, after which the data is ready for training the model. In this stage, the data is preprocessed by ensuring that any missing values are handled, outliers are removed, and normalization is performed to ensure consistency in the data. Next, the data is transformed to a suitable form for use in deep learning algorithms, known as a time series. After the data is preprocessed, a deep learning model is implemented using the Long Short-Term Memory (LSTM) algorithm, which is used to analyze the patterns in the air pollution dataset collected. In this stage, the collected dataset is split into two parts: the training dataset and the testing dataset. The training dataset is used to train the deep learning model, enabling it to learn the relationship between the concentrations of pollutants and the meteorological conditions.

Model Performance and Pollution Trend Analysis

This section includes the graphical results for the analysis of the performance of the deep learning model in predicting the air quality. The graphs show the model's prediction accuracy and performance as well as the trends in PM2.5 pollution.

Actual vs Predicted AQI (LSTM Model Performance)

The actual vs Predicted AQI chart compares the actual AQI values and the AQI values predicted by the deep learning model based on the LSTM algorithm. The actual vs Predicted AQI chart can be used to assess the accuracy of the proposed prediction system. It is evident from the actual vs Predicted AQI chart that the predicted AQI values are following the actual AQI value trends. This implies that the proposed model based on the LSTM algorithm has the potential to learn the trends from the historical air quality data. The differences between the actual and predicted AQI values are minimal, and hence the model performance is good. Therefore, the model can be regarded as reliable for predicting the air quality in the future.

(LSTM Model Performance)

Training vs Validation Loss

The Training vs Validation Loss graph shows how the deep learning model learns during the training process. The training loss shows the amount of error computed by using the training data set, while the validation loss shows the amount of error computed by using unseen test data sets. As more epochs are added in this graph, both values gradually decrease over time. This shows that the model is gaining more prediction ability during the training process. The similarity in both values shows that the model is not overfitting. The graph shows that the model is well trained and stable.

PM2.5 Pollution Trend

The graph of the PM2.5 pollution trend illustrates how much the amount of PM2.5 has changed over a particular time period. PM2.5 refers to tiny particles in the atmosphere that have the potential to affect people's health and the quality of the environment. The average amount of PM2.5 varies from day to day and can also be influenced by things like industrial emissions and climatic conditions. Areas with high PM2.5 levels are typically very polluted.

According to the Model Performance and Pollution Trend Analysis, the values predicted by the LSTM model match the actual values, which means the model is performing well. The training and validation losses decrease as the model trains, which means the model is learning as it trains.

RESULTS AND DISCUSSION

The experimental results show that the suggested deep learning model is efficient in predicting air quality level in Perambalur and Ariyalur districts. The AQI category distribution figure shows that most of the days in the region are in Moderate (101-200) and Satisfactory (51-100) categories, which implies moderate air quality level in Perambalur and Ariyalur industrial regions. However, some of the days are in Poor (201-300), Very Poor (301-400), and Severe (401-500) categories, which may be caused by increased air pollution due to industries, vehicles, and weather conditions.

AQI Categories Used (India Standard)

The performance of the model was assessed based on the performance metrics such as MAE, RMSE, and R^2 score. The performance of the LSTM model was found to be the highest compared to the other models. The performance metrics were found to be MAE = 4.82, RMSE = 6.9, and R^2 = 0.92. The performance metrics for the Random Forest model were found to be MAE = 6.1, RMSE = 9.1, and R^2 = 0.86. The performance metrics for the SVM model recorded MAE = 7.35, RMSE = 10, and R^2 = 0.81. These results show that the LSTM model provides higher accuracy and better prediction performance compared to Random Forest and SVM for air quality prediction.

CONCLUSION

This study developed a deep learning–based air quality prediction model for the industrial districts of Perambalur and Ariyalur. The Long Short-Term Memory (LSTM) model was used to analyze historical air pollution and meteorological data to predict the Air Quality Index (AQI). The results show that the proposed model can accurately predict air quality levels and performs better than traditional machine learning models such as Random Forest and Support Vector Machine (SVM). The developed system can help environmental authorities monitor pollution levels and take effective measures to control air pollution in industrial regions.

ABSTRACT

Combretum indicum mediated synthesis of silver nanoparticles (CIAgNPs) was created as a green and sustainable process and their physicochemical and biological characteristics were analysed. Aqueous leaf extract of *Combretum indicum* was used to reduce Ag^{+} to Ag^{0} and form a visible colour change at room temperature. An intrinsic surface plasmon resonance (SPR) band at 400 nm was obtained. The FTIR spectrum showed the participation of phenolics, flavonoids, proteins and carbohydrates in the reduction and capping (notable at 3067 cm^{-1}, 1609 cm^{-1}, 1314 $cm^{-1,}$ 1165 cm^{-1}, 1054 cm^{-1}), while XRD displayed Bragg reflections consistent with face-centred cubic silver (2θ = 38.2°, 44.4°, 64.6°, 77.5°) with an average crystallite size 25 nm. TEM and SEM imaging revealed predominantly spherical/oval nanoparticles with size distribution 18.8 nm to 41.2 nm. EDS confirmed an elemental Ag along with organic constituents from the extract. CIAgNPs exhibited good biocompatibility in human PBMCs (LC_{50} = 467.3 μg mL^{-1}) and dose dependent cytotoxicity against MCF-7 breast cancer cells (EC_{50}/IC_{50} = 144.6 μg mL^{-1}), with a selectivity index 3.23 In vitro scratch assays revealed that concentration-dependent inhibition of MCF-7 migration occurred, hence, anti-metastatic activity. Antioxidant profiling (DPPH, LPO/MDA, GSH, SOD, catalase) detected a decrease of lipid peroxidation and an increase of antioxidant enzyme activity (in particular, SOD. Collectively, these results position CIAgNPs as a multifunctional nanomaterial with selective anticancer, anti-migratory and antioxidant properties. Additionally, mechanistic research and extensive in vivo biosafety tests are suggested to develop translational potential.

Keywords: *Combretum indicum*, Silver Nanoparticle, Anticancer activity; MCF-7 cells, Phytochemical capping; Antioxidant activity.

INTRODUCTION

Nanoparticles are particularly important and necessary for better efficacy in biological applications due to their distinctive features which include huge surface area [1], stability, lower melting temperatures and exceptional mechanical strength [2]. Physical and chemical method involves the utilization of harmful and reactive chemicals and high temperatures and energy that disrupt the ecosystem. As a result, the scientific community is always working to create simple, inexpensive and environmentally acceptable biological procedures for the synthesis of Metallic Nanoparticles (MNPs) [3,4]. In addition to being environmentally beneficial, the synthesis of NPs can be made more sustainable by applying industrial and agricultural waste [5]. The new age of "green synthesis approaches" is receiving an abundance of interest from current scientific and technology studies. At present, there are number of research articles are available on the green synthesis of copper, zinc, iron, silver, titanium, nickel, tungsten, ruthenium, palladium, and bismuth nanoparticles [6-14]. The use of silver is one of the fundamental substances and hence makes our world as 'silver', Due to this silver has role in medicine and preservative as long tradition [15]. Numerous bacterial strains and other microbes frequently found in industries have long been known to be inhibited by silver [16]. Silver nanoparticles have been used in numerous antibacterial [18], wound-healing [19], anti-cancer [20], anti-inflammatory [21], food packaging and catheters for drug delivery applications [17], etc. A petiole climber for outdoor gardens is *Quisqualis indica* Linn. (*Combretum indicum*) which belongs to family Combretaceae. The plant is commonly known as Rangoon Creeper [22,23]. The plant has shown a potential herbal medicinal property. It is an annual evergreen ornamental plant and is readily available because most the people used it to decorate homes and gardens and for fencing [24]. 21 additional tannins, including 11 ellagitannins and phenol-carboxylic acids (gallic acid, ellagic acid) were extracted from the fruits or leaves [25,27]. Total phenolic content shows the highest antioxidant activities identified [25,26,27]. The leaves of the plant contain L-asparagine, rutin, quisqualic acid, L-proline and trigonelline [28]. The stem bark contains four diphenylpropanoids as well as palmitic, linoleic, oleic and stearic acids.

Using UPLC-QTOF/ESI-MS (Ultra-performance liquid chromatography coupled with time-of-flight mass spectrometry), the ethanol leaf extract was examined and it was shown to contain a complex combination of terpenoids, flavonoids and glycosides of diverse classes as studied by Forid *et al*., 2021 [26]. The plant showing immunomodulatory, antibacterial, anti-hyperlipidemic, antioxidant, antirheumatic, antiviral, antifungal, antiseptic, antidiarrheal, antipyretic, anthelmintic, diabetes activities [25,26].Rutin (quercetin-3-O-rutinoside) is a flavonoid found in plant and explains the mechanism of reducing Ag ions to nanoparticles. Each catechol group in rutin from a plant extract of the plan yields two protons reducing two silver ions [28]. Biomolecules such as Terpenoids, flavonoids, alkaloids, steroids, saponins and tannins in the leaf extract of the plant but showing the absence of anthraquinones. Flavonoids, phenolic compounds and other biomolecules play essential roles in AgNP synthesis. Flavonoids and phenolic compounds serve as reducing agents while proteins and phytochemicals act as both capping and reducing agents. These biomolecules release electrons, breaking O-H bonds and converting Ag^{+} ions into Ag^{0} [29]. Gupta *et al*. (2021) studied that flower extracts comprise gallic acid, linalool oxides (furanoid), quinole carbonitrile and flavonoids such as quercetin and rutin. The plant exhibits potent immunomodulatory effects and inhibits acetylcholinesterase (AChE). It is also recognized for its efficacy in treating conditions such as spermatorrhoea, weakness, leucorrhoea and diabetes [30]. *Combretum indicum* (madhumalti) is a woody vine, widely used in Indian ayurveda and Thai traditional medicine for generations. Traditionally, root, seed, fruit or flower preparations have been employed for various remedies. The seed's unique shape conceals oil and quisqualic acid known for their anthelmintic properties against roundworms, especially Ascaris. The flowers are rich in flavonoid glycosides like pelargonidin-03-glucoside and rutin. The flower extracts exhibit immunomodulatory properties and effective inhibition of acetylcholinesterase (AChE), offering relief from spermatorrhoea, weakness, leucorrhoea, diabetes, colds and coughs. Notably, this plant's flower extract demonstrates significant, dose-dependent anti-inflammatory activity in acute and chronic models using Wistar rats. This study describes the biosynthesis of the distributed AgNPs which involved reducing the silver salt with an aqueous petal extract of *Combretum indicum* [31].

MATERIAL AND METHODS

MATERIALS

Combretum indicum leaves were collected from the Amravati district of Maharashtra, India, in order to prepare silver nanoparticles. The Botanical Survey of India, Western Regional Center, Koregaon Road, Pune, verified the specimen's botanical identity. The study's solvents, culture media, and chemicals were all purchased from Merck Limited in India.

Preparation of Extract

To provide a sustainable and environmentally benign method, the aqueous extract of *Combretum indicum* leaves was chosen for SNP synthesis. To get free of clinging contaminants, fresh leaves were first rinsed with tap water and then three times with distilled water. After being cleaned, the leaves were air-dried and wisely cut. A 200 mL round-bottom flask with 100 mL of distilled water was filled with 10 grams of the processed leaves. After giving the mixture a good stir, it was heated to between 60 and 80 degrees Celsius for around half an hour. The solid plant material was extracted and the clear extract was gathered once it had cooled to room temperature. This extract was kept at 5 °C.

Biosynthesis of Silver nanoparticles

$AgNO_3$ was used to synthesize silver nanoparticles according alongside standard procedures. First, 20 mL of the RC leaf extract and 5 mL of 0.001 M silver nitrate solution were stirred together at room temperature. The reaction mixture was then constantly rotated on a magnetic stirrer for two hours. The brown precipitate that resulted from this process was centrifuged for 15 minutes at 15,000 rpm and then rinsed twice with sterile deionized water. After that, the material was dried for an entire night at 60 °C. During the drying stage, full transformation into CI-SNPs was seen [28].

Qualitative Phytochemical Analysis of *Combretum indicum* Leaf Extract. Phytochemical screening of *Combretum indicum* leaf extracts was conducted utilizing standard qualitative tests to detect significant primary and secondary metabolites, including carbohydrates, proteins, phenols, flavonoids, tannins, saponins. The presence of reducing sugars was verified by the development of reddish-brown and brick-red precipitates in Benedict's and Fehling's tests, respectively. Proteins were identified via Millon's test by the formation of a white precipitate that transitioned to red with mild heating. Alkaloids were detected through the formation of a reddish-brown precipitate with Mayer's reagent. Phenolic substances yielded a profound bluish-green hue with ferric chloride, whereas flavonoids were signified by the emergence of pink to bluish-green colors in the Shinoda reaction. A blue-green color shift in the ferric chloride test indicated the presence of tannins [32].

Characterization of CI- AgNPs

Primary analysis of synthesis Ag nanoparticles from plant extract was observed by the physical change in color of the reaction solution from yellow to dark brown. Furthering the tracking process, a UV-Vis spectrum (ShimadzuUV-1900i, Japan) may find Ag nanoparticle peaks between 300-700 nm [28]. The size, shape, dispersion and structure of nanoparticles may be studied using other methods such as SEM (JSM-6390LV, JEOL, Japan), TEM (JEM-2100, JEOL, Japan) and energy dispersive spectroscopy (EDAX). XRD analysis is a significant way of assessing nanoparticle formation. Additionally, FTIR (Thermo Nicolet Avatar 370, USA) spectroscopy may be used to monitor biomolecules that affect the stability and production of nanoparticles as match previously. X-ray diffraction analysis was carried out using a Bruker AXS D8 Advance diffractometer equipped with CuKα radiation (λ = 1.5405 Å), recording diffraction patterns over a 2θ range of 20°–80° [28-29]. All characterization investigations were performed at the Sophisticated Test and Instrumentation Centre (STIC) in Kochi.

Evaluation of the bioactive potential of CIAgNPs

MCF-7 Cell Culture

Minimum Essential Medium (MEM) supplemented with 10% fetal bovine serum and 1% antibiotic–antimycotic solution (HiMedia, India) was used to cultivate MCF-7 cells obtained from the National Centre for Cell Science (NCCS), Pune, India. In growth flasks covered with poly-L-lysine, cells were kept at 37 °C in a humidified environment with 95% air and 5% CO_2 [34].

PBMC Cell Culture

The Ficoll–Histopaque density gradient method was used to separate peripheral blood mononuclear cells (PBMCs), which were then grown in Dulbecco's Modified Eagle Medium (DMEM) supplemented with 10% fetal bovine serum and 1% antibiotic–antimycotic solution (HiMedia, India). The cells were kept at 37 °C in poly-L-lysine-coated culture flasks with 95% air and 5% CO_2.

Drug formulation of CIAgNPs

As part of his doctoral research, Mr. Suraj Adole produced nanoparticle formulations of *Combretum indicum*, which were developed in powdered form. A 0.22–0.25 µm syringe filter was used to filter out 100 mg of CIAgNPs after it had been dissolved in 10 mL of nutrient combination medium and cultured for 24 hours. For subsequent investigations, the resulting filtrate was used as a 10 mg/mL stock solution.

Measurement of cell viability by Trypan blue exclusion assay

Cell viability based on membrane integrity was evaluated using trypan blue exclusion. Trypan blue (50µl) and PBS (400µl) were combined with washed cells (50µl), and the mixture was put into a hemocytometer for counting. Non-viable cells showed blue staining as a result of membrane rupture, but live cells remained unstained. Colorless live cells in each of the four chambers were counted under a light microscope to estimate the cell density.

Cell concentration per millilitre was calculated using the following formula:

Cell concentration (cells/mL) = Average number of cells per large square × dilution factor × 10^4,

Where the dilution factor is typically 2 for a 1:1 trypan blue dilution, and 10^4 is the conversion factor from 10^{-4} mL to 1 mL.

Measurement of cytotoxicity

By measuring mitochondrial enzyme activity, which converts XTT to a colorful formazan product proportionate to cell viability, the XTT assay was used to evaluate cytotoxicity[35]. Peripheral blood mononuclear cells (PBMCs) were inoculated in 48-well plates at a density of 2 × 10^4 cells per well and subjected to five distinct doses of Arjuna and CIAGNP nanoparticles, while control wells were left untreated. Following a 48-hour incubation at 37 °C, XTT reagent was introduced, and the plates were subsequently incubated for an additional 4 hours before measuring absorbance at 450 nm[36]. The identical technique was employed to assess anticancer efficacy, in conjunction with the Sulphorhodamine B assay to quantify cellular protein levels and cell density in MCF-7 cells following 48 hours of therapy. Linear regression analysis was used to calculate EC_{50} and LC_{50} values, and cell viability was represented in relation to untreated controls (100%).

Scratch test

The scratch assay is an in vitro method employed to assess cell migration by creating a linear gap in a merging cell monolayer and observing its closure over time[36,37]. MCF-7 cells were inoculated in 48-well plates at a density of 2 × 10^4 cells per well and permitted to proliferate for 24 hours. A linear scratch was subsequently created at the middle of each well utilizing morphologically intact cells, followed by the elimination of detached cells through washing. The cells were subsequently exposed to CIAgNPs at doses of 6, 12.5, 25, 50, and 100µg/mL and incubated for 48 hours to evaluate migration.

Sulphorhodamine dye assay. The SRB experiment was conducted following the protocol established by Vichai and Kirtikara, utilizing sulforhodamine B dye to evaluate cell viability via protein staining [36,37]. The anticancer efficacy of the nanoparticles against MCF-7 cells was examined in 96-well culture plates. After nanoparticle treatment and a 48-hour incubation, cell proliferation was halted by the addition of 10% trichloroacetic acid (100 µL/well), followed by incubation of the plates at 4 °C for 1 hour to fix adherent cells. The wells were subsequently drained, rinsed four times with distilled water, and air-dried. Cells were stained with 0.05% SRB in 1% acetic acid for 30 minutes at ambient temperature, followed by four washes with 1% acetic acid and subsequent drying. The bound dye was solubilized in 0.01 M Tris-HCl buffer (pH 10.4), incubated for 10 minutes, and the absorbance was recorded at 540 nm using an ELISA plate reader (Robonik Readwell Touch, India).

Antioxidant Study

DPPH Assay

The antioxidant activity was determined by the DPPH radical scavenging assay. Reduction of DPPH by antioxidants caused a color change from purple to yellow with decreased absorbance [39,40,41]. Briefly, 100 µL of CIAgNPs samples or ascorbic acid was mixed with 3 mL of 0.004% methanolic DPPH and incubated for 30 min. The reduction in DPPH absorbance was measured at 570 nm against a methanol blank.

Lipid peroxidation (LPO/MDA)

Malondialdehyde (MDA), an indicator of lipid peroxidation, interacts with thiobarbituric acid to produce TBARS, which are measured spectrophotometrically. MDA concentrations in cell culture supernatants were assessed using a modified approach by Satoh *et al*. (1978). In summary, 100 µL of sample or blank was combined with acetic acid and thiobarbituric acid, diluted to 2 mL, heated at 95 °C for 60 minutes, cooled, then centrifuged at 10,000 rpm for 10 minutes. Absorbance was measured at 532 and 600 nm, and MDA concentration (nM/mL) was calculated as (A532 −A600)/155×10.

Reduced Glutathione (GSH)

A spectrophotometric test based on Ellman's method was used to quantify reduced glutathione (GSH). In this assay, GSH and 5,5′-dithiobis(2-nitrobenzoic acid) (DTNB) react to create the yellow chromophore 5′-thio-2-nitrobenzoic acid (TNB), which is detectable at 412 nm. The concentration of GSH is directly correlated with TNB intensity. Reduced glutathione standards ranging from 4 to 256 µM were used in a modified Moron *et al*. (1979) procedure to measure GSH levels in cell culture supernatants.

Catalase Activity

A modified Sinha (1972) approach was used to measure the catalase activity in cell culture supernatants. This assay uses an unstable perchromic acid intermediate to reduce dichromate in acetic acid to chromic acetate when heated in the presence of $H2O_2$. Catalase activity was measured as µmol of $H2O_2$ consumed per minute per mL, and the resultant chromic acetate was measured colorimetrically at 583 nm.

Superoxide Dismutase (SOD) Activity

The Marklund and Marklund (1972) method, modified by Li (2021), was used to measure the superoxide dismutase (SOD) activity in cell culture supernatants. In short, 100 µL of the pH 7.4 sample was combined with pyrogallol (60 mM in 1 mM HCl) and Tris–HCl buffer (0.05 M, containing 1 mM Na_2EDTA), incubated at 37 °C, and quickly mixed. For five minutes, the rise in absorbance at 325 nm was measured every minute. The % inhibition of pyrogallol auto-oxidation was used to calculate SOD activity: $(\Delta A_{cont.}/T - \Delta A_{samp.}/T)/ (\Delta A_{cont.}/T) \times 100\%$. 50% inhibition was considered one unit of SOD, and activity was calculated as U/mL using the formula SOD (U/mL) = (% inhibition/50) × 10.

Photomicrographs and Statistical Analysis

An inverted tissue culture microscope (Metzer, India) was used to record the morphological changes in MCF-7 cells after treatment with CIAgNP. For the purpose of reproducibility, every experiment was conducted in triplicate. Zone

of inhibition and MIC values were among the data that were presented as mean ± standard deviation or %. MedCalc software (version 10) was used to do statistical comparisons using a t-test; differences were deemed significant at $p < 0.05$.

RESULT AND DISCUSSION

Qualitative Phytochemical analysis of *Combretum indicum* leaves aqueous extract.

The phytochemical analysis of *Combretum indicum* identified significant bioactive compounds. Carbohydrates, proteins, phenols, tannins, and alkaloids were prominently identified, whilst flavonoids were found in low to moderate concentrations. This profile verifies that *Combretum indicum* possesses a rich chemical composition, making it appropriate for medicinal and nanoparticle manufacturing applications.

Biosynthesis and characterization of CIAgNPs.

The reduction of silver ions to elemental silver (Ag^0) facilitated by *Combretum indicum* extract was visually apparent from the alteration in the reaction mixture's color from pale yellow to brown, thereby verifying the successful synthesis of AgNPs (Figure 1. A).

UV–vis spectroscopic analysis of CIAgNPs

UV–Vis spectroscopy serves as a dependable method for the initial characterisation of silver nanoparticles mediated by *Combretum indicum*. CIAgNPs were measured between 200–800 nm (Shimadzu UV-1900i) to verify nanoparticle production and aqueous stability. The minimal energy gap between the valence and conduction bands of CIAgNPs facilitates electron mobility, resulting in a pronounced SPR peak at 400 nm that verifies the synthesis of nanoscale particles [28]. Mie's theory postulates that the presence of a singular surface plasmon resonance (SPR) peak signifies spherical nanoparticles. The existence of several SPR peaks indicates the creation of nanoparticles with varied morphologies [29]. Fig.1(A)Biosynthesis of CIAgNPs. Fig.1(B)UV–vis spectroscopic analysis of CIAgNPs.

FTIR analysis of CIAgNPs

The FTIR spectra of the *Combretum indicum* aqueous extract and the synthesized CIAgNPs are presented in Figure 2. broad band at 3067.44 cm^{-1} signifies aromatic C–H stretching, indicating the presence of phenolic and flavonoid chemicals that facilitate Ag^+ reduction. The strong peak observed at 1609.21 cm^{-1} is indicative of aromatic C=C stretching, hence affirming the presence of polyphenols that function as reducing and stabilizing agents. The 1438.08 cm^{-1} peak signifies phenolic O–H and aliphatic C–H bending, corroborating phytochemical capping. The 1314.09 cm^{-1} peak is attributed to C–N and C–O stretching in proteins and phenols, signifying surface stability. Peak at 1165.58 cm^{-1} and 1054.06 cm^{-1} validate C–O stretching in carbohydrates and glycosides, resulting in a protective organic layer. The peak at 920.90 cm^{-1} is indicative of aromatic C–H bending, but the low-frequency bands ranging from 877 to 762 cm^{-1} signify aromatic ring deformations. The peak of the band at 511.00 cm^{-1} corroborates Ag–ligand interaction, confirming nanoparticle production and bio-capping. FTIR data show that Plant proteins carbohydrates, flavanoid, and polyphenols efficiently affect the synthetic silver nanoparticles' reduction, stability, and function. FTIR analysis of the aqueous leaf extract of CIAgNPs (Fig. 2).

Scanning Electron Microscopy analysis of CIAgNPs

High-resolution surface morphology and topography of materials may be seen using scanning electron microscopy (SEM) which provides comprehensive structural data. The presence of numerous spherical forms that were predominantly aggregated was shown by a SEM (Figure 3.A), and the conglomeration of certain nanoparticles has been observed and may have resulted from sample centrifugation.

Transmission electron microscopy analysis of CIAgNPs

Different electron microscopy techniques are used to identify the shape, size, morphology and composition of various materials. The TEM images (Figure 3.B) reveal that the aqueous leaf extract of CIAgNPs is effectively

dispersed and exhibits an oval-shaped morphology with no evident associations. The analysis of size dispersion demonstrated that the aqueous leaf extract of CIAgNPs exhibits a size range from 18.79 to 41.18 nm, as shown in figure 3B. Fig. 3A. SEM image of CIAgNPs. Fig. 3B. SEM image of CIAgNPs.

X-ray diffraction (XRD) analysis of CIAgNPs

For characterizing the structure of crystalline metallic nanoparticles, X-ray diffraction (XRD) show in Figure 4. Its deep-penetrating, intense X-rays disclose bulk structural features in a unique way. The X-ray diffraction (XRD) analysis of the sample unveiled the presence of four well-defined peaks, clearly discernible on the XRD diffractogram with corresponding 2θ values of 38.216°, 44.419°, 64.567° and 77.527°. The planes are represented by the appropriate (hkl) values (111), (200), (220) and (311) as shown in Figure 4. The above value shows that the sample is crystalline and may be attributed to face-centered cubic lattices. The Scherrer formula was used to calculate the average crystallite size of RC-SNPs associated with the strongest diffraction peak.

$$D=\frac{0.9\,\lambda}{\beta cos\theta}$$

In this context, λ signifies the wavelength of the X-ray radiation utilized in XRD analysis, whereas β indicates the complete breadth of the diffraction peak assessed at half of its maximum intensity. The average crystallite size of the CIAgNPs was found to be approximately 25 nm. The findings align with previous reports on plant-derived AgNPs, where broad XRD peaks were typically detected, signifying their nanocrystalline characteristics [28].

Energy-dispersive X-ray spectroscopy (EDS)

To determine and measure the elements present in the specific sample EDS analysis Shown in Figure 5.The EDX examination of *Combretum indicum* AgNPs leaf extract indicated a higher concentration of the Ag element at 3keV because of the surface plasmon resonance absorption band and also has a strong peak of O and C due to the biomolecule of plant extract. The emergence of carbon, Si, S, P, Cl signals can be ascribed to the grid material employed during analysis. The calcium peak observed in the EDS spectrum originates from prismatic calcium oxalate crystals inherently found in the dried leaf powder of the collected plant material [28].

Biological Activity of CIAgNPs

This work carefully examined the cytotoxic effects of silver nanoparticles produced from *Combretum indicum* on PBMCs and MCF-7 cells, as well as their anticancer, anti-metastatic, antioxidant, and antibacterial properties. The cytotoxic and anticancer effects were tested using XTT, SRB, scratch assay, and morphological analysis, while oxidative stress regulation was assessed by LPO/MDA, GSH, SOD, catalase, and DPPH Assay. XRD analysis of CIAgNPs (Fig 4). EDS analysis of CIAgNPs (Fig.5).

Result of cytotoxicity assay of CIAgNP in PBMCs

As shown in **Figure 6** *Combretum indicum* extract demonstrated as biocompatibility with minimum cytotoxicity in PBMCs, suggesting moderate safety at lower concentrations but requiring caution at higher dose. Cytotoxicity assessment of *Combretum indicum* silver *nanoparticles* on PBMCs with LD_{50} estimation. Bar graphs show the percent viability of PBMCs treated with increasing concentrations (6–100 μg/mL) of *Combretum indicum* silver nanoparticles for 24 hours. The LD_{50} values were found to be 467.28 μg/mL for *Combretum indicum* silver nanoparticles. *Combretum indicum* silver nanoparticles showed moderate toxicity, characterized by a relatively low LD_{50}, indicating acceptable safety at low concentrations, while caution is advised at higher doses. Fig. 6 A. Bar Graphs show cytotoxic analysis of CIAgNP on PBMCs at different concentrations (6–100 μg/mL). Fig 6 B. Shows linear regression plots of CIAgNP.

Anticancer activity of *Combretum indicum* Silver Nanoparticle (CIAgNP) in MCF cells: Figure 7 shows control cells exhibited a strong, spindle-shaped morphology with elevated cell density, while *Combretum indicum* Silver *Nanoparticle (*CIAgNP) -treated cells demonstrated pronounced dose-dependent cytotoxicity, characterized by morphological distortion, cellular shrinkage, and detachment, especially at concentrations ≥25 μg/mL, thereby affirming their dose-dependent anticancer efficacy. Fig. 7*: Cytotoxic effects of Combretum indicum* silver *nanoparticles on MCF7 cells. MCF7* cells were treated with different concentrations (6, 12.5, 25, 50, and 100 μg/mL) for 48 hours.

Control (Untreated cells). The cytotoxic potential of *Combretum indicum* silver *nanoparticles* was evaluated against MCF-7 breast cancer cells using the Sulphorhodamine B (SRB) assay. As shown in Figure 4- *Combretum indicum* silver *nanoparticle (*CIAgNP) showed a clear dose-dependent inhibition of MCF-7 cell growth. The cytotoxic effect of *Combretum indicum* silver *nanoparticle (*CIAgNP) increased progressively with concentration, reaching its peak at 100 µg/ml. To quantify the potency of the treatments, EC_{50} values were calculated using linear regression analysis. As seen in fig 4b, the linear regression plot for *Combretum indicum* silver *nanoparticle (*CIAgNP) show a strong positive correlation between concentration and % inhibition ($y = 0.3459x$, $R^2 = 0.8356$), with an estimated IC_{50}value of 144.55 µg/mL. These results demonstrated that nanoparticle formulation *Combretum indicum* silver *nanoparticle (*CIAgNP) is a promising candidate for further investigation in cancer therapy. Fig. 7 (A) Percentage inhibition of MCF-7 cell growth following treatment with various concentrations (6, 12.5, 25, 50, and 100 µg/mL) of *Combretum indicum* silver nanoparticle formulation (CIAgNP), assessed via the SRB assay. Data are represented as mean ± SD. (B) Linear regression for CIAgNP reveals a dose-dependent inhibition with the equation $y = 0.3459x$, $R^2 = 0.8356$, and an EC_{50} value of 144.55µg/mL. **P < 0.05 compared to respective control (for a)*. The Selectivity Index (SI) was calculated to determine the preferential cytotoxicity of the nanoparticle toward cancerous cells over normal cells. This was done using the LC_{50} value for the normal PBMC cell line and the EC_{50} value for the MCF-7 cancer cell line, following the protocol described by Bułakowska *et al*. (2023).

The Selectivity Index (SI) [38] was calculated to determine their selectivity toward cancer cells.
SI = LC_{50} (PBMC cells) / IC_{50}(MCF-7 cells).
CIAgNP showed an LC_{50} of 467.28 µg/mL for PBMC and an IC_{50} of 144.55 µg/mL for MCF-7 cells, yielding an SI of 3.23. This value surpasses the threshold of 2, suggesting that CIAgNP demonstrates potential selectivity toward cancer cells and may be considered a potential anticancer agent. These findings further reinforce the utility of SI as a valuable metric for identifying compounds with selective cytotoxicity toward cancer cells. Table 1: The selectivity index values in relation to MCF-7 cells for CIAgNP. *Note:* SI > 2 indicates potential selectivity toward cancer cells; SI > 10 is often considered very promising for further development.

Result of Anti-metastasis activity of Arjuna and CIAGNP on MCF cells
Scratch assay is a wound healing assay used to evaluate cell migration and assess the anti-metastatic potential of compounds in vitro [39]. The scratch assay image shows the effect of *Combretum indicum* silver *nanoparticle (*CIAgNP)on the migration of MCF-7 breast cancer cells over 0, 24, and 48 hours (Figure 8). In the untreated control group, significant cell migration was observed, with the scratch area nearly closing by 48 hours, indicating active wound healing and cellular motility. In contrast, CIAgNP-treated groups exhibited a concentration-dependent reduction in wound closure. At the lowest concentration (6 µg/ml), partial inhibition of cell migration was evident, with slower closure of the scratch area compared to control. As the concentration increased (12.5 µg/ml and 25 µg/ml), further suppression of migration was observed, with notable gaps remaining at 48 hours. At higher concentrations (50 µg/ml and 100 µg/ml), the wound area showed minimal or no closure, suggesting strong inhibition of cell motility. Overall, increasing CIAgNP Concentrations progressively reduced the ability of MCF-7 cells to migrate and fill the wound gap. The inhibition of wound healing by CIAgNP highlights its role in impairing cellular motility, a key feature involved in cancer invasion and progression. These findings suggest that CIAgNP possesses anti-migratory properties and may serve as a potential therapeutic agent to restrict breast cancer metastasis. Fig.8: Scratch assay showing the effect of CIAgNP on MCF-7 cell migration over 0, 24, and 48 hours. Cells were treated with increasing concentrations of CIAgNP (6, 12.5, 25, 50, and 100 µg/ml). Dotted lines represent the scratch margins at 0 hours. Images were captured at 0, 24, and 48 hours to monitor cell migration into the wound area. The DPPH assay results presented in Figure 9 demonstrate the antioxidant potential of CIAgNPs in comparison to ascorbic acid (AA), a well-established standard antioxidant. The figure includes visual evidence of color change in the test tubes and a bar graph showing absorbance (OD) at 570 nm, which inversely correlates with antioxidant activity lower OD values indicate higher free radical scavenging activity. The deep purple color of the DPPH control reflects high absorbance and minimal radical scavenging. Ascorbic acid exhibits a pronounced reduction in absorbance, approaching zero, confirming its strong antioxidant efficacy. CIAgNPs also shows a clear decrease in DPPH absorbance compared to the control, indicating notable free radical scavenging activity, although its effect is

lower than that of ascorbic acid. Overall, the results confirm that CIAgNPs possesses significant antioxidant potential, while ascorbic acid remains the most effective antioxidant among the tested samples. Antioxidant activity of CIAgNP by DPPH Assay (Fig.9).

Result of antioxidant activity of CIAgNP against MCF7 using LPO/MDA, GSH, SOD, Catalase and DPPH Assay respectively : LPO/MDA, GSH, SOD, and Catalase assays assess oxidative stress and antioxidant defense status in cells by measuring lipid peroxidation, glutathione levels, superoxide dismutase, and catalase activity, respectively [40,41,42].After CIAgNP treatment, lipid peroxidation, measured by MDA levels (Figure 10a), showed a concentration-dependent decrease, indicating a more effective reduction of Oxidative stress. Glutathione (GSH) levels (Figure 10b) in CIAgNP -treated cells exhibited relative stability at lower dosages (6 and 12.5 μg/mL) and shown no significant alteration at elevated concentrations, suggesting negligible modification of GSH by CIAgNP. The activity of superoxide dismutase (SOD) (Figure 10c) significantly increased in CIAgNP -treated cells starting at 12.5 μg/mL and continued to elevate at higher concentrations, signifying a notable rise of antioxidant defense. Catalase activity (Figure 10d) remained rather stable throughout concentrations, with CIAgNP consistently demonstrating marginally greater activity, indicating a minor advantage in hydrogen peroxide detoxification. In summary CIAgNP has significant antioxidant potential by increasing essential antioxidant enzymes, notably SOD and catalase, and by efficiently lowering oxidative stress, as indicated by reduced MDA levels, reflecting a strong antioxidant response across the evaluated concentration.

CONCLUSION

This study demonstrated that the nanoparticle formulation CIAgNP possesses notable biocompatibility at lower concentrations while exhibiting clear, dose-dependent cytotoxic effects against MCF-7 breast cancer cells. CIAgNP showed selective anticancer activity, reflected by a favorable selectivity index (SI = 3.23), indicating preferential toxicity toward cancer cells over normal PBMCs. In vitro migration (scratch) assays confirmed that CIAgNP effectively inhibited cancer cell migration in a concentration-dependent manner, highlighting its strong anti-metastatic potential. Antioxidant evaluations revealed that CIAgNP significantly reduced lipid peroxidation and enhanced endogenous antioxidant defenses, particularly superoxide dismutase and catalase activities, supporting its role in mitigating oxidative stress. Additionally, CIAgNP exhibited substantial antibacterial activity against both *Escherichia coli* and *Staphylococcus aureus*, confirming its broad-spectrum antimicrobial potential. Overall, these findings position CIAgNP as a promising multifunctional nanomaterial with selective anticancer, anti-metastatic, antioxidant, and antibacterial properties. Further mechanistic investigations and comprehensive biosafety assessments are strongly warranted to support its future therapeutic development. Antioxidant activity of CIAgNP against MCF7 using a. LPO/MDA, b. GSH, c. SOD, d. Catalase (Fig. 10).

ACKNOWLEDGMENT

The authors extend their deepest gratitude to the Principal of Dr. Ambedkar College, Nagpur, and Dr. Utpal Dongre, Head of the Department of Biochemistry, for facilitating the requisite laboratory facility for this research. Profound gratitude is expressed to Ph.D. supervisor Dr. Bhuwaneshwari Mehere for her unwavering technical supervision and moral support. The authors express gratitude to Dr. Vishal Deshmukh of Jagadamba Mahavidyalaya, Achalpur, for his significant support in selecting the research plant and for his ongoing academic support. Gratitude is expressed to the Botanical Survey of India, Western Regional Centre, Pune, for verifying the plant material. The authors express gratitude to STIC, Kochi, Kerala, for supplying instrumental facilities for XRD, SEM, TEM, and FTIR characterisation investigations.

CONFLICTS OF INTEREST

The authors declare no conflict of interest

ABSTRACT

Mobile Ad hoc Networks (MANETs) are decentralized, infrastructure-less wireless networks characterized by dynamic topology, limited bandwidth, and resource constraints. Due to their open medium and lack of centralized control, MANETs are highly vulnerable to various security threats such as black hole, wormhole, Sybil, and Distributed Denial of Service (DDoS) attacks. Traditional intrusion detection systems (IDS) based on signature or rule-based mechanisms often fail to detect evolving and unknown attack patterns in highly dynamic MANET environments. This research proposes a deep learning-based intrusion detection framework designed to enhance security and resilience in MANETs. The framework utilizes a hybrid deep neural network architecture combining Convolutional Neural Networks (CNN) for spatial feature extraction and Long Short-Term Memory (LSTM) networks for temporal traffic pattern analysis. Network traffic parameters such as packet delivery ratio, routing overhead, node mobility, delay, and throughput are used as input features for training and classification. The proposed model is trained and evaluated using simulated MANET datasets generated through NS-3 under varying node densities and mobility scenarios. Experimental results demonstrate that the proposed deep learning framework achieves higher detection accuracy, reduced false positive rate, and improved detection speed compared to traditional machine learning approaches such as SVM and Random Forest. The system also maintains energy efficiency, making it suitable for resource-constrained MANET nodes. The findings indicate that deep learning-based IDS can significantly strengthen MANET security while adapting to dynamic network conditions.

Keywords : Mobile Ad hoc Networks (MANET), Intrusion Detection System (IDS), Deep Learning, Convolutional Neural Network (CNN), Long Short-Term Memory (LSTM), Network Security, Anomaly Detection, Black Hole Attack, Wormhole Attack, Distributed Denial of Service (DDoS), Energy-Efficient Routing, NS-3 Simulation.

INTRODUCTION

Mobile Ad-hoc Networks (MANETs) are decentralized wireless networks where mobile nodes communicate with each other without relying on fixed infrastructure such as routers or access points. In MANET environments, nodes dynamically join or leave the network, and each node acts both as a host and as a router that forwards data packets to other nodes. Due to their flexibility, self-configuring nature, and ease of deployment, MANETs are widely used in applications such as military communication, disaster recovery operations, emergency response systems, and temporary network setups. However, the open and dynamic nature of MANETs makes them highly vulnerable to various security threats and attacks. Since there is no centralized authority to monitor network activities, malicious nodes can easily disrupt communication by launching attacks such as black hole attacks, wormhole attacks, denial of service (DoS), and packet dropping attacks. These attacks can significantly degrade network performance by reducing packet delivery ratio, increasing delay, and consuming network resources. Therefore, ensuring security in MANETs has become a major challenge for researchers. Intrusion Detection Systems (IDS) play a crucial role in enhancing network security by monitoring network traffic and identifying malicious activities. Traditional intrusion detection techniques often rely on rule-based or signature-based methods, which may not effectively detect new or unknown attacks in dynamic MANET environments.

Objectives of the Study

The main objectives of this research are:

1. To analyze security vulnerabilities and attack patterns in dynamic MANET environments.
2. To design a deep learning-based intrusion detection framework capable of identifying multiple network attacks.
3. To develop a hybrid CNN-LSTM model for capturing both spatial and temporal traffic patterns.
4. To minimize false positive rate and detection delay in comparison with traditional ML techniques.
5. To ensure energy efficiency and low computational overhead suitable for resource-constrained MANET nodes.
6. To evaluate the proposed framework under varying node densities and mobility scenarios using simulation tools.

REVIEW OF LITERATURE

Security in Mobile Ad-hoc Networks (MANETs) has been an important research area due to the decentralized and dynamic nature of these networks. Conti, Giordano, and Stojmenovic (2014) discussed the evolution, milestones, and challenges of MANET technology and emphasized the need for improved security mechanisms to protect communication among mobile nodes. Similarly, Buttyán and Hubaux (2007) analyzed security and cooperation mechanisms in wireless networks and highlighted the importance of trust management and intrusion detection systems in decentralized network environments. Traditional intrusion detection systems mainly rely on signature-based and anomaly-based techniques. Garcia-Teodoro et al. (2009) presented a comprehensive study on anomaly-based network intrusion detection techniques and identified their advantages in detecting unknown attacks. However, these traditional methods often suffer from limitations such as high false positive rates and difficulty in detecting complex attack patterns in dynamic network environments.

With the advancement of artificial intelligence, deep learning techniques have gained significant attention in cybersecurity applications. LeCun, Bengio, and Hinton (2015) demonstrated that deep learning models can automatically learn hierarchical features from large datasets, making them suitable for complex pattern recognition tasks. These capabilities have encouraged researchers to apply deep learning approaches to intrusion detection systems for improved accuracy and adaptability. Several recent studies have focused on applying deep learning models to network intrusion detection. Abbood, Atilla, and Aydin (2023) proposed a deep learning-based intrusion detection system specifically designed for routing in MANET networks, showing improved detection accuracy compared with traditional machine learning methods. Similarly, Awajan (2023) developed a deep learning-based intrusion detection framework for IoT networks, demonstrating the ability of deep neural networks to identify

abnormal traffic patterns effectively. Further advancements have been made in hybrid deep learning architectures. Du, Guo, and Zhang (2024) introduced an intrusion detection model that integrates Convolutional Neural Networks (CNN) with advanced architectures such as Vision Transformers to improve feature extraction and classification performance. In addition, Wu, Zou, and Cao (2024) analyzed the current status and challenges of deep learning-based intrusion detection models and emphasized the need for more efficient and scalable solutions for real-time network security.

Survey-based studies have also provided insights into the development of intrusion detection systems. Ramathilagam et al. (2024) presented a comprehensive survey of deep learning-based intrusion detection and prevention systems, highlighting the effectiveness of neural network architectures in detecting modern cyber threats. Similarly, Datta (2024) discussed next-generation network intrusion detection systems and explained how deep learning techniques can improve threat detection in complex network environments. Recent research has also explored advanced distributed learning methods for intrusion detection in MANETs. Joseph, Ranjani, and Suresh Kumar (2025) proposed a federated deep learning-based intrusion detection system capable of detecting multiple types of attacks in MANET environments while preserving data privacy. Additionally, Zhang, Muniyandi, and Qamar (2025) provided a comprehensive review of deep learning applications in intrusion detection systems and highlighted the potential of hybrid models combining multiple neural network architectures.

The application of artificial intelligence in MANET security has also been emphasized in recent work. The study "Enhancing MANET Security Using AI-Driven Intrusion Detection Systems" (2025) discussed the role of AI-driven techniques in improving detection accuracy, reducing false alarms, and strengthening network resilience against attacks. Supporting these studies, Network Simulator Project (2023) provides the NS-3 simulation platform, which is widely used for modeling MANET environments and evaluating network performance under various attack scenarios.Overall, the literature indicates that while traditional intrusion detection techniques provide a basic level of protection, they are often insufficient for handling the complex and evolving threats in MANET environments. Deep learning-based approaches, particularly hybrid and distributed models, offer promising solutions for improving detection accuracy, scalability, and adaptability. Therefore, this research focuses on developing an efficient deep learning-based intrusion detection framework to enhance security in MANET networks.

Problem Statement

Mobile Ad hoc Networks (MANETs) operate without fixed infrastructure and centralized administration, making them highly flexible but inherently vulnerable to security threats. The dynamic topology, frequent node mobility, limited bandwidth, and energy constraints create significant challenges in ensuring secure and reliable communication. Due to the open wireless medium and cooperative routing mechanism, MANETs are highly susceptible to various attacks such as black hole, wormhole, Sybil, flooding, and Distributed Denial of Service (DDoS) attacks.

Traditional intrusion detection systems (IDS) in MANETs rely on signature-based or rule-based mechanisms, which are limited in detecting unknown, evolving, and complex attack patterns. Conventional machine learning approaches improve detection accuracy but often fail to capture temporal traffic behavior and dynamic network variations effectively. Additionally, many existing solutions introduce high computational overhead, making them unsuitable for resource-constrained MANET nodes.

PROPOSED METHODOLOGY

The proposed deep learning-based intrusion detection framework for secure MANET environments is implemented through several systematic phases. In the first phase, data collection is performed by simulating a Mobile Ad-hoc Network (MANET) using the NS-3 network simulator. In the second phase, the collected data undergoes preprocessing to improve the quality and reliability of the dataset.

The third phase involves model development using a hybrid deep learning architecture. A Convolutional Neural Network (CNN) layer is employed to extract spatial features from the network traffic data, enabling the system to identify important patterns related to intrusion behavior. In the fourth phase, the developed model is trained and tested using the prepared dataset. Typically, 70–80% of the dataset is used for training the model, allowing it to learn patterns from the data, while the remaining portion is used for testing. Cross-validation techniques are also applied to ensure the reliability and robustness of the model. In the final phase, performance evaluation is conducted to assess the effectiveness of the proposed intrusion detection framework. Various evaluation metrics are used, including accuracy, precision, recall, and F1-score to measure detection performance.

Network Simulation Environment

To evaluate the proposed intrusion detection framework, a Mobile Ad Hoc Network (MANET) environment was simulated using the **NS-3 network simulator**. The simulation was configured to represent realistic dynamic network conditions with varying node density and mobility patterns.

Multiple simulation runs were conducted under normal and attack scenarios to generate labeled datasets.

Dataset Generation and Feature Extraction

Network traffic traces were collected from NS-3 simulations and converted into structured datasets for analysis. In this dataset, each record represents an individual network traffic instance and is labeled as either Normal or Attack, allowing the system to distinguish between legitimate and malicious activities within the network environment. Several important performance and traffic-related features were extracted from the collected data to support effective analysis and classification. These features include Packet Delivery Ratio (PDR), End-to-End Delay, Throughput, Packet Loss Rate, Routing Overhead, Hop Count, Node Mobility Speed, Residual Energy, and the Number of Route Requests (RREQ)**.** These parameters represent key aspects of network performance and routing behavior in Mobile Ad hoc Networks (MANETs). To improve the efficiency and accuracy of the analysis, a correlation-based feature selection technique was applied. This method evaluates the relationship between features and removes redundant or highly correlated attributes, ensuring that only the most relevant features are retained for further processing and model training.

Data Preprocessing

Before training the model, the collected dataset was subjected to several preprocessing steps to ensure data quality and improve the performance of the learning algorithms. First, data cleaning was performed to remove incomplete, inconsistent, or corrupted entries that could negatively affect the analysis. This step helped ensure that only reliable and valid records were used for further processing.

Next, normalization was applied using the Min–Max scaling technique, which transforms all feature values into a uniform range between 0 and 1**.** This process helps maintain consistency among features with different scales and improves the efficiency of machine learning algorithms during training. After normalization, label encoding was carried out to convert categorical class labels into numerical form. In this study, a binary encoding scheme was used where 0 represents Normal traffic and 1 represents Attack traffic**.** Finally, the processed dataset was divided into different subsets for model development and evaluation. The dataset was split into 70% training data**,** 15% validation data**,** and 15% testing data, ensuring that the model could be effectively trained, tuned, and evaluated for performance.

RESULTS AND DISCUSSION

Table 1. Basic characteristics of different machine learning algorithms

The table presents a comparative analysis of five algorithms: **SVM, Random Forest, ANN, LSTM, and the proposed CNN-LSTM model** based on several performance factors such as accuracy, false positive rate, temporal learning capability, energy efficiency, and computational complexity.

- **SVM (Support Vector Machine)** shows moderate accuracy but suffers from a **high false positive rate**, which may incorrectly classify normal network traffic as attacks. However, it has **low complexity**, making it computationally simpler.
- **Random Forest** improves detection accuracy compared to SVM and provides a **moderate false positive rate**, but it lacks temporal learning ability because it does not analyze sequential data patterns.
- **ANN (Artificial Neural Network)** achieves higher accuracy than SVM and Random Forest but requires **high computational complexity**, which may increase resource usage in mobile networks.
- **LSTM (Long Short-Term Memory)** is designed to handle **temporal or sequential data**, making it more suitable for detecting evolving attack patterns. It provides **very high accuracy and a low false positive rate**.
- The **proposed CNN-LSTM model** combines the strengths of **CNN for feature extraction and LSTM for temporal learning,** resulting in **very high accuracy, very low false positive rate, improved energy efficiency, and optimized complexity.**

Table 2. Intrusion detection performance.

The table compares the algorithms using **Accuracy, Precision, Recall, F1-Score, and False Positive Rate**.

- **SVM** achieves an accuracy of **87.4%**, which is the lowest among the compared methods. Its higher false positive rate (8.6%) indicates less reliable detection.
- **Random Forest** improves performance with **91.8% accuracy**, better precision, and a reduced false positive rate.
- **ANN** further increases detection performance, achieving **93.2% accuracy** and improved precision and recall.
- **LSTM** demonstrates strong performance with **95.6% accuracy**, benefiting from its ability to analyze sequential network traffic patterns.
- The **proposed CNN-LSTM model achieves the highest accuracy of 97.8%**, along with **high precision (97.1%), recall (96.9%), and F1-score (97%)**, while maintaining the **lowest false positive rate (2.3%)**.

These results indicate that the proposed hybrid deep learning model provides **more reliable intrusion detection compared to traditional machine learning techniques**.

Network Performance Metrics

3. overall network performance each algorithm.

The performance of the algorithms is analyzed using **Packet Delivery Ratio (PDR), End-to-End Delay, Throughput, and Routing Overhead**.

- **SVM** has the lowest network performance with **82.5% packet delivery ratio and higher delay (210 ms)**, indicating inefficient detection and recovery during attacks.
- **Random Forest** improves network stability, increasing the **packet delivery ratio to 86.7%** and reducing delay.
- **ANN** further enhances network performance with **88.3% PDR and lower delay**.
- **LSTM** provides better results with **91.5% PDR and improved throughput**, due to more accurate detection of malicious traffic.
- The **proposed CNN-LSTM model achieves the best network performance**, with **94.8% packet delivery ratio, lowest delay (145 ms), highest throughput (820 kbps), and lowest routing overhead (9%)**.

This demonstrates that **accurate intrusion detection helps maintain network stability and improves communication efficiency in MANET environments**.

Energy & Computational Efficiency Analysis

Table 6.4 Energy consumption and computational efficiency of the algorithms.

The comparison includes **energy consumption per node, detection time, model complexity, and scalability**.

- **SVM** consumes **1.85 J energy per node** and has the fastest detection time due to its low complexity, but its detection accuracy is limited.

- **Random Forest** and **ANN** consume more energy and require higher computational resources.
- **LSTM** provides improved detection but still has **high complexity**, which may affect resource-constrained mobile networks.
- The **proposed CNN-LSTM model achieves the lowest energy consumption (1.74 J)** while maintaining high detection performance and scalability.

Although its detection time is slightly higher than SVM, the model provides a **better balance between energy efficiency, scalability, and detection accuracy**.

CONCLUSION

Mobile Ad hoc Networks (MANETs) are dynamic and infrastructure-less networks widely used in applications such as military communication, disaster management, and IoT environments. However, their decentralized architecture and frequent topology changes make them highly vulnerable to various security attacks. Traditional intrusion detection methods often fail to effectively detect complex and evolving threats in such networks.

This study proposed a **Deep Learning-Based Intrusion Detection Framework** using a hybrid **CNN-LSTM architecture** to enhance MANET security. The model analyzes important network parameters such as packet delivery ratio, delay, throughput, routing overhead, and packet loss rate to accurately identify malicious activities. Experimental results show that the proposed framework performs better than conventional machine learning methods like **SVM and Random Forest**, achieving high detection accuracy (around **97%**) with reduced false positive rates. The system also maintains energy efficiency, making it suitable for resource-constrained MANET environments. Overall, the integration of deep learning techniques improves the **security, reliability, and scalability** of MANET systems and provides an effective solution for protecting dynamic wireless networks.

Future Scope

Future research can further enhance the proposed framework by exploring several advanced technologies and deployment strategies. One possible extension is the incorporation of **federated learning**, which allows distributed model training across multiple nodes without requiring centralized data sharing, thereby improving privacy and scalability. Another promising direction is the integration of **blockchain-based trust management mechanisms** to ensure secure and reliable routing decisions among network nodes. Additionally, the framework can be deployed and evaluated in **real-time large-scale MANET testbeds** to assess its performance under practical network conditions. Future studies may also explore **lightweight transformer-based deep learning architectures** to improve detection accuracy while reducing computational complexity and energy consumption. Furthermore, the proposed model can be extended to emerging networking environments such as **UAV-assisted networks and 5G/6G-enabled MANET scenarios**, where secure and efficient communication is essential.

ABSTRACT

Human longevity has increasingly been challenged by age-related cerebrovascular and cardiovascular disorders, often linked to modern sedentary and stress-driven lifestyles. Traditional health systems emphasized postural and lifestyle practices aimed at maintaining physiological balance and long-term vitality. This conceptual paper explores the hypothesis that prolonged exposure to gravitational forces in predominantly upright postures may contribute to age-associated reductions in cerebral blood flow, thereby increasing susceptibility to conditions such as cerebral ischemia, haemorrhage, and cardiovascular events. In contemporary life, individuals typically remain in standing or seated upright positions for extended periods each day, during which gravity continuously opposes blood flow from the heart to the brain. While younger individuals generally compensate for this effect due to vascular elasticity and cardiac efficiency, advancing age is associated with arterial stiffening and reduced cardiovascular reserve, potentially exacerbating cerebral hypoperfusion. Ancient Ayurvedic and yogic traditions describe *Sirsasana* (headstand) as a restorative inverted posture intended to temporarily counter gravitational stress and enhance cerebral circulation. In parallel, modern biomedical advancements have introduced wearable technologies capable of monitoring cerebral blood flow in real time, including temple-based sensors designed to detect changes in superficial cerebral arterial circulation. This paper conceptually compares *Sirsasana* as an active physiological intervention with temple-based cerebral flow sensors as passive diagnostic tools. While the sensor provides continuous surveillance and early warning of circulatory alterations, *Sirsasana* may serve as a non-pharmacological approach to transiently modulate cerebral perfusion. The integration of ancient postural practices with modern cerebral monitoring technologies may represent a complementary strategy for promoting brain health, mitigating age-related cerebrovascular risk, and supporting healthy longevity. Further

experimental and clinical studies are required to validate this hypothesis and to quantify the effects of gravity modulation on cerebral blood flow and ageing physiology.

Keywords: Longevity and gravity; Cerebral blood flow; *Sirsasana*; Temple-based cerebral sensors; Ageing physiology; Holistic health practices; Modern lifestyle

INTRODUCTION

Human longevity has drastically changed and challenging by age-initiated cerebrovascular and cardiovascular disorders, often linked to modern sedentary and stress driven lifestyle. Ancient health system supported postural and lifestyle practises aimed to maintaining a quality driven physiological balance among body coordination and long-term viability. This conceptual paper explores the hypothesis that prolonged exposure to the gravitational forces in predominantly upright postures may contribute to age associated reductions I cerebral blood flow thereby increasing susceptibility to condition such as cerebral ischemia, haemorrhages and cardiovascular events. In contemporary life individuals typically remains in standing or seated upright positions with hanging legs for extended periods each day, during which gravity continuously opposes blood flow from elasticity and cardiac efficiency, advancing age is associated with arterial stiffening and reduced cardiovascular reverse, potentially exacerbating cerebral hypoperfusion ancient ayurvedic and yogic tradition describe Sirs asana(headstand) as a restorative inverted posture intended to temporarily counter gravitational stress and enhance cerebral circulation. In parallel modern biomedical advancements have introduced rear able technologies capable of monitoring cerebral blood flow in real time including temple-based sensor designed to detect changes in superficial cerebral arterial circulation this paper compares sir's asana as an active physiological intervention with temple- based cerebral flow sensors as passive diagnostic tools. While the sensor provides continuous surveillance and early warning of circulatory alteration, sirs asana nay serves as a non-pharmacological approach to transiently modulate cerebral perfusion the integration of ancient postural practices with modern cerebral monitoring technologies may represent a complementary strategy for promoting brain health, mitigating age related cerebrovascular risk, supporting healthy longevity. Further experimental and clinical studies are required to validate this hypothesis and to qualify the effects of gravity modulation on cerebral blood flow and ageing physiology.[1,2]

Age related cerebrovascular decline is multifaced process characterized by progressive changes in vascular structure and function leading to impaired cerebral blood flow (CBF) and increased vulnerability to cognitive impairment and neurodegenerative diseases. Key physiological alteration includes vascular inflammation, endothelial dysfunction, arterial stiffening and reduced vasodilatory capacity which collectively contribute to chronic hyper perfusion. These changes begin early in adulthood and accelerate with age, often exacerbated by modern lifestyle factors such as sedentary behaviour, chronic stress, poor diet and obesity[3].

Sedentary habits, common in modern society encourage arterial rigidity and endothelial impairment decreasing brain blood flow and elevating oxidative stress research shows that extended periods of sitting are linked to decreased CBF and an increased risk of cognitive decline regardless of physical activity levels. Chronic stress exacerbates this by stimulating the sympathetic nervous system, resulting in vasoconstriction and high blood pressure, which hinder cerebrovascular autoregulation. Nutritional elements such as elevated fat consumption play a role in arthrosclerosis and microvascular reduction restricting oxygen supply to brain tissue[4].

Epidemiological data connect these elements to a higher prevalence of vascular cognitive impairment and dementia. For example, hypertension and obesity in midlife are linked to cerebral hypoperfusion and neurodegenerative in later life. Aerobic exercise and caloric restriction can alleviate these effects by enhancing vascular elasticity and decreasing inflammation. Grasping this interaction is vital for formulating approaches to maintain cerebrovascular health in older population[5].

The role of gravity in daily postural physiology and cerebral perfusion

Gravity exerts a constant influence on human physiology, particularly in upright position, where it creates hydrostatic pressure gradients that challenge cerebral perfusion. In the standing position blood must be pumped against gravity, resulting in reduced venous return and cardiac output, which can decrease CBF by 14-21% compared to supine values. This gravitational stress is compounded by postural changes, where transitions from supine to upright reduce central venous provoke compensatory mechanism like baroreflex activation.[6] Daily activities predominantly involve upright postures leading to chronic opposition of blood flow to the brain. Hydrostatic gradients cause blood pooling in lower extremities, increasing peripheral resistance and potentially inducing orthostatic hypotension in autoregulation fails. Overtime this may contribute to microvascular damage and reduced oxygenation, especially in aging individuals with diminished vascular compliance. [7]

Cerebral autoregulation mitigates these effects by adjusting vascular resistance to maintain stable CBF across a range of perfusion pressures. However, prolonged gravitational exposure in sedentary lifestyle may overwhelm this mechanism leading to hypoperfusion and increased neurodegenerative risk [8]

Overview of traditional practices countering gravitational stress

Traditional yogic and ayurvedic practices, such as inversions (e.g. sirs asana) were designed to counteract gravitational stress by reversing hydrostatic gradients and enhancing cerebral circulation. These postures temporarily invert the body promoting venous return and reducing lower extremities which may alleviate chronic hypertension[9]. Inversion like shoulderstand and headstand stimulate blood flow to the upper body, potentially improving oxygenation and reducing stress on the cardiovascular system. Historical texts such as Hath yoga Pradipika, describe these asanas as rejuvenating, enhancing vitality and balancing prana. Practices like Viparita Karani emphasize gravitational reversal for therapeutic benefits, including improved digestion and mental clarity.[10]. Modern interpretations suggest these interventions mitigates age related decline by promoting autonomic balance and reducing sympathetic overactivity.

Emergence of modern non- invasive cerebral monitoring technologies

Advancements in non-invasive cerebral blood flow monitoring has changed neurological assessment, enabling real time detection of perfusion changes. Techniques like speckle contrast optical spectroscopy (SCOS) offer high resolution wearable solution for continuous CBF measurement distinguishing scalp from brain signal ultrasound patches provide three-dimensional data on cerebral hemodynamic ideal for monitoring postural and age-related variations. Optical methods including near infrared spectroscopy allows for portable cost-effective tracking of microvascular flow. These technologies facility early detection of hypoperfusion in ageing population, supporting intervention for cerebrovascular health.[11]

Rationale and hypothesis of the paper

This paper hypothesis that chronic gravitational stress I upright postures contribute to age related cerebral perfusion, increasing neurodegenerative risk. Traditional inversions like sirsasana may counter this by reversing gradients, while modern wearables enable monitoring. Integrating these approaches could enhance brain health, warranting further research to quantify benefits.

Physiological effects of gravity on cerebral blood flow

Hydroststic pressure gradients in upright position

In the upright position gravity imposes a significant hydrostatic pressure gradient along the vascular column. The brain positioned approximately 25-35 cm above true heart in adults experiences a reduction in perfusion pressure due to this gradient. For the every 1 cm of vertical hight hydrostatic pressure decreases by about 0.77 mmHg in arterial blood and increases similarly in venous blood below the heart level. This results in a net decrease in cerebral perfusion pressure (CPP=MAP-ICP) of roughly 20-30 mmHg compared to supine posture. [12]. Blood pooling occurs in the compliant veins of the lower extremities and splanchnic circulation, reducing central venous pressure and venous return to the heart. The decreases stroke volume and cardiac output by 20-30% upon standing, further

challenging cerebral Blood flow CBF. Compensatory mechanism, including baroreflex-mediated vasoconstriction and increased heart rate, partially restore MAP but cerebral arteries must dilate to maintain flow. Prolonged upright posture in sedentary lifestyle amplifies these effects, contributing to chronic low-grade reduction in CBF.[13]

Cerebral autoregulation mechanism and their limitation with ageing

Cerebral autoregulation maintains relatively constant CBF (approximately 50ml/100g/min) over a MAP range of ~60-160 mmHg through myogenic, metabolic and neurogenic mechanism. Dynamic autoregulation responds to rapid chonmages, while static autoregulation handles sustained pressures[14]. Aging impairs autoregulation due to arterial stiffening, endothelial dysfunction, diminished vasodilatory reserve and altered ion channel function in vascular smooth muscle. Studies show that older adults exhibit higher gain in low frequency oscillations of CBF during challenges, indicating less effective damping of pressure fluctuation, while some research finds preserved dynamic autoregulation in healthy aging, others demonstrate reduced capacity during orthostatic stress or hypertensive stimuli, increasing vulnerability to hypoperfusion or hyperperfusion injury. Comorbidities like hypertension exacerbate this limitation, linking them to white matter lesions and congnitive decline.[15].

Evidence from Postural challenges (e.g. orthostates, head-up tilt, microgravity studies)

Head-up tilt test simulates orthostates, revealing CBF reduction of 10-20% in healthy individuals with greater drops in older adults due to impaired baroreflex and autoregulation. Orthostatic stress often provokes transient hypoperfusion, sometimes leading to presyncope. Microgravity studies show cephalad fluid shifts reducing ICP and increasing CBF initially but long-term exposure leads to orthostatic intolerance upon return to gravity. Hypegravity studied demonstrate stepwise CBF decrease with increasing G-forms despite stable gear level MAP due to amplified Hydroststic effects and reduced end tidal CO_2 .These models highlight gravity's role in modulating CBF: upright postures oppose flow, while inversion or microgravity reverses gradients. Age amplifies impairment during transitions with slower recovery in older subjects[16].

Long term implications: chronic hyoperfusion, Agenung and neurovegetative Risk

Chronic cerebral hypoperfusion CCH from prolonged upright/sedentary exposure promotes oxidative stress, blood-brain barrier disruption, inflammation, white matter rarefaction and amyloid pathology accumulation. Animal models of bilateral carotid occlusion mimic CCH, showing memory deflects, synaptic dysfunction, reduced O-GlcNAcylation and neurodegenerative resembling Alzheimer's disease and vascular cognitive impairment.[17] . In humans reduced CBF precedes cognitive decline and increases dementia risk, with midlife hypoperfusion linked to late-life neurodegeneration. CCH exacerbated AD pathology by impairing amyloid clearance and promoting vascular and promoting amyloid clearance and promoting vascular contributions to mixed dementia. Sedentary lifestyles compound these risks underscoring gravity's chronic opposition to CBF as a modifiable factor in brain ageing.[18]

Ancient yogic and Ayurvedic perspectives: sirs asana as a gravitational counter measure

Historical and textual description of sir's asana in Yoga and ayurveda

Sirsanana is extensively describes in classical Hatha yoga texts notable the hatha yoga Pradipika by swami swartmarma, where it is termed the king of asanas for its purported supremacy in rejuvenating the body and mind. The text outline the technique: the practitioner interlocks fingers, places the crown of the head on the ground between the hands, and lifts the body into full inversion with legs extended upward. Similar instructions appears in the Gherardi Samhita, emphasizing controlled entry and exit to avoid strain[19]. Ayurvedic literature, including the charka Samhita and sushruta Samhita (circa 100-600 BCE) inversion align with rasayana therapies aimed at enhancing ojas, balancing the tridosha and promoting longevity. Sirsasana is viewed as directing prana upward to the sahasrara chakra, nourishing the brain, eyes and sensory organ while countering the downward pull of gravity on bodily fluids and tissues. [20].

Traditional claims regarding cerebral circulation and vitality

Traditionally sources assert that Sirsasana dramatically enhances cerebral circulation by reversing gravitational drainage, flooding the brain with oxygenated blood, nutrient and prana. This is claimed to sharpen intellect, improve memory, concentration and mental clarity while alleviating condition like insomnia, fatigue, headaches and premature aging. It is said to stimulate the pineal and pituitary glands, balance hormones, detoxify the head region and rejuvenate the entire nervous system. Long term practice is linked to enhanced vitality, emotional stability and spiritual awakening, positioning sirsanana as a core practice for rasayana and anti-ageing.[21]

Physiological Rationale for inversion: reversal of hydrostatic gradients

From a modern physiological lens, inversion in Sirsasana reverses the upright hydrostatic pressure gradient. In standing posture, gravity creates a ~20-30 mmHg drop in cerebral perfusion pressure due to the brain's elevation above the heart. Inversion shifts thus: arterial inflow increases cranially while venous outflow is facilitated by gravity enhancing venous return from form the lower body and reducing pooling. Thus, transiently elevated cranial arterial pressure and promotes cerebral venous drainage via jugular veins and dural sinuses. Short duration practice ~1-5 min may improve nutrient, oxygen and waste clearance via glymphatic like mechanism countering chronic upright hypoperfusion.[22]

Potential Mechanism beyond simple perfusion (e.g. venous return, intracranial pressure modulation, Autonomic Balance

Beyond direct perfusion, inversions enhances venous return by compressing abdominal thoracic veins, increasing preload and cardiac output temporarily. Intracranial pressure may be modulated initial rise from arterial inflow is offset by improved venous drainage, potentially stabilizing or reducing net ICP over time. Autonomic effects include baroreceptors stimulation from elevated cranial pressure, triggering parasympathetic dominance, reduced sympathetic outflow, lower heart beat and blood pressure post practice. Additional mechanism involve neuroendocrine modulation, improved lymphatic drainage from the head or neck and enhanced proprioceptive feedback contributing to stress reduction, mood elevation and perceived vitality independent of sustained CBF increase.[23]

Modern evidence on inverted Postures and cerebral perfusion

Studies on Headstand (sirsasana) and cerebral blood flow

Key modern studies using transcranial doppler ultrasound on the internal carotid artery (ICA) during sirsasana contradict traditional perfusion claims. A prominent 2019 study measured ICA flow in 20 healthy participants (ages 10-59) and found no increase in cerebral blood flow instead peak systolic and diastolic velocities decreased significantly reducing arterial blood delivery to the brain. Vessel diameter remained stable and flow returned to baseline immediately post-inversion, attributed t intact cerebral autoregulation preventing hypoperfusion and increased ICP counteracting hydrostatic grains. Other Doppler and arterial spin labelling MRI studies on head-down position show variable CBF responses some report modest increases in specific regions, but overall autoregulation maintain near contrast global despite postural inversion[24,25]

Reconciling traditional claims with cerebral autoregulation findings

The discrepancy arises because cerebral autoregulation robust maintains CBF (~50ml/100g/min) across wide pressure ranges, overriding hydrostatic changes in healthy individuals. Traditional benefits – enhanced vitality, mental clarity, reduced stress- likely stem from secondary mechanism autonomic rebalancing (parasympathetic shift), reduced sympathetic tone, improved venous/lymphatic drainage, glymphatic clearance during relaxation phases, neuroendocrine effects and physiological factors (e.g. mindfulness, endorphin release). Perceived nourishment may reflect better oxygen extraction efficiency or original perfusion changes by global perfusion changes not captured by global ICA measures, rather than bulk CBF increases.[26,27]

Other inversion practices and related postural interventions

Sarvang asana, viparita karani and passive inversion tables show similar transient gradient reversal often with greater venous return benefits due to less cervical loading. Passive inversion may yield higher CBF increases (~20%) than active yoga inversion (~13%) as they avoid muscular effort that could alter CO_2 levels or autoregulation. Related intervention include tilt- table therapy and anti-gravity yoga which demonstrate improved orthostatic tolerance and reduced sympathetic activity in aging or sedentary population.[28]

Safety consideration and contraindications in modern contexts

Modern evidence highlights risks cervical spine loading peak forces 40-48% body weight, risking load in ~50% of individual, especially with poor techniques or pre-existing degeneration, elevating intraocular pressure (contraindicated in glaucoma/retinal issues), transient ICP spikes, baroreflex overstimulation, all fall risk. Absolute contradictions include uncontrolled hypertension, glaucoma, detached retina, recent strokes /TIA, cervical instability/osteoporosis, heart conditions pregnancy and sins/ear infection relative risks rise with age poor alignment or prolonged holds. Safety requires gradual progression, supervision, wall support, medical screening and avoidance in at risk groups modified inversion offer lower risk alternatives.[29]

Advances in wearable technologies for cerebral Blood flow monitoring

Overview of Non-invasive techniques

Recent innovation includes soft stretchable ultrasound patches providing continuous 3D CBF via Doppler at the temple. Speckle contrast optical spectroscopy uses laser light to measure microvascular flow and volumes with high temporal resolution distinguishing brain from scalp signals. These surpass traditional transcranial Doppler of fMRI by enabling ambulatory real time monitoring without technicians.[30]

Temple – based and wearable sensors: design, functionality and real time capabilities

Temple mounted devices use lase sources and CMOS detectors for non-invasive wireless operations ultrasound patches employ flexible arrays for velocity/ volume tracking with stretchable materials ensuring comfort during daily activities. Real time capabilities include high frequency sampling. Artifact rejection, and integration with apps for pattern analysis (e.g. postural changes, stress Reponses) [31]

Application in detecting postural, gravitational Nd age related perfusion changes

These warbles detect acute orthostatic drop gravity induced variations across postures and progressive autoregulation impairment in aging. They enable longitudinal tracking of sedentary effects, early hypoperfusion alerts and evaluation of interventions like inversion like inversions in real world settings.[32]

Comparison: passive monitoring vs active intervention

Passive sensors offer continuous surveillance, objective data and early warning user efforts ideal door diagnostics and trend analysis active interventions e.g. sirs asana provide modulation and holistic benefits but require practice and carry risks. Synergy arises when monitoring validates interventions effects, enabling personalized dosing (e.g. inversion duration based on real time CBF feedback).[33]

Bridging ancient practices and modern Monitoring – A conceptual intergation

Complementary roles- sirsasana as transient modulation vs sensor as continuous surveillance

Sirsana serves asana active short duration physiological intervention delivering transient reversal of hydrostatic gradients, enhanced venous return from lower extremities, baroreceptors stimulation and parasympathetic activation. These effects promote acute autonomic reset (e.g. reduced sympathetic tone, lower post- practice heart rate/ blood pressure) improved lymphatic/ glymphatic drainage and potential regional perfusion or oxygen extraction efficiency even if global IVA flow does not increase due to autoregulation. Benefits are primarily indirect-stress reduction neuroendocrine balance and subjective vitality- rather than sustained bulk CBF augmentation.[34]

In contrast temple based wearable sensors (e.g. soft ultrasound patches or SCOS headbands) enables passive, continuous surveillance over hours to days. US San Diego's 2024 stretchable ultrasound patch adheres to the temple,

providing real time 3D CBF velocity data via Doppler arrays detecting fluctuations fraipontites activity sleep or aging related autoregulation decline without requiring user intervention. SCOS system use laser speckle for high temporals resolution microvascular flow distinguishing brain from scalp signals wirelessly.[35] The synergy forms a closed loop biofeedback system sensors flag hypoperfusion episodes(e.g. prolonged upright drops > 10-25% or age related baseline decline) promoting timed inversion practice post inversion data quantifies acute modulation allowing iterative protocol

Potential synergistic application for brain health and longevity

Wearables could quantify and personalize inversion protocols- e.g. deterring optimal hold duration intensity based on real time CBF response or HRV correlates, or recommending passive inversion (legs-up-the-wall or supported tilt) which preliminary reports suggest may yield modest CBF gains (e.g. ~7-20% in some passive setup VS. active sir sansa). Longitudinal monitoring tracks cumulative effects pre/post yoga program changes in baseline CBF, autoregulation index during orthostatic challenges, or nocturnal recovery pattern linked to glymphatic clearance.[36]

Application include:-

Prevention brain heath- early detection of orthostasis intolerance or age related CBF decline guiding intervention before cognitive symptoms emerge

Bio feedback guided yoga- Apps integrating sensor data to coach safe practice, optimizing for individual autoregulation capacity

Longevity program- Tracking inversion frequency against aging biomarkers

Rehabilitation- Post stroke or orthostatic hypertension patients using monitored short inversion to tarin vascular reactivity

This integration shifts from anecdotal tradition to date driven personalization, potentially amplifying benefits chronic hypertension- linked decline

Addressing the Gravity- aging hypothesis in light of inversion and monitoring data

The gravity aging hypothesis posits that ~16 hours/day of upright posture imposes chronic low grade CBF reduction (10-20% below supine baseline, compounded by 20-40% lifetime loss from annual declines) preferentially affecting vulnerable regions like the hypothalamus, brainstem perforators and hippocampus with limited collateral flow. Thus under perfusion is hypothesized as an upstream driver of aging hallmarks mitochondrial dysfunction inflammation, impaired waste clearance sympathetic overdrive and systemic dysregulation , accelerating neurodegenerative independent of traditional CVD risks.[37]

Inversion data offers partial support while active sirs asana reduces ICA flow acutely passive inversion may provide transient gains or better venous drainage/ICP modulation long term PR actioners show preserved cerebrovascular elasticity and delayed vessel sing or imaging. Wearables monitoring provides critical testability- quantifying upright hypoperfusion burden inversion induced recovery kinetics and longitudinal trends in risk population.[38,39]

Data could validate or refute but measuring (a) cumulative daily CBF deflects vs inversion dose (b) regional flow in key aging hubs (c) correlation with cognitive/ motor decline or biomarker (amyloid, tau, inflammation). Rigorous RCTs are essential as current evidence is largely acute or anecdotal and autoregulation limits direct perfusion claims.[40,41]

Holistic vs Reductionist approaches in cerebrovascular health

Reductionist approaches wearables deliver precision quantifiable metrics (CBF velocity, volume, autoregulatory indices), objective endpoints for trails and personalized alerts aligning with biomedical paradigms emphasizing measurables. holistic approves (yogic inversion, ayurveda) integrate mind body autonomic balance breathwork mindfulness and lifestyle context yield emergent benefits (stress, sleep quality, adherence) beyond isolated CBF metrics. Traditional wisdom views gravity modulation as part of prana/dosha balance and Ramayana potentially enhancing neuroplasticity and vitality holistically[42,43]

Bridging fosters hybrid models tech validates selects elements of tradition pessimizes dosing and measures holistic outcomes this comprehensive framework respects cultural origins exile advancing evidence based prevention optimizing cerebrovascular resilience for health aging.[44,45]

DISCUSSION

Strengths and Limitations of Current Evidence

Strength include well established physiological models (hydrostatic gradients, autoregulation mechanism via myogenic/metabolic/neurogenic pathways), consistent postural challenge data (HUT, orthostatic showing 10-20% CBF drops amplifies in aging), and robust validation of emerging wearables (UCSD patch correlates with transcranial Doppler, SCOS differentiates signals accurately). Limitation; most inversion studies are acute, small- sample (n=20 for sir's asana), on healthy young/middle-aged adults, lacking long term or againg-psecific data. Global ICA measures may miss regional CBF changes passive vs active inversion differences are under explored. Wearable tech is recent, with limited real-world/longitudinal deployment. The gravity-aging hypothesis remains conceptual/provocative, integrating existing models but requiring direct casual evidence requiring direct casual evidence beyond correlations.

Gaps in research

Major gaps:-

Longitudinal RCTs- Chronic effects of regular inversion on CBF trajectories, infinitive function and neurodegeneration biomarker in adults>60

Aging population- Data on autoregulation- compromised elderly, those with hypertension. Our early MCI, safety/efficacy of modified inversion

Combined intervention- Yoga and wearable biofeedback trails measuring adherence, CBF changes and endpoints

Mechanistic studies- Regional CBF (MRI, fNIRSand wearables) glymphatic dynamics during intervention, dose response and comparison to other countermeasures.

Diversity – effects across sexes, ethnicities, comorbidities and cultural contexts

Clinical and Public Health Implications for Sedentary Lifestyles

In sedentary population (~16 hours upright) promoting accessible inversion (wall supported, 5-10 min daily) alongside wearable monitoring could mitigate hypoperfusion burden, potentially reducing vascular cognitive impairment, dementia risk and cardiovascular events. Clinical used: orthostatic screening, post-stroke rehab, hypertension adjunct or biofeedback for stress management. Public health scalable, low-cost interventions for workplaces/schools/eldercare policy integration into wellness program education on safe practice. In aging societies, thus hybrid strategy addresses modifiable gravity/lifestyle factors, complementing pharmacotherapy and exercise for broader cerebrovascular protection and healthier longevity

Ethical and Practical Considerations for Integrating Traditional Practices with Technology

Ethical: cultural origin of yogaayurveda- avoid appropriation by framing as evidence-informed rather than commodified biohacking. Ensure informed consent, data privacy (CBF metrics are sensitive neurological data) equitable access and avoidance of harm. Do not over medicalize spiritual practices

Practical: training for safe technique(props), device usability(comfort), cost, validation across population integration without replacing holistic benefits. Challenges include user adherence, air fact-free data in motion, and clinician adoption. Balanced integration-tech as enabler, tradition as foundation-maximizes benefits while minimizing risks.

CONCLUSION

This conceptual paper has explored the interplay between graviatational forces, age related cerebrovascular decline, and potential countermeasures through the lens of ancient yogic practices and modern technology. Prolonged

upright postures in modern sedentary lifestyle chronic hydrostatic opposition to cerebral blood flow, contributing to low grate hypoperfusion that compounds with aging-related arterial stiffening, reduced autoregulatory reserve and microvascular changes. This process may accelerate vulnerability to cerebral ischemia, white matter pathology, cognitive impairment and neurodegenerative conditions, aligning with the emerging gravity – aging hypothesis which posits that decades of upright postures create a cumulative perfusion deflect, particularly affecting high-metabolic, watershed brain regions that regulate systemic aging processes. Ancient traditions particularly sirsasana and related inversion in yoga and ayurveda offer a time tested approach to transiently reverse these gravitational gradients. By elevating the head below the heart, inversion enhances venous return, modulate intracranial pressure dynamics, stimulate baroreceptor and promote parasympathetic dominance-yielding benefits in autonomic balance stress reduction, lymphatic clearance perfusion are not supported by modern evidence, indirect methods such as improved venous drainage neuroendocrine effects. Passive inversion may provide more favourable transient CBF modulation compared to active poses suggesting a pathway for safer, more effective application in ageing population.

Advancements in non-invasive, wearable cerebral monitoring technologies- such as temple based ultrasound patches and speckle contrast optical spectroscopy system now enable continuous real time tracking of CBF changes across postures, daily activities and age related trajectories. These tools offer passive surveillance, early detection of hypoperfusion pattern and objective quantification of intervention effects, transforming anecdotal benefits into measurables, personalized insights. Integrating these paradigms creates a powerful complementary framework: ancient inversion provides active, transient physiological modulation and holistic mind body restoration, while modern sensors deliver continuous data driven feedback and long-term surveillance. This hybrid approach could enable biofeedback-guided protocols, personalized prevention strategies for sedentary individual, and rigorous testing of the gravity-aging hypothesis through longitudinal monitoring of perfusion trends, autoregulation capacity, and adding biomarkers. Despite promising physiological rationale and preliminary observations, the evidence base remains limited: most inversion studies are acute and conducted in healthy, younger cohorts' long term RCTs in aging population are scarce and combined yoga -wearables interventions await systematic evaluation. Safety considerations- particularly cervical loading intraocular pressure elevation, and contraindications in hypertension, glaucoma and spinal conditions must guide implementation.

In conclusion the convergence of traditional postural wisdom and cutting-edge monitoring technologies represents a compelling, non-pharmacological strategy to mitigate gravity-imposed cerebrovascular burdens in an increasingly sedentary world. By addressing chronic upright hypoperfusion through safe evidence informed inversion monitored in real time this integrative model holds potential to support cerebrovascular resilience, cognitive vitality and healthier longevity. Future research-prioritizing longitudinal trails ging specific cohort's regional perfusion mapping and hybrid intervention design is essential to validate these concepts, quantify dose response relationship and translate them inti accessible clinical and public health recommendation. Ultimately, bridging ancient practices with modern precision, may offer a meaningful countermeasure to one of the humanity's most pervasive yest underappreciated physiological stressors: Gravity itself.

ABSTRACT

Bacterial vaginosis (BV) is a common cause of vaginal discharge in reproductive-age women, characterized by altered vaginal microbiota and raised vaginal pH. In Ayurveda, BV can be correlated with *KaphajaArtavaDushti/Yonivyapad*, where *Yonidhavana* is a recommended local therapeutic procedure. Triphala, a classical polyherbal formulation, possesses antimicrobial, anti-inflammatory, antioxidant, and biofilm-disrupting properties. To evaluate the efficacy and safety of TriphalaYonidhavana in the management of bacterial vaginosis. A prospective, randomized, controlled pilot clinical study was conducted on 20 women diagnosed with BV based on Amsel's criteria and Nugent scoring. Participants were randomly allocated into two groups: Group A (TriphalaYonidhavana) and Group B (standard conventional management). Primary outcomes included change in vaginal pH and Nugent score. Secondary outcomes included improvement in clinical symptoms (vaginal discharge, odor, itching) and recurrence within 4 weeks. Group A showed statistically significant improvement in vaginal pH normalization and reduction in Nugent score compared to baseline ($p < 0.05$). Symptomatic relief was comparable to the control group, with a lower recurrence trend observed in the Triphala group. TriphalaYonidhavana is a safe and effective local therapy for bacterial vaginosis and may serve as a complementary or alternative option, especially in recurrent cases.

Keywords: Triphala, Yonidhavana, Bacterial vaginosis, Ayurveda, Vaginal pH

INTRODUCTION

Bacterial vaginosis is the most prevalent cause of abnormal vaginal discharge among women of reproductive age, accounting for 40–50% of cases. It is characterized by replacement of normal *Lactobacillus*-predominant flora with anaerobic organisms such as *Gardnerella vaginalis*, *Mobiluncus* spp., and *Atopobiumvaginae*. Clinically, BV is associated with malodorous discharge, raised vaginal pH (>4.5), and clue cells. Despite effective antibiotics like metronidazole, including vaginal metronidazole gel 0.75% administered once daily for 5 days**,** high recurrence rates (30–50% within 3–6 months) and antimicrobial resistance remain major concerns. Hence, there is a need for alternative and complementary approaches.

In Ayurveda, BV can be correlated with *Kaphaja Artava Dushti* and *Shleshmala Yonivyapad*, characterized by *picchila*, *bahala*, *durgandhitasrava* and *kandu*. *Yonidhavana* (vaginal douche) using herbal decoctions is described for cleansing (*shodhana*), pacifying *Kapha*, and restoring vaginal health. Triphala—comprising *Haritaki (Terminalia chebula)*, *Bibhitaki (Terminalia bellirica)*, and *Amalaki (Emblicaofficinalis)*—is described as *Tridoshaghna* and *krimighna*.

MATERIALS AND METHODS

Study Design
Prospective, randomized, controlled, pilot clinical study.
Study Setting
Conducted at the Department of Prasuti Tantra &StreeRoga of Parul Institute of Ayurveda Hospital.

Sample Size
20 patients (pilot study):
- Group A: 10 patients (TriphalaYonidhavana)
- Group B: 10 patients (Conventional management)

Inclusion Criteria
- Women aged 18–45 years
- Diagnosed with BV fulfilling at least 3 of Amsel's criteria
- Nugent score ≥7
- Willingness to provide informed consent

Exclusion Criteria
- Pregnancy and lactation
- Coexisting vulvovaginal candidiasis or trichomoniasis
- Pelvic inflammatory disease
- Recent use of antibiotics or vaginal medications (within 14 days)
- Immunocompromised conditions

Intervention
Group A (Trial Group):
- TriphalaYonidhavana once daily for 7 consecutive days.
- Preparation: Coarse powder of Triphala (100 g) boiled in 1600 ml of water and reduced to 400 ml, filtered, and used lukewarm.

Group B (Control Group):
- Standard conventional treatment as per institutional protocol using **vaginal metronidazole gel 0.75%**, administered **once daily intravaginally for 5 consecutive days**.

- Standard conventional treatment as per institutional protocol (oral/vaginal metronidazole).

Assessment Criteria

Primary Outcomes:

- Vaginal pH (measured using pH strips)
- Nugent score (Gram-stained vaginal smear)

Secondary Outcomes:

- Vaginal discharge (quantity and consistency)
- Vaginal odor
- Itching (*kandu*)
- Recurrence rate at 4-week follow-up

Assessment Timeline

- Baseline (Day 0)
- End of treatment (Day 7)
- Follow-up (Day 28)

Statistical Analysis

Data were analyzed using paired and unpaired t-tests for parametric data and Wilcoxon signed-rank test for non-parametric data. $p < 0.05$ was considered statistically significant.

RESULTS

TriphalaYonidhavana showed significant reduction in vaginal pH and Nugent score from baseline to Day 7 ($p < 0.05$). Symptom scores for discharge, odor, and itching were significantly reduced. No adverse events were reported. Recurrence at Day 28 was lower in Group A compared to Group B.

DISCUSSION

Justification for choice of conventional therapy: Vaginal metronidazole gel (0.75%) was preferred over oral metronidazole to achieve high local drug concentration at the site of infection with minimal systemic exposure and fewer adverse effects. This route also allows a more appropriate comparison with local Ayurvedic therapy (Yonidhavana) while adhering to international treatment guidelines.

The therapeutic efficacy of TriphalaYonidhavana may be attributed to its *kashaya* and *amla rasa*, *rukshaguna*, and *krimighna* properties, which help in reducing *Kapha* and eliminating pathogenic microorganisms. Modern pharmacological studies have demonstrated Triphala's antibacterial activity against *Gardnerellavaginalis*, antioxidant potential, and ability to disrupt microbial biofilms. Yonidhavana mechanically cleanses the vaginal canal, reduces local microbial load, and helps restore physiological vaginal pH, thereby promoting recolonization by lactobacilli. The lower recurrence observed suggests a possible role in preventing dysbiosis.

Limitations

- Small sample size
- Short follow-up duration
- Open-label design

CONCLUSION

Triphala Yonidhavana is an effective, safe, and economical local therapy in the management of bacterial vaginosis. Larger randomized controlled trials with longer follow-up are recommended.

Ethical Considerations

The study was approved by the Institutional Ethics Committee. Written informed consent was obtained from all participants.

Table 1: Comparison between Metronidazole Gel and TriphalaYonidhavana

Parameter	Metronidazole Vaginal Gel (0.75%)	TriphalaYonidhavana
Nature of therapy	Synthetic antimicrobial	Herbal local therapy
Route of administration	Intravaginal gel	Intravaginal decoction (Yonidhavana)
Mechanism of action	DNA damage in anaerobic bacteria leading to microbial death	Antimicrobial, anti-inflammatory, antioxidant, biofilm-disrupting actions; *Kaphashamana*
Effect on vaginal microbiome	Reduces anaerobes but does not actively restore *Lactobacillus* flora	Helps normalize vaginal pH and supports recolonization of healthy flora
Recurrence tendency	High recurrence (30–50%) reported	Lower recurrence trend observed in the present study
Adverse effects	Local irritation, metallic taste (if absorbed), recurrence	No adverse effects reported in present study

ABSTRACT

Meanwhile, the need for monitoring frameworks such as those that dynamically collect, process and respond to environmental data in an effective manner is only increasing with the recent trend of smart surroundings or cyber-physical systems. New systems work off of an infinite stream of data generated by connected devices. It's sound reason to continue monitoring effectively, based on lessons learned from addressing this continual stream of data. It makes use of flexible processing, data-driven decision support and adaptation in ways that have applications within IoT; nesting intelligent systems to build an environment where sensors, communications networks and computational elements cooperate with each other to facilitate automated reasoning processes. Now, the traditional IoT architecture does have some weaknesses. Sending everything to a centralized server may lead to high latencies… and one can have multiple sensors. In the Data transmission part, we might as well get charged on excessive use of stream option. Reasons number two: security and privacy. However, and at the same time, though practically this single platform as big data transportation would expose them to various sources of vulnerabilities on existing systems. To mitigate these limitations, an Edge–Cloud Integrated Smart Monitoring System (ECISMS) architecture is proposed. In the framework which have implemented for help system improvements at run-time, dependency on IoT sensing devices, edge level data processing and cloud-based analytics are clearly visible. The edge layer performs preliminary processing and data filtering on time-sensitive operations, while cloud environment processes more complex analytical tasks.

Experimental results validate that they reduce latency, are energy-efficient and scalable with respect to the existing cloud-oriented IoT architectures.

Keywords: Internet of Things, Smart Systems, Edge Computing, Smart Monitoring, Cyber-Physical Systems, Smart Environment

INTRODUCTION

The connection of billions of different smart appliances that can sense, communicate and react to the environment is a significant technology enabler for smart environments in what we call Internet of Things (IoT). The use of IoT infrastructure drives a wide range of applications in smart cities, chronic healthcare monitoring, smart transportation, industrial automation and environmental surveillance. Connected sensors, communications networks, and computing platforms that leverage real time data comprise IoT systems. They are developed specifically to assist with automating humanistic decision-making and increase the operational aptitude of various domains. However, exponential growth in connected devices results in extremely high data volumes leading storage and processing capacity to be up-to-date with real-time analytics. In traditional cloud-based IoT architectures, all the data processing is done in a centralized infrastructure — high latency and network congestion may result from sending chunks of raw data collected by thousands (if not millions) of devices to the cloud. One such approach, edge computing, works to solve these problems by pulling the processing of devices' data near the devices themselves and minimizing latency so that systems are more responsive. Fog computing takes this further by introducing a layer of distributed, flexible processing resources between the end devices and the cloud. It allows high throughput with lower bandwidth consumption. Typical IoT architectures have layers, such as sensing devices, communication networks, processing platforms and application services. This multi-layer architecture allows for heterogeneous devices with inter-operability and provides a transport implementation of a scalable system. However, due to different characteristics of IoT sensing, edge computing and cloud analytics the design of smart systems based on these elements is still an active area of research - ideally, they should work together efficiently.

LITERATURE REVIEW

The development of the Internet of Things (IoT) has allowed for the creation of smart monitoring systems that are connected via the internet and can collect, transmit, and analyze environmental data continuously. Liquid IoT technologies have been extensively utilized in smart cities, environmental monitoring, industrial automation and healthcare systems [1], [2]. Most of the early work on IoT architectures assumed a cloud-based architecture in which sensor data are transmitted to a centralized cloud server for storage and processing. As the complexity of distributed IoT networks grows, it is clear that existing data management systems will be unable to handle this increase in sensor data [3]. However, cloud computing offers powerful computational capabilities and storage facilities, and cloud-based IoT architectures suffer from high latency and network congestion due to the sheer amounts of real-time sensor data that must be handled [4].

To overcome those limitations, researchers propose the idea of edge computing, where data are processed closer to IoT devices and do not rely exclusively on cloud infrastructures. However, traditional cloud computing suffers from high communication latency, large bandwidth utilization and slow response time [5]. Edge computing significantly reduces these problems- higher delay and less responsive and hence is an ideal computing model for real-time processing of data in low latency-based applications including environmental monitoring systems (e.g., smart factories) for industrial automation. Building upon this method, the emergence of distributed computing models that make use of computation requests at the edge of a network to increase responsiveness and demonstrate dynamic scaling have come about [6]. In addition, the fog computing paradigm extends cloud components to intermediate

nodes which mediate between IoT devices and cloud data centres. The architecture allows much of the raw data to be processed on site and thus reduces latency in addition to a properly working IoT system [6]. Some of the recent papers explored AI and ML technology applications that can be applied to intelligent decision systems merged with IoT models for predictive analytics. Some other applications that are using machine learning algorithms includes Sensor data, anomaly detection, environmental condition prediction etc. [8]. More advanced models (e.g. convolutional neural networks (CNNs) and recurrent neural networks (RNNs)) have shown high classification performance for detecting environmental patterns and predicting the next step [9]. Additionally, big data platforms [10], including distributed databases and cloud-based analytics frameworks, are commonly used to manage large-scale Internet of Things (IoT) data. While these technologies allow for distributed, scalable processing of high throughput streams of data coming from sensors, they are still highly dependent on heavy weight (centralized) cloud infrastructures which can be a serious performance bottleneck in the case of latency sensitive applications.

However, there are some issues with the existing IoT-based environmental monitoring systems despite these technological advancements. Most existing solutions do not have integrated intelligence to ensure efficient predictive analytics, and resource management including secure communications mechanisms. In addition, security and privacy issues are significant challenges considering that IoT networks consist of large number of interconnected devices susceptible to cyberattacks, unauthorized access, corruption and manipulation [11]. Recently, the hybrid edge–cloud architecture has received much attention in the area of edge computing because such an architecture provides a promising solution for improving system performance by distributing diverse workloads mixed between end-user devices and cloud servers; however, while several works try to unify IoT task processing with parameter prediction, fewer studies provide comprehensive components that cover all layers including massive sensing opportunities at lower layer (IoT) and intelligent analytics in higher-level cloud service. This work proposed an Edge-Cloud Integrated IoT Smart Monitoring System which can overcome these limitations and characterizes effective real-time environmental monitoring with intelligent decision support. The performance comparison with existing IoT monitoring systems are listed in Table 1.

Research Gap

Many IoT-based smart monitoring systems have been introduced; however, there are still few significant limitations:

- Centralized cloud processing with high latency
- Time-sensitive IoT applications may suffer greatly since a lot of such systems push all their sensor data to cloud servers for acting on it, which causes delays.
- Scalability bottleneck for large IoT deployments
- A growing number of sensors produce enormous streams of data that can bog down cloud capabilities.
- Resource-limited IoT devices energy wastefulness
- Challenges in security and privacy concerning distributed IoT networks
- Lack of integrated Edge-Cloud intelligence

However, most of the existing designs are either concentrated on only cloud-based architectures or edge computing but very few functions efficiently merge them both (cloud and edge computing) for real-time smart system implementations. In order to address the above limitations, this research introduces Edge–Cloud Integrated IoT Smart System to facilitate intelligent monitoring and decision making for an efficient environment.

Proposed System Architecture

The overall architecture of the proposed IoT based smart environmental monitoring system for real time data acquisition, intelligent processing and user level visualization is presented in Figure 1. The IoT Sensors Layer, the first layer, constantly collects environmental data like temperature, air quality, and humidity through distributed nodes. The Edge Gateway Layer then receives this raw data from the sensors. This layer then performs initial filtering and local analysis to remove noise and redundant information. Edge processing is performed to reduce the latency and makes sure that bandwidth usage is optimized before sending up to higher layers for further processing.

The Communication Network Layer makes use of IoT communication protocols - such as WiFi, 5G and MQTT protocols to provide a reliable and efficient transmission of interpreted data. It is also the glue that binds the two -- enabling edge devices to communicate and share data with cloud infrastructure. Cloud Platform Layer: Utilization of a cloud-based big data storage process designed to store large amounts of sensor data. It also applies innovative AI and machine learning algorithms to mine data for predictive models of the likelihood of environmental conditions, spotting trends. The cloud is designed in a way that when these models need to scale, they get the capability of scaling on a high-performance data store similar to a warehouse with analytics capabilities. Since they are redirected towards the Smart Application Layer (dashboard visualization tools and mobile interfaces) for processing of the insight of the data passing component, in which not only allow to monitor in real time both on automatic generating alerts but also it does interact for users. That's empowering, because environmental data is how people who can make a difference know whether things are good and what action to take — in time, if resource reports gets made available through easy-to-read dashboards. Entire infrastructure: IoT sensors + edge computing + cloud base analysis + smart applications This synergy gives the technical viability and scalability to environmental monitoring.

Mathematical Model

Consider an IoT system with N sensors that generate environmental data.

- **Sensor Data Vector:**

$D = \{d_1, d_2, d_3, \ldots, d_N\}$

where d_i represents data collected from sensor i

- **Edge Processing Function:**

$E(D) = f(d_1, d_2, ..d_k\}$

where

- E(D) represents processed data at the edge
- $k < N$

Edge nodes perform filtering and anomaly detection before forwarding to the cloud.

- **Cloud Prediction Model:**

$R(t) = g(E(D_t))$

where R(t) = predicted environmental condition at time t.

- **System Latency:**

$L = L_{edge} + L_{network} + L_{cloud}$

Goal: min L

Edge computing reduces $L_{network}$ and L_{cloud}.

METHODOLOGY

A systems-level approach is presented for IoT applications that addresses real-time streaming environmental data analysis through edge and cloud computing Sensing, Storage and Centralized Learning enhanced by machine learning methods making this system reliable. The overall methodology includes a number of sequential phases starting from the acquisition of sensor data to visualization and alert generation. In this process, it is the diagram specifically characterized as in Figure 2.

Sensor Data Collection:

In the initial step, environmental data are collected with IoT sensors installed in the monitoring environment. These sensors constantly monitor real-time environmental factors as:

- Temperature
- Air quality
- Humidity
- Pollution levels

These sensors produce raw data streams that reflect the present environmental conditions. This data is then sent periodically or in real-time to the next level of the system.

Data Transmission via IoT Protocol:

After collecting the sensor data, it sends to the processing infrastructure through IoT communication protocols. IoT works will common protocols range from MQTT to WiFi & most popular — 5G Networks that guarantee low overhead and high-speed communication.

This stage ensures:

- Data retention Sensor connectivity (Configuration)
- Secure and efficient data transmission
- Lowered communication latency on real-time monitoring systems

Edge Data Processing:

In this step, the incoming sensors data are processed at edge computing layer and after being sent to cloud. Edge devices or gateways are responsible for initial pre-processing tasks like:

- Data filtering
- Noise removal
- Data aggregation
- Preliminary analytics

Processing data at the edge minimizes the amount of duplicate data sent to the cloud and enhances the response time of the system.

Anomaly Detection:

The system has to pre-process on the data and then perform anomaly detection to find unusual environmental conditions. Unusual behaviour in a machine can be detected using statistical techniques or lightweight machine learning algorithms on the sensor readings.

Examples of anomalies include:

- Sudden increase in pollution levels
- Abnormal temperature fluctuations
- Hazardous environmental conditions

That it detects anomalies in its early phase enabling the system to take quick action towards environmental threats.

Cloud Data Storage:

The pre-processed data are sent to the cloud infrastructure for permanent storage and further large-scale processing. Cloud platforms offer scalable storage systems that can store volumes of IoT data. Functions of this stage include:

- Big data storage
- Data management and indexing
- Historical data archiving
- Cloud storage also allows environmental data viewing remotely for further analysis.

Machine Learning Analysis:

This data is analysed in the cloud environment by machine learning algorithms to recognise patterns and trends, based on the environmental data collected. Regression models, decision trees, neural networks and other predictive models may be used. The goals of this step are:

- Environmental pattern recognition
- Trend analysis
- Predictive modelling
- The model settles based on historical data to get its predictions more accurate with time.

Prediction of Environmental Conditions:
The trained machine learning models are used by the system to forecast future environmental conditions. Predictive analytics allows the system to learn and forecast various factors, such as:

- Air quality levels
- Temperature changes
- Pollution concentration

These predictions enable authorities and other stakeholders to take preventive actions before environmental conditions become dangerous.

Alert Generation:
Based on the predefined threshold levels, if any of the aforementioned predicted or detected environmental values cross(increase or decrease) using IoT-based smart sensor modules then system triggering alerts and notifications automatically. The alerts can be sent via: Mobile notifications and Email alerts.

Smart Dashboard Visualization:
The last phase shows all the processed and predicted data in a smart dashboard presentation. Users can interact with a virtual dashboard to track environmental status and measure levels in real time. The dashboard boasts several key features:

- Visual representations of sensor data.
- Ongoing environmental monitoring is crucial.
- Reviewing historical information.
- Notifications have been triggered.

The data is then interpreted using a visualization layer and to grasp the overview of facts and take decisions accordingly.

Algorithm: IoT Smart Monitoring Algorithm
Input: Sensor data S
Output: Smart alerts and predictions
Step 1: Initialize IoT sensors
Step 2: Collect environmental data
Step 3: Transmit data to edge gateway
Step 4: Perform data filtering and pre-processing
Step 5: Detect anomalies using threshold rules
Step 6: Send processed data to cloud server
Step 7: Apply machine learning prediction model
Step 8: Generate environmental predictions
Step 9: If threshold exceeded
    send alert to user
Step 10: Display results on dashboard

RESULTS AND DISCUSSION

An in-depth comparison with three major KPIs of IoT environmental monitoring systems were presented: latency, energy efficiency and scalability. This is what the system excels at -- in terms of processing streaming sensor data, and providing that scale of reliability for IoT deployments. Table 2 indicates the performance results on all three architectures. This typical operation of Cloud-Only solution, which represents the higher latency with transmitting raw information from all sensor devices to a centralized cloud server for processing in any situation, how appropriately the certifications stays subject to a coherent reasoning and senseless functions up time-backed systems.

This heavily-market-oriented system jeopardizes real time critical applications like environmental monitoring realized in cloud platforms, which provide strong computational resources and a large amount of storage space but less responsive to computation that concentrates on processing data in the centralized manner. In the opposite way, the Edge-Only architecture takes the data closer to its origin and works with it at edge devices sitting close to the sensors that generated it, which allows for a very low-latency operational pipeline. Before passing selected data up to higher-order systems, they perform preliminary operations such as filtering, aggregation and localized analytics. This kind of architecture increases energy efficiency as it makes fewer data packets transmitted across a network. For edge-only strategy, scaling this up is not very easy as the devices on edge usually have limited computation and storage. One of the processing issues we face with edge-only systems, as more IoT devices grow up in this way. An Edge–Cloud integrated architecture fuses the benefits of edge and cloud computing paradigms. The edge layer carries out time-critical tasks, like data pre-processing and anomaly detection, whereas machine learning analysis and predictive modelling are carried out in the cloud. This hybrid approach guarantees that local and centralized resources are utilized effectively.

Experimental results show that the proposed system has a latency reduction of about 35% compared to traditional cloud-based architecture. Most of this improvement comes from edge-level data processing, which lessens the amount of raw sensor data that has to make it to the cloud. The system reduces irrelevant network communication and enhances latency by executing local filtering and aggregation. Moreover, the proposed architecture further significantly minimizes 28% of the overall network bandwidth consumption. As only processed and relevant data is sent to the cloud from the edge layer, there will be a sharp decline in overall transmitted data. This helps in efficiently utilizing communications and reduces network congestion, something that is critical in large-scale IoT deployments. Another important characteristic of an IoT system is energy efficiency because many sensors and edge devices are battery-powered. Notably, the proposed architecture is an also illustrates the prominent energy-efficient edge of local processing in transferring important data directly towards wireless transfer. In addition, if computation is made between edge and cloud layers then this assists resource-constrained devices to prevent processing heavyweight algorithms that execute as lightweight while dissipating heavier operations to powerhouse Cloud Servers.

CONCLUSION

This work put forward the conceptual framework for an Edge–Cloud Integrated Internet of Things (IoT) Smart Monitoring System that encouraged intelligent decision making and real-time environmental observation. In this paper we propose an infrastructure that can overcome the drawbacks of current IoT platforms by using a caching layer with analytics on top of atmospheric computing (i.e. IoT sensing devices, edge computing gateways and cloud-based analytics). Splitting computation between edge and cloud not only helps to relieve the network latency but also provides more scalability options for the system and improves energy efficiency as demonstrated through these experiments. This architecture will also enable large-scale deployments for smart cities, industrial automation and environmental monitoring systems. Last but not least the proposed architecture would pave ways to innovate sophisticated smart infrastructures whereby IoT devices, edge computing and AI are interconnected one another for autonomously intelligent environments.

FUTURE WORK

The paper will discuss several facets of its IoT based smart monitoring system and in the long run it aspires for making the same more intuitive, secure to use and scalable by adding better algorithms to integrate. Use AI-Powered Predictive Analytics For Anomaly Detection In Passage The better way is to adopt some of the advances such as blockchain based security systems making sure data integrity in IoT units and also allowing secure data transfer. Furthermore, digital twin models can facilitate simulation and optimization for smart infrastructures. The model proposed can be used to develop generalized systems in different domain such as smart farming and disaster discovery system integration with 5G networks for ultra-low latency communication for real-time applications.

ABSTRACT

Sturge-Weber Syndrome (SWS) is an uncommon congenital neurocutaneous disorder marked by vascular malformations, including capillary-venous angiomas involving the facial dermis, leptomeninges, choroid of the eye, and intraoral hemangiomas. This report presents a case of SWS with intraoral hemangioma, emphasizing the importance of comprehensive clinical management of a pediatric patient with sclerosing agents in optimizing patient outcomes.

Key words : Sclerotherapy, Sturge weber syndrome, hemangiomas

INTRODUCTION

Sturge–Weber syndrome (SWS), Sturge– Weber disease, meningococcal angiomatosis, and Sturge–Weber–Dimitri syndrome is a rare congenital disorder occurring due to dysfunction of embryonal vascular system characterized by the presence of leptomeningeal angiomas, port wine stains accompanied with ocular disorders, mental retardation, and oral involvement. This disorder occurs in 1:50 000 live births. [1,2]

Oral manifestations in SWS include angiomatosis of lips, buccal mucosa, palate, and floor of the mouth; gingival enlargement varying from light vascular hyperplasia to severe overgrowth, bleeding following minimal trauma; pyogenic granulomas; unilateral hypertrophy of alveolus, ipsilateral premature eruption, or delayed eruption.[3]. The report holds importance for pediatric dentists by illustrating effective sclerotherapy management of a rare intraoral hemangioma in a 12-year-old with Sturge–Weber syndrome, emphasizing practical, evidence-based guidance for treating vascular lesions in growing children.

CASE REPORT

An 11-year-old male patient reported to the Department of Oral Medicine and Radiology with a complaint of swelling over the left upper back teeth region for the past 2 months. History revealed a bean-sized swelling over the left maxillary posterior teeth region, gradual in onset and progression, associated with occasional bleeding while eating and not associated with pain. There were no apparent aggravating and relieving factors. The patient also reported the presence of an erythematous patch over the left side of the mid-face region since birth, for which he underwent LASER therapy 5 years ago and had no relief.

A general examination showed stable vital signs with no significant systemic abnormalities. Extraoral examination revealed a well-defined erythematous patch over the overlying skin of the left mid-face region extending mediolaterally from 1cm below the nasal bridge up to 8 cm in front of the left external auditory meatus and supero-inferiorly from the left eyebrow up to the left upper lip.[Figure 1]. Intraoral examination revealed a well-defined irregular soft tissue swelling of size approximately 3x2cm in relation to 24, 25 over the alveolar ridge and 2cm palatally. On palpation, the swelling was soft in consistency, non-compressible, non-tender, and bleeding on probing. It was bright red and showed blanching when applied pressure, suggesting angiomatous enlargement [Figure 2].

A provisional diagnosis of arterio-**v**enous malformation was given based on clinical features. The differential diagnoses included Hemangioma, Sturge-Weber syndrome, and Lymphangioma. The CECT face and neck showed minimally enhancing soft tissue density lesion measuring approximately 2x3 cm present in relation to erupting 24, 25 and few abnormal capillaries in subcutaneous fat on the left side of the cheek with supply from the superficial temporal artery [Figure 3]

The physician's consent was obtained prior to treatment. All the hematological investigations were within normal limits, so considering the patient's age, size, and extent of the lesion, it was planned to treat the patient with intralesional sclerotherapy with sodium tetra-decyl sulfate. 1 ml of an intralesional sclerosing agent (sodium tetradecyl sulfate, with the trade name of SETROL) was injected intralesional in a circumferential manner around the lesion under aseptic conditions. A plaque control regimen was started, which included oral prophylaxis at regular intervals, oral hygiene instructions, and patient motivation at each visit. Regular follow-ups were done at 24 hrs., 15 days, and at weekly intervals up to one month [Figure 4] and at six months. No complications were noted. After six months, the patient reported no complications and improved clinical picture, i.e., disappeared lesion and no bleeding on probing. At the 6-month follow-up examination, with no evidence of recurrence, no further treatment was deemed necessary.

REVIEW OF SCLEROSING AGENTS

Sclerosing agents are the medicaments injected into blood vessels and lymphatic sinuses, causing localized thrombosis, fibrosis, or obliteration of the vessels**.** Various sclerosing agents have been used to treat hemangiomas and other benign vascular lesions for over a century. Table 1. shows the classification of the sclerosing agent based on the mechanism of action. Sodium tetradecyl sulfate (STS), sodium-1isobutyl-4 ethyloctyl sulfate, a clear anionic surfactant with low surface tension, is used as an intravascular sclerosing agent. It acts principally on the endothelium of the vein, resulting in thrombus formation and sclerosis. It can also induce a hypercoagulable state,

possibly by selective inhibition of protein C, and promote platelet aggregation (Figure 4).STS should be avoided during pregnancy, in newborns, during lactation, and in cases of local infection or uncontrolled diabetes. [7] The amount of sclerosing agent injected and the number of treatment sessions in sclerotherapy depends on the lesion's size, location, and extent of involvement of surrounding structures. Figure 6 describes the mechanism of action of STS. Sclerosing agent offers a minimally invasive, cost-effective treatment that usually requires no anesthesia and is done on an outpatient basis. It ensures quick recovery, minimal pain, high patient compliance, and improved quality of life. The procedure is effective in resolving small vascular lesions, leaves little to no scarring, and has a low risk of complications or allergic reactions. Despite their advantages, sclerosing agents also have certain disadvantages. The procedure can be more time-consuming and may involve several potential side effects, including postoperative pain, allergic reactions, a burning sensation, hemolysis, tissue necrosis (reported in about 4% of cases), and temporary myoglobinuria (in approximately 2% of cases).[8]

DISCUSSION

SWS is a rare congenital neurocutaneous disorder. Previous research has identified a somatic activating mutation in the *GNAQ* gene as a contributing factor. It is characterised by leptomeningeal angiomatosis and a facial port-wine stain typically located in the ophthalmic branch distribution of the trigeminal nerve. Neurological manifestations include seizures, hemiparesis, recurrent headaches, stroke-like episodes, psychomotor delay, and intellectual disability.[3] Intraoral manifestations of angiomatosis may include involvement of the lips, buccal mucosa, palate, and floor of the mouth. Gingival enlargement can present with varying severity, ranging from mild vascular hyperplasia to extensive overgrowth that can severely impair mouth closure. The other abnormalities reported are pyogenic granulomas, unilateral hypertrophy of the alveolus, ipsilateral premature eruption, or delayed eruption and malocclusion. [1,10]. SWS is divided into three types based on the combination of facial angiomas, leptomeningeal angiomas, and glaucoma. Type I is the most common and involves both facial and leptomeningeal angiomas, often accompanied by glaucoma. Type II is characterized by the presence of a facial angioma and glaucoma but without any evident brain involvement. Type III is the rarest form, marked by leptomeningeal angiomas without a facial angioma and usually without glaucoma.

Depending on the location, size, and behavior only 10- 20% of hemangiomas need intervention. Various therapeutic approaches may be considered, such as micro embolism, LASER therapy, corticosteroids, radiotherapy, electrocoagulation, surgery, cryosurgery, carbon dioxide snow, silver nitrate, and sclerosing solutions. However, when feasible, complete surgical removal provides the greatest likelihood of achieving a cure [3,11] but if the lesion is too big, the resection would produce a significant defect with significant risk of haemorrhage. That is where sclerosing agents come to the rescue. Sclerotherapy is the targeted eradication of small vessels, varicose veins, and vascular malformations by injecting a sclerosant into the vessel's lumen.

This case offers meaningful insight into the clinical features, diagnostic process, and management strategies for Sturge-Weber Syndrome (SWS) in a pediatric patient. While the case demonstrates the effectiveness of medical management, it explores the specific outcomes of sclerotherapy—an important treatment option in cases where standard therapies are ineffective. In the present case, the patient's young age was a key determinant in opting for a conservative, sclerosing-agent-based approach to minimize invasiveness and preserve developing oral structures, thereby aligning with the principles of pediatric dental care.

ABSTRACT

Helminth infections present a critical public health challenge, driving malnutrition and anemia globally. With rising resistance to synthetic drugs like Albendazole, identifying sustainable botanical alternatives is essential. This study investigated the anthelmintic efficacy of *Curcuma longa* , *Zingiber officinale* , and *Curcuma amada* extracts, both individually and in a 1:1:1 polyherbal combination. Phytochemical screening revealed a rich presence of phenols, flavonoids, terpenoids, and alkaloids across all extracts, providing a biochemical basis for parasite interference. Results demonstrated dose-dependent activity, with *Curcuma amada* emerging as the most potent individual extract. Significantly, the polyherbal combination exhibited a powerful synergistic effect; at 100 mg/ml, it induced paralysis in 19±0.5 minutes and death in 25±0.4 minutes. This performance closely mirrors the standard drug. The findings suggest that this synergistic blend offers a promising ray of hope against multi-drug resistant helminths. These widely available plants provide a foundation for developing accessible, cost-effective, and potent natural anthelmintic therapies to improve global health outcomes.

Keywords: Anemia, Flavonoids, Paralysis, Helminth, Synergistic

INTRODUCTION

Helminth infections remain a major public health concern in many developing regions, where parasitic worms significantly affect human health, animal productivity, and socioeconomic stability. These infections, caused primarily by the phyla *Nematoda* and *Platyhelminthes*, lead to chronic morbidity, malnutrition, impaired growth, and reduced immunity, especially in children and immune compromised populations [1]. Soil-transmitted helminths such as *Ascaris lumbricoides*, *Trichuris trichiura*, and *hookworms* continue to infect millions of individuals globally,

while *trematodes* and *cestodes* contribute to systemic complications involving the liver, intestines, and blood vessels [2]. Current estimates suggest that more than one billion people are affected by helminthiases worldwide, with substantial mortality linked to severe worm burdens, anemia, and organ dysfunction [3]. Although synthetic anthelmintic drugs such as albendazole, mebendazole, praziquantel, and ivermectin remain the mainstay of treatment, increasing reports of drug resistance, limited therapeutic efficacy, and concerns regarding toxicity have highlighted the urgent need for safer and more effective alternatives [4,5].

In this context, medicinal plants have gained renewed attention for their broad-spectrum bioactivities, affordability, and cultural acceptance. Traditional systems of medicine including Ayurveda, Siddha, Tibb-Unani, and traditional Chinese medicine have long utilized botanicals for managing parasitic infections, inflammation, gastrointestinal disorders, and infections of microbial origin [6]. Among these, species belonging to the *Zingiberaceae f*amily, such as *Curcuma longa*, *Zingiber officinale*, and *Curcuma amada*, hold significant therapeutic potential due to their rich phytochemical profiles and demonstrated biological activities [7].

Phytochemicals derived from these species have been shown to disrupt helminth neuromuscular activity, impair energy metabolism, damage cuticular structures, and elevate oxidative stress within parasitic organisms, mechanisms essential for effective anthelmintic action [8]. Moreover, the growing demand for plant-based therapies is supported by their low toxicity, high availability, and potential to circumvent the resistance associated with conventional drugs [9]. Therefore, exploring the pharmacological activities of *Curcuma longa*, *Zingiber officinale*, and *Curcuma amada*, particularly their antioxidant, anti-inflammatory, antimicrobial, antiviral, and anthelminthic effects, is crucial for developing novel and sustainable therapeutic approaches.

MATERIALS AND METHODS

Collection of Plant Materials

The plant materials, namely turmeric (*Curcuma longa*), ginger (*Zingiber officinale*), and Amada (*Curcuma amada*), were collected from the surrounding village areas of Rajnagar, Daspur, West Medinipur and Barasat, West Bengal, India. Healthy and disease-free plant parts were selected and transported to the laboratory for further processing.

Authentication of Plant Materials

The collected plant materials were authenticated by Prof. (Dr.) D. Seal, Principal, Mata Gujri College of Pharmacy, Kishanganj, Bihar, India.

Drying and Extraction

The collected plant materials were thoroughly washed with water to remove adhering soil and debris and then shade-dried for 10–25 days until they became suitable for grinding. The dried materials were coarsely powdered using an electric grinder and stored separately in airtight containers for further use. Approximately 500 g of powdered turmeric, ginger, and mango ginger were subjected to extraction. Each plant material was extracted for 24 hours in a Soxhlet apparatus using a hydroalcoholic solvent system consisting of methanol and water (1:1, 500 ml each). After completion of extraction, the solvent was evaporated using a rotary evaporator to obtain a concentrated solid mass, which was stored at 4 °C for subsequent analysis [10].

Phytochemical Analysis of Extracts

The prepared extracts were subjected to qualitative phytochemical screening to detect the presence of various phytoconstituents. About 1 g of each extract was dissolved separately in 100 ml of 95% ethanol, and these solutions were used for preliminary phytochemical tests following standard procedures reported in the literature. [11,12,13,14]

Test for Phenolics

To 1 ml of plant extract, a few drops of 10% ferric chloride solution were added. The development of green, red, purple, or blue-black coloration indicated the presence of phenolic compounds.

Test for Flavonoids (Shinoda test):

One milliliter of plant extract was mixed with 3 ml of boiled water and incubated for 5 minutes. A small amount of magnesium powder and 1 ml of concentrated HCl were added and shaken. The appearance of red, yellow, or orange color indicated flavonoids. In the ammonia test, 5 ml of dilute ammonia solution was added to the extract followed by concentrated sulphuric acid. Formation of yellow precipitate indicated the presence of flavonoids.

Test for Alkaloids:

- *Wagner's test:* Addition of Wagner's reagent to the extract produced a reddish-brown color indicating alkaloids.
- *Mayer's test:* Formation of pale yellow precipitate after adding Mayer's reagent confirmed alkaloids.
- *Dragendorff's test:* Orange-red precipitate after treatment with Dragendorff's reagent indicated alkaloids.

Test for Phytosterols:

Five milliliters of extract solution was treated with 1 ml concentrated sulphuric acid and allowed to stand for 5 minutes. Formation of golden yellow color in the lower layer indicated the presence of phytosterols.

Test for Tannins

One milliliter of extract was mixed with 5 ml distilled water and treated with 5% ferric chloride solution. Blue-black or blue-green coloration indicated tannins**.**

Test for Saponins (Foam test)

One milliliter of extract was shaken vigorously with 3 ml boiled water. Formation of stable foam persisting for 1–2 minutes indicated saponins.

Test for Glycosides

The extract was hydrolysed with hydrochloric acid on a water bath and subjected to Fehling's test. Appearance of yellow or red precipitate indicated reducing sugars and the presence of glycosides**.**

Test for Amino Acids

Few drops of 5% ninhydrin solution were added to the extract and heated. Development of red or blue coloration indicated amino acids.

Test for Terpenoids (Salkowski test)

Five milliliters of extract was mixed with chloroform and carefully layered with concentrated sulphuric acid. Reddish-brown coloration at the interface indicated terpenoids.

Anthelmintic Assay

Collection of Worms

Adult Indian earthworms (*Pheretima posthuma*) were collected from water-logged soil areas of Habra, North 24 Parganas district, West Bengal. The worms were washed with normal saline to remove adhering soil and faecal matter. Earthworms measuring 5–8 cm in length and 0.1–0.2 cm in width were used for the experiment**.**

Anthelmintic Activity of *Curcuma longa*, *Zingiber officinale*, and *Curcuma amada* Extracts

Hydroalcoholic extracts of *Curcuma longa*, *Zingiber officinale*, and *Curcuma amada* were evaluated for anthelmintic activity against *Pheretima posthuma*. Different concentrations of each extract (125, 250, 500 and 1000mg/ml) were prepared and tested to determine the time of paralysis and death of the worms. Albendazole was used as the standard reference drug, and normal saline served as the control.[15]

The assay was carried out using adult earthworms due to their anatomical and physiological similarity to human intestinal roundworms and their easy availability for in vitro studies.[16- 20] In each experiment, groups of six earthworms were placed in 25 ml of extract solution, standard drug solution, or saline control. All solutions were freshly prepared prior to the experiment.Observations were recorded for the time required to induce paralysis and death of the worms. Paralysis was noted when no movement was observed except upon vigorous shaking. Death was confirmed when the worms completely lost motility and their body color faded.

RESULT AND DISCISSION

Helminth infections are among the commonest infections in man, affecting a large proportion of the world's population. In developing countries, they pose a major threat to public health and contribute to the prevalence of malnutrition, anemia, eosinophilia, and pneumonia many helminths. Some helminth also live-in tissues, or their larvae migrate into tissues. They harm the host by depriving him of food, causing blood loss, injury to organs, intestinal or lymphatic obstruction and by secreting toxins. But now a days they are becoming resistant to synthetic anthelmintics. The challenges posed by multi-drug resistance in synthetic anthelmintics, the potential of plant extracts as an alternative helminth control option offers a ray of hope. In our study we did the phytochemical screening and a of anthelmintic activity of crude extracts of *Curcuma longa, Zingiber officinale, and Curcuma amada*. Phytochemical screening of plant crude extracts of *Curcuma longa*, *Zingiber officinale*, and *Curcuma amada* showed that the extract of three plants has phenols, flavonoids, alkaloids, tannins, saponins, glycosides, amino acids and terpenoids (Table 1).

The anthelmintic activity of *Curcuma longa*(CL), *Zingiber officinale*(ZO), and *Curcuma amada*(CA) extracts, individually and in combination(1:1:1), against helminth was investigated using Albendazole as a standard reference drug. The results, presented as the mean time taken for paralysis and death of the organisms ± standard deviation, demonstrate a dose-dependent effect for all extracts. The control group, treated with normal saline, showed no signs of paralysis or death throughout the observation period, indicating the viability of the helminth and the inertness of the solvent (Table 1).

Albendazole, the standard drug, exhibited the most rapid anthelmintic action. At conc of 50, 75, and 100 mg/ml, it induced paralysis at 24±0.4 min, 17±0.9 min, and 13±0.5 min, respectively, and death at 28±0.8 min, 24±0.4 min, and 22±0.4 min, respectively. This establishes a baseline for potent anthelmintic efficacy. The extract *Curcuma longa*(CL) of also demonstrated anthelmintic properties, albeit with a slower onset of action compared to Albendazole. Paralysis was observed at 32±0.6 min, 30±0.3 min, and 29±0.3 min, while death occurred at 69±0.5 min 59±0.3 min, and 50±0.3 min for concentrations of 50, 75, and 100 mg/ml, respectively. This indicates that *Curcuma longa* (CL) possesses anthelmintic compounds, but they are less potent or slower acting than Albendazole at the tested concentrations.

Similarly, the extract of *Zingiber officinale* (ZO)showed notable anthelmintic activity, showed less activity compare to the other extracts (Curcuma longa, *Curcuma amada*), as well as to standard, with paralysis recorded at 52.±0.2 min, 42.±0.6 min, and 37±0.6 min at concentration 50, 75, and 100 mg/ml, death was recorded at 69.±0.5 min, 62±0.3 min, and 54±0.4 min, respectively. The extract of *Curcuma amada* showed good activity as compared to *Zingiber officinale* and *Curcuma longa,* which is also compare able to standard drug Albendazole. It showed paralysis at 36±0.6, 30±0.3 and 28 ±0.3 and death time 50±0.3,47±0.3 and 40±0.4 at concertation 50 , 75 and 100mg/ml respectively. The polyherbal combination of all three extracts (1:1:1) at 100 mg/ml induced paralysis in 19±0.5 min and death in 25±0.4 min. These results are remarkably comparable to the standard drug, Albendazole.

CONCLUSION

Helminth infections remain a formidable global health challenge, particularly in developing nations where they exacerbate conditions like malnutrition, anaemia, and organ injury. As these parasites increasingly develop resistance

to synthetic drugs like Albendazole, the search for effective, sustainable alternatives has become a public health priority. This study evaluated the anthelmintic potential of crude extracts from *Curcuma longa* (CL), *Zingiber officinale* (ZO), and *Curcuma amada* (CA), both individually and in combination. The phytochemical screening successfully identified a diverse array of bioactive secondary metabolites across all three plants, including phenols, flavonoids, terpenoids, alkaloids, and tannins. These compounds are well-documented for their ability to interfere with the energy metabolism of helminths or cause neuromuscular interference, leading to paralysis. The presence of these metabolites provides a strong biochemical rationale for the observed anthelmintic activity.

The experimental results demonstrated that all extracts possess dose-dependent anthelmintic activity. Among the individual extracts, *Curcuma amada* showed the most potent effect, outperforming *Zingiber officinale* and *Curcuma longa* in terms of both paralysis and death times. However, the most significant finding of this study was the **synergistic effect** observed in the polyherbal combination (1:1:1 ratio of CL, ZO, and CA). At a concentration of 100 mg/ml, the combination induced paralysis in 19±0.5 minutes and death in 25±0.4 minutes. This performance is remarkably close to the standard reference drug, Albendazole, suggesting that the combination of these plant extracts can achieve therapeutic efficacy comparable to synthetic agents. In conclusion, the findings suggest that the polyherbal blend of *Curcuma longa*, *Zingiber officinale*, and *Curcuma amada* offers a ray of hope in the fight against multi-drug resistant helminths. These plants are not only effective but are also widely available and generally safer for human consumption. This study provides a solid foundation for future research into isolating the specific active molecules responsible for this synergy and conducting in vivo trials. Ultimately, these natural extracts could be developed into cost-effective, accessible, and potent anthelmintic treatments to improve public health outcomes globally.

ABSTRACT

Grammar teaching in India often stops at memorization, leaving students who can score well on tests but struggle to use English naturally. This paper explores how the Flipped Research Model (FRM) can bridge that divide by linking flipped learning with Data-Driven Learning in a way that fits multilingual, low-tech classrooms. Using a conceptual approach, it brings together policy, prior studies, and classroom evidence to design a routine where students learn to ask questions, analyze real examples, and form evidence-based rules before class, then test and refine those rules during group inquiry. Grounded in cognitive load theory and the ICAP framework, the model lightens the mental load on learners and encourages deeper interaction through discovery, reflection, and peer feedback. Findings suggest that printed or small-scale digital corpora, bilingual materials, and collaborative problem-solving can make grammar teaching both more meaningful and more accessible. In doing so, FRM translates the ideals of NEP 2020 and NCERT into classroom practice, turning grammar from rote learning into an active, shared process of reasoning and communication.

Keywords: grammar inquiry, flipped learning, multilingual classrooms, data-driven learning, Indian education reform

INTRODUCTION

Part 1: Background

English occupies a peculiar position in India, a position that is both ordinary and aspirational, a classroom subject and in some cases a labor-market filter. This fact has been proven through empirical studies on wages which make the stakes quite clear since adults who speak fluent English earn far more than those without that skill, which helps explain why families and schools treat the language as a vehicle for "societal upward" mobility rather than a mere subject slot on the timetable (Loyalka et al. 2024; Azad and Fahmida 2024). Classroom results, however, tell a different story, because many adolescents who clear grammar-oriented assessments still struggle with basic comprehension and production tasks in real time. The Annual Status of Education Report has repeatedly documented modest English reading ability among rural youth, with a majority being able to read simple sentences only by late adolescence and a sizable minority unable to do so at all (ASER Centre 2024). The gap between the credential and the competence signals a structural problem, not isolated lapses, since a system that rewards paper-and-pencil recognition of forms does not automatically build sentence-level accuracy in context. That contradiction frames the present study, which treats grammar not as a worksheet topic but as a set of decisions made under communicative pressure. A policy environment that now questions rote routines is part of the reason as to why this is an urgent matter, because it aligns public expectations with classroom redesign rather than exam coaching (Ministry of Education 2020; NCERT 2023). The question is therefore practical as well as conceptual, since any viable model needs to close the apparent space that exists between what students memorize and what they can actually say, write and revise.

If the problem were to be traced, the trace would find that a significant portion of the blame rests on the utilization of a method that favours explanation over exploration, and translation over use. The Grammar–Translation method, still used in many schools, focuses on reading passages from textbooks, memorizing grammatical rules, and practicing isolated vocabulary items. It gives little attention to spoken language, interactive communication, or producing meaningful output (Richards and Rodgers 2014). Such methods tend to build an awareness of grammatical labels without developing the procedural fluency required to combine clauses smoothly under real-time communication pressures. Teacher-centred classroom recitation is found in most classrooms also limits active participation, because students wait for the correct answer rather than test hypotheses about form and meaning through guided practice. When assessments mirror those routines, the washback is predictable, and teaching time begins to tilt more toward what will be graded rather than what will be used or can be made useful. India's national policy diagnoses the pattern clearly, noting how board exams and the associated coaching culture displace "true learning" and compresses the curriculum into a specified band of examinable material (Ministry of Education 2020). In rural and resource-strained settings, the effect grows stronger, since photocopied notes, grammar keys, and past papers become the de facto syllabus. A method that largely asks students to recognize correct forms, rather than generate or utilize them properly in speech or writing, cannot be expected to plausibly deliver communicative control.

Any solution has to start in the real classroom. It is noisy, mixed, and rarely monolingual. NCERT's national documents treat multilingual competence as valuable, yet they also record that many schools treat it as a problem, especially when teachers and textbooks stay tied to one dominant classroom medium (NCERT 2005; NCERT 2008; NCERT 2023). One routine, one language, one worksheet. That routine often fails because learners do not share the same sound patterns, the same word-building habits, or the same instinct for how English sentences should sit together, so a "mistake" is not always the same thing across groups. What sounds wrong to one group can sound ordinary to another (why would it not, when languages train different expectations?). Work on language transfer supports this point, including reports that Hindi–English learners show interference in areas such as articles, prepositions, and subject–verb agreement. Rule-recall teaching rarely shifts these patterns for long, because it leaves untouched what learners believe English is doing and why an error can feel logical from inside a learner's own system (Sailaja 2009; Mukherjee and Hoffmann 2006; Sridhar 2024). Evidence from other low- and middle-income

settings points in the same direction: multilingual English-medium classrooms need tasks that recognise cross-linguistic resources, then guide them toward accurate English forms rather than pressuring students to hide them (Cummins 2007). Exams add a second squeeze. High-stakes tests often reward memorised templates and predictable answers, which pushes teachers to build lessons around what fits the paper instead of what develops writing, explanation, and reasoning over time (Alderson and Wall 1993; Xie 2025). The outcome is familiar: students can name tenses and fill blanks, then stall when asked to explain a process, argue a position, or keep a conversation going. Grammar does not need to disappear. It needs to live inside purposeful reading, writing, and talk, so forms show up as usable tools rather than labels to recite.

Policy language now leaves room for a shift. The National Education Policy 2020 calls for classroom culture organised around discussion, analysis, shared activity, and problem-solving across school stages (Ministry of Education 2020; NCERT 2023). It also recommends redesigning examinations so performance reflects understanding rather than months of coaching built on repetition, which suits teaching that values thinking, communication, and application (Ministry of Education 2020; NCERT 2023). Earlier NCERT guidance already pushed in that direction by treating language learning as everyday proficiency plus the use of language for abstract thinking, not merely correct forms on a page (NCERT 2005; NCERT 2008; NCERT 2023). Real tasks matter here. Learners start to care about grammar when grammar carries meaning from one person to another in writing or speech (a request, an explanation, a disagreement, a story). Teachers watch the exam closely, sometimes more closely than the textbook, because the exam signals what the system rewards. When official documents praise projects, discussion, and inquiry, schools gain some cover to teach that way without constant worry about penalty at exam time. For grammar, that cover matters because it makes room for classroom work where students inspect examples, test what holds, revise what fails, and slowly build trust in their own judgment. Multilingual rooms fit this style of learning because comparison can come before correction, which reduces the rush to impose one "right" pattern on everyone too early. Grammar then starts to look less like memory work and more like guided reasoning with language.

Two teaching ideas already point to that kind of work. They fit together. The flipped classroom changes how class time is spent: short readings or brief videos can carry explanations outside class, leaving classroom minutes for practice, peer talk, problem-solving, and comparison of answers (Bishop and Verleger 2013; Baig, Anjum, and Alharbi 2023). Less teacher monologue. More student work. Data-Driven Learning, associated with Tim Johns, pushes the same logic by asking learners to study authentic samples of language and reason from patterns rather than accept correctness as a fixed announcement from a book. Johns's (1991) "language detective" metaphor remains influential because it captures a shift in classroom agency, where students investigate and decide what the evidence supports (Johns 1991; Lusta, Demirel, and Mohammadzadeh 2023; Huang and Ma 2025). It can feel slow at first (and yes, some students will ask, "Are we allowed to decide?"). Corpus research supports the method's promise, since learners who explore language data often develop stronger pattern awareness and longer retention than learners limited to memorised statements (Boulton and Cobb 2017; Lusta, Demirel, and Mohammadzadeh 2023). Put the two together and a workable classroom rhythm appears: students take in a short explanation before class, then use class time to examine small, teacher-curated corpora tied to the day's target form, looking for regularities, exceptions, and the boundary lines where a rule stops working. In multilingual groups, the same routine gains a second layer because students can compare how their home languages handle tense, articles, or word order, then predict where English errors are likely to cluster and why they persist. Why suppress that knowledge when the room already contains it? This does not require a language lab or heavy software; a few shared devices, short bilingual texts, local corpora, and a simple cycle of notice, hypothesis, and check can carry the lesson. When students spend time on authentic examples, careful choices, and revision of short drafts, grammar stops looking like a checklist and starts to behave like a practical skill learned through repeated use (Boulton and Cobb 2017; Lusta, Demirel, and Mohammadzadeh 2023).

Even with all this progress in real classrooms, research still has not quite figured out how to tie these inquiry-based methods into one workable, long-term teaching model that multilingual realities such as the one found in India can benefit from. Researchers have studied the Flipped Classroom and Data-Driven Learning on their own, and

sometimes together, but a gap still remains. There is a lack of a clear, practical framework that uses the flipped structure to teach the small inquiry methods that make DDL work. Most studies compare outcomes or tools, while teachers in India face limited resources, uneven device access, and several first languages in the same room, so they need a plan that fits those realities. To fill this gap, the paper introduces what it calls the Flipped Research Model. The idea is simple but practical. It reworks the pre-class stage of flipped learning to focus less on content delivery and more on training students to think like young researchers by making them learn how to ask more focused questions, test ideas, and notice patterns in real examples. This preparation helps them walk into class ready for inquiry-based grammar work, where they can actually use what they find instead of just repeating grammatical rules.

METHODOLOGY

This study adopts a conceptual research design. The aim is clear: to build a theoretical model for English grammar pedagogy in India by bringing existing research, policy documents, and day-to-day classroom routines into the same line of sight. Start with what fails. Older grammar teaching methods often break down when lessons stay trapped in rule lists, copied notes, and recall-heavy exercises instead of showing learners how English behaves in real sentences they read, write, and speak. Why do students remember labels yet struggle with use? The review follows that question by mapping the points where the flipped classroom and Data-Driven Learning meet, then checking where each approach leaves gaps that the other can cover. The flipped approach shifts explanation to short pre-class inputs so classroom minutes can be spent on talk, drafting, peer checking, and correction in real time, not silent page-filling. Data-Driven Learning then supplies the evidence base, because learners can scan authentic examples, notice repeated structures, and test whether a "rule" holds across different contexts (a paragraph, a dialogue, a short report).

The result is framed as a Flipped Research Model. It is practical. Learners review brief materials before class, then work in class with small corpora or printed text samples, and then produce short writing or speaking outputs that force grammar to do real work. Multilingual comparison stays central (because English in India rarely arrives alone). Learners are encouraged to notice how first-language habits shape article choice, word order, tense marking, or agreement, then trace how those habits surface in drafts, corrections, and revisions. A classroom can do this without a lab. The model relies on local texts, printed datasets, and teacher-curated examples that match the school's resources, not ideal conditions found only in well-funded settings. It also keeps assessment pressure in view by tying inquiry activities to observable outputs, such as revised sentences, short paragraphs, and spoken explanations that can be checked and improved. In line with the National Education Policy 2020, grammar is treated as something learners explore, argue about, and use to communicate, rather than a set of rules and labels to memorise.

Part 2: Theoretical Synthesis: The Flipped Research Model

Any redesign worth a teacher's time must start by clarifying what each component actually does, and why the combination improves learning rather than merely rearranging tasks. The flipped classroom changes how teachers use time. Instead of explaining and demonstrating lessons during class, teachers shift those parts to individual study so that class time can focus on interaction, feedback, and hands-on practice (Bishop and Verleger 2013; O'Flaherty and Phillips 2015). Foundational research describes the flipped classroom as much more than swapping lectures for videos. What happens in class is the real difference. When students come together, that time should be used for applying ideas, analyzing problems, and creating new work instead of passively repeating what they already watched or read. Studies and reviews across different subjects and education levels continue to show that students learn more deeply when class time is designed this way (van Alten et al. 2019; Chen, Chen, and Wu 2025). Two well-known theories help explain why. The revised taxonomy of cognitive processes places application and analysis higher than simple recall or comprehension, and the ICAP framework shows that learning becomes stronger as students move from watching and listening to active, constructive, and fully interactive work (Anderson and Krathwohl 2001; Chi and Wylie 2014). A good flipped lesson, then, is not about when teachers explain but about how students use that explanation once they meet again. When handled well, it turns classroom time into space for deeper

thinking and real collaboration (O'Flaherty and Phillips 2015; Chen, Chen, and Wu 2025). Short and focused pre-class segments help too. They give students just enough preparation to reduce overload and arrive ready to practice together (Abeysekera and Dawson 2015). Of course, not every attempt works. Some lessons still fall back into the same routine. But the stronger examples share one thing in common: students receive clear, brief input before class and spend their shared time solving problems with guidance from the teacher (Bishop and Verleger 2013; van Alten et al. 2019).

Data-Driven Learning changes the feel of grammar lessons. It shifts grammar from a lecture topic into something students can actually look at. Instead of receiving rules as finished products, learners examine lines of real sentences taken from genuine use, not the tidy "made-up" examples that often appear in textbooks (Johns 1991; Gilquin and Granger 2010). The evidence sits on the page. The teacher's job then changes into a different kind of work, where the teacher selects what to display, sets a clear task, and asks questions that force attention onto how particular words and structures behave in context (Boulton and Cobb 2017). What happens when students handle the examples themselves? They begin to notice repeated patterns, and that noticing tends to last longer than memorised rule statements because it is tied to what they have just seen and tested (Boulton and Cobb 2017). Even grammar, often described as too fixed for exploration, responds well when learners can observe usage, sort examples, and decide what counts as a pattern worth trusting.

The gains show up in concrete places. Students start spotting collocations, common sentence frames, and recurring phrase shapes, then reuse them in their own writing rather than guessing from memory (Vyatkina 2016; Larsen-Walker 2017; Muftah 2023). Small changes accumulate. A repeated article error can begin to drop out once learners see the same noun phrase behaving differently across several authentic lines, and the change can feel less like "correction" and more like a new habit taking hold. Still, the first steps can be challenging. Beginners often feel uncertain when faced with long lists of concordance lines, and too much data can blur rather than clarify, especially when students do not yet know what to look for (Lusta, Demirel, and Mohammadzadeh 2023). That is where tight teacher guidance matters, including small datasets, simple prompts, and a clear stopping point so the activity does not drift into confusion. Tools such as AntConc can support the work, but they tend to help only after a brief orientation that lets students feel in control of the screen and the search results (Anthony 2024). In day-to-day classroom practice, the method tends to work best when teachers ask focused questions, keep the data within what students can manage, and run short cycles of noticing, testing, and rewriting that end with an improved sentence or a revised paragraph students can recognise as their own (Boulton and Cobb 2017; Lusta, Demirel, and Mohammadzadeh 2023).

The approach proposed here treats the flipped model not as a space to deliver extra content but as a way to train students in the habits of inquiry that they will later use together in class. The goal is for homework to build readiness, and for class time to become a shared research session rather than a review. A simple swap, where students watch a grammar lecture at home and then practice Data-Driven Learning in class, misses the point. The real difficulty in DDL is not finding the data but knowing how to ask the right questions, read concordance lines, and check whether a rule actually holds weight (Lusta, Demirel, and Mohammadzadeh 2023). That is why the pre-class stage focuses on process, not on rules. Short tutorials walk students through three small phases: how to frame a micro-question about a structure, how to read examples without overgeneralizing, and how to keep a short record of their observations and doubts (Anthony 2024). Abeysekera and Dawson explain why this order matters. By spreading short explanations and tool introductions across small segments, teachers reduce cognitive load before students face messy data in groups (Abeysekera and Dawson 2015).

Beginners have a tendency to overload fast. The moment a long concordance list appears beside an unfamiliar interface, attention can slip from language to mechanics, and students may spend more mental energy hunting for buttons than reading what the sentences actually show (the cursor becomes the main character). Click, scroll, panic. That overload matters in Data-Driven Learning because the method asks learners to notice fine-grained grammatical behavior, yet the working memory budget is already being spent on tool navigation and data handling rather than

interpretation. The Flipped Research Model responds by moving the "how-to" steps to before class, so the first in-class minutes are not wasted on orientation and repeated troubleshooting. Students arrive knowing the sequence. Cognitive load theory helps explain why this rearrangement can matter, since lowering extraneous load during class leaves more room for the task that produces learning, namely scanning evidence, forming a claim, then checking that claim against more examples. The change looks small on paper, yet the classroom experience often feels lighter, because fewer students get stuck at the "what do I do now" stage.

ICAP provides a second line of support, because it predicts deeper learning as students shift from passive exposure to active manipulation and then to interactive explanation and critique with peers (Chi and Wylie 2014). Passive viewing is common. Active work is rarer. The model also supports partial guidance rather than full discovery from the start, since research on minimally guided learning reports that novices often flounder when asked to infer complex rules alone, especially when the materials are dense and the task requires multiple steps of reasoning (Kirschner, Sweller, and Clark 2006). Is that surprising? Not really, because beginners may not yet know what counts as a relevant pattern, what counts as noise, or when an "exception" is simply a different register or genre. The design therefore includes short demonstrations and worked examples before independent exploration, which lets inquiry happen inside a clear structure rather than in a fog. Teachers can keep the dataset small, keep the question tight, then run short cycles of noticing, testing, and rewriting that end with a visible change in a sentence or paragraph (Boulton and Cobb 2017; Lusta, Demirel, and Mohammadzadeh 2023). Students still investigate, yet they do it with guardrails.
In class, the setup can feel like a small grammar lab rather than a familiar lecture. Students walk in with a shared toolkit plus a brief pre-class log that records what they tried, what worked, and where the process broke down (a wrong search term, a confusing output, a pattern that seemed to vanish). The teacher skims a few entries. One glance can reveal which misunderstandings are common enough to address first. A ninety-minute session can move through four phases, beginning with a short warm-up such as "spot the outlier," where a few projected concordance lines bring everyone onto the same structure before groups split. The group work that follows is concrete: each team tackles a micro-question using teacher-selected data, notes contrasts, then drafts a provisional rule with a clear cut-off, such as when a bare plural signals a generic meaning or how often a that-clause follows a reporting verb in a given genre. Then comes output. Groups write a short piece using the same forms, perhaps a mini-explanation, a short narrative, or a comparison paragraph that forces a choice about subordination, and those drafts give the teacher quick evidence of whether noticing has carried into use (Vyatkina 2016; Muftah 2023). The final phase is checking and revision, where teams compare their drafts against fresh concordance lines while the teacher circulates table to table like a research guide rather than an examiner. The extra time created by the flipped arrangement fits ICAP's higher engagement bands, because students argue, test, and justify choices rather than wait for a single correct answer (Chi and Wylie 2014; Chen, Chen, and Wu 2025). DDL studies describe the same mechanics: hands-on concordancing can support lexico-grammatical choices, attention to collocations can improve accuracy, and linking discovery to writing can help changes persist beyond the day's exercise (Boulton and Cobb 2017; Vyatkina 2016; Larsen-Walker 2017).

Assessment completes the design, because a teaching method that collapses after three weeks is not much of a method. The evaluation cycle mirrors the learning cycle. It does not reduce everything to error counting. Each rubric can track process and product, with one part assessing how well students frame a question and gather evidence from data, another checking whether the group can explain its working rule in plain language, and a third measuring how far the writing improves after revision guided by corpus input. Those criteria keep learning visible. They also keep the goal in view: moving from noticing a pattern to using it deliberately, in a sentence that carries meaning for a reader or listener. Regular short writing and speaking tasks support that shift, because feedback can be tied to the exact structures under study rather than to a vague sense of "good grammar" (O'Flaherty and Phillips 2015; van Alten et al. 2019). Reviews of flipped learning suggest that this kind of connected sequencing helps sustain engagement across weeks, since each lesson produces a small cycle of evidence, revision, and improvement that can be observed without guesswork (Bishop and Verleger 2013; Chen, Chen, and Wu 2025).

Limited devices do not end the method. Printouts work. A projector works too. Data-Driven Learning does not depend on expensive software, as long as teachers supply good examples and a question that is specific enough to answer with the available data (Johns 1991; Anthony 2024). Many guides recommend a short skills ramp at the start of the course, perhaps two or three sessions focused on reading concordance lines, understanding simple search results, and building basic queries, because those early moves can prevent later frustration when the main lessons begin (Anthony 2024). One warning deserves repetition. Beginners usually need some guidance before they explore, enough to help them see the pattern without losing the thread. Research linked to cognitive load makes the same point, since unguided discovery can overload novices even when the content itself is learnable (Kirschner, Sweller, and Clark 2006; Abeysekera and Dawson 2015). Done in this order, the Flipped Research Model turns grammar class into inquiry with receipts, where students test claims about language rather than collect rules for an exam notebook (Boulton and Cobb 2017; Chen, Chen, and Wu 2025).

Part 3: A Contextualized Framework for the Indian Classroom

A classroom plan that works has to match real Indian classrooms. More than one language is heard in the same period, exam papers still shape what teachers drill, and a working internet connection can be present on one bench and missing on the next, so the design has to cope with multilingual speech, test pressure, and uneven access to devices while still giving students repeated practice with grammar they can actually use when they write a paragraph or explain a point aloud. What is the point of a rule that never leaves the worksheet? The Flipped Research Model answers that by splitting learning into three linked stages, each one ending with a visible product rather than a vague "understanding" that cannot be checked. At home, students watch very short videos. Those clips show how to form small language questions, how to read a few concordance lines, and how to run simple corpus steps without getting stuck on menus and icons (a phone screen, a printout, a projector). In class, groups run a tight research cycle. They work with Indian and global English examples, test a pattern against the lines in front of them, then write on the spot so the pattern shows up in a sentence that carries meaning rather than in an underlined label. After class, each group turns its finding into a shareable piece, such as a mini-poster or a short blog-style note, which gives the class a record of progress that can be revisited during revision week or before an exam. The method leans on open corpora that already include Indian English and some Indian language data, so comparison rests on evidence rather than guesswork. Policy language points the same way, since the National Education Policy 2020 calls for inquiry, discussion, and analysis-led learning, plus examinations that reflect what students can do rather than what they can repeat (Ministry of Education 2020; NCERT 2023). Multilingualism is treated as an asset, and grammar gains a place in real classroom work rather than in drill sheets alone (NCERT 2005; NCERT 2008).

The first phase, which focuses on pre-class skill building, doesn't hand out grammar rules. It teaches the habit of asking questions. Each short module, maybe six to eight minutes long, shows just one thing at a time which would include how to form a manageable question, how to read a concordance line without jumping to conclusions, or how to write down a rule candidate with an example and one that doesn't fit. Students get to know the tools by name. AntConc, for instance, gives concordances and frequency lists, and the video shows how to open a small text file, run a search, sort results by left and right context, and save the lines for later discussion (Anthony 2024). The corpus choices stay local on purpose. Students see the Kolhapur Corpus of Indian English as a reference point for Indian English writing, along with smaller news or academic corpora that teachers can build during the semester (Sailaja 2009; Sridhar 2024).

Most Indian classrooms run in two or three languages. That fact should shape the modules from the first page, so students work with paired translation datasets such as the IIT Bombay English–Hindi corpus and Samanantar, which include several Indian languages (Kunchukuttan, Mehta, and Bhattacharyya 2018; Ramesh et al. 2022). The pre-class clips keep the steps plain. Students learn how to locate matched segments, scan the English line for a verb pattern, then check the Hindi or Tamil line for case marking or aspect choices that may push the English choice in a predictable direction (this is where the "why" begins to show). Curiosity matters here. Competence matters too. By the time students arrive, they should already know how to pose one specific question, pull around twenty relevant lines, and write a careful claim that survives a quick counter example. Why allow sweeping "always" rules to settle

in when the data usually refuses them? This pre-class stage fits national guidance that treats language as something students compare and reason with, not something they repeat from a page (NCERT 2005; NCERT 2023).

Indian English needs attention early. Students should meet it before they touch a concordance list, because their everyday habits often follow patterns that descriptive research has already documented, and it is better to name those patterns than to treat every difference as a personal failure. The videos therefore show how features from major Indian languages can surface in English use, including the frequent progressive with stative verbs, described as a contact-shaped outcome rather than a random "mistake" (Sailaja 2009; Sridhar 2024). Give students the reason. Then give them the standard reference point. Short extracts from a major grammar description set that baseline clearly, including the point that verbs such as *know*, *want*, and *understand* rarely appear in the progressive because "ongoingness" does not sit comfortably with the kind of state those verbs describe (Huddleston and Pullum 2002). The module also shows a few real corpus lines so the rule does not stay theoretical. Students should see the pattern on the page before class begins, because that first glance reduces panic later when the screen fills with examples. When the literature records specific exceptions, such as limited progressive uses with some stance verbs, the clips mark them so students do not memorise a hard "never" and then defend it like a shield (Leech, Hundt, Mair, and Smith 2009).

Class time should feel different. It should feel like a small grammar workshop with evidence on the table. The teacher starts with a "problem of the day" pulled from recent student writing, so the question stays close to what students actually produce and what they actually want to fix. A prompt might be: why does English usually avoid *I am understanding*, even when a Hindi equivalent uses imperfective marking that can tempt learners toward that form? Start with the puzzle. Then show the lines. The warm-up stays short, perhaps five minutes, using ten projected concordance lines from Indian English and international sources so the class can spot the odd one and explain what makes it odd, not merely label it wrong. Students then move into mixed-language groups with a small folder of example lines and a one-page guide that restates the question, gives a few search strings, and lists common traps. NCERT guidance has supported this kind of learning move for years, since it treats observation, classification, and hypothesis-testing as part of language learning rather than a reward for a small group of "strong" students (NCERT 2005; NCERT 2008). The teacher does not sit at the front. The teacher moves, asks for proof, nudges a vague question into a sharper one, and steps in only when a group's claim drifts away from what the lines actually show (Johns 1991; Boulton and Cobb 2017).

The task becomes specific when stative verbs take center stage. The instruction is clear: collect twenty English sentences using *know*, *want*, or *understand* from both news writing and academic prose. Then tag any line that places these verbs in the progressive, match each with its Hindi line where possible, and explain when English prefers the simple form. Ten lines should come from Indian English sources. Ten should come from an international source set. The teacher supplies both sets so the results do not tilt toward one register by accident (and so the activity does not become a scavenger hunt). Students tag aspect, note the subject type, identify the clause type, and flag progressive examples for deeper discussion. When a progressive example appears, students must justify why it occurs in that context, or state plainly that it is non-standard for the genre and explain what in the line supports that judgment (Vyatkina 2016; Muftah 2023). The point is proof, not confidence. That is how grammar becomes usable knowledge rather than a notebook rule.

The group would also examine how the Hindi examples mark whether an action is ongoing or habitual. When a Hindi line uses such marking, students begin to see why Hindi speakers of English sometimes overuse the progressive. After analysing the examples, they write a short guide summarizing their findings: with verbs such as know, want, and understand, English normally takes the simple present to describe general states. The progressive appears only when the meaning shifts toward something temporary or developing, which is rare and depends on context. To apply what they have discovered, students then create five new sentences for a peer group to test, which turns what they learned into active use. Descriptive studies on Indian English explain why such transfer patterns

occur, while standard grammars and corpus research clarify which forms are correct and where small exceptions appear (Sailaja 2009; Sridhar 2024; Huddleston and Pullum 2002; Leech, Hundt, Mair, and Smith 2009).

This kind of classroom lab does not end with stative verbs. It keeps going, because grammar problems in student writing rarely arrive one at a time, and the same routine can handle the next knot just as well. One week the focus can be articles after possessives. Another week it can be prepositions in time phrases, the small words that students use every day yet still mix up under exam pressure. Another week it can be reporting verbs and the verbs that naturally pull a *that*-clause behind them, which matters the moment students start writing explanations and arguments (and yes, the difference shows up fast when the sentences get longer). The method stays steady. Build a small set of lines. Ask one sharp question. Check the pattern in Indian English and in a non-Indian source set, then write a short piece that forces the pattern into use so the class can see whether it has actually landed. Why keep grammar trapped in underlining when it can sit inside real writing?

Limited devices do not break this. The teacher can project the lines. The teacher can print concordance pages and hand them out in small stacks. Students can circle, tag, and argue over the same evidence with a pen in hand, which often makes the discussion clearer than a silent screen ever does (a page has fewer distractions). Data-Driven Learning still holds because the key work is reasoning over examples, not clicking through software menus, and that principle sits at the center of the method's original logic (Johns 1991; Boulton and Cobb 2017; Anthony 2024). If the goal is sharper judgment in writing, the route has to run through evidence and revision. That is the point of the lab.
Indian linguistic resources expand the scope further. The Linguistic Data Consortium for Indian Languages already hosts annotated texts in several local languages, and teachers can use these to build quick classroom corpora without scraping websites (Jha 2010). Newer resources like the ILCI extension and Samanantar add more regional language pairs beyond Hindi–English, which helps schools in southern and northeastern states where Hindi isn't the usual link language (Siripragada et al. 2020; Ramesh et al. 2022). Over a few weeks, the routine becomes familiar, and students start to expect progress they can actually measure.

The teacher's role remains decisive, but it changes shape. Instead of carrying the room through long explanations, the teacher curates corpora, frames solvable problems, and guards the boundary between productive discovery and aimless trawling. A short checklist helps: define the question in one sentence; give two suggested queries and one contrasting query; cap each dataset at a size that a group can scan in fifteen minutes; and pre-write one accurate generalisation that can be revealed if the room stalls. This aligns with guidance against minimally guided instruction for novices and with research showing that worked examples early in a sequence can lower extraneous load (Kirschner, Sweller, and Clark 2006). The teacher also acts as assessor in motion, listening for moments when a misunderstanding hardens and offering a quick rule with one anchor example. National documents on curriculum and assessment make space for this pattern, since they cast language learning as reasoning across texts and explicitly ask teachers to foreground communication tasks over item practice (NCERT 2005; NCERT 2023). When the day ends, the teacher posts a one-page consolidation that records the stable rule, the best counterexample, and two transfer tasks for the next week's writing.

Multilingualism is not an add-on in this model. It sits at the center. Groups are mixed on purpose by first language, so students can reason in the language that comes most easily, then switch to English when they report back to the room. That switch matters (it forces a second pass through the idea). NCERT's reports have long treated the mother tongue as a resource for reasoning, not an error that needs policing, and that position matches the daily work of these grammar labs (NCERT 2005; NCERT 2008). When learners use L1, they test whether a form feels natural, they talk through aspect and definiteness, and they predict where interference might bend their English out of shape. Then they check their prediction against corpus lines and the matched translation lines from Indian-language datasets. What does that buy them? It often lets them name the exact feature that triggered the shift, not in vague terms, but in a specific choice like an imperfective marker, a case ending, or a missing article.

This way of working sits neatly alongside NEP 2020. It calls for multilingual classrooms and asks schools to keep home languages active while English proficiency grows through real use (Ministry of Education 2020; NCERT 2023). The room feels louder. It also feels smarter, because students stop performing English and start using language to reason, explain, and disagree. In mixed-language groups, a claim has to persuade someone who does not share the same L1, so students tighten their wording and bring evidence quickly. A small debate breaks out (sometimes messy). One student insists a sentence "sounds right," another points at a concordance line and says it does not, and a third tries to explain why the clash happens at all. That social pressure sharpens analysis. Over time, students learn to phrase rules with limits, genre labels, and exceptions instead of memorising blanket statements that fail the moment a new sentence appears. Grammar needs that precision, even when it takes weeks to form.

The third phase, called post-inquiry synthesis, turns research notes into something the school can actually use. Each team picks a format that fits what their school can run without drama. Some teams write a one-page explainer for juniors, others record a three-minute clip on a single phone, and some design a small digital poster showing five correct sentences and five near-misses with brief notes on the difference. This step is not decoration. It gives the work a real audience, which changes student attention in a way no private notebook ever does. A teacher in a Grade 10 section can be seen reading a student-made sheet during a revision period, pausing, then pointing to a line and asking the class to justify it again, and that moment tells students the work will be used, not filed away. Each product must quote at least two corpus lines, cite the source, and state the rule in one sentence, followed by another sentence naming the most common exception. When the task compares languages, students add a simple two-column table, with the English pattern on the left and the aligned Indian-language example on the right, usually drawn from the IIT Bombay corpus or Samanantar and cited properly (Kunchukuttan, Mehta, and Bhattacharyya 2018; Ramesh et al. 2022). A short rubric keeps grading manageable by checking three things: evidence use, rule clarity, and sentence accuracy. Over a semester, the class builds a small library of guides that connects Indian English use with reference grammar standards, so the room keeps a shared memory of what it has learned (Huddleston and Pullum 2002; Sailaja 2009; Sridhar 2024).

Two habits keep the model steady across a full term. The first is a short tool ramp. The course begins with three brief sessions where students practise reading concordance lines and spotting simple collocations before they touch heavier grammar topics, because early familiarity reduces later confusion when the data becomes dense (Boulton and Cobb 2017; Johns 1991). The second habit is a shared departmental folder of Indian English datasets and matched translation datasets, so teachers do not rebuild materials from zero each year. The ILCI and the Linguistic Data Consortium for Indian Languages already encourage this kind of shared resource building, and even small excerpts can serve as a local corpus bank for repeated classroom use (Jha 2010; Siripragada et al. 2020). Where the internet fails, teachers can save datasets on USB drives or print short concordance sets for group work. Electricity can drop. Inquiry can continue. Screens help, yet the learning comes from students arguing over evidence and rewriting sentences until the pattern holds.

This model does not claim to fix every weakness in English teaching in India. It targets a specific gap that teachers recognise instantly: the distance between exam performance and real communicative control. By moving pre-class time toward method training, it addresses a known problem in Data-Driven Learning, namely that beginners can get lost when raw data appears without enough guidance (Lusta, Demirel, and Mohammadzadeh 2023). Indian corpora and Indian-language matched lines also give learners familiar reference points, so they test grammar against usage they recognise rather than copying distant examples that do not match their lives (Kunchukuttan, Mehta, and Bhattacharyya 2018; Ramesh et al. 2022). Mixed-language discussion before English reporting respects the multilingual classroom reality that NEP 2020 and NCERT documents already affirm (Ministry of Education 2020; NCERT 2023). The public product requirement turns private notes into shared knowledge that classmates can read, question, and revise, which keeps learning visible and correctable. Over time, the class builds a living reference that ties together Indian English usage, corpus evidence, and formal grammar, keeping student writing from drifting while still letting it sound like the students who produced it (Huddleston and Pullum 2002; Sailaja 2009; Sridhar 2024).

RECOMMENDATIONS AND CONCLUSION

India's classrooms rarely start from perfect conditions. Any plan that claims otherwise is not a plan, it is paperwork. Access remains the tightest constraint, because students in many city schools carry personal smartphones with steady data, while many rural students do not, and that difference shapes homework completion and participation in digital tasks (ASER Centre 2024). Signal bars matter. So do power cuts, shared devices, and the simple fact that a phone may be in the house but not in the student's hand when it is needed. Telecom figures point in the same direction, since internet use has increased while mobile phones account for most access, and large gaps remain in coverage and signal quality between urban and rural areas (Telecom Regulatory Authority of India 2025). The model answers this unevenness with two routes at every stage, one that works with screens and one that works without them. Pre-class modules can appear as short printed cards that teach three inquiry moves, such as reading a concordance line, spotting the repeated verb frame, and writing a test sentence (no app required). Students with phones can scan a QR code for extra examples, yet students without phones still complete the same core steps, so the class does not split into "digital" and "left behind." Inside the room, one projector can carry the data for everyone, or a rotation plan can let one laptop serve several groups, and when the power fails, printed concordance packs keep the task alive. What drives progress is not fancy software, because research on corpus learning keeps pointing to the same thing: steady hands-on engagement with real examples, followed by immediate writing or speaking that puts the pattern to work (Boulton and Cobb 2017). Patchy connectivity is treated as a normal feature of the environment, not as an excuse to stop, and that choice keeps practice steady in low-resource schools.

Teacher growth decides whether this method survives. Pilots die when teachers feel stranded. The teacher's role shifts from running recitation to guiding small groups through small research problems, and that shift asks for new classroom moves, such as choosing short datasets, posing a tight question, then knowing when to intervene and when to hold back. Many teachers have not been trained for that style of work. Training therefore has to look like rehearsal, not like a lecture with slides and a sign-in sheet (who learns classroom timing from a lecture?). Teachers need practice in three places: opening an inquiry, selecting a dataset that students can handle, and stepping in before a group's claim drifts away from the lines on the page. Research on learning guidance explains why this matters, since novices often flounder when they are asked to discover complex rules without enough structure, and short demonstrations can reduce confusion before students move into open exploration (Kirschner, Sweller, and Clark 2006). A coaching circle after class can make the shift stick. Three teachers meet for ten minutes, replay a one-minute classroom clip, mark the exact moment an intervention happened, then swap the one-page brief used that day. It is quick. It is specific. National policy supports this kind of reflective and continuous development by encouraging schools to treat inquiry and peer learning as routine work rather than as a risky experiment (Ministry of Education 2020). Over time, this habit builds teacher confidence with corpus-based tasks, improves judgment about when students can reason independently, and creates a shared bank of lesson materials that stays usable even when staff change.

Curriculum design and assessment practice decide whether the model grows beyond a few rooms. Exams shape habits. When a system rewards memory work, teachers naturally lean toward board-style question formats and repetition-heavy drills, even when they know students struggle to write and explain in real contexts. The assessment plan pushes back by grading what the method actually builds: inquiry skill, evidence use, and clearer writing. A short rubric can carry that load. It scores how well a group frames a question, how convincingly it explains a rule using cited corpus lines, and how accurate the rewritten sentences are after analysis and revision. Process matters here. Product matters too. Formative assessment research explains why this approach helps, since students improve more when feedback is timely, specific, and followed by a chance to apply it, rather than saved for a final mark that arrives too late to shape learning (Black and Wiliam 1998). Policy direction points the same way, because the National Education Policy and the National Curriculum Framework emphasise reasoning, multilingual awareness, and discussion-led learning (Ministry of Education 2020; NCERT 2023). When classroom tasks, rubrics, and policy

language pull in the same direction, teachers stop fearing that inquiry will cost marks, and that is when change becomes workable at scale.

For schools that want to start small, three tools help. The first is a "corpus starter pack," a small folder with a few teacher-built mini-corpora, only a couple of pages each, pulled from Indian English newspapers, open corpora, and textbooks, sometimes with short aligned translations from major Indian languages. Each page already includes a citation line so teachers can model proper source credit. The second tool is a problem bank. It holds ready-to-run briefs with search strings, two warnings about likely errors, and one complete example that can be shown if groups get stuck. It's a small detail but it saves hours of setup time. The third is a quick reference sheet that explains basic AntConc functions for classes with computers and gives a paper version of the same workflow for those that do not. Both routes keep the core activity the same: ask a real question, check real lines, and test what you find (Boulton and Cobb 2017).

The setup also includes some quiet design choices about fairness. Every student contributes at least one cited line and one corrected sentence, so nobody drifts while others work. Mixed-language teams talk through ideas in their L1 before switching to English for the public write-up, and this habit draws strength from the multilingualism that Indian classrooms already live with (NCERT 2023; Ministry of Education 2020). Over time, these cycles build a local library of classroom-tested problems and student-created grammar guides. Each new class starts from a stronger base than the one before. What begins as a small adjustment, a move from repeating rules to testing them, would gradually reshape how learners think about grammar itself. They start to treat it not as a set of commands to memorize, but as a system they can prove, question, and defend.
And maybe that's the real shift here: classrooms moving from correctness for its own sake to a kind of accuracy that comes from understanding why something works.

Indian students often score well on grammar tests. The stubborn gap appears when that test-room success fails to travel into speaking, short writing, or real-time explanation, largely because lessons reward recall over investigation and because exams prize recognition over use. That pattern is not subtle. It shows up when learners can circle the right option on an MCQ sheet, yet hesitate when asked to describe a process, summarise a paragraph, or defend a claim in a short answer. Why does this happen so predictably? The answer sits in the lesson format itself, where rule names, tense labels, and "correct" options crowd out the slower work of noticing how English behaves across many sentences. In one Grade 9 class, a student could recite the rule for subject–verb agreement, then produced three different agreement errors in a single paragraph draft, not from carelessness but from speed, pressure, and the absence of practice that links form to meaning. That is the core weakness. A system that trains recognition will keep producing recognition.

The Flipped Research Model tackles that weakness head-on. It combines short pre-class inquiry training with in-class corpus work, then closes the loop with small synthesis tasks that make learning visible to students and teachers. The sequence is deliberate: pre-class material shows the steps, class time is spent on evidence and argument, and post-class synthesis turns findings into a usable school artifact (a one-page explainer, a short clip, a poster with examples). Cognitive load theory supports this ordering because it removes tool confusion from the lesson hour, leaving attention for reading lines, forming claims, and revising sentences when the evidence contradicts an early guess. The ICAP model strengthens the same point by predicting deeper learning as students move from passive viewing to active handling of examples and then to peer critique, where an explanation has to stand up in front of classmates. The model's power sits in three parts: a flipped phase that trains students to ask specific questions and test them; a simple Data-Driven Learning routine that treats multilingual knowledge as a working resource; an assessment loop that rewards inquiry and revision, not mere mechanical accuracy. Access gaps do not break the design, because printed concordance sets, school-based text collections, and a rotation plan around one screen can carry the same reasoning moves in low-tech rooms. Later studies can test effects on sentence accuracy, short writing fluency, retention of patterns over time, and teacher workload, since those outcomes decide whether the method scales beyond early adoption. By tying inquiry-based grammar work to NEP 2020 and NCERT goals, the model turns

policy language into daily classroom routines and shifts the emphasis from "getting it right" to knowing why it is right.

ABSTRACT

Educational institutions are producing a lot of academic information that can be studied to enhance instruction and help students succeed. This is why predictive analytics of academic achievement has been an important employment of educational data mining and machine learning is predictive modelling of student academic achievement. The identification of students at risk of failing can assist educational institutions in offering timely and personalized interventions to help them learning successfully. The research featured in this essay provides a comparison of different machine learning techniques for predicting student academic achievement. Specifically, classifiers such as Decision Trees, Support Vector Machines (SVM), K-Nearest Neighbors (KNN), and Random Forest were assessed using a publicly available dataset of students. Preprocessing was done using feature encoding techniques, normalization, and dataset splitting before model training occurred. All methods were evaluated using a variety of metrics including accuracy, precision, recall, and F1 score. Results demonstrated that ensemble-based machine-learning algorithms, specifically Random Forests outperformed each individual classifier. The results provide evidence for the efficacy of machine-learning techniques in educational analytics as well as direction on which models to select when predicting student academic achievement.

Keywords: Educational Data Mining, Student Academic Performance Prediction, Machine Learning Algorithms, Predictive Analytics in Education, Decision Tree Classifier, Support Vector Machine (SVM), K-Nearest Neighbors (KNN), Random Forest, Student At-Risk Identification, Educational Analytics.

INTRODUCTION

In the world today, school systems are starting to bring in digital technology, which produces large amounts of data about how students learn, how they get grades, and how they learn over time. This data can tell us how things work now and can also allow us to learn how we might make school better and get better student learning results. To extract the right information from education databases, you will need to use advanced analytical approaches. One type of analysis that is becoming increasingly popular in education is machine learning. Machine learning can be used to analyze complex data and find relationships that may not otherwise be identified using traditional statistical approaches. Many school systems are beginning to apply machine learning to gain insights into student performance, identify students at risk of failing, understand the behaviours of students while they are learning, and help educators make decisions about what is happening in their schools.

The application of educational data mining to predicting student performance is arguably one of the most significant applications. Institutions of higher education are often confronted with high rates of drop out, poor academic performance, and unequal learning outcomes. In order to provide support for at-risk students, educators need early warnings so they can implement appropriate interventions such as tutoring, counseling, and the development of individualized learning plans. As with traditional means of evaluating students' academic success, conventional assessment methods continue to rely on periodic examinations and subjective evaluation, which makes it difficult for an educator to distinguish the factors impacting academic performance. Using machine learning, a large number of variables, such as demographic qualities (e.g., age), attendance, study habits, and more, can all be analyzed by the same machine learning model.

Background and Related Work

The field of educational data mining (EDM) is an interdisciplinary research area that utilizes methods from data mining, statistics and machine learning to help analyze the collection and use of educational information. The primary focus of EDM is to gain insight into student learning and academic performance through the analysis of educational data. So far, many studies have investigated the use of machine learning techniques to make predictions about student performance. In past research, the focus was primarily on developing statistical models, such as regression models and decision trees, to investigate how to analyze student data, including factors that influence student academic performance, like attendance, socioeconomic status and study habits. As new methods of machine learning have continued to be developed, researchers have begun to apply a greater variety of sophisticated algorithms, such as Support Vector Machines and neural networks and ensemble learning techniques. These methods generally provide better predictive accuracy than more traditional models.

Decision Tree Algorithms are widely used in the field of educational data mining, providing a model that is relatively easy to understand, enabling educators to derive some insight into how various factors affect student performance. In Decision Tree Algorithms, the dataset is recursively partitioned based on the values of various attributes, resulting in a collection of decision rules arranged as a tree-like structure. The K-Nearest Neighbor (KNN) classification algorithms are among the most popular types of classifiers. KNN is a nonparametric classification algorithm that classifies data instances by their similarity based on features of the data. This makes KNN particularly useful in scenarios where there is a complex relationship between input variables (features) and target variables (labels).

Support Vector Machines (SVM) are among the most effective supervised-learning classifiers. SVMs are designed to find the optimal hyperplane that will separate different classes from one another in the data set. The ability of SVMs to work with high-dimensional data and classify data with non-linear relationships is accomplished through the use of kernel functions by SVMs. Random Forest is an ensemble-learning scheme that is designed to combine multiple classification using different decision-trees to increase the accuracy of predictions made by the Random Forest. In the

Random Forest model, each of the decision-trees is trained using a random set of training data instances and a random subset of input features, thereby reducing the likelihood of overfitting and increasing the robustness of the Random Forest. There is considerable evidence in the literature that using an ensemble approach such as Random Forest or Gradient Boosting provides better predictive capabilities than using a single classifier when performing predictive modeling. This is because these models will produce a more accurate and stable result when aggregating the predictions of multiple classifiers. While there is increasing interest in predictive modeling of student performance, there is a greater need for comparative analysis of machine-learning methods on standardized data sets that can be used for the purpose of comparing various machine-learning algorithms by researchers and educational professionals for the purpose of identifying the best suited algorithm for use in educational settings.

Objectives

- To evaluate factors impacting student academic performance, including prior academic history, attendance, the number of hours spent studying, demographics, etc.
- To gather educational databases and preprocess the data for use with machine learning methods by filling in missing entries, creating numeric representations of categorical data, and making all of the data compatible for processing by machine learning algorithms (e.g. normalizing the data).
- To utilize a variety of different algorithms for machine learning algorithms used to develop a model for predicting student academic performance.
- To compare the prediction capabilities of each of the various machine learning models on the basis of characteristics of the models, such as accuracy, precision, recall, F1 score, and confusion matrix.
- To determine the extent to which the attributes of the model are contributing to accuracy predictions, utilizing feature selection or feature importance analysis.
- To create a predictive model for identifying students who may require assistance to achieve academic success in the earliest possible instance.
- To provide new avenues of consideration for enhanced education decision-making and education-based academic planning through machine learning analysis.

Research gap

There have been numerous studies that have utilized machine learning techniques in order to make predictions about student academic performance; however, the majority of studies have utilized limited data sets, primarily focus on accuracy or prediction, and fail to adequately compare multiple algorithms. Furthermore, when it comes to predicting student success there are many factors involved in the learning process that are not being taken into consideration and there is no discussion as to how the results of the prediction can be used to develop educational interventions. Thus, a systematic comparative analysis of machine-learning algorithms is needed, using appropriate data preprocessing techniques and evaluation metrics, to develop valid, reliable, and interpretable models for predicting student academic performance.

Proposed System Architecture

This diagram represents the **architecture of the student prediction system**.

Explaining Each Component

Education Database Student Records

Student data shows student characteristics including scores or marks, whether or not the student has attended classes, demographic details about the student and other academic attributes.

Data Preprocessing Cleaning & Encoding
Pre-processing of data to eliminate noisy data, and also clean up & prepare the dataset through data cleansing, missing value handling, categorical data encoding, and normalization.

Feature Extraction
The feature(s) of the dataset that most influence student performance will be selected and converted into a format that can be understood by machines.
Model Evaluation Accuracy Metrics
Evaluate model performance through metrics such as accuracy, precision, recall, and F1-score.
Performance Output
Identify the best-performing algorithms/approaches to model student data using the performance metrics. Prediction of Student Academic Achievement
Use the predictive model developed to output predictions of students' academic achievement and identifies students who are.

Dataset Description
In this research study, a dataset containing details of students academic performances from secondary school students across 4 different areas was used as a part of the analysis. These areas include various attributes that can have an effect on student performance; examples include:
- Demographic information
- Review of previous academic performance
- Time studied
- How often attended school
- Family background / environment
- Access to books / materials
- Participation in extracurricular activities

The dataset contains a target variable that defines the overall academic achievement of the student.
The dataset utilized for this research was taken from the UCI machine learning repository, and includes a number of features that allow for analysis of the relationship between multiple variables and academic achievement.
In order for appropriate machine learning algorithms (e.g. [decision tree]) to be applied, the dataset will need to go through a processing/reprocessing phase to assure the quality of the data and its consistency.

Data preprocessing
When analyzing machine learning techniques for different datasets, preprocessing of data is essential because raw datasets frequently contain missing values, formatting problems, and unwanted features. The following preprocessing steps were taken in this dataset.

Addressing Missing Data
When there are incomplete rows due to missing information, it can adversely impact a model's prediction ability. Missing value errors may be corrected by removing rows with missing data or imputing them with estimates based on the statistical distribution of existing data points in that column; typically, this includes either mean or median imputation.

Converting Categorical Data into Numerical Form
Many columns in this dataset are categorical in nature (e.g., gender, type of school, and level of education of the parent). All categorical columns should be encoded to numeric format using a method called "one-hot" encoding.

Selecting Features

Selecting features hinders dimension reduction and enhances machine learning models by using only those columns relevant to predicting students' academic performance.

Normalizing Data

Normalizing the numerical features ensures all features are in a comparable range. This tends to be more bad when machine learning algorithms (like K-nearest neighbors [KNN] and support vector machines [SVM]) depend on distance computations.

Partitioning of the Data

When partitioning the data into training and test sets, the algorithms used to measure the performance are evaluated; the size of the test set will typically be 20%, with the remaining data into two parts (training set) and 80% for testing only. The model will train using the training data and measure the accuracy of prediction it can make using the test data.

Machine learning algorithms used

Decision Trees

Decision Trees are an example of a supervised learning algorithm that can be applied to both classification, as well as regression tasks. A Decision Tree operates by organizing the decisions that the model has made into a tree-like structure; each of these decisions corresponds to the internal bottom of the tree, while the terminal nodes represent the values of the variable you are trying to predict.

Because Decision Trees are relatively easy to read and can be easily visualized, they have become very popular educational tools. Their transparency is an important reason why they are ideally suited for use as educational tools (i.e., they provide both teachers and students with access to learning opportunities).

K-Nearest Neighbors

K-Nearest Neighbors is a very simple, yet highly effective classification technique. The K-nearest neighbors algorithm assigns a data-point to the cluster which has the most members within a distance of K from that point. K represents the number of neighbors that you're going to want to check against your new point in order to make a prediction.

Support Vector Machine

Support Vector Machines (SVMs) represent a very powerful classification model that aim to find the best possible boundary between two or more classes of data points. SVMs tend to work especially well in high-dimensional space and can handle linear as well as non-linear classification tasks.

Random Forest

Random Forest is an ensemble method for learning that combines multiple decision trees by randomly selecting a set of observations (rows) and/or features (columns) from the dataset to train each decision tree in an ensemble (or forest of trees). The prediction made by a Random Forest model will generally be more accurate and stable than that of a decision tree because it combines many different trees together using different selections of data and/or features for each tree.

Implementations and experiments

1. Import Libraries
2. Prepare Data Set
3. Extract Features/Target
4. Convert Categorical to Numeric Data
5. Normalize Data
6. Split Data into Training/Test Sets
7. Define Four Classification Algorithms:

- Decision Tree: creates a tree structure from rules used to make decisions
- K-Nearest Neighbors (KNN): classifies based on K closest neighbors
- Support Vector Machine (SVM): identifies the optimal hyperplane between classes
- Random Forest: combines outputs of many decision trees

8. Train Models
9. Predict Output
10. Calculate Accuracy
11. Output Classification Reports
12. Compare All Models
13. Output Results.

Training the Models

Four machine learning models were selected based on their ability to create accurate predictions and for the purposes of our comparative study. The following are the four algorithms that were used to conduct the analysis and produce comparable results: Decision Tree; K-Nearest Neighbor (KNN); Support Vector Machine (SVM); and Random Forest. Each of the four machine learning models used the training dataset for training purposes, and predictions were generated using the test dataset following the training process.

The above code trains and evaluates four machine learning algorithms on the student dataset.

The above code evaluates and trains four different machine learning algorithms using the student dataset. To accomplish this, the code uses the Pandas, scikit-learn, and Numpy packages to load and prepare the dataset, standardise it, and then create a train and test split.

Models include Decision Trees, k-NN, SVM, and Random Forests. Each algorithm is fitted using the training data, with predictions made on the test dataset by each algorithm. The performance (accuracy and classification report) of each tested model is printed to the console.

Diagrammatic representation

Experiment results

To evaluate performance of the machine learning models, the following classification metrics have been evaluated:

- Accuracy: The percentage of correct predictions of the classifier.
- Precision: The number of correct predictions of positive outcomes by the classifier divided by the total number of predicted positive outcomes made by the classifier.
- Recall: The number of correct predictions of positive instances made by the classifier divided by the total number of actual positive instances.
- F1 Score: The harmonic mean of precision and recall.

Comparing Model Performance

A clear winner in the experiment is the Random Forest Algorithm with an overall accuracy of 89%, thus outperforming all other models.

Graphical Representation

A Bar Chart can be used to represent the performance comparison of each Algorithm.

When comparing the four algorithms, the Random Forest Algorithm performs better than all others because it uses the Ensemble Learning technique in which multiple Decision trees are used to increase the accuracy of prediction.

DISCUSSION

Machine learning techniques have proven to be a very good way to predict the academic performance of students, according to the results of the experiment. All of the algorithms were able to predict success with varying degrees of accuracy, based on how the data set was structured. Decision Tree classifiers had intermediate accuracy; however, due to the easy-to-understand nature of Decision Tree classifiers, educators may find them helpful for determining what effects different factors have on a student's level of academic success.K-Nearest Neighbor (KNN) was more accurate than Decision Trees. However, as KNN uses more of the data to calculate predictions, the amount of time it takes for KNN to predict outcomes will continue to grow. Support Vector Machines (SVM) also yielded good prediction outcomes and were able to identify complex relationships between many variables. Random Forests produced the highest accuracy rate among all of the algorithms. This was due to the way in which multiple Decision Trees are combined through ensemble learning techniques to help minimize overfitting and increase the prediction accuracy of the models. Overall, the results of the study suggest that ensemble models are well-suited for educational data-mining purposes, as they capture the complex nature of the relationships between the many types of data collected on students.

Future work

The possibilities for further developments in predicting student performance are numerous. Deep learning models, including Artificial Neural Networks (ANN) and Long Short-Term Memory networks (LSTM), may be applied to analyse the educational data of students sequentially. Another new area of research is using Explainable Artificial Intelligence (XAI) technologies to enable educators to understand how predicted results from machine learning algorithms were generated. Additionally, researchers should investigate the use of real-time learning analytics available from online educational platforms as a basis for developing dynamic student performance prediction systems. Finally, hybridisation (combining several different machine learning algorithms) will likely improve the accuracy of prediction models.

CONCLUSION

A comparative analysis was conducted of multiple machine learning algorithms for the prediction of student academic outcomes based on a student data set, using the following types of models: Decision Tree; K-Nearest Neighbor; Support Vector Machine; and Random Forest. Random Forest produced the best prediction accuracy. Results indicate the substantial potential of using machine learning techniques to analyze education related data for the purposes of aiding in educational decision making. Educational institutions can use machine learning-based predictive systems to provide students that need support with an enhanced probability of success and to diminish the number of drop-outs. Machine Learning in the field of educational analytics is a significant development toward data-based education systems.

ABSTRACT

Dentists employed orthodontic braces, such as Ni-Cr, SS 18/8, SS 316, etc., to control tooth arrangement. However, these wires are prone to corrosion in the salivary medium. In addition to saliva, the intake of food, medications, and beverages further accelerates their corrosion. The corrosion protection of Stainless Steel 18/8 in artificial saliva (AS) was examined using polarization techniques and AC impedance spectroscopy, both in the presence and absence of Rasna, a soft drink concentrates. Results revealed that the presence of Rasna significantly reduces the corrosion resistance of SS 18/8. This is evidenced by decreased values of Charge Transfer Resistance (Rt), Linear_ Polarization_ Resistance (LPR), impedance, and overall corrosion resistance, along with an increased Double Layer Capacitance (Cdl). Specifically, the LPR value decreased from 3,488,228 to 395,624 $\Omega \cdot cm^2$, while the corrosion current increased from 1.447×10^{-8} $A \cdot cm^2$ to 10.52×10^{-8} $A \cdot cm^2$. Similarly, Rt dropped from 37,796 to 1,594 $\Omega \cdot cm^2$, and Cdl rose from 1.349×10^{-10} to 31.99×10^{-10}

F/cm². Based on these findings, individuals with orthodontic braces made of SS 18/8 should avoid consuming Rasna juice, as it accelerates the corrosion process.

Keywords: Orthopaedic braces, SS18/8, Artificial Saliva or Syntheticsputum, Corrosion resistance, Rasna liquid.

INTRODUCTION

Animal sputum, a fluid that is produced in the mouth and released from the salivary glands. Human saliva is composed of approximately 98% water, along with mucus, white blood cells, electrolytes, epithelial cells (a source of retrievable DNA), glycoproteins, enzymes such as lipase and amylase, and antimicrobial agents including secretory IgA and lysozyme. Sputum contains enzymes essential for initiating the digestion of lipids and carbohydrates. These enzymes aid in the breakdown of food particles stuck in dental fissures, shielding teeth from oral germs. Saliva also acts as a lubricant, preventing desiccation of the mucosal surfaces of the mouth cavity and soaking food to facilitate the beginning of swallowing. Saliva has a variety of purposes for different animal species that extend beyond pre-digestion. Some swifts construct their nests with their gooey saliva. Teeth that sparkle are appealing. There are individuals whose teeth are arranged. One of the most popular Indian brands of non-carbonated soft drink concentrate is Rasna, established in the 1970s. It is a fruit-flavoured product that made it convenient and affordable for consumers to prepare their own beverages. By simply mixing water with the concentrate, a refreshing drink could be obtained. In addition, Rasna is enriched with vitamins and minerals, thereby enhancing its nutritional value. In orthodontics, wires are a fundamental component used to align teeth. They are attached to brackets fixed on the teeth and exert controlled forces to gradually move the teeth into the desired positions. Orthodontic wires are available in various materials, sizes, and designs, each selected based on the clinical requirements. Brackets, which serve as the attachment units, are classified into different types such as metal, self-ligating, lingual, and ceramic. Orthodontic materials are broadly categorized into stainless steel, nickel-titanium, and beta-titanium alloys, each offering distinct mechanical and elastic properties suitable for different treatment stages. Stainless steel orthodontic wires, typically manufactured from AISI 302 or 304 grades, are composed primarily of chromium, iron, and nickel, which confer corrosion resistance and excellent formability, making them a reliable choice in clinical practice. By using electrochemical techniques like Electrode polarization studies and EIS technique, the current work aims to investigate the metal deterioration protection of SS 18/8 alloy orthodontic arch wires in synthetic salivary environment with Rasna drink, one of the flavoured drinks concentrates in India.

LITERATURE REVIEW

In this regard, similar research findings have previously been published. The foundation of bird's nest soup is an aero dramusnest [1]. The effects of a tablet on braces wires made of stainless steel 316L alloy in synthetic sputum have been studied by Agnes Brigitta *et al* [2]. Anandan *et al*. investigated the effects of certain drugs on the decay resistance of orthopaedic braces made of SS 316 L alloy in manmade sputum by using electrochemical techniques like polarization studies and AC impedance spectra[3].Through electrochemical investigations, Renita D'Souza *et al*. have investigated the Corrosion opposition of SS 316L alloy in Synthetic Sputum when toothpaste is present[4]. Agnes Brigitta *et al*. have examined the corrosion resistance of Gold 22 carat, SS18/8, SS 316L and Gold 18 carat, alloy in synthetic sputum under both conditions[5]. Saranya and Rajendran used electrochemical studies to examine the effect of D-glucose on the resistance to corrosion of SS 316L in the existence of manmade sputum [6].Zhang *et al*. looked into how heat treatment affected the mechanical and corrosion characteristics of Co, Cr, Mo alloys made by selective laser melting [7]. Li *et al*.'s study [8] examined the reaction of fluoride on the nanostructured Ti-24Nb-4Zr-8Sn alloy's corrosion behaviour in acidulated sputum manmade. Savencu *et al* [9] examined the decay etiquette of Co-Cr orthopaedic wire prepared using proxy CAD/CAM technologies in human made sputum solutions. The released titanium ions in titanium alloys used in dentistry has been thoroughly covered by Sam *et al*. [10]. The

electrochemical behaviour and galvanic effects of titanium implants coupled to metallic suprastructures in artificial saliva have been studied by Mellado-Valero *et al*. [11].Innovations like instant beer powder demonstrate the growing role of nanotechnology in beverage formulation and storage (Betsy Clarebel *et al*., *Nanotechnology in Beverage Industry*)[12].This study similarly explores the interaction of a flavored liquid, Rasna, with orthodontic materials in a salivary environment. *Aloe vera* extract has been explored as an eco-friendly corrosion inhibitor for mild steel in well water, showing promising inhibitory performance due to its phytochemical constituents by Epshiba *et al*[13]. In previous work reported by Betsy Clarebel *et al*, kinetic studies on a cobalt μ-peroxo complex provided insights into metal reactivity in acidic environments. Building on this approach, the present study investigates the effect of orally consumed Rasna liquid on the corrosion behaviour of SS 18/8 orthodontic arch wire in an artificial salivary medium, offering a biomimetic perspective on metal-environment interactions[14]. Based on earlier kinetic studies of cobalt μ-peroxo complexes in acid media by Betsy Clarebel and Amaldasan this work explores how fructose-containing Rasna liquid affects the corrosion of SS 18/8 wire in an artificial salivary environment [15].Over time, scientifically based orthodontics has evolved considerably, with numerous innovations in material science and computational applications contributing to the development of new treatment approaches and modalities [16]. In contrast to earlier trends, the number of adult patients seeking orthodontic treatment has increased substantially in recent years [17]. In today's medical scenario, bioimplants are widely utilized across various applications, including dental implants, resulting in a significant rise in their demand[18]. Corrosion behaviour of various metals and alloys have been investigated in presence of artificial saliva [19-30].

MATERIALS AND METHODOLOGY

Metal specimen making procedure

For this work, a wire made of Stainless-Steel alloy 18/8is used as analysis sample. The alloy's compound arrangements is as follows: 18% Ni, Cr, 8%, and the remaining 8% Fe. The Teflon rod contained the orthodontic wire. It was utilized for electrochemical research after being polished to a mirror shine.

Making of Artificial Saliva

The Fusayama–Meyer artificial saliva (AS) formulation was adopted for the preparation of the test solution. The laboratory preparation included the following constituents: urea (1 g/dm³), NaCl (0.4 g/dm³), $CaCl_2{\cdot}2H_2O$ (0.906 g/dm³), KCl (0.4 g/dm³), $NaH_2PO_4{\cdot}2H_2O$ (0.690 g/dm³), and $Na_2S{\cdot}9H_2O$ (0.005 g/dm³).

Rasna

In India, Rasna is one of the concentrated flavoured drinks. It's a soft drink with a higher concentration of vitamins and fruit powder, and it usually contains glucose.

Potentiodynamic polarization study

The electrochemical investigations made use of a CH Instruments 660 workstation model. Three-terminal electrochemical **setup** was utilizedfor the polarization analysis(Scheme A). The platinum served as the counter electrode (SCE) served as the sample electrode, and SS 18/8 served as the working electrode. Following the completion of IR, Polarization research was conducted at a (value of 0.01 V/S). The evaluation included key corrosion factors such as Tafel slopes (βa, βc), Icorr, Ecorr, and LPR. Three-electrode system (Figure 1).

Alternating Current impedance spectra

Using the same three-electrode cell configuration employed for the polarization studies, alternating current impedance spectra were registered. Impeding factoralues were obtained across varying frequencies, with the real (Z′) and unreal (Z″) components of the system's impedance being determined. From these measurements, the electrochemical parameters Cdl and Rt were derived.

Consequence and analysis

Effect of Rasna liquid on resistance to corrosion of SS18 / 8 in Simulated Saliva.

Doctor in dental surgery advice using orthopaedic braces to control tooth arrangement. Following the law, people began consuming various artificially flavoured juices orally. Saliva in particular, which is one of these flavoured juices, has the potential to corrode oral wiring. Therefore, research into how Rasna, or artificially flavoured juice, affects orthodontic wires prepared from various alloys and their ability to withstand corrosion is necessary. This section presents the decay protection of SS18/8 inartificial sputum (AS) with and without Rasna juice. In India, Rasna is one of the concentrated flavoured drinks. It is a soft drink with a higher concentration of fruit powder and vitamins, and it usually contains glucose. The impact of Rasna on the resistance to corrosion of alloy SS 18/8 in AS has been examined using AC impedance spectra and Polarization testing.

Polarization Study

Polarization analyses were executed in this study using a CHI Electrochemical Analyser (Model 660A), equipped with an automatic iR compensation capability. A standard three-electrode configuration was employed, with SS 18/8 alloy serving as the working electrode, a saturated calomel electrode (SCE) as the reference electrode, and platinum as the counter electrode. It took the system between five and ten minutes to reach a constant state unsealed circuit potential. Both platinum and working electrodes have been submerged in seawater, both with and without an inhibitor. A salt bridge was used to link the test solution and the saturated calomel electrode. Corrosion parameters obtained from the polarization study included linear polarization resistance (LPR), Tafel slopes (βa, βc), erosion potential (Ecorr), and degradation current density (Icorr). The experiments were conducted with a scan speed of 0.01 V/S, a quiet time of 2 S, and a hold time at Efcs of zeroS. Figure 1 illustrates the polarization curves of the SS 18/8 alloy in artificial sputum, both in presence and absence of 500 ppm Rasna. Table 1 lists the parameters related to corrosion. Table 1 shows that the resistance to corrosion of SS 18/ 8 in humanmade sputum drops when Rasna is present. This is demonstrated by the fact that corrosion current increases and the Rasna LPR value of SS 18/8 falls (Figure 2). Comparison of LPR values (Figure 3). Additionally, it is noted that the disintegration potential changes (from -276 to -404 mV) VS SCElectrode in presence of Rasna. It is assumed that the cathodic process is primarily restricted when Rasna is present.

Alternating current Impedance Spectra

The Impedance spectra were captured in thecurrent investigation using the same instrument setup that was utilized for the polarization study. The system required approximately 5–10 minutes to stabilize at the open-circuit potential (OCP). At different frequencies, of the cell impedance, the real (Z')and unreal ($-Z''$) were documentedin ohms at different frequencies. The AC impedance spectra were registered using the following experimental conditions: initial potential (E) = 0 V, upper frequency limit = 1×10^5 Hz, lower frequency limit = 1 Hz, amplitude = 0.005 V, and quiet time = 2 S. The double-layer capacitance 15 (Cdl) and charge transfer resistance (Rt) were subsequently computed from the Nyquist plots.

$$\mathbf{R_t = (R_s + R_t) - R_s}$$

Where, Rs is Resistance of the solution.

Cdl data were obtained by the following equation.

$$Cdl = 3.14 \times (1/2) \times Rt \times f\ max$$

Where, fmax is thefrequency associated with the maximum Z″ value.

Figures 4, 5, 6, 7, and 8 displays the Alternating current impedance spectrum of the Stainless-Steel alloy 18/ 8 dipped in manmade saliva in the absentia and existence of 500 ppm of Rasna. Figures 3 and 4 present the Nyquist Plots. Figures 7 and 8 display the Bode plots. Table 2 lists the corrosion parameters, including Cdl values, impedance value, and Rt. Comparison of Rt values (Figure 6). Table 2 shows that the resistance to corrosion of SS 18/ 8 in Synthetic Saliva drops when Rasna is present. This is evidenced by a decrease in Rt and overall impedance, along with an enhancement in Cdl in presence of Rasna (Figure 5).

Implication

Rasna reduces the corrosion protection of Stainless-Steel alloy 18/ 8 in synthetic sputum. Rasna should therefore not be taken orally by anyone who has orthopaedic braces made from alloy SS 18/ 8 clipped.

CONCLUSION

"Spectrum of AC impedance and Polarization studies were adopted to explore the corrosion behavior of SS 18 /8 alloy in artificial saliva (AS), both in the presence and absence of Rasna. It is assumed that the existence of Rasna diminishes the corrosion resistance of SS 18/8 alloy in artificial saliva, as evidenced by reduced LPR and Rt values, decreased impedance, increased corrosion current, and elevated double-layer capacitance (Cdl).Therefore, it suggests that individuals who have orthopaedic braces made of SS 18/8 alloy clipped must refrain from consuming Rasna orally".

ABSTRACT

Prebiotics are nondigestible selectively fermentable dietary constituent that controls gut microbiota and leads to metabolic, immune, and gastrointestinal wellbeing. There is mounting data that demonstrates the relationship between prebiotic regular consumption and the decreased risk of chronic illnesses and host physiological functions, which indicates their importance in everyday nutrition. This review is a summary of natural food sources of prebiotics, such as chicory root, garlic, onion, oats, bananas and other sources of prebiotics in plant foods and how food processing affects prebiotic materials and bioavailability. The evidence of human and preclinical studies is provided to show the physiological mechanisms of the prebiotic activities that include the regulation of gut microbiota and the production of short-chain fatty acids. The use of prebiotics supplement, synbiotics and functional foods on the improvement of gastrointestinal functioning, metabolic and immune regulation is critically evaluated. Plans of beneficial diet incorporation, food preparation and phase of life aspects also come into the limelight. In addition, the novel trends of personal dieting, green food processing technologies, and sustainable production of prebiotics are revised. Overall, the article identifies the potential of prebiotics as safe, effective and sustainable food ingredients in chronic disease prevention and gut health promotion.

Keywords: microbiota, prebiotic, synbiotics, Diet, ingredients, foods.

INTRODUCTION

In the human body, there is a huge quantity of microbial cells, mainly located in the intestines, which constitute the Gut microbiota. They can be classified primarily into a simple community of Proteobacteria and Actinobacteria, and develop further during infancy into adulthood, with Enterobacteriaceae, Bifidobacterium, and the Bifidobacteria family [1]. It has been reported that prebiotics, being a food supplement, prevent infection and support the body's defence mechanism. During the COVID-19 pandemic, they have also received immense attention. Several vitamins,

including C, D, and E, have been found to enhance the immune response against viral infections [2]. Nutrition has become an important part of life, not only in providing nutrients but also in health and disease prevention. With the current high rate of processed foods, there is increased emphasis on the quality and safety of consumed food products. [3]. There are problems such as food poisoning, obesity, allergies, cardiovascular diseases, and cancer, and hence the quality of food is of primary relevance. Probiotics and prebiotics have been reported by scientific sources to be health beneficial in nutrition. The name probiotic for life was probably developed by Ferdinand Vergin in 1954, in opposition to the harmful effects of antibiotics on intestinal microbiota, and the positive effects of good bacteria. [4]. Also probiotics have been reported to be effective in the treatment of obesity, insulin resistance syndrome, diabetes type 2 and non-alcoholic fatty liver disease.[5]. Dietary fibres are carbohydrate polymers which are neither digested nor absorbed, but fermented by the bacteria in the gastrointestinal tract, and affect the bacterial populations and microbial metabolic processes, including the generation of end products. These fibres may serve as prebiotics, selectively fermented components that modulate the contents and functions of the microbiota of the gastrointestinal tract, which are beneficial to the host. [6]. According to the initial studies, *Bifidobacterium* and *Lactobacillus* selectively used prebiotic substrates. The availability of evidence on the alterations in gut microbial ecosystem to use the prebiotic substrates was lacking owing to the shortage of culture methods.[7].

Recent high-throughput sequencing techniques have revealed additional autochthonous gut bacteria, such as *Faecalibacterium prausnitzii* and *Akkermansia muciniphila*, that increase in abundance with prebiotic intake. Prebiotics and probiotics can be combined into synbiotics, enhancing the growth of probiotics through prebiotic fermentation. As of January 2022, 277 clinical trials worldwide, primarily in Europe, have investigated the impact of prebiotics, alone or with probiotics, on various conditions, including obesity, type 2 diabetes, gastrointestinal disorders, and other health issues like anxiety and arthritis [8]. It has become a popular product with young consumers, with probiotic products becoming more popular, and they have been categorized as nutraceuticals in the functional foods industry. They are also known to promote gastrointestinal activity and immunity. The global market of probiotic products is estimated to be US$46.54 billion in 2017 and is projected to increase at a CAGR of 7.5 per cent between 2019 and 2023. The Covid-19 pandemic has only increased the pressure on the immune-boosting supplements further, with more new products containing pro- or synbiotics appearing on the shelves of supermarkets. Nevertheless, technological obstacles are also present with a significant proportion on the viability and functional stability of such ingredients in prepared foods. [9]. Therefore, approaches such as different methods of production have been implemented to overcome the effects of instability of probiotics, such as encapsulation and carrier systems using edible films or coatings. In this regard, the emergence of edible films/coatings integrated with pre-, pro-, or synbiotics is gaining importance as a novel technology for food scientists and other experts involved in the food industry. Thus, it cannot be doubted that in the years to come, there will be more research done on this fascinating concept that will concentrate on different raw materials, manufacturing methods, stabilities research [10]. Figure 1 is a schematic summary of the systemic advantages of fucoidan driven by prebiases. depression[13].

Chicory roots

There are a large number of dietary and medicinal effects have been found from industrial chicory [*Cichorium intybus var. sativum*]. Some amounts of clinical evidence proved that chicory has the anti-diabetic, immunomodulatory, anti-tumour, anti-oxidant, anthelmintic and prebiotic effects [14]. The chicory is converted into flour and can be used for making pastries[15].

Garlic, Onion, Oats, Banana and Asparagus

Onions, garlic, and oats are also among the common sources of prebiotics [16], whereas green bananas are a source of resistant starch with an impact on hypoglycaemia. According to the Association of Official Analytical Collaboration [AOAC], the concentration of High-Amylose Maize Starch [HAMS] is 46%, and green banana flour also has similar quantities [44%]. In some studies, postprandial glycaemic responses were enhanced and supplemented meal intake was lowered using 38.3-40 g of native banana starch [7]. Just a few studies have reported the daily intake of different amounts and types of resistant starch [17-66 g] resulted in a high concentrations of short-chain fatty acids [SCFA] after just 1-3 weeks, it is unknown whether such a lower dose of diversified fiber could yield GI and glycemic effects
