## ABSTRACT

The addition of Unmanned Aerial Vehicles (UAVs) to the sixth-generation (6G) wireless networks comes with new demands of intelligent and adaptive physical-layer technologies, specifically, Automatic Modulation Recognition (AMR). These environments are extremely dynamic (highly dynamic UAV communication) and therefore traditional feature-based AMR techniques cannot keep up with the reliability challenges of the channel variation, Doppler and on-board resources. The main aim of the proposed study is to examine and study Convolutional Neural Network (CNN)-based AMR algorithms, which can be highly accurate without requiring too much resource constraints that would be on UAV platforms. The suggested methodology studies the recent lightweight and deep CNN models, reviews alternative signal representations, and studies their behaviour in diverse signal-to-noise ratios and mobility. Existing studies have shown comparative insights based on the fact that CNN-based AMR greatly excels as compared to traditional methods in terms of robustness and classification accuracy even under low-SNR conditions. Findings also indicate that lightweight CNN models provide a good trade-off between performance in recognition and computational efficiency and thus can be used to implement UAVs in real-time. Finally, AMR based on CNN is one of the enabling factors of intelligent 6G networks with UAVs, and further studies are necessary on adaptive, secure, and energy-efficient learning models to be applied to large-scale systems in practice.

**Keywords:** Automatic Modulation Recognition, Convolutional Neural Networks, Sixth-Generation (6G) Networks, Unmanned Aerial Vehicles, Wireless Communications.

## INTRODUCTION

The sixth-generation (6G) wireless network rapidly envisions an interoperable and totally unified its terrestrial, aerial and space communication networks to assert ultra-reliable, low-latency and high-capacity services. Intelligent communication mechanisms will be lightweight and energy-efficient in this paradigm, and the aerial platforms in this paradigm will have stringent hardware limitations [1]. Recent progress in deep residual learning also proves the possibility of strong modulation classification in the context of complex wireless conditions [2].Unmanned Aerial Vehicles (UAVs) are identified as one of the enabling factors of 6G networks as they allow flexible deployment, expand into space, and offer flexibility in connectivity between air, ground, and space infrastructures [3]. The UAV-to-ground communication setting has also explored self-attention-based learning models to enhance the modulation recognition performance of the mobility and channel variability in the environment [4]. Automatic Modulation Recognition (AMR) represents a fundamental physical-layer which is an intelligent spectrum awareness and adaptive communication feature in such environments [5].

Given the real-time requirements, to address the needs of lightweight AMR solutions with compressive sensing and deep learning have been proposed to simplify the computation complexity without compromising accuracy [6]. At the network level, the role of artificial intelligence will likely be centralized when it comes to the automation of operations, resource savings, and smart control in 6G networks [7]. In addition to modulation recognition, ensemble learning models have also been used in passive RF fingerprinting and UAV identification in next-generation networks [8]. Recently, transformer-based architectures have become promising alternatives to CNNs and can provide better adaptation to dynamic spectrum situations in drone communication systems [9]. The spectrum monitoring methods using deep learning also introduce AMR features to multi-signal acquisition and situational awareness of UAV networks [10]. Robust AMR methods that are resilient to phase differences and synchronization degradation have also been researched to increase the reliability in a real-life scenario [11].Intelligent vehicular and V2X communications are also boosted by 6G networks with the use of UAVs, which implement a distributed learning and federated clustering system [12]. Quantized deep neural networks have been created with AMR applications in mind to enable them to be deployed on resource-constrained platforms [13]. Dual-stream spatiotemporal fusion networks and hybrid data augmentation have proven to be more resilient in the case of drone-based modulation classification [14].

One of the key obstacles to UAV communications is low-SNR conditions that encourage the creation of robust AMR models that can be used to keep the performance of AMR in noisy environments [15]. It has been suggested that dual-path deep residual shrinkage networks can be used to reduce noise and better discriminative features extraction without being too large networks [16]. AMR is also applicable in wider UAV remote identification and surveillance structures that are important in airspace security [17].AMR is also used in emerging 6G architectures that include UAVs, satellites, and high-altitude platforms in the context of non-terrestrial networks [18]. The application of beam forming and backscatter communication methods (as a deeper example of deep learning-based methods) also underscores the persuasive value of UAVs in massive IoT connections [19]. Regarding security, AMR augments physical-layer security models inspired by artificial intelligence in 6G networks [20].Machine learning-based AMR are well-known as the underpinning technologies of beyond-5G and 6G wireless intelligence [21]. Nonetheless, AI-controlled UAV communications are challenged with the matters of scalability, robustness, and energy efficiency and require further studies [22]. In the end, AMR is clearly supposed to be a pillar of self-education, independent 6G networks to serve smart cities and digital ecosystems [23].

The primary paper contributions include three aspects: (i) the background research and comparative analysis of the recent AMR, UAV communication, and AI-enabled 6G research; (ii) the detailed discussion of signal representations, CNN architecture, challenges, and security concerns unique to UAV-based AMR; and (iii) revealing open research directions towards lightweight, robust, and secure AMR solutions. The rest of the paper is structured in the following

way: Section 2 presents related literature; Section 3 explains UAV-based 6G architecture, Section 4-6 explain CNN-based AMR principles and architecture, Sections 7-8 discuss the challenges and security concern and finally, Sections 9 and 10 discuss the paper and provide conclusions, respectively.

In this figure 1, a UAV-aided 6G communication architecture that has UAV-to-Satellite, UAV-to-UAV and UAV-to-Ground connections are featured using realistic constraints, including low battery capacity, payload, and onboard computation. It proposes a CNN-based Automatic Modulation Recognition (AMR) system based on 1D and 2D lightweight CNN models to achieve customer robustness at low-SNR signal recognition and counter security threats such as jamming, spoofing, and adversarial attack. The suggested design can facilitate the deployment of energy-efficient UAV and ensure flawless connectivity to use it in managing smart cities, autonomous vehicles, and remote surveillance.

**Background study**

Sarkar et al. (2025) [1] In this paper, the authors propose a super-light CNN to automatic modulation recognition (AMR) in 6G networks of the UAVs with the minimal complexity. This is the limitation to the research because it reaches high accuracy with the limitations of the UAVs such as low power and processing. The classification of the modulation is carried out using a shallow CNN that has optimized parameters. Although it is an efficient one, it is performance-degrading under severe channel impairments competition performance is exhibited with lower cost of computation. This study introduces a masked modeling and residual neural network to make the modulation classification better, as suggested by Peng et al. (2023) [2]. The used gap is the lack of the feature generalization of the traditional deep AMR models. Masked learning residues provide resistance to noise. The model is however computationally demanding; it has been established that the model is more accurate in different circumstances of a channel. This article [3] by Othman et al. is a review of enabling technologies to 6G, specifically focusing on UAVs, THz communication, and intelligent reflecting surfaces. The problem is the failure to have holistic integration frameworks of these technologies. Techniques that are compared are comparative review techniques, and the analytical review techniques. As a survey, it cannot be regarded as an experimentally proven one, yet as a strategic source of information on future 6G architectures.

The authors of the study recommend a multi-subsampling self-attention network to be applied to the UAV-to-ground AMR systems (Shen et al., 2023) [4]. The gap that is taken care of is the inadequate adaptability of CNNs to the unrelated UAV signal dynamics. A self-attention mechanism captures long distance dependencies. It is a complex model and results have shown that it performs better when it comes to UAV communication. Kaleem et al. (2021) [5] the article provides an AI-based real-time AMR system in the next-generation cellular networks. The difference is real-time deployment capability of deep learning AMR. Neural models of low weight and latency are used. Scalability is still a problem but the results on improvements of accuracy in real-time are valid.

LightAMC [6] LightAMC is a lightweight AMR model, based on deep learning and compressive sensing. The research gap is associated with the ability to decrease the model size without compromise of accuracy. CNN is used to represent a compressed signal. At extremely low SNRs, the performance decreases, and at very high SNRs, efficiency is observed to be appropriate to edge devices. Alhammadi et al. (2024) [7] This article presents a review of AI applications, opportunities, and challenges of 6G wireless networks. The addressed gap is the discontinuous knowledge on AI roles in 6G. The systematic literature review is carried out. The absence of the details of the implementation is a weakness; findings present major obstacles and the development of the research in the future. Zahid et al. (2024) [8] the authors suggest a compound ensemble learning framework of passive drone RF fingerprinting in 6G. The weakness is in dependable identification of drones when operating in dynamic conditions. Several classifiers are combined in order to augment discrimination. Computational overhead is an issue, and the accuracy of fingerprinting has been high. MobileRaT [9], Zheng et al. develop a lightweight radio transformer of AMR in drone communication systems. The gap that is being solved is transformer inefficiency in mobile platforms. Small transformer architecture is developed. Little testing conditions are a disadvantage; performance is shown to be great when there is less complexity. Hou et al. (2023) [10] in this study, the authors provide a deep learning-driven

multi-signal spectrum monitoring of UAV communications. The gap is a simultaneous detection of several types of signals. Multi-signal classification based on CNN is implemented. The training data is still high; the results are showing better spectrum awareness. Shi et al. (2020) [11] the article suggests a deep learning AMR algorithm that is phase offset resistant. The performance degradation caused by uncertainty in phases is addressed. CNNs have phase-invariant feature learning. Only limited modulation types are taken into account and the results demonstrate improved robustness. Azeemi et al. (2023) [12] this paper examines an intelligent V2X communication with federated clustering based on UAV enabling 6G communication. The privacy learning gap of the UAV-assisted networks is its preserving learning. Clustering and federated learning methods are employed. It has a weakness in communication overhead; there are better results in network efficiency.

Gomez et al. (2022) [13] the authors suggest a technique of designing AMR quantumized deep neural networks. The absence is deficiency of systematic quantization schemes of AMR models. Quantization and optimization models are used. There is a possibility of accuracy loss, yet the results indicate that the results are appropriate in low-power devices. Gong et al. (2023) [14] in this paper, a hybrid data augmentation and two streams of spatiotemporal fusion of AMR on a drone are presented. The gap that was bridged is lack of diversity in training. Dual-stream CNNs are used to augment the data. The complexity of the model is increased; it results in high accuracy improvements. An and Lee (2023) [15] the article is concerned with strong AMR when in a low SNR condition. The discontinuity is the poor performance of AMR in noisy conditions. Deep learning architecture that is resistant to noise is suggested. Channel generalization is not available and performance is shown to be high in low SNR.

Table 1, a comparative background study of the recent researches on automatic modulation classification, UAV communications and AI-enabled 6G networks is presented. It indicates the main ideas, methodology and detected gaps in the research, where the trade-offs between the performance, complexity and practicability issues are noted. In general, the table offers a condensed perspective of the existing developments and shortcomings, which allows determining the direction of future research in the area of lightweight, intelligent, and scalable 6G communications.

**UAV-Based 6G Wireless Communication Architecture**

A 6G wireless communication architecture based on UAVs allows aerial platforms to be used as smart communication nodes, relays, or base stations to provide ultra-reliable, low-latency, and high-capacity services. The 6G networks will be able to provide a seamless connectivity in the terrestrial, aerial, and space domains by using UAV mobility, flexible deployment, and AI-driven intelligence.

The 2 figure shows a UAV-supported 6G communication architecture that incorporates UAV-to-Ground (U2G), UAV-to-UAV (U2U), and UAV-to-Satellite (U2S) connections with the purpose of providing seamless air-ground-space communication. It draws attention to the main wireless issues like path loss, channel variations fast, high mobility, change in altitude and Doppler that affect UAV communications. They are also highlighted by the diagram with practical constraints such as limited energy, payload capacity, and power management and how UAVs interface with the 6G core network in order to accommodate smart city and edge-enabled applications.

**UAV Communication Models (U2G, U2U, U2S)**

**UAV-to-Ground (U2G):**

UAVs in U2G communication establish wireless networks with whatever exists on the ground, whether it is a base station, mobile user or the objects of Internet of things (IoT). UAVs can also be used to play the role of aerial base station, relays to enhance its coverage in remote areas, disaster prone areas and urban centres. U2G enjoys a benefit of the likelihood of high line-of-sight (LoS) propagation in comparison with earthly connections.

**UAV-to-UAV (U2U):**

U2U communication is the one that supports direct communication of data between a group of UAVs, which can be applied in cooperative networking, swarm intelligence and multi-hop aerial relaying. The model improves the resilience of the networks, latency and distributed sensing and decision making in the swarm of UAVs.

**UAV-to-Satellite (U2S):**
U2S communication links UAVs to low-earth orbit (LEO) or geostationary satellites so that it covers the entire world. Beyond-line-of-sight missions, maritime surveillance, and remote monitoring in remote locations that lack terrestrial infrastructure are some of the important uses of this model.

**Characteristics of UAV Wireless Channels**
The UAV wireless channels possess some unusual characteristics as opposed to terrestrial channels. UAV links are likely to have high LoS components, less shadowing, and less multipath because of high altitudes. Nevertheless, the quick movement of UAVs in position and orientation cause rapidly varying channel conditions, varying path loss, and occasional non-line-of-sight (NLoS) operation, particularly in cities.

**Mobility, Altitude, and Doppler Effects**
The great UAV mobility and time-varying altitude provides a substantial Doppler shift and time-selective fading. High speed movement results in frequency imbalances that worsen signal synchronization and the accuracy of modulation recognition. Path loss and interference patterns are impacted by changes in altitude and thus demand adaptive modulation, coding and smart signal processing schemes to ensure a stable communication in 6G UAV networks.

**Integration of UAVs in 6G Networks**
In 6G systems, UAVs will be combined with land networks, edge computing, and cloud computing infrastructure. Mobile edge computing, network slicing, and AI-based resource allocation are some of the functions supported by UAVs. They provide ultra-low latency services, dynamic coverage boosting, and connectivity continuity in deployments of smart cities, autonomous systems, and massive IoT, due to their integration.

**Energy and Payload Constraints in UAV Systems**
There exist stringent energy and payload restrictions on UAVs because of battery size and weight. Both communication modules, sensors and on board AI processing consume more power and payload. Power management, lightweight hardware design and energy conscious communication protocols are required to extend the UAV flight time and make it sustainable in 6G networks.

**Deep Learning for AMR: Role of CNNs**
Automatic Modulation Recognition (AMR) is an essential role of the UAV-assisted 6G wireless, and the entity facilitates smart spectrum control and dynamic communication [1]. Convolutional Neural Networks (CNNs) and other forms of deep learning have become an effective AMR tool because of its capacity to automatically detect discriminative signal features in raw or transformed signal [2].

**CNNs for Modulation Recognition**
Convolutional Neural Networks (CNNs) are particularly suitable to wireless signal analysis as they preferably capture local spatial features that exist in time-series and time frequency representations [4]. They allow direct end-to-end learning on raw IQ samples, spectrograms, or wavelet-transformed signals, and it greatly decreases the manual feature engineering that is necessary [6]. CNNs have the ability to automatically differentiate varying modulation properties after learning hierarchical features representations [9]. In addition, they have high resiliency to noise and multipath fading. This strength is expanded to Doppler effects that are normally observed to occur in the dynamic UAV communication environment [10].

**Feature Learning Capability of CNNs**
CNNs are able to discover hierarchical features, moving straight in terms of low-level signal patterns like amplitude, phase, and waveform edges, to high-level modulation-Entities-specific features [11]. Their convolutional filters are very flexible to signal distortions caused by UAV mobility and channel fading [14]. Through aggregation of local

information CNNs encode discriminative structures in various signal conditions [9]. Also, pooling layers allow the translation invariance, which is beneficial to the robustness to small variations in signal representations [13].

**Comparison with ML and Other DL Models**

Table 2 between the various machine learning and deep models used to perform automatic modulation recognition on UAV based communication systems indicates their ability to extract features and their ability to resist the dynamic aerial channel conditions. Classic machine learning offers hand-designed features and is less adaptive whereas deep learning methods learn discriminative features with enhanced mobility, noise, and channel sensitivity. Spatial architecture Hybrid between spatial and temporal learning have the greatest classification accuracy but require much more computational complexity, rendering implementation on resource-limited UAV platforms more difficult.

**Advantages of CNNs in UAV-Based AMR**

AMR models based on CNN are quite robust to UAV dynamics because they can handle Doppler shifts, changes in altitude, rapidly changing aerial channels among others. Small and compressed CNN models also support on-board inference on UAVs that have small energy and computation capabilities, and thus can be deployed on edges. These models are very scalable and adaptable as they can be further refined with attention mechanisms to enhance accuracy on a variety of modulation schemes and channel conditions that are not visible. In addition, CNN-based AMR can be incorporated easily in 6G intelligence personnel like federated learning, edge AI, and multi-UAV collaborative structures to assist with distributed and autonomous spectrum sensing.

**Signal Representation for CNN-Based AMR**

Signal representation is an important factor in the Automatic Modulation Recognition (AMR) systems that operate on CNN [16]. As the representation of a signal influences the ability of a CNN to extract useful information that can be used to classify a modulation when it is difficult to predict in advance, the representation of a signal is especially crucial in UAV-enabled 6G networks where the signal is highly dynamic, and the state of the channel is hard to predict and analyze [18].

**Raw IQ Signal Representation**

A complex pre-processing is avoided by directly entering the in-phase (I) and quadrature (Q) into a 1D CNN to allow the model to learn amplitude and phase characteristics of the received signal [6].This method retains full signal data and allows effective application of light CNN designs that can be used on-board on UAVs [16]. Nevertheless, direct I/Q depictions are very vulnerable to channel noise and Doppler shift that can deteriorate recognition capability in UAV communication in high mobility settings [14].

**Time-Domain Signal Processing**

The extraction of time-domain features makes instantaneous features of the signal, like amplitude, phase, and other higher-order derivatives, to describe modulation behavior [11]. It can well represent temporal variation that is essential in the separation of the various modulation schemes and is ideally applicable in low-latency communication systems [16]. Nonetheless, its performance can be impaired in the presence of complex modulation formats like OFDM because of low frequency-domain understanding [14].

**Frequency and Time-Frequency Representations**

Frequency-domain and time-frequency feature extraction systems, FFT, STFT, and CWT, do not operate on signals directly, but convert them to display their spectral and joint-time-frequency properties [13]. These representations underline both modulation-specific patterns and capture both temporal and spectral changes and allow feature learning with CNNs to become more effective [14]. They however have increased computational and memory overhead and it is more difficult to deploy in real-time on resource-constrained UAV platforms [16].

**Image-Based Signal Encoding for CNN Input**

In this method, communication signals are converted into two-dimensional representations, including spectrograms or constellation diagrams and analyzed with 2D CNNs [9]. This makes it possible to learn spatial features effectively, resistant to noise and channel impairment and it suits well to hybrid UAV-ground CNN architectures [14]. Nonetheless, the extra pre-processing represents a computational load and needs special scaling and normalization to be used in the deployment of UAVs in real-time [16].

**CNN Architectures for AMR in UAV-6G Networks**

The figure 3 shows a hierarchical convolutional neural network (CNN) architecture of processing and analyzing time-series and spatial information. It starts with 1D, 2D and 7D CNN models that operate on raw time-series data, no convolutional 2D data and feature maps, respectively, to feed into specialized AMR and AMh systems which are optimized to run onboard navigation and ground station processing. The framework combines lightweight CNNs and hybrid temporal analyzers to make complex autonomous systems to be able to extract, classify, and analyze features in real time and with end-to-end feature extraction.

**1D CNN Models**

Convolutional Neural Networks 1D are run on raw time-series IQ signals, and they extract time-based information with high efficiency [2]. They can be used in tasks that require middle-level computing capabilities and have good accuracy, maintaining signal dynamics [4].

**2D CNN Models**

2D CNNs take spectrograms or time-frequency representations of signals as their input with features in both time and frequency domain [9]. This is most effective when the classification performance is required to be high in the circumstances of low SNR or in multipath channel conditions [10].

**Lightweight CNNs for On-Board UAV Processing**

Lightweight CNNs are trained with less layers and parameters to execute on UAVs with low computational capabilities [6]. They allow real-time AMR of on board UAVs and strike a balance between accuracy and energy efficiency [16].

**Deep CNNs for Ground-Station Processing**

Deep CNNs make use of multi-convolutional layers in order to form hierarchical and high level features of UAV signals[11]. They are deployed at ground stations, where they deal with the underlying complex variations in channels and overall AMR accuracy is enhanced without resource limitations of UAVs[14].

**End-to-End CNN-Based AMR Frameworks:**

This is because end-to-end CNN systems combine feature extraction and modulation classification into a single pipeline[16]. These models have the benefit of simplifying processing chain, manual feature engineering and performing well in a large number of UAV communication scenarios[14].

**Challenges in CNN-Based AMR for UAV-6G**

**Fast-Varying Aerial Channels**

The mobility and changes in altitude of the UAVs lead to rapidly varying channel conditions, which cause time varying fading, Doppler shifts and varying signal-noise ratios (SNR) [14]. Such dynamics lower the accuracy of CNN-based modulation recognition because the learned features are not likely to be applicable in rapidly changing situations. They frequently need adaptive training or online learning procedures to sustain performance[16].

**Limited UAV Computational Resources**

UAVs demand severe power, memory, and CPU/GPU restrictions on the on-board. Large parameter CNNs can go beyond these constraints, and real-time AMR becomes difficult [16]. To achieve a trade-off between accuracy and

computational cost, lightweight CNN models or model compression methods (e.g., pruning, quantization) are needed[6].

**Generalization across Environments**

The CNN models might fail in the unseen conditions when they are trained to be in a particular UAV scenario (e.g., urban, rural, or particular altitude ranges). The accuracy of models can be compromised by the environmental factors, which include interference, multipath effects, and weather conditions [10]. It is important to guarantee strong generalization to be deployed in different operational environments.

**Dataset Scarcity**

Quality, labelled data of UAV-based AMR are scarce, especially of dynamic aerial channel or multi-modulation signals [16]. Minimal data can cause over fitting, which decreases the reliability of the model. This can be partially solved by data augmentation, synthetic signal generation or federated learning between UAV networks [18].

**Energy Efficiency Constraints**

The endurance of UAVs is dependent on energy consumption. Inference of CNN and signal processing on board consumes more battery, which decreases flight duration [22]. There is need to have energy efficient algorithms, hardware acceleration, and lightweight models to ensure a trade-off between modulation recognition accuracy and the UAV operational sustainability.

**Security and Reliability Issues in UAV-Based CNN AMR Systems**

Automatic Modulation Recognition (AMR) is a CNN-based feature that has been integrated into UAV-assisted 6G networks, which presents a number of security and reliability issues. UAVs work in dynamic and usually hostile environments, and as such, they are susceptible to targeted assaults and uncontrolled failures[20]. The safety and efficiency of the network functioning is dependent on the reliability and security of AMR systems.

**Jamming and Spoofing Attacks**

UAV communications are susceptible to jamming attacks, where the opponents send high-power jamming signals that reduce the signal-to-noise ratio and result in wrong AMR classification [22]. This interference may seriously interfere with mission critical UAV links. Spoofing attacks constitute additional attacks that impingement on system integrity through the release of signals that are similar to the legal UAV transmissions and deceive the AMR system. A combination of these attacks makes CNN-based AMR considerably less reliable, particularly when using swarms of UAVs and beyond line of sight processes.

**Adversarial Attacks on CNN Models**

Models based on CNN are susceptible to adversarial attacks whereby well-crafted signal perturbations can initiate misclassification without causing any perceivable alterations to a human perceiver[14]. The slightest distortion in the signal sent to a UAV in AMR systems can lead to wrong modulation identification. Enemies can also use UAV mobility and the quickly shifting channel conditions to inject said perturbations on a dynamic basis[10]. Such attacks have the potential to compromise the reliability and validity of autonomy AMR decision-making. Such vulnerability therefore presents critical risks to assured spectrum management, network independence and the reliability of the mission on UAV communications.

**Robust and Secure AMR Techniques**

In response to them, one can use adversarial training where the CNN models are made vulnerable to corrupted signals, thus enhancing their resistance to malicious manipulations [4]. Before AMR classification can occur, methods of signal authentication and verification, e.g. cryptographic techniques or RF fingerprinting, are used to identify spoofed transmissions before authentication. Powerful feature extraction with time frequency representation, self-attention network, or multi signal fusion makes it harder to jam and harder to be noisy [9]. The further improvement of reliability can be provided by the redundant UAV swarm architectures which allow cooperative detection and

classification [12]. Also, through federated learning, resilient and privacy-preserving AMR can be supported since model updates are distributed between UAV nodes to ensure secure operation in adversarial and uncertain contexts [18].

## DISCUSSION

This paper emphasizes that CNN-based Automatic Modulation Recognition is increasingly becoming significant in UAV-based 6G wireless networks that have unpredictable channels, mobility, and resource capacity. It is evident in the literature that the complexity of a model is traded against the real-time deployability where lightweight CNNs are being used as a pragmatic solution to on-board processing of UAVs whereas more sophisticated and hybrid models are used at ground stations. Representation of signals is also important since encodings based on time-frequency and images enhance the robustness but they raise the computation costs. Other security and reliability problems, including jamming, spoofing, and adversarial attacks also make the implementation of AMR more complicated, which underscores the necessity of robust and secure learning strategies. In general, the combination of effective CNN architectures and adaptive learning, energy-consciousness, and security tools will make AMR in the future UAV-based 6G networks scalable and reliable.

## CONCLUSION

The present paper was the in-depth investigation of CNN-based Automatic Modulation Recognition in UAV-enabled 6G wireless networks with a focus on lightweight and robust learning models applicable in dynamic aerial setting. CNNs were demonstrated to perform well to digest modulation-specific features and also to balance between accuracy, computational complexity, and energy efficiency. Although these benefits exist, such challenges as rapidly changing channels, the lack of UAVs, the lack of data sets, and security concerns are still critical. The future direction of work will be on the creation of ultralightweight and adaptive CNN models via model compression, federated learning, and edge intelligence. The reliability in harmful environments can further be increased with the incorporation of self attention, transformer-aided hybrid architectures and adversarially robust training. Moreover, real-world UAV datasets and hardware-in-the-loop experimentation on a large scale are needed to prove the applicability of 6G networks to the real world.

## ABSTRACT

This study examines the efficiency differences between organic and inorganic solar cells, focusing on material characteristics, energy conversion performance, stability, cost factors, and technological advancements. Organic photovoltaic (OPV) cells have gained attention for their flexibility, lightweight nature, and low-cost manufacturing, while traditional inorganic solar cells—such as crystalline silicon and thin-film technologies—remain the industry standard due to their high efficiency and superior long-term stability. Through an analytical review of existing data and scientific literature, this paper highlights that inorganic solar cells consistently outperform organic cells in power conversion efficiency (PCE), typically achieving 18–25%, compared to 10–18% for OPVs. However, organic cells show promise for niche applications requiring mechanical flexibility and eco-friendly manufacturing. The study concludes by recommending hybrid and perovskite-integrated cell designs for future research and improved efficiency.

**Keywords:-** Organic solar cells, Inorganic solar cells, Organic photovoltaic (OPV), Crystalline silicon, Thin-film solar cells, Power conversion efficiency (PCE), Material characteristics, Energy conversion performance, Stability, Cost analysis, Technological advancements, Hybrid solar cells, Perovskite solar cells, Flexible photovoltaics, Eco-friendly manufacturing.

## INTRODUCTION

Solar energy technologies have witnessed rapid growth due to the global emphasis on clean and renewable energy sources. Among these, solar photovoltaic (PV) cells play a critical role in harnessing sunlight and converting it into electrical energy. Traditionally, inorganic solar cells, primarily crystalline silicon-based, have dominated the PV industry owing to their high efficiency and durability. However, organic solar cells (OSCs)—made from carbon-based polymers and small organic molecules—have emerged as promising alternatives due to their low weight, ease of fabrication, low-temperature processing, and potential for large-area flexible applications. This article aims to provide a detailed comparison of organic and inorganic solar cells, focusing on their efficiency parameters, technological attributes, material properties, and application scope. The study highlights performance trends and identifies areas where future breakthroughs could enhance the commercial viability of organic PV technology.

## LITERATURE REVIEW

The efficiency and performance of solar cells have been critical research areas in renewable energy studies. Inorganic solar cells, particularly crystalline silicon, have been extensively studied due to their mature manufacturing processes and high energy conversion efficiencies, often exceeding 20%. Thin-film inorganic systems, including CdTe and CIGS, also demonstrate competitive efficiencies at reduced manufacturing costs. Research by Green et al. (2023) highlights the long-term stability and predictable performance of inorganic PV technologies. Conversely, organic solar cells (OSCs) have gained interest for their unique mechanical properties, especially flexibility and low-temperature fabrication. Studies by Li and Jen (2022) emphasize advancements in donor–acceptor polymer structures, improving PCE values to 15–18% under laboratory conditions. However, OSCs suffer from degradation due to oxygen and moisture exposure, limiting their operational life. Perovskite–organic tandem systems have shown promise, achieving efficiencies above 20%, merging the benefits of low-cost organic layers with high-performing inorganic perovskites. Comparative studies consistently indicate that inorganic PV systems lead in efficiency and stability, while OSCs excel in sustainable, lightweight, and customizable applications. The evolution of hybrid architectures presents an opportunity to bridge the gap between the two technologies.

**Objectives of the Study**

- To compare the energy conversion efficiency of organic and inorganic solar cells.
- To analyze the material differences contributing to efficiency variations.
- To examine the stability, durability, and operating lifetime of both technologies.
- To identify potential future applications and technological innovations.

**Working Model of Organic and Inorganic Solar Cells**

A solar cell—whether organic or inorganic—can be represented using an equivalent electrical circuit model to understand its current–voltage (I–V) behavior and power output. Both types of solar cells operate on the photovoltaic principle, where incoming light generates electron–hole pairs, producing current when the circuit is closed.

In inorganic solar cells such as crystalline silicon or thin-film CdTe/CIGS, the circuit model commonly includes a photogenerated current source (I<sub>ph</sub>), a diode representing the p–n junction, a series resistance (R<sub>s</sub>) accounting for contact and material resistance, and a shunt resistance (R<sub>sh</sub>) representing leakage pathways. These components accurately reflect the high carrier mobility and strong built-in electric field of inorganic materials. Their high R<sub>sh</sub> and low R<sub>s</sub> contribute to superior efficiency and fill factor. In organic solar cells, the model is similar but adjusted for organic semiconductor behavior. Organic materials have lower carrier mobility, higher recombination rates, and more interface defects. Therefore, their equivalent circuit often shows higher series resistance and lower shunt resistance. Organic devices rely on donor–acceptor heterojunctions, and exciton dissociation inefficiencies are incorporated into the model via modified diode

parameters. Overall, the circuit model helps analyze how material properties—mobility, recombination, interface quality, and resistances—affect solar cell efficiency, enabling performance prediction and optimization for both organic and inorganic technologies.

**Factors Influencing Solar Cell Efficiency**

The factors influencing Solar Cell Efficiency in this study is built on comparing the key determinants of efficiency in organic and inorganic solar cells. It emphasizes four primary factors: material properties, device architecture, environmental stability, and manufacturing characteristics. Material properties such as bandgap and absorption ability influence how effectively each type converts sunlight into electricity. Device architecture, including layer configuration and interface engineering, determines charge transport and recombination rates. Environmental stability highlights the role of heat, oxygen, and UV resistance in long-term performance. Finally, cost and manufacturing scalability shape commercial viability. Together, these elements guide the evaluation of efficiency differences between organic and inorganic solar cells.

**Comparative Analysis of Organic and Inorganic Solar Cells**

The analysis clearly shows that inorganic solar cells outperform organic solar cells in terms of overall power conversion efficiency and long-term reliability. Crystalline silicon cells consistently achieve 20–25% laboratory efficiencies, with commercial modules reaching around 18–22%. Thin-film inorganic cells such as CdTe and CIGS offer 12–20% efficiency with lower production costs. Their stability under outdoor conditions ensures operational lifetimes exceeding 20 years.

Organic solar cells, despite notable progress in donor–acceptor engineering, achieve laboratory efficiencies of 15–18% and commercial efficiencies usually around 10–12%. Their primary limitations stem from sensitivity to moisture and UV exposure, resulting in faster degradation. However, OSCs offer advantages in flexibility, lightweight construction, semi-transparency, and eco-friendly printing techniques. These characteristics make them suitable for portable electronics, indoor energy harvesting, and building-integrated photovoltaics where aesthetics and flexibility matter. The study determines that while inorganic solar cells remain dominant for large-scale power generation, OSCs hold significant promise in niche markets. Future innovations involving hybrid structures and perovskite-integrated organic designs may further boost efficiency and stability.

## FINDINGS, SUGGESTIONS, AND FUTURE IMPLICATIONS

The findings of the study indicate that inorganic solar cells, particularly crystalline silicon and thin-film technologies, continue to outperform organic solar cells in terms of efficiency, long-term stability, and commercial maturity. Their higher carrier mobility, strong p–n junction characteristics, and resistance to environmental degradation make them suitable for large-scale power generation. Organic solar cells, while achieving lower efficiencies and shorter lifespans, demonstrate significant advantages in flexibility, lightweight structure, low-temperature fabrication, and aesthetic adaptability. These features position them well for portable electronics, indoor applications, and building-integrated photovoltaic systems. Based on these findings, key suggestions include focusing on improving the environmental stability of organic solar cells through advanced encapsulation, molecular engineering, and interface optimization. Collaboration between material scientists and industry stakeholders can accelerate the transition of laboratory-level OPV technologies to commercial products. For inorganic solar cells, further cost reduction and development of eco-friendly manufacturing methods are recommended. Future implications highlight the promising potential of hybrid and tandem systems that combine organic and inorganic layers, particularly perovskite-integrated structures. These innovations may merge the strengths of both categories, achieving high efficiency with added mechanical flexibility. As research progresses, such next-generation solar technologies could reshape renewable energy deployment across consumer, industrial, and architectural sectors.

## CONCLUSION

The comparative study concludes that inorganic solar cells currently remain superior in terms of efficiency, performance consistency, and lifespan, making them the preferred choice for large-scale power generation. Organic solar cells, however, present exciting opportunities due to their lightweight, flexible, and environmentally friendly characteristics. While OSCs still face challenges in stability and efficiency, ongoing advancements in material science, molecular engineering, and hybrid perovskite technologies may significantly narrow the performance gap in the coming years. The future of solar energy will likely involve coexistence of both technologies, each serving distinct applications based on their strengths.

**ABSTRACT**

The present study documents the avifaunal diversity of Rajnandgaon and Khairagarh districts of Chhattisgarh, India. A total of 296 bird species belonging to 77 families and 18 orders were recorded, highlighting the rich taxonomic diversity of the region. The bird community showed a clear dominance of Passeriformes, accounting for 123 species (41.6%). This was followed in decreasing order of representation by Charadriiformes (35 species), Pelecaniformes (24 species), Accipitriformes (23 species), and Anseriformes (17 species). Accipitridae, Anatidae, Muscicapidae, and Ardeidae were among the most speciose families, whereas nearly one-third of the recorded families were represented by a single species, indicating a combination of ecological specialization and diverse habitat conditions. In addition to diversity patterns, the study provides confirmed breeding evidence for 58 species across varied habitats, strengthening the ecological value of these landscapes. Remarkably, the River Tern (*Sterna aurantia*) and Asian Brown Flycatcher (*Muscicapa dauurica*) are reported for the first time as breeding species from Chhattisgarh, along with several other noteworthy records. Additionally, this study records the presence of the Cinereous Vulture in Chhattisgarh for the first time. The findings highlight the critical role of wetlands, forests, and scrub–grassland mosaics in sustaining a rich community of resident as well as migratory birds. Notably, the checklist also includes 16 species of conservation concern listed in the IUCN Red List, underscoring the conservation value of these landscapes. The findings emphasize the role of habitat diversity in sustaining avifaunal richness and highlight the need for integrated conservation

strategies to safeguard critical habitats, particularly wetlands and forest patches, against growing anthropogenic pressures.

**Keywords:** IUCN Red List, critical habitats, diversity, Observations, Avifaunal

## INTRODUCTION

The districts of Rajnandgaon and Khairagarh (KHG) in Chhattisgarh encompass varied forest types and geographical features that support considerable mammalian and avifaunal diversity. Located in the southeastern part of the Satpura Range, the region is characterized by heterogeneous topography and climate, giving rise to distinct ecological zones. Forests of both districts fall under the Dry Deciduous and Southern Tropical Moist Deciduous forest categories (Champion & Seth, 1968) and cover approximately 2,923 km², accounting for about 36.4% of the total geographical area (CBSAP, 2003). Recent studies have recorded 35 mammal species across seven orders, identifying the landscape as an active tiger corridor, while also indicating possible local declines linked to habitat fragmentation (Thakur et al., 2024). Avifaunal diversity in Chhattisgarh is high, with 502 species documented to date (Arjun et al., 2023), and several additional records reported subsequently (Thakur, 2023; Thakur, 2024; Sharan et al., 2025; Thakur et al., 2025). Wetland-focused studies from Khairagarh district have recorded high floral diversity dominated by Poaceae and Cyperaceae, supporting rich bird assemblages exceeding 200 species, particularly migratory waterbirds (Thakur et al., 2025, unpublished). Several wetlands, including Baghnadi, Chhindari, Khatutola Barrage, and Khairabana, support bird communities exceeding 100 species. While Dongargarh Dhaara Reserve represents one of the most diverse forest patches, large parts of the Khairagarh forest remain poorly explored. Grassland habitats in the region are limited and increasingly degraded due to anthropogenic pressures, reducing their suitability for breeding grassland birds.

Breeding records of several shoreline and wetland-associated species in Chhattisgarh have so far been largely restricted to the Dhamtari region (Bharos et al., 2019, 2020, 2021).While recent studies have added breeding records of Sarus Crane and Lesser Adjutant Stork (Thakur et al., 2024; Thakur et al., 2025). Observations by local birders and year-round occurrence data further suggest that breeding activity of several species may be underreported, emphasizing the need for systematic documentation.

## METHODOLOGY

Bird surveys were conducted using an opportunistic sampling approach, with study sites visited without a predetermined sampling design. Observations were made using binoculars, cameras, and standard field equipment. All species records were supported by either photographic documentation or sound recordings.The cumulative survey effort totaled approximately 850 observation hours, primarily during morning, afternoon, and evening periods. Nocturnal sampling was limited and comprised only 8–9 night visits. Author 1 and Author 3, residents of Rajnandgaon district, carried out regular opportunistic observations during visits to nearby habitats. Author 2 contributed continuous observations from 2019 to 2022, while Author 4 conducted periodic surveys between 2014 and 2016.A total of 296 bird species were recorded. Most records were supported by photographic evidence, while 5–6 species were documented exclusively through call recordings. Species identification followed standard bird field guides (Grimmett et al., 2017; Ali & Ripley, 1987) and was further validated through expert consultation.

**Study area:** The study was conducted from 2o14 to 2025 in various habitat (Fig. 1) in Rajnandgaon and Khairagarh district of Chhattisgarh.

## RESULTS

At the family level, Accipitridae (22 species) was the most species-rich, reflecting the abundance of raptors in the region. Other diverse families included Anatidae and Muscicapidae (17 species each), Ardeidae (12), and Scolopacidae (11). Moderate representation was observed in *Cuculidae* (9 species), followed by *Rallidae*, *Charadriidae*, and *Motacillidae* (8 species each). Likewise, the families Columbidae, Strigidae, Picidae, and Phylloscopidae were each represented by seven species. In contrast, nearly one-third of the families were represented by only a single species, underscoring the taxonomic breadth of the avifauna despite low representation in several groups. The dominance of Passeriformes reflects their high species richness and broad ecological adaptability. The presence of key waterbird families emphasizes the importance of wetlands, while raptors indicate a balanced trophic structure. Families with few species highlight habitat heterogeneity, underscoring the role of diverse ecosystems in maintaining avian diversity.

Between 2019 and 2025, breeding was confirmed for 56 bird species across wetlands, forests, gardens, and open habitats, based on observations of nesting, feeding, fledging, and colony formation. Successful reproduction by wetland and forest species, along with varied nesting strategies and adaptability to human-modified landscapes, highlights the region's high breeding diversity and conservation importance. The checklist includes 16 IUCN Red List species, underscoring the region's global conservation significance and the urgent need to protect key habitats, particularly wetlands and forest remnants.Overall, the study highlights that Rajnandgaon and Khairagarh districts harbor a rich and ecologically significant bird assemblage, making them vital for regional and migratory avifaunal conservation.

**Tagged bird**

**Cinerous vulture-**In South Asia, the Cinereous Vulture inhabits arid and semi-arid mountain regions of Pakistan and occurs at lower elevations in the Himalayas. Within India, it is mainly a winter visitor to the northwestern regions and occasionally strays into peninsular areas, reaching as far as Dhulia in Maharashtra. (Ali & Ripley 1987). Recently, Samson et al. (2019) reported its migration records mainly between December and February from six districts across Telangana, Kerala, Karnataka, Tamil Nadu, Maharashtra, and Andhra Pradesh. Additionally, Mall et al. (2022) documented its presence in Bihar and Jharkhand**.** On 16 January 2023, a rescued Cinereous Vulture was ringed (M63) at Jungle Safari, Raipur, and released by the Forest Department at Singarghat, Khairagarh district, Chhattisgarh. The following day, the bird was observed flying northwards towards the Maikal Range in Madhya Pradesh. This rescue and release represents the first documented record of the species from Chhattisgarh.

**Several other rare species were also noted.** Black-winged Cuckooshrike was recorded during winter migration around Paniyajob, Ningo, and Kolarghat (Dongargarh). Painted Sandgrouse was sighted 2–3 times, restricted to Ningo Dam. Sirkeer Malkoha was recorded once at Surhi Dam (Gandai) and also from Udaipur Hills, Surguja. A local passage of Glossy Ibis was noted at Ruse Dam, Khairagarh (10 November 2024). Indian Blackbird and Puff-throated Babbler were recorded for the first time from Achanakmar Tiger Reserve(Anthony et al., 2018). Calls of Oriental and Indian Scops Owls were recorded; Brown Hawk-Owl is likely present based on adjacent records (Bhoramdev wildlife sanctuary).

**Taxonomic varients:** Rare taxonomic variants such as the Orange-headed Thrush (*Geokichla citrina*), Black-eared Kite (*Milvus lineatus*), and Peregrine Falcon (*Falco peregrinus*) have also been reported from the region.

## DISCUSSION

Birds in the study area are exposed to several anthropogenic pressures, including habitat degradation, hunting, road mortality, pesticide misuse, and infrastructure-related hazards, as also noted from other parts of central India (Ali & Ripley, 1983; Chandra & Singh, 2004; Thakur et al., 2024). Among these, loss of nesting and roosting trees was

identified as the most critical threat. Clearing of trees at Dongargarh (Mahaveer Para) led to the destruction of a communal nesting site used by egrets, herons, and cormorants, while removal of dry and partially submerged trees at Khatutola Barrage reduced nesting opportunities for Asian Openbill Storks and cormorants. In another instance, the felling of a single nesting tree resulted in the failure of a breeding attempt of the Asian Brown Flycatcher, which also constitutes the first breeding record of the species from theregion (Rasmussen & Anderton, 2005; Mohan & Murlidhar, 2019).

Roadkill incidents were recorded for both small passerines and large birds such as the Barn Owl (*Tyto alba*), particularly along roads passing through agricultural and forested landscapes. Illegal hunting using air guns and slingshots was observed near several wetlands. Mortality associated with power transmission structures was documented, including a Common Crane found dead near a high-voltage tower at Ruse Dam. Additionally, a pesticide-related mass mortality event reported from Ambagarh Chowki in 2022 primarily affected granivorous species. Conservation measures should prioritize the protection of nesting trees, mitigation of road mortality, regulation of pesticide use, and increased community awareness. Local initiatives such as Mangata Park and the Chhindari Ke Parindey eco-tourism program demonstrate that community participation can play a positive role in conserving avifaunal diversity.

## CONCLUSION

This first documented bird checklist for Rajnandgaon and Khairagarh districts records 296 species spanning 77 families and 18 orders, featuring 17 species listed on the IUCN Red List and confirmed breeding activity for 56 species. The data highlight the mosaic of habitats—wetlands, forests, grasslands, and human-modified landscapes—that sustain both resident and migratory birds. Breeding records, such as range expansions (Asian Brown Flycatcher),The breeding distribution of the Asian Brown Flycatcher within the peninsular region remains inadequately documented. (Rasmussen & Anderton 2005).From Peninsular India the breeding records has been reported from Madhya Pradesh, Kerela, Rajasthan, Gujrat, Karnataka Tamilnadu, Andhra Pradesh, Telangana, Maharashtra, Haryana, Delhi.[V. Santharam (2003), Singh et al. (2009) & Mohan et al. (2019)] .Multiple broods (White-browed Fantail), and nesting colonies (River Tern, Asian Openbill), highlight the ecological significance of the region. Additionally, the Cinereous Vulture represents the first record of this species from Chhattisgarh. The documentation of breeding records offers insights into habitat suitability and species-specific reproductive preferences. Given the diversity of threatened species and ongoing human pressures, conservation of wetlands, mature forests, and grasslands is crucial for sustaining avifaunal diversity. In particular, Dongargarh Dhaara Reserve Forest, owing to its rich birdlife and ecological value, holds strong potential to be designated as a Conservation Reserve, ensuring long-term protection and community-based conservation of its habitats.

## ACKNOWLEDGEMENT

We express our sincere gratitude to Forest Officers IFS, CCF Bastar Alok Tiwari, IFS Aayush Jain, IFS Shashi Kumar, IFS Pankaj Rajput and SDO Mona Maheshwari as well as the Rajnandgaon Forest Department for their constant support and co-operation. We also extend our special thanks to Mr Ravi Naidu and Mr A M K Bharos for his valuable assistance in species identification and for his encouragement and motivation throughout the survey. We also gratefully acknowledge Prakriti Shodh Evam Sanrakshan Welfare Society and its members Ramesh Kumar Thakur, Anjal Nigam, and Ravi Pandey for their valuable support and contributions to the survey.

**Table 1. Bird species habit and observations**

| S No. | Species | Nesting type / Habitat | Observation |
|---|---|---|---|
| 1 | River Tern | Ground nesting/ Around wetland | In western India, breeding may commence early when such islands emerge, while in eastern India nesting generally occurs between March and June (Ali & Ripley 1983; Mundkur 1991).Breeding of River Tern was confirmed at Paniyajob Dam with adults incubating eggs (Apr 2024) and a parent was videographed at Raurkasa Dam guiding a fledgling in prey-catching behavior using wooden stick, indicating successful breeding (Jun 2023), extending the known breeding range in Chhattisgarh. The species was recorded year-round at multiple reservoirs, with a maximum count of ~20 individuals at Baghnadi Dam (May 2023) |
| 2 | Little Tern | Ground nesting/ Around wetland | Two nests with seven adults recorded at Paniyajob Dam (28 Apr 2024) |
| 3 | Little Pratincole | Ground nesting/ Around wetland | Breeding colony (30 birds) recorded at Paniyajob Dam; fledglings observed in May; additional breeding at Dangbora Dam. |
| 4 | Asian Brown Flycatcher | Tree nesting/ Forest or Thick vegetation | Breeding activity of the Asian Brown Flycatcher was confirmed within the study area, representing an extension of its known breeding range in peninsular India. Courtship was documented in May 2021, followed by two active nests in June 2021, all situated in tree forks. Adults were observed provisioning nestlings with |

| | | | |
|---|---|---|---|
| | | | insects and removing fecal sacs. One nesting attempt was unsuccessful due to the felling of a nearby tree, underscoring the susceptibility of nesting sites to unintentional human disturbance. |
| 5 | White browed fantail | Tree nesting/ Forest or Thick vegetation | White-browed Fantail breeding was recorded between April and June 2021, with seven nests documented during the season. A nest containing a recently hatched chick was observed on 28 May 2021 along a forest foot trail, with both parents actively feeding. Regular provisioning with flies and fecal sac removal were noted on 29 May. By 2 June, only a single chick remained, which fledged by 5 June. The nest was found empty on 8 June, and the family was subsequently observed on 15 June with healthy, volant juveniles. Notably, a second clutch was initiated in the same nest on 28 June, indicating within-season nest reuse. This observation supports earlier suggestions that fantails may reuse nests under favorable conditions and highlights site fidelity and the potential for multiple broods within a single breeding season. (Copestake 2021) |
| 6 | Egyptian Vulture | Tower nesting/ Open field | Nest with one nestling recorded on power transmission tower (Mar 2021). |
| 7 | Crested tree swift | Tree nesting/ Forest or Thick vegetation | Nesting colonies recorded at Kurejhar, Kolarghat, and Raurkasa; largest flock ~300; observed near Kahuwapani–Kalghurra area. (June-2023) |
| 8 | Asian Open bill stork | Flooded tree nesting/ Around wetland | Breeding colonies recorded with 12–30 nests between 2021–2022; both parents involved in incubation and feeding. (Sep–Nov 2021; Jun–Nov 2022). |
| 9 | Mottled wood Owl | tree cavity / Forest | Successful breeding recorded annually (2021–2023); fledglings documented; predation event by Monitor Lizard noted in 2024. |
| 10 | Grey headed fish eagle | Tree nesting/ Wetland | Empty and active nests recorded; nest-building observed in Nov 2024; vocal activity restricted to nesting phase. |
| 11 | Little ringed plover | Ground nesting/ Around wetland | Active nesting and fledglings recorded at Paniyajob Dam (Apr–May 2024). |
| 12 | Little cormorant &Indian cormorant | Tree nesting/ Wetland | Mixed breeding colony recorded at Khatutola (Nov 2022) and other wetlands. |
| 13 | Indian paradise flycatcher | Tree nesting/ Forest | Multiple nesting records (May-June; 2020–2023); cinnamon and moulting morph males documented; nestling period ~14 days; diverse prey delivery recorded. |
| 14 | Indian white eye | Tree nesting/ Forest | Nesting recorded; unusual interspecific feeding of Indian Paradise Flycatcher nestlings observed. (May-June) |
| 15 | Lesser Whistling Duck and Spot billed duck | Ground nesting/ wetland | Adults with chicks recorded during Dec–Jan at multiple tanks; nests inferred from presence of fledglings. |
| 16 | Barn Owl | Old building or tree cavity/ Urban Area | Successful fledging recorded in 2021 and 2023 at residential site; regular nocturnal activity noted. |
| 17 | White naped woodpecker | tree cavity / Forest | Nest cavity use recorded(March 2021) ; repeated drumming during breeding season observed. |
| 18 | Red vented Bulbul | Tree nesting/ Dense vegetation or garden | Active nest and juveniles recorded; breeding confirmed in residential garden.(June 2021) |

| | | | |
|---|---|---|---|
| 19 | Spotted owlet | Cavity nesting/ Open field | Mating and family groups (Dec-Feb; 2021-24)(4–5 individuals) recorded; multiple nesting sites documented. |
| 20 | Peacock and Red Jungle fowl | Ground nesting/ forest | Females with chicks recorded; breeding inferred from displays and juvenile presence. (Aug 2021; May 2023) |
| 21 | Red naped Ibis | Tree nesting and Tower/ Wetland | Active nests recorded (Nov 2024); adults observed carrying prey to nestlings in flight. (Nov 2021) |
| 22 | Black winged Kite | Tree nesting/Open field | Mating behaviour recorded near Chhichola (Nov 2020) |
| 23 | Tailor bird | Suspended or hanging nesting/ Garden | Nest construction activity recorded in June 2021 |
| 24 | Golden Oriole | Tree nesting/ Forest or thick vegetation | Active hanging, Cup shaped nest recorded with incubation behaviour. (Jun 2021) |
| 25 | Small minivet | Tree nesting/ Open woodland | Nest-building recorded in May 2022; additional breeding activity observed in 2025. |
| 26 | White bellied drongo | Tree nesting/ Open woodlands | Active nesting recorded in cup-shaped nest (May 2021) |
| 27 | Black kite | Tree nesting/ Open field | Nestlings recorded at nesting trees (Jan 2022; Mar 2023) |
| 28 | Black Drongo | Tree nesting/ Forest | Active nesting recorded (Apr 2023); mobbing of predators observed during nesting period. |
| 29 | Shikra | Tree nesting/ Open field | Nest with two nestlings recorded; prey delivery observed (May 2023) |
| 30 | Common Moorhen | Ground nesting /Wetland | Adults with freshly hatched chicks recorded (Aug 2020; 2024) |
| 31 | Gray Francolin | Ground nesting /Open field | Family groups recorded; breeding vocalizations documented (Apr 2022). |
| 32 | Yellow wattled lapwing and Red wattled lapwing | Ground nesting /Open field or wetlands | Parents with chicks recorded (Sep–Oct). |
| 33 | White browed bulbul | Tree nesting/ Garden | Active nest recorded with successful fledging (Jun 2024) |
| 34 | Scally breasted munia, House sparrow and Red munia | Tree and shrub nesting/ Garden and Open field | Nesting recorded seasonally: House Sparrow (May), Scaly-breasted Munia (Oct), Red Avadavat (Oct). |
| 35 | Greater racket tailed drongo | Tree nesting/ Forest | Active nest with incubation recorded near Madiyan Dam (Jul 2024) |
| 36 | Plain Prinia | Ground nesting/ Open field | Nest material carrying recorded near Cross Hill (Sep 2022). |
| 37 | Baya weaver | Suspended tree nesting/ Open field | Multiple nesting colonies recorded (Sep–Oct) |
| 38 | Black naped monarch | Tree nesting/ Forest | Active nests recorded (May–Jul 2023). |
| 39 | Rose ringed parakeet | tree cavity / Forest | Active cavity nesting recorded (Mar 2024); family association observed until May 2024. The other two species, Plum-headed Parakeet and Alexandrine Parakeet, were recorded throughout the |

| | | | |
|---|---|---|---|
| | | | year and are also commonly kept as pets in the region. |
| 40 | Brahminy starling | tree cavity / Forest | Nesting recorded in reused woodpecker cavities (Mar–Apr 2021–2022). |
| 41 | Spotted Dove | Tree nesting/ Forest | Loosely built active nest recorded (Mar 2024) |
| 42 | Tickells blue flycatcher | Tree nesting/ Forest | Nest recorded (May 2023); fledgling observed (Jul 2020). |
| 43 | Indian roller | tree cavity / Forest | Nesting in old woodpecker cavity recorded (Apr 2022); prey delivery with scorpion documented (Apr 2025). |
| 44 | Bronze Winged Jacana | Floating nesting/ Wetland | Female with chicks recorded, confirming breeding (Nov 2021). |
| 45 | Coppersmith Barbet | tree cavity / Forest | Nest excavation recorded (Dec 2022); feeding of nestling observed (Apr 2025). |
| 46 | Indian scimitar babbler | Forest | Family group with juveniles recorded; active feeding observed (May 2025) |
| 47. | Commony Myna | Tree cavity/ forest | Nesting recorded in reused parakeet cavity (Apr 2024) |
| 48. | Asian Pied starling. | Electric poles/ Urban | Nesting on electric poles recorded in urban area (Apr–May) |
| 49. | Cattle egret, Little egret & Intermediate egret | Tree nesting/ Open fields, urban or around wetland | Colonial nesting recorded during monsoon season (Jul–Sep). |

**Table 2 Bird species, nesting habitats & field observations**

| S. No. | Common name / Scientific name | Description |
|---|---|---|
| **1** | Ferruginous Duck *Aythya nyroca* | Occasional sightings were recorded from Rajnandgaon and Surguja districts in January 2021. Historically reported from central Chhattisgarh wetlands including Maroda (Durg), Bangoli, Ghughwa and Kurud tanks in Raipur district and Gidhwa Tank in Bemetara district (Bharos et al., 2015), and from Achanakmar Tiger Reserve (Anthony et al., 2018). |
| **2** | Malabar Pied Hornbill *Anthracoceros coronatus* | Small groups of 1–3 individuals were observed in September 2021, increasing to about 20 individuals near Kursipar village, Dongargarh, in December 2021. A male's mating call indicates probable local breeding. |
| **3** | Heart-spotted Woodpecker *Hemicircus canente* | Observed in hilly forest patches of Dongargarh in 2021, with a confirmed photographic record on 13 June 2023. No subsequent sightings were recorded. Earlier regional records are available from Bastar, Udyanti (Gariyabandh) and Dantewada districts (Bharos et al., 2019). |
| **4** | Brown-breasted Flycatcher *Muscicapa muttui* | First photographed on 19 September 2021 near Chichola, Rajnandgaon district, and later on 18 September 2024 at Cross Hill and Raurkasa Dam. Previously reported from Kanger Valley National Park (Bharos et al., 2019). |
| **5** | Rufous-bellied Eagle *Lophotriorchis kieneri* | An adult was observed on 1 November 2021 at Kahuwapani Waterfall, and a juvenile was recorded on 20 November 2022 in Dhaara Reserve Forest. The species was again photographed on 11 December 2022 at Mainpat, representing a new locality along the Surguja–Raigarh border. Earlier records exist from Kanger Valley National Park (Dutta, 2015) |

| | | |
|---|---|---|
| **6** | Common Crane *Grus grus* | A flock of 21 individuals was recorded at Ruse Dam on 14 February 2021, with maximum counts increasing to 24 individuals by 2025. Birds were frequently observed feeding in chana fields and along wetland margins, often in association with Painted Storks and Eurasian Spoonbills. This represents the first record from the area after a gap of nearly 15 years. |
| **7** | Eurasian Spoonbill *Platalea leucorodia* | Regularly observed at Ruse Wetlands during the past four years, with a maximum count of 17 individuals. The species forages in shallow water by sweeping and probing the bill. |
| **8** | Grey-necked Bunting *Emberiza buchanani* | Eight individuals were observed near Bamleshwari Temple hill, Dongargarh, between January and March in dry, open scrub habitat. Only a few earlier records are available from Chhattisgarh. |
| **9** | Besra *Tachyspiza virgata besra* | Two individuals were recorded at Raurkasa Dam, Dongargarh, in May 2021. The species is considered a sporadic visitor to Chhattisgarh, with its main distribution in central India and the Western Ghats (Praveen, 2025) |
| **10** | Eastern Orphean Warbler *Curruca crassirostris* | Photographed near the outskirts of Dongargarh on 2 February 2023 and earlier at Ruse Dam on 14 January 2021. Previously reported from Raipur district, Surguja division and Bastar district (Bharos et al., 2019, 2022, 2023) |
| **11** | Slaty-breasted Rail *Lewinia striata* | Photographed at a small tank near Palloti School, Dongargarh, in August 2020 and July 2021, with three to four additional sightings. The species is rare in Chhattisgarh, with earlier confirmed records only from Surguja Division (Bharos et al., 2022). |
| **12** | Long-legged Buzzard *Buteo rufinus* | A single individual was observed near Paniyajob Dam, Dongargarh, in March 2020 during return migration. The species is a known winter visitor across India (Praveen, 2025) |
| **13** | Chestnut-headed Bee-eater *Merops leschenaultia* | Two individuals were photographed at Cross Hill on 26 March 2023, while seven individuals were recorded in October 2020 near Dhaar Dam, Dongargarh. Earlier records exist from Surguja and Bastar divisions (Bharos et al., 2019, 2022). |
| **14** | Grey-headed Lapwing *Vanellus cinereus* | A solitary individual was recorded twice, once at Pandariya Tank, Khairagarh, and again at Kunwarpur Dam, Surguja, in November 2024. Previous records are known from central India (Bharos et al., 2019) |
| **15** | Bar-winged Flycatcher-shrike *Hemipus picatus* | Photographic evidence was obtained from Dongargarh in May 2025, with additional records from Surguja district. The species is resident and fills a distribution gap across peninsular India (Grimmett et al., 2017). |
| **16** | Greater Sand Plover *Charadrius leschenaultii* | Recorded in August 2025 near Baldeopur and Atariya Tank, Khairagarh, along with Lesser Sand Plover; one earlier sighting was made in 2022 at Ruse Dam. The species is considered a rare migratory wader in Chhattisgarh. |
| **17** | Bar headed Goose *Anser indicus* | On 28 February 2024 at 20:02 h, 15 Bar-headed Geese were observed flying near Saraswati Shishu Mandir, Dongargarh, though photographic evidence could not be obtained due to poor visibility. Another flock of seven individuals was recorded at the same site on 2 March 2024, with calls documented for confirmation. Five sightings were made during the 2024 return migration. The geese followed a low-altitude flight path (<300 m) between Cross Hill (≈438 m) and Budha Dev Hill (≈400 m), avoiding the surrounding hilltops. These observations contribute to understanding the species' local migratory route. |

**Table 3. Several threatened bird species were recorded during the study:**

| S. No. | Species (IUCN status) | Record details |
|---|---|---|
| 1 | Indian Spotted Eagle (Vulnerable) | Recorded 4–5 times across different habitats in the study area |

| | | |
|---|---|---|
| 2 | Pallid Harrier (Near Threatened) | Observed in upland grasslands of the Dongargarh Dhaara forest region |
| 3 | Lesser Adjutant (Vulnerable) | Juvenile recorded from Khairagarh city (Thakur et al. 2024) |
| 4 | Indian Roller (Near Threatened) | Maximum flock of 82 individuals recorded at Ruse Dam (2022); smaller flocks (3–10) at other waterbodies. |
| 5 | Woolly-necked Stork (Near Threatened | Occasional sightings, with group sizes ranging from 1–8 individuals. |
| 6 | Common Pochard (Vulnerable) | Large flocks (>500) at Baghnadi and Chhindari dams; 3–100 individuals at other sites. |
| 7 | Greater Spotted Eagle (Vulnerable) | Single individual observed near Chhuikhadan, Khairagarh, in February 2023 |
| 8 | Curlew Sandpiper (Vulnerable) | Recorded at Ruse Tank during two consecutive migratory seasons (Nov 2021, Sept 2022). |
| 9 | Eurasian Curlew (Near Threatened) | Single record from Chhindari Dam on 22 October 2022 |
| 11 | River Tern (Vulnerable) | recorded from several wetlands, with confirmed breeding at select sites; the highest count was 12 individuals at Baghnadi Reservoir. |
| 11 | **Grey-headed Fish Eagle (Near threatened)** | Observed in forest-edge wetlands, mostly as solitary individuals or in pairs. |
| 12 | **Egyptian Vulture (Endangered)** | Mainly recorded from open plain areas, with a maximum count of five individuals. |
| Other threatened bird mentioned are Ferruginous duck(Near threatened), Malabar pied hornbill (Near threatened), Rufous bellied Eagle (Near threatened)& Cinerous vulture (Near threatened) | | |

## ABSTRACT

Medication errors continue to represent one of the most significant and persistent threats to patient safety across healthcare systems worldwide. Despite advances in pharmacotherapy, digital health, and clinical governance, preventable medication-related harm remains highly prevalent in both developed and developing nations. Among the most effective human-centered strategies for improving medication safety is the active involvement of clinical pharmacists in direct patient care. Over the past three decades, the role of pharmacists has evolved from a traditional dispensing-focused function to a patient-centered clinical discipline embedded within multidisciplinary healthcare teams. This narrative review provides a comprehensive synthesis of global hospital-based evidence on the impact of clinical pharmacist interventions in reducing medication errors and preventing adverse drug events. The review examines pharmacist contributions across all stages of the medication-use process, including prescribing review, medication reconciliation, therapeutic drug monitoring, adverse drug reaction surveillance, patient counselling, and transitions of care. Evidence consistently demonstrates that pharmacist-led interventions significantly reduce prescribing errors, prevent high-risk drug-related harm, improve treatment appropriateness, and enhance patient outcomes. The review also explores economic benefits, interprofessional collaboration, implementation challenges, and future directions for expanding clinical

pharmacy services, particularly in resource-limited settings. Strengthening the clinical role of pharmacists represents a cost-effective, scalable, and sustainable strategy for advancing global medication safety.

**Keywords:** Clinical pharmacist, medication errors, patient safety, hospital pharmacy, medication reconciliation, Adverse drug events

## INTRODUCTION

Medication use is central to modern healthcare delivery, forming the cornerstone of disease prevention, treatment, and palliation. However, the medication-use process is complex, involving multiple professionals, high-risk decision-making, and dynamic patient-specific factors. As a result, medication errors remain one of the most common and preventable causes of patient harm in healthcare systems worldwide. Errors may occur at any stage of the medication-use process, including prescribing, transcribing, dispensing, administration, and monitoring. The consequences range from minimal clinical impact to catastrophic injury and death [1]. Over the past two decades, patient safety has emerged as a global priority, driven by landmark reports highlighting the unacceptable burden of preventable medical errors. Medication-related harm contributes substantially to healthcare morbidity, mortality, and economic loss. Hospitalized patients are particularly vulnerable due to polypharmacy, critical illness, frequent transitions of care, and exposure to high-alert medications [2]. In response to this challenge, a wide range of safety strategies have been implemented, including electronic prescribing, clinical decision support systems, standardized treatment protocols, and barcode medication administration. While these technologies have improved certain aspects of medication safety, they have not eliminated the problem. Human expertise, clinical judgment, and interdisciplinary collaboration remain essential components of safe medication practice. Among healthcare professionals, clinical pharmacists occupy a uniquely strategic position in the medication-use process. As specialists in pharmacotherapy, pharmacokinetics, and medication safety, clinical pharmacists are ideally positioned to identify inappropriate therapy, prevent harmful drug interactions, optimize dosing, monitor therapeutic outcomes, and educate both patients and healthcare providers. Their integration into direct patient care represents one of the most consistently effective interventions for reducing medication errors and adverse drug events [3, 4]. This narrative review comprehensively examines the evolving role of clinical pharmacists in preventing medication errors within hospital settings. It synthesizes global evidence on pharmacist-led interventions across the medication-use continuum, explores their clinical and economic impact, identifies implementation barriers, and discusses future directions for strengthening clinical pharmacy services worldwide.

### Evolution of Clinical Pharmacy Practice

#### Clinical Pharmacy

Clinical pharmacy is now widely defined as a health science discipline in which pharmacists provide patient-centered care to optimize medication therapy and promote health, wellness, and disease prevention. The primary focus is on ensuring the safe, effective, and rational use of medications at the individual patient level. Clinical pharmacists apply specialized knowledge of pharmacokinetics, pharmacodynamics, drug interactions, and therapeutic guidelines to support evidence-based prescribing [5].

#### From Dispensing to Direct Patient Care

Historically, the role of pharmacists was primarily product-oriented, focusing on the preparation, compounding, and dispensing of medications. For much of the twentieth century, pharmacists had limited involvement in therapeutic decision-making or direct patient care. Their primary responsibility was ensuring that medications were accurately prepared and supplied according to physicians' orders [6]. The emergence of clinical pharmacy as a discipline in the latter half of the twentieth century marked a paradigm shift in pharmacy practice. This transformation was driven by the increasing complexity of drug therapy, the expansion of pharmacological knowledge, and growing recognition of

medication-related morbidity and mortality. Pharmacists began to move beyond the dispensary and into clinical wards, participating in patient rounds, therapeutic decision-making, and medication monitoring [7].

**Global Expansion of Clinical Pharmacy Services**

High-income countries such as the United States, the United Kingdom, Canada, Australia, and several European nations have progressively integrated clinical pharmacists into hospital care teams. In these settings, pharmacists participate in daily ward rounds, manage antimicrobial stewardship programs, lead medication reconciliation initiatives, and contribute to critical care management. In contrast, the expansion of clinical pharmacy services in low- and middle-income countries has been slower and less uniform. While academic programs in clinical pharmacy have expanded in regions such as South Asia, the Middle East, and parts of Africa, the actual deployment of clinical pharmacists in hospital wards remains limited in many institutions due to workforce shortages, funding constraints, and lack of regulatory mandates [5].

**Medication Errors: Scope and Clinical Impact**

**Definition and Classification**

Medication errors are defined as any preventable event that may cause or lead to inappropriate medication use or patient harm while the medication is under the control of the healthcare professional, patient, or consumer. These events may occur at any stage of the medication-use process and may or may not result in harm.

**Common categories of medication errors include:**

- Prescribing errors
- Transcription errors
- Dispensing errors
- Administration errors
- Monitoring errors

Each category involves distinct risk factors and requires targeted safety strategies [7, 8].

**Global Burden of Medication Errors**

Medication errors represent a major global health burden. Studies across diverse healthcare systems consistently demonstrate that a significant proportion of hospitalized patients experience at least one medication-related error during their admission. Polypharmacy, complex dosing regimens, comorbid illnesses, and high-alert medications further increase vulnerability. The economic cost of medication-related harm is substantial. Preventable adverse drug events contribute to prolonged hospital stays, additional diagnostic testing, increased drug utilization, litigation costs, and productivity losses. From a societal perspective, the financial burden extends far beyond healthcare institutions to patients, families, and national economies[7].

**High-Risk Settings and Patient Populations**

Certain clinical settings exhibit particularly high rates of medication errors, including intensive care units, emergency departments, oncology wards, and geriatric units. Vulnerable populations such as older adults, children, patients with renal or hepatic impairment, and those receiving high-alert medications face elevated risk of serious harm from medication errors[9].

**Rationale for Pharmacist Involvement in Medication Safety**

**Unique Expertise in Pharmacotherapy**

Clinical pharmacists possess specialized training in pharmacology, therapeutics, pharmacokinetics, and drug safety. This expertise allows them to identify subtle prescribing errors that may not be immediately apparent to other clinicians. Pharmacists evaluate the appropriateness of drug selection, dosing accuracy, route of administration, frequency, duration, and potential interactions[9].

**Independent Medication Review**

Unlike prescribers, who are often focused on diagnosing and managing disease, pharmacists provide an independent and medication-centered perspective. This independent review function allows early detection of potentially inappropriate therapy and provides a critical safety checkpoint in the medication-use process[10].

**Continuous Monitoring and Follow-Up**

Clinical pharmacists actively monitor treatment response, laboratory parameters, and adverse drug reactions. This ongoing surveillance allows timely intervention when therapy becomes unsafe or ineffective, thereby preventing progression to serious harm[10].

**Role of Clinical Pharmacists**

**In Preventing Prescribing Errors**

Prescribing errors represent the most frequent and clinically significant category of medication errors in hospital practice. These errors commonly involve inappropriate drug selection, incorrect dosing, wrong frequency, failure to consider patient-specific factors such as renal or hepatic impairment, duplication of therapy, and clinically significant drug–drug interactions. Because prescribing decisions are made at the beginning of the medication-use process, errors at this stage often propagate downstream and increase the likelihood of patient harm. Clinical pharmacists play a critical role in intercepting prescribing errors through prospective review of medication orders. In hospitals where pharmacists participate in daily ward rounds, they routinely evaluate prescriptions for therapeutic appropriateness, dosing accuracy, safety, and adherence to clinical guidelines. Multiple studies have demonstrated that a significant proportion of pharmacist interventions at the prescribing stage result in meaningful modifications to therapy, including dose adjustment, discontinuation of unnecessary drugs, substitution with safer alternatives, and optimization of antimicrobial therapy[11]. Pharmacist involvement is particularly valuable in high-risk populations such as elderly patients, those with multiple comorbidities, and individuals receiving polypharmacy. Age-related changes in pharmacokinetics and pharmacodynamics significantly alter drug disposition, making standard doses potentially unsafe. Clinical pharmacists routinely adjust doses based on renal function, liver enzyme levels, body weight, and therapeutic response, thereby preventing both subtherapeutic treatment and toxicity. In addition, pharmacists play an essential role in preventing prescribing errors related to drug-drug interactions. With patients frequently receiving ten or more medications during hospital admission, the risk of harmful interactions is substantial. Pharmacists possess the expertise and tools to identify interactions that may lead to QT prolongation, bleeding, nephrotoxicity, serotonin syndrome, or central nervous system depression. Early identification of such risks allows proactive modification of therapy before adverse outcomes occur[12]. Prescribing errors are also common in antimicrobial therapy, where inappropriate selection, incorrect dosing, and unnecessary prolonged use contribute not only to individual patient harm but also to antimicrobial resistance. Clinical pharmacists involved in antimicrobial stewardship programs consistently demonstrate reductions in inappropriate antibiotic use, improved guideline adherence, and better patient outcomes[12,13].

**In Medication Reconciliation and Transitions of Care**

Transitions of care represent some of the most vulnerable points in the medication-use process. These transitions include hospital admission, transfer between wards, movement to intensive care units, and discharge back to the community. During these periods, patients are highly susceptible to unintentional medication discrepancies, including omitted drugs, duplicated therapy, incorrect dosing, and continuation of inappropriate medications[14]. Medication reconciliation is a structured process aimed at ensuring accurate and complete transfer of medication information across transitions of care. Clinical pharmacists are uniquely positioned to lead this process due to their detailed understanding of pharmacotherapy and their ability to obtain accurate medication histories[15]. At hospital admission, pharmacists collect comprehensive medication histories by interviewing patients and caregivers and reviewing previous prescriptions, community pharmacy records, and discharge summaries from earlier admissions. These histories are compared with admission orders to identify discrepancies. Studies consistently show that pharmacist-led medication reconciliation identifies significantly more discrepancies than standard physician- or nurse-led processes. At discharge, pharmacists ensure that inpatient medication changes are clearly communicated to

patients, caregivers, and primary care providers. Discharge counseling by pharmacists improves patient understanding of medication regimens, reduces post-discharge adverse drug events, and decreases avoidable hospital readmissions. Patients who receive pharmacist discharge counseling demonstrate better adherence, fewer medication errors at home, and improved satisfaction with care[8,9]. In healthcare systems where continuity between hospital and community care is fragmented, pharmacist-led transitional care services serve as an essential bridge to prevent medication-related harm after discharge.

**In Adverse Drug Reaction Monitoring and Prevention**

Adverse drug reactions [ADRs] are a major source of hospital-related morbidity and mortality. Many ADRs are predictable and preventable when appropriate monitoring strategies are implemented. Clinical pharmacists actively contribute to ADR prevention through routine surveillance, early detection, causality assessment, and reporting. Pharmacists monitor patients for early signs of drug toxicity through clinical review and laboratory evaluation. For example, nephrotoxic drugs require close monitoring of serum creatinine and urine output, while hepatotoxic agents require periodic liver function testing. Pharmacists also assess patient-reported symptoms that may indicate evolving adverse reactions, such as dizziness, gastrointestinal upset, skin rashes, or abnormal bleeding[16]. When an ADR is suspected, pharmacists assist in performing structured causality assessments, determining severity, and recommending appropriate therapeutic modifications. They also play a key role in documenting and reporting ADRs to pharmacovigilancecenters, thereby contributing to national and global drug safety surveillance[17]. Importantly, pharmacist involvement in ADR monitoring promotes a proactive rather than reactive safety approach. Instead of responding only after severe toxicity occurs, pharmacists identify high-risk patients and implement preventive strategies such as dose adjustments, enhanced monitoring, or drug substitution.

**In Therapeutic Drug Monitoring [TDM]**

Therapeutic drug monitoring is essential for medications with narrow therapeutic indices, high interindividual variability, or significant toxicity risks. Drugs such as vancomycin, aminoglycosides, antiepileptics, immunosuppressants, and certain cardiovascular agents require careful monitoring to maintain plasma concentrations within safe and effective ranges. Clinical pharmacists oversee TDM programs in many hospitals. Their responsibilities include selecting appropriate sampling times, interpreting drug concentrations, adjusting doses based on pharmacokinetic principles, and monitoring for toxicity or treatment failure. Pharmacist-led TDM services have consistently demonstrated improved target drug attainment, reduced toxicity, and enhanced clinical outcomes[18]. In critically ill patients, physiological changes such as altered volume of distribution, hypoalbuminemia, and organ dysfunction significantly affect drug handling. Pharmacists apply individualized dosing strategies in these patients to avoid underexposure or drug accumulation. Their involvement reduces the risk of nephrotoxicity, ototoxicity, neurotoxicity, and therapeutic failure[19].

**In Managing High-Alert Medications**

High-alert medications are drugs that carry a heightened risk of causing severe or fatal patient harm when used in error. These include insulin, anticoagulants, opioids, chemotherapeutic agents, concentrated electrolytes, neuromuscular blockers, and parenteral nutrition. Errors involving these agents often lead to life-threatening outcomes.

**Clinical pharmacists play a central role in ensuring the safe use of high-alert medications. Their interventions include**

- Independent double-checking of high-risk doses
- Verification of infusion concentrations and rates
- Assessment of contraindications and patient-specific risk factors
- Monitoring laboratory parameters such as INR, aPTT, blood glucose, and electrolyte levels
- Educating nurses and physicians on safe handling and administration

For example, insulin therapy requires careful dose titration based on blood glucose monitoring, nutritional intake, and concomitant illness. Pharmacist involvement reduces the incidence of hypoglycemia, dosing errors, and inappropriate insulin regimens. Similarly, anticoagulant therapy requires precise monitoring to balance the risks of

bleeding and thrombosis. Pharmacist-managed anticoagulation services demonstrate superior safety outcomes compared to usual care[20]. In oncology, pharmacists verify chemotherapy protocols, calculate individualized doses based on body surface area and organ function, prevent vesicant-related injuries, and monitor for cumulative toxicity. These safety checks are critical in preventing fatal chemotherapy errors.

**In Low- and Middle-Income Countries**

The need for clinical pharmacy services is arguably greatest in low- and middle-income countries (LMICs), where healthcare systems are often characterized by high patient volumes, limited staffing, variable prescribing practices, and inadequate monitoring infrastructure. However, these same constraints also make implementation more challenging. In LMIC settings, clinical pharmacists often function across multiple wards, balancing dispensing responsibilities with limited clinical duties[21]. Despite these constraints, available evidence indicates that even modest pharmacist involvement in medication

**Economic Impact of Clinical Pharmacist Interventions**

Beyond improving clinical outcomes, clinical pharmacist interventions have demonstrated substantial economic benefits for healthcare systems. Medication errors and adverse drug events impose a significant financial burden through prolonged hospital stays, additional laboratory investigations, increased drug utilization, intensive care admissions, litigation, and readmissions. By preventing these avoidable outcomes, pharmacists directly contribute to cost containment and more efficient use of healthcare resources. Numerous economic evaluations have shown that pharmacist-led medication review programs yield a favorable cost–benefit ratio. The cost of employing clinical pharmacists is frequently outweighed by the savings achieved through reduction in preventable adverse drug events. These savings arise from shortened length of stay, reduced need for expensive rescue therapies, and avoidance of complications such as renal failure, major bleeding, or severe hypoglycemia. In antimicrobial stewardship programs, pharmacist involvement has been associated with reduced use of broad-spectrum antibiotics, lower antimicrobial expenditure, and decreased rates of multidrug-resistant infections. This not only improves patient safety but also delivers long-term economic benefits by preserving the effectiveness of existing antimicrobials. Pharmacist-led medication reconciliation and discharge counseling services have also been shown to reduce hospital readmissions, particularly among elderly and chronically ill patients. Avoidable readmissions represent a major source of unnecessary healthcare expenditure, and preventing them through pharmacist intervention contributes directly to financial sustainability[21,22]. Importantly, economic benefits are not limited to high-income settings. Even in resource-constrained environments, modest investments in clinical pharmacy services often yield disproportionately large returns by preventing costly adverse outcomes that hospitals may be ill-equipped to manage.

**Interprofessional Collaboration and Safety Culture**

Medication safety is inherently a team-based responsibility that requires effective communication and collaboration among physicians, nurses, pharmacists, and other healthcare professionals. The integration of clinical pharmacists into multidisciplinary care teams has consistently been associated with improvements in communication, shared decision-making, and safety culture[23]. Clinical pharmacists serve as accessible medication experts within clinical teams. Their presence during ward rounds fosters real-time discussion of therapeutic plans, early identification of potential safety concerns, and consensus-based decision-making. This collaborative model reduces hierarchical barriers and encourages open dialogue regarding medication-related risks. From a patient safety perspective, pharmacists contribute to the development of a non-punitive culture that emphasizes learning from errors rather than assigning blame. When pharmacists actively participate in error reporting systems, root cause analyses, and quality improvement committees, they help transform medication safety from a reactive process to a continuous learning system. The visibility of pharmacists on wards also reinforces a culture of vigilance and shared accountability. Nurses and junior doctors often seek guidance from pharmacists regarding dosing, compatibility, and monitoring requirements, which further strengthens safety practices. In many institutions, pharmacists also play a leadership role in staff education programs on medication safety, high-alert drugs, look-alike/sound-alike

medications, and safe injection practices. These educational initiatives enhance the overall safety competence of healthcare teams[24].

**Digital Health, Automation, and the Expanding Role of Pharmacists**

The rapid expansion of digital health technologies has transformed many aspects of medication management. Electronic health records, computerized physician order entry systems, clinical decision support tools, automated dispensing cabinets, and barcode medication administration systems are now widely used to reduce medication errors. Clinical pharmacists play a pivotal role in optimizing the use of these technologies for patient safety. Pharmacists contribute to the design and refinement of electronic prescribing systems by helping to develop dosing protocols, drug interaction alerts, allergy warnings, and renal dose adjustment algorithms. Their involvement ensures that digital tools reflect real-world clinical practice and minimize unnecessary alerts that contribute to alert fatigue[25]. In automated dispensing environments, pharmacists oversee medication storage, labeling, and verification processes. They also monitor for discrepancies, stock errors, and unauthorized access, thereby strengthening medication security. The emergence of data analytics and artificial intelligence has further expanded the scope of pharmacist involvement. Pharmacists increasingly participate in the development and validation of predictive models for adverse drug events, high-risk prescribing patterns, and patient-specific risk stratification. Their clinical insight is essential to ensuring that such tools are clinically meaningful, interpretable, and ethically deployed. Despite these technological advances, it is important to recognize that digital systems do not replace the clinical judgment of pharmacists. Instead, technology serves as an adjunct that enhances the ability of pharmacists to identify risks earlier, manage larger patient populations, and focus their expertise where it is most needed[26].

**Barriers to Expanding Clinical Pharmacy Services**

Despite robust evidence supporting the value of clinical pharmacists in improving medication safety, the expansion of clinical pharmacy services remains uneven across healthcare systems. Several persistent barriers limit widespread implementation.

**Workforce Limitations**

Many countries face shortages of trained clinical pharmacists. Even where pharmacy graduates are available, formal residency training and clinical specialization opportunities may be limited. This constrains the number of pharmacists who are adequately prepared to function in advanced clinical roles.

**Limited Institutional Support**

In some hospitals, the role of pharmacists remains confined to dispensary functions due to historical practice models and limited recognition of their clinical value. Administrative support is often essential for redefining job roles, allocating ward-based responsibilities, and integrating pharmacists into care teams[9,27].

**Financial Constraints**

Healthcare institutions, particularly in the public sector, may perceive clinical pharmacy services as an additional cost rather than an investment. Budgetary limitations frequently restrict recruitment and expansion of pharmacist positions, even when long-term economic benefits are evident.

**Lack of Regulatory Mandates**

In many jurisdictions, there are no regulatory requirements mandating the presence of clinical pharmacists in hospital wards. Without policy-level support, the adoption of clinical pharmacy services often depends on individual institutional leadership rather than systematic planning[10,28].

**Interprofessional Resistance**

In some settings, role ambiguity and traditional professional hierarchies may hinder interprofessional collaboration. Physicians or nurses may initially be reluctant to accept pharmacists as equal partners in clinical decision-making. Overcoming these cultural barriers requires sustained engagement, education, and demonstration of value. This

comprehensive narrative review demonstrates that clinical pharmacists play a pivotal and indispensable role in reducing medication errors and enhancing patient safety across hospital settings worldwide. The evidence consistently indicates that pharmacist-led interventions significantly reduce prescribing errors, prevent adverse drug events, optimize medication therapy, and improve both clinical and economic outcomes. These findings reinforce the growing international recognition of clinical pharmacy as a core component of modern healthcare delivery. One of the most important insights emerging from this review is the broad impact of pharmacists across the entire medication-use continuum. Unlike single-point technological interventions, clinical pharmacists influence multiple high-risk stages, including prescribing, medication reconciliation, administration oversight, therapeutic drug monitoring, adverse drug reaction surveillance, and discharge transitions. This continuous presence allows pharmacists to function as dynamic safety barriers capable of preventing errors before they reach the patient. The proactive nature of pharmacist involvement distinguishes it from many reactive safety strategies that only respond after harm has occurred. Prescribing errors emerged as the most frequent and clinically significant source of medication-related harm. The review highlights that pharmacist participation in ward rounds and real-time medication order review leads to substantial reductions in dosing errors, inappropriate drug selection, duplicate therapy, and dangerous drug–drug interactions. These findings are particularly important in vulnerable populations such as the elderly, critically ill, and patients receiving polypharmacy. The ability of pharmacists to tailor doses based on renal and hepatic function, pharmacokinetic variability, and therapeutic response remains one of the most powerful tools for preventing avoidable toxicity and treatment failure. Transitions of care represent another critical vulnerability in medication safety. This review confirms that pharmacist-led medication reconciliation at admission and discharge dramatically reduces unintentional discrepancies that commonly lead to post-discharge adverse drug events and hospital readmissions. The effectiveness of pharmacists in obtaining accurate medication histories, identifying omissions and duplications, and ensuring continuity between inpatient and outpatient care underscores their essential role in preventing fragmented medication management. In healthcare systems facing increasing pressures from early discharge and outpatient-based care, this function becomes even more vital.

The role of clinical pharmacists in adverse drug reaction prevention and pharmacovigilance further strengthens their contribution to patient safety. Through structured monitoring, early detection, causality assessment, and systematic reporting, pharmacists help shift healthcare systems toward a proactive model of medication safety. This not only reduces immediate patient harm but also contributes to broader national and global drug safety surveillance systems. Importantly, pharmacist involvement enhances the detection of preventable ADRs related to dosing errors, drug interactions, and inadequate monitoring. Therapeutic drug monitoring represents another area where pharmacist expertise is irreplaceable. The review clearly demonstrates that pharmacist-managed TDM services for drugs with narrow therapeutic indices significantly improve target concentration attainment while minimizing toxicity. In critically ill patients, where altered physiology profoundly affects drug disposition, individualized pharmacist-guided dosing becomes essential to avoid both underexposure and life-threatening accumulation. These benefits are consistently observed across antibiotics, antiepileptics, immunosuppressants, and cardiovascular drugs. High-alert medications continue to account for a disproportionate share of fatal and life-threatening medication errors. The review affirms that pharmacist oversight of insulin, anticoagulants, opioids, chemotherapeutic agents, and concentrated electrolytes substantially reduces catastrophic harm. By ensuring independent double-checking, appropriate monitoring, and staff education, pharmacists function as final safety guardians for the most dangerous drugs used in hospitals. Beyond clinical safety, this review highlights the strong economic justification for expanding clinical pharmacy services. Preventable adverse drug events impose a heavy financial burden through prolonged hospitalization, costly rescue treatments, and avoidable readmissions. Pharmacist-led interventions consistently demonstrate favorable cost–benefit and cost-effectiveness profiles. Notably, these economic benefits are evident not only in high-income healthcare systems but also in resource-constrained environments, where preventing a single major adverse event can offset months of staffing costs. This economic dimension strengthens the policy argument for embedding clinical pharmacists within routine hospital care. Interprofessional collaboration emerges as a central mechanism through which pharmacist interventions achieve their full impact. The review demonstrates that the integration of pharmacists into multidisciplinary teams improves communication, reduces hierarchical barriers, and fosters a shared culture of medication safety.

Pharmacists serve as accessible medication experts, supporting physicians and nurses in real-time decision-making while reinforcing standardized safety practices. Their involvement in education, quality improvement, and incident review further institutionalizes medication safety as a collective professional responsibility [29]. The rapid expansion of digital health technologies presents both opportunities and challenges for clinical pharmacy practice. While electronic prescribing, decision support systems, and automation reduce certain types of errors, they also introduce new risks such as alert fatigue, system overrides, and automation bias. This review emphasizes that pharmacists are essential in optimizing digital systems by ensuring that alerts are clinically meaningful, protocols are evidence-based, and technology complements rather than replaces human judgment. The emerging role of pharmacists in data analytics and artificial intelligence further illustrates how their expertise will remain central in future medication safety strategies. Despite overwhelming evidence of benefit, multiple systemic barriers continue to limit the widespread implementation of clinical pharmacy services. Workforce shortages, inadequate institutional support, financial constraints, regulatory gaps, and interprofessional resistance remain major challenges, particularly in low- and middle-income countries. However, the review also demonstrates that even limited pharmacist involvement in these settings produces meaningful improvements in medication safety. This suggests that scalable, context-specific models of clinical pharmacy practice can yield substantial returns even under resource constraints [30]. Importantly, this review also identifies key evidence gaps. While most studies demonstrate reductions in error rates and adverse events, fewer evaluate long-term patient-centered outcomes such as mortality, quality of life, and functional status. Additionally, standardized outcome measures and robust multicenter randomized trials remain limited in many regions. Future research should prioritize harmonized measurement frameworks, implementation science approaches, and economic evaluations tailored to diverse healthcare systems.

## CONCLUSION

Medication errors remain a persistent and preventable threat to patient safety despite advances in pharmacotherapy and healthcare technology. The evidence synthesized throughout this review indicates that clinical pharmacists represent one of the most effective system-level interventions for improving medication safety in hospital settings. By contributing expertise in pharmacotherapy across key stages of the medication-use process—including prescribing review, medication reconciliation, therapeutic drug monitoring, adverse drug reaction surveillance, and transitions of care—clinical pharmacists function as critical safeguards capable of identifying and mitigating medication-related risks before they reach the patient. Importantly, the impact of pharmacist-led interventions extends beyond error interception to strengthening multidisciplinary collaboration, improving guideline adherence, and promoting a proactive culture of medication safety. The consistent demonstration of favorable clinical and economic outcomes further reinforces the value of integrating pharmacists into routine patient care. However, the translation of this evidence into practice remains uneven, particularly in low- and middle-income countries, where workforce limitations, institutional barriers, and limited regulatory support constrain the expansion of clinical pharmacy services. As healthcare systems increasingly incorporate digital health technologies and automated prescribing platforms, pharmacist expertise will remain essential to contextualize clinical decision-support outputs and mitigate emerging technology-related risks. Future research should prioritize robust multicenter studies and standardized outcome frameworks to better quantify the long-term patient and system-level impact of pharmacist interventions. Ultimately, embedding clinical pharmacists within multidisciplinary care teams should be recognized not merely as an enhancement to hospital practice but as a fundamental component of safe, high-quality healthcare delivery.

## ABSTRACT

Stroke is the most common neurological disorder and 2nd biggest cause of morbidity and mortality worldwide. Balance, gait, trunk impairment, and motor function deficits are common following stroke. Research has supported that trunk control; balance performance and balance confidence are important to enhance the functional mobility among patients with stroke. This study aimed to establish whether the relationship exists between balance confidence and trunk control, functional mobility in individuals with stroke. Design: - The study had observational cross-sectional research design. Participants: - Seventy-five participants with a mean age of 52 years participated in the study. Intervention: - Not applicable. Main Outcome Measures: Balance confidence, trunk control, balance performance and functional mobility were measured by using Activities specific balance confidence Scale (ABC-S), Trunk impairment scale (TIS), Berg balance scale (BBS) and Time up and go test (TUG) respectively. Descriptive statistics were used to assess the level of confidence, trunk control, functional mobility, and balance performance. Pearson's test was used to evaluate the association of balance confidence with trunk control, balance performance and functional mobility. Majority of patients had ischaemic stroke and 76 % of overall population had right side hemiplegia. About one-third of subjects have moderate risk of falls and moderate level of trunk control along with moderate level of balance confidence in physical functioning. Pearson's correlation showed positive correlation between balance confidence and trunk control, balance performance and functional mobility (r = 0.78, r = 0.72, r= 0.77, respectively.) This study reveals that balance confidence is

positively correlated withtrunk control, balance performance and functional mobility among patients with stroke.

**Keywords:** Stroke patients, balance, balance confidence, trunk control, functional mobility.
**Abbreviations:** ABC-S : Activities Specific Balance Confidence Scale, BBS : Berg Balance Scale, CONFbal: Confidence Balance Scale, CVA : Cerebrovascular Accident, TIS : Trunk Impairment Scale, TUG: Time Up And Go Test, WHO : World Health Organisation, ADLs: Activities of daily living

## INTRODUCTION

Stroke, also known as cerebrovascular accident (CVA), is defined as the sudden loss of neurological function due to interrupted blood flow to the brain. According to the World Health Organization (WHO), stroke is the second leading cause of mortality globally and a major contributor to functional impairment. By 2050, it is estimated that 80% of strokes will occur in low- and middle-income countries, with India experiencing an incidence rate ranging from 105 to 152 per 100,000. Prevalence rates in India vary significantly, from 26 to 752 per 100,000, with case fatality rates between 18-42% in the first month post-stroke. Stroke often results in motor deficits characterized by hemiplegia or hemiparesis, affecting trunk control and strength in the shoulder girdle and lower limbs. About 90% of stroke survivors face mobility issues, 80% have trouble performing activities of daily living (ADLs), and 56% have trouble walking, leading to frequent falls. Balance performance is typically disrupted after a stroke, leading to impaired gait symmetry and dynamic stability, which are crucial for maintaining functional independence. Static balance, which maintains the body's centre of gravity within the base of support, and dynamic balance, which involves movement, are both essential for everyday activities. Hemiparetic stroke impacts the ability to execute standing turns and reorient their body segments, making them low Confidence in performing tasks is vital for independent living, as fear of falling can restrict participation in daily activities and lower overall quality of life. Although individuals' post-stroke may grapple with the fear of falling, they also contend with neurological injuries that further diminish their balance confidence. While balance training is essential to improve physical abilities, failure to simultaneously enhance balance confidence can restrict their capacity to perform daily activities. Therefore, a decreased sense of balance capability often leads individuals to refrain from activities they are physically able to undertake. Rehabilitation interventions aimed at enhancing balance performance are crucial for improving the overall physical function of stroke survivors. Addressing multiple-task balance challenges is especially important, as such impairments are predictive of negative outcomes, underscoring the need for targeted therapeutic approaches in stroke rehabilitation.

Trunk control, which involves coordinating trunk muscle activation to maintain posture and balance, is crucial for stability and movement. Unfortunately, rehabilitation efforts often neglect trunk rehabilitation in Favor of limb recovery. Impaired trunk control significantly affects balance and the ability to perform rotational movements during ambulation. Research indicates that trunk performance is closely associated with balance capacity, walking ability, and overall physical function in stroke patients. Systematic reviews have demonstrated that trunk exercise programs, whether on stable or unstable surfaces, are effective in improving trunk control, balance, and mobility. The trunk muscles are essential for stabilizing the torso and pelvis, playing a pivotal role in functional activities. Studies suggest that better trunk performance correlates with improved functional status in late-stage stroke recovery. Despite the established connection between balance capacity, self-confidence in balance, and physical functioning in chronic stroke patients, the relationship between trunk control and balance confidence remains poorly understood in scientific discourse. Trunk muscle weakness can hinder balance and functional tasks post-stroke, highlighting the need for targeted rehabilitation strategies. Functional mobility encapsulates the ability to move effectively within one's environment, including walking and transitioning between different positions. Functional mobility is critical for an individual's ability to navigate their environment, encompassing activities like walking, transitioning between positions (e.g., standing from sitting), and maintaining stability during these movements. In stroke patients, these

capabilities are frequently compromised due to factors like muscle weakness, coordination deficits, balance impairments, and sensory losses. Such balance issues can severely limit functional mobility, increase the risk of falls and diminish independence in activities of daily living (ADLs). Consequently, rehabilitation programs often prioritize enhancing both balance and functional mobility to support comprehensive recovery and improve the quality of life for stroke survivors. Through targeted interventions, patients can regain confidence in their mobility and better manage their daily tasks.

## MATERIALS AND METHODS

**Design:** The design of the study was Observational Cross-sectional design which was conducted from August 2023 to July 2024, and was approved by the Institutional Ethical Committee. Informed consent was obtained from all participants.

**Sample:** A total of 75 adults with clinically diagnosed with stroke were included. Inclusion criteria also required participants to be aged 18 years or older, stable patients both male and female with the ability to follow instructions. Exclusion criteria included any orthopaedic condition and neurological or psychiatric condition other than stroke Patients with unstable vitals and not willing to be a part of study. Participants were recruited using convenience sampling method.

**Instrument/ tools used.**

1. Berg Balance Scale
2. Trunk Impairment Scale
3. Activities-Specific Balance Confidence Scale
4. Time Up and Go Test

**Trunk Impairment Scale:** Trunk Impairment Scale (TIS). Patients must perform every item of the scale three times which are intended to measure the static and dynamic sitting balance and coordination. The TIS consists of three sub-scales: static sitting balance, dynamic sitting balance and coordination. The sub-scale contains 3 items in static sitting balance subscale, 10 items in dynamic sitting balance subscale and 4 items in coordination subscale. For each item, a 2-, 3- or 4-point ordinal scale is used. The TIS score ranges from a minimum of 0 to maximum of 23.

**Berg Balance Scale:** The BBS is a 14-item scale with each item consisting of a five-point ordinal scale ranging from (0-4) that quantitatively assess balance through direct observation of their performance and measures the patient ability to maintain balance either statically or while performing various functional movements for a specified duration of time. The items are scored from 0 to 4 with a score of 0 representing an inability to complete the task and a score of 4 representing in dependent item completion. A global score is calculated out of 56 possible points. Score of 0 to 20 represent severe balance impairment, 21 to 40 represent moderate balance impairment, and 41 to 56 represent mild balance impairment. The BBS measures both static and dynamic aspects of balance.

**Activities specific balance confidence Scale:** The ABC scale is a 16-item self-report questionnaire that assess individual balance confidence in performing specific ambulatory activities on numerical rating scale (0-100). A score of 0 represents no confidence, while a score of 100 represents complete confidence in performing the activity. The overall ABC score for each participant is calculated by adding the individual item scores together (maximum score=1600) and then dividing by the total no of items [16].

**Time up and go test:** the time up and go test developed by Podsiadlo and Richardson is a simple and quick functional mobility test. The TUG test records the time it takes for a participant to complete the consecutive test of standing up from a chair, walking 3-meters forward, turning 180-degree, and sitting back down on the chair to assess the one's dynamic balance and ambulation ability.

## RESULTS

Out of seventy-five total participants with a mean age of 52.30 years as shown in Table 1. Fifty- two (69.3%) were males and twenty- three (30.7%) were females who participated in the study. Data was analysed with the help of Pearson's product-moment method of correlation to find the relationship among different variables**.** The correlation coefficient was calculated for finding association between balance confidence and balance performance, trunk control, functional mobility variables. The Activities specific Balance Confidence Scale (ABC-S) results evaluate the balance confidence among patients with stroke. Almost more than half (61.3%) had moderate balance confidence during physical functioning, while (13.3%) exhibited good level of balance confidence during physical functioning. However, a concerning (25.3%) reported low confidence level in physical functioning. The Berg Balance Scale (BBS) results evaluate the balance performance among patients with stroke. Almost more than half (58.7%) had mild impaired balance, while (22.7%) had moderately impaired balance and remaining (18.7%) exhibited highly impaired balance. The Trunk Impairment Scale (TIS) results evaluate the trunk control among patients with stroke. Trunk control among post-stroke patients were represented as (61.3%) moderate trunk impairment, (18.7%) mild trunk impairment and (20%) maximal trunk impairment. Assessment of functional mobility using Time Up and Go Test (TUG) indicates that almost more than half (57.3%) had moderate risk of falls, while (2.7%) had low risk of falls and (40%) had high risk of falls with poor functional mobility. For the sample population, significant ($p<0.05$), strong and positive correlations were seen between balance confidence and balance performance, trunk control, functional mobility ($r = 0.72, 0.78, 0.77$ respectively). Table 1: Demographic characteristics. Table 2: Correlation between balance confidence and balance performance, trunk control, functional mobility. ** Correlation is significant at the <0.05 level (2-tailed)

## DISCUSSION

Stroke is known as most common neurological disorder. Despite the pharmaceutical intervention physical therapy was also play remarkable role in management of stroke patients. The main objective of the study was to figure out the relationship between balance confidence and trunk control, functional mobility, balance performance among patients after stroke. We included total of 75 participants to find out the association between balance confidence and trunk control, functional mobility, balance performance in patients with stroke. Results can be explained by the improvement noticed in the patients with stroke who had good balance performance and trunk control showed better functional mobility and higher the balance confidence. G. jijimol *et al*[14] first reported the relationship between trunk impairment and balance in chronic stroke patients and they reported the strong positive correlation between trunk performance and balance in post stroke. The result of the study has very much clinical importance in the rehabilitation of stroke patients. Since trunk performance and static or dynamic balance are correlated with each other, any step to improve the trunk performance will facilitate the balance in stroke patients. This study promotes the indication of usage of trunk exercises in post stroke patients in the acute stage itself. It is estimated that trunk stability is an essential core component of balance and coordinated extremity use in daily functional activities and performance of higher-level motor tasks. Additional trunk exercises in the rehabilitation of stroke patients can transfer the improved balancing activities needed for the standing and walking thereby improving efficient motor strategies. Borade P. *et al*[15] found that there was a significant association between fall efficacy, balance performance and functional mobility among subacute and chronic patients with stroke. This relationship has an implication for the development of rehabilitation programs that aim to improve the balance confidence as well to diminish its impact on function in stroke patients. Karthik Babu S. *et al*[5] reported that trunk control had a high correlation with core muscle strength and balance confidence in people with chronic stroke living in the community. Due to poor muscular activity and weakness of abdominals and hip extensors in the seated position, patients with stroke tend to flex their upper torso excessively against posteriorly tilted pelvis during arm forward reaching functional tasks.

The disuse related core muscles weakness and soft tissue adaptations around the spine in chronic stage stroke might further limit their dynamic balance control and movement coordination between upper and lower trunk movement.

The chronic stroke survivors usually stiffen the axial-scapular muscles excessively by retracting the shoulder girdle, thus extension- rotation of the upper trunk on the most involved side as one of the compensatory balance strategies. Compensatory movement recovery of either excessive trunk flexion or hyperextension of the torso would restrict the physiological range of thoracic rotation mobility, allowing weakness of trunk rotators on both sides. The motor control of trunk rotators is conditional for proximal dynamic stability and dissociated movements between torso and extremities during most of the daily functional activities. It was found that poor trunk control and core muscle weakness are positively correlated to balance and daily functional mobility tasks. Regardless of the side of cortical vascular lesion, there is a strong correlation of trunk control with core muscles strength and balance confidence of chronic stroke survivors. Previous studies demonstrated that community dwelling stroke survivors having poor balance capacity and mobility problems, experience less balance confidence, exhibit perception of becoming unsteady and fear of falling during daily activities. Saeys W. *et al*[16] found strong evidence that trunk training is able to improve trunk control, sitting and standing balance and mobility after subacute and chronic stroke. Results comply with previous reviews concluding that trunk training is a good rehabilitation strategy for improving dynamic sitting balance. In patients suffering from stroke, there is a strong amount of evidence showing that trunk training is able to improve trunk control, sitting and standing balance and mobility. Shah ZR. *et al*[4] analyses the correlation between CONFbal (confidence balance scale)and BBS shows highly significant moderate level of negative correlation ($r = (-0.4370)$ and $p < 0.001$). But as the lower score of CONFbal implies better confidence; hence it is proven that balance confidence and balance performance is correlated with each other. The stroke patients who have low balance performance demonstrates low confidence or high fear of fall and high balance performance will show high confidence level and low level of fear of fall. Above mentioned studies have some limitations like factor of response bias, crosssectional nature of study, small sample size, and these limitations need to be addressed in future.

## CONCLUSION

In conclusion, the comprehensive evaluation of balance confidence, trunk control, balance performance, and functional mobility is essential for effectively understanding and improving an individual's functional abilities, especially among populations at risk of falls such as the elderly and stroke survivors. The strong association between these factors underscores the intricate relationship necessary for maintaining stability and mobility. Targeted assessment and intervention strategies that enhance balance confidence and trunk control can lead to significant improvements in balance performance and functional mobility. Ultimately, this integrated approach supports greater independence and quality of life, emphasizing the need for ongoing research and refined evaluation techniques to optimize rehabilitation outcomes.

**ABSTRACT**

Explainable Artificial Intelligence (XAI) has emerged as a critical field in modern machine learning, seeking to make complex models interpretable and trustworthy. As artificial intelligence becomes embedded in critical systems, the need for mathematical transparency grows. This paper explores the mathematical underpinnings of explainability through three major lenses: Linear Algebra, Information Theory, and Topological Data Analysis (TDA). It presents models, tables, and schematic figures illustrating how these mathematical frameworks contribute to interpretability and model accountability. Together, these approaches offer a robust mathematical foundation for explainable AI systems.

**Keywords:-**Explainable AI, Linear Algebra, Information Theory, Topological Data Analysis, Interpretability, Transparency

## INTRODUCTION

Artificial Intelligence (AI) systems, particularly deep learning models, have achieved remarkable success across various domains. However, their decision-making processes often remain opaque, giving rise to the "black box" problem. Explainable AI (XAI) seeks to enhance transparency and interpretability, allowing humans to understand how models generate predictions (Doshi-Velez & Kim, 2017). Mathematics provides the foundation for these explanations through three core domains: linear algebra, which decomposes and interprets model structures; information theory, which measures and quantifies information flow; and topological data analysis (TDA), which captures and visualizes the geometric nature of decision boundaries.

**Linear Algebra and Model Analysis**

Linear algebra forms the foundation for understanding neural networks, where transformations are represented by weight matrices (W). The relationships among features can be analyzed through eigenvalue decomposition and singular value decomposition (SVD). Singular values reveal dominant patterns within the data, facilitating dimensionality reduction and feature relevance analysis, which are essential for model interpretation and optimization.

**Information-Theoretic Foundations**

Information theory assesses unpredictability and interpretability through measures such as entropy (H) and mutual information (I). Entropy captures the degree of randomness or disorder in model predictions, while mutual information evaluates the dependency or shared information between inputs and outputs. The Information Bottleneck principle (Tishby&Zaslavsky, 2015) formalizes how models compress irrelevant information while preserving essential predictive content.

**Topological Data Analysis**

TDA provides a geometric view of model behavior. Using persistent homology, TDA identifies patterns such as clusters, loops, and voids within data manifolds. These structures reveal the organization and complexity of the decision space and detect anomalies or overfitting (Carlsson, 2009; Hofer et al., 2017).

**Integrated Mathematical Framework**

Explain ability arises from the synthesis of algebraic, informational, and topological perspectives. Each framework contributes unique insights—linear algebra for structure, information theory for flow, and TDA for global geometry. Together they enable multi-scale, quantitative interpretability.

## CONCLUSION

Mathematics forms the backbone of explainable AI. Linear algebra decodes the structure of models, information theory measures ambiguity and communication efficiency, and topological data analysis reveals overarching geometric structures. These frameworks together create a mathematically rigorous foundation for transparency, enabling models that are not just precise but also interpretable and reliable.

## ABSTRACT

The introduction of quantum machine learning (QML) offers a breakthrough way to detect hate content in online platforms, addressing the growing incidence of harmful speech. Traditional machine learning techniques often struggle with linguistic complexity and nuances, making it challenging to accurately detect hate speech. QML uses quantum computing principles such as superposition and entanglement to improve the efficiency and accuracy of content classification. This analysis examines the present environment of QML applications in hate content identification, emphasizing the possible benefits over traditional methods, such as faster processing and the capacity to catch detailed patterns in data. We explore several quantum algorithms, including Quantum Support Vector Machines and Quantum Natural Language Processing, that show potential for improving identification capabilities across various material types, such as text from social media posts, comments, and video transcripts. Despite its potential, the application of QML confronts major hurdles, including technical constraints, the requirement for huge labeled datasets, and ethical concerns about bias in automated systems. This study intends to present a comprehensive assessment of the current status of QML in this domain, as well as to outline future research approaches that could improve the effectiveness of hate content recognition.

**Keywords:** QML, data, Quantum, Learning, application, domain

# INTRODUCTION

The widespread use of social media and online communication platforms has resulted in an alarming rise in hate speech and destructive content, providing enormous issues for users, platforms, and regulatory organizations. Hate speech refers to any kind of communication that incites violent or discriminatory behavior against individuals or groups based on characteristics such as race, religion, ethnicity, sexual orientation, or gender identity. Unchecked hate speech can have serious effects, including real-world violence, social strife, and mental health difficulties among those targeted [1]. Traditional hate speech detection methods rely on machine learning algorithms that have been trained on labeled datasets. These methods, which include logistic regression, support vector machines, and neural networks, have demonstrated various levels of efficacy in detecting hate speech. However, they frequently struggle understanding the nuances and context inherent in human language. Sarcasm, irony, and context-specific interpretations, for example, are easily misinterpreted by conventional models, resulting in a high percentage of false positives and negatives. Furthermore, the constant growth of language, particularly in online environments, presents an ongoing challenge for these systems [2].

Quantum machine learning (QML) emerges as a possible alternative to traditional methodologies by exploiting quantum computing principles to improve data processing capabilities. QML can dramatically increase the accuracy and efficiency of hate content detection by leveraging quantum algorithms, which process information in fundamentally different ways than classical algorithms. This study covers the present landscape of QML applications in hate content identification, assessing their potential benefits over traditional methods and discussing recent breakthroughs in the field [3].

**Fundamentals of Quantum Machine Learning**

Quantum machine learning integrates quantum computing concepts and machine learning techniques, allowing for data processing and analysis in ways that classical computers cannot. The fundamental concepts of quantum machine learning are:

**Quantum Bits (Qubits)**

Quantum bits, or qubits, are the fundamental units of quantum information and are important to quantum computing. Qubits, unlike classical bits, can exist in several states at the same time due to the phenomena of superposition. This characteristic enables quantum computers to do several calculations simultaneously, significantly enhancing their processing capability. Furthermore, qubits can be entangled, which means that the state of one is inextricably linked to the state of another, regardless of distance. This entanglement allows for intricate correlations and interactions that classical systems cannot mimic [4].

**Quantum Algorithms**

Quantum algorithms use qubits' unique features to solve problems more efficiently than classical algorithms. Notable quantum algorithms for machine learning include:

• Quantum Support Vector Machines (QSVM) use quantum computing for better classification of high-dimensional data. It works by translating data points to a higher-dimensional space where linear separation becomes possible. This method can greatly minimize the computational complexity involved in training models on large datasets.

• Quantum Neural Networks (QNN) use quantum circuits to simulate neural network structures and encode sophisticated functions. These networks can learn from data more efficiently than standard neural networks, which could improve the performance of hate content identification algorithms.

**Quantum Data**

Quantum data is information that is designed to be processed using quantum algorithms. Unlike classical data, which is often organized in binary formats, quantum data can incorporate the principles of superposition and

entanglement, resulting in much faster training and inference tasks. For example, when analyzing hate speech across numerous formats—such as text, audio, and video—quantum algorithms can simultaneously examine multiple parts of the data, boosting the model's ability to detect nuanced hate speech. [5].

The use of quantum machine learning in hate content identification is still in its early stages, but preliminary research indicates great promise. Using quantum algorithms, researchers can better capture the complexity of language and context in hate speech detection. For example, QML can improve sentiment analysis by processing massive amounts of text data from social media sites, enabling for real-time detection of hazardous content. Furthermore, quantum algorithms can scan video transcripts and audio-visual features, broadening the scope of hate content detection beyond text-based inputs[6].

**Applications in Hate Content Identification**

**Traditional Approaches**

Classical machine learning approaches, such as logistic regression, support vector machines, and deep learning, are commonly employed to detect hate speech. However, they have limits in scalability and context awareness.

**Quantum Machine Learning Approaches**

Recent studies have begun to explore the application of QML in hate content identification:

- Social Media Posts: QML can scan text data from social media platforms such as Twitter, Facebook, and Instagram to uncover hate speech patterns that traditional approaches may miss. Quantum algorithms can improve sentiment analysis, allowing for more accurate classification of dangerous content. Hate speech can appear in videos through spoken language or visual clues, not just in print [7-9].
- Video Content: QML can detect hate speech by processing video transcripts and analyzing audio-visual attributes. Quantum Natural Language Processing (QNLP) can be used to transcribe and analyze spoken content, while quantum computer vision algorithms can evaluate visual aspects for context [10-13].
- **Multimodal Content**: The integration of text, audio, and visual data poses a unique difficulty. QML can provide multimodal analysis, allowing for the detection of hate speech in many formats and so offering a more full understanding of harmful content [14-16].

**Advantages of QML in Hate Content Identification**

**Increased Efficiency**: Quantum algorithms can handle large datasets faster than classical algorithms, enabling real-time detection.

**Improved Accuracy**: The capacity to detect complicated patterns in data can lead to more precise identification of hate content.

**Enhanced Feature Extraction**: QML can reveal hidden links in data, enhancing the model's comprehension of context and purpose.

**Challenges and Limitations**

Despite its potential, several challenges hinder the widespread adoption of QML in hate content identification:

- **Technical Limitations**: Quantum hardware is still in its infancy, and scalability remains a concern.
- **Data Availability**: The lack of large, labeled datasets for training QML models can impede progress.
- **Ethical Considerations**: The use of automated systems for content moderation raises ethical questions regarding bias and accountability.

**Future Directions**

Looking ahead, the future of quantum machine learning in hate content identification is set to make considerable advances, demanding a diversified approach to solve existing obstacles and maximize potential. Researchers should work on hybrid models that combine conventional machine learning techniques with quantum algorithms, using the benefits of both paradigms to improve performance in real-world applications. This combination could result in more robust systems capable of comprehending the nuances of language and context, which are important for effectively identifying hate speech. Furthermore, the development of comprehensive datasets specifically designed for hate speech detection will be critical; these datasets should include a wide range of linguistic expressions and cultural contexts to guarantee that models are trained on a variety of scenarios, hence boosting their generalisability.

Additionally, resolving ethical concerns about bias and responsibility in automated content moderation systems is critical. Creating transparent algorithms that can be examined and refined can assist to reduce bias and build user trust. Finally, multidisciplinary collaboration among computer scientists, linguists, ethicists, and social scientists will be required to develop comprehensive solutions that not only increase technology capabilities but also take into account the societal ramifications of using QML in content regulation. As the technology advances, continuing research and innovation will be critical to ensuring that quantum machine learning remains a viable tool for establishing safer online environments.

## CONCLUSION

Quantum machine learning shows great promise for improving hate content identification. Researchers can use quantum computing to construct more efficient and accurate models for combating online hate speech. Continued research and innovation in this area are required to fully achieve QML's potential in developing safer online environments.

**ABSTRACT**

Temporomandibular joint (TMJ) dislocation is a painful condition in which the mandibular condyle is displaced anteriorly beyond the articular eminence, preventing spontaneous return to the glenoid fossa. It commonly arises from trauma, excessive mouth opening, yawning, or iatrogenic factors, presenting with inability to close the mouth, drooling, pain, and speech difficulty. Closed reduction remains the first-line management due to its safety, minimally invasive nature, and high success rates. Conventional methods, including the Hippocratic, wrist pivot, extraoral, syringe, gag reflex, and unilateral reduction techniques, are well-established for acute cases. However, recurrent or chronic dislocations pose challenges due to muscular hyperactivity, fibrosis, or patient intolerance. Recent non-invasive adjunctive modalities—such as transcutaneous electrical nerve stimulation (TENS), therapeutic ultrasound, and low-level laser therapy (LLLT)—facilitate muscle relaxation, reduce pain, and improve the likelihood of successful reduction. This review synthesizes current evidence on conventional and advanced closed reduction strategies, emphasizing indications, clinical utility, advantages, and limitations. A comprehensive understanding of these approaches enables clinicians to tailor treatment to patient-

specific needs, optimize outcomes, minimize recurrence, and reserve surgical intervention for refractory cases [1–6].

**Keywords:** Temporomandibular Joint, Dislocation, Closed Reduction, TENS, Ultrasound, Low-Level Laser Therapy, Physiotherapy

## INTRODUCTION

The temporomandibular joint (TMJ) is a specialized synovial articulation crucial for mastication, speech, and facial expression. Its high mobility and anatomical complexity make it susceptible to displacement and dysfunction [1,2]. TMJ dislocation occurs when the mandibular condyle moves anteriorly beyond the articular eminence and cannot spontaneously return to the glenoid fossa. Clinically, patients present with an open-mouth posture, inability to occlude teeth, drooling, difficulty speaking, and acute discomfort [3,4]. Left untreated, dislocations can result in soft tissue trauma, articular degeneration, and chronic pain [5]. TMJ dislocations are classified as acute, chronic, or recurrent. Acute dislocations often result from trauma, excessive mouth opening, or dental procedures, whereas recurrent or chronic dislocations may involve neuromuscular dysfunction, connective tissue laxity, or anatomical variations [6,7]. Epidemiological data indicate a higher prevalence among women and elderly individuals, potentially due to ligamentous laxity and altered neuromuscular coordination [8]. Management strategies range from conservative to surgical. Closed reduction is the cornerstone due to its efficacy, minimal invasiveness, and accessibility [9]. Conventional techniques, including the Hippocratic, wrist pivot, extraoral, syringe, gag reflex, and unilateral methods, form the foundation of acute management. However, muscular hyperactivity, chronic fibrosis, or patient anxiety can limit the success of manual reduction [10,11]. Non-invasive adjunctive modalities—such as TENS, therapeutic ultrasound, and low-level laser therapy—have emerged to enhance reduction success by promoting muscle relaxation, reducing pain, and improving joint mobility [12–16]. This review critically evaluates conventional and advanced closed reduction approaches, highlighting their indications, clinical outcomes, advantages, limitations, and practical considerations for individualized patient care.

**Conventional Closed Reduction Techniques**

**Hippocratic Technique**

The Hippocratic method, also known as the bimanual intraoral technique, is the most commonly described approach for acute bilateral dislocations. The operator places gauze-covered thumbs on the mandibular molars while stabilizing the mandible externally. A downward and posterior force disengages the condyles from the articular eminence, allowing their return to the glenoid fossa. This technique is widely recognized for its simplicity and high success rate in cooperative patients. Operator thumb injury is a notable risk, which can be mitigated by protective devices [1,2]. (FIGURE-1A)

**Wrist Pivot Technique**

The wrist pivot method modifies the Hippocratic approach to improve ergonomics and safety. Fingers are placed on the molars intraorally while the thumbs rest externally under the chin. A pivoting motion of the wrists applies downward and posterior forces to reposition the condyles. This technique reduces operator fatigue and risk of injury but may be less effective in patients with severe masseteric spasm or long-standing dislocations [2,3]. (FIGURE-1B)

**Extraoral Technique**

The extraoral approach is useful for patients with poor oral hygiene, oral trauma, or pronounced gag reflex. The clinician applies pressure externally over the coronoid processes while stabilizing the mandible inferiorly. Advantages include improved patient comfort and avoidance of intraoral manipulation. However, it requires precise anatomical knowledge and is associated with lower success rates than intraoral methods [4].(FIGURE-1C AND D)

**Supine (Recumbent) Method**

This modification of the Hippocratic technique is performed with the patient in a supine position. Gravity assists in condylar relocation, and sedation or muscle relaxants enhance effectiveness. It is particularly suitable in hospital settings but less practical in outpatient or emergency care [5]. (FIGURE-1E)

**Syringe Technique**

The syringe method, described by Chen *et al*. (2009), is a patient-assisted approach. A 5–10 mL syringe is positioned between posterior teeth, and the patient rolls it back and forth, allowing the condyles to glide inferiorly and return to the fossa. The technique is safe, simple, and effective in acute non-traumatic dislocations but may fail in chronic cases with muscular fibrosis [6].(FIGURE-1F)

**Gag Reflex Method**

Stimulation of the posterior pharyngeal wall induces a gag reflex, relaxing the elevator muscles and facilitating reduction. While non-invasive and rapid, tolerance is limited, and results may be inconsistent [7].

**Unilateral Reduction**

In unilateral dislocations, ipsilateral manipulation minimizes stress on the contralateral joint. This approach is effective in isolated cases but requires skilled technique and patient cooperation [8,9].

**Advanced Adjunctive Techniques**

**Transcutaneous Electrical Nerve Stimulation (TENS)**

TENS therapy delivers low-voltage electrical currents via surface electrodes to the masticatory muscles. This stimulates sensory nerves and promotes endogenous endorphin release, reducing muscular hyperactivity and pain. The resulting relaxation facilitates condylar repositioning. TENS is non-invasive, safe, and well-tolerated, particularly in patients with acute or recurrent dislocations complicated by muscle spasm [12,13,21,24,26].(FIGURE-2A)

**Therapeutic Ultrasound**

Therapeutic ultrasound applies continuous or pulsed sound waves to the TMJ region, generating deep tissue heating that improves circulation, increases tissue extensibility, and reduces muscle spasm. Administered for 5–10 minutes before reduction, ultrasound enhances mandibular mobility and comfort. It is especially valuable in patients with chronic stiffness or post-traumatic muscular hyperactivity. Limitations include equipment requirements and operator training, restricting use in some settings [14,15,22,30].(FIGURE-2B)

**Low-Level Laser Therapy (LLLT)**

LLLT, or cold laser therapy, delivers low-intensity laser energy to the TMJ and surrounding musculature, producing analgesic, anti-inflammatory, and muscle-relaxing effects. Cellular metabolism is stimulated, inflammatory mediators are modulated, and tissue repair is promoted. Application before or during reduction reduces pain and facilitates muscle relaxation, enhancing success rates. LLLT is non-invasive and rapid, though protocol standardization and high-quality clinical evidence remain limited [9,10,23].(FIGURE-2C)

## DISCUSSION

Closed reduction remains the primary management strategy for TMJ dislocation due to its safety, minimal invasiveness, and high effectiveness. Conventional methods—Hippocratic, wrist pivot, extraoral, syringe, gag reflex, and unilateral techniques—have long-standing clinical support and remain indispensable in emergency and routine care. Their advantages include simplicity, accessibility, and minimal cost, while limitations include operator injury, patient discomfort, and reduced effectiveness in cases with chronic muscular hyperactivity or fibrosis [1–11]. Advanced non-invasive modalities such as TENS, therapeutic ultrasound, and LLLT enhance conventional approaches by addressing the underlying muscular resistance and pain. TENS improves muscle relaxation and

provides analgesia; ultrasound increases tissue extensibility and circulation; and LLLT modulates inflammation and facilitates muscle relaxation [12–16,21–24,26–30]. Together, these modalities improve the likelihood of successful reduction, patient comfort, and post-reduction function. Despite their benefits, widespread adoption of advanced techniques is limited by equipment availability, operator expertise, and the lack of standardized protocols. Comparative high-quality studies between conventional and adjunctive methods remain scarce, and cost considerations may restrict their use in resource-limited settings. Clinicians must therefore individualize management, balancing the urgency of reduction, patient-specific factors, and available resources. Acute, uncomplicated dislocations are often managed effectively with conventional techniques alone, while adjunctive modalities are most valuable for chronic, recurrent, or resistant cases. Surgical intervention remains a last resort when conservative strategies fail [25–29].

## CONCLUSION

TMJ dislocation is a distressing condition that requires prompt and effective management to restore function and alleviate discomfort. Conventional closed reduction techniques continue to serve as the mainstay due to their simplicity, accessibility, and high success rates. Advanced non-invasive modalities—including TENS, therapeutic ultrasound, and LLLT—enhance reduction success in recurrent or challenging cases by promoting muscle relaxation, reducing pain, and improving joint mobility. A comprehensive understanding of both conventional and advanced strategies allows clinicians to tailor management to individual patient needs, optimize outcomes, and minimize recurrence, reserving surgical intervention for refractory cases. Continued research is warranted to standardize adjunctive therapy protocols and validate long-term outcomes [1–30].

**ABSTRACT**

This paper introduces the concept of pentapartitioned neutrosophic $\alpha$-generalized semi-closed mappings in a pentapartitioned neutrosophic topological space and investigates several of their basic properties and characteristics.

**Keywords:** $\mathcal{P}n$set;$\mathcal{P}n_{\alpha gs}-\mathcal{CS}$;$\mathcal{P}n_{\alpha gs}-\mathcal{OS}$; $\mathcal{P}n_{\alpha gs}-\mathcal{C}.\mathcal{M}$;$\mathcal{P}n_{\alpha gs}$-$\mathcal{O}.\mathcal{M}$.

## INTRODUCTION

In 1999, Florentin Smarandache first proposed the idea of neutrosophic sets, which is a generalization of intuitionistic fuzzy sets by Atanassov. After that the pentapartitioned neutrosophic set and its characteristics are introduced by Rama Malik and Surapti Pramanik[4] in 2020. In the path of them, Suman Das and Binod Chandra Tripathy [10] introduce various sets namely Pentapartitioned Neutrosophic semi-open sets, $\alpha$-open sets, and pre-open sets in 2021.In the present work, we introduce the notion of pentapartitioned neutrosophic $\alpha$-generalized semiclosed mappings and explore several of their fundamental properties.

## PRELIMINARIES

**Definition 2.1**[4] Let $Q$ be a universal set. An object of the form $K = \{< q, T_K, C_K, I_K, U_K, F_K >: q \in Q\}$ is a $\mathcal{PnS}$ $K$ over $Q$ where $0 \leq T_K + C_K + I_K + U_K + F_K \leq 5$. Here, $T_K(q)$ is truth membership, $C_K(q)$ is contradiction membership, $I_K(q)$ isignorance membership, $U_K(q)$is unknown membership, $F_K(q)$ is false membership.

**Definition 2.2**[4] let Q be a universal set. Consider Two $\mathcal{Pn}$ sets $\mathrm{K} =< q, \mathrm{T_K}, \mathrm{C_K}, \mathrm{I_K}, \mathrm{U_K}, \mathrm{F_K} >$ and $\mathrm{L} =< q, \mathrm{T_L}, \mathrm{C_L}, \mathrm{I_L}, \mathrm{U_L}, \mathrm{F_L} >$.

i. $\mathrm{K} \subseteq \mathrm{L}$ iff $\mathrm{T_K} \leq \mathrm{T_L}$,$\mathrm{C_K} \leq \mathrm{C_L}$,$\mathrm{I_K} \geq \mathrm{I_L}$, $\mathrm{U_K} \geq \mathrm{U_L}$, and $\mathrm{F_K} \geq \mathrm{F_L}$.
ii. $K \cup L = \{< q, max(T_K, T_L), max(C_K, C_L), min(I_K, I_L), min(U_K, U_L), min(F_K, F_L) >\}$.
iii. $K \cap L = \{< q, min(T_K, T_L), min(C_K, C_L), max(I_K, I_L), max(U_K, U_L), max(F_K, F_L) >\}$.
*iv.* If $K = \{< q, T_K, C_K, I_K, U_K, F_K >: q \in Q\}$ then $K^C = \{< q, F_K, U_K, 1 - I_K, C_K, T_K >: q \in Q\}$.

**Definition 2.3**[4] A $\mathcal{Pn}$ set K over the universe Q is said to be null $\mathcal{PnS}$ if $0_{\mathcal{P}n} = \{< q, 0,0,1,1,1 >: q \in Q\}$.

**Definition 2.4**[4] A $\mathcal{Pn}$ set K over the universe Q is said to be absolute $\mathcal{PnS}$ if $1_{\mathcal{P}n} = \{< q, 1,1,0,0,0 >: q \in Q\}$.

**Definition 2.5**[10]Consider Q be the universal set. Then the collection $\Gamma$ of $\mathcal{PnS}$ over Q is known as a $\mathcal{PnT}$ on Q, if the following conditions are satisfied.

i. $0_{\mathcal{P}n}, 1_{\mathcal{P}n} \in \Gamma$
ii. $R_1, R_2 \in \Gamma$,then $R_1 \cap R_2 \in \Gamma$
iii. $\{\mathrm{R_i}: \mathrm{i} \in \mathrm{J}\} \in \Gamma$then $\cup_{\mathrm{i} \in \mathrm{J}} \mathrm{R_i} \in \Gamma$

A Pentapartitioned Neutrosophic Topological Space $(\mathcal{PnTS})$ is the term used to describe the pair $(Q, \Gamma)$. Every component of $\Gamma$ is called a pentapartitioned Neutrosophilic open set $(\mathcal{PnOS})$, $R^C$ is considered as a pentapartitioned Neutrosophic closed set $(\mathcal{PnCS})$ if $R \in \Gamma$.

**Definition 2.6**[4] Let $K$ be a $\mathcal{PnS}$in $\mathcal{PnTSQ}$.Then,

i. $\mathcal{P}nint(K) = \cup\{Y : Y\ is\ an\ (\mathcal{PnOS})in\ Q\ and\ Y \subseteq K\}$.
ii. $\mathcal{P}ncl(K) = \cap\{Z : Z\ is\ an\ (\mathcal{PnCS})in\ Q\ and\ K \subseteq Z\}$.

**Definition 2.7**[10] The following describes a $\mathcal{PnSK}$ of a $\mathcal{PnTSQ}$ as : (i) a pentapartitioned neutrosophic semi-open set $(\mathcal{PnS}\text{-}\mathcal{OS})$ if $K \subseteq \mathcal{P}ncl(\mathcal{P}nint(K))$ (ii) a pentapartitioned neutrosophic $\alpha$-open set $(\mathcal{Pn}_\alpha\mathcal{OS})$ if $K \subseteq \mathcal{P}nint(\mathcal{P}ncl(\mathcal{P}nint(K)))$ (iii) a Pentapartitioned neutrosophic pre-open set$(\mathcal{Pn}\text{-}\mathcal{POS})$ if $K \subseteq \mathcal{P}nint(\mathcal{P}ncl(K))$.

**Definition 2.8**(6) Let ƒbe a mapping from an $\mathcal{PnTS}(Q, \Gamma)$, into an $\mathcal{PnTS}(R, \Omega)$.Thenƒis said to be an

i. pentapartitioned neutrosophic$\alpha$-open mapping $(\mathcal{Pn}_\alpha\text{-}\mathcal{O}.\mathcal{M})$ifthe image of each$\mathcal{PnOS}$in$Q$is a$\mathcal{Pn}_\alpha$ $\mathcal{OS}$in $R$.
ii. pentapartitioned neutrosophic pre-open mapping$(\mathcal{PnP}\text{-}\mathcal{O}.\mathcal{M})$ if the image of each$\mathcal{PnOS}$in$Q$is a$\mathcal{PnP}\text{-}\mathcal{OS}$in$R$.

**Definition 2.9**(5)A $\mathcal{PnSK}$ of a$\mathcal{PnTS}$ in $Q$ is said to be a Pentapartitioned Neutrosophic $\alpha$-generlized semi closed set $(\mathcal{Pn}_{\alpha gs}\text{-}\mathcal{CS})$ if $\mathcal{Pn}_\alpha cl(K) \subseteq U$ whenever $K \subseteq U$ and $U$ is a $\mathcal{PnS}\text{-}\mathcal{OS}$ in $Q$.The complement $K^C$of a $\mathcal{Pn}_{\alpha gs}\text{-}\mathcal{CS}K$is a $\mathcal{Pn}_{\alpha gs}\text{-}\mathcal{OS}$ in $Q$.

**Definition 2.10**(3)A$\mathcal{PnTS}(Q, \Gamma)$ is said to be a Pentapartitioned Neutrosophic$\alpha ga\mathcal{T}_{1/2}(\mathcal{Pn}_{\alpha ga}\mathcal{T}_{1/2})$ space if every $\mathcal{Pn}_{\alpha gs}\text{-}\mathcal{CS}$ in $Q$ is a $\mathcal{PnCS}$ in$Q$.

## RESULTS AND DISCUSSION

**Pentapartitioned Neutrosophic $\alpha$-Generlized Semi Closed Mappings**

**Definition 3.1.1.**A mapping $f:(Q,\Gamma)\to(R,\Omega)$is called pentapartitioned neutrosophic $\alpha$-generlized semi closed mapping$(\mathcal{P}n_{\alpha gs}\text{-}\mathcal{C}.\mathcal{M})$ if for every$\mathcal{P}n\mathcal{C}\mathcal{S}K$ of $(Q,\Gamma)$,$f(K)$is a $\mathcal{P}n_{\alpha gs}\text{-}\mathcal{C}\mathcal{S}$ in$(R,\Omega)$.

**Example3.1.2**.Let$Q=\{u_1,u_2\}$ and$R=\{v_1,v_2\}$.Then $\Gamma=\{0_{\mathcal{P}n},U_1,1_{\mathcal{P}n}\}$and $\Omega=\{0_{\mathcal{P}n},U_2,1_{\mathcal{P}n}\}$ are $\mathcal{P}n$ topologies on $Q$ and $R$ respectively, where$U_1=<q,(0.8,0.3,0.5,0.3,0.2),(0.9,0.4,0.5,0.4,0.1)>$ and $U_2=<r,(0.7,0.3,0.5,0.3,0.3),(0.8,0.4,0.5,0.4,0.2)>$.Define a mapping$f:(Q,\Gamma)\to(R,\Omega)$ by $f(u_1)=v_1$ and $f(u_2)=v_2$. Here the $\mathcal{P}n\mathcal{S}{U_1}^C=<q,(0.2,0.3,0.5,0.3,0.8),(0.1,0.4,0.5,0.4,0.9)>$ is a $\mathcal{P}n\mathcal{C}\mathcal{S}$ in $Q$, $f({U_1}^C)$ is a $\mathcal{P}n_{\alpha gs}\text{-}\mathcal{C}\mathcal{S}$ in $R$.Therefore$f$ is a $\mathcal{P}n_{\alpha gs}\text{-}\mathcal{C}.\mathcal{M}$.

**Definition 3.1.3**. A mapping $f:(Q,\Gamma)\to(R,\Omega)$ is called pentapartitioned neutrosophic $\alpha$-generlized semi open mapping$(\mathcal{P}n_{\alpha gs}\text{-}\mathcal{O}.\mathcal{M})$ if for every$\mathcal{P}n\mathcal{O}\mathcal{S}K$ of $(Q,\Gamma)$,$f(K)$ is a $\mathcal{P}n_{\alpha gs}\text{-}\mathcal{O}\mathcal{S}$ in$(R,\Omega)$.

**Example3.1.4**.Let$Q=\{u_1,u_2\}$ and$R=\{v_1,v_2\}$.Then $\Gamma=\{0_{\mathcal{P}n},U_1,1_{\mathcal{P}n}\}$ and $\Omega=\{0_{\mathcal{P}n},U_2,1_{\mathcal{P}n}\}$ are $\mathcal{P}n$ topologies on $Q$ and $R$ respectively, where$U_1=<q,(0.9,0.3,0.5,0.3,0.1),(0.9,0.4,0.5,0.4,0.1)>$ and $U_2=<r,(0.6,0.3,0.5,0.3,0.3),(0.9,0.4,0.5,0.4,0.1)>$.Define a mapping$f:(Q,\Gamma)\to(R,\Omega)$ by $f(u_1)=v_1$ and $f(u_2)=v_2$. Here the $\mathcal{P}n\mathcal{S}U_1=<q,(0.9,0.3,0.5,0.3,0.1),(0.9,0.4,0.5,0.4,0.1)>$ is a $\mathcal{P}n\mathcal{O}\mathcal{S}$ in $Q$, $f(U_1)$ is a $\mathcal{P}n_{\alpha gs}\text{-}\mathcal{O}\mathcal{S}$ in $R$.Therefore$f$ is a $\mathcal{P}n_{\alpha gs}\text{-}\mathcal{O}.\mathcal{M}$.

**Theorem 3.1.5**. Every $\mathcal{P}n_{\alpha}\text{-}\mathcal{C}.\mathcal{M}$ is a $\mathcal{P}n_{\alpha gs}\text{-}\mathcal{C}.\mathcal{M}$.

**Proof**: Let$f:(Q,\Gamma)\to(R,\Omega)$ be a$\mathcal{P}n_{\alpha}\text{-}\mathcal{C}.\mathcal{M}$. Let $K$ be a$\mathcal{P}n\mathcal{C}\mathcal{S}$ in $(Q,\Gamma)$.Then by hypothesis, $f(K)$ is a $\mathcal{P}n_{\alpha}\text{-}\mathcal{C}\mathcal{S}$ in$(R,\Omega)$.Since every$\mathcal{P}n_{\alpha}\text{-}\mathcal{C}\mathcal{S}$is a$\mathcal{P}n_{\alpha gs}\text{-}\mathcal{C}\mathcal{S}$,$f(K)$ is a $\mathcal{P}n_{\alpha gs}\text{-}\mathcal{C}\mathcal{S}$ in $(R,\Omega)$. Hence$f$ is a $\mathcal{P}n_{\alpha gs}\text{-}\mathcal{C}.\mathcal{M}$.

**Example 3.1.6**. $\mathcal{P}n_{\alpha gs}\text{-}\mathcal{C}.\mathcal{M}$ is not $\mathcal{P}n_{\alpha}\text{-}\mathcal{C}.\mathcal{M}$.
Let$Q=\{u_1,u_2\}$ and$R=\{v_1,v_2\}$.Then $\Gamma=\{0_{\mathcal{P}n},U_1,1_{\mathcal{P}n}\}$ and $\Omega=\{0_{\mathcal{P}n},U_2,1_{\mathcal{P}n}\}$ are $\mathcal{P}n\mathcal{T}$on $Q$ and $R$ respectively, where$U_1=<q,(0.1,0.3,0.5,0.3,0.9),(0.2,0.4,0.5,0.4,0.8)>$ and$U_2=<r,(0.1,0.3,0.5,0.3,0.8),(0.3,0.4,0.5,0.4,0.6)>$. Define $f:(Q,\Gamma)\to(R,\Omega)$ by $f(u_1)=v_1$ and $f(u_2)=v_2$. Since the $\mathcal{P}n\mathcal{S}{U_1}^C=<q,(0.9,0.3,0.5,0.3,0.1),(0.8,0.4,0.5,0.4,0.2)>$ is a $\mathcal{P}n\mathcal{C}\mathcal{S}$ in $(Q,\Gamma)$, $f({U_1}^C)$ is a $\mathcal{P}n_{\alpha gs}\text{-}\mathcal{C}\mathcal{S}$ but not $\mathcal{P}n_{\alpha}\text{-}\mathcal{C}\mathcal{S}$ in $(R,\Omega)$.Therefore$f$ is a $\mathcal{P}n_{\alpha gs}\text{-}\mathcal{C}.\mathcal{M}$ but not $\mathcal{P}n_{\alpha}\text{-}\mathcal{C}.\mathcal{M}$.

**Remark 3.1.7.** $\mathcal{P}n\mathcal{P}\text{-}\mathcal{C}.\mathcal{M}$ and $\mathcal{P}n_{\alpha gs}\text{-}\mathcal{C}.\mathcal{M}$ are independent of each other.

**Example 3.1.8**. $\mathcal{P}n\mathcal{P}\text{-}\mathcal{C}.\mathcal{M}$ is not $\mathcal{P}n_{\alpha gs}\text{-}\mathcal{C}.\mathcal{M}$.
Let $Q=\{u_1,u_2\}$ and$R=\{v_1,v_2\}$.Then $\Gamma=\{0_{\mathcal{P}n},U_1,1_{\mathcal{P}n}\}$ and $\Omega=\{0_{\mathcal{P}n},U_2,1_{\mathcal{P}n}\}$ are $\mathcal{P}n\mathcal{T}$on $Q$ and $R$ respectively, where$U_1=<q,(0.7,0.2,0.5,0.2,0.2),(0.8,0.3,0.5,0.3,0.1)>$ and$U_2=<r,(0.4,0.2,0.5,0.2,0.6),(0.3,0.3,0.5,0.3,0.5)>$. Define $f:(Q,\Gamma)\to(R,\Omega)$ by $f(u_1)=v_1$ and $f(u_2)=v_2$. Since the $\mathcal{P}n\mathcal{S}{U_1}^C=<q,(0.2,0.2,0.5,0.2,0.7),(0.1,0.3,0.5,0.3,0.8)>$ is a $\mathcal{P}n\mathcal{C}\mathcal{S}$ in $(Q,\Gamma)$, $f({U_1}^C)$ is a $\mathcal{P}n\mathcal{P}\text{-}\mathcal{C}\mathcal{S}$but not $\mathcal{P}n_{\alpha gs}\text{-}\mathcal{C}\mathcal{S}$in$(R,\Omega)$.Therefore$f$ is a $\mathcal{P}n\mathcal{P}\text{-}\mathcal{C}.\mathcal{M}$but not $\mathcal{P}n_{\alpha gs}\text{-}\mathcal{C}.\mathcal{M}$.

**Example 3.1.9**. $\mathcal{P}n_{\alpha gs}\text{-}\mathcal{C}.\mathcal{M}$ is not $\mathcal{P}n\mathcal{P}\text{-}\mathcal{C}.\mathcal{M}$.
Let $Q=\{u_1,u_2\}$ and$R=\{v_1,v_2\}$. Then $\Gamma=\{0_{\mathcal{P}n},U_1,1_{\mathcal{P}n}\}$ and $\Omega=\{0_{\mathcal{P}n},U_2,1_{\mathcal{P}n}\}$ are $\mathcal{P}n\mathcal{T}$on $Q$ and $R$ respectively, where $U_1=<q,(0.4,0.4,0.5,0.4,0.6),(0.5,0.2,0.5,0.2,0.5)>$ and$U_2=<r,(0.3,0.4,0.5,0.4,0.7),(0.4,0.2,0.5,0.2,0.6)>$.Define $f:(Q,\Gamma)\to(R,\Omega)$ by $f(u_1)=v_1$ and $f(u_2)=v_2$. Since the $\mathcal{P}n\mathcal{S}{U_1}^C=<q,(0.6,0.4,0.5,0.4,0.4),(0.5,0.2,0.5,0.2,0.5)>$ is a $\mathcal{P}n\mathcal{C}\mathcal{S}$ in $(Q,\Gamma)$, $f({U_1}^C)$ is a $\mathcal{P}n_{\alpha gs}\text{-}\mathcal{C}\mathcal{S}$ but not $\mathcal{P}n\mathcal{P}\text{-}\mathcal{C}\mathcal{S}$in $(R,\Omega)$.Therefore$f$ is a $\mathcal{P}n_{\alpha gs}\text{-}\mathcal{C}.\mathcal{M}$ but not $\mathcal{P}n\mathcal{P}\text{-}\mathcal{C}.\mathcal{M}$.

**Theorem 3.1.10.**Let $f:(Q,\Gamma)\to(R,\Omega)$be a mapping and let $f(K)$be a $\mathcal{P}n\mathcal{R}-\mathcal{C}\mathcal{S}$in$(R,\Omega)$for every$\mathcal{P}n\mathcal{C}\mathcal{S}K$in$(Q,\Gamma)$. Then$f$is a$\mathcal{P}n_{\alpha gs}\text{-}\mathcal{C}.\mathcal{M}$.

**Proof:** Let $K$ be a $\mathcal{PnCS}$in$(Q,\Gamma)$.Then $f(K)$ is a $\mathcal{PnR}-\mathcal{CS}$ in $(R,\Omega)$.Since every $\mathcal{PnR}-\mathcal{CS}$ is a $\mathcal{Pn}_{\alpha gs}$-$\mathcal{CS}$,$f(K)$is a$\mathcal{Pn}_{\alpha gs}$-$\mathcal{CS}$ in$(R,\Omega)$.Hence$f$ is a$\mathcal{Pn}_{\alpha gs}$-$\mathcal{C}.\mathcal{M}$.

**Theorem 3.1.11.** Let $f:(Q,\Gamma)\to(R,\Omega)$be a mapping from a$\mathcal{PnTS}(Q,\Gamma)$intoa$\mathcal{PnTS}(R,\Omega)$.Then upcoming results are equivalent if$(R,\Omega)$is a$\mathcal{Pn}_{\alpha ga}\mathcal{T}_{1/2}$ space.

1. $f$ is a $\mathcal{Pn}_{\alpha gs}$-$\mathcal{O}.\mathcal{M}$.
2. If $K$is a $\mathcal{PnOS}$ in$(Q,\Gamma)$then$f(K)$is a$\mathcal{Pn}_{\alpha gs}$-$\mathcal{OS}$ in$(R,\Omega)$.
3. $f(\mathcal{P}nint(K))\subseteq\mathcal{P}nint(\mathcal{P}ncl(\mathcal{P}nint(f(K))))$ for every$\mathcal{PnS}K$in $(Q,\Gamma)$.

**Proof.** (1) ⇒ (2) is obviously true.
(2) ⇒ (3) Let$K$be any $\mathcal{PnS}$ in$(Q,\Gamma)$. Then$\mathcal{P}nint(K)$ is a$\mathcal{PnOS}$ in$(Q,\Gamma)$.Then $f(\mathcal{P}nint(K))$ is a $\mathcal{Pn}_{\alpha gs}$-$\mathcal{OS}$in$(R,\Omega)$. Since$(R,\Omega)$ is a $\mathcal{Pn}_{\alpha ga}\mathcal{T}_{1/2}$ space,$f(\mathcal{P}nint(K))$is a $\mathcal{PnOS}$ in$(R,\Omega)$.Therefore$f\big(\mathcal{P}nint(K)\big)=\mathcal{P}nint(f(\mathcal{P}nint(K)))\subseteq\mathcal{P}nint(\mathcal{P}ncl(\mathcal{P}nint(f(K))))$.
(3)⇒(1) Let$K$be any$\mathcal{PnOS}$ in$(Q,\Gamma)$.By hypothesis,$f(\mathcal{P}nint(K))\subseteq\mathcal{P}nint(\mathcal{P}ncl(\mathcal{P}nint(f(K))))$. This implies that $f(K)\subseteq\mathcal{P}nint(\mathcal{P}ncl(\mathcal{P}nint(f(K))))$. Hence $f(K)$ is a $\mathcal{Pn}_{\alpha}\mathcal{OS}$ in$(R,\Omega)$.Since every $\mathcal{Pn}_{\alpha}\mathcal{OS}$ is a $\mathcal{Pn}_{\alpha gs}$-$\mathcal{OS}$,$f(K)$ is a $\mathcal{Pn}_{\alpha gs}$-$\mathcal{OS}$in $(Q,\Gamma)$. Hence $f$ is a $\mathcal{Pn}_{\alpha gs}$-$\mathcal{O}.\mathcal{M}$.

**Theorem 3.1.12.** Let $f:(Q,\Gamma)\to(R,\Omega)$be a mapping.Then following results are equivalence if $(R,\Omega)$is a $\mathcal{Pn}_{\alpha ga}\mathcal{T}_{1/2}$ space.

1. $f$ is a $\mathcal{Pn}_{\alpha gs}$-$\mathcal{C}.\mathcal{M}$.
2. $f(\mathcal{P}nint(K))\subseteq\mathcal{Pn}_{\alpha}int(f(K))$for each$\mathcal{PnS}$ $K$of$(Q,\Gamma)$.
3. $\mathcal{P}nint(f^{-1}(L))\subseteq f^{-1}(\mathcal{Pn}_{\alpha}int(L))$ for every$\mathcal{PnS}L$of$(R,\Omega)$.

**Proof.** (1) ⇒ (2)Let $f$be a $\mathcal{Pn}_{\alpha gs}$-$\mathcal{C}.\mathcal{M}$.Let$K$be any $\mathcal{PnS}$ in$(Q,\Gamma)$. Then$\mathcal{P}nint(K)$ is a$\mathcal{PnOS}$ in$(Q,\Gamma)$.By hypothesis, $f(\mathcal{P}nint(K))$ is a $\mathcal{Pn}_{\alpha gs}$-$\mathcal{OS}$in$(R,\Omega)$. Since$(R,\Omega)$ is a $\mathcal{Pn}_{\alpha ga}\mathcal{T}_{1/2}$ space,$f(\mathcal{P}nint(K))$ is a $\mathcal{PnOS}$ in$(R,\Omega)$.We know that every$\mathcal{PnOS}$ is a $\mathcal{Pn}_{\alpha}$-$\mathcal{OS}$ ,$f(\mathcal{P}nint(K))$is a $\mathcal{Pn}_{\alpha}$-$\mathcal{OS}$in$(R,\Omega)$. Therefore$\mathcal{Pn}_{\alpha}int(f\big(\mathcal{P}nint(K)\big))=f\big(\mathcal{P}nint(K)\big)$.Hence$f\big(\mathcal{P}nint(K)\big)=\mathcal{Pn}_{\alpha}int(f(\mathcal{P}nint(K)))\subseteq\mathcal{Pn}_{\alpha}int\big(f(K)\big)$.
(2) ⇒ (3) Let$L$be any $\mathcal{PnS}$ in$(R,\Omega)$.Then$f^{-1}(L)$ is a$\mathcal{PnS}$ in$(Q,\Gamma)$. By hypothesis,$f(\mathcal{P}nint\big(f^{-1}(L)\big)\subseteq\mathcal{Pn}_{\alpha}int(f(f^{-1}(K)))\subseteq\mathcal{Pn}_{\alpha}int(L)$.Therefore$\mathcal{P}nint\big(f^{-1}(L)\big)\subseteq f^{-1}\big(\mathcal{Pn}_{\alpha}int(L)\big)$.
(3)⇒(1) Let us assume that $K$ be any$\mathcal{PnOS}$in$(Q,\Gamma)$.Then$\mathcal{P}nint(K)=K$and $f(K)$is a$\mathcal{PnOS}$ in$(R,\Omega)$. Then by hypothesis, $\mathcal{P}nint(f^{-1}(f(K)))\subseteq f^{-1}(\mathcal{Pn}_{\alpha}int(f(K)))$.Now $K=\mathcal{P}nint(K)\subseteq\mathcal{P}nint(f^{-1}\big(f(K)\big)\subseteq f^{-1}\left(\mathcal{Pn}_{\alpha}int\big(f(K)\big)\right)$.Therefore$f(K)\subseteq f(f^{-1}(\mathcal{Pn}_{\alpha}int(f(K))\subseteq\mathcal{Pn}_{\alpha}int(f(K))\subseteq f(K)$.Thus $\mathcal{Pn}_{\alpha}int(f(K))=f(K)$is a$\mathcal{Pn}_{\alpha gs}$-$\mathcal{OS}$in $(R,\Omega)$.Therefore $f$is a $\mathcal{Pn}_{\alpha gs}$-$\mathcal{C}.\mathcal{M}$.

**Theorem 3.1.13**Let$f:(Q,\Gamma)\to(R,\Omega)$ be a mapping. Then the following results are equivalence if $(R,\Omega)$ is a $\mathcal{Pn}_{\alpha ga}\mathcal{T}_{1/2}$ space.

1. 1.$f$ is a $\mathcal{Pn}_{\alpha gs}$-$\mathcal{C}.\mathcal{M}$.
2. 2.$\mathcal{P}ncl(\mathcal{P}nint(\mathcal{P}ncl(f(K))))\subseteq f(\mathcal{P}ncl(K))$ for every$\mathcal{PnS}K$in $(Q,\Gamma)$.

**Proof.** (1) ⇒ (2)Let$K$be any $\mathcal{PnS}$ in$(Q,\Gamma)$. Then$\mathcal{P}ncl(K)$ is a$\mathcal{PnCS}$ in$(Q,\Gamma)$.By hypothesis, $f(\mathcal{P}ncl(K))$ is a $\mathcal{Pn}_{\alpha gs}$-$\mathcal{CS}$in$(R,\Omega)$. Since$(R,\Omega)$ is a $\mathcal{Pn}_{\alpha ga}\mathcal{T}_{1/2}$ space,$f(\mathcal{P}ncl(K))$ is a $\mathcal{PnCS}$ in$(R,\Omega)$. Therefore $\mathcal{P}ncl(f\big(\mathcal{P}ncl(K)\big))=f\big(\mathcal{P}ncl(K)\big)$. Now clearly.$\mathcal{P}ncl(\mathcal{P}nint(\mathcal{P}ncl(f(K))))\subseteq\mathcal{P}ncl(f(\mathcal{P}ncl(K)))=f\big(\mathcal{P}ncl(K)\big)$. Hence$\mathcal{P}ncl(\mathcal{P}nint(\mathcal{P}ncl(f(K))))\subseteq f(\mathcal{P}ncl(K))$.
(2)⇒(1) Let$K$be any$\mathcal{PnCS}$ in$(Q,\Gamma)$.. By hypothesis,$\mathcal{P}ncl(\mathcal{P}nint(\mathcal{P}ncl(f(K))))\subseteq f\big(\mathcal{P}ncl(K)\big)=f(K)$. This implies$f(K)$ is a $\mathcal{Pn}_{\alpha}\mathcal{CS}$ in$(R,\Omega)$ and hence$f(K)$ is a $\mathcal{Pn}_{\alpha gs}$-$\mathcal{CS}$ in$(R,\Omega)$. That is$f$ is a $\mathcal{Pn}_{\alpha gs}$-$\mathcal{C}.\mathcal{M}$.

## CONCLUSION

This work introduce and examines $\mathcal{P}n_{\alpha gs}$-closed mappings and explores their properties. Further research may focus on extending these notions to $\mathcal{P}n_{\alpha gs}$-homeomorphism.

## ACKNOWLEDGEMENTS

The author would like to thank everyone who supported and guided the completion of this research work.

## ABSTRACT

The present investigation was undertaken to determine the toxic effects of sub- lethal concentrations of the herbicide diuron on haematological and biochemical parameters of freshwater fish, *Anabas testudineus*. Regardless of sex, the uniformly sized fishes were randomly divided into 6 groups (11.25 ± 1.07 cm of total length, 32.4 ± 1.42 g of weight) and exposed to diuron at concentration 0.5 ppm,1 ppm,1.5 ppm and 2 ppm along with control. The biochemical constituents such as protein, lipids, glycogen, carbohydrates and cholesterol were analyzed from muscle and liver of the fish using standard procedures. As the concentration of diuron increased, the glycogen concentration in liver and muscle tissues showed a decreasing trend from the control value. Additionally, lipid concentrations in the liver and muscle tissues of diuron exposed to varying concentrations of diuron showed significant decrease compared to control fish whereas protein concentrations in both tissues also showed a declining trend as herbicide concentration increased. This study demonstrated that the metabolic characteristics of fresh water fish, *Anabas testudineus* were markedly altered by sublethal concentrations of diuron. Therefore, the significant alterations in these biochemical markers suggested some important and potential aftereffects of diuron pollution in freshwater ecosystems.

## INTRODUCTION

Water quality in rivers, lakes, and marine habitats is under risk due to the escalated use of fertilizer and pesticides brought on by the growth and intensification of agriculture [1]. Overabundance of nutrients from agricultural runoff can cause eutrophication, which lowers oxygen levels in water bodies and results in algal blooms. Aquatic animals and ecosystems may be impacted by habitat fragmentation and destruction brought on by agricultural practices. Both developed and underdeveloped countries are significantly impacted by agricultural practices. However, in developing nations, the importance of these effects is more noticeable. The primary source of pesticide deposition in aquatic ecosystems is agricultural runoff close to water bodies. By upsetting ecological relationships between organisms and causing biodiversity loss, bioaccumulations of these pesticides endanger long-term survival of fishes [2,3,4]. Prolonged exposure to pesticides causes physiological disturbance, behavioral changes, histopathological damages, haematological changes, biochemical alterations, hormone disruption, immunological suppression, reproductive abnormalities and cancer. The likelihood that pesticides will get into surface and ground water is increased by irrigation. Additionally, pesticides have the ability to modify phytoplankton communities, which can impact ecosystem function and water quality. Pesticides have the ability to modify food webs, which can impact the structure and function of ecosystems. Diuron is a typical pesticide used in Kuttanad's agricultural fields to manage weeds. It prevents weed seeds from sprouting, preventing weeds from establishing themselves before crops are sown. Diuron strongly inhibits the plant's photosynthesis II system through the Hill reaction. For some crops, diuron can be used as a defoliant to facilitate harvesting. Diuron is persistent in sediment and soils, with a DT50 of 90 to 180 days [5]. It will stay active in soil for four to eight months when used normally [6]. Ingestion, dermal absorption, or inhalation can all result in sickness. Canals, reservoirs, wetlands, swamps, and estuaries are the main habitats of the climbing perch, *Anabas testudineus*. It is a potamodromous fish species that can live in both fresh and brackish water. The labyrinth organ, an additional air-breathing organ, allows *Anabas testudineus* to withstand harsh aquatic circumstances like low oxygen levels and dirty water. The diuron contamination of waterbodies can result in fish mortality that results in the raising of the concentrations of chemicals in edible fish tissue or reduces fish production capability, both of which can harm consumer health. Because of the persistent nature of pesticides in aquatic environments, bioaccumulation has become an increasingly significant issue for pesticides in recent years, posing a substantial risk to the ecosystem as a whole, including humans. Pesticide pollutants directly damage vital organs such the gills, liver, heart, kidney, and gut and are directly linked to the food chain and water body contamination, it is crucial to assess the harmful consequences of these pollutants on fish [7].Therefore, the present study was undertaken to evaluate the toxic effects of diuron on the haematological parameters and the biochemical profile of the *Anabas testudineus*.

## MATERIALS AND METHODS

The freshwater fish *Anabas testudineus* (Bloch, 1792), commonly called climbing perch and locally known in Kerala as Kallelmutti, was used as the test organism. Healthy adult fishes of uniform size (mean weight 32.4 g; mean length 11.25 cm) were obtained from Aquarius Farm Products. The fishes were disinfected in 0.1% potassium permanganate for two minutes and acclimatized for one week in aerated, dechlorinated tap water. They were fed commercial pellets twice daily, and waste materials were removed regularly. Diuron [3-(3,4-dichlorophenyl)-1,1-dimethylurea] was used as the toxicant. A 100 mg $L^{-1}$ stock solution was prepared and diluted to obtain required concentrations. Chronic exposure experiments were conducted in glass aquaria containing 300 L solution. Based on range-finding and $LC_{50}$ determination, four concentrations (0.5, 1.0, 1.5 and 2.0 ppm) along with a control were maintained. Mortality was recorded at 24, 48, 72 and 96 h and $LC_{50}$ was calculated using probit analysis [8]. One-fourth of the 96-h $LC_{50}$ was taken as the sublethal concentration for further study. Thirty fishes were introduced into each aquarium and exposed for 14 days. Seventy-five percent of the medium was renewed twice with fresh solution, and fishes were fed daily. Behavioural changes such as colour variation, opercular movement, abnormal swimming, mucus secretion and loss of equilibrium were recorded. The experiment was performed in five replicates and a control without diuron was maintained under identical conditions. At the end of exposure, liver and muscle tissues were collected for

biochemical analysis. Total protein, lipid, glycogen and carbohydrate were estimated by standard methods [9,10,11,12]. Data were analyzed using SPSS software 20, and significance between control and treated groups was tested by ANOVA and paired *t*-test.

## RESULTS AND DISCUSSION

The mortality rates were recorded at 24 hours, 48 hours, 72 hours, and 96 hours. At 24 hrs., the percentage mortality observed at different concentrations, 0.5 ppm,1ppm,1.5ppm and 2ppm, was 5%, 9%,14% and 44% respectively. At 96 hrs., the percentage mortality observed at different concentrations 0.5 ppm,1ppm,1.5ppm and 2ppm was 30%, 58%, 75% and100% respectively. The safe and sub-lethal concentration of diuron treated *Anabas testudineus* was found to be 0.47 and 0.83 ppm. With increasing pesticide concentrations and time duration, mortality increased gradually. The control group showed zero percent mortality. The morphological and behavioural studies show a dose-dependent response in *Anabas testudineus* to diuron exposure (Table I). As the concentration of the herbicide increased, morphological and behavioural changes became severe such as fatigue, excessive mucus secretion and sluggishness. The visual observation indicates that diuron has significant toxic effects on fish physiology and morphological and behaviour even at low concentrations. The above behavioural results were similar to the study of [13] for cadmium toxicity in *Anabas testudineus*. The Table II indicates the impact of elevating diuron concentration (0.5 to 2.0 ppm) on different biochemical constituents (carbohydrate, glucose, cholesterol, lipids and protein) of muscle and liver tissues of *Anabas testudines*. A noticeable dose dependent reduction is seen in almost all observed parameters. The carbohydrate content is observed in both tissues gradually declined with elevating diuron concentration. In liver, it was observed as 11±0.9 mg/g in control and 5.5±1.8 mg/g at 2 ppm where as in muscle, 9.8±0.2 mg/g in control and 3.8±1.2 mg/g in 2 ppm respectively. The decline shows that the body uses more carbohydrates as fuel while under dangerous stress, using up stored reserves to satisfy higher metabolic demands. In the case of glycogen, a continuous decline was noticed in both tissues. In liver, it was observed as 7.2±0.2 mg/g in control and 3.9±0.5 mg/g in 2 ppm and in muscle, 5.6±1.2 mg/g in control and 1.6±1.5 mg/g in 2 ppm. Numerous studies have documented the decrease in muscle and liver glycogen in aquatic animals as a result of toxic stress [14,15]. Stress-induced glycogenolysis causes the principal energy store, glycogen, to be depleted, releasing glucose to meet the energy needs of survival and detoxification. The protein content was also showed a marked decline with increasing exposure of diuron. In liver, it was noted as 14±1.4 mg/g in control and 5.2±1.5 mg/g in 2 ppm.

In muscle, it was observed as 18.1±2.1 mg/g in control and 10.1±1.8 mg/g in 2 ppm. [16] found that liver damage in *Astyanax altiparanae* results in significant drop in total protein and albumin levels in liver tissues and blood plasma. Proteolysis, in which proteins are broken down into amino acids and used for tissue repair and energy production under adverse conditions, is indicated by the decrease in protein. The lipid content is found to be decreased in both tissues of diuron treated *Anabas.* In liver, it declined from 13.6± 0.8 mg/g in control group to 7.1±1.5 mg/g in high concentrations whereas in muscle it was 10.4±1.2 mg/g in control to 5.3±1.0 mg/g at high concentration. Cholesterol content also shows the same trend. When carbohydrate levels are no longer sufficient, fat mobilization causes the depletion of lipids. Since cholesterol is a crucial structural element of membranes and the generation of steroids, a decrease in cholesterol indicates liver metabolic malfunction and damage to cell membranes. Similarly, [17] observed sublethal concentrations of diuron showed a marked decrease in total lipid and cholesterol levels in liver and blood of *Channa punctatus*. The two-way analysis of variance (ANOVA) showed a highly significant ($P<0.05$) decrease in glycogen, protein, carbohydrate cholesterol and lipid concentration of diuron exposed fishes with respect to control. Paired t-test of all parameters also showed significant variation (P value<0.05) of diuron concentration between control and test groups. Haematological parameters of *Anabas testudineus* (Table III) revealed a remarkable decline in red blood cell (RBC) count was recorded as $4.8 \times 10^6$ cells/mm$^3$(control), significantly decreased to $3.5 \times 10^5$ cells/mm$^3$ in the test group. Similarly, white blood cell (WBC) count was dropped from 1,94,800 thousand cells/mm$^3$(control) to 1,66,300 thousand cells/mm$^3$ in the treated group. Furthermore, the haemoglobin content decreased from 7 gm% in the control to 5 gm% in the exposed group. These results indicate that exposure to sub-lethal levels of diuron adversely affects the haematological parameters of *Anabas testudineus*, leading to reductions in RBC count, WBC

count, and haemoglobin levels. According to [18], decrease in erythrocyte count and rise in leucocyte count in *Prochilodus lineatus* are probably due to oxidative damage and immunological activation. Carbohydrates, glycogen, protein, lipids and cholesterol are gradually depleted in both liver and muscle tissues as toxicant concentration rises. The liver is the main target organ since it exhibits a larger decline than muscle. Under toxic exposure, these biochemical changes show significant metabolic stress, elevated energy demand and compromised physiological functioning in the fish.

## CONCLUSION

According to the study, increased utilization of energy molecules in *Anabas testudineus* to meet energy requirements for the detoxification process is the cause of the changes in glycogen, total lipid, carbohydrate, cholesterol and lipid concentration that were detected in response to diuron. It has also been noted that even at low concentrations, sublethal exposure causes physiological and morphological changes. These alterations show the stress response and disturbance of metabolic processes, which may eventually hinder survival, development, and reproduction.

**ABSTRACT**

Data Loss Prevention (DLP) technologies are foundational controls for reducing the risk of unauthorized disclosure of sensitive data across endpoints, networks, and cloud services. However, traditional DLP systems—largely rule- and signature-driven—struggle with evasive exfiltration tactics, encrypted traffic, and the velocity/variety of enterprise data. This article proposes an AI-augmented DLP framework that combines representation learning for content understanding, behavioral modeling for insider-risk detection, and policy optimization for adaptive responses. We formulate the problem, describe an end-to-end system architecture, define evaluation metrics, and discuss deployment considerations including privacy, explainability, and governance. A reference pipeline and experiment design are provided to help practitioners reproduce and benchmark results.

**Keywords:-**Data Loss Prevention, Insider Risk, Exfiltration, Natural Language Processing, Representation Learning, Behavioral Analytics, Explainable AI.

## INTRODUCTION

Organizations face persistent risks of data exfiltration from external threats and insider actions, whether malicious or inadvertent. DLP systems monitor data at rest, in motion, and in use to prevent sensitive information from leaving trusted boundaries. Classic DLP depends on pattern matching (e.g., regular expressions for credit card or national IDs), fingerprints of known sensitive documents, and file-type controls. While effective for known patterns and governed repositories, such approaches struggle with:

- Context-dependent sensitivity (e.g., project code names, research drafts).
- Evasive exfiltration (e.g., steganography, homomorphic obfuscation, exfil via screenshots or screen recordings).
- Cloud/SaaS sprawl with bring-your-own-apps and shadow IT.
- High false positives that desensitize users and security teams.

AI can enhance DLP by learning content and context, modeling user and machine behavior, and recommending risk-aware responses. We present an AI-enabled DLP blueprint and practical guidance to implement, evaluate, and operate it at scale.

**Background and Related Concepts**

**DLP Scope**
- Data in Motion: Network egress (email, web uploads, APIs, messaging).
- Data at Rest: File shares, endpoints, cloud storage (S3/Blob/GCS), SaaS repositories.
- Data in Use: Clipboard, print, screen capture, peripheral devices, local transforms.

**Threat Models**
- Malicious insiders: Privileged engineers or contractorsexfiltrating source code or customer data.
- Careless insiders: Accidental sharing to personal email or misaddressed messages.
- External attackers: Using compromised accounts or implants to stage and exfiltrate data.
- Advanced evasion: Compression, encryption, chunked exfiltration, living-off-the-land tools (e.g., curl, netcat), covert channels (DNS, SaaS notes).

**Limits of Traditional DLP**
- Reliance on brittle rules.
- Inability to generalize to novel sensitive concepts.
- Limited visibility into user intent or context.

**AI-Augmented DLP: System Overview**
**Design Objectives**
1. Content understanding: Learn semantic representations of text, code, tables, and images to detect sensitivity beyond regexes.
2. Behavioral context: Model sequences of user/device actions to infer intent and anomalies.
3. Adaptive control: Optimize policy actions (block, coach, quarantine, escalate) based on predicted risk and business impact.
4. Explain ability: Provide human-interpretable rationales to analysts and end-users.
5. Privacy-preserving: Minimize data exposure via on-device inference, redaction, and federated learning where feasible.

**Reference Architecture**

**Sensors/Collectors**
- Endpoint agents: file I/O, clipboard, print, screen, removable media, IDE plugins for code artifacts.
- Network taps/proxies: SMTP/HTTP(S) via SSL inspection where lawful; CASB/SSE integrations for SaaS.
- Cloud connectors: APIs for storage/SaaS (M365, Google Workspace, Salesforce, Git, Jira).

**Data Pipeline**
- Normalization (PCAP to flow records, file parsing, OCR for images/PDFs).
- Content extraction (text, code, tables, images), PII/PHI redaction for training logs.
- Feature store keyed by entity (user, device, repo, project).

**AI Services**

- Sensitivity classifier: Multimodal encoder for text/code/images → sensitive/non-sensitive labels + category (e.g., customer data, financials, trade secrets).
- Anomaly & intent model: Time-series model over sequences (e.g., uploads per hour, destination reputation, app novelty).
- Policy optimizer: Contextual bandit or constrained RL to recommend actions, honoring compliance constraints.
- Explainability: SHAP/LIME, exemplar retrieval, attention heatmaps, and rule backstops.

**Policy Engine**

- Combines AI risk score with mandatory policies (e.g., block PCI DSS to external domains).
- Action set: allow, coach (just-in-time banner), encrypt, auto-label, quarantine, block, escalate to SOC.

**SOC and Governance**

- Case management, playbooks (SOAR), feedback loop for active learning, audit trails.

## METHODOLOGY

**Data and Labeling**

- Sources: Historical DLP incidents, red-team simulations, synthetic generation of sensitive/non-sensitive corpora (balanced for text, code, tabular, images).
- Label Taxonomy: {Public, Internal, Confidential, Restricted} × {PII, PHI, Finance, Source Code, Legal, Research, Client Data}.
- Weak Supervision: Distant labels from regexes and dictionaries; human-verified subsets to correct biases.
- De-identification: Redact PII/PHI in training logs; hash identifiers; store only features where possible.

**Models**

- Text & Code: Transformer encoders (document-level) with domain-adaptive pretraining on internal corpus; optional code-aware encoders for repositories.
- Images/PDFs: OCR + vision transformer for screenshots/scan exports; table structure recognition.
- Behavioral Modeling: Sequence models (GRU/Transformer) on user-session features (e.g., data volume deltas, destination novelty, off-hours activity).
- Fusion: Concatenate content and behavior embeddings; train a calibrated classifier (e.g., gradient-boosted trees on embeddings) to predict risk (\hat{y}\in[0,1]).

**Policy Optimization**

- Objective: Maximize prevented loss while minimizing disruption.
- Formulation: Contextual bandit with constraints (legal/policy hard rules). Reward approximates prevented exfiltration minus cost of false positives.
- Safe Exploration: Offline policy evaluation (counterfactual estimation) before production rollout.

**Explainability and Analyst UX**

- Local explanations: Top n tokens/spans contributing to sensitivity; example similar incidents.
- Global dashboards: Drift detection for features and label distribution; false-positive heatmaps by policy.

## EVALUATION

**Metrics**

For classification (sensitive vs. not):

- Precision, Recall, F1; area under PR curve (AUPRC) preferred for imbalanced data.

- Business-weighted F1: weight by asset criticality (e.g., Restricted=3, Confidential=2, Internal=1).

**For anomaly/intent detection:**
- Precision@k for top alerts per day.
- Time-to-detect (TTD) and time-to-respond (TTR).
- Analyst effort: alerts per analyst hour and resolved-to-escalated ratio.

**For policy efficacy:**
- Block accuracy (true positive blocks ÷ total blocks).
- User friction index (fraction of workflows interrupted).
- Data-loss averted (estimated, via baselines or tabletop simulations).

**Baselines**
- Regex/dictionary only.
- Document fingerprinting (exact/near-duplicate).
- Vendor default policies.

**Experimental Design**
- Data split: Temporal split to simulate future drift (train on months 1–6; validate on 7; test on 8–9).
- Ablations: (a) content only, (b) behavior only, (c) fusion, (d) fusion + policy optimizer.
- Offline evaluation: For actions, use logged propensities and inverse-propensity scoring where available.
- Pilot rollout: Shadow mode → coach-only → selective block with human-in-the-loop.

## RESULTS & DISCUSSIONS FOR THE ABOVE ILLUSTRATION

**On a mixed enterprise dataset (≈30M events, 120k labeled incidents):**
- Fusion model improved AUPRC by ~21% over content-only; false positives reduced by ~35% at iso-recall.
- Behavioral sequence features contributed most to early detection of low-and-slow exfiltration (chunked uploads).
- Policy optimizer reduced unnecessary blocks by ~18% while maintaining recall, improving user satisfaction scores in post-event surveys.

**Error Modes**
- Ambiguous projects: New codenames not in dictionaries; mitigate via few-shot labeling and retrieval-augmented encoders.
- Image-only exfiltration: Screenshots of terminals or tables; mitigate with OCR+vision and on-device scanning for privacy.
- Encryption and tunnels: TLS/SSH/ZIP with passwords; rely on metadata/behavior, DLP on endpoints pre-encryption, and egress controls.

**Privacy and Compliance**
- Minimize content retention; favor on-device inference and feature-only logging.
- Apply data minimization and purpose limitation; document DPIAs where required.
- Honor legal holds and retention schedules; robust consent and transparency for workforce monitoring.

**Explainability and Trust**
- Provide user-facing just-in-time coaching: "This file appears to contain client identifiers; sending externally may violate policy X."
- Analyst-facing rationales with highlighted spans and similar prior cases.
- Maintain a clear appeals process and human override with audit trails.

**Operations and MLOps**

- Drift monitoring: Track label/feature drift; retrain cadence (e.g., monthly) with active learning.
- Feedback loops: Analysts tag false positives/negatives; auto-curate hard examples for retraining.
- Versioning: Snapshot models, features, and policies; rollback plans for safety.

**Pseducode Reference**

```
# Training
for event in events:
content = extract_text_code_image(event.artifact)
ocr = run_ocr_if_needed(event.artifact)
x_content = content_encoder(content + ocr)
x_behavior= behavior_features(event.user,event.device,
time_series_window=30d
X.append(concat(x_content, x_behavior))
y.append(label_from_policy_or_analyst(event))

clf = train_calibrated_classifier(X, y)
save_model(clf)

# Inference
def assess(event):
content = extract(event.artifact); ocr = maybe_ocr(event)
  x = concat(encode_content(content+ocr), behavior_features(...))
risk = clf.predict_proba(x)
action = policy_engine(risk, hard_rules, user_context)
explain = explainer(clf, x)
return action, explain
```

**Limitations And Future Work**

- Generalization: Tailoring to each enterprise's data semantics remains necessary; few-shot learning and retrieval can help.
- Adversarial robustness: Attackers may manipulate content to evade detectors; explore adversarial training and ensemble defenses.
- Cross-border data transfer: Federation and split learning can reduce movement of sensitive data.
- Real-time constraints: On-device inference must meet latency budgets; consider distilled models and approximate nearest neighbor search.

## CONCLUSION

AI augments DLP by learning what is sensitive, understanding how users behave, and selecting context-appropriate responses with human-interpretable reasoning. A fusion approach—content + behavior + policy optimization—yields measurable improvements in precision/recall and reduces user friction. Successful deployments prioritize privacy, explainability, and continuous feedback to sustain performance against evolving exfiltration tactics.

**Table 1. Comparison of DLP Approaches**

| Approach | Strengths | Weaknesses | Best Use |
|---|---|---|---|
| Regex/Dictionary | Simple, fast, deterministic | Misses context, brittle, high FP | Known PII patterns |
| Fingerprinting | Precise for known docs | Fails on transformations/derivatives | Contracts, templates |
| Heuristics (size/type) | Lightweight | Easy to evade | Triage, coarse filters |
| **AI Content Classifier** | Understands semantics | Needs labeled data, drift | Unstructured text/code |
| **Behavioral Modeling** | Captures intent patterns | Cold-start risk | Insider risk, anomalies |
| **Policy Optimizer** | Balances risk/friction | Needs logged policies | Action selection |

**Table 2. Key Metrics and Targets (Illustrative)**

| Metric | Target | Notes |
|---|---|---|
| Precision (High-risk) | ≥ 0.85 | Analyst workload control |
| Recall (High-risk) | ≥ 0.70 | Prevent leakage |
| AUPRC | +15% vs. baseline | Class imbalance aware |
| Block Accuracy | ≥ 0.80 | Minimize business disruption |
| User Friction Index | ≤ 0.05 | % workflows interrupted |

**ABSTRACT**

The tomato is a highly valued source of nutrition that contributes to the global nutrition of both rural and urban populations. Low tomato yields are caused by a variety of causes, including weed competition and fungal, bacterial, nematode, or viral infections. One of the most significant and pervasive diseases of the cultivated tomato is *Fusarium* wilt disease, which is brought on by *Fusariumoxysporum f. sp. lycopersici.* The only target of this soil-borne disease, which belongs to the class Hyphomycetes, is the tomato, which wilts when it is exposed to it. Vein-let clearing and petiole drooping on young plants are the first indications. The oldest lower leaves start to yellow as the first sign of *Fusarium* wilt. Lower leaves turn yellow and eventually perish. This review documented many methods used to combat the disease, which is extremely harmful in tomatoes grown in nurseries and fields. The most economical and environmentally responsible method is Integrated Disease Management (IDM), which has been promoted as being safe and non - toxic, priceless organisms, plants, animals, and human beings. However, instead of focusing only on the greenhouse, measures should be taken to examine and increase their effectiveness, efficiency, and stability on the fields.

**Keywords:** Tomato**,** *Fusariumoxysporum* f. sp. *Lycopersici*, Integrated Disease Management

## INTRODUCTION

Tomato (*Lycopersicon esculentum* Mill.) is belongs to Solanaceae family includes tomato which are grown total area of 4.5 million hectare and a yield of 115.5 million metric tons. It is one of the most important vegetables in the world (Kaiser and Erns,2011). Because it is a crop with a short growing season and a high yield, it is commercially appealing, and the cost of cultivation is growing every day. In terms of both area and output, it comes in third place globally behind potatoes and sweet potatoes (Naika *et al*, 2005). From a total cultivated areas of 27.56 million

hectares, India produced roughly 333.25 metric tons of tomatoes in 2020–21. The average tomato yield per hectare in the world was 34.85 tones, whereas the yield per hectare in India was 21.18tones. India is the world's second-largest tomato growing country. Primarily in highly populated urban regions, there is an internal market for local fresh tomato fruit. There is also a growing opportunity for processing companies for the foreign and Indian markets as tomato sauce, ketchup, squeeze, and tomato glue (puree) etc. (AVRDC,2003). The climate and soil in India are ideal for growing a variety of fruits and vegetables, including tomatoes. The best temperature range for tomato growth is between $15^0$C and 25 °C, despite the fact that it is actually adaptable. High temperatures reduce the productivity. While temperatures above 30° C hinder the lycopene formation and flavor of tomato fruit, exceptionally low temperatures can have an impact on production. Tomatoes grow best in areas with low to moderate precipitation and an effective watering system during the off-season. Disease attacks increase under wet conditions, which also affect fruit ripening. Tomatoes thrive in a variety of soil types with a pH range of 5.5-7.5, high organic matter content, and good drainage. (Hanaa *et al*, 2011, Waiganjo *et al,* 2006). The best soil for tomato plants is one that has been thoroughly amended with organic matter and is well drained. It is important for the soil to be capable of holding moisture (Robert, 2005). Tomato yield is restricted by a variety of factors. . These include: a dearth of enhanced, high-performing cultivars; poor fruit setting brought on by severe rainfall and extremely high temperatures; and pests and illnesses. A common occurrence is yield losses of 100 percent, especially when tomatoes are affected at an initial phase of development (Cohen and Antinus, 1994). The world average crop loss due to all illnesses put together was around 12.8% of the crop productivity, whereas the tomato alone saw a loss of 21.8 percent. The main biotic restrictions in India are caused by disease and insect pest damage. Much research has been done on the country's pathological and entomological concerns in order to reduce harm caused by illness and insect pests. As a result, roughly 13 illnesses brought on by various fungal, bacterial, and viral pathogens have been found and documented (Jones *et al*, 2014) and commercially significant insect and mite pests targeting tomatoes have also been reported (Elsafie *et al*, 2017). Previous research has identified early blight (*Alternaria solani*), late blight (*Phytopthora infestans*), septoria leaf spot (*Septoria lycopersici*), and viruses as the four most commercially significant tomato diseases (Winad and Willium, 1999). A major financial loss is brought on by the illness *Fusarium* wilt of tomato, which is brought on *by Fusarium oxysporum* f. sp. *lycopersici.* On an astonishing variety of host plants, *Fusarium* species produce a wide variety of illnesses. The fungus can be retrieved from any part of the plant, from the deepest root to the topmost flower, and it can be conveyed in the soil, the air, or in plant residue (Singha *et al,* 2011). Wilted plants, yellowed leaves, and root rot are the hallmarks of the fungus's sickness, which also causes a low or nonexistent agricultural output. This disease is particularly destructive to tomato types that are sensitive to it during the summer season when soil and air temperatures are typically high (Akrami and Yousefi 2015).

**Pathogen**

The *Fusarium* genus is among the most versatile and diverse species in the Eumycota, and the *Fusarium oxysporum* species complex has a wide variety of non-diseases in addition to plant, animal, and human pathogens (Gorden, 2017). Numerous soil-borne infections of a variety of horticultural and food crops, including members of the *Fusarium* genus, are responsible for the deadly vascular wilts, rots, and damping-off diseases (Bodah, 2017). More than 150 hosts are affected by wilt disease caused by the *Fusarium oxysporum* species, which has a variety of distinct formae speciales (Bertoldo *et al*, 2015). *Fusarium oxysporum* Schlectend was mentioned in reports (Asha *et al,* 2011, Nirmala Devi and Srinivas, 2012). The most severe reduction in yield was caused by F. sp. lycopersici (Sacc.) W.C. Snyder and H.N. Hansen (FOL), which causes vascular, wilt of tomato disease (Asha *et al,* 2011). *F. oxysporum* can survive for a long time in soil as dormant propagules, which is a feature of soil-borne pathogens (chlamydospores). Chlamydospore germination is triggered by the presence of host roots. The infected hyphae stick to the root surface before penetrating it. The mycelium enters the vascular system through the xylem pits and interpenetrates the root cortical cells. The fungus then exhibits a distinct mode of infection in which it prefers to grow just within the xylem vessels before quickly invading the host (Srinivas *et al,* 2019). The fungus begins to develop microconidia inside the vessels, and as they separate, they are carried upward through the sap stream. Furthermore, the top vessels are penetrated by mycelial growth as a result of microconidia germination. The typical wilt symptoms manifest as vascular blockage brought on by the accumulation of fungal hypae and a mixture of host-pathogen interactions, including the production of toxins, the creation of gums, gels, and tyloses (Khan,*et al*, 2017, Cha *et al,*2016) The

appearance of typical disease symptoms such leaf epinasty, vein clearing, wilting, and defoliation inevitably precedes the death of the host plant (Fig. 1). During this phase the vascular wilt fungus, which stays limited to the xylem vessels, propagates through parenchymatous tissue and begins to sporulate abundantly on surface of the plant such as, leaf, steam etc. Dissemination of the pathogen can occur via seeds, transplants, soil or other means (Mc Govern, 2015, Joshi, 2018).

**SYMPTOMS OF *FUSARIUM* WILT DISEASE ON TOMATO**

Inoue *et al.* (2002) found that the fungus directly invades roots and colonizes vascular tissue. *Fusarium* wilt symptoms can include growth retardation, chlorosis and drooping of the leaves, reddish deep gouges of the xylem vessels (perceptible inside the stem as strands or dots in transverse section), and on the infected parts of the plant whitish pink fungal growth was seen (particularly in wet conditions). They can also affected root or stem decay. Attack signs initially manifest as modest vein clearing on the young leaves' outer surface, proceeded by epinasty of the mature leaves (Sally *et al,* 2006). This condition frequently only affects one side of the plant or one stalk. Before the plant reaches maturity, successive leaves normally turn yellow, wilt, and fall. Growth is sometimes stunted and almost no fruit typically begins as the condition worsens. Dark brown stripes that run vertically through the main stem can be noticed if the stem is sliced. The disease's characteristic tanning of the vascular system can typically be utilised to identify it (Mui Yun, 2003). The symptoms frequently appear on mature plants following blooming and during the start of fruit 21 setting, as demonstrated by Walker (1971). A small amount of wilting on a portion of the plant may be the first sign. Chlorotic symptoms first occur on one side of the leaf before turning that side of the foliage yellow. Wilting is frequently related to one side of the plant as conditions worsen. Fig. 1 [A] Showing only affects one side of the plant; leaf turned yellowing, wilt and fall. [B] Dark brown stripes that run vertically through the main stem

**Etiology of Pathogen**

Mycelia of *Fusarium oxysporum* range from sparse to profuse and are delicate whitish pink, frequently with a purple tinge. The fungus creates three different types of spores: chlamydospores, macroconidia, and microconidia. Microconidia are plentiful, oval-ellipsoid, straight to curved, 5-12 x 2.2-3.5 mm, non-septate, and borne on simple phialides emerging laterally. Macroconidia are thin-walled, three- to five-septate, fusoid-subulate, pointy at both ends, and have a pedicellate base. They are borne on branched conidiophores or on the surface of sporodochia and can range in number from sparse to profuse. Conidia with three septa are 27–46 x 3-5 mm in size, whereas those with five septa are 35–60 x 3-5 mm. The three-septate spore is more prevalent. The three-septate spore is more prevalent. There are many chlamydospores, both smooth and rough walled, and they can form terminally or intercalarily. Although they sometimes form pairs or chains, they are typically single. The perfect stage is unknown (Gerlach,1982). Fig. 2. [A] Profuse whitish purple mycelium growth of *F. oxysporum* [B] Microscopic observation of *F. oxysporum* including; macroconidia, microconidia and chlamydospore

**Ecology and Spread of the Infection**

A soil-borne pathogen that may survive for many years in the soil without a host is the cause of *Fusarium* wilt. The community surrounding infected tomato detritus is where the majority of infections start. Healthy plants may contract *F. oxysporum* infection if the soil they are growing in harbours the pathogen (Walker, 1971). In all kinds of soil, *Fusarium oxysporum* can be found, it can survive there, and it can grow there, but sandy soil offers the best condition for this to happen. Since it is soil-borne, the pathogen can survive in infected soil for many years. Pathogen thrives in environments with soil and air temperatures are 28 °C. The pathogen will spread to the lower regions of the stem if air temperatures are below $25^0$C but at optimal soil temperatures the plants won't show any visual signs. Nitrate nitrogen reduces pathogen virulence while micronutrients, phosphorus, and ammonium nitrogen increase it (Mui, 2003). The disease can spread over long distances via infected soil or transplants (Agrios, 1988), but it is more commonly short distance transmission by irrigation water and contaminated farm tools(Stephen, 2003).Furthermore, the disease can spread through contaminated soil and infected plant debris. Other ways of disease transmission include direct contact between a human and an infected field, the use of irrigation water or equipment that has formerly been used on a diseased crop, and direct contact between a human and an affected crop (Ajigbola, 2013).

**Epidemiology of Disease**

According to Sally *et al*. (2006), the pathogen enters the plant by the root hairs and can survive in the soil for many years (Thangavelu *et al*, 2003). Mycelium develops in xylem channels where it blocks water flow, causing wilting (Stephen and Andre, 2003). *Fusarium* wilt frequently coexists with nematode colonization, with the worms serving as the fungus' entry point. Additionally, enzymes may make it easier for *Fusarium* to enter the plant host (Babalola, 2010). Warm temperature as well as low soil moisture increase infection and disease development in *Fusarium* wilt (Lewis, 2003).

**Treatment of *Fusarium* Wilt Disease**

*Fusarium* wilt in tomato plants needs to be managed if plant health, fruit quality, and yield are to be preserved. Management of *Fusarium* wilt is challenging [38, 39, and 40]. Several strategies have been put out to control this fungus pathogen. However, due to the introduction of new pathogenic strains, efforts to end the pandemic have mostly failed. The control of this pathogen is documented using a variety of techniques, including cultural, biological, resistance-based, chemical, and the use of natural materials (Pottorf, 2006).

**Control by Culture Practices**

Agriculture procedures and tactics that boost productivity and production while minimizing the consequences of illness are referred to as cultural control. To prevent plant diseases, it includes non-mechanical ecosystem manipulation. It requires altering agricultural methods to create a hostile environment for the growth of disease pathogen (Islam, 2001).It might also refer to the deliberate control of plant development, planting, and culture in a farm or yard to decrease plant disease. It has been found that treating soil-borne pathogens with cultural methods enhances soil composition, which minimizes the incidence of disease (Neshav, 2008). These techniques are mostly preventative, because controlling the spread of disease necessitates thorough understanding of the concept, habit, and environmental factors that the disease agent prefers. For a while, it was difficult to control soil- and seed-borne pathogens like *Fusarium* wilt, which is caused by a *Fusarium* species. To reduce fungus infestations and prevent disease issues unique to this type of vegetable, crop rotation with non-Solanaceous plants for 4-6 seasons is typically advised. Cereal crops should rotate with the grain whenever possible (Sally, 2006). Weed management, soil moisture management, and soil heating are all benefits of mulching, or topping the soil surface with a thick layer of mulch. As the tomato receives shadow from the maize and is grown out of season, intercropping of tomato and corn should be promoted in order to increase the farmer's productivity and profitability. This technique enhanced production in Cuba by 5–6 tones/ha per year. By creating unfavorable conditions for soil-borne microorganisms, it aids in disease control. The hydrated tomato leaves are kept free of soil-borne germs by mulching. The farmer's advantage and yield would improve as a result (Maurya *et al*, 2019). Diseases like *Fusarium* spp. can be avoided through weed control. The virus can infect plants when sick weeds are destroyed. The *Fusarium* wilt pathogen can more easily infect plants when they are subjected to excessive plant care techniques such tying, trimming, and pruning (Ajigbola and Babalola, 2013).

**Biological treatment**

The use of hostile microorganisms is a different disease prevention technique for having a *Fusarium* disease control system that is eco - friendly alternative (Lutenberg, 2009). Biological control agents can accomplish their objectives directly, indirectly, or through a combination of both (Pal and Gardner, 2006). There have been reports of great success using bio agents to control the *Fusarium* wilt disease on tomatoes (Freeman *et al,* 2002). Non-pathogenic *F. oxysporum* and *F. solani* were successfully identified and prevented *Fusarium* wilt in greenhouse testing (Momol, 2003). When applied quickly, CS-20, CS-1, CS-24, and Fo-47 were among the consistently effective isolates. Since being sprinkled with *Phytophthora cryptogea* zoospores and then injected with the disease's pathogen, tomato plants don't exhibit symptoms of wilt disease (Attitala *et al*, 2001). According to Kapoor and Kar (1988), *Arthobacter, Bacillus*, and *Pseudonomas* species are among the bacterial antagonists. 30 biological control agents, including bacteria and non-pathogenic strains of *Fusarium oxysporum*, have been identified by Lemanceae and Alabouvett (1991) and Fuchs *et al*. (1997) as having potential for controlling *Fusarium* wilt of tomato. In comparison to field circumstances, controlled greenhouse conditions have shown biological control agents to be more effective at decreasing *Fusarium*

wilt in tomato plants. *Fusarium oxysporum* f.sp. *lycopersici* incidence on tomato was found to be reduced by 6–15 percent by coating seeds with *Trichoderma viridae* culture (Panteleev 1973). An innovative disease management technique is the employment of antagonistic microorganisms, which can provide an eco-sustainable *Fusarium* disease control system (Lutenberg and Kamilova, 2009). According to Pal and Gardener (2006), the biological control agents' mechanisms may be direct, indirect, or a combination of both. According to Freeman *et al*. (2002) the application of biological agents was quite successful in preventing *Fusarium* wilt disease in tomato plants. Researchers have observed the inhibition of plant pathogens by halophilic and green manure, especially *Rhizoctonia, Phytopthora, Plasmidiophora brassicae*, *Gaeumannomyces graminis,* and *Fusarium* (Pitt *et al*, 1998,, Kannangowa *et al*, 2000, Cotxarrera, 2002). It was discovered that *G. intraradices* and a few gram-negative and fluorescent RB (rhizobacteria), *P. fluorescens*, *P. putida*, and *Enterobacter cloaceae*, were efficient against *Fusarium oxysporum* f. sp. Lycopersici in the rhizoplane of solanaceous plants (Akkopru and Dermir, 2005). The bacterial biocontrol agents *B. subtilis*, *Streptomyces corchorusii*, *S. pulcher*, and *S. mutabilis* have been shown to exhibit promising biocontrol actions against wilt (Monda,2002)]. By generating phytohormones including Indole acetic acid, Ethylene, Cytokinin, Gibberelin, and mineral elements, rhizobacteria can operate as biofertilizers and biostimulants. They can also provide as a passive barrier to harmful microorganisms by generating antibiotics and siderofore (McMillan, 2007 and Smith, 2007). According to Widnyana *et al*., (20130, three isolates of rhizobacteria known as *Pseudomonas alcaligenes,* KtS1, TrN2, and TmA1, were taken from the rhizobia of plants belonging to the families Solanaceae and Leguminoseae and demonstrated inhibitory action against *Fusarium oxysporum* f. sp. lycopersici by significantly lowering the wilt disease. Numerous crops are said to be induced to grow by biological agents. These responses could be brought on by (i) suppressing harmful root microflora, including those that aren't directly causing disease, and (ii) producing growth-stimulating substances. (iii) Improved root development and/or solubilization of nutrients, which resulted in an increase in nutrient intake. *Trichoderma* is one of the most well-known and frequently utilized organisms for promoting plant development and biologically controlling plant diseases (Shirzad *et al*, 2016, Vipin Kumar *et al*, 2017, Kloepper, 1993).

**Mechanisms of bio control by PGPB**

The fight for resources and space at the infection site, the creation of metabolites, and the modification of bacterial signalling molecules are frequently used as disease controls by BCA (biocontrols) (Raaijmakers *et al* 2002). All of these situations involve pathogens being agitated by the existence and actions of other species (Fig. 1). The release of substances like siderophores, which effectively sequester iron and deny the pathogen of this crucial element, is the key process of pathogen suppression via nutritional competition (Whipps, 2001). Some bacteria secrete metabolites, such as antibiotics, toxins, surface active substances (biosurfactants), and cell wall-degrading enzymes, which suppress the growth of pathogens (Compant *et al*,2005, Haas and Defago, 2005, Kumar *et al*, 2015). However, their particular byproducts also cause the induction of systemic resistance (Van Loon *et al*, 1998). Some *Bacillus* and *Pseudomonas* species produce several antibiotic substances that fight pathogenic bacteria, nematodes, helminths, fungus, and more (Thomashow and Weller, 1995, Raaijmakers *et al* 2002, Almaghrabi, 2013). Different bacterial strains, including *Pseudomonas* (Ligon *et al*, 2000), *Serratia* sp. (Kalbe *et al*, 1996), and *B. cepecia* (Burkhead, 1994), create secondary metabolites, such as pyrrolnitrin (3-chloro-4- (20-nitro-30-chlorophenyl) pyrrole, which is efficient against various infections. The primary tactics applied by BCA to suppress soil-borne pathogens are the production and release of cell wall-degrading enzymes (Kobayashi *et al*, 2003). The structural rigidity of the target pathogen's cell wall is impacted by these enzymes. B-1, 3-glucanase, chitinase, cellulase, and protease were the cell wall-degrading enzymes that biocontrol strains released (Budi *et al*, 2000). Plant Growth Promoting Bacteria shows Antagonistic Activity (Fig. 3).

**Use of Botanicals**

The use of medicinal herbs for the control of *Fusarium* wilt in crops is limited, despite the fact that numerous research activities have been made to identify alternative and environmentally acceptable strategies for controlling plant diseases (Agbenin, *et al*, 2004, Agbenin *et al*, 2006)). When compared to synthetic pesticides, plant metabolites and plant-based pesticides are recognised to have less of an adverse effect on the environment and pose fewer risks to consumers. Therefore, they seem to be one of the better alternatives. As natural products that are freely accessible and have no negative effects, the demand for plant-based therapies is rising in developing nations. The goal of the

current study was to assess the effectiveness of certain plant extracts in preventing the tomato wilt disease caused by *Fusarium oxysporum* f. sp. *lycopersici.* When compared to synthetic pesticides, plant metabolites and plant-based pesticides are recognised to have less of an adverse effect on the environment and pose less risk to consumers. Therefore, they seem to be among the better options. As natural products that are freely accessible and have no negative effects, the demand for plant-based therapies is rising in developing nations. The goal of the current study was to assess the effectiveness of certain plant extracts in preventing the tomato wilt disease caused by *Fusarium oxysporum* f. sp. *lycopersici.* Daradka *et al*(2021) were investigating the antifungal activity of ten plant extracts against A. *alternata* and F.*oxysporum*, the causative agents of tomato early blight and wilt diseases. The tested plants belonged to several families. Plant extracts had an inhibitory impact on *A. alternata* and *F. oxysporum* that ranged from 10-29 and 12-31 mm zone of inhibition, respectively. *Citrullus colocynthis*, *Psiadia arabica*, and *Olea chrysophylla* extracts were the most potent antifungals, followed by extracts of *Pulicaria crispa*. Using 50 plant extracts, Ramaiah and Garampalii (2015) assessed *in vitro* antifungal activity against *Fusarium oxysporum* f. sp. *lycopersici* (FOL) using the food poison approach. Three plants out of fifteen were shown to have the potential to slow the growth of the FOL: *Solanum indicum* (78.33%), *Azadirachta indica* (75.00%), and *Oxalis latifolia* (70.33 percent ). Three chemical fungicides, namely (Mancozeb with 82.66 percent, Copper oxychloride with 79.33 percent, and Copper sulphate with 82.33 percent) at various concentrations, were compared for their antifungal effectiveness. The antifungal crude extract at varying concentrations (ten percent, twenty percent, forty percent, and sixty percent) on the mycelial development of FOL was assessed using the poison food method.As a result of this work, it is possible to develop effective plant-based fungicides that can be utilised in organic farming to treat *Fusarium oxysporum* f. sp. *lycopersici* using botanical extracts as a better option.

**Application of Resistance Crop species**

The use of disease resistance, when available, is the most economical and environmentally secure way of control. The greatest method for disease control is the use of resistant cultivars, which is also one of the finest alternative methods for wilt disease management (Sheu *et al.,* 2006). But the utility of several resistant cultivars is limited to just a few years because of the loss of resistance in the face of significant pathogenic diversity in the pathogen population. For some plants, such as peas and China asters, cultivars that are resistant to or tolerant of *Fusarium* wilt are available. The other races of the same forma specialise may not be resistant to a cultivar that is resistant to a forma specialise (Burgess *et al,* 2008). Identification and usage of tomato plant types that are disease-resistant constitute a viable alternative to the use of chemicals (Pritesh and Subramanian, 2011). When there is no known dominant gene, breeding for resistance might be extremely challenging. The development of novel pathogen races that are able to overcome host resistance has also been reported by Momol and Pernenzy (2003). This approach has the benefits of reducing the cost of disease-controlling chemicals and maximising the cultivation of previously diseased fields.

**Chemical Control**

Chemicals are frequently used in agriculture to control diseases and pests. The incidence of tomato wilt is significantly decreased in seeds treated with synthetic fungicides. However, using them is expensive and environmentally harmful (Song and Goodman, 2001). The primary technique for managing plant diseases is fungicides, however biological agents, particularly *Trichoderma* species, are also effective at limiting the pathogenic activities of phytopathogenic fungus (Taran,2000). It is therefore crucial to implement a good management approach to combat tomato *Fusarium* wilt. Prochloraz, propiconazole, thiabendazole, carbendazim, benomyl, thiophane, fuberidazole, and all of the benzimidazoles are a few of these substances. Using the root dip treatment approach, benomyl was found to be only moderately effective against F. *oxysporum* f. sp. cubense (Nel *et al.* 2007). When this technique was used to treat *Fusarium* wilt-infected tomato seedlings, it increased yield by roughly 24 percent (Khan and Khan, 2002). The introduction of alternative approaches to disease management has been prompted by factors such as the high frequency of chemical usage, non-target effects, and the development of chemical resistance, the persistence of pathogens for long periods of time, and hazards to human health and the environment. Additionally, compared to their soil-borne competitors, insecticides are typically more effective against aerial plant diseases. The range of approved chemicals is dwindling as bioactive molecules are withdrawn for toxic effects and environmental reasons; for example, methyl bromide has already been carried out due to its extremely high potential to deplete the

ozone layer. It is also technically challenging to treat large amounts of soil. Chemical control techniques lead to microbial population imbalances that may be detrimental to the activities of beneficial soil microorganisms and may also encourage the emergence of infections with heightened resistance. Overuse of chemicals in the soil has polluted the environment and harmed humanity (Asaka and Soda, 1996). Chemical control techniques lead to microbial population imbalances that may be detrimental to the activities of beneficial soil microorganisms and may also encourage the emergence of infections with heightened resistance. Overuse of chemicals in the soil has polluted the environment and harmed humanity (Asaka And Soda, 1996). Some chemicals like Topsin-M, Nativo, Curzate, Carbendazim, Cabriotop, Prevail, and Antracol showed fungicidal activity against *Fusarium oxysporum f*.sp. *lycopersici.* Blosch *et al*. 2021investigated the effectiveness of fungicides, such as etalaxyl+mancozeb, copper oxychloride, benalaxyl+mancozeb, carbendazim, and mancozeb, at increasing doses (2, 2.5, 3, 3.5, and 4 g/litre water), against the *Fusarium* wilt of tomato affected by *Fusarium oxysporum* f. sp. The outcome showed that copper oxychloride was efficient in all of its doses to control the *Fusarium* wilt of tomato; the most effective dose was 3 g/l at which disease incidence was only recorded 6.2 percent.

## CONCLUSION

In summary, efforts should be focused on evaluating and improving these technologies' utility, productivity, and stability on the fields rather than merely in the greenhouse, aside from considering the fact that they are working in various ways. In biological control, it is also crucial to consider the specific microbial product compositions that would produce the best results. Therefore, a focus should be placed on training farmers on how to employ cultural traditions appropriately and how to incorporate them into other tactics for a healthier and cheaper outcome.

## ABSTRACT

Melanoma remains the most fatal form of skin cancer due to its rapid metastatic progression, making early and precise diagnosis essential for patient survival. Manual diagnosis through dermoscopy, although widely practiced, is limited by subjectivity and inter-observer variability. Deep learning has shown great promise in melanoma detection; however, achieving consistent performance across heterogeneous datasets, particularly the highly imbalanced SIIM–ISIC dataset, continues to pose challenges. This study introduces a Met heuristic-Optimized Ensemble Deep Intelligence Framework (MO-EDIF) that integrates advanced pre-processing, multi-architecture deep feature extraction, and a hybrid metaheuristic optimization algorithm. The framework employs adaptive contrast enhancement, lesion-focused cropping, and Test-Time Augmentation (TTA), followed by an ensemble of EfficientNet-B4, ResNet101, and Inception-V3. To further enhance performance, a novel Arithmetic–Jellyfish Hybrid Optimization Algorithm (AJHOA) is used to optimize hyper parameters and ensemble fusion weights. Experimental evaluation on the SIIM–ISIC dataset demonstrates that MO-EDIF achieves 93.8% accuracy, 92.5% sensitivity, 94.6% specificity, and an AUC of 0.962, surpassing state-of-the-art baselines. Ablation studies confirm the critical role of metaheuristic optimization in stabilizing ensemble learning. Findings suggest that MO-EDIF offers a robust and clinically relevant solution for high-precision melanoma diagnosis.

**Keywords:** Melanoma diagnosis, deep learning, metaheuristics, ensemble learning, SIIM–ISIC dataset, medical imaging, soft-voting, optimization.

# INTRODUCTION

Melanoma is the most aggressive form of skin cancer due to its ability to metastasize rapidly, often resulting in life-threatening outcomes if not detected early. Although melanoma accounts for a relatively small fraction of skin cancer cases, it is responsible for nearly 75% of global skin cancer–related deaths [1]. Early detection significantly improves prognosis, with survival rates exceeding 95% when melanoma is diagnosed at an early stage. However, the diagnostic process remains challenging in clinical settings due to heterogeneous lesion appearances, subtle malignant features, and visual similarities between melanoma and benign lesions. Dermoscopy has substantially improved skin lesion assessment by revealing sub-surface structures not visible to the naked eye [2]. Nevertheless, dermoscopic interpretation is influenced by clinician expertise, fatigue, and subjective judgment. High intra-class variability, where melanoma can take on diverse colors and shapes, combined with high inter-class similarity, where benign lesions mimic malignant patterns, further complicates diagnosis [3]. These challenges underscore the need for reliable, objective, and automated diagnostic systems capable of supporting dermatologists in early melanoma detection. Deep learning (DL) approaches, particularly convolutional neural networks (CNNs), have transformed computational dermatology by offering automated feature extraction and superior diagnostic performance compared to traditional machine-learning methods [4]. Benchmark datasets such as ISIC 2017–2020 and the SIIM–ISIC Melanoma Classification Challenge have catalysed research in automated melanoma detection [5]. Despite these advancements, DL-based systems still face three major challenges: (i) high model instability due to heterogeneous image distributions, (ii) sensitivity to hyper parameter choices, and (iii) severe class imbalance, with melanoma representing only ~2% of SIIM–ISIC images [6]. Ensemble learning has emerged as a promising approach to address variability by integrating multiple models that capture complementary feature representations [7]. However, ensemble performance heavily depends on the selection and weighting of individual models, which is typically performed heuristically. Furthermore, hyper parameter tuning in deep learning remains computationally expensive and inefficient when approached through manual trial-and-error. Metaheuristic optimization offers a powerful alternative due to its ability to perform global search in high-dimensional parameter spaces [8]. Algorithms such as Genetic Algorithms, Particle Swarm Optimization, and Jellyfish Optimization have demonstrated effectiveness in tuning deep-learning models; however, their use in ensemble-weight optimization for melanoma classification remains limited. To address these gaps, this study proposes the MO-EDIF framework, which integrates heterogeneous deep-learning models and optimizes them through a novel hybrid metaheuristic algorithm. The goal is to create a highly accurate, stable, and clinically reliable melanoma classifier.

**Literature survey, problem identification, research objectives, and contributions**

## LITERATURE SURVEY

Melanoma detection has progressed through several distinct research phases, each shaped by the limitations of previous approaches. Early work relied heavily on handcrafted features extracted from dermoscopic images. These included geometric indicators such as asymmetry, irregular borders, and variations in color patterns—commonly known under the ABCD rule [9]. Although these features made intuitive sense to dermatologists, their performance was inconsistent. Many benign lesions can appear irregular, while some melanomas remain deceptively simple in appearance. Studies such as those by [9] repeatedly noted poor generalization when handcrafted descriptors were applied to images from different devices, lighting conditions, or ethnic skin tones. The emergence of deep learning fundamentally changed the field. Convolutional neural networks (CNNs) demonstrated that models could learn discriminative patterns directly from image pixels. Architectures like VGGNet and ResNet became early favourites, quickly outperforming classical machine-learning pipelines. This shift was further accelerated with the introduction of deeper and more efficient networks such as DenseNet [10]. Despite these milestones, real-world deployment remains difficult. Datasets like SIIM–ISIC suffer from extreme class imbalance, often containing fewer than 2% melanoma cases. As noted by [11], this imbalance consistently pulls models toward high specificity but poor sensitivity, making them less reliable for early melanoma screening. In addition, dermoscopic images vary widely in appearance due to differences in acquisition devices, patient demographics, skin tone, and image artifacts such as

hair, air bubbles, shadows, and ink markings. Several studies [12] emphasize that these variations disrupt CNN learning unless carefully preprocessed. To counter these issues, ensemble learning has gained popularity. The intuition is straightforward: different architectures capture different visual cues, and their combination tends to yield more stable predictions. Researchers have experimented with soft voting, weighted voting, and stacked generalization, often reporting noticeable improvements [13]. However, the challenge lies in determining optimal ensemble weights. Most studies rely on manual tuning or simple grid searches. As point out, such methods are inefficient and do not fully exploit the potential of ensemble models [14]. This brings attention to another growing trend—metaheuristic optimization. Algorithms inspired by natural processes, such as Particle Swarm Optimization (PSO), Genetic Algorithms (GA), Jellyfish Search, and Arithmetic Optimization, have shown promise in optimizing neural network hyper parameters. They are particularly effective in complex, nonconvex search spaces [15],[16] While individual metaheuristic approaches have been applied in medical image classification, the literature shows very few attempts to optimize both hyper parameters and ensemble weights simultaneously, especially within the context of melanoma detection [17]. A further observation from recent literature is that most melanoma-related studies focus either on improving CNN architectures, enhancing data augmentation, or experimenting with loss functions (e.g., focal loss). However, very few studies bring together pre-processing, heterogeneous ensembles, and metaheuristic optimization into a unified framework specifically designed for the SIIM–ISIC dataset. This gap motivates the development of the proposed MO-EDIF framework, which attempts to integrate these otherwise separate research directions into a single optimized pipeline.

**Problem Identification**

**Based on the literature reviewed above, the following problems are consistently reported and remain insufficiently addressed**

1. Severe class imbalance (≈2% melanoma) leads to models biased toward benign predictions, significantly lowering sensitivity
2. High intra-class variability (melanoma can appear in many forms) and high inter-class similarity (benign lesions often mimic melanoma), making discrimination difficult.
3. Noise and artifacts in dermoscopic images—hair strands, ink marks, shadows—disrupt feature extraction
4. Hyper parameter tuning and ensemble weight selection are mostly manual, which is inefficient and suboptimal
5. Lack of unified, optimization-driven frameworks that combine pre-processing, CNN architectures, and metaheuristic strategies specifically for SIIM–ISIC.

These limitations reduce the reliability of existing models in clinical settings.

## RESEARCH OBJECTIVES

**To address the above challenges, the study defines the following objectives**

1. To develop a heterogeneous CNN ensemble (EfficientNet-B4, ResNet101, Inception-V3) capable of capturing diverse lesion characteristics.
2. To design a hybrid metaheuristic strategy (AJHOA) that jointly optimizes learning rate, batch size, dropout, and ensemble fusion weights.
3. To build a robust pre-processing and augmentation pipeline that reduces artifact-driven noise and dataset variability.
4. To validate the proposed framework on SIIM–ISIC using strong baselines, evaluation metrics, and ablation studies.
5. To investigate the contribution of metaheuristic optimization in improving sensitivity and stability under class imbalance.

**Major Contributions**

**This study offers the following contributions**

1. A task-specific hybrid optimization strategy (AJHOA) combining Arithmetic Optimization and Jellyfish Search, enabling automated tuning of critical hyper parameters and ensemble weights for melanoma classification.
2. A heterogeneous ensemble framework integrating EfficientNet-B4, ResNet101, and Inception-V3, leveraging complementary multi-scale and structural feature representations. AJHOA identifies optimal ensemble fusion weights.
3. A unified pre-processing and augmentation pipeline including hair removal, color normalization, lesion-centered cropping, and Test-Time Augmentation (TTA), improving image consistency across the SIIM–ISIC dataset.
4. A comprehensive experimental analysis showing that the metaheuristic-guided ensemble significantly outperforms individual backbones and non-optimized ensembles in accuracy, sensitivity, specificity, and AUC.

## PROPOSED METHODOLOGY

The Metaheuristic-Optimized Ensemble Deep Intelligence Framework (MO-EDIF) is an end-to-end pipeline designed to address the principal challenges identified in previous sections: image artifacts and variability, class imbalance, hyper parameter fragility, and heuristic ensemble weighting.

**MO-EDIF comprises five modular stages:**

i. Image pre-processing and augmentation,
ii. Backbone training and fine-tuning,
iii. Hybrid metaheuristic optimization (AJHOA),
iv. Metaheuristic-guided soft-voting fusion and threshold selection, and
v. Interpretation and post-hoc validation. Each stage is described below with the specific procedures used in our experiments.

**Dataset and Experimental Splits**

We perform experiments on the SIIM–ISIC Melanoma Classification dataset. Following standard practice and to ensure reproducibility:

**Total images:** 33,126 (as described in Section 4).

**Train / Validation / Test split:** 70% / 15% / 15% (stratified by class to preserve melanoma ratio).

**Class imbalance handling:** no oversampling in the primary split; imbalance is addressed in training via loss design and in evaluation by reporting sensitivity and AUC in addition to accuracy. All random splits use a fixed seed to ensure reproducibility.

**Image Pre-processing and Augmentation**

Pre-processing is applied deterministically to all images before model input; augmentation is applied during training and at test time as described.

**Artifact Detection and Removal**

**Hair/ink removal:** An enhanced Dull Razor pipeline is implemented: morphological top-hat filtering highlights thin, elongated structures; connected component analysis isolates hair candidates; small patches are in painted using a Telea-like in painting algorithm to preserve texture continuity. This step reduces false activations from occlusions (Patel and Zhao, 2020).

**Local Contrast Enhancement**

**CLAHE** (Contrast Limited Adaptive Histogram Equalization) is applied per channel to improve local contrast while avoiding over-amplification in homogeneous regions (Lopez and Ahmed, 2022).

**Lesion Localization and Cropping**
**If segmentation mask available:** crop tight bounding box around lesion + 10% padding.
**Otherwise:** compute approximate centroid using intensity-weighted centre; extract centred square crop.
**Resize:** All crops are resized to 224 × 224 (bilinear interpolation) to match the input size of selected backbones.

**Training Augmentations**
**Randomized augmentations applied per epoch**
**Rotation:** uniform [0°, 360°]
**Horizontal/vertical flips:** p = 0.5
**Random zoom:** 0.8–1.2 scale
**Color jitter:** brightness/contrast/saturation ±20% These increase model robustness to acquisition variability.

**Test-Time Augmentation (TTA)**
At inference, predictions are averaged over a deterministic set of K augmentations (rotations + flips). We used K = 8 in experiments; averaged probabilities are used for ensemble fusion.

**Feature Extraction: Heterogeneous Ensemble Backbones**
We employ three complementary CNN backbones to capture multi-scale, hierarchical, and texture information:
**EfficientNet-B4** —for efficient compound scaling and fine-detail modelling.
**ResNet101**— for deep hierarchical/residual feature learning.
**Inception-V3** — for multi-scale receptive fields and texture sensitivity.

**Model heads and initialization**
- All backbones are initialized with Image Net pretrained weights.
- For each backbone, we replace the final classification layers with: Global Average Pooling → Dropout (rate tuned) → Dense (1) with sigmoid.
- We fine-tune the entire network using AJHOA-suggested hyper parameters.

**Hybrid Metaheuristic Optimization (AJHOA)**
AJHOA (Arithmetic–Jellyfish Hybrid Optimization Algorithm) jointly optimizes training hyper parameters and ensemble fusion weights. The goal is to discover hyper parameter sets that yield robust base models and to allocate ensemble weights that maximize discrimination and calibration on validation data.

**Optimization variables (θ)**
**Learning rate (lr):** continuous, log scale ∈ [1e-6, 1e-2]
**Batch size (b):** discrete ∈ {8, 16, 32, 64} (encoded as integer)
**Dropout rate (d):** continuous ∈ [0.0, 0.6]
**Ensemble weights ($w_1$,$w_2$,$w_3$):** continuous, unconstrained during search; mapped to probabilities via softmax: $\widetilde{w}_i = \frac{e^{w_i}}{\sum_j e^{w_j}}$so that $\sum_i \widetilde{w}_i = 1$.

**Fitness Function**
We define a composite fitness evaluated on the validation split after a short warm-retraining (e.g., Nwarm = 5 epochs) to keep optimization tractable:
Fitness (θ)=α·(1−ErrorRateval) +β·AUCval−γ·ValLoss
We used example weights (alpha = 0.3, beta = 0.6, gamma = 0.1) to emphasize AUC and stable discrimination; these can be adjusted depending on application priorities (higher sensitivity vs. specificity).

**AJHOA High-Level Procedure**

**AJHOA alternates between AOA-driven exploration and JSO-driven exploitation:**

- **AOA phase (Exploration):** apply arithmetic transformations to generate a diverse population across each parameter dimension (broad search).
- **JSO phase (Exploitation):** apply Jellyfish-inspired local moves—passive drifting around promising solutions and active foraging towards best solutions—to refine candidates.

To avoid premature convergence, AJHOA includes mutation (Gaussian perturbation) and boundary reflection for variables exceeding ranges.

**AJHOA Pseudo code**

Algorithm 1 outlines the hybrid Arithmetic–Jellyfish Optimization Algorithm (AJHOA), which jointly searches for the optimal hyper parameters and ensemble fusion weights. The algorithm begins by initializing a population of candidate solutions and evaluating their fitness on the validation set. During the early iterations (exploration phase), Arithmetic Optimization (AOA) generates diverse candidate configurations by applying arithmetic transformations to encourage broad search across the hyper parameter space. After the exploration threshold is reached, the algorithm switches to the Jellyfish Search Optimization (JSO) exploitation phase, where each solution performs passive drifting or active foraging around the current best candidate to refine parameter values. Each updated candidate undergoes a short fine-tuning cycle to obtain a validation fitness score. Elitism is used to retain the top-performing solutions across generations, while Gaussian mutation introduces controlled randomness to avoid premature convergence. After the final iteration, the best solution $\theta^*$ is selected, and its raw ensemble-weight parameters are normalized via softmax to obtain the final fusion weights.

**Algorithm 1:** AJHOA – Hybrid Optimization for Hyper parameters and Ensemble Weights

Input:

**N -** population size

**MaxIter -** maximum iterations

**T_explore**- iterations allocated to AOA exploration (≈ 0.4 · MaxIter)

**Search space-** {lr, batch size, dropout, w1, w2, w3}

**Output**

**θ* -** best optimized solution

**(w1, w2, w3) -** normalized ensemble fusion weights

```
Initialize population {θ_i | i = 1...N} by uniform sampling in parameter ranges
Evaluate Fitness (θ_i) for all i
for iter = 1 to MaxIter do
    if iter ≤ T_explore then
        for each θ_i in population do
            θ_i' = AOA_Transform (θ_i)
        end for
    else
        best = argmax (Fitness (θ_i)) over all i
        for each θ_i in population do
            θ_i' = JSO_Move (θ_i, best)
        end for
    end if
    for each θ_i' do
        Perform short fine-tuning (N_warm epochs) using θ_i'
        Evaluate Fitness (θ_i')
    end for
    Combine old and new candidates
```

20: Select top-N solutions → new population
21: With probability p_mut:
22: Apply Gaussian perturbation to selected dimensions
23: end for
24: θ* = best solution in final population
25: (w1, w2, w3) = SoftMax (θ*.raw weights)
26: return θ*, (w1, w2, w3)

**Computational considerations**

To reduce runtime, AJHOA evaluates candidates using a short fine-tuning schedule (e.g., 5 epochs) or lower resolution proxies during early iterations; final best candidates are fully trained for final evaluation.

**AJHOA** – Hybrid Optimization for Hyper parameters and Ensemble Weights (Figure 1).

**Metaheuristic-Guided Ensemble Fusion and Decision Thresholding**

Following AJHOA convergence, we fuse the three backbone outputs using the optimized softmaxed weights:

$$P_{fused}(x) = \sum_{i=1}^{3} \widetilde{w}_i \cdot P_i(x)$$

Where Pi(x)are TTA-averaged probabilities from each base model. The binary decision threshold (τ) is selected by maximizing the Youden Index on validation:

τ∗=argmax (Sensitivity(τ)+Specificity(τ)−1)

This yields a clinically balanced operating point that can be adjusted based on screening priorities (e.g., prioritize sensitivity).

**Training Details and Regularization**

**Optimizer:** Adam with AJHOA-selected initial learning rate; weight decay of 1e-5.

**Loss:** Binary Cross-Entropy combined with Focal Loss ($\gamma$ = 2.0) to emphasize hard examples subject to class imbalance (Lin *et al.*, 2017). The combined loss is a weighted sum (0.5 BCE + 0.5 Focal) in our experiments.

**Epochs:** up to 50 with early stopping (patience = 10, monitored on validation AUC).

**Regularization:** dropout (AJHOA-selected), L2 weight decay, and data augmentation.

**Hardware:** NVIDIA T4 GPU (single card used for experiments; multi-GPU training can speed up backbone fine-tuning).

**Evaluation Protocol and Statistical Analysis**

**Metrics reported:** Accuracy, Sensitivity (Recall for melanoma), and Specificity, AUC (ROC), and confusion matrix values.

**Statistical significance:** For main comparisons, we report mean ± standard deviation across 5 random seeds and perform paired t-tests where relevant to assess significance ($p < 0.05$) between MO-EDIF and baseline ensembles.

**Ablation suite**

- Single-backbone baselines (each model trained with best AJHOA hyper parameters independently).
- Ensemble without optimization (equal weights, best manual hyper parameters).
- Ensemble with hyper parameter optimization only (equal weights).
- Ensemble with weight optimization only (manual hyper parameters).
- Full MO-EDIF (joint optimization).

These ablations quantify the contribution of AJHOA and pre-processing components.

**Interpretability and Post-hoc Validation**

- Grad-CAM maps are generated for representative true positives, false negatives, and false positives to qualitatively inspect whether attention is focused on lesion structures rather than artifacts (Lopez and Ahmed, 2022).
- **Failure analysis:** examine false negatives for common patterns (e.g., small lesions, heavy occlusion) to guide future improvements.
- **Cross-dataset sanity check (optional):** transfer test on a small held-out external dataset (e.g., HAM10000) to gauge generalization beyond SIIM–ISIC.

**Reproducibility**

To facilitate reproducibility, we provide the following in supplementary material (or upon request):

- AJHOA pseudo code and parameter settings.
- Exact data split indices and random seeds.
- Backbone architecture details and code snippets for pre-processing.
- Final model weights and evaluation scripts.

## RESULTS AND DISCUSSION

This section presents the empirical evaluation of the proposed Metaheuristic-Optimized Ensemble Deep Intelligence Framework (MO-EDIF) on the SIIM–ISIC melanoma classification dataset. Results are reported in five parts: baseline comparisons, confusion matrix and ROC analysis, ablation studies, impact of the hybrid metaheuristic optimizer, qualitative analysis using interpretability methods, and statistical significance assessment. Together, these analyses demonstrate both the quantitative and qualitative strengths of the proposed approach.

**Performance Comparison with Baselines**

**Summary of Primary Results**

Table 1 summarizes classification results for single backbones, a non-optimized ensemble (equal weights), and the proposed MO-EDIF model optimized through AJHOA. The values for each model correspond to the standard test split described in Section 3. Classification Performance (Table 1).

The results clearly demonstrate the advantage of meta heuristically guided ensemble learning:

**Accuracy Improvement**

MO-EDIF boosts accuracy by 3.0 percentage points over the non-optimized ensemble (90.8 → 93.8%) and by 4.5–7.4 points compared to individual backbones.

**Sensitivity (Critical Clinical Metric)**

MO-EDIF achieves 92.5% sensitivity, significantly higher than any single backbone (range: 78.5–82.4%). This reflects improved detection of melanoma cases—the minority and clinically most important class.

**Discriminative Power (AUC)**

An AUC of 0.962 shows excellent separability between malignant and benign lesions. This is substantially higher than single CNNs (0.892–0.914), indicating that AJHOA contributes to improved ranking across varying decision thresholds. Overall, Table 1 confirms that joint AJHOA optimization of hyper parameters and ensemble weights materially enhances discrimination, calibration, and class-balanced performance.

**Multi-Run Stability Analysis**

To assess generalizability, we trained each model across five random seeds. The mean ± standard deviation of test metrics is presented in Supplementary Table 2. Performance Across 5 Independent Runs (Table 2). MO-EDIF exhibits the lowest performance variance, highlighting improved stability across training seeds. Individual models show

higher sensitivity variance, reflecting susceptibility to class imbalance. The equal-weight ensemble improves consistency over single backbones but remains clearly inferior to the optimized ensemble.

**Statistical Significance Tests**

Paired t-tests were used to compare MO-EDIF with baseline ensembles and single backbones across five runs. All improvements were statistically significant at $\alpha = 0.05$. MO-EDIF vs. Equal Weight Ensemble (Paired t-Test) (Table 3). All p-values fall far below 0.05, confirming that MO-EDIF's improvements are unlikely due to randomness. MO-EDIF vs. Individual Backbones (Table 4). These results show that MO-EDIF consistently and significantly outperforms all baselines in every metric.

**Confusion Matrix and ROC Analysis**

**Confusion Matrix**

The confusion matrix for the MO-EDIF test results is shown below:

Confusion Matrix (Table 5).

- High true negatives (4202) relative to false positives (242) correspond to the strong specificity (94.6%) reported.
- False negatives (40) are substantially fewer than true positives (486), aligning with the model's high sensitivity (92.5%).
- Despite the severe class imbalance (melanoma ≈ 2%), the model maintains a favorable balance of sensitivity and specificity, critical for clinical triage systems.

**ROC Curve and AUC**

- MO-EDIF achieves AUC = 0.962, demonstrating excellent discriminatory ability across varying decision thresholds.
- Compared to single CNN backbones (AUC = 0.892–0.914), MO-EDIF significantly improves global separability between malignant and benign lesions.
- The large AUC margin confirms that AJHOA-optimized fusion provides a more calibrated and reliable score distribution.

**Sensitivity–Specificity Trade-offs**

Threshold selection via the Youden Index ensures a balanced clinical operating point. Because of MO-EDIF's high AUC, the threshold can be adjusted:

- Increasing sensitivity → fewer missed melanomas (reducing false negatives).
- Slight acceptable rise in false positives can still maintain manageable specificity.

This flexibility is key for real-world deployment where the cost of a false negative is substantially higher than that of a false positive.

**Ablation Study Results**

To evaluate the impact of each component in MO-EDIF, ablation studies were conducted. Supplementary Table S4 summarizes the findings.

**Ablation Study (Table 6).**

**Effect of Pre-processing**

Removing pre-processing (hair removal, CLAHE, lesion cropping) results in:

- ~1.5% accuracy drop
- ~12% sensitivity drop compared to the optimized model
- ~0.059 AUC reduction

This demonstrates that artifact suppression and contrast normalization significantly improve the quality of learned features.

**AJHOA Hyperparameter Optimization**

Optimizing lr, batch size, and dropout alone yields noticeable improvements over manually tuned hyper parameters. This confirms that backbone training stability and sensitivity are strongly dependent on hyper parameter selection.

**Ensemble Weight Optimization**

Learning ensemble fusion weights provides a consistent AUC improvement over equal-weight fusion. MO-EDIF assigns higher weights to models that generalize better within the SIIM–ISIC distribution.

**Effect of Test-Time Augmentation**

TTA yields small but reliable performance gains, reducing variance and improving stability on borderline lesions.

**Combined Effect (Full MO-EDIF)**

Integrating all components produces the highest performance across all metrics:

- 93.8% accuracy
- AUC = 0.962
- lowest ± standard deviation across runs

This demonstrates that each module contributes additively, with AJHOA providing the largest incremental benefit.

**Impact of the Hybrid Metaheuristic (AJHOA)**

**Convergence Behaviour**

AJHOA exhibits a two-stage convergence pattern:

**AOA exploration phase:** Rapid diversification, broad search across hyper parameter and weight space.

**JSO exploitation phase:** Fine-grained improvement, reduction in variance, stabilization around optimal regions.

Compared to single-strategy optimizers (PSO, GA), AJHOA converges to higher fitness values with fewer iterations.

**Stability across Seeds**

Models trained with AJHOA-selected configurations show:

- Lower variance across seeds
- Higher consistency in both validation and test metrics
- More stable learning curves and fewer oscillations during fine-tuning

This suggests that AJHOA increases robustness against stochasticity inherent in mini-batch training.

**Comparison with Other Optimizers**

**AJHOA vs. Other Optimizers (Table 7).**

AJHOA delivers the best performance and fastest convergence, benefiting from both systematic exploration and guided exploitation.

**Qualitative Analysis (Grad-CAM)**

**Visual Examination of Heatmaps**

Grad-CAM visualizations for true positive classifications show strong focus on:

- Pigmentation patterns
- Irregular borders
- Dermoscopic structures such as streaks and atypical networks

This indicates that the ensemble learns clinically meaningful features.

**Attention vs. Artifacts**

Even in images where residual hair or ink remained after pre-processing, Grad-CAM highlighted the lesion region rather than artifacts—confirming the value of the pre-processing pipeline.

**Failure Case Patterns**

False negatives often correspond to:

- Very small lesions
- Low-contrast melanomas
- Heavily occluded images

False positives typically involve benign atypical lesions with irregular patterns that resemble melanoma. These insights highlight opportunities for future improvements, such as higher-resolution models and metadata integration.

**Statistical Significance and Confidence Intervals**

All primary comparisons were evaluated using paired t-tests or Wilcoxon tests where assumptions of normality were violated.

- MO-EDIF's improvement in accuracy and AUC over baseline ensembles is statistically significant ($p < 0.05$), with p-values reported in Supplementary Table S2.
- Confidence intervals for MO-EDIF reinforce the robustness of these improvements.

Confidence Intervals (Table 8). The narrow confidence intervals indicate high reliability and low variance across runs. Across all analyses—point metrics, variability measures, confusion matrix, ROC curves, ablation studies, optimizer comparisons, and qualitative inspections—the MO-EDIF framework consistently outperforms both single CNN backbones and non-optimized ensembles. The hybrid AJHOA metaheuristic is shown to significantly and reliably enhance performance, with clear clinical implications for high-precision melanoma diagnosis. MO-EDIF successfully addresses the key practical challenges highlighted in the literature: it raises sensitivity (critical for early detection), improves ranking performance (AUC), and yields stable results through joint metaheuristic optimization. While parts of the pipeline (CLAHE, DullRazor, and Efficient Net/ResNet/Inception) are standard, their integration and the joint AJHOA optimization provide meaningful, measured gains.

## LIMITATIONS AND FUTURE WORK

- The approach is computationally heavier than single-model solutions; a detailed runtime / GPU-hour analysis should be included to inform deployment decisions.
- Cross-dataset generalization needs further validation; a transfer experiment to HAM10000 or Derm7pt is recommended.
- Further work could examine lightweight variants for deployment on mobile dermoscopy devices and explore transformer-based backbones in the ensemble.

## CONCLUSION

This study introduced the Metaheuristic-Optimized Ensemble Deep Intelligence Framework (MO-EDIF), a unified pipeline designed to address the persistent challenges of melanoma diagnosis from dermoscopic images, including severe class imbalance, heterogeneous lesion appearances, image artifacts, and hyper parameter sensitivity. By integrating advanced pre-processing, heterogeneous CNN backbones, and a novel hybrid metaheuristic optimizer (AJHOA), the framework delivers a robust and stable approach to high-precision melanoma classification. Extensive experiments on the highly imbalanced SIIM–ISIC dataset demonstrate that MO-EDIF consistently outperforms individual models and traditional ensembles across all major evaluation metrics. The optimized ensemble achieved 93.8% accuracy, 92.5% sensitivity, 94.6% specificity, and an AUC of 0.962, establishing clear improvements in both discrimination and clinical utility. Ablation studies further confirm that each component—artifact-aware pre-processing, backbone diversity, and joint metaheuristic optimization—adds measurable value, with AJHOA contributing the largest performance gains through stable hyper parameter and ensemble-weight selection. Statistical tests validated that all improvements over baselines are significant at $p < 0.05$, reinforcing the reliability and

reproducibility of the results. Despite these strengths, MO-EDIF has two primary limitations: its relatively high computational cost compared to single-model systems, and the need for broader cross-dataset generalization studies. Future work will therefore focus on (i) developing lightweight variants suitable for mobile or point-of-care diagnostic platforms, (ii) incorporating transformer-based or self-supervised vision models into the ensemble, (iii) exploring cost-sensitive or clinically adaptive decision thresholds, and (iv) validating the framework on external datasets such as HAM10000, Derm7pt, or real clinical workflows. In summary, the proposed MO-EDIF framework demonstrates that combining heterogeneous deep architectures with hybrid metaheuristic optimization can substantially enhance melanoma detection performance. The findings highlight the clinical relevance and translational potential of meta heuristically guided ensemble intelligence for early skin cancer diagnosis.

## ABSTRACT

This study seeks to undertake a comprehensive webometric analysis of the digital presence and online visibility of the Indian Institutes of Science Education and Research (IISERs) during 9th-12thOctober2025. Using multiple evaluative criteria, the study examines the websites of all 7 IISERs, including web analytic indicators like bounce rate, average visit duration, page per visit, and total visits, site popularity scores, domain authority, page authority, available rich files, total number of web pages, internal and external links, Google PageRank, marketing channels. Data were collected throughout the study period using the Google search engine, selected search engine optimization (SEO) tools, and manual verification to ensure accuracy and consistency. In addition, web impact-namely the Simple Web Impact Factor (SWIF), Internal Web Impact Factor (IWIF), and External Web Impact Factor (EWIF)-were calculated to provide comparative insights and facilitate the ranking of IISERs based on their relative authority and visibility. The findings revealed substantial variations among the institutions in terms of digital visibility, authority and web impact with the Indian Institute of Science Education and Research Pune consistently outperforming other IISERs across most indicators. Notably, this study represents one of the earliest systematic attempts to evaluate IISER websites, and its findings offer valuable implications for policymakers, institutional administrators, and web developers seeking to enhance the digital presence and institutional visibility of the IISERs in an increasingly competitive academic environment.

**Keywords:** IISER, Indian Institute of Science Education and Research, Web Analytics, Webometric, Web Page Analysis, Ranking Evaluation, Site Popularity, Google PageRank, Rich Files.

## INTRODUCTION

In the contemporary digital environment, institutional websites have become vial determinants of visibility, accessibility, and international standing. Within higher education, websites serve not merely as sources of information but as strategic platform that facilitate academic outreach, collaboration and engagement with diverse stakeholders. Bjoneborn (2004) conceptualized webometrics as the quantitative study of the development and utilization of web-based information resources, structures, and technologies, grounded in bibliometric and informetric methodologies. Accordingly, indicators such as domain authority, web link structures, and web impact factors are extensively used to assess and compare the online presence and influence of academic institutions across the globe.Webometric research conducted on universities, colleges, and libraries in India has emphasized the necessity for enhancing website design, online visibility, and overall web performance. However, limited scholarly attention has been directed toward the Indian Institutes of Science Education and Research (IISERs), despite their status as some of the country's most prestigious science education institutions. Established between 2006 and 2016, the 7 IISERs have achieved significant academic distinction, yet their digital presence remains uneven and insufficiently examined. The main issue addressed in this study is the limited understanding of the relative visibility and online influence of the Indian Institutes of Science Education and Research (IISER) websites, despite their role as official portals for researchers, prospective students, and another stakeholder worldwide. To address this gap, the study applies a range of webometric indicators to evaluate the websites of all 7 IISERs. The parameters examined include web analytics indicators like bounce rate, visit duration, pages per visit, and total visits, site popularity scores, domain and page authority, rich files, Google PageRank. Furthermore, the study computes web impact factor-namely the Simple Web Impact Factor (SWIF), Internal Web Impact Factor (IWIF), and External Web Impact Factor (EWIF)- to rank the IISERs and identify areas requiring improvement. A strong digital presence is essential for enhancing global competitiveness, whereas deficiencies in web performance may limit institutional outreach and reputation.

## REVIEW OF LITERATURE

A substantial body of webometric research has examined the online presence of various categories of educational institutions in India. For example, Devaki and Ranganathan (2025) conducted webometric studies on both Indian Open Universities and the Indian Institutes of Management, highlighting variations in visibility and web performance across institutions. Yadav *et al*. (2024) analysed the National Institutes of Technology, while Suman, Patel and Kishore (2024) focused on state universities in Bihar. Additional studies include examinations of Indian Physical Education colleges by Bakkiyaraj and Kalidasan (2023), state universities in Assam by Dey and Sarmah (2023), and Central Universities in Eastern India Suman and Patel (2023). Earlier investigations assessed state universities in Andhra Pradesh conducted by Madhuri, Babu and Ramesh (2013) and the Indian Institutes of Technology analysed by Madhusudhan and Prakash (2013). Comparable webometric studies have also been undertaken internationally, including evaluations of Iranian Medical Universities by Dastani, Panahi and Sattari (2019) and Tafaroji *et al*. (2014). Although a limited number of studies have addressed science education institutions, further systematic evaluation remains necessary. Accordingly, research of this nature contributes to a more comprehensive assessment of major technical and higher education institutions in India by enhancing understanding of their digital presence and web performance.

## SCOPE OF THE STUDY

This study conducts a webometric analysis of the websites of the Indian Institutes of Science Education and Research (IISERs) in India. At present, there are 7 IISERs across the country. The primary objective of the study is to develop an academic ranking of IISER websites based on web impact factors and link analysis indicators.

## OBJECTIVE OF THE STUDY

1. To found the top-level domain extension of the IISER websites.
2. To carry out the web analytic indicators
3. To analyse the site popularity scores of the IISER websites.
4. To show the domain and page authority and rich files.
5. To assess the internal, external, total links and web pages of the websites.
6. To calculate the web impact factor of three (Simple, Internal and External).
7. To found the Google PageRank and Marketing Channels of the IISERs.

## METHODOLOGY

This study employed a quantitative research design using a webometric approach to evaluate the digital presence and online visibility of the Indian Institutes of Science and Research (IISERs). All seven IISERs currently operating in India were included in the analysis, ensuring comprehensive coverage of the study population. Data were collected using a combination of Search Engine Optimization (SEO) tools and search engine queries. Specifically, tools such as Seomator and Similarweb were used to obtain website performance. In addition, the Google search engine was utilized to retrieve data on indexed web pages and rich files availability using advance query syntax (site:URLfiletype:pdf). Manual inspection of each institutional website was also conducted to verify the accuracy and consistency. The collected data were systematically tabulated and analyzed using Microsoft Excel to compute various webometric indicators, including web impact factors. Data collection was carried out over a defined period, from 9th-12th October 2025, to ensure temporal consistency in the results.

**Data Analysis and Interpretation**

**Year of Establishment and Domain Extension**

From Table 1 it is clear that the seven IISERs were established between 2006 and 2016 across the country. All seven institutions have the same domain extension, ". ac.in". Table 1 List of Indian Institutes of Science Education and Research in India *(Source: https://www.education.gov.in/en/iisc-bangalore-iisers*)

**Web Analytics of the IISER**

Web analytics is the process of gathering, measuring, analysing, and reporting statistics on website usage in order to understand how people interact with a website and how well it fulfils its objective. It gives information about user behaviour, traffic sources, popular content, bounce rate, total visits, visit duration and engagement trends. The bounce rate is the proportion of website visitors who leave after just seeing one page. A bounce rate of 60% or above may indicate that the university needs to improve the website's content to make it more engaging for users. A bounce rate of 40% or less is ideal. It is clear from the table below that IISER Thiruvananthapuram need to examine its bounce rate (54.12%) whereas IISER Bhopal has a respectable bounce rate (30.12%). The average amount of time visitors spend on a website is measured by the average visit duration. A lengthy average visit duration may indicate that users find the website fascinating and spend a lot of time perusing its material. Users may not be able to find more interesting material on a website with a short average visit duration. The table below shows that IISER has a short visit duration of 01.05 and IISER Berhampur has a long visit duration of 04.23. The number of websites that a certain user or group of users views on single website is known as pager per visit. High-quality content on a specific website and its related content is typically indicated by a higher number of pages per visit. A low number of pages per visit may be a sign of either insufficient content or challenging navigation. According to the following table, IISER Pune has 3.05 with little content or is hard to navigate, while IISER Kolkata has 5.88 with excellent content. A total visits metric calculates the total number of visitors to a website over a given time period. As a consequence, Table 2 shows that IISER Bhopal has the highest visitation of 2,22,139, while IISER Tirupati has the lowest at 22,966. Web Analytics of IISER Websites (Table 2).

**Site Popularity Scores**

The popularity score of a website is another important element that helps promote it. Page views and unique site visits are combined to determine a website's score. The popularity scores of the seven IISERs are shown in Table 3. IISER Tirupati has the highest score among the websites at both the global and country scores (9,87,006 and 76,850, respectively), according to the data. At both the global and country levels, IISER Bhopal has the lowest score (1,59,419 and 11,856 respectively), and among the websites IISER Pune and IISER Kolkata don't have sufficient data. Site Popularity Scores of IISER Websites (Table 3).

**Domain and Page Authority**

The performance of a website or domain in search results is predicted using a metric known as domain authority. A website is more likely to score highly in search results if it has a high domain authority. IISER Pune has a high domain authority of 52, ranked first, but IISER Tirupati has a low domain authority of 36, ranked last, according to Table 4. Domain and Page Authority of IISER Websites (Table 4). The ability of a page to rank in a search engine is evaluated by page authority. A page that has a high page authority is more likely to rank highly in search engine results. The table below show that IISER Berhampur has the lowest score of 36, ranked last, while IISER Pune and IISER Thiruvananthapuram have the highest score of 46 and ranked first.

**Rich Files**

Rich files are a variety of file formats for electronic documents. For this study, five rich file formats '.pdf', '.doc', '.ppt', '.ps', '.xls' were selected, retrieved, and tabulated. In order to examine the rich files of the selected websites, this study used google, the largest and most popular search engine, to collect raw data. Rich files are dominated by PDFs as seen in Table 5. With 1,04,680 rich files, IISER Pune is in lead, ranked first, while IISER Berhampur with13,568 rich files ranked seven. Rich Files of IISER Websites (Table 5).

**Links Analysis and Web Pages**

Table 6 presents the number of internal links, external link, total links, and number of web pages of the IISERs. The IISER Bhopal ranked first, with a total of 279, which incorporates 171 internal links and 108 external links. IISER Mohali placed last with a total of 131, including 109 internal links and 22external links. According to the number of web pages, IISER Berhampur seized first place with 344539, followed by IISER Tirupati with a total number of 255692 web pages. Link Analysis and Web Page of IISER Websites (Table 6).

**Web Impact Factors**

Table 7 displays the WIF scores for the IISER websites. The SWIF is calculated by dividing the total number of links on the website by the total number of sites. While IWIF is calculated by dividing the total number of internal links by the total number of webpages on that website. EWIF is determined by dividing the total number of external links by the total number of websites on that particular website. For SWIF, IISER Kolkata secured first rank (0.00270), and for IWIF, IISER Pune seized first rank with 0.00205. IISER Bhopal is ranked first for EWIF with 0.00095. Web Impact Factors of IISER Websites (Table 7).

**Google PageRank**

Links from several websites are seen as endorsements by Google PageRank algorithms which assign a popularity rating between 1 and 10. According to the Table 8, IISER Pune and IISER Kolkata have a PageRank of 5, ranked first place, while the remains are have PageRank of 4, ranked second place. Google PageRank of IISER Websites (Table 8).

**Marketing Channels**

Overall, Table 9 make it quite evident that the institutes' primary marketing channel wasOrganic Search (62.15%), with Direct (30.15%) being the secondary channel. According to the table, all the seven institutes' preferable channel was organic search, followed by direct. Marketing channels of IISERs (Table 9).

**Major Findings**

- All seven Indian Institutes of Science Education and Research (IISERs) were established between 2006 and 2016, and all institutions operate under the "ac.in" domain.
- IISER Bhopal recorded a favourable bounce rate (30.12%), IISER Berhampur exhibited the longest average visit duration of 04.23 minutes, IISER Kolkata achieved a content score of 5.88, andIISER Bhopal registered the highest website visitation with 2,22,139 total visits.
- IISER Tirupati attained the highest global rank of 9,87,006 and country rank of 76,850 among the IISERs.
- IISER Pune achieved the highest domain authority score of 52,while IISER Pune and IISER Thiruvananthapuram shared the highest page authority score of 46, ranking first.
- IISER Pune led in the availability of rich files, with 1,04,680 files indexed, securing the first rank.
- The IISER Bhopal ranked first in the link analysis with a total of 279 links, comprising 171 internal links and 108 external links. In terms of the number of indexed web pages, IISER Berhampur secured the first position with 344539 pages.
- Woth respect to web impact factors, IISER Kolkata secured the first rank for the Simple Web Impact Factor (SEIF) with a value of 0.00270, IISER Pune ranked first for the Internal Web Impact Factor (IWIF) at 0.00205, and IISER Bhopal achieved the highest External Web Impact Factor(EWIF)of 0.00095.
- IISER Pune and IISER Kolkata both recorded a PageRank score of 5, placing them jointly in the first position.
- Analysis of traffic sources revealed that organic search served as the primary marketing channel for IISER websites, accounting for 62.15% of total traffic.

## CONCLUSION

This study evaluates the websites of 7 Indian Institutes of Science Education and Research (IISERs) in India by examining a range of webometric indicators, including web analytics, popularity scores, web impact factors, availability of rich files, Google PageRank, marketing channels, link analysis, and ranks the institutions accordingly. The findings indicate that the Indian Institute of Science Education and Research Pune consistently performs strongly across most webometric measures. The study identifies both the strengths of IISER websites and areas requiring improvement, highlighting the need for enhanced digital platforms to increase institutional visibility and improve overall user satisfaction. Moreover, the study underscores the importance of extending similar webometric evaluations to teacher education institutions and other technical institutions across India, thereby contributing to a more comprehensive understanding of the digital landscape of higher education and informing strategies for achieving a more effective and competitive digital presence.

## ABSTRACT

This paper presents a novel Artificial Neural Network (ANN)-based Decision Support System (DSS) that utilizes intuitionistic fuzzy matrix information, aggregated through a newly developed Hamming distance-influenced operator. The study investigates the effectiveness of combining multiple learning rulesincluding backpropagation with momentum, delta, Levenberg–Marquardt, Perceptron, and correlation-inspired updateswithin the ANN framework to address Multiple Attribute Group Decision Making (MAGDM) problems under intuitionistic fuzzy environments. A comprehensive analysis of aggregation operators and learning mechanisms demonstrates their capability to handle uncertain and imprecise data effectively. The proposed momentum-based backpropagation enhances convergence speed and stability, while the other learning rules provide alternative perspectives on the ranking process. The framework is validated through a numerical example, showing that the integration of these learning strategies improves accuracy, reduces bias, and outperforms conventional ANN approaches in MAGDM scenarios. These results underline the potential of the proposed system to deliver more robust and intelligent decision-making solutions.

**Keywords:** MAGDM, ANN, Learning Rules, Aggregation operators, Back Propagation, Intuitionistic Fuzzy sets.

## INTRODUCTION

Artificial Neural Networks (ANNs) are computational frameworks designed to operate as parallel distributed systems that emulate the cognitive and adaptive behavior of the human brain. These models serve as mathematical

abstractions of biological neural processes and are capable of processing information through interconnected artificial neurons. Each neuron acts as a fundamental processing entity, transmitting signals to other neurons through weighted interconnections. The associated connection weights determine the strength and direction of influence among neurons, and the aggregated input is transformed through an activation function that regulates the neuron's output. An ANN is generally characterized by three essential components: its architecture, representing the structural configuration of inter-neuronal connections; its activation function, defining the nonlinear transformation of inputs; and its learning strategy, which governs the adjustment of connection weights through either supervised or unsupervised mechanisms. The conceptual design of an artificial neuron draws inspiration from biological neurons, wherein the output is determined entirely by the sum of weighted inputs. While conventional digital computers perform computations sequentially, neural networks inherently employ parallel information processing, rendering them suitable for tasks such as image analysis, pattern recognition, and speech processing—domains that demand high levels of parallelism similar to that of the human brain.

Several researchers have made significant contributions to the theoretical and practical advancements of ANNs ([1]–[4], [9], [10], [11], [13]). In parallel, numerous studies ([6]–[8], [11], [14], [15]) have focused on the development of aggregation operators for Multiple Attribute Group Decision-Making (MAGDM) problems. Furthermore, the integration of fuzzy logic and machine learning methodologies has been explored in [3], [5], [11], and [12] to address uncertainty and imprecision in complex decision-making environments. Despite extensive research in these areas, limited attention has been given to the incorporation of intuitionistic fuzzy environments within ANN structures, particularly in the context of backpropagation-based learning models. In this chapter, an innovative framework is introduced that combines the capabilities of Intuitionistic Fuzzy Sets (IFSs) with the adaptive learning power of neural networks. The proposed model employs a newly formulated Intuitionistic Fuzzy Power Generalized Weighted Averaging (IFPGWA) operator, which flexibly accommodates diverse distance and similarity measures to construct representative input patterns for the neural network. The model, termed Backpropagated Intuitionistic Fuzzy Neural Network (BP-IFNN), provides a more resilient and interpretable decision-support mechanism, particularly when the available information is incomplete or uncertain. The performance of the proposed system is subsequently assessed by comparing its outcomes with existing ANN-based methods and alternative ranking procedures, thereby validating its efficiency and reliability in addressing complex MAGDM scenarios.

In this study, the Backpropagation with Momentum approach is utilized to accelerate convergence by incorporating a memory term that smooths weight updates and avoids oscillations. The Delta Learning Rule is employed to fine-tune connection weights based on the instantaneous error gradient, ensuring precise local adjustments during training. The Levenberg–Marquardt algorithm is integrated for its hybrid optimization capability that balances the advantages of gradient descent and Gauss–Newton methods, enhancing the network's adaptability to nonlinear patterns. The Perceptron Learning Rule contributes a foundational perspective by enabling linear separability within the intuitionistic fuzzy data representation. Finally, a Correlation-Inspired Learning Rule is introduced to align weight modifications with the relational strength between alternatives and attributes, thereby reinforcing decision reliability in the MAGDM process.

**The Back Propagation Method in Ann**

Since their origin, Artificial Neural Networks (ANNs)which are inherently recursive and nonlinear learning systems—have played a transformative role in modern machine learning. The effectiveness of any ANN model depends primarily on its training process, as appropriate weight adjustments determine the accuracy and generalization capability of the network. Among the various training strategies, the backpropagation algorithm remains the most widely adopted due to its mathematical elegance and efficiency. This algorithm employs the chain rule of calculus to evaluate how changes in individual connection weights influence the overall loss function, thereby guiding the optimization process. Unlike conventional computational models that provide limited interpretability regarding gradient flow, backpropagation systematically computes and propagates error derivatives layer by layer, thereby refining the delta learning rule into a generalized gradient-based learning approach.

Conceptually, the backpropagation procedure involves two distinct computational phases. During the forward pass, the input data traverse the network sequentially from the input layer to the output layer. Each neuron aggregates its inputs through weighted summation, applies a nonlinear activation function such as the sigmoid, hyperbolic tangent, or ReLU, and transmits the resulting signal to the next layer. The network's predicted output is then compared with the target output to compute the error value. In the backward pass, the computed error is propagated in the reverse direction—from the output layer back to the input layer—allowing the algorithm to determine the gradient of the loss function with respect to each weight. These gradients are subsequently used to update the weights via optimization strategies such as gradient descent or its variants, ensuring progressive error minimization across successive epochs.

An ANN typically comprises several integral components:

- Input Layer, which receives and encodes the feature set;
- Hidden Layers, responsible for extracting complex, nonlinear relationships within the data;
- Output Layer, which produces the final prediction or classification result;
- Loss Function, which quantifies the discrepancy between the predicted and actual outcomes; and
- Learning Rate, which regulates the magnitude of weight adjustments during training.

The backpropagation method offers several notable advantages. It supports the universal approximation property, enabling feedforward networks to approximate any continuous function given sufficient neurons and layers. Its adaptive learning capability allows it to model intricate nonlinear mappings found in real-world data. Moreover, the algorithm ensures systematic error reduction, making it a robust choice for diverse applications ranging from image and speech recognition to optimization, forecasting, and decision-making systems. Due to its computational efficiency, scalability, and compatibility with deep learning architectures, backpropagation continues to serve as the foundational learning mechanism in neural computation.

**The Intuitionistic Fuzzy Power Generalised Weighted Averaging Operator**

**Definition:** For a clump of Intuitionistic Fuzzy Numbers with a weighting vector with the usual properties of their application in MAGDM problems, the Intuitionistic Fuzzy Power Generalized Weighted Average (*IFPGWA*) operator is proposed as follows:

$IFPGWA(\tilde{x}_1, \tilde{x}_2, \ldots, \tilde{x}_n) = \left( \frac{\sum_{j=1}^{n} \omega_j \left(1+K(\tilde{x}_{ij})\right) \tilde{x}_j^a}{\sum_{j=1}^{n} \omega_j \left(1+K(\tilde{x}_{ij})\right)} \right)^{\frac{1}{a}}$, wherea is a positive real numberand$K(x_i) = \sum_{\substack{j=1 \\ j \neq 1}}^{n} Sup(\tilde{x}_i, \tilde{x}_j)$ and $Sup(\tilde{a}_i, \tilde{a}_j)$ is support between two entries.

**Algorithm for the Classical Back Propagation with Bias and If PGWA**

The following is a proposed algorithm for backpropagation with bias:

**Step 1**: Input - decision matrix from decision makers information, where the decision maker weights,$\sum w_{ij} = 1$. $w_{ij}$can be asked as an input (or) a single weight can be made as combinations by itself on its own.

**Step 2**: Using aggregation operators (IFPGWA) these decision matrices can be made into decision collective column matrix.

**Step 3**:Now the input transformed to column matrix,weights will be given as combinations to suit the hidden layers, and learning rate fixed.

**Step 4**:Forward Pass: Calculate net input to each hidden layer: $Z_{inj}=V_{oj}+\sum_{i=1}^{n} w_{ij}x_i$( i=1,2,…,n)

**Step 5**: Apply activation function to calculate output: $Z_j= f(z_{inj}) =\frac{1}{1+e^{-Zinj}}$

**Step 6**: To get the network output: $Y_{in-k}= w_{ok} +\sum_{i=1}^{n} z_i w_{ij}$

**Step 7**: Apply activation function: $f(y_{in-k})= \frac{1}{1+e^{-Yin-k}}$

**Step 8**: To calculate error: $[1]_{1xj} – f(y_{in-k})$

**Step 9**:Weight optimization : To update the change in weights and bias

$\delta_k$ = (desired output – network output)$^T$ $f'(Y_{in-k})$; where $f'(Y_{in-k}) = f(Y_{in-k})(c_i – f(Y_{in-k}))$

$\Delta w_{jk} = \alpha\, \delta_k Y_k$; $\Delta w_{ok} = \alpha\, \delta_k$ where $\delta_k$ is error correction, $\alpha$ is learning rate, $Y_k$ is output.
$\delta_{in\text{-}j} = \sum_j \delta_k w_{ij}$; $\delta_j = \delta_{in\text{-}j}{}^{T} f(Z_{in\text{-}j})\,(1\text{-}f(Z_{in\text{-}j}))$.

**Step 10**: Compute new weights: $w_{ij}(new) = w_{ij}(old) + \Delta w_{ij}$; $\Delta w_{ij} = \alpha\delta_j x_i$
Compute new bias: $v_{0j}(new) = v_{0j}(old) + \Delta v_{0j}$ ; $\Delta v_{0j} = \alpha\delta_j$ (bias)
**Step 11**: Now, restart the process again using new weights and new bias but with same input.
**Step 12**: Continue this process until we obtain the target or desired output 1.

The proposed algorithm begins with the aggregation of intuitionistic fuzzy decision matrices using the IFPGWA operator, followed by the initialization of the weight vector. Each individual decision matrix is then transformed into an intuitionistic fuzzy preference form, from which attribute-based weight values are computed. To prepare the data for neural network processing, the intuitionistic fuzzy elements are defuzzified column-wise, resulting in a collective decision matrix that reflects the overall preference structure. The defuzzified input vectors are further refined through customized defuzzification functions incorporating hesitation degrees. The training phase employs a backpropagation-based learning process, where the network performs forward passes to compute neuron activations, evaluates the difference between predicted and target outputs, and updates connection weights and biases accordingly. This iterative process continues until the error function reaches an acceptable level of convergence. Once the model stabilizes, the final decision is made by computing the weighted arithmetic averages of alternatives across all matrices and evaluating their distance measures. The alternative that minimizes the deviation between the computed output and target threshold is ultimately identified as the optimal choice in the MAGDM framework.

**Numerical Illustration For Backpropagated-Ann With Bias**

In the modern financial environment, strategic investment planning has become a vital component of personal and institutional decision-making. To illustrate the applicability of the proposed model, consider an investment organization that seeks to allocate its capital among five potential sectors. The available alternatives are defined as follows:

A1 – Automobile manufacturing firm, A2 – Beverage production company, A3 – Software development enterprise, A4 – Heavy alloy industry, and A5 – Oil and gas corporation.
Each alternative is evaluated based on four critical financial attributes:
G1 – Risk assessment, G2 – Cash-flow performance, G3 – Liquidity position, and G4 – Debt-to-equity structure.
To ensure an objective and expert-driven analysis, three financial analysts were invited to provide their opinions regarding the relative importance of each criterion. The corresponding weighting vectors and intuitionistic fuzzy decision matrices supplied by these experts form the primary input data for this study. These matrices encapsulate the evaluators' confidence levels, hesitation margins, and perceived uncertainties associated with each investment option. The aggregated decision information, derived through the proposed Intuitionistic Fuzzy Power Generalized Weighted Averaging (IFPGWA) operator, is subsequently utilized to determine the most promising investment alternative under uncertain financial conditions [10].

$$\tilde{I}_1 = \begin{pmatrix} (0.4,0.3)(0.5,0.2)(0.2,0.5) & (0.1,0.6) \\ (0.6,0.2)(0.6,0.1)(0.6,0.1) & (0.3,0.4) \\ (0.5,0.3)(0.4,0.3)(0.4,0.2) & (0.5,0.2) \\ (0.7,0.1)(0.5,0.2)(0.2,0.3) & (0.1,0.5) \\ (0.5,0.1)(0.3,0.2)(0.6,0.2) & (0.4,0.2) \end{pmatrix}; \tilde{I}_2 = \begin{pmatrix} (0.5,0.4)(0.6,0.3)(0.3,0.6) & (0.2,0.7) \\ (0.7,0.3)(0.7,0.2)(0.7,0.2) & (0.4,0.5) \\ (0.6,0.4)(0.5,0.4)(0.5,0.3) & (0.6,0.3) \\ (0.8,0.1)(0.6,0.3)(0.3,0.4) & (0.2,0.6) \\ (0.6,0.2)(0.4,0.3)(0.7,0.1) & (0.5,0.3) \end{pmatrix};$$

$$\tilde{I}_3 = \begin{pmatrix} (0.4,0.5)(0.5,0.4)(0.2,0.7) & (0.1,0.8) \\ (0.6,0.4)(0.6,0.3)(0.6,0.3) & (0.3,0.6) \\ (0.5,0.5)(0.4,0.5)(0.4,0.4) & (0.5,0.4) \\ (0.7,0.2)(0.5,0.4)(0.2,0.5) & (0.1,0.7) \\ (0.5,0.3)(0.3,0.4)(0.6,0.2) & (0.4,0.4) \end{pmatrix}.$$

Calculate the Intuitionistic Fuzzy Power Generalized Weighted Average (*IFPGWA*) Operator:*IFPGWA*

$Suppose\ a = 1, \tilde{z}_{11}$ = (1- $((1-\mu_{11})^{\tilde{\omega}_{11}} \times (1-\mu_{12})^{\tilde{\omega}_{12}} \times (1-\mu_{13})^{\tilde{\omega}_{13}} \times (1-\mu_{14})^{\tilde{\omega}_{14}}$ ),

1-(1- $\left((1-(1-\Upsilon_{11})\right)^{\tilde{\omega}_{11}} \times \left(1-(1-\Upsilon_{12})\right)^{\tilde{\omega}_{12}} \times \left(1-(1-\Upsilon_{13})\right)^{\tilde{\omega}_{13}} \times (1-(1-\Upsilon_{14}))^{\tilde{\omega}_{14}}$ ))) = (1-$((1-0.4)^{0.3092} \times (1-0.5)^{0.1936} \times (1-0.2)^{0.2061} \times (1-0.1)^{0.2908})$, 1-(1-$((1-(1-0.3))^{0.3092} \times (1-(1-0.2))^{0.1936} \times (1-(1-0.5))^{0.2061} \times (1-(1-0.6))^{0.2908})$)) = (0.3084, 0.3770).

Proceeding with similar computations, and defuzzifying the IFS entries, we get the following:

$R_1 = \begin{bmatrix} 0.3146 \\ 0.2855 \\ 0.2726 \\ 0.3360 \\ 0.3795 \end{bmatrix}$; $R_2 = \begin{bmatrix} 0.1045 \\ 0.0717 \\ 0.0914 \\ 0.1680 \\ 0.2245 \end{bmatrix}$; $R_3 = \begin{bmatrix} 0.1031 \\ 0.0702 \\ 0.0910 \\ 0.1626 \\ 0.2207 \end{bmatrix}$, which are the input training vectors for the ANN.

**The Momentum Based Backpropagation Algorithm Together With Four Other Learning Rules**

The proposed framework implements a neural network-based approach for evaluating alternatives using five learning rules: backpropagation, delta, Levenberg–Marquardt, Perceptron, and correlation-inspired updates. The input data matrix and target scores are first normalized, and the network employs a single hidden layer of six neurons with a sigmoid activation function. For each learning rule, the network weights are initialized randomly and updated iteratively over multiple epochs. During each epoch, a forward pass computes the hidden and output activations, the error, and the mean squared error (MSE), followed by gradient computation. The weights are then adjusted according to the specific learning rule, with the correlation-inspired method modulating the gradient based on the correlation between neurons and target values. Adaptive learning rates and damping factors are applied where appropriate to ensure smooth convergence. Finally, the network outputs are used to compute and rank the alternatives, and convergence is visualized through individual and combined MSE plots for all learning rules.

**Pseudo-Code for the Algorithm for ANN with 5 different Learning Rules**

START

1. Input:
   - X = data matrix (alternatives × criteria)
   - y = target scores (desired ranking values)
   - alternatives = ["A1", "A2", "A3", ...]
   - learning_rules = ["backprop", "delta", "levenberg", "perceptron", "correlation"]
2. Normalize X and y
   - Make all values between 0 and 1
3. Define sigmoid function:
   - sigmoid(x) = 1 / (1 + $e^{(-x)}$)
   - sigmoid_derivative(x) = x * (1 - x)
4. For each learning_rule in learning_rules:
   a. Initialize neural network weights randomly:
      - W1 = weights from input → hidden layer
      - W2 = weights from hidden → output layer
      - hidden layer has 6 neurons

- output layer has 1 neuron
b. Set initial learning rate (lr) and damping factor (beta, for Levenberg)
c. For each epoch from 1 to max_epochs:
i. Forward pass:
- Hidden layer output H = sigmoid(X × W1)
- Network output O = sigmoid(H × W2)
- Error = y - O
- MSE = mean squared error of Error
- Store MSE in error_curve
ii. Compute gradients:
- d_output = Error × sigmoid_derivative(O)
- d_hidden = d_output × W2^T × sigmoid_derivative(H)
iii. Adjust learning rate adaptively:
- If MSE decreased → slightly increase lr
- Else → decrease lr
- Clamp lr to a reasonable range
iv. Update weights according to learning_rule:
- BACKPROP:
W2 += lr × H^T × d_output
W1 += lr × X^T × d_hidden
- DELTA:
W2 += lr × normalized(H^T × Error)
W1 += lr × normalized(X^T × (Error × W2^T))
- LEVENBERG:
damping = beta / (1 + epoch / 300)
W2 += lr × (H^T × d_output - damping × W2)
W1 += lr × (X^T × d_hidden - damping × W1)
Adjust beta slightly depending on MSE
- PERCEPTRON:
W2 += lr × H^T × Error
W1 += lr × X^T × (Error × W2^T)
- CORRELATION-INSPIRED:
1. Compute correlation between hidden neurons and target (corr_Hy)
2. Compute correlation between input and hidden neurons (corr_XH)
3. Scale gradients by (1 + |correlation|):
W2 += lr × (H^T × d_output) × (1 + |corr_Hy|)
W1 += lr × (X^T × d_hidden) × (1 + |corr_XH|)
d. Store final output and MSE curve for this learning rule
5. Plot MSE curves:
- Individual plot for each learning rule
- Combined plot for all rules
6. Compute ranking of alternatives:
- For each learning rule:
- Sort alternatives based on final output scores
- Display rankings from lowest → highest
- Best alternative = highest score
END

**Key Points of the ANN process for MAGDM**

1. The neural network has *input* → *hidden* → *output* layers.

2. Each rule changes how the network learns from error:
   - Backprop = classic gradient descent
   - Delta = normalized gradient
   - Levenberg = gradient with damping
   - Perceptron = continuous gradient update
   - Correlation = gradient modulated by correlation with target
3. MSE curves show how error decreases over time.
4. Rankings are computed from final outputs.

In this study, the classical Perceptron algorithm, which is primarily designed for binary classification and employs a hard threshold activation, was adapted for continuous-valued outputs by replacing the threshold with a sigmoid activation function and updating weights using the continuous error signal through gradient descent. This modification ensures smooth learning and convergence for regression tasks such as MAGDM problems. Similarly, the traditional correlation-based weight update, which relies directly on the raw correlation between neuron activations and the target, was enhanced by applying the correlation as a scaling factor to the standard backpropagation gradients. This approach preserves the true gradient direction while modulating the learning rate according to the correlation strength, allowing neurons more strongly aligned with the target to receive larger updates, thereby ensuring reliable convergence to minimal error. Additionally, the backpropagation rule was further improved by incorporating momentum, where a fraction of the previous weight update is added to the current adjustment. This momentum-based modification accelerates convergence and smooths the mean squared error (MSE) curves by reducing oscillations during training. All other learning rules remain unchanged, with the correlation-inspired rule continuing to use gradient-modulated-by-correlation updates. Collectively, these enhancements enable all five learning rules—backpropagation with momentum, delta, Levenberg, Perceptron, and correlation-inspired—to converge reliably to near-zero MSE, with convergence visualizations provided both individually and in a combined comparative format.

Best alternative: A1 (Score=0.980849)

**Interpretation of Error Convergence Curves**

The diagram illustrates the error convergence behavior of different learning rules—Backpropagation (with momentum), Delta rule, Levenberg–Marquardt rule, Perceptron rule, and Correlation rule—over 4000 training epochs. The vertical axis represents the Mean Squared Error (MSE), while the horizontal axis indicates the number of epochs. From the plot, it is evident that all learning algorithms show a decreasing trend in error as training

progresses, confirming that the neural network successfully learns and adapts its weights over time. However, the rate and stability of convergence vary significantly among the rules:

- Backpropagation rule (with momentum) demonstrates a smooth and gradual decline in MSE, achieving one of the lowest final errors. The inclusion of momentum helps the model overcome local minima and ensures stable convergence.
- The Delta rule also converges quickly, reaching a low error level within a few hundred epochs, though its final MSE is slightly higher than that of backpropagation.
- The Levenberg–Marquardt rule shows a rapid early reduction in error, indicating its superior optimization efficiency, but later stabilizes at a comparable minimum error level.
- In contrast, the Perceptron rule reaches a plateau early, indicating limited adaptability and an inability to minimize the MSE further. This reflects its simplicity and linear separability limitation.
- The Correlation rule initially exhibits a steep rise followed by a sharp decay, suggesting instability in early learning but eventual stabilization at a moderate error value.

Overall, the Backpropagation rule with momentum emerges as the most reliable and efficient learning strategy, balancing convergence speed, accuracy, and stability. The comparative analysis highlights that advanced gradient-based algorithms outperform simpler linear rules, especially for nonlinear learning tasks.

## DISCUSSION

The experimental results demonstrate the effectiveness and versatility of the proposed ANN-based framework in solving MAGDM problems under intuitionistic fuzzy environments. Among the five learning rules implemented back propagation with momentum, delta, Levenberg–Marquardt, Perceptron, and correlation-inspired updateseach exhibited distinct learning dynamics and convergence behavior. The momentum-enhanced backpropagation consistently provided the fastest convergence and the smoothest mean squared error (MSE) curves, highlighting the benefits of incorporating previous weight updates to accelerate training and mitigate oscillations. The delta and Levenberg–Marquardt rules also achieved stable convergence, with the latter benefiting from adaptive damping to handle potential gradient irregularities. The modified Perceptron, employing sigmoid activation and continuous error-driven weight updates, successfully adapted a traditionally classification-oriented algorithm to regression-based MAGDM ranking, converging reliably despite its original limitations. The correlation-inspired learning rule, enhanced by modulating gradients according to the correlation between hidden neuron activations and target outputs, ensured that neurons more aligned with the desired ranking received proportionally larger updates. This approach preserved the true gradient direction while incorporating domain-specific insights, preventing divergence and promoting convergence to minimal error. Comparative analysis of the final rankings across all five learning rules revealed minor variations in score distributions, reflecting the inherent differences in learning dynamics and gradient sensitivity. However, all methods converged to near-zero MSE, validating the robustness of the network design and the efficacy of the modified learning strategies. Overall, the results underscore the advantage of combining multiple learning paradigms within an ANN framework, offering flexibility, improved convergence, and reliable decision-making for complex MAGDM problems.

## CONCLUSION

This study presented an enhanced Artificial Neural Network (ANN) framework driven by the Backpropagation algorithm for solving Multi-Attribute Group Decision-Making (MAGDM) problems under intuitionistic fuzzy environments. A novel aggregation operator was formulated to integrate multiple expert evaluations into a unified decision matrix, enabling the ANN to process complex fuzzy data more effectively. Through iterative learning and weight adjustments across forward and backward passes, the proposed model produced reliable ranking outcomes that reflect both the degree of membership and non-membership inherent in intuitionistic information. All the

proposed five methods of ANN in this work prove to be effective methods especially in the context of decision making with multiple attributes. A comparative assessment with conventional MAGDM approaches demonstrated that the Backpropagation-based ANN significantly reduces computational challenges, particularly those related to weight updating and convergence control. The proposed system thereby provides a more flexible and adaptive mechanism for modeling decision-maker uncertainty. Furthermore, incorporating a bias vector within the neural architecture improved the model's learning precision and overall decision stability. Future research could extend this framework by introducing deeper hidden layers and nonlinear activation dynamics, which may further enhance the model's capability to capture complex relationships among decision attributes. The integration of the Backpropagated Intuitionistic Fuzzy ANN model with advanced hybrid aggregation schemes also holds potential for broader applications across economics, finance, and engineering decision domains.

**Table-1: Abbreviations of the terminologies used for the ANN representations**

| Abbreviation | Meaning / Description |
|---|---|
| X | Input matrix containing alternatives and criteria (features) |
| y | Target vector representing desired output scores or rankings |
| H | Hidden layer output after applying activation function |
| O or output | Final network output after passing through hidden layer |
| W1 | Weight matrix connecting *input → hidden layer* |
| W2 | Weight matrix connecting *hidden → output layer* |
| lr | Learning rate, determines step size for weight updates |
| d_output | Gradient at output layer, used to update weights |
| d_hidden | Gradient at hidden layer, used to update weights |
| MSE | Mean Squared Error: average squared difference between predicted output and target |
| corr_Hy | Correlation between hidden neurons and target output (used in correlation-inspired rule) |
| corr_XH | Correlation between input features and hidden neurons (used in correlation-inspired rule) |
| beta | Damping factor for Levenberg–Marquardt method |
| epoch | Iteration number in training loop |
| error_curve | Array storing MSE at each epoch for plotting convergence |
| alternatives | List of alternatives (A1, A2, …) being ranked |
| learning_rule | Name of the learning method used (backprop, delta, levenberg, perceptron, correlation) |

**Table-2: Comparison of the proposed ANN Methods with existing methods**

| Sl. No.: | Method | Ranking of Alternatives |
|---|---|---|
| 1 | ANN Method-Backpropagation Robinson [10] | $A_5<A_4<A_1<A_3<A_2$ A5 is the optimal alternative |
| 2 | Proposed ANN with Momentum based Backpropagation and Error convergence | $A_5<A_4<A_3<A_2<A_1$ A1 is the optimal alternative |
| 3 | Proposed ANN with Delta Rule and Error convergence | $A_5<A_4<A_3<A_2<A_1$ A1 is the optimal alternative |
| 4 | Proposed ANN with Levenberg Rule and Error convergence | $A_5<A_4<A_3<A_2<A_1$ A1 is the optimal alternative |

## ABSTRACT

This work presents a mathematical framework for the study of unsteady, incompressible fluid flows, including viscous, couple stress, and magnetohydrodynamic (MHD) regimes. The study first investigates the existence of exact solutions using the Ansatz method and the topology conservation principle of the vorticity vector field. By assuming suitable vector potentials, the governing nonlinear partial differential equations are transformed and solved, demonstrating that the topology of the vorticity field is invariant even in MHD flows under specific extreme magnetic energy conditions. In order to bridge the gap between idealised exact solutions and the inherent unpredictability of physical systems, the study also proposes a neutrosophic numerical scheme. Truth-Indeterminacy-Falsity (T-I-F) triples are used in this framework to represent uncertainties in significant physical parameters such as kinematic viscosity, magnetic diffusivity, and coupled stress velocity. Using the BVP4C solver, governing equations are transformed into neutrosophic differential equations to propagate indeterminacy throughout the flow topology. The combined findings demonstrate that topological invariants provide a stable geometric basis for fluid mechanics, while the neutrosophic approach provides a dependable mechanism for simulating complex, real-world uncertainty structures. Graphical analysis of velocity vectors and T-I-F triples validates the dual methodology, offering new insights for applications in astrophysical plasmas, micro-MHD devices, and liquid-metal cooling.

**Keywords:** MHD Flow, Hall Effect, T-I-F Triples, Navier-Stokes Equations, Ansatz Method, Topology Conservation, Neutrosophic Logic, and Uncertainty Quantification.

## INTRODUCTION

This research utilizes micro continuum fluid theory as its primary theoretical framework. Stokes (1966) was the first to demonstrate the 'couple stress' theory by establishing a characteristic length to account for the rotation of the fluid elements; traditional navier-stokes theory does not provide this characteristic length. Devakar and Iyengar (2008) were able to solve the first-order problem of Stokes in couple stress fluids and established that the problem requires the no-spin boundary condition. Further development of incorporating magnetic effects was introduced through the work of Srinivasacharya and Kaladhar (2016) to show that the Lorentz force provides gravitational stability to couple stress fluid flows. Recently, Hayat *et al*. (2017) looked at these phenomena in more complex geometries with the finding that the interaction between micro-rotation and magnetic forces reduces the thickness of the boundary layer, which will be significant to your analysis of "extreme energy". According to Wang (1991), through the Ansatz method, exact solutions can be found for nonlinear PDEs in terms of specific, manageable ODEs in a certain class of potential functions. However, whether or not the structure of these solutions is maintained when solved and the structure of the fluid is classified as topologically sound is unknown. Moffatt (1969) and Arnold and Khesin (1998) showed the fundamental principle known as "topological fluid mechanics," stating that the "topological structure" (or helicity) associated with the vortex lines will remain constant in cases where idealized conditions exist. Furthermore, According to Enciso and Peralta-Salas (2012) the existence of complex topological structures (or knots) in steady solutions of the Euler equations can be rigorously demonstrated theoretically and you have extended it to include the unsteady regime of MHD, thus demonstrating that the topological nature of vorticity in MHD remains invariant, even when subjected to extreme magnetic energy.

Given the extreme magnetic energy level, there are many cases in which it would cause a mathematical model ultimately to exhibit bifurcation points, therefore the literature on hydrodynamics demonstrates the need to move beyond binary logics. Smarandache's (1998, 2002) introduction of neutrosophic logic allows for the possibility of implementing indeterminate logics (*I*) and was modified by Wang *et al*. (2010) to meet the requirements of engineering applications. Using these logic triples in the context of fluid dynamics has recently received increasing attention in the literature. Moi *et al*. (2021) examined second order boundary value problem through neutrosophic differential equation. By enabling the simultaneous representation of truth, indeterminacy, and falsity components, the neutrosophic framework offers a useful tool for modeling uncertain boundary-value problems in MHD flows and fluid mechanics (Abdel-Basset *et al*., 2023; Rahaman and Das, 2025). The study of couple-stress fluids, which are non-Newtonian, electrically conducting fluids, is becoming increasingly important for bio-mechanical and industrial lubrication applications. However, the extreme magnetic energy experienced by these fluids frequently results in the governing nonlinear partial differential equations (PDEs) reaching a "bifurcation point" where standard stability analysis does not apply. Research has mostly focused on the velocity/pressure profiles of fluid flow in a quantitative way; however, there is a lack of qualitative knowledge/understanding of the topological robustness of the vorticity field and an absence of a logical framework for understanding and accounting for the mathematical indeterminacy associated with high-energy bifurcation. In the absence of a means to quantify this uncertainty, the physical veracity of all "exact solutions" has not been verified. This research resolves this gap by creating a methodology that combines topological conservation laws with neutrosophic logic, creating a dual-path verification method for evaluating fluid structural integrity.

## RESEARCH OBJECTIVES

The following goals are developed in order to tackle the mentioned issue:

1. To develop the governing 4th-order momentum and vorticity equations in order to build a solid mathematical model for unsteady, incompressible MHD couple-stress flow.
2. To reduce complicated PDEs into a system of first-order ordinary differential equations (ODEs) using the Ansatz Method and use the bvp4c numerical solver to confirm the existence of exact solutions.

3. Using the Helmholtz-Lie topology conservation principle, demonstrate the topological invariance of the vorticity vector field under extreme magnetic energy conditions.
4. In order to quantify the effect of couple-stress and magnetic parameters on the certainty of the flow structural stability, a Neutrosophic Sensitivity Analysis based on $\langle T, I, F \rangle$ triples must be developed.
5. To create a Score Function ($S$) that bridges the gap between logical mathematical certainty and geometric topological proof by serving as a reliability index.

**Basic definitions**

**Definition 3.1: Neutrosophic set**

Neutrosophic Set is a set such that an element belongs to the set with a neutrosophic probability, i.e. t% is true that the element is in the set, t% false, and i% indeterminate.

**Definition 3.2: Neutrosophic logic**

Neutrosophic Logic means the study of neutrosophic logical values of the propositions.

**Definition 3.3: Score Function**

In Neutrosophic theory, the most common score function $S$ is designed to reward Truth ($T$) while penalizing Indeterminacy ($I$) and Falsity ($F$):

$$S(N) = \frac{1 + T - 2I - F}{2}$$

where the value of $S$ typically ranges from -1 (Total Failure) to 1 (Absolute Certainty).

**Basic governing equations**

In continuous motion, a necessary and sufficient condition stating the vorticity field in inviscid and viscous fluid flows is conserved when the flux of an arbitrary vector field S passes through an arbitrary material surface Topology.

$$\frac{\partial S}{\partial t} + (\omega.\nabla)S - (S.\nabla)\omega + S(\nabla.\omega) = 0 \quad (1.1)$$

Furthermore, for vector tube S to exist, the following conditions must be satisfied: $$S \times \left(\frac{\partial S}{\partial t} + (\omega.\nabla)S - (S.\nabla)\omega\right) = 0 \quad (1.2)$$

Here, $\omega$ is the generating vector field.

Mathematically, topological conservation exists if the vorticity vector field satisfies the Helmholtz-Truesdell condition for an arbitrary vector field S:

$$\frac{\partial S}{\partial t} + (\omega.\nabla)S - (S.\nabla)\omega = \lambda S \quad (1.3)$$

Here, $\lambda$ is a scalar function in a smooth Euclidean domain$\Omega \subseteq R^3$.For an incompressible fluid, the continuity and momentum conservation equation incorporates the standard Navier-Stokes terms along with the couple stress and magnetic Lorentz force

$$\nabla.u = 0 \quad (1.4)$$

$$\rho\left(\frac{\partial u}{\partial t} + (u.\nabla)u\right) = -\nabla p + \nabla\varphi + \mu\nabla^2 u - \eta\nabla^4 u + \vec{J} \times \vec{B} \quad (1.5)$$

Here,

$\mu\nabla^2 u$: Classical viscous force

$\eta\nabla^4 u$: Couple stress term, where $\eta$ is the couple stress viscosity coefficient

$\vec{J} \times \vec{B}$: Lorentz force (MHD), representing the interaction between current density $\vec{J}$ and the magnetic field $\vec{B}$

$u(x,t)$: Time dependent vector field (or) velocity field,

$\nabla\varphi$: Conservative body force

$\mu$: Coefficient of dynamic viscosity ($\mu > 0$)

$\eta$: Couple stress velocity parameter ($\eta > 0$)

$p(x,t)$: Pressure function

$\rho$:Density

$\nabla = \left(\frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z}\right)$: Hamilton operator

$\nabla^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}$: Laplace operator and

$\nabla^4 = \frac{\partial^4}{\partial x^4} + \frac{\partial^4}{\partial y^4} + \frac{\partial^4}{\partial z^4} + 2\frac{\partial^4}{\partial x^2 \partial y^2} + 2\frac{\partial^4}{\partial x^2 \partial z^2} + 2\frac{\partial^4}{\partial y^2 \partial z^2}$ : Biharmonic operator

Using the curl of equations (1.2), the vorticity equation for the incompressible couple stress fluid flow is given as follows:

$$\frac{\partial \omega}{\partial t} + \nabla \times (\omega \times u) = \nu \nabla^2 \omega - \gamma \nabla^4 \omega + \frac{1}{\rho} \nabla \times \left(\vec{J} \times \vec{B}\right) \quad (1.6)$$

where $\omega = \nabla \times u (or) curl u$

$\nu = \frac{\mu}{\rho}$ is the kinematic viscosity

$\gamma = \frac{\eta}{\rho}$ is the kinematic couple stress parameter

In the context of incompressible couple stress fluid flows, we must determine if topology conservation of vorticity field lines occurs or not. If there is such flow, the vorticity vector field must satisfy both equations (1.3) and (1.5) simultaneously. In the next section, exact solutions for couple stress MHD fluid flows with topology-conserving vorticity fields are derived which satisfies equations (1.5) and (1.6), respectively.

**Exact solution by Ansatz method**

Consider an unsteady flow over a flat plate with no-slip at the boundary along$y > 0$ and unidirectional $\left(u = (u(y,t), 0, 0)\right)$. A transverse uniform magnetic field $B_0$is applied in the y-direction. For this specific geometry, the reduced momentum equation is

$$\rho \frac{\partial u}{\partial t} = \mu \frac{\partial^2 u}{\partial y^2} - \eta \frac{\partial^4 u}{\partial y^4} - \sigma {B_0}^2 u \quad (2.1)$$

The corresponding boundary conditions are

$u(0,t) = U_0 e^{-nt},\ u'(0,t) = 0$ at $y = 0$

$$u(y,t) \longrightarrow 0 \text{ as } y \longrightarrow \infty \quad (2.2)$$

Assume that, velocity decays exponentially in time with specific spatial structure

$$u(y,t) = e^{-nt} f(y) \quad (2.3)$$

Where, n is the decay rate of unsteady flow.

Applying (2.2) into (2.1) and (2.2), it becomes

$$\eta f'''' - \mu f'' + \left(\sigma {B_0}^2 - \rho n\right) f = 0 \quad (2.4)$$

The associated boundary conditions are

$$f(0) = U_0,\ f'(0) = 0, f(\infty) \to 0 \quad (2.5)$$

By solving (2.4) with boundary condition (2.5), the general spatial solution is

$$f(y) = C_1 e^{-m_1 y} + C_2 e^{-m_2 y} \quad (2.7)$$

Where $m_1 = \sqrt{\frac{\mu + \sqrt{\mu^2 - 4\eta(\sigma {B_0}^2 - \rho n)}}{2\eta}}$, $m_2 = \sqrt{\frac{\mu - \sqrt{\mu^2 - 4\eta(\sigma {B_0}^2 - \rho n)}}{2\eta}}$, $C_1 = \frac{m_1 U_0}{m_1 - m_2}$ and $C_2 = \frac{-m_2 U_0}{m_1 - m_2}$

By substituting (2.7) in (2.3), the fluid velocity is

$$u(y,t) = \frac{U_0 e^{-nt}}{m_1 - m_2}(m_1 e^{-m_1 y} - m_2 e^{-m_2 y}) \quad (2.8)$$

For the unidirectional flow, the vorticity vector is $\omega = \nabla \times u = \left(0, 0, \frac{\partial u}{\partial y}\right)$

The corresponding vorticity equation $\nabla \times (\omega \times u) = 0$ is satisfied.

Hence, we can conclude that, the topology of its vorticity is conserved.

**BVP4C approach**

BVP4C approach is adopted to solve the third order boundary value problem (BVP) by converting into initial value problem (IVP). By this method, we guess the initial conditions for the IVP at $y = 0$ the first order ODE's are solved by adjusting the guessed initial conditions to satisfy the boundary conditions at the end point $y \longrightarrow \infty$.

Equation (2.4) is transformed into first order ODE's in the form

$$\begin{pmatrix} y_1' \\ y_2' \\ y_3' \\ y_4' \end{pmatrix} = \begin{pmatrix} y_2 \\ y_3 \\ y_4 \\ \frac{1}{\eta}\left(\mu y_3 - \left(\sigma {B_0}^2 - \rho n\right) y_1\right) \end{pmatrix} \quad (3.1)$$

with corresponding boundary conditions

$y_1(0) = U_0, y_2(0) = 0$

$y_1(\infty) = 0 y_2(\infty) = 0$ (3.2)

**Fig 1.** Comparison of velocity profile between Ansatz and BVP4C Approach

**Fig 1.** indicates that the Ansatz produces an effective "exact" approximation of the flow characteristics very quickly; however, for a more precise boundary layer evaluation in couple-stress modes, a more precise method for numerically evaluating the boundary layer flow is to be derived using the bvp4c solver (as noted above

**Topological Vs Neutrosophic approach**

Classically, a solution is defined as either true or false, though an increasingly common occurrence throughout such systems (due to their necessary level of complexity) is uncertainty or contradictory data regarding particular locations. Neutrosophic logic allows one to handle both of these issues through the establishment of a wide range of states represented as three components (T = truth, I = indeterminate, and F = false), at least one of which can be associated with the physical behaviour of a flowing fluid in relation to magnetic hydrodynamics and couple stress:

**Truth component** - (T) It shows the degree to which exact solution holds. For example, T=0.9 indicates that there is a relatively high degree of confidence between the mathematical model and actual physical observations.

**Indeterminacy component** - (I) The level of uncertainty or "hidden" physics/parameters that have not been captured by the analyses required to generate an isolated event, particularly those parameters associated with either turbulence-related fluctuations or numerical rounding errors in bvp4c.

**False component** - (F) The level of conservation principle violation (if the topology of the vorticity field appears to have "broken," for instance, due to magnetic reconnection, F would be at a very high level).

The following table presents the effect of various features on classical and Neutrosophic logic. Classical vs. Neutrosophic Representation (Table 1).

Define a Neutrosophic Set (N) that represents the governing dynamics and topological preservation of the fluid system using Neutrosophic Logic, where each state of the flow will have a triple $\langle T, I, F \rangle$ associated with it.In the case of couple-stress fluids, determining the parameter $\eta$(the micro-rotation viscosity) experimentally is frequently problematic. Thus, the couple-stress parameter must be regarded as an indeterminate variable. Based on the assumption, define the indeterminacy of a couple-stress variable as:

$I(\eta) = 1 - e^{-\sigma_\eta}$

Here, $I \longrightarrow 0$representsthe couple-stress effect is perfectly known, whereas$I \longrightarrow 1$represents the micro-rotation effects are complex

According to the research study, the property of topology is in variant and can thus be state as a neutrosophic triple $\Omega = \langle T_\Omega, I_\Omega . F_\Omega \rangle$.

where $T_\Omega$ adherence to $\nabla \times (\omega \times u) = 0$, therefore$T_\Omega \approx 1 \Rightarrow$ the Ansatz provides evidence that the structure is locked.

$I_\Omega$- the "indeterminacy" of extreme amounts of magnetic energy and the relationship between chaos and high magnetic energy.

$F_\Omega -$ the "breaking" of vortex lines due to the product of the magnetic reconnection terms being greater than viscous damping

**Neutrosophic Score Function** is formulated to condense the triple $\langle T, I, F\rangle$into a single scalar value $(S)$which helps in determining the "reliability" of the topological conservation under extreme magnetic energy.

The behaviors of score function in two different paths are given below:

**Path A: Low Magnetic Energy (Normal Regime)**

By considering the Neutrosophic Triple as$\langle 0.95, 0.10, 0.05\rangle$, the score function is

$$S = \frac{1 + 0.95 - 0.2 - 0.05}{2} = 0.85$$

**Path B: Extreme Magnetic Energy (The Study's Focus)**

By considering the Neutrosophic Triple as $\langle 0.85, 0.60, 0.10\rangle$, the score function is

$$S = \frac{1 + 0.85 - 1.2 - 0.10}{2} = 0.275$$

From the two paths, one can conclude that Path A is highly reliable. Hence, the Ansatz method is an excellent representation of the flow in the case of low magnetic energy. But in the case of high magnetic energy, it is not suitable. Due to high indeterminacy in Path B, one can conclude that, the system is at a tipping point. (i.e) topology is conserved due to "frozen in" condition. Fig 2. Decay of Score Function in Extreme MHD Regimes. Fig 2. Shows that, there is a decrease in the Neutrosophic Score (S), which declines with increasing Magnetic Energy Level. At low Energy Level (0.1), the Neutrosophic Score (S) is approximately 0.72, indicating high mathematical certainty. At Energy Level 3 (maximum), the NeutrosophicScore(S)is a 0.20. Thus, there exists large amounts of topological breach risk associated with magnetic energy levels.

**Sensitivity analysis**

To assess Sensitivity Analysis, the Neutrosophic Score Function Partial Derivatives concerning Physical Parameters can be computed. This allows determination as to which force (Magnetic or Couple Stress) causes distress to Logical Certainty(i.e., Provides Greatest Likelihood of "Destabilization"). The Score Sensitivity S concerning the parameter P(Since P could be either Magnetic Energy or Couple Stress) is

$$\frac{\partial S}{\partial P} = \frac{1}{2}\left(\frac{\partial T}{\partial P} - 2\frac{\partial I}{\partial P} - \frac{\partial F}{\partial P}\right)$$

Comparison of Sensitivity Results (Fig 3). From Fig 3, one can understand that, when M exceeds the threshold, there is a sudden down-dipping of sensitivity vectors; indicating that there is a potential for the topological to reconnect. Also, it is evident that the fluid becomes more "stiffer" due to micro-rotational stresses, tends to lose the ability to calculate topology.

## CONCLUSION

This research proposes two different types of mathematics to establish the structural integrity of the unsteady, incompressible MHD couple-stress flows. The first type, referred to as the Topological Aspect, supports the invariance of the vorticity vector field through a mathematical grounding of the Helmholtz-Lie Theorem. Whereas the second type, called the Neutrosophic Aspect, serves as an additional means of ;earner-supported, epistemic verification. Through the use of mapping the flow dynamics to $\langle T, I, F\rangle$ triplets, strong evidence was presented demonstrating that, although the governing equations will bifurcate to yield high levels of indeterminacy (I) due to extreme magnetic energy conditions, the topological "truth" (T) of dimensional conservation remains intact. The ultimate result is the Neutrosophic Score Function acts as a conduit for quantifying the robustness of the vortex structures. This analysis not only yields an exact solution, but also provides a measure of the reliability of the solution. Also, topology is extremely sensitive to Magnetic energy in the high-energy range and S is more sensitive to Couple Stress effect with respect to the amount of Indeterminacy.

**ABSTRACT**

Low back pain (LBP) is one of the most prevalent musculoskeletal disorders worldwide and a major contributor to disability and reduced quality of life. Physiotherapy plays a crucial role in the prevention, management, and rehabilitation of individuals with low back pain. This narrative review aims to summarize current evidence regarding physiotherapy interventions for the management of low back pain. Literature was collected from databases including PubMed, Scopus, and Google Scholar focusing on studies published between 2015 and 2025. Evidence indicates that physiotherapy interventions such as exercise therapy, manual therapy, spinal stabilization exercises, and patient education significantly improve pain and functional outcomes. Recent advancements also include digital rehabilitation, motor control training, and multidisciplinary rehabilitation programs. The findings highlight the importance of individualized physiotherapy approaches for effective management of low back pain and improved patient outcomes.

**Keywords:** Low back pain, Physiotherapy, Rehabilitation, Exercise therapy, Manual therapy, Musculoskeletal disorders

## INTRODUCTION

Low back pain (LBP) is a widespread musculoskeletal condition affecting nearly 70–80% of the population at some stage of life. It is considered one of the leading causes of disability globally and imposes a substantial socioeconomic

burden on healthcare systems. Low back pain may originate from structures such as intervertebral discs, facet joints, ligaments, muscles, and nerve roots in the lumbar spine[1]. In many cases, the condition is classified as non-specific low back pain, where no single anatomical cause can be clearly identified. Risk factors contributing to low back pain include sedentary lifestyle, poor posture, obesity, occupational stress, and lack of physical activity. In recent years, physiotherapy has gained significant attention as a primary non-pharmacological intervention for managing low back pain. Physiotherapy interventions aim to reduce pain, restore functional mobility, strengthen spinal musculature, and prevent recurrence of symptoms. Therefore, understanding current physiotherapy approaches is essential for improving patient care[2].

## METHODOLOGY

This review was conducted using a narrative literature review approach.

**Scientific databases searched included**

- PubMed
- Scopus
- Web of Science
- Google Scholar

**Keywords used in the search strategy included**

- "Low back pain"
- "Physiotherapy management"
- "Exercise therapy for low back pain"
- "Manual therapy"
- "Rehabilitation for lumbar pain"

**Inclusion criteria**

- Articles published between 2015 and 2025
- Peer-reviewed journals
- Randomized controlled trials, systematic reviews, and clinical guidelines
- Articles written in English

Exclusion criteria included non-peer-reviewed studies, case reports, and studies unrelated to physiotherapy management.

**Epidemiology of Low Back Pain**

Low back pain is a significant public health concern worldwide. According to recent global estimates, approximately 540 million people suffer from low back pain at any given time[3]. The prevalence is highest among individuals aged 30–60 years, although increasing cases have been reported among younger populations due to sedentary lifestyles and prolonged screen use.

**Major risk factors include**

- Prolonged sitting
- Poor workplace ergonomics
- Obesity
- Lack of physical activity
- Repetitive heavy lifting
- Psychological stress

Low back pain is also one of the leading causes of work absenteeism and decreased productivity[4].

**Role of Physiotherapy in Low Back Pain Management** Physiotherapy plays a critical role in both acute and chronic low back pain management. The primary goals include:

- Pain reduction
- Improvement of spinal mobility
- Strengthening of core muscles
- Restoration of functional activities
- Prevention of recurrence

Physiotherapy treatment strategies are often individualised depending on the patient's condition, severity of symptoms, and functional limitations[5].

**Physiotherapy Interventions for Low Back Pain**

**Exercise Therapy** Exercise therapy is widely considered the cornerstone of physiotherapy management for low back pain.

**Common exercise programs include**

- Core stabilization exercises
- Lumbar strengthening exercises
- Flexibility and stretching exercises
- Aerobic conditioning

Regular exercise improves muscle strength, spinal stability, and overall functional capacity[6].

**Manual Therapy** Manual therapy techniques are commonly used to reduce pain and improve spinal mobility.

**These techniques include**

- Spinal mobilization
- Spinal manipulation
- Soft tissue mobilization
- Myofascial release

Studies suggest that manual therapy combined with exercise therapy provides better outcomes than exercise alone[7].

**Postural Training and Ergonomic Education** Postural correction and ergonomic training are essential components of physiotherapy management.

**Physiotherapists educate patients about**

- Correct sitting posture
- Proper lifting techniques
- Workplace ergonomics
- Back care during daily activities

Such interventions help prevent recurrence of symptoms[8].

**Electrotherapy Modalities** Electrotherapy modalities are sometimes used as adjunct therapies to relieve pain.

**Common modalities include**

- Transcutaneous Electrical Nerve Stimulation (TENS)
- Ultrasound therapy
- Interferential therapy
- Heat and cold therapy

These treatments mainly provide short-term pain relief[9].

**Motor Control and Core Stabilization Training** Motor control exercises focus on improving coordination and activation of deep spinal muscles such as:

- Transversus abdominis
- Multifidus

These muscles play an important role in stabilizing the lumbar spine[10]. Research indicates that motor control exercises significantly improve functional outcomes in patients with chronic low back pain[11].

**Emerging Physiotherapy Approaches** Recent advances in physiotherapy include innovative approaches for managing low back pain.

**These include**

- Tele-rehabilitation programs
- Virtual exercise monitoring
- Wearable posture correction devices
- Multidisciplinary rehabilitation programs

Such approaches are particularly useful for improving patient adherence and accessibility to rehabilitation services[12].

## DISCUSSION

The management of low back pain has shifted from passive treatment methods toward active rehabilitation strategies. Evidence suggests that exercise therapy combined with patient education and manual therapy produces the best outcomes[13]. Physiotherapy interventions also help reduce dependence on medications and invasive procedures. However, treatment outcomes may vary pending on patient compliance, severity of symptoms, and psychosocial factors. Future research should focus on personalized rehabilitation programs and integration of digital technologies in physiotherapy practice[14].

## CONCLUSION

Low back pain remains one of the most common musculoskeletal conditions worldwide. Physiotherapy plays a vital role in its management through evidence-based interventions such as exercise therapy, manual therapy, and patient education. A multidisciplinary and patient-centred approach is essential for achieving optimal outcomes. Continued research and innovation in physiotherapy practices will further enhance the effectiveness of low back pain rehabilitation strategies.

## ABSTRACT

Enterprises today operate in complex, data-intensive environments where timely and accurate decision-making is essential for competitiveness. This study develops and evaluates an AI-enabled decision-support prototype aimed at improving organizational effectiveness by blending predictive analytics with cognitive reasoning. The prototype, designed using Python's scikit-learn toolkit, processes real operational data to deliver actionable recommendations related to resource utilization, performance forecasting, and risk assessment. A controlled experiment was carried out in a mid-sized enterprise to compare traditional managerial decision approaches with the AI-assisted model. Quantitative analysis revealed marked improvements—decision accuracy increased by 32 percent, response time decreased by 45 percent, and alignment with strategic objectives significantly improved. These findings demonstrate that AI integration not only enhances decision efficiency but also contributes to measurable gains in organizational performance. The paper further proposes a techno-managerial adoption framework that outlines practical steps for embedding AI-based decision systems into enterprise management practices, offering valuable insights for both researchers and practitioners pursuing intelligent organizational transformation.

**Keywords:-**Artificial Intelligence (AI), Decision Support Systems (DSS), Predictive Analytics, Managerial Decision-Making, Organizational Effectiveness

## INTRODUCTION

The rapid evolution of digital technologies has fundamentally transformed the way enterprises operate and compete in the global marketplace. Among these technologies, Artificial Intelligence (AI) has emerged as a dominant force, enabling organizations to automate analytical reasoning, optimize operations, and make informed decisions at unprecedented speed and scale. In data-driven environments, managerial decision-making—once dependent on experience, intuition, and periodic reporting—is increasingly augmented by AI-based Decision Support Systems (DSS) that provide predictive insights and evidence-based recommendations. This transition marks a paradigm shift from descriptive decision models to intelligent, adaptive, and self-learning systems capable of continuously improving decision quality. Managers today face complex challenges characterized by volatile markets, dynamic customer behavior, and the constant influx of digital information. Traditional decision-making approaches, which rely heavily on human judgment, often fall short in coping with such complexity. AI, through Predictive Analytics and cognitive reasoning, offers the capability to analyze large datasets, uncover hidden patterns, and forecast future outcomes with a high degree of accuracy. These capabilities empower managers to respond proactively rather than reactively, aligning decisions with organizational goals and performance metrics. As enterprises adopt AI to enhance productivity and competitiveness, understanding its role in improving Organizational Effectiveness becomes critical.
Recent studies highlight that AI integration leads to measurable improvements in operational efficiency, cost reduction, and strategic agility (Kaplan &Haenlein, 2022; Dwivedi et al., 2023). However, successful implementation requires more than technical deployment—it demands managerial adaptation, process redesign, and trust in machine-generated recommendations. The interplay between technological capability and managerial cognition forms the foundation of AI-driven decision-making. While earlier research explored algorithmic efficiency or data-science models in isolation, limited studies have examined how AI-based decision prototypes influence managerial behavior and organizational outcomes within real enterprise settings.

To address this gap, the present study develops and evaluates an AI-driven decision-support prototype that integrates machine-learning algorithms with managerial decision processes. The prototype is designed to provide real-time recommendations in areas such as resource allocation, performance forecasting, and risk assessment—core components of enterprise management. Built using Python's scikit-learn library and trained on operational datasets, the system demonstrates how AI can convert raw data into actionable insights accessible through an intuitive decision dashboard. By comparing traditional decision workflows with AI-assisted processes, the study investigates whether algorithmic support can significantly enhance decision accuracy, responsiveness, and strategic alignment.
This research contributes to both computer science and management disciplines in three key ways. First, it presents a techno-managerial framework that links AI functionality with managerial effectiveness. Second, it empirically validates the prototype's performance in an enterprise context, bridging the gap between theoretical AI capabilities and practical adoption. Third, it offers insights into human–AI collaboration—particularly how interpretability and trust influence managers' willingness to rely on AI-generated insights.

The overarching goal is to demonstrate that AI is not a substitute for human judgment but a catalyst that enhances decision quality and consistency. When implemented strategically, AI transforms managerial decision-making from intuition-based to evidence-driven, fostering a culture of continuous learning and innovation. The outcomes of this study are expected to help organizations develop systematic approaches for embedding AI into their decision cycles, ultimately leading to improved organizational agility and effectiveness. The remainder of this paper is structured as follows: Section 2 reviews existing literature on AI applications in decision-making and organizational performance. Section 3 introduces the conceptual framework and hypotheses. Section 4 details the research methodology and prototype design. Section 5 presents the experimental results and discussion. Section 6 outlines managerial and theoretical implications, followed by the conclusion and directions for future research.

## REVIEW OF LITERATURE

**Artificial Intelligence in Managerial Decision-Making**

Artificial Intelligence (AI) has evolved from a computational research concept into a strategic enabler of organizational competitiveness. AI-driven tools such as machine learning, natural-language processing, and predictive analytics now support managerial decisions by processing large-scale, unstructured datasets in real time. According to Dwivedi et al. (2023), AI transforms managerial roles by shifting focus from operational control to strategic interpretation, enabling leaders to concentrate on value creation rather than routine analysis. Similarly, Brynjolfsson and McElheran (2022) observed that enterprises adopting AI analytics achieve faster decision cycles and greater forecasting precision than those relying solely on traditional business intelligence. AI's cognitive capabilities allow managers to simulate scenarios, evaluate alternatives, and mitigate risk under uncertainty. Recent frameworks propose *augmented intelligence*, where human intuition and algorithmic reasoning coexist (Haenlein et al., 2021). This paradigm enhances decision consistency and minimizes cognitive bias, a limitation frequently identified in intuitive managerial behavior. However, scholars such as Shrestha et al. (2022) caution that excessive reliance on AI without interpretability mechanisms may lead to "automation complacency," emphasizing the need for transparency and user trust in AI-driven recommendations.

**Decision Support Systems and Predictive Analytics**

The integration of AI into Decision Support Systems (DSS) represents a major evolution in managerial information systems. Classical DSS models provided static, rule-based analysis, whereas modern AI-driven DSS employ machine learning to learn from historical decisions and continuously refine their predictive capacity (Power, 2021). Predictive analytics further extend this capability by identifying latent patterns that improve resource allocation, customer behavior forecasting, and operational risk assessment. Empirical studies have demonstrated that AI-based DSS significantly improve decision timeliness and accuracy. For instance, Kumar and Gupta (2023) implemented a neural-network-based DSS for project portfolio selection, reducing decision latency by nearly half. Similarly, Li et al. (2022) reported that predictive analytics integrated with enterprise dashboards enhanced managerial responsiveness in supply-chain operations. These findings affirm that the fusion of AI and predictive analytics enables adaptive decision environments that evolve with organizational data streams.

Despite these advancements, challenges persist regarding data quality, algorithmic bias, and model interpretability. Without proper governance frameworks, predictive models may amplify pre-existing biases embedded in training datasets (Raisch&Krakowski, 2021). Therefore, contemporary research emphasizes explainable AI (XAI) as a necessary feature for managerial adoption, ensuring that decision rationale is transparent and auditable.

**Organizational Effectiveness and Digital Transformation**

Organizational Effectiveness (OE)—the degree to which an enterprise achieves its strategic objectives efficiently—has been central to management research for decades. The emergence of digital transformation has reframed OE as a dynamic construct influenced by technology integration, knowledge sharing, and innovation agility. According to George et al. (2023), AI enhances OE by improving resource utilization, forecasting accuracy, and cross-functional coordination. AI's analytical capabilities also foster data-driven cultures that align operational metrics with strategic goals.

Research in this domain identifies multiple dimensions through which AI contributes to OE:

1. Process Efficiency – automating repetitive managerial tasks.
2. Decision Quality – providing real-time evidence for strategic choices.
3. Strategic Flexibility – enabling rapid adaptation to market changes.
4. Human Capital Empowerment – freeing managers to focus on creativity and innovation.

However, the effectiveness of AI initiatives depends on managerial readiness, organizational culture, and trust in technology (Tambe et al., 2020). A techno-centric implementation without change management often yields limited impact. Hence, scholars propose *techno-managerial frameworks* that integrate AI capabilities with human decision competencies and organizational learning mechanisms (Leung & Hong, 2022).

**Gaps Identified in Existing Research**

Although numerous studies have examined AI's algorithmic performance or its theoretical influence on management, relatively few have empirically validated prototype-based AI systems within real enterprise settings. Existing literature tends to focus either on the technical optimization of AI models (accuracy, precision, recall) or the strategic implications of AI adoption at a conceptual level. What remains underexplored is the middle ground—the techno-managerial integration where AI prototypes directly support managerial decision processes and yield quantifiable improvements in organizational effectiveness. Moreover, while prior works highlight the potential of predictive analytics, limited research measures how specific AI features (e.g., interpretability, response speed, or recommendation quality) affect managerial trust and adoption. This creates a gap for hybrid studies that assess not only system performance but also the human factors influencing AI acceptance.

The review reveals that AI-driven decision support and predictive analytics have proven benefits in accuracy, efficiency, and responsiveness. However, most research lacks empirical evidence from implemented prototypes within managerial environments. Addressing this void, the present study develops an AI-driven decision-support prototype that bridges computational intelligence and managerial cognition. By experimentally comparing traditional and AI-assisted decision workflows, the study aims to validate whether AI integration leads to measurable improvements in decision quality and overall organizational effectiveness.

This literature synthesis establishes a foundation for the conceptual framework and hypotheses discussed in the next section.

**Conceptual Framework and Hypotheses**

The conceptual foundation of this study rests on the idea that integrating Artificial Intelligence (AI) into managerial workflows fundamentally reshapes how decisions are made, evaluated, and implemented in enterprises. In conventional settings, managerial choices depend heavily on human experience, intuition, and periodic reports, which can introduce cognitive bias and delay. By contrast, AI-enabled systems leverage Predictive Analytics, machine-learning models, and Decision Support Systems (DSS) to process vast data streams in real time and provide actionable insights.

The proposed framework integrates three primary dimensions:

1. AI-Driven Decision Capability (AIDC): The organization's technological ability to capture, analyze, and interpret data using AI models.
2. Managerial Decision Quality (MDQ): The extent to which AI insights improve accuracy, consistency, and timeliness of managerial decisions.
3. Organizational Effectiveness (OE): The overall improvement in operational performance, resource utilization, and strategic alignment as a result of AI-enhanced decisions.

Supporting factors include User Trust and Interpretability (UTI), which mediate the relationship between AI capability and perceived effectiveness. The model assumes that when AI systems are transparent and interpretable, managers are more likely to rely on their outputs, leading to higher organizational gains. The AI-Driven Decision Capability represents the core technological driver that enables predictive modeling and data intelligence. Managerial Decision Quality functions as an intermediary construct, capturing how AI recommendations influence decision accuracy and responsiveness. Organizational Effectiveness denotes the outcome variable, representing measurable improvements in enterprise performance. User Trust and Interpretability act as a psychological bridge, ensuring that managers understand, validate, and adopt AI recommendations confidently. Figure 1 shows the conceptual framework of the system.

The framework (Figure 1) aligns with the Technology–Organization–Environment (TOE) Model and the Technology Acceptance Model (TAM), integrating technical readiness with managerial cognition to explain AI adoption in decision processes.

**Hypothesis Development**

**H1: AI-Driven Decision Capability and Managerial Decision Quality**

AI technologies enhance managerial decisions by providing data-backed predictions and minimizing subjective bias. Studies by Dwivedi et al. (2023) and Li et al. (2022) demonstrate that predictive models substantially improve decision reliability and speed. Hence:

H1: AI-driven decision capability has a positive and significant impact on managerial decision quality.

**H2: Managerial Decision Quality and Organizational Effectiveness**

Decision quality directly affects an organization's ability to achieve its strategic objectives efficiently. Improved accuracy, timeliness, and rationality translate into higher productivity and reduced operational risk (George et al., 2023). Therefore:

H2: Enhanced managerial decision quality positively influences organizational effectiveness.

**H3: AI-Driven Decision Capability and Organizational Effectiveness**

Beyond decision quality, AI itself contributes to organizational performance by enabling automation, cost optimization, and agile forecasting (Brynjolfsson&McElheran, 2022). Hence:

H3: AI-driven decision capability has a direct positive impact on organizational effectiveness.

**H4: Mediating Role of User Trust and Interpretability**

The degree of trust managers place in AI recommendations determines adoption success. When systems are explainable and transparent, acceptance increases (Raisch&Krakowski, 2021). Accordingly:

H4: User trust and interpretability mediate the relationship between AI-driven decision capability and managerial decision quality.

**H5: Moderating Role of Managerial Experience**

Managerial experience moderates the effectiveness of AI recommendations. Experienced managers may use AI outputs differently than novices, influencing overall effectiveness (Shrestha et al., 2022). Therefore:

H5: Managerial experience moderates the relationship between AI-driven decision capability and managerial decision quality.

The conceptual framework posits that AI-driven decision capability acts as a technological catalyst that enhances managerial decision quality, which in turn strengthens organizational effectiveness. The framework further recognizes the human–technology interface, asserting that user trust and managerial experience shape how effectively AI can transform enterprise decision processes.

Empirical validation of this model through a prototype-based experiment—in which managers interact with the developed AI decision-support system—will test the proposed hypotheses quantitatively. Findings are expected to clarify both the direct effects of AI integration and the socio-cognitive factors influencing its adoption.

## RESEARCH METHODOLOGY

**Research Design**

This study adopts a prototype-based experimental research design that combines quantitative analysis with practical system implementation. The objective is to evaluate how an AI-driven decision-support prototype can enhance managerial decision quality and overall organizational effectiveness. The research follows a design–develop–evaluate approach inspired by the Design Science Research (DSR) methodology, emphasizing artifact creation, functionality validation, and empirical testing.

The prototype was deployed in a mid-sized enterprise environment to compare two decision-making conditions:
1. Traditional managerial decisions based on human intuition and manual analysis.
2. AI-assisted decisions generated through the developed predictive model.
Performance outcomes from both scenarios were measured and analyzed to determine the degree of improvement achieved through AI integration.

**Prototype Development**
The prototype—named AIDeM (AI-Driven Managerial Decision System)—was developed using an agile software engineering process consisting of four iterative stages:
1. Requirement Analysis: Identified key decision parameters such as project prioritization, resource allocation, and risk scoring.
2. Data Engineering: Collected and cleansed enterprise data from finance, HR, and operations modules.
3. Model Development: Implemented predictive algorithms using Python's scikit-learn library.
4. Interface Design: Built a web-based dashboard using Flask for real-time visualization and decision recommendations.
The architecture integrates three core layers:
• Data Layer: Enterprise datasets stored in a MySQL database.
• Intelligence Layer: Machine-learning engine performing regression and classification analysis.
• Presentation Layer: Interactive dashboard providing recommendations, charts, and what-if analysis.
This layered design ensures scalability, interpretability, and ease of integration with existing enterprise systems.

**Data Collection and Sample**
Data for training and testing the prototype were obtained from anonymized enterprise operational records spanning 18 months, covering performance metrics, budget utilization, project timelines, and personnel data. To validate managerial outcomes, a sample of 30 mid-level managers from the organization participated in the experimental phase. Each participant was asked to perform identical decision tasks under both the traditional and AI-assisted conditions.
A structured questionnaire (based on a five-point Likert scale) captured perceptions related to:
• Decision accuracy,
• Timeliness,
• Trust in AI output, and
• Perceived organizational impact.
The mixed dataset (system-generated metrics + survey responses) provided a robust foundation for statistical and behavioral analysis.

**Variables and Measures (Table 1.)**

**Tools and Techniques**
- Programming & Frameworks: Python 3.11, Flask, scikit-learn, pandas, NumPy.
- Database: MySQL 8.0 for secure structured data storage.
- Visualization Tools: Matplotlib and Plotly for analytics dashboards.
- Statistical Analysis:
- Descriptive statistics for demographic profiling.
- Paired-sample t-tests to compare traditional vs AI-assisted decision outcomes.
- Regression analysis to examine causal relationships among variables.
- Structural Equation Modeling (SEM) using SmartPLS for hypothesis validation.

**Evaluation Metrics**
Prototype performance and managerial impact were assessed using a mix of technical and behavioral metrics.

**Experimental Procedure**

1. Baseline Phase: Participants made decisions using existing organizational methods.
2. AI-Assisted Phase: The same tasks were repeated using the AIDeM prototype's recommendations.
3. Data Recording: Decision outcomes, timing, and user feedback were automatically logged.
4. Analysis Phase: Statistical tests compared outcomes across both conditions to validate hypotheses H1–H5.

The controlled setup ensured that any observed performance improvement could be attributed to the AI system rather than external factors.

This methodological framework ensures a rigorous empirical foundation for assessing how AI-driven decision-support systems influence managerial and organizational outcomes. By combining prototype implementation, real-world experimentation, and statistical validation, the study bridges the gap between technical design and managerial impact. The next section presents the results and discussion, analyzing how AI integration transforms decision efficiency, quality, and organizational effectiveness.

## RESULTS AND DISCUSSION

This section presents the empirical findings derived from the prototype implementation and controlled experimental study. The results were obtained by analyzing both system-generated data (performance metrics) and managerial feedback (survey responses). The analysis compares traditional decision-making processes with AI-assisted decision-making using the AIDeM prototype to evaluate improvements in decision accuracy, timeliness, and organizational effectiveness. Thirty (30) mid-level managers from a mid-sized enterprise participated in the study. Participants represented diverse functional areas such as operations, finance, and human resources, ensuring a balanced view of managerial decision practices. Table 3 summarizes participant demographics.

The diverse experience distribution supported the analysis of managerial experience (H5) as a moderating factor.

The AI model embedded in the prototype (Decision Tree + Random Forest ensemble) was trained and tested using enterprise datasets. The dataset was split into an 80:20 training–testing ratio. Performance metrics were computed as follows:

The ensemble model achieved **90% accuracy**, demonstrating high reliability in predicting decision outcomes such as project prioritization, risk scores, and resource utilization. These findings validate the AI-Driven Decision Capability (AIDC) component of the conceptual framework.

**Comparative Analysis: Traditional vs. AI-Assisted Decisions**

The experimental results indicated a significant improvement in managerial performance after integrating AI support. Table 5 presents a summary of comparative metrics.

As shown in Figure 2, decision accuracy increased from 68 percent to 90 percent, while average decision time was nearly halved following AI implementation.

The reduction in decision time and improvement in decision accuracy demonstrate the effectiveness of AI integration, supporting H1 and H3.

A paired-sample t-test confirmed statistical significance for all observed improvements ($p < 0.01$), indicating that results were not due to chance.

The results reveal that AI-Driven Decision Capability (AIDC) significantly influences both Decision Quality (MDQ) and Organizational Effectiveness (OE), with partial moderation from Managerial Experience. The mediation of User Trust and Interpretability (UTI) further highlights the importance of human acceptance in AI adoption.

The trend in Figure 3 demonstrates continuous improvement in organizational effectiveness over successive months of AI usage.

## DISCUSSION OF FINDINGS

The experimental outcomes strongly support the conceptual framework proposed in Section 3. The AI-driven decision-support prototype demonstrably enhanced the accuracy, timeliness, and strategic coherence of managerial decisions. The findings are consistent with prior studies (Dwivedi et al., 2023; Haenlein et al., 2021) that highlight AI's ability to augment managerial cognition through real-time data analytics.

**Enhanced Decision Quality (H1):**
Managers equipped with AI recommendations exhibited higher decision confidence and fewer analytical errors. The AI model effectively reduced human bias, validating that predictive analytics can significantly refine decision quality.

**Improved Organizational Effectiveness (H2 & H3):**
The observed gains in productivity and strategic alignment demonstrate that AI adoption has measurable organizational benefits. These results align with George et al. (2023), who noted similar improvements in digital transformation contexts.

**Role of Trust and Interpretability (H4):**
Managers showed greater reliance on AI outputs when the prototype provided explainable results. This confirms the mediating influence of trust and interpretability, echoing Raisch and Krakowski's (2021) findings on explainable AI (XAI) in management.

Figure 4. Correlation between managerial trust in AI outputs and decision accuracy (r = 0.67).
Managers with higher trust levels in AI recommendations tended to make more accurate and consistent decisions. As depicted in Figure 4, there exists a strong positive correlation (r = 0.67) between trust in AI and decision accuracy, reinforcing the mediating effect proposed in H4.

**Moderating Influence of Experience (H5):**
Experienced managers were more selective in accepting AI recommendations, suggesting that human expertise and AI intelligence are complementary rather than substitutive.

**Techno-Managerial Synergy:**
The combination of AI analytics and managerial judgment produced superior decisions, validating the techno-managerial integration model proposed in this research. The results imply that AI should not be viewed as a replacement for human managers but as an augmenting partner that enhances decision precision and organizational agility. For practitioners, the findings emphasize the importance of designing explainable and interactive AI systems that encourage user trust. For researchers, the study demonstrates the empirical viability of prototype-based validation as a means of bridging the gap between theoretical AI models and real-world decision-making. The experimental validation confirms that AI-driven decision-making significantly improves managerial decision quality and overall organizational effectiveness. The quantitative outcomes substantiate all major hypotheses, providing evidence that integrating AI into decision workflows yields tangible performance gains. The next section explores the implications, limitations, and future research directions to strengthen the practical and theoretical contribution of this study.

**Implications of the Study**

**Managerial Implications**

The findings of this study have strong implications for organizations seeking to enhance decision efficiency through artificial intelligence (AI). The empirical evidence demonstrates that AI-driven decision-support systems can substantially improve decision accuracy, reduce response time, and strengthen strategic alignment. These outcomes highlight the necessity for enterprises to move beyond conventional analytics and adopt AI-assisted managerial ecosystems.

**Evidence-Based Decision Culture:**

Organizations should promote a culture of data-driven decision-making where managerial choices are informed by predictive insights rather than intuition alone. The use of AI-generated recommendations improves objectivity, enabling consistent and rational decision outcomes.

**Augmentation, Not Replacement:**

The study confirms that AI complements managerial expertise rather than replacing it. Managers should be trained to interpret and validate AI insights, fostering collaborative human–AI interaction that leverages both analytical precision and human judgment.

**Building Trust and Interpretability:**

Transparency in AI algorithms is critical for adoption. Managers are more likely to trust AI systems that explain how predictions are derived. Hence, enterprises should invest in Explainable AI (XAI) interfaces and visualization tools that promote clarity and accountability in automated recommendations.

**Strategic Integration:**

AI implementation should align with business goals and governance structures. Establishing a Techno-Managerial Integration Framework—combining data science capabilities with leadership decision protocols—will ensure sustainable adoption and measurable organizational impact.

**Theoretical Implications**

From a theoretical perspective, this research contributes to the intersection of computer science and management science by validating how AI technologies translate into tangible organizational outcomes. The study extends the Technology–Organization–Environment (TOE) and Technology Acceptance Model (TAM) frameworks by incorporating Managerial Decision Quality (MDQ) and User Trust and Interpretability (UTI) as key mediating constructs. Furthermore, it reinforces the concept of Augmented Intelligence, positioning AI as a decision enhancer rather than an autonomous decision-maker. By empirically testing a prototype in an organizational setting, this research bridges the gap between theoretical AI adoption models and real-world managerial applications, offering a replicable model for future hybrid studies.

**Practical Implications For Industry And Policy**

The results have broader implications beyond the enterprise level. Policymakers and technology strategists can draw on these insights to design AI governance guidelines that balance innovation with ethical responsibility. Industry leaders should prioritize AI literacy programs and change management strategies to ensure smooth integration of AI systems into existing decision workflows. The proposed AIDeM prototype serves as a practical example that can be adapted by small and medium enterprises (SMEs) for incremental digital transformation without heavy infrastructure investments.

## CONCLUSION

This study provides empirical evidence that integrating AI into managerial decision processes significantly enhances organizational effectiveness. The development and evaluation of the AIDeM prototype demonstrated measurable

improvements in decision accuracy, timeliness, and strategic coherence, validating the proposed conceptual framework. By merging technological precision with managerial cognition, AI emerges as a transformative catalyst for decision-making excellence. The results reinforce that the future of management lies not in replacing human intelligence but in augmenting it through intelligent systems that enable faster, fairer, and more informed decisions. The research concludes that sustainable organizational effectiveness in the digital era depends on how well enterprises embed AI into strategic decision cycles—balancing automation with human insight, and technology with trust.

**Table 1. Variables and Measures**

| Construct | Type | Operational Definition | Measurement Approach |
|---|---|---|---|
| **AI-Driven Decision Capability (AIDC)** | Independent | Extent to which AI generates reliable, data-driven insights | Algorithmic accuracy, prediction reliability |
| **Managerial Decision Quality (MDQ)** | Mediator | Improvement in decision accuracy and responsiveness | Comparison of pre- and post-AI decisions |
| **Organizational Effectiveness (OE)** | Dependent | Improvement in performance metrics and strategic alignment | Productivity, cost efficiency, satisfaction scores |
| **User Trust & Interpretability (UTI)** | Mediator | Degree of managerial trust in AI recommendations | Survey responses and feedback logs |
| **Managerial Experience (ME)** | Moderator | Years of experience influencing adoption behavior | Demographic data |

**Table 2. Evaluation Metrics**

| Category | Metrics | Purpose |
|---|---|---|
| **Technical Performance** | Accuracy, precision, recall, F1-score | Evaluate model efficiency |
| **Decision Process** | Average decision time, recommendation reliability | Assess process enhancement |
| **Organizational Impact** | Productivity index, task completion rate | Quantify overall effectiveness |
| **Managerial Perception** | Trust score, usability rating, interpretability index | Gauge human–AI acceptance |

**Table 3.Participant Profile**

| Parameter | Category | Percentage |
|---|---|---|
| Gender | Male (60%), Female (40%) | 100% |
| Age Group | 30–40 (50%), 41–50 (35%), 51+ (15%) | 100% |
| Experience | 5–10 years (40%), 11–15 years (33%), 16+ years (27%) | 100% |
| Department | Operations (40%), Finance (30%), HR (30%) | 100% |

**Table 4.Model Performance Metrics**

| Metric | Decision Tree | Random Forest | Ensemble Average |
|---|---|---|---|
| Accuracy | 0.88 | 0.93 | **0.90** |
| Precision | 0.86 | 0.91 | **0.89** |
| Recall | 0.84 | 0.90 | **0.87** |
| F1-Score | 0.85 | 0.91 | **0.88** |

**Table 5. Comparative Decision Outcomes**

| Metric | Traditional Decision Process | AI-Assisted Decision Process | % Improvement |
|---|---|---|---|
| Decision Accuracy | 68% | **90%** | +32% |
| Average Decision Time (minutes) | 45 | **25** | –45% |
| Resource Allocation Efficiency | 72% | **88%** | +22% |
| Strategic Alignment Score | 3.5/5 | **4.6/5** | +31% |
| Managerial Satisfaction | 3.2/5 | **4.5/5** | +41% |

**Table 6. Hypothesis Validation Results**

| Hypothesis | Statement | Result | Statistical Test |
|---|---|---|---|
| H1 | AI-driven decision capability → managerial decision quality | **Supported** | Regression ($\beta = 0.68$, $p < 0.01$) |
| H2 | Managerial decision quality → organizational effectiveness | **Supported** | SEM ($\beta = 0.74$, $p < 0.01$) |
| H3 | AI-driven decision capability → organizational effectiveness | **Supported** | Regression ($\beta = 0.59$, $p < 0.01$) |
| H4 | User trust & interpretability mediates AI → MDQ relationship | **Supported** | Mediation analysis ($R^2$ change = +0.12) |
| H5 | Managerial experience moderates AI → MDQ relationship | **Partially Supported** | Moderation test ($\beta = 0.21$, $p < 0.05$) |

## ABSTRACT

Periodontal teeth staging is crucial for assessing structural alterations in the supporting tissues of teeth using dental radiographs. This research introduces a Dental Radiograph-Based TRAC-ConvNeXt architecture for the automatic classification of periodontal tooth stages. The suggested approach combines the hierarchical feature extraction capacity of ConvNeXt with Token Relational Attention and Channel Recalibration (TRAC) to improve spatial and contextual feature representation in radiographic images. Dental radiographs collected from Kaggle were subjected to preprocessing, including scaling, normalization, and augmentation, to facilitate effective learning. The TRAC modules are integrated into ConvNeXt stages to enhance inter-feature interactions and augment stage-level discriminating. The model executes multi-class classification into Stage 1, Stage 2, Stage 3, and Stage 4 classes based on the radiographic features of periodontal tooth structures. Experimental assessment reveals exceptional classification efficacy, attaining an accuracy of 99.06%, precision of 98.14%, recall of 98.13%, and an F1-score of 98.13%. The findings demonstrate robust feature representation capacity and dependable discrimination of periodontal tooth stages, establishing an efficient automated framework for radiograph-based periodontal evaluation.

## INTRODUCTION

Periodontal teeth staging is crucial for assessing structural alterations in the supporting tissues of teeth using dental radiographs. Radiographic evaluation offers essential information on alveolar bone levels, tooth integrity, and the state of supporting tissues that signify the advancement of periodontal disease. Precise staging is crucial for therapeutic planning, ongoing surveillance, and preventive healthcare. Nonetheless, the manual interpretation of dental radiographs is labor-intensive and reliant on clinical experience, potentially leading to subjectivity and inter-observer heterogeneity. Progress in deep learning has enabled the automated examination of medical and dental images with exceptional accuracy. Convolutional Neural Networks (CNNs) have shown significant proficiency in extracting hierarchical spatial characteristics from radiography images. Recently, transformer-inspired architectures like ConvNeXt have enhanced feature representation by integrating contemporary design concepts into convolutional frameworks. Notwithstanding these advancements, traditional convolutional architectures may continue to encounter constraints in representing long-range connections and contextual interactions inside radiographic structures. The study presents a Dental Radiograph-Based TRAC-ConvNeXt architecture for the classification of periodontal teeth stages to overcome these problems. The suggested methodology incorporates TRAC inside ConvNeXt stages to improve feature discrimination and contextual comprehension. The design incorporates relational attention mechanisms inside hierarchical convolutional blocks to capture spatial patterns and inter-feature relationships pertinent to periodontal stage distinction. Dental radiographs reveal nuanced structural differences between periodontal phases. Variations in bone height, periodontal ligament space, and structural integrity often need nuanced representation learning. The TRAC technique improves channel-wise relevance weighting during the modelling of token-level interactions, enabling the network to prioritize clinically significant characteristics. This integration enhances classification accuracy throughout various periodontal stages. The system executes multi-class categorization into four distinct categories such as Stage 0, Stage I–II, Stage III, and Stage IV. Preprocessing methods like normalization and scaling provide uniformity among radiographs. The network acquires discriminative representations by hierarchical feature extraction, followed by global pooling and fully linked classification layers. The performance study reveals a solid categorization ability at all phases, underscoring the resilience of the suggested architecture. The suggested framework enhances automated dental radiograph analysis by refining stage-level discrimination while preserving architectural efficiency. It offers a systematic deep learning methodology that aids clinical decision-making and diminishes manual diagnostic tasks.

**The primary contributions of this study are summarized as follows:**

- A novel Dental Radiograph-Based TRAC-ConvNeXt architecture for multi-class periodontal teeth stage classification.
- Integration of Token Relational Attention and Channel recalibration within ConvNeXt stages to enhance contextual feature representation.
- A hierarchical feature learning strategy tailored for subtle radiographic variations in periodontal staging.
- Comprehensive experimental evaluation demonstrating high accuracy, precision, recall, and F1-score, AUC Curve across four periodontal stages.
- A structured and scalable framework suitable for clinical support systems and automated radiographic assessment.

The remainder is organized into five sections. Section 1 presents the introduction and outlines the motivation and contributions of the proposed work. Section 2 reviews related literature on dental radiograph analysis, ConvNeXt architectures, and attention-based deep learning models. Section 3 describes the proposed TRAC-ConvNeXt architecture, preprocessing methods, and classification framework in detail. Section 4 presents the experimental setup, evaluation metrics, results, and performance analysis. Section 5 concludes the paper with a summary of findings and future research directions.

## RELATED WORKS

Improve dental disease diagnosis using a cross-attention-based hybrid DeiT-CoAtNet model was detailed in [1]. A hybrid deep learning framework combines Data-efficient Image Transformer (DeiT) and Convolutional Attention Network (CoAtNet) for dental disease classification. Both models extract complementary global and local features, which are integrated using a cross-attention fusion mechanism. Final prediction was enhanced using a stacking ensemble classifier consisting of SVM, XGBoost, and MLP.3. U-Net-based deep learning for panoramic radiograph primary and permanent tooth segmentation and agenesis identification was discussed by [2]. A U-Net-based deep learning framework was employed for simultaneous segmentation of primary and permanent teeth and automated agenesis detection in panoramic radiographs. The architecture follows an encoder–decoder structure with skip connections, integrating dilated convolutions to capture multi-scale contextual features. Adam optimization and Dice loss were used to enhance segmentation precision and detection reliability. Primary molar furcation lesion identification and clinical decision support using panoramic radiograph-based deep learning models was briefed by [3]. A transformer-based object detection framework was implemented for automated diagnosis of furcation lesions in pediatric panoramic radiographs. The study fine-tuned YOLOv12x, RT-DETR-L, and RT-DETR-X using COCO-pretrained weights. Lesions were localized using bounding boxes, and detection outputs were linked with treatment decision thresholds for clinical decision support.

An AI periodontitis classification model: Systematic review was shown in [4]. A systematic review analysed artificial intelligence methods for periodontitis classification using dental radiographs and intraoral images. Most studies employed deep learning models, mainly CNN-based architectures (VGG, ResNet, U-Net, Mask R-CNN) and hybrid frameworks integrating segmentation with staging. Traditional machine learning classifiers such as SVM, Random Forest, and XGBoost were also reported. ViT classifies apical closure. Vision transformer architecture apical closure evaluation in panoramic radiographs was detailed in [5]. A Vision Transformer (ViT)-based classification framework was utilized for detecting open and closed apex conditions from panoramic radiographs. Images are cropped into ROI patches, resized, and normalized. ViT Base Patch16 and Patch32 extract global contextual features using self-attention, followed by an MLP classifier for binary prediction. Transformer-based YOLO with GA optimisation automatically identifies and classifies dental abnormalities and tooth kinds in [6]. It modifies the CSPDarknet53 backbone of YOLOv4 by integrating a Multi-Head Self-Attention (MHSA) block to capture global contextual tooth features from panoramic X-ray images. Additionally, GA-based hyperparameter tuning optimizes learning rate, batch size, anchor boxes, filters, and convolution layers to improve detection and classification performance.

Generational adversarial networks for data augmentation in synthetic orthopantomography image generation was discussed in [7]. A GAN-based deep learning pipeline was employed to generate high-resolution synthetic panoramic dental radiographs (OPG) for dataset augmentation. Multiple GAN variants were trained using diverse multi-source OPG images, and the best models were selected based on anatomical realism. Synthetic image quality was evaluated using a YOLO-based detection model and expert dental scoring. Dental and craniofacial ailment classification and identification using deep learning was detailed in [8]. A transfer learning–based deep learning framework was implemented using a pre-trained MobileNet architecture for classification of dental and craniofacial conditions. The model applies image resizing and normalization, followed by MobileNet feature extraction and a customized dense classifier. The framework supports multiclass prediction of cavities, fractures, gum disease, malignent, and receding gums. Automatic identification of maxillary and mandibular third molar extraction difficulties and post-extraction problems using deep learning was shown in [9]. A two-stage deep learning framework was developed for automated third molar diagnosis using panoramic OPG radiographs. DeepLabv3+ performs semantic segmentation of third molars, second molars, maxillary sinus, and inferior alveolar canal. The segmented mask was fused with ROI images and classified using a ResNet50 + Vision Transformer hybrid model. Automatic age and sex assessment from dental panoramic radiographs was detailed in [10].

A multitask deep learning framework called DeepToothDuo was developed using EfficientNetB0 as the backbone for simultaneous age regression and sex classification from panoramic radiographs. The model applies transfer learning by freezing convolution layers initially, followed by fine-tuning selected layers. A weighted loss combines MSE for age prediction and binary cross-entropy for sex classification. Attention-enhanced deep learning for panoramic X-ray multi-label dental diagnosis was discussed in [11]. An attention-enhanced deep learning framework for multi-class dental condition classification from panoramic X-ray images was used. It applies preprocessing (brightness adjustment, CLAHE, normalization, masking, resizing) and evaluates a custom CNN with attention, transfer learning models (VGG16, ResNet50, Xception) with attention, and hybrid CNN feature extraction combined with SVM, Random Forest, and Decision Tree classifiers. Deep learning-automated mandibular third molar impaction angulation measurement for Winter's classification was shown in [12]. A comparative AI-based framework for dental age estimation from orthopantomography (OPG) images was discussed. It reviews traditional staging methods (Nolla, Demirjian, Willems, Haavikko) and modern AI approaches using deep learning. CNN architectures such as AlexNet and ResNet, along with machine learning models like SVM and Random Forest, are highlighted for automated age prediction. Impacted teeth, periodontitis, and dental caries multi-center dental panoramic radiography image dataset was Compared for segmentation and classification tasks in [13]. A multi-center panoramic dental radiography dataset was introduced for impacted teeth, periodontitis, and dental caries analysis. Benchmarking was performed using deep learning segmentation models including UNet, TransUNet, TA-Net, CE-Net, and DS-TransUNet. For classification, pretrained CNN backbones such as AlexNet, VGG, GoogLeNet, ResNet, and ResNet with CBAM attention were evaluated. AI diagnosis accuracy for periapical lesions in panoramic radiography and CBCT imaging was used in [14]. A deep learning–based diagnostic framework was implemented to detect periapical lesions using both panoramic radiographs (OPG) and CBCT images. The system applies an AI model for automated lesion identification and compares its diagnostic performance with expert clinicians. The study evaluates sensitivity, specificity, and accuracy across imaging modalities to validate AI-assisted periapical pathology identification. Automatic dental type and pathology classification using panoramic radiography and random forests was shown in [15]. A Random Forest ensemble framework was used for automatic classification of tooth types and dental anomalies from panoramic radiographs.

Geometric features such as bounding box coordinates, area, and perimeter are extracted. Ten decision trees are trained using bagging, and majority voting produces final prediction. Genetic Algorithm optimizes hyperparameters for improved classification. Deep learning for dental panoramic radiograph age group classification was detailed in [16]. A deep learning–based age group classification framework was developed using panoramic dental radiographs. The system applies preprocessing and trains CNN-based models to learn discriminative tooth growth patterns. Transfer learning was incorporated to improve feature extraction, and a softmax-based classifier predicts age group categories from learned deep feature representations. Deep convolutional neural network for dental radiograph periodontal disease classification of PDCNET was briefed in [17]. It uses a custom deep CNN architecture named PDCNET for periodontal disease classification from dental radiographs. The workflow applies image normalization and one-hot encoding, then handles class imbalance using SMOTE–Tomek resampling. PDCNET contains five Conv2D blocks (Conv2D + ReLU + MaxPooling), followed by Dropout, Flatten, a Dense layer, and a SoftMax classifier. Grad-CAM heatmaps are used for explainability. Fully automatic deep learning third molar development classification was shown in [18]. The technique refers to a transfer learning–based model optimization approach in which multiple pretrained deep CNN architectures are evaluated for the same classification task. Networks such as EfficientNet, EfficientNetV2, MobileNet (Large and Small), ResNet18, and ShuffleNet are fine-tuned by modifying the final classification layers and adjusting training hyperparameters. The best-performing optimized backbone was then selected for final prediction. A hybrid transfer learning method for orthopantomogram radiograph tooth diagnosis was used in [19]. A hybrid transfer learning framework was used for teeth diagnosis from panoramic OPG radiographs. Two strategies are applied: direct classification using fine-tuned deep models, and a hybrid pipeline were pretrained CNN/ViT models extract deep features, optionally reduced using PCA, then classified using machine learning models such as SVM, Random Forest, KNN, and Logistic Regression. Orthopantomogram radiograph-based hybrid transfer learning tooth diagnosis was discussed in [20]. A hybrid transfer learning framework was used for diagnosing dental conditions from panoramic X-rays. It performs tooth cropping,

preprocessing, and class balancing through rotation-based augmentation. Deep features are extracted using pretrained CNNs and Vision Transformers. PCA reduces feature dimensionality, and classifiers such as SVM, KNN, Logistic Regression, and Random Forest perform final prediction.

## METHODS AND MATERIALS

The proposed Dental Radiograph-Based TRAC-ConvNeXt framework is designed for automated periodontal teeth stage classification using dental radiographs. The architecture integrates hierarchical convolutional feature extraction with TRAC to enhance discriminative feature learning. The system classifies radiographic inputs into four periodontal stages: Stage 0, Stage I–II, Stage III, and Stage IV.

The overall pipeline consists of:

1. Image preprocessing
2. Patch embedding
3. ConvNeXt hierarchical feature extraction
4. Embedded TRAC attention refinement
5. Global feature aggregation
6. Fully connected classification

**Let the input dental radiograph be denoted as**

$$X \in \mathbb{R}^{H \times W \times C} \quad (1)$$

where $H$, $W$, and $C$ represent height, width, and channel dimensions.

***Image Preprocessing***

The input image undergoes resizing and intensity normalization to standardize radiographic distribution.

***Normalization***

$$X_{norm} = \frac{X - \mu}{\sigma} \quad (2)$$

where $\mu$= mean pixel intensity, $\sigma$= standard deviation. This improves training stability and reduces illumination variation.

***Patch Embedding Layer***

The normalized image is divided into non-overlapping patches and projected into embedding space.

Let:

$$P_i \in \mathbb{R}^{p \times p \times C} \quad (3)$$

represent the $i^{th}$patch.

*Linear projection:*

$$Z_i = W_p \cdot \text{Flatten}(P_i) + b_p \quad (4)$$

where:$W_p$= patch embedding weight matrix, $b_p$= bias term

The embedded tokens form:

$$Z = \{Z_1, Z_2, \ldots, Z_N\} \quad (5)$$

***ConvNeXt Hierarchical Feature Extraction***

**ConvNeXt adopts depthwise separable convolution for efficient spatial learning**

***Depthwise Convolution***

$$Y = X * W_d \quad (6)$$

where $W_d$= depthwise kernel, $*$= convolution operation

***Pointwise Convolution***

$$Y' = W_{pw} * Y \quad (7)$$

**This captures inter-channel interactions.**
**Each ConvNeXt block applies**

$$F_{out} = X + \text{MLP}(\text{LayerNorm}(Y')) \quad (8)$$

where residual connection preserves gradient flow.
Figure 1 presents the overall architecture for periodontal teeth stage classification using panoramic dental radiographs. The workflow begins with input image acquisition, followed by preprocessing to normalize intensity values and standardize image dimensions. The feature extraction network learns hierarchical spatial patterns associated with periodontal bone loss and gum degradation. These extracted representations are transformed into discriminative feature vectors through a feature representation stage. The classification layer then maps the learned features into predefined periodontal stages. Finally, the softmax output layer predicts one of four categories: Stage 0 (Healthy), Stage 1 (Mild), Stage 2 (Moderate), or Stage 3 (Severe), enabling automated assessment of disease severity. Periodontal Teeth Stage Classification Architecture (Figure 1).

**TRAC Module Integration**
The TRAC module enhances feature representation by modeling token relationships and recalibrating channel importance.

**Token Relational Attention**
**Given feature map $\boldsymbol{F} \in \mathbb{R}^{\boldsymbol{N}\times\boldsymbol{d}}$, Query, Key, and Value projections**

$$Q = FW_Q, K = FW_K, V = FW_V \quad (9)$$

**Attention weights**

$$A = \text{Softmax}\left(\frac{QK^T}{\sqrt{d}}\right) \quad (10)$$

**Relational attention output**

$$F_{att} = AV \quad (11)$$

***Channel Recalibration***
**Global pooling**

$$s_c = \frac{1}{HW}\sum_{i=1}^{H}\sum_{j=1}^{W} F_{ijc} \quad (12)$$

**Channel excitation**

$$e = \sigma(W_2 \cdot \delta(W_1 s)) \quad (13)$$

whereas $\delta$= ReLU, $\sigma$= Sigmoid

**Final refined feature**

$$F' = F_{att} \odot e \quad (14)$$

where $\odot$ denotes channel-wise multiplication.

**Global Average Pooling**

**After hierarchical learning, features are aggregated**

$$G = \frac{1}{HW} \sum_{i=1}^{H} \sum_{j=1}^{W} F'_{ij} \quad (15)$$

This produces compact global representation.

**Classification Layer**

**The pooled vector is passed through fully connected layer**

$$z = W_f G + b_f \quad (16)$$

**Final stage probabilities**

$$\hat{y} = \text{Softmax}(z) \quad (17)$$

where:

$$\text{Softmax}(z_i) = \frac{e^{z_i}}{\sum_{k=1}^{4} e^{z_k}} \quad (18)$$

**Loss Function**

**Multi-class cross-entropy loss**

$$\mathcal{L} = -\sum_{i=1}^{4} y_i \log(\hat{y}_i) \quad (19)$$

where: $y_i$= ground truth label, $\hat{y}_i$= predicted probability

**Optimization Strategy**

**The model parameters θare optimized using Adam optimizer**

$$\theta_{t+1} = \theta_t - \eta \frac{\hat{m}_t}{\sqrt{\hat{v}_t} + \epsilon} \quad (20)$$

where: $\eta$= learning rate, $\hat{m}_t$, $\hat{v}_t$= bias-corrected moments

**Stage Classification Decision Rule**

**Final prediction**

$$\text{Stage} = \arg\max(\hat{y}) \quad (21)$$

Mapping:

- 1 → Stage I
- 2 → Stage II
- 3 → Stage III
- 4 → Stage IV

Figure 2 illustrates the overall architecture of the proposed TRAC-ConvNeXt model designed for classification of panoramic dental radiographs. The process begins with input radiographic images, followed by preprocessing to standardize image size and intensity distribution. The patch embedding layer converts the image into structured feature representations suitable for deep processing. Multiple ConvNeXt stages perform hierarchical feature extraction to capture spatial patterns and anatomical structures. The TRAC attention module refines these features by modeling token-level relationships and enhancing discriminative regions. Global average pooling aggregates the learned representations into a compact feature vector, which is passed through fully connected layers. Finally, a softmax output layer predicts the corresponding dental condition class, enabling accurate automated diagnosis. Architecture of Panoramic Dental Radiograph-Based TRAC-ConvNeXt (Figure 2).

## RESULTS AND DISCUSSION

The Periodontitis Disease dataset available on Kaggle (muflihsan/periodontitis-disease) contains dental radiographic images collected for automated periodontal disease analysis. The dataset was composed of dental X-ray images that highlight tooth structures, gingival regions, and alveolar bone areas, which are essential for identifying periodontal bone loss and infection-related tissue degradation [21]. The images are arranged into class-specific folders, enabling supervised learning for periodontitis detection and classification. Each image was provided with image-level labelling based on periodontal disease condition, making the dataset suitable for deep learning–based classification frameworks such as CNN and transfer learning models. The dataset does not provide bounding box or pixel-level annotations, and therefore it was mainly applied for classification rather than segmentation. Since the images vary in quality and illumination, common preprocessing steps such as resizing, normalization, contrast enhancement, and noise filtering are typically applied before training. This dataset supports research in periodontal disease screening and decision support systems using dental X-ray imaging. The data augmentation was done for attaining better accuracy. In a total image of 3924 the split ratio of 70:30 was done. In training the images were 2747 and in testing the images was 1177. Figure 3 Shows panoramic dental radiographs from four periodontal disease stages. Figure 3. Panoramic Dental Radiographs Across Periodontal Disease Stages. The first row shows Stage I images with little bone loss. Stage II instances with little bone support are in the second row. Stage III images demonstrate advanced bone degeneration and aberrant periodontal architecture. Stage IV radiographs with significant bone resorption and periodontal disease are on the final row. These examples demonstrate TRAC-ConvNeXt learning stage-wise adjustments.

**Evaluation Metrics**

The performance of TRAC-ConvNeXt was evaluated using accuracy, precision, recall, and F-score, AUC is show in Table 1. Table 1 presents the performance metrics of the proposed TRAC-ConvNeXt architecture for periodontal teeth stage classification. The model achieved an accuracy of 99.06%, with precision and recall values of 98.14% and 98.13%, respectively. The F1-score of 98.13% indicates balanced predictive performance. The false positive rate ranges between 0.0057 and 0.0092, while the average AUC of 0.9875 demonstrates strong class separability and reliable multi-class classification capability. Performance Evaluation Metrics of the Proposed TRAC-ConvNeXt Model (Table 1). Figure 4 illustrates the confusion matrix of the TRAC-ConvNeXt model for periodontal teeth stage classification. The model correctly classified 285 Stage I–II, 289 Stage III, 293 Stage IV, and 287 Stage 0 samples. Minor misclassifications include 3, 4, and 2 samples between adjacent stages. Stage IV shows the highest correct predictions (293), indicating strong discriminative capability. Overall, the matrix demonstrates high classification accuracy with minimal cross-stage errors. Confusion Matrix Analysis for Periodontal Teeth Stage Classification (Figure 4). Figure 5 illustrates the ROC curves for the four periodontal teeth stages using the proposed TRAC-ConvNeXt model. The AUC values are 0.9819 for Stage 1, 0.9887 for Stage 2, 0.9937 for Stage 3, and 0.9858 for Stage 4. All curves lie close to the top-left corner, indicating strong classification performance with high true positive rates and very low false positive rates across all stages. ROC Curve for Periodontal Teeth Stage Classification (Figure 5). Figure 6 compares the performance of TRAC-ConvNeXt with other periodontal classification methods using accuracy, precision, recall, and F1-score values. Performance Comparison of TRAC-ConvNeXt with Existing Techniques (Figure 6). Traditional deep learning approaches show comparatively lower performance, while hybrid and transfer learning models achieve improved results. The suggested TRAC-ConvNeXt framework achieves the highest performance with an accuracy of 99.06%, precision of 98.14%, recall of 98.13%, and F1-score of 98.13%. This indicates strong feature learning and reliable periodontal stage classification capability

## CONCLUSION

This research established a TRAC-ConvNeXt framework based on Panoramic Dental Radiographs for precise classification of periodontal tooth stages. The suggested approach increases diagnostic reliability by tooth-region adaptive cropping, which minimises irrelevant background interference and boosts discriminative feature learning.

ConvNeXt proficiently captures hierarchical spatial characteristics that delineate periodontal structural changes linked to disease development. The framework enhances exact stage identification and clinical interpretability by concentrating on tooth-level patterns. The experimental assessment of the Kaggle periodontal dataset exhibited outstanding classification ability, attaining elevated accuracy, precision, recall, and F1-score. The findings validate that TRAC-ConvNeXt offers a reliable and effective approach for automated periodontal diagnosis with panoramic radiography. Future research may enhance this approach by testing it with bigger multi-centre datasets and using explainable AI methods to emphasise clinically relevant tooth areas, hence augmenting confidence and usefulness in practical dental decision support systems.

## ABSTRACT

Lung cancer remains the leading cause of cancer-related mortality worldwide despite significant advances in chemotherapy, targeted therapy, radiotherapy, and immunotherapy. Therapeutic resistance, systemic toxicity, tumor heterogeneity, and limited long-term survival outcomes underscore the need for novel and complementary therapeutic strategies. Natural products derived from plants, marine organisms, microorganisms, and dietary sources have historically served as foundational sources of anticancer drugs and continue to represent a vast reservoir of structurally diverse bioactive compounds. These agents exert pleiotropic anticancer effects through induction of apoptosis and autophagy, modulation of oxidative stress, inhibition of angiogenesis and metastasis, cell cycle arrest, and regulation of multiple oncogenic signaling pathways including PI3K/Akt/mTOR, MAPK, NF-κB, STAT3, and Wnt/β-catenin. Emerging evidence also highlights their role in epigenetic regulation, tumor microenvironment modulation, immune enhancement, and reversal of drug resistance. This comprehensive review discusses the classification of natural compounds relevant to lung cancer therapy, molecular mechanisms of action, preclinical evidence in cellular and animal models, clinical trial outcomes, pharmacokinetic limitations, formulation strategies, and regulatory challenges. Additionally, we explore nanotechnology-based delivery systems, multi-omics-guided discovery, systems pharmacology approaches, and integration with immunotherapy and precision oncology. Although promising, rigorous large-scale clinical

validation remains necessary to establish natural products as standard therapeutic agents in lung cancer management.

**Keywords:** Lung cancer; phytochemicals; natural products; apoptosis; metastasis; PI3K/Akt; chemoprevention; immunomodulation; nanomedicine; precision oncology

## INTRODUCTION

**Global Epidemiology and Burden**

Lung cancer continues to impose a substantial global health burden, accounting for approximately 2.2 million new cases and 1.8 million deaths annually. It remains the most common cause of cancer mortality across both developed and developing nations. The primary histological subtypes includenon-small cell lung cancer (NSCLC) (~85%) and small cell lung cancer (SCLC) (~15%). Adenocarcinoma, squamous cell carcinomaand large cell carcinoma are the main types of NSCLC. The major risk factors of lung cancer include tobacco smoking, air pollution, occupational carcinogens (asbestos, radon), and genetic predisposition. Despite advances in early detection and screening programs, most patients present at advanced stages, limiting curative treatment options[1–3].

**Limitations of Current Therapies**

Despite major advances in lung cancer management, current therapeutic strategies remain associated with significant clinical limitations that restrict long-term treatment success. Conventional chemotherapy, particularly platinum-based regimens, often results in severe systemic toxicities such as myelosuppression, nephrotoxicity, neurotoxicity, and gastrointestinal complications, which compromise patient quality of life and limit dose intensity[4]. Although targeted therapies directed against molecular alterations such as EGFR mutations and ALK rearrangements have improved outcomes in selected patient populations, their benefits are frequently short-lived due to the rapid emergence of acquired resistance mechanisms, including secondary mutations, pathway bypass signalling, and tumour heterogeneity[5]. Immunotherapy with immune checkpoint inhibitors has transformed the therapeutic landscape; however, only a subset of patients experiences durable responses, and treatment can induce immune-related adverse events affecting multiple organs[6]. Furthermore, the high cost of novel therapies, lack of predictive biomarkers for optimal patient selection, and late-stage diagnosis in most cases further contribute to poor overall survival. Collectively, these challenges highlight the urgent need for safer, multi-targeted, and more effective therapeutic approaches to improve lung cancer outcomes[7].

**Rationale for exploring natural products**

Natural products represent a highly valuable and strategic resource in the search for improved lung cancer therapies due to their remarkable chemical diversity and broad spectrum of biological activities, which far exceed the structural complexity typically achieved through synthetic drug libraries. These compounds frequently exert multi-targeted effects by simultaneously modulating several signaling pathways involved in tumor growth, apoptosis, metastasis, and immune regulation, making them particularly effective against the heterogeneous and adaptive nature of cancer cells[8]. In comparison to conventional chemotherapeutic agents, many natural products exhibit lower systemic toxicity and improved tolerability, allowing for prolonged use and potential incorporation into combination regimens. Their ability to synergize with chemotherapy, targeted therapy, and radiotherapy further enhances therapeutic efficacy while potentially reducing required drug dosages and adverse effects. Additionally, natural compounds are often more cost-effective and accessible, especially in resource-limited settings. Importantly, the historical success of natural products in oncology is well established, with over 60% of currently approved anticancer drugs derived directly or indirectly from natural sources, underscoring their critical role in drug discovery and their continued promise for the development of innovative lung cancer treatments.

## SCOPE AND OBJECTIVES

This review aims to provide a comprehensive and systematic overview of the role of natural products in lung cancer therapy by classifying the major categories of bioactive compounds with demonstrated anticancer potential and summarizing their chemical and biological characteristics. It seeks to elucidate the underlying molecular mechanisms through which these natural agents exert their effects, including modulation of apoptosis, angiogenesis, metastasis, and key oncogenic signaling pathways. Additionally, the review evaluates current preclinical evidence from *in vitro* and *in vivo* studies to assess therapeutic efficacy and mechanistic insights, alongside a critical analysis of available clinical trial data investigating safety, tolerability, and clinical outcomes. Furthermore, it discusses the major translational challenges hindering clinical implementation, such as bioavailability, standardization, and regulatory issues, while highlighting emerging research directions including advanced drug delivery systems, multi-omics approaches, and precision medicine strategies to guide future development of natural product-based therapies for lung cancer. In a previous review we try to integrate combination therapies in lung cancer treatment but not focus on the natural compounds [9]. Current review will focus on that.

**Classification of Natural Products in Lung Cancer Therapy**

Natural products used in lung cancer research are commonly classified according to their chemical structure and biosynthetic origin, reflecting their diverse biological functions and therapeutic mechanisms. Alkaloids represent an important class of nitrogen-containing heterocyclic compounds, including vinca alkaloids such as vincristine and vinblastine, camptothecin derivatives, and berberine, which exert anticancer effects primarily through microtubule destabilization, inhibition of topoisomerase enzymes, and interference with DNA replication[10]. Flavonoids, a large group of polyphenolic compounds abundant in fruits and vegetables, such as quercetin, kaempferol, apigenin, and luteolin, demonstrate strong antioxidant and pro-oxidant activities, suppress oncogenic signaling pathways including PI3K/Akt and NF-κB, and inhibit epithelial–mesenchymal transition associated with metastasis. Terpenoids, derived from isoprene units, including paclitaxel, triptolide, and ursolic acid, induce mitotic arrest, promote mitochondrial-mediated apoptosis, and suppress inflammatory signaling cascades[11,12]. Polyphenols such as curcumin, resveratrol, and epigallocatechin gallate (EGCG) modulate oxidative stress, inhibit transcription factors such as STAT3, and regulate epigenetic enzymes involved in tumor progression. Saponins and glycosides, including ginsenosides and diosgenin, disrupt cancer cell membrane integrity while regulating survival and apoptotic pathways[13,14]. In addition, marine-derived compounds obtained from ocean biodiversity, such as trabectedin, bryostatin, and dolastatin derivatives, provide structurally unique molecules that target microtubules and transcriptional machinery, further expanding the therapeutic potential of natural products in lung cancer treatment[15,16]. The following table that is Table 1 represents the natural compounds play vital role in lung cancer treatment. Natural Compounds in Lung Cancer Therapy (Table 1).

**Molecular Mechanisms of Action and Tumor Microenvironment Modulation**

Natural products exhibit pleiotropic anticancer effects by targeting multiple hallmarks of lung cancer progression through interconnected molecular pathways. A primary mechanism involves the induction of apoptosis via both intrinsic and extrinsic pathways, where phytochemicals modulate the Bax/Bcl-2 ratio, promote mitochondrial cytochrome c release, and activate caspase-9 in the intrinsic pathway, while simultaneously stimulating death receptor signalling and caspase-8 cleavage in the extrinsic pathway[17,18]. Many natural compounds further enhance reactive oxygen species (ROS) generation beyond cellular tolerance levels, leading to mitochondrial dysfunction and programmed cell death. In addition to apoptosis, natural products regulate autophagy by influencing key molecular markers such as Beclin-1 and LC3-II and by inhibiting mTOR signalling, with autophagy functioning as either a tumour-suppressive or cytoprotective process depending on the cellular context[19,20]. Cell proliferation is suppressed through cell cycle arrest at the G0/G1 phase via upregulation of p21 or at the G2/M phase through downregulation of cyclin B, thereby preventing uncontrolled tumour growth[21]. Natural compounds also inhibit angiogenesis by reducing vascular endothelial growth factor (VEGF) expression, destabilizing hypoxia-inducible factor-1$\alpha$ (HIF-1$\alpha$), and limiting endothelial cell migration, which collectively restrict tumour blood supply.

Metastatic progression is suppressed through downregulation of matrix metalloproteinases MMP-2 and MMP-9, reversal of epithelial–mesenchymal transition marked by increased E-cadherin expression, and inhibition of transforming growth factor-β (TGF-β) signalling[22,23]. Furthermore, phytochemicals modulate key oncogenic signaling pathways including PI3K/Akt/mTOR, which governs cell survival and metabolism, MAPK/ERK involved in proliferation, NF-κB responsible for inflammatory and survival signaling, and STAT3 frequently overactivated in lung cancer, with compounds such as curcumin, quercetin, and resveratrol demonstrating potent inhibitory effects[24,25]. Beyond these molecular actions, natural products also exert significant influence on epigenetic regulation by modulating DNA methyltransferases, histone deacetylases, and microRNA expression, thereby restoring tumor suppressor gene activity[26]. Additionally, they reshape the tumor microenvironment by reducing pro-inflammatory cytokines such as IL-6 and TNF-$\alpha$, regulating tumor-associated macrophage polarization, enhancing $CD8^+$ T-cell infiltration, and decreasing PD-L1 expression on tumor cells, suggesting strong potential for synergistic integration with immune checkpoint inhibitor therapies in lung cancer treatment[27,28]. The following Figure 1 integrates the overall mechanism of natural compounds in relation with the regulation of cancer progression. Mechanism of action of the natural compounds in case of the regulation of cancer progression (Figure 1).

**Natural Products in Combination Therapy**

Natural products have demonstrated significant potential as adjuvant agents in combination therapy by enhancing the efficacy of conventional lung cancer treatments and mitigating therapeutic resistance. In chemotherapy-based regimens, compounds such as curcumin have been shown to increase tumor cell sensitivity to cisplatin by promoting apoptosis, suppressing survival signaling pathways, and reducing inflammation, while quercetin effectively downregulates multidrug resistance proteins, including P-glycoprotein, thereby improving intracellular drug accumulation[29,30]. Berberine has also exhibited synergistic effects with epidermal growth factor receptor (EGFR) inhibitors by enhancing receptor inhibition and suppressing compensatory signaling pathways responsible for resistance[31]. In the context of radiotherapy, several phytochemicals that elevate intracellular reactive oxygen species levels intensify radiation-induced DNA damage, leading to enhanced tumor cell death and improved therapeutic response[32]. Moreover, natural products play a crucial role in overcoming drug resistance through multiple mechanisms, including inhibition of drug efflux transporters, reversal of epithelial–mesenchymal transition that contributes to metastatic and resistant phenotypes, and suppression of cancer stem cell markers associated with tumor recurrence and treatment failure[33]. Collectively, these synergistic interactions highlight the promise of integrating natural compounds into combination therapeutic strategies for more effective and durable lung cancer treatment outcomes[34].

**Preclinical Evidence**

Extensive preclinical investigations have established the anticancer potential of natural products in lung cancer using both *in vitro* and *in vivo* experimental models. *In vitro* studies commonly employ human lung cancer cell lines such as A549, H1299, H1975, and H460 to evaluate cytotoxicity, apoptotic induction, and molecular pathway modulation. These studies utilize a range of assays including MTT and related cell viability assays to determine dose-dependent growth inhibition, flow cytometry-based techniques to quantify apoptosis and cell cycle arrest, Western blot analysis to assess changes in oncogenic and apoptotic signaling proteins, and colony formation assays to examine long-term proliferative capacity following treatment. Complementary *in vivo* studies further validate therapeutic efficacy using xenograft mouse models, orthotopic lung cancer implantation systems that more accurately mimic tumor microenvironment, and genetically engineered mouse models that recapitulate human disease progression. Across these models, treatment with natural compounds consistently results in significant reductions in tumor volume, suppression of metastatic spread to distant organs, and prolonged overall survival, providing strong biological evidence supporting the translational potential of natural products for lung cancer therapy[35–37].

**Clinical Trials**

Clinical investigations evaluating natural products in lung cancer therapy have provided encouraging evidence regarding safety, tolerability, and potential therapeutic benefit, although efficacy outcomes remain variable and require further validation. Several phytochemicals, including curcumin, green tea catechins such as epigallocatechin

gallate (EGCG), resveratrol, ginseng extracts, and berberine, have progressed into early-phase clinical trials either as standalone interventions or in combination with conventional chemotherapy and targeted therapies. These studies have demonstrated favorable safety profiles with minimal severe adverse effects and have reported biological activity such as reduced inflammatory markers, modulation of apoptotic pathways, improved quality of life, and enhanced sensitivity to standard treatments[38–40]. However, many trials have been limited by small sample sizes, short treatment durations, inconsistent formulations, and poor systemic bioavailability of the compounds, which complicate interpretation of clinical efficacy. While some trials suggest modest improvements in tumour response and symptom control, large-scale randomized controlled studies are still lacking[41,42]. Consequently, although natural products show promise as adjunct therapeutic agents, rigorous clinical evaluation with standardized dosing, optimized delivery systems, and well-defined endpoints is essential to establish their role in lung cancer management[43,44]. Natural products have emerged as highly promising multi-targeted therapeutic agents capable of addressing the complex biological heterogeneity that characterizes lung cancer. Unlike conventional single-target drugs, phytochemicals and other naturally derived compounds exert broad-spectrum anticancer effects by concurrently modulating multiple hallmarks of cancer, including induction of apoptosis, suppression of angiogenesis, inhibition of metastatic progression, regulation of immune evasion, and reversal of therapeutic resistance[45]. This pleiotropic mode of action is particularly advantageous in overcoming pathway redundancy and adaptive resistance mechanisms that often undermine targeted therapies. Furthermore, the ability of natural compounds to influence the tumour microenvironment and enhance responses to chemotherapy, radiotherapy, and immunotherapy highlights their potential as valuable components of combination treatment strategies[46].

## DISCUSSION

Despite strong mechanistic rationale and compelling preclinical data, the translation of natural products into effective clinical therapies has been limited by several critical challenges. One major barrier is the lack of standardization of plant extracts, as variations in cultivation conditions, harvesting time, processing methods, and solvent extraction techniques can significantly alter chemical composition and biological activity. This leads to substantial batch-to-batch variability, making reproducibility of experimental results and clinical outcomes difficult to achieve. Additionally, many natural compounds face weak intellectual property protection due to their occurrence in nature, reducing commercial incentives for pharmaceutical companies to invest in costly large-scale clinical trials and formulation development. Consequently, limited industrial involvement has slowed regulatory approval processes and hindered the transition from laboratory research to clinically approved therapies. Addressing these challenges through improved quality control, standardized formulations, innovative drug delivery technologies, and supportive regulatory frameworks will be essential to fully realize the therapeutic potential of natural products in lung cancer treatment.

## CHALLENGES AND LIMITATIONS

Despite the promising anticancer potential of natural products, several critical challenges continue to limit their successful translation into clinical lung cancer therapies. One of the most significant obstacles is poor bioavailability, as many phytochemicals exhibit strong anticancer activity at nanomolar concentrations *in vitro* but fail to reach effective therapeutic levels in systemic circulation due to low solubility, rapid metabolism, and limited absorption. This pharmacokinetic limitation substantially reduces their clinical efficacy and necessitates the development of advanced delivery systems. Toxicity concerns also arise when higher doses are administered to compensate for poor bioavailability, with some natural compounds causing hepatotoxicity, nephrotoxicity, or gastrointestinal disturbances, particularly with prolonged use. In addition, regulatory challenges present major barriers to clinical approval, as botanical drugs often exhibit complex chemical compositions and batch variability, making it difficult to meet stringent pharmaceutical quality and consistency standards required by regulatory agencies. Furthermore, the difficulty in patenting naturally occurring compounds significantly diminishes commercial incentives for pharmaceutical companies to invest in expensive drug development and large-scale clinical trials. Collectively, these

limitations highlight the need for improved formulation strategies, standardized production protocols, supportive regulatory frameworks, and innovative intellectual property approaches to facilitate the successful integration of natural products into lung cancer therapeutics[47,48].

## FUTURE PERSPECTIVES

Future research on natural products in lung cancer therapy is increasingly focused on overcoming current translational barriers through innovative technological and biological approaches. Nanotechnology-based drug delivery systems, including liposomes, polymeric nanoparticles, solid lipid nanoparticles, and targeted nanocarriers, offer powerful strategies to improve the solubility, stability, and bioavailability of phytochemicals while enhancing tumor-specific accumulation and minimizing systemic toxicity through controlled and sustained release. These advanced formulations can significantly increase therapeutic efficacy by protecting natural compounds from rapid metabolism and directing them preferentially to tumor tissues. In parallel, multi-omics technologies encompassing genomics, transcriptomics, proteomics, and metabolomics are revolutionizing natural product research by enabling comprehensive identification of molecular targets, prediction of biological mechanisms, discovery of novel bioactive compounds, and stratification of patients based on tumor-specific molecular signatures. Such integrative datasets support the development of personalized treatment strategies and predictive biomarkers for therapeutic response. Artificial intelligence and machine learning platforms further accelerate natural product discovery by rapidly screening vast chemical libraries, optimizing compound structures, predicting pharmacological properties, and identifying synergistic drug combinations, significantly reducing time and cost in drug development pipelines[49,50]. Moreover, growing evidence suggests that natural compounds can synergize with immunotherapy by enhancing PD-1 and PD-L1 blockade efficacy, promoting cytotoxic T-cell activation, improving antigen presentation, and modulating immunosuppressive elements of the tumor microenvironment, thereby potentially expanding immunotherapy responsiveness to a broader patient population[51,52]. Finally, the integration of precision medicine approaches, where patient-specific molecular profiling guides the selection of targeted phytochemicals or combination regimens, holds great promise for maximizing therapeutic benefit while minimizing adverse effects. Together, these emerging strategies are expected to transform natural products from experimental agents into clinically effective, personalized therapies for lung cancer management[53,54].

## CONCLUSION

Natural products represent a promising yet largely underutilized resource in the treatment of lung cancer, offering a diverse array of bioactive compounds capable of targeting multiple molecular pathways involved in tumour growth, metastasis, immune evasion, and therapeutic resistance. Extensive mechanistic studies and robust preclinical evidence have demonstrated their ability to induce apoptosis, inhibit angiogenesis, modulate the tumour microenvironment, enhance immune responses, and overcome drug resistance, highlighting their potential as both primary and adjunct therapeutic agents. Although early clinical investigations have shown encouraging safety profiles and biological activity, widespread clinical adoption remains limited due to challenges related to inconsistent formulations, poor bioavailability, insufficient large-scale randomized controlled trials, and complex regulatory frameworks. Addressing these barriers through standardized production methods, advanced drug delivery technologies, harmonized regulatory pathways, and well-designed clinical studies will be essential for successful translation into routine oncology practice. Looking ahead, the integration of natural products with nanomedicine, systems biology, precision oncology, and immunotherapy holds significant promise for unlocking their full therapeutic potential and improving treatment outcomes for patients with lung cancer.

## ABSTRACT

The discharge of dye-laden effluents from industrial activities poses a serious environmental threat due to the chemical stability and toxicity of synthetic dyes. In this work, we present a sustainable strategy for wastewater remediation through the green synthesis of copper oxide nanoparticles (CuO NPs) using *Smilax ehineusis* Linn root extract. Phytochemicals present in the extract, including flavonoids and steroids, acted as natural reducing and stabilizing agents, eliminating the need for hazardous chemicals. The formation of CuO NPs was confirmed by a distinct UV–Vis absorption peak at 324 nm, while FTIR spectroscopy indicated phytochemical involvement in nanoparticle stabilization. FE-SEM analysis revealed predominantly spherical morphologies with some agglomeration, and dynamic light scattering estimated particle sizes in the range of 124–148 nm. When exposed to natural sunlight, the CuO NPs exhibited remarkable photocatalytic efficiency, achieving rapid degradation of methylene blue, eosin yellow, and rhodamine B. The enhanced photodegradation performance is attributed to efficient electron–hole pair generation and subsequent reactive oxygen species (ROS)-mediated oxidation of dye molecules. This study highlights a facile, eco-friendly, and scalable approach for synthesizing CuO NPs

with high photocatalytic activity, offering significant potential for sustainable wastewater treatment and environmental management.

**Keywords:** Photodegradation, Copper oxide nanoparticles, FTIR, SEM, and *Smilax Ehineusis* Linn.

## INTRODUCTION

The risk of environmental contamination has grown as industrialization has progressed. Various types of waste gravely threaten water bodies. The culinary, pharmaceutical, leather, textile, ink, cosmetic, and other sectors create organic dyes, which are major pollutants. Numerous tons of complicated dyes are produced annually and released into waterways, endangering aquatic life [1]. One novel approach of significant interest in the application of nanotechnology within the wastewater treatment sector. Many nanomaterials have been investigated for reducing the levels of dangerous pollutants in wastewater because of the enhanced qualities that the nanoscale impact has brought about. Nanomaterials are more sensitive, have a high surface-to-volume ratio, and are excellent at adsorption [2].Aspects of nanotechnology include the creation, characterization, manufacturing, and use of materials at the nanoscale that are controlled by size and form. Another definition from the same dictionary is the meticulous and regulated manipulation, precise positioning, modeling, measurement, and manufacturing of materials at the nanoscale to create objects, systems, and technologies with essentially unique characteristics and capabilities [3]. Photodegradation is a genuine method that can effectively address organic contaminants in the water system. Photocatalysts are widely used in wastewater treatment, air and water purification, deodorization, the water splitting reaction to produce hydrogen, the conversion or degradation of most pollutants, and the elimination of microorganisms. Nowadays, there is an increasing demand for creating nanoparticle (NP) solutions that are economical, low energy, clean, environmentally friendly, and time efficient. To get around the drawbacks of physical and chemical approaches through synthesis. Metal oxides of NPs, including copper, silver, zinc, and gold, have physicochemical characteristics such as size, zeta, surface area, and surface shape. Also, charges and potential that control their behavior for biotechnological use [4]. In any photocatalytic reaction, the ability to absorb light is an essential element that significantly influences the photocatalytic effectiveness of the catalyst.

Copper is an excellent photocatalyst [5]. Semiconductor photocatalysts under UV light, copper oxide-based nanoparticles (NPs) are thought to be the most promising because of their complex production processes, limited availability, low toxicity, and band gap (1.35 and 3.5 eV). The recombination of electron pairs at the interface can be restricted by the remarkable propensity of copper oxide (CuONPs) to absorb molecular oxygen and their vital role in scavenging photogenerated electrons. Still, these processes involve harmful chemicals, consume a lot of energy, and pollute the environment by generating high temperatures and pressures, which necessitate several chemical and physical techniques for creating Copper oxide (CuO NPs). Still, these methods involve hazardous chemicals, consume a significant amount of energy, and pollute the environment due to the high temperatures and pressures required. Increasingly, green synthesis is being used as an inexpensive, eco-friendly, straightforward, and non-toxic biological solution to these issues [6]. Synthesis of Copper oxide (CuO NPs) nanoparticles, which have proven superior performance when compared to their bulk counterparts, can enhance these unique features. A variety of Copper oxide (CuO NPs) nanostructures are created, including nanowires, nanorods, nanoneedles, nanoflowers, and nanoparticles. CuO nanoparticles of various sizes. Over the last few decades, several methods, such as fast precipitation, thermal oxidation, sonocatalytic, and combustion, have been used to create forms. The photocatalytic technique is one of these simple procedures that has garnered significant interest from companies due to its low temperature and energy requirements, low cost, and high yield for large-scale production [7]. The production of metal oxide nanoparticles is a typical application of green synthesis. According to recent research, metal nanoparticles generated from plants are safe, reliable, and ecologically friendly in both chemical and physical systems. Additionally, it eliminates hazardous substances created by chemical reactions as well as organic solvents from synthetic processes.

Plant-based nanoparticle synthesis is a low-cost method that is poised to become a practical manufacturing choice. A practical substitute known as "green synthesis" may be used to impregnate metal particles at the nanometric scale, increasing yields while lowering environmental impact [8]. Recently, there has been increased focus on the production of nanoparticles (NPs) due to their potential biotechnological uses in several domains. Because of their antibacterial and antifungal properties, copper-based nanoparticles can be used in food preservation, water treatment, agriculture, and the textile industry. Copper oxide nanoparticles (CuO NPs) are beneficial for adsorption and a variety of applications due to their small size, vast surface area, natural availability of their starting material, low fabrication costs, and non-toxic nature. The element copper is found naturally in the Earth's crust with a concentration of 146, or about 60 g per ton. Since this kind of adsorbent is regularly researched, it is essential to evaluate the key conclusions [9]. CuO Photocatalytic dye degradation caused by nanoparticles has garnered significant attention as a successful and sustainable water treatment technique. CuOnanoparticles' remarkable photocatalytic properties, such as their enormous surface area and suitable bandgap energy, enable them to generate reactive oxygen species (ROS) when exposed to visible light. Through oxidation processes, these ROS can effectively break down a variety of organic dyes, eliminating hazardous contaminants from wastewater. The advantages of environmentally friendly synthesis and effective pollutant removal are combined in the CuO nanoparticles produced environmentally for photocatalytic dye degradation [28].Scientists have been increasingly interested in the science and technology of the nanoscale range over the past few decades. Since atoms and molecules make up every material particle, nanoscience and nanotechnology have been proposed to encompass all scientific and technological domains.

It is considered a highly advanced interdisciplinary topic of study in science and technology in recent years. Despite having different physical and chemical properties from those of bulk material, metal oxide nanoparticles in particular have become well-known for their applications in a wide range of scientific fields, such as drug gene delivery, electronics, biomedical sciences, biosensors, molecular catalysts, magnetic materials, and the chemical industry [10]. The creation of multifunctional nanomaterials for various applications, including solar cells, optical and medical devices, biomedical and drug delivery systems, energy storage, food, cosmetics, paints, and the textile sector, is being led by nanotechnology [11]. Currently, green synthesis is required to produce copper oxide nanoparticles. It eliminates hazardous compounds created by chemical reactions, as well as the organic solvents from synthetic treatments. Plant extracts offer a biological synthesis pathway for a variety of nanoparticles that is more economical, non-toxic, comfortable, and environmentally friendly. It also offers a controlled synthesis with specific nanoparticle size and shape[12]. One effective technique for eliminating dyes from wastewater is the photocatalytic destruction of dyes using semiconductor photocatalyst materials [13]. The use of green nanotechnology is crucial. Green nanotechnology is the process of turning extra-bioactive goods into more ecologically friendly and commercially viable green nanomaterials and using clean technologies for environmental rehabilitation. As the population grows, human bio waste increases, posing a severe danger to environmental purity. The development of a safe and economical solution to this problem, which has a substantial environmental cost, is therefore imperative. From this perspective, several academics have recently explored ways to profit from these bioresources by recycling them into goods that are both acceptable and environmentally friendly [14].

Because they require little upkeep and are inexpensive, plants are known as nature's chemical factories. Because even minute concentrations of these heavy metals can be harmful [15]. A member of the Smilacaceae family, *Smilax Ehineusis Linn* is found across the world in both tropical and temperate climates, with a particular emphasis on East Asia. This perennial climber is rather woody, with paired tendrils and aculeated skin that facilitate climbing. *Smilax Ehineusis Linn* tubers have been used in traditional medicine to treat TB, gout, malignancies, and inflammation, according to several studies [16]. The green synthesis process can be used to produce nanoparticles on a large scale, utilizing plant resources, making it an economical, quick, environmentally safe, and sustainable approach. Leaf extracts from *Smilax Ehineusis* Linn were used as capping and reducing agents to create CuO NPs [17]. Ecologically beneficial CuO nanoparticles were prepared using the underutilized plant *Smilax Ehineusis Linn*. "Fat, gum, starch, flavonoids, tannins, terpenes, alkaloids, saponins, and glycosides are the main chemical components of Smilax china. Almost 13 different chemicals were found in the roots. Glucopyranoside, engeletin, isoengeletin, kaempferol, and dihydrokaempferol are among them. The creation of alternative medications free from the negative side effects of

manufactured pharmaceuticals is greatly aided by medicinal plants. Both contemporary and traditional remedies are based on plants and natural ingredients, which are also now frequently utilized in the manufacturing of pharmaceuticals for commercial usage[18]. A high degradation efficiency was demonstrated by the photocatalytic degradation of methylene blue when exposed to sunlight. In this study, copper oxide nanoparticles and water filtration technologies were developed using the *Smilax Ehineusis Linn* extract.

## MATERIALS AND METHODS

## MATERIALS

To prepare Copper oxide (CuONPs), *Smilax Ehineusis* Linn root extract, and analytical grade (AR) chemicals, Copper sulphate ($CuSO_4$), and Sodium hydroxide (NaOH), of high purity were included. We gathered *Smilax Ehineusis Linn* plants from local market.

**Preparation of leaf extract**

Following a methodical cleaning process, the entire *Smilax Ehineusis Linn* root was allowed to air dry at ambient temperature. Fine powders were obtained by grinding the thoroughly dried plants. Deionized water (50 mL) was used to dissolve 4 g of powder, and the resulting mixture was held at 60 °C for 30 minutes. Lastly, Whatman No. 1 filter paper was used to remove the plant extract from the mixture. For further processing, the finished *Smilax Ehineusis Linn root* extract was kept at four degrees Celsius.

**Green Synthesis of Copper Oxide Nanoparticles**

CuO nanoparticles (NPs) were prepared by dissolving copper sulfate dehydrate (0.5 M) in 100 mL of double-distilled water. The solution was stirred at constant room temperature until. It became clear. Following the consumption, two grams of sodium hydroxide were gradually mixed with a solution of copper sulfate. Five milliliters of *Smilax Ehineusis Linn* extract were added to the resulting solution and stirred continuously for two hours. The pH of the fluid was maintained at 12. Subsequently, the mixture was heated until the watery aqueous solution turned into a blue paste. Centrifugation at 4500 RPM for 30 min produced the final blue creamy precipitates. After being repeatedly cleaned with deionized water, the gathered CuO NPs were dried at 60°C in a two-hour oven. The final product was calcined for two hours at 400°C in a muffle furnace. For characterization, a blue-coloured powder was collected and packaged. The general term for processes that exploit a material's solubility by subjecting it to extremely hot water and high pressure, which produces crystalline structures, is hydrothermal synthesis, also known as solvothermal synthesis. The products are prepared by heating a steel autoclave filled with precursors, stabilizing agents, water (or another solvent), and then operating the autoclave for a predetermined amount of time. The autoclave operator can alter the geometry, size, and morphology of the solution by adjusting the precursors, pH, and temperature of the autoclave. The autoclave cycle is followed by cleaning, drying, and cooling the products to room temperature[19]. Copper sulfate, represented by the chemical formula $CuSO_4$, dissolves in an appropriate solvent, such as water. A copper hydroxide precipitate ($Cu(OH)_2$) was created once a base solution (such as NaOH) and plant extract from Ehineusis Linn was gradually added.

**$CuSO_4$(aq) + 2NaOH(aq) + *Smilax Ehineusis Linn* ->$Cu(OH)_2$(s)**

The precipitate was collected by centrifugation, cleaned, dried, and calcined at high temperatures (400–500 °C) in a controlled setting. This calcination procedure converts cadmium hydroxide to copper oxide (CuO) while removing any remaining impurities or volatile materials.

**CuO(s) + $H_2O$(g) ->$Cu(OH)_2$(s)**

**Preparation of Copper oxide (CuONPs) (Figure 1).**

**Characterization methods**

The diffraction patterns of the CuO NPs were captured between 20° and 80° using an X-ray diffractometer (X'PERT PRO PANAnalytical). A Perkin-Elmer spectrometer was used to record the FTIR spectra. An energy dispersive X-ray spectrometer was used to identify the topological characteristics of the K and L lines. Using a scanning electron microscope (SEM, JEOL JSM 6390), the optical absorption and transmittance of the CuO NPs were measured at room temperature using a UV-visible spectrometer (Model λ35, PerkinElmer).

**Photocatalytic reaction**

The methylene blue (MB), Eosin Yellow, and Rhodamine dye breakdown rates under sunlight irradiation were used to assess the photocatalytic activity of the synthesized CuO NPs. The dye solution was dissolved in 0.034g CuO NPs. The mixture was stored in a dark place under aeration-controlled conditions for half an hour to reach absorption–desorption equilibrium. After 20 minutes of visible light exposure, a 2 mL sample was taken out of each tube and centrifuged in a microcentrifuge to extract copper oxide nanoparticles from the mixture.

$$\text{Percentage of degradation} = \frac{C_i - C_f}{C_i} \times 100$$

Where $C_i$ is the initial dye concentration, Cf represents the concentration of the dye after a specific irradiation time.

## RESULT AND CONCLUSION

**X-ray diffraction and Fourier Transform Infrared spectrum (FTIR) analysis**

X-ray diffraction (XRD) is a method used to examine a material's crystallographic structure. A substance is exposed to X-ray radiation, and the intensity and scattering angles of the X-rays that are reflected or diffracted by the material are measured. The primary purposes of this approach are to identify a material's phases and ascertain its crystal structure. XRD measurements confirmed the formation of CuO nanoparticles. In figure 2(a), the (020), (021), (110), (002), (111), (042), (130), (131), (151), (200), (152), and (202) planes in the XRD analysis indicate monoclinic crystallite formation. The two significant theta values corresponded to the (020), (021), (002), (111), (042), (138), and (131) planes, respectively, and were found at 18.3 °, 24.4 °, 33.6 °, 34.6 °, 35.2 °, 38.2 °, and 42.7 °. These results closely resemble those found in JCPDS File No. 5-0661 [20].The Debye-Scherrer equation was used to calculate the average crystallite size of the produced samples as follows:

$$D = K\lambda/\beta\text{Cos}\theta$$

where β is half of the highest intensity, λ is the wavelength of X-ray radiation, D is the average crystallite size, θ is Bragg's angle, and K is Scherrer's constant (0.9). The average crystallite size of the environmentally produced CuO NPs was 31 nm. Figure 2.(a) XRD pattern and (b) FTIR spectra of CuONPs The Fourier Transform Infrared spectrum (FTIR) analysis spectra of produced CuO NPs, as shown in Figure 2(b), revealed six major peaks at 847, 1136, 1628, 620, 424, and 3423 $cm^{-1}$. C-O asymmetric stretching, C=O stretching, C-Ni stretching, Cu-O stretching, O-H stretching, and C-C stretching vibrations (phenolic or alcoholic) are represented by these peaks. Furthermore, the hydroxyl and carbonyl bonds are the extract constituents that convert copper ions into copper nanoparticles. Additionally, phenolic chemicals may act as a capping agent, increasing the stability of nanoparticles, because they are adsorbed on their surface [24]. FTIR spectroscopic analysis of *Abutilon indicum* leaf extract confirms the presence of flavonoids, tannins, terpenes, alkaloids, saponins, and glycosides. The production of Cu-O bonds is indicated by a prominent peak in the CuO nanoparticle spectra at 424 $cm^{-1}$. Because nanocrystalline materials have a high surface-to-volume ratio, the adsorbed water molecules are responsible for the broad absorption peak at about 3423 $cm^{-1}$[25].

**Field Emission Scanning Electron Microscope (FE-SEM) analysis**

The surface shape and elemental analysis of the hydrothermally produced CuO nanoparticles were investigated using FE-SEM and EDX techniques, as shown in Fig. 3 (a-d). An FESEM image of the CuO nanoparticles is shown in

Figure. More aggregation of spherical nanoparticles is shown in this figure. The figure illustrates the hydrothermal production of CuO nanoparticles using energy-dispersive X-ray diffraction. By using this spectrum, it was possible to verify that the CuO nanoparticles contain both cadmium and oxygen. The cadmium and oxide weight percentages were determined to be 62.74% and 37.26%, respectively. Therefore, only Cu and O are shown as impurity elements[21]. A thorough perspective of the CuO-NPs is provided by the SEM images shown in Figure, which have many resolutions[22].In addition, Fig(s).3 a, b, c, and d displayed every potential nearly spherical form. On average, the CuO NPs were 125 - 148 nm in diameter. The chemical makeup of the phytochemicals that act as capping agents surrounding the particles is what causes the heterogeneous morphological characteristics of NPs to develop. Energy Dispersive X-ray Analysis is a method for determining a sample's elemental composition. To produce X-rays from a sample's atoms, an electron beam is used to stimulate them. The elemental composition of the CuO NPs was determined by EDAX analysis of the NPs. The emergence of peaks for the elements Cu, C, and O in the spectrum supports the purity of the NPs shown in Fig. 4 [23]. Figure 3: FE-SEM images of CuO nanoparticles at nano-scale (a), and micro-scale (c), with corresponding size distributions at nano-scale (b), and micro-scale (d). EDAX spectrum analysis of CuONPs (Figure 4).

**UV- Visible Analysis**

One method for analyzing nanomaterials is 'UV-Vis' spectroscopy, which measures the amount of light absorbed and scattered in the visible and ultraviolet region of the electromagnetic spectrum. UV-visible (UV-Vis) spectroscopy is a crucial characterization method in the photophysical analysis of the generated materials, and an absorption spectrum with a range of wavelengths of 200-650 nm was used to examine the green synthesized CuO NPs. Fig.6. shows obtained outcomes. The UV-Vis spectrum revealed a series of absorption peaks at 324 nm [26].The band gap value indicates that the CuO NPs may absorb energy up to this threshold, which is enough to enable photocatalytic reactions and excite electrons [27]. An absorbance band frequently indicates a molecule's existence of particular electronic transitions or chromophores at 324 nm in a UV-Vis spectrum. Chemicals with polyphenolic structures and benzenoid rings commonly exhibit this band. UV spectra analysis of CuONPs (Figure 5).

**Photocatalytic degradation of MB dye**

Common uses for synthetic dyes include ink, paper, textiles, adhesives, cosmetics, food, and medications. Textile industry effluents frequently emit Eosin Yellow, Methylene Blue, and Rhodamine. It causes the loss of oxygen from the surfaces of water bodies, which affects aquatic life. Apart from being a risk to the environment, it is also known to be hazardous to people. Therefore, it is very justified to degrade the three dyes in effluents to eliminate their harmful effects. CuONPs with the right size and shape can function as suitable catalysts for dye degradation due to their high ratio of surface area to volume [28]. The CuONPs exhibited outstanding photocatalytic ability and, when exposed to sunlight, decolorized the starting concentrations of Methylene blue, Eosin yellow, and Rhodamine B. The addition of CuONPs to the solution causes the dyes to lose their hue quickly, as indicated by the decrease in absorption values at the dyes matching $\lambda$ max values [29]. CuO NPs degraded MB, Eosin yellow, and Rhodamine B when exposed to sunlight. Methylene blue, Eosin yellow, and Rhodamine B dyes have all been studied for their relative deterioration over time, as shown in Figures 6a, b, c, and d. Figure 6 b shows a comparison of methylene blue, Rhodamine B, and Eosin Yellow dyes. Green-synthesized $Cu_2O$ NPs have a greater photocatalytic activity because of their greater surface area.

$$\mathbf{D\% = (A_0 - A_t)/A_0X100}$$

Where A0 is the absorbance of the original dye solution, D is the percentage of degradation, and $A_t$ is the absorbance following illumination.

The gradual reduction in the characteristic absorption peaks of Methylene blue dye at 700 nm, eosin yellow, and rhodamine dye at 550 nm and 640 nm over time demonstrated the photocatalytic activity of the green-synthesized CuO NPs. The light source used to assess dye degradation was natural sunshine, and the degrading activity was significantly affected by the larger surface area and smaller bandgap. Absorption spectra were obtained for each experiment using a UV-Vis spectrometer at regular intervals. As the amount of time spent in sunlight increases, the

intensity of the absorption band reduces[30].These electrons in the conduction band combine with oxygen in the atmosphere to form a highly reactive superoxide anion (O2*). When these superoxide anions come into contact with organic dyes (MB), their strong reducing nature causes them to break down, releasing non-toxic byproducts such as

$CO_2$ and $H_2O$.

(VB) $h^+$ + photocatalyst + hv → (CB) $e^-$

Organic dye (MB) + Atmospheric $O_2$ + (CB) $e^-$ → Super Oxide Anion ($O_2$*)

$H_2O$ + (VB) $h^+$ → $H^+$ + Hydroxyl radical ($OH^·$)

$OH^·/O_2$* Outcomes ($CO_2$ + $H_2O$)

Similarly, when extra energy is absorbed, electrons that have jumped to a higher energy level leave holes in the valence band, which water molecules react with to form the hydroxyl radical (OH)[32].

Figure 6: Photodegradation of (a) methylene blue, (b) rhodamine B, and (c) eosin yellow using CuO nanoparticles, with (d) a comparative photodegradation profile of all three dyes.

## CONCLUSION

This study successfully demonstrated the green synthesis of copper oxide nanoparticles (CuO NPs) using *Smilax china* Linn. root extract, establishing an inexpensive, sustainable, and eco-friendly route for nanoparticle fabrication. The biosynthesized CuO NPs exhibited a monoclinic crystalline structure with spherical morphology, as confirmed by XRD and SEM analyses. At the same time, UV–Vis and FTIR characterization verified the formation and phytochemical-assisted stabilization of the nanoparticles. Photocatalytic investigations revealed notable dye degradation efficiencies under sunlight, achieving 59% removal of methylene blue, 39% of rhodamine B, and 20% of eosin yellow within 180 minutes. These results highlight the strong potential of green-synthesized CuO NPs as effective photocatalysts for wastewater treatment and environmental remediation. Looking ahead, future research should focus on optimizing synthesis conditions to enhance photocatalytic efficiency, exploring the degradation pathways of diverse industrial dyes and emerging contaminants, and evaluating the reusability and long-term stability of the catalysts. Furthermore, coupling CuO NPs with other semiconductors or carbon-based materials may further improve charge separation and broaden visible-light activity. Scaling up this eco-friendly synthesis and integrating the materials into pilot-scale wastewater treatment systems could significantly advance their practical applications in sustainable environmental management.

## ABSTRACT

This study aims to evaluate the structural quality and crystalline purity of commercially available table salts commonly consumed in Tiruchirappalli, Tamil Nadu, India, using an unsupervised neural network approach Powder X-ray Diffraction (XRD) patterns of four salt samples—Himalayan Rock Salt (HRS), Sea Crystal Salt (SS), TATA Iodized Salt (TATA), and Government Tamil Nadu Salt (GTS)—were analyzed to extract peak positions and relative intensities. These features were vectorized and normalized as input to a deep autoencoder neural network. The model was trained to reconstruct the input data, and reconstruction error was used as a quantitative metric to rank the salts. Training and validation loss curves over 3000 epochs ensured stable convergence and minimal overfitting. The autoencoder effectively captured structural variations among the salts. Himalayan Rock Salt exhibited the lowest reconstruction error, followed by SS, TATA, and GTS, indicating higher crystalline order and structural fidelity.The model achieved a reconstruction loss of <0.005 with consistent convergence after 2800 epochs, indicating stable learning of crystallographic features. This XRD–autoencoder framework provides a rapid, non-destructive, and objective tool for assessing table salt quality and ranking commercially available salts, complementing conventional chemical and structural analyses for local markets.

**Keywords:** X-ray Diffraction (XRD); Autoencoder Neural Network; Reconstruction Error; Crystalline Purity; Table Salt Quality; Tiruchirappalli, India.

**Highlights**

- An unsupervised autoencoder neural network was applied to XRD peak positions and intensities of commercially available table salts.
- Reconstruction error from the autoencoder was used as a quantitative metric to rank salts based on crystalline purity and structural fidelity.
- Four commonly consumed salts in Tiruchirappalli, Tamil Nadu—Himalayan Rock Salt (HRS), Sea Crystal Salt (SS), TATA Iodized Salt (TATA), and Government Tamil Nadu Salt (GTS)—were evaluated.
- HRS exhibited the lowest reconstruction error, followed by SS, TATA, and GTS, indicating superior crystalline order.
- The proposed XRD–autoencoder framework provides a rapid, non-destructive, and objective tool for quality assessment and ranking of table salts, complementing traditional chemical analyses.

# INTRODUCTION

**Context and Literature Review**

Table salts vary in crystallinity, purity, and trace minerals; structural variations affect taste, solubility, and market value. Salt has long been recognized not only as a dietary necessity but also as a material of scientific interest due to its rich mineral composition and diverse crystalline structures. Its physical and chemical variations often reflect geological origin, environmental exposure, and purification methods. Classic studies by Durack et al. (2008) and Fenner and Wright (2014) drew attention to the differences in trace elements and nutritional quality among various salts, paving the way for modern mineralogical investigations. In recent years, X-ray diffraction (XRD) has become an indispensable technique for understanding these variations, revealing patterns of crystallinity, impurity levels, and lattice symmetry with exceptional precision.The characterization of salt samples from India by Santhanakrishnan et al. (2015) demonstrated how environmental factors could influence crystal morphology and mineral inclusions. Extending this approach, Di Salvo et al. (2023) compared a wide range of gourmet salts using XRD, showing that each variety exhibits a distinctive diffraction fingerprint linked to its geological source. Likewise, Bozkaya and Aluç (2024) explored Turkish spring salts and noted a close relationship between crystallinity and mineral purity, while also identifying trace microplastic residues. Ercoşkun (2023) provided a complementary view by analyzing impurity effects on salt quality and potential health implications. More recently, Meng et al. (2024) combined XRD with dielectric analysis for Himalayan and bamboo salts, concluding that higher crystallinity corresponds to greater structural stability and distinctive dielectric responses. Collectively, these works confirm that XRD is not merely a structural probe but a diagnostic indicator of purity and provenance.

Parallel developments in material analysis, particularly SEM–EDX and FTIR studies, have enhanced the interpretation of salt mineralogy. Research by Bharti et al. (2017) and Bora et al. (2021) used these complementary techniques to map surface morphology and trace minerals, while Bosch-Reig et al. (2017) advanced spectral quantification through ATR-FTIR and regression modeling. These approaches laid the groundwork for data-driven analyses in geochemistry. Subsequently, Barrera et al. (2023) and Choudhary et al. (2023) applied matrix factorization and receptor models for source apportionment, illustrating how machine-learning concepts could be adapted to mineral characterization.Beyond physical and statistical analysis, handling uncertain or imprecise data has become equally crucial. Foundational work by Atanassov, Sotirov, and Angelova (2020) introduced Intuitionistic Fuzzy Neural Networks (IFNNs) for modeling uncertainty within complex datasets. Building on this, Leonishiya and Robinson (2023) proposed a Linguistic Intuitionistic Fuzzy Artificial Neural Network (LIFANN) capable of blending linguistic information with neural computation. Their subsequent developments (Robinson &Leonishiya, 2024; Robinson & Saranraj, 2024) refined learning algorithms and ranking strategies for Multiple Attribute Group Decision Making (MAGDM). Such hybrid models enhance interpretability and resilience in uncertain environments—an essential feature when analyzing XRD data where subtle measurement noise can affect classification.

Bringing these threads together, the integration of crystallographic data with fuzzy-neural intelligence represents a promising new direction. XRD outputs can be transformed into intuitionistic fuzzy inputs, allowing neural models to learn complex mineral relationships and rank salts by purity, structure, or representativeness. This cross-disciplinary synthesis aligns with the broader movement toward explainable artificial intelligence in materials research. The present study builds upon these insights, proposing an IFNN-based framework that fuses experimental diffraction data with intelligent decision analysis to achieve a comprehensive evaluation of salt quality and structure. The ANN-predicted purity scores exhibited strong agreement with existing results of NaCl, confirming that the integrated XRD–ANN framework effectively discriminates high-quality, crystalline-pure salt samples suitable for human use.

**Problem gap:** Existing XRD analyses rely on expert interpretation, lacking automated pattern-based ranking.
**Innovation:**Introduce the "AI–XRD" approach as a new paradigm which will be a non-destructive, data-driven structural assessment tool.

## MATERIALS AND METHODS

**Crushing and Grinding**

Before subjecting the four commercial table salts—Himalayan Rock Salt (HRS), Sea Crystal Salt (SS), TATA Iodized Salt (TATA), and Government Tamil Nadu Table Salt (GTS)—to X-ray Diffraction (XRD), X-ray Fluorescence (XRF), and dielectric measurements, the samples were first converted into fine powder form. Proper sample preparation is essential, as raw particles larger than 40 μm may lead to incomplete diffraction from certain crystallographic planes and inaccurate intensity readings. Each salt sample was initially coarsely crushed using a clean, non-contaminating mechanical crusher to break down larger aggregates. The crushed material was then finely ground manually using an agate mortar and pestle to achieve a uniform powder texture. The grinding process was continued until the powder exhibited no perceptible graininess when rubbed between the fingers, indicating particle sizes below 40 μm [18]. The finely ground samples were subsequently stored in airtight polyethylene containers to prevent moisture absorption and contamination prior to further analytical measurements.

**XRD Data Collection and Instrumental Parameters**

X-ray Diffraction (XRD) measurements for the four commercial table salts—HRS, SS, TATA, and GTS—were conducted using a Cu K$\alpha$ radiation source ($\lambda$ = 1.5406 Å) on a powder diffractometer. The finely ground powders were carefully loaded onto a low-background sample holder, ensuring a uniform surface to minimize preferred orientation effects. The scans were performed over a 2$\theta$ range of 10°–80° with a step size of 0.02° and a counting time of 1 second per step to achieve adequate peak intensity and resolution.Baseline correction and intensity normalization were applied to the raw diffraction data to remove background noise and instrument-related variations. Characteristic diffraction parameters such as peak positions, relative intensities, full width at half maximum (FWHM), and interplanar spacing (d-values) were extracted using standard peak-fitting routines. These parameters formed the numerical feature vectors used as inputs for the Artificial Neural Network (ANN) analysis. All measurements were repeated in triplicate to ensure reproducibility, and the powdered samples were stored in airtight containers between scans to avoid moisture absorption or contamination.

**Feature Extraction and ANN Modeling**

The processed XRD patterns of the four commercial table salts—HRS, SS, TATA, and GTS—were analyzed to extract quantitative features for Artificial Neural Network (ANN) modeling. Key parameters, including peak positions (2$\theta$), relative intensities, full width at half maximum (FWHM), and interplanar spacing (d-values), were systematically recorded for each sample. These features were organized into numerical vectors, forming the input dataset for the ANN.The ANN model was structured with an input layer corresponding to the extracted XRD features, a single hidden layer with non-linear activation functions, and an output neuron producing a purity or quality index for each salt sample. Training was conducted using the back-propagation algorithm with a mean-squared-error loss function and an adaptive learning rate optimizer. The dataset was split into training (80%) and validation (20%) subsets, and

early stopping was employed to prevent overfitting. Convergence of training and validation errors was monitored to ensure stable learning. The ANN output scores were subsequently used to rank the salt samples according to crystalline purity and structural regularity inferred from their diffraction patterns.Triplicate measurements and repeated feature extraction ensured consistency, and the ANN predictions were cross-validated with Rietveld refinement and chemical assays to confirm reliability.

## RESULTS

**XRD Patterns of Commercial Table Salts**

The XRD patterns of the four commercial table salts—HRS, SS, TATA, and GTS—are shown in Figures 1 to 4. All samples exhibited the characteristic cubic NaCl diffraction peaks at 2θ values corresponding to (111), (200), (220), and (311) planes. Minor variations in peak intensities and full width at half maximum (FWHM) were observed among the samples, indicating slight differences in crystallinity and structural uniformity. HRS and SS showed sharper peaks with higher relative intensities, suggesting better crystalline order, while TATA and GTS exhibited broader peaks indicative of smaller crystallite sizes or minor structural imperfections.

**ANN Training and Convergence Analysis**

The extracted XRD features were used to train the Artificial Neural Network (ANN). The program presents the convergence of the training and validation loss curves over 300 epochs. The loss values decreased steadily and approached near-zero, demonstrating effective learning and minimal overfitting. Early stopping based on validation loss ensured that the model maintained generalization capability. The ANN effectively captured the subtle differences in diffraction features among the salt samples, enabling quantitative ranking based on crystalline purity. This program implements a deep autoencoder-based ranking model for analyzing and comparing X-ray Diffraction (XRD) data of different salts. It integrates multiple structural parameters—peak position, height, full width at half maximum (FWHM), d-spacing, and relative intensity—to evaluate and rank salts based on their similarity and structural consistency. The workflow combines machine learning principles, signal processing, and materials characterization to identify the salt exhibiting the most stable and representative diffraction pattern.

The method is a Deep Autoencoder trained using Backpropagation,with Adam optimizer, ReLU activations in hidden layers, and Sigmoid activation in the output layer,minimizing Mean Squared Error (MSE) over normalized XRD peak feature vectors.Adam (Adaptive Moment Estimation) was chosen instead of plain SGD because it: i) Adapts learning rates individually for each parameter, ii) Converges faster and more stably for complex nonlinear data (like XRD peaks + intensities + FWHM), iii) Reduces the need for manual learning-rate tuning.

**Data Preparation**

The program begins by defining the XRD peak data for four salts—GTS, HRS, SS, and TATA. Each salt's dataset contains five quantitative features for each peak: position (°2θ), peak height, FWHM, d-spacing (Å), and relative intensity (%). These collectively describe the crystal structure characteristics of each material.

**Input:**

XRD peak data of salts $S$={GTS,HRS,SS,TATA}.

Each salt $s_i \in S$ has features:

F={Position (2θ),Height,FWHM,d-spacing,Relative Intensity}

**Output:**

Ranked salts based on reconstruction error (lower = better).

Data Acquisition and Feature Preparation

i) For each salt $s_i$, form a feature list of all observed peaks:$P_i = \{p_{i1}, p_{i2}, \dots, p_{in}\}$.
ii) Construct a combined peak set: $\hat{P}_i = \cup_i P_i$.
iii) For each salt $s_i$, create a fixed length feature vector: $X_i = [f_{ij1}, f_{ij2}, \dots, f_{ijk}]$, where $f_{ij1} \in F$ are values corresponding to each peak in $\hat{P}_i$. (missing peaks are marked with 0)

To ensure uniformity across samples, the program constructs a combined vector using the union of all unique peak positions across salts. This allows every salt to be represented by a consistent-length feature vector, even if some peaks are missing (filled with zeros).

**Normalization**

Since the features vary in scale (e.g., peak heights in thousands while FWHM values are below 1), the program uses Min–Max normalization to rescale all data to a [0,1] range. This ensures balanced feature influence and improves neural network convergence stability.

$X'_i = \frac{X_i - X_{min}}{X_{max} - X_{min}}$, where $X'_i \in [0,1]$. This equalizes the influence of all parameters.

**Model Architecture – Deep Autoencoder**

A deep autoencoder neural network is built with symmetrical encoding and decoding layers (512 → 256 → 128 → 256 → 512 → output). Its goal is not classification but self-reconstruction where the model learns to reproduce its input data at the output layer. The reconstruction loss (mean squared error) measures how well the autoencoder captures the internal structure and relationships among input features.

Encoder path (512 → 256 → 128) compresses the XRD data into a latent code that captures the "essence" of each salt's diffraction pattern. Decoder path (128 → 256 → 512) tries to reconstruct the original XRD curve from that compact code. The difference between input and reconstructed output (called *reconstruction error*) tells how well the salt structure fits the learned crystalline pattern.

Let $x \in R^{512}$ be the input XRD vector, and the encoder maps it as:

$z = f(Wx + b)$ , where f is the activation function (ReLU or Sigmoid),

and $z \in R^{128}$ is the latent code.

Then the decoder reconstructs as follows: $\hat{x} = g(Wz + b)$.

This model is trained to minimize the reconstruction error as:

$L = \|x - \hat{x}\|^2$, where L is the Mean Squared Error (MSE).

A smaller L will give a better reconstruction leading to higher structural fidelity.

The autoencoder architecture (512–256–128–256–512–output) performs a symmetrical compression and reconstruction of the XRD features. The central bottleneck layer (128 neurons) represents the essential crystallographic signature of each salt. Lower reconstruction error indicates higher structural regularity and purity, allowing objective ranking of the samples.

**K-Fold Cross-Validation**

To enhance reliability, a 4-fold cross-validation strategy is employed. The data is split into four subsets; in each iteration, three are used for training and one for validation. This approach prevents overfitting and evaluates model generalization. Each fold's loss and validation curves are recorded for later analysis.

Partition the dataset into K=4 folds:

Where $D = \{(X_{train}, X_{val})_1, (X_{train}, X_{val})_2, \dots, (X_{train}, X_{val})_K\}$.

For each fold k=1,2,…,K:

- Train the model using $X_{train}$
- Validate on $X_{val}$
- Record: $L^k_{train}(t), L^k_{val}(t)$ across epochs t.

**v-Convergence and Validation Curves:**

The training loss curve shows how quickly the model learns the patterns within the data, while the validation loss indicates its ability to generalize. A smooth convergence of both curves toward near-zero loss signifies that the autoencoder has learned the intrinsic structure of the salts without overfitting. Divergent curves would indicate model instability or non-representative data.

Plot the training and validation loss curves:

- If $L_{train}^{k}(t) \approx L_{val}^{k}(t) \rightarrow 0$, we get a stable convergence and generalization achieved.
- If the curve diverges, then the model is overfitting or inconsistent XRD patterns.

**vi-Reconstruction Error and Ranking:**

After training, each salt's reconstruction error (difference between input and reconstructed output) is calculated. A lower error implies the salt's pattern fits the learned structural manifold better and the meaning it is more representative, consistent, and structurally stable. The salts are ranked accordingly, and the best-performing one is visually highlighted in the final bar chart.

For each salt $s_i$, compute the reconstruction error is:

$E_i = \frac{1}{d}\sum_{j=1}^{d}\left(X'_{ij} - \hat{X}'_{ij}\right)^2$, where $d$ is the total number of features.

The average reconstruction across all folds is:

$$\bar{E}_i = \frac{1}{K}\sum_{k=1}^{K} E_i^{(k)}.$$

Sort the salts in ascending order of $\bar{E}_i$: Rank ($s_i$)=argsort ($\bar{E}_i$).

Display the results as a bar chart, highlighting the lowest-error(best) salt.

This ANN is constructed in four different categories:

I. ANN producing better score values for the 4 different types of salts in the study only taking the highest Peak values as inputs.
II. ANN producing better score values for the 4 different types of salts in the study taking all the peak values as inputs (Error convergence reaches zero and validation not converging to zero).
III. ANN producing better score values for the 4 different types of salts in the study taking all the peak values as inputs (Error convergence and validation converging to zero).
IV. ANN producing better score values for the 4 different types of salts in the study by taking Full XRD Dataset Including 2θ, Intensity, and Peak Positioning.

**Advantages and Significance**

**This program has multiple scientific and analytical advantages:**

- **Comprehensive Feature Integration:**

By including position, height, FWHM, d-spacing, and intensity, the analysis goes beyond conventional peak-only studies, capturing both geometric and energetic aspects of crystal behavior.

- **Automated and Quantitative Ranking:**

Instead of subjective visual interpretation of XRD peaks, the autoencoder provides a numerical metric (reconstruction error) for structural consistency.

- **High Sensitivity to Structural Deviations:**

Even minor variations in diffraction patterns influence reconstruction loss, allowing detection of subtle crystallographic differences among salts.

- **Validation via Convergence Behavior:**

The convergence of the error and validation curves ensures that the model has reached a stable learning point. The salt with the smallest reconstruction error is most in harmony with the learned structural representation, reflecting better crystallinity or phase purity.

- **Material Selection Insight:**

The best-performing salt can be interpreted as having the most consistent internal crystal ordering, making it potentially more reliable for further applications (e.g., catalysis, sensors, or energy materials).

In essence, this autoencoder-based framework bridges machine learning and materials science, allowing intelligent and objective selection of the most structurally coherent salt based on complete XRD feature profiles. The close

alignment of convergence and validation curves reflects the robustness of the learning process and confirms that the chosen salt exhibits optimal internal consistency.

**ANN Results: Convergence Curve and Best Validation Epoch (Highest Peak Point Only)**

The ANN produced a **purity index** for each salt sample, reflecting structural regularity and crystalline order. The samples were ranked according to the predicted index, as shown in **Table 1**. HRS received the highest purity score, followed by SS, TATA, and GTS, consistent with visual assessment of peak sharpness and intensity from XRD patterns. The ranking was further validated against Rietveld refinement results and chemical assays of NaCl content, which confirmed the reliability of the ANN-based approach.

Average validation loss across folds: 0.0031074487749407353

This convergence plot illustrates the learning behavior of the autoencoder when trained exclusively on the highest-intensity diffraction peak of each salt sample. The network exhibits a smooth and monotonic decline in both training and validation loss, converging stably near zero at epoch 393, which is marked as the best validation epoch. The perfect overlap between training and validation curves indicates excellent generalization and the absence of overfitting. Since only the dominant peak intensity was considered, the model efficiently captured the most defining crystalline signature of each salt. The extremely low mean squared error (MSE) at convergence suggests that even a single prominent diffraction feature carries sufficient structural information for distinguishing high-purity salts such as Himalayan Rock Salt. This single-peak-based ANN performance demonstrates the discriminative power of primary lattice reflections in identifying structural order among crystalline materials.The curve shows both training and validation loss decreasing rapidly at the beginning (first 0–100 epochs), then flattening to almost zero. This indicates:

- The model learned the data's structure efficiently.
- There's no divergence or oscillation — meaning stable optimization and proper learning rate control.

The ANN's parameters converged smoothly, minimizing the mean squared error (MSE) between predicted and actual salt quality scores.Both curves (blue for training, orange dashed for validation) almost overlap throughout the training process.

- The model generalizes extremely well.
- There's no overfitting — since validation loss didn't rise after convergence.
- The data is likely simple and consistent, allowing the ANN to fit without memorizing.

The model maintains a nearly perfect balance between fitting the training data and predicting unseen validation samples. The red marker at epoch 393 shows the point where the validation loss reached its minimum (≈ 0.0000). That is the optimal stopping point, where:

- The network achieves the smallest possible prediction error.
- Beyond this, training would yield no further improvement (and might overfit).

The early stopping mechanism correctly identifies epoch 393 as the most efficient point, restoring weights from this point for final evaluation.

Since this is a small, clean dataset (4 salts × 4 features), the ANN can achieve almost zero loss. The flat tail of both curves confirms the model reached its global minimum and has no further optimization needed. The convergence plot demonstrates that the ANN model achieves perfect convergence and generalization. Both training and validation errors diminish rapidly and stabilize near zero, indicating an optimal fit to the salt composition–quality relationship. The identified best epoch (393) marks the precise point of minimal validation loss, confirming effective early stopping and a high-fidelity learning process.

**Interpretation of the Convergence Curve**

The convergence curve of the proposed Artificial Neural Network (ANN) model demonstrates a smooth and efficient learning process. Both training and validation losses decrease sharply during the initial epochs, indicating rapid acquisition of the nonlinear relationship between the input salt features and their corresponding quality scores. The two curves remain closely aligned throughout training, showing that the model generalizes well without overfitting.The early stopping mechanism successfully identifies the optimal point of convergence at epoch 393, where the validation loss reaches its minimum (MSE ≈ 0.0000). This point marks the best balance between learning accuracy and generalization capability. The near-zero loss values for both training and validation confirm that the model achieves high predictive precision and numerical stability. The absence of oscillations or divergence highlights the suitability of the chosen architecture, activation functions, and optimization algorithm.Overall, the convergence curve reflects a well-trained, robust ANN model that efficiently learns the mapping between the salts' structural characteristics and their quality indices. The synchronized decline and stabilization of both losses validate the model's effectiveness, reliability, and strong generalization performance within the given dataset.

**ANN Results: Convergence Curve and Best Validation Epoch (ALL Peak Points)**

In this configuration, the autoencoder was trained on all extracted peak positions and relative intensities from the XRD profiles. The plot shows multi-fold (k-fold) validation across four training–validation splits, where each fold demonstrates stable convergence toward near-zero loss values within the first 50 epochs. Minor oscillations in certain validation folds reflect the increased complexity of input data, yet the overall convergence pattern remains smooth and consistent. Incorporating multiple peaks enables the model to learn finer-grained crystallographic patterns, including secondary reflections and defect signatures, leading to a richer representation of each sample's structural fingerprint. The minimal validation loss across folds confirms that the model maintains robustness even under cross-validation, validating the reliability of reconstruction-based ranking among the salt varieties. The combined convergence and validation curves reveal that the training loss rapidly converges to near zero within the first few epochs, indicating that the autoencoder efficiently learns to reconstruct the training data. However, the validation loss plateaus around 0.13–0.18 and does not converge to zero, suggesting limited generalization. This behavior indicates mild overfitting or inherent variability in the validation samples. In the context of salt ranking, this non-zero validation loss is meaningful, as it reflects the distinctiveness of each salt's mineral composition. A higher validation loss signifies greater uniqueness, while a lower one represents higher representativeness within the dataset.

**ANN Results: Convergence Curve and Best Validation Epoch (ALL Peak Points)**

**ANN Results: Convergence Curve and Best Validation Epoch (Full XRD Dataset Including 2θ, Intensity, and Peak Positioning)**

**Combined Convergence & Validation Curves (Full XRD Dataset Including 2θ, Intensity, and Peak Positioning)**

This final convergence diagram represents the autoencoder trained with the complete XRD dataset — including all 2θ values, intensities, full peak positioning, and relative spacing parameters. The plot demonstrates a uniform and stable convergence trend across all folds, reaching near-zero loss after approximately 150 epochs and maintaining consistency through 700 epochs. The tight clustering of all training and validation loss curves indicates exceptional reproducibility and model stability. By ingesting the entire diffraction pattern, the ANN captures both global and local structural variations among the salts, effectively encoding the complete crystallographic landscape. The negligible reconstruction error confirms that the model has learned an intrinsic manifold of the salt structures, allowing for high-fidelity ranking based purely on physical diffraction data.

**Comparative Interpretation Across All Three Figures**

Collectively, the three convergence diagrams depict the progressive evolution of model learning as the feature dimensionality of XRD data increases. The first model, trained on a single dominant peak, achieved rapid and smooth convergence, emphasizing the predictive power of the most intense reflection. The second model, incorporating all significant peaks, introduced moderate complexity but improved the model's sensitivity to subtle

lattice variations. Finally, the third model, trained on the complete XRD dataset, demonstrated the highest stability and precision, capturing the full structural diversity inherent in the salts. The consistent decline to near-zero loss across all experiments highlights the robustness of the unsupervised ANN framework and its capability to autonomously extract meaningful crystallographic representations. This comparative progression—from single-peak learning to full-pattern encoding—clearly establishes the scalability and generalization strength of the proposed XRD–autoencoder methodology for objective, non-destructive material quality assessment.

## DISCUSSION

The XRD analysis revealed that all four commercial table salts namely HRS, SS, TATA, and GTS have exhibited characteristic cubic NaCl peaks, confirming their primary composition. However, subtle differences in peak sharpness, relative intensity, and FWHM suggested variations in crystallinity and microstructural order among the samples. Himalayan Rock Salt (HRS) and Sea Crystal Salt (SS) displayed sharper peaks and higher intensities, indicating superior crystalline purity, whereas TATA and GTS exhibited slightly broader peaks, suggestive of smaller crystallites or minor structural imperfections. The ANN model effectively leveraged these diffraction features to generate a quantitative purity index for each salt. The convergence of training and validation losses to near-zero values indicated stable learning and minimal generalization error. The ANN ranking (HRS > SS > TATA > GTS) closely matched the results obtained from Rietveld refinement and chemical assays of NaCl content, demonstrating the reliability of combining XRD with machine learning for rapid, non-destructive quality assessment.While XRD-ANN analysis provides an efficient screening tool for crystalline purity, it should be noted that chemical safety and trace element content are critical for human consumption. The selected samples were further validated through chemical assays and trace element measurements (Pb, Cd, As), confirming that all four salts fall within safe limits for consumption. Thus, the ANN ranking reflects structural quality rather than absolute safety, which is ensured by complementary chemical testing.

## CONCLUSION

This study demonstrated that integrating X-ray Diffraction (XRD) analysis with Artificial Neural Network (ANN) modeling provides an effective approach for evaluating the crystalline purity and structural regularity of commercially available table salts in Tamil Nadu. The ANN model achieved strong convergence and accurately ranked the salt samples in agreement with Rietveld refinement and chemical assay results. The proposed XRD–ANN framework serves as a reliable, non-destructive, and rapid screening tool for assessing salt quality. Future work may extend this approach to larger datasets and other mineral-based food products for enhanced generalization.The proposed XRD–autoencoder pipeline demonstrates that deep learning can autonomously infer crystal quality and purity from diffraction data. This methodology can be generalized to quality control in food-grade minerals, pharmaceuticals, and nanomaterials.This framework can be extended to identify adulteration or process-induced lattice distortions in other crystalline food products. Future studies may integrate elemental composition data (e.g., EDS or Raman spectra) with XRD for multimodal AI-based material fingerprinting.

## ACKNOWLEDGEMENT

The authors sincerely acknowledge Bishop Heber College, Tiruchirappalli, for providing the research facilities and continuous encouragement to carry out this work. The X-ray Diffraction (XRD) measurements were performed at the HAIF Laboratory, whose technical assistance and support are gratefully appreciated. The authors also thank the Department of Science and Technology (DST-FIST), Government of India, for the instrumental and infrastructural support extended to the Department of Mathematics and the research laboratories of Bishop Heber College.

**ABSTRACT**

This study aims to explore the bibliometrics study of the journal Manthan Journal of Commerce and Management from the year 2022 to 2024. This study highlights the various aspects of the journal Manthan Journal of Commerce and Management such as distribution of articles published in each month, authorship pattern, affiliation wise distribution, citation analysis and location distribution of authors. The study indicates that. 540no. of articles were published in the journal.

**Keywords:** Bibliometrics, Authorship Pattern, Citation analysis, Manthan Journal of Commerce and Management.

## INTRODUCTION

The term bibliometrics was derived from "Biblion" meaning book and "Metron" meaning measure. This term was coined by Alan Pritchard in the year 1969. He defined bibliometrics as the application of mathematical and statistical methods to books and other communication media. Bibliometrics is concerned with theoretical and philosophical foundations. The primary objective of bibliometrics research is the development of a general and systematic set of theories from which hypothesis can be generated and tested. They adopt different methods of data collection as well as different techniques. In addition use of algebraic symbols varies from one study to another. Bibliometrics is a set of methods to quantitatively analyse academic literature. Citation analysis and content anlaysis are commonly used bibliometric methods. While bibliometric methods are most commonly used in the field of Library and Information Science. Bibliometrics have wide applications in other areas. Many research fields use bibliometric methods to explore the impact of their field, the impact of a set of researchers, or the impact of a particular paper. Historically

bibliometric methods have been used to trace relationship amongst academic journal citations. Citation analysis, which involves examining an item's referring documents, is used in searching for materials and analyzing their merit. Citation indices such as institute for scientific information, web of science, allow users to search forward in time from a known article to more recent publications which cite the known item. Data from citation indexes can be analysed to determine the popularity and impact of specific articles, authors, and publications. Bibliometrics are now used in quantitative research assessment exercise of academic output which is starting to threaten practice based research. Other bibliometrics applications include creating thesauri, measuring term frequencies as metrics in scientometric analysis exploring grammatical and syntactical structures of texts, measuring usage by readers.

## REVIEW OF LITERATURE

**Waleed Iqbal.(2019)**.A bibliometric analysis of publications in computer networking research. Scientometrics: An International Journal for all Quantitative Aspects of the Science of Science, Communication in Science and Science Policy, Vol.119.: This study, proposes a methodology and framework for performing a comprehensive bibliometric analysis on computer networking research.

**Rabia Bag Soytas (2021).** A Bibliometric Analysis of Publications on COVID-19 and Older Adults. Annals of Gereotric Medicine and Research. Vol 7, 25(3). The results of the bibliometric analysis provided information about the quality and research areas of published studies on COVID-19 and older adults. Social and psychological support, nutrition, vaccines, and telemedicine may be hot research topics for the future.

## OBJECTIVES OF THIS STUDY

1. To find out the month wise distribution of articles
2. To examine the authorship patterns
3. To classify the geographical distribution of articles
4. To find the citations of articles

## METHODOLOGY

Bibliometric Analysis methodology is used to find the bibliographic features and citation analysis of the articles published in Manthan Journal of Commerce and Management from the year 2022 to 2024. The data related to Manthan Journal of Commerce and Management regarding 54 articles from the year 2022 to 2024. All the bibliographic details are entered in a excel spreadsheet and analysed in depth.

**Analysis of Data**

The details of authors, titles, year of publication, paginations, and institutional affiliations of authors published in the articles from the year 2022 to 2024 in Manthan Journal of Commerce and Management is analysed.

**Issue wise distribution of articles in the year 2022 to 2024 (Table: 1)**.

The table 1 indicates the issue wise distribution articles published in Manthan Journal of Commerce and Management during the period 2022 to 2024. The table reveals that highest number of articles published in the issues of July-December 2023 and July-December 2024 and the lowest number of articles published in the issues of July-December 2022 and January-June 2023.(Fig 1).

**Authorship Patterns(Table: 2)**

The table 2 describes the authorship pattern of the issues published in Manthan Journal of Commerce and Management during the period 2022 to 2024. The table indicates that publication of two authorship pattern (61.11%) is high and publication of more than three authorship pattern (7.41%) is low.

**Types of Affiliation of Contributors(Table: 3)**.
The table 3 describes the affiliation of authors in the issues published in Manthan Journal of Commerce and Management during the period 2022 to 2024. The table shows that majority of authors are affiliated to Universities (64.81%) and least number of authors affiliated to Research Institutions (3.70%)(Fig 3).

**Geographical Distribution of Articles(Table: 4)**.
The table 4 explains the geographical distribution of articles received in the issues published in Manthan Journal of Commerce and Management during the period 2022 to 2024. It is found that majority of the articles received from India (88.88%).(Fig 4).

**Citation Analysis(Table: 5)**
The table 5 elucidates the number of citations received in the issues published in Manthan Journal of Commerce and Management during the period 2022 to 2024. It is found that majority of the citations received in the issue dated July-December 2023 and lowest citations received in the issue dated January-June 2024.(Fig 5).

**Findings of the Study**

1. There are 54 number of articles published in Manthan Journal of Commerce and Management during the period 2022 to 2024 and highest number of articles published in the issues of July-December 2023 and July-December 2024.
2. Most number of articles published with two authorship patterns in Manthan Journal of Commerce and Management during the period 2022 to 2024 and majority of authors are working in the Universities.
3. Majority of articles were received from Indian authors in the articles published in Manthan Journal of Commerce and Management during the period 2022 to 2024.
4. There are 1250 citations received in the issues published in Manthan Journal of Commerce and Management during the period 2022 to 2024.

## CONCLUSION

This study shows that maximum contributors are from India with two authorship pattern and large number of citations was received for the articles published in Manthan Journal of Commerce and Management during the period 2022 to 2024. The study reveals that the journal stipulates the research in the field of commerce and management. The publishing totally depends upon the productivity of contributions, quality of research and pattern of contributions.

## ABSTRACT

Periodontal diseases are chronic inflammatory conditions characterized by microbial dysbiosis and host immune responses leading to progressive destruction of tooth-supporting tissues. Conventional clinical parameters reflect historical tissue damage rather than ongoing biological activity, creating a need for predictive and early diagnostic approaches. Metabolomics, the comprehensive analysis of small-molecule metabolites in biological systems, has emerged as a promising tool in periodontal research. It provides insight into host–microbe interactions, disease pathogenesis, biomarker discovery and therapeutic monitoring. Biological fluids such as saliva, gingival crevicular fluid (GCF), serum and plasma have been extensively explored for metabolic signatures associated with periodontal health and disease. Studies have identified consistent metabolite alterations, including amino acids, organic acids and bacterial metabolites such as butyrate, lactate and phenylalanine derivatives. Metabolomics also enables differentiation of disease stages, assessment of treatment outcomes and exploration of links between periodontitis and systemic conditions. Despite its promising clinical potential, challenges remain, including methodological variability, small sample sizes and lack of standardized protocols. This review discusses principles of metabolomics, analytical platforms, key findings in periodontal research, diagnostic applications, therapeutic monitoring and future directions for integrating metabolomics into personalized periodontal care.

**Keywords:** Metabolomics, Periodontitis, Saliva, Biomarkers, Gingival crevicular fluid, Precision dentistry

## INTRODUCTION

Periodontal diseases are among the most prevalent chronic inflammatory conditions worldwide and represent a significant public health burden[1]. Traditional diagnostic measures — clinical probing, radiographs, and inflammatory indices — offer limited insight into the underlying biochemical pathways and early disease detection. This has spurred interest in systems biology approaches such as genomics, proteomics, and particularly metabolomics, which focuses on the end products of cellular processes that reflect real-time physiological changes[2]. Metabolomics refers to the comprehensive profiling of metabolites — small molecules such as amino acids, lipids, sugars, and nucleotides — present in cells, tissues, or biofluids[3]. It offers a dynamic picture of health and disease, bridging gaps between genotype and phenotype.

## REVIEW OF LITERATURE

Metabolomics has gained considerable attention in periodontal research over the past two decades due to its ability to capture dynamic biochemical alterations associated with inflammation, tissue destruction, and host–microbe interactions. Several investigations have evaluated salivary, gingival crevicular fluid (GCF), and serum metabolomic profiles in periodontal health and disease. Nicholson and Lindon (2008) first emphasized the potential of metabolomics as a systems biology tool capable of reflecting real-time physiological changes in disease conditions, thereby laying the conceptual foundation for metabolomics applications in inflammatory disorders including periodontitis[4]. Patti *et al*. (2012) further highlighted metabolomics as the functional readout of cellular activity and an important bridge between genotype and phenotype, underscoring its diagnostic potential[5]. Kuboniwa and Wong (2017) reviewed the integration of oral microbiome and salivary biomarkers, noting that metabolomics can detect microbial metabolic byproducts such as short-chain fatty acids (SCFAs), amines, and sulfur-containing compounds that are strongly associated with periodontal destruction[6]. Their work emphasized the diagnostic relevance of saliva as a non-invasive diagnostic medium. Barnes *et al*. (2014) conducted metabolomic profiling of saliva in periodontitis patients and demonstrated significant differences in amino acid metabolism and polyamine levels compared to healthy controls[7]. Elevated levels of putrescine and cadaverine were associated with microbial proteolysis and tissue breakdown. Dunn *et al*. (2015) explored salivary metabolomic signatures using mass spectrometry and reported distinct clustering patterns between periodontitis and healthy individuals based on multivariate statistical analysis[8]. The study suggested that metabolic fingerprints may serve as discriminatory biomarkers for disease status. In the context of gingival crevicular fluid, Sakanaka *et al*. (2017) performed metabolomic analysis of GCF samples and identified increased lactate, butyrate, and inflammatory-related metabolites in periodontitis sites[9]. Their findings supported the hypothesis that anaerobic glycolysis and bacterial fermentation products contribute to periodontal tissue destruction.

Psychogios *et al*. (2011) characterized the human serum metabolome and established reference metabolite databases that later facilitated comparative studies evaluating systemic metabolic alterations in inflammatory diseases, including periodontitis[10]. Subsequent studies identified altered lipid metabolism and branched-chain amino acid profiles in periodontitis patients, supporting the systemic impact of periodontal inflammation. Goodson *et al*. (2017) explored oral microbial interaction networks and their metabolic outputs, demonstrating that periodontal pathogens such as *Porphyromonas gingivalis* significantly influence amino acid fermentation pathways[11]. This reinforced the concept that metabolomics can help elucidate host–microbe metabolic crosstalk. Hajishengallis (2014) described the inflammophilic nature of periodontal microbiota, suggesting that dysbiotic microbial communities thrive in inflammatory environments and modify local metabolic landscapes[12]. Metabolomics provides measurable evidence of these metabolic shifts. Zhang *et al*. (2016) highlighted saliva metabolomics as a promising diagnostic tool due to its non-invasive collection and reflection of both local and systemic changes[13]. They emphasized its application in chronic inflammatory diseases including periodontitis. Johnson *et al*. (2016) discussed metabolomics beyond biomarker discovery and proposed its role in understanding mechanistic pathways[14]. In periodontal research, this approach has facilitated mapping of altered arginine metabolism, collagen degradation pathways, and energy

metabolism shifts. Hasin *et al*. (2017) advocated multi-omics integration to better understand complex diseases[15]. In periodontology, integrating microbiomics with metabolomics has revealed correlations between specific bacterial taxa and metabolite production patterns. Proctor *et al*. (2018) performed integrative analyses combining oral microbiome sequencing and metabolomic profiling, identifying associations between microbial composition and metabolic outputs in periodontal disease[16]. This study supported precision diagnostics in periodontology. Seneviratne *et al*. (2020) discussed translational metabolomics in dentistry and emphasized the potential for chairside diagnostic tools based on metabolic biomarkers[17]. They proposed that metabolomic signatures may enable early detection before clinical attachment loss becomes evident. Despite promising findings, Goodacre *et al*. (2007) pointed out the need for standardization in metabolomics research, including sample handling, analytical platforms, and reporting guidelines[18]. Variability in methodology remains a limitation in periodontal metabolomics studies.

**Principles of Metabolomics**

Metabolomics aims to identify and quantify the complete set of metabolites — the metabolome — in a biological system[19]. Unlike the relatively static genome, the metabolome is highly responsive to internal and external stimuli, making it a sensitive indicator of pathophysiological states[20].

**There are two major approaches**

**Targeted metabolomics:** Quantifies predefined metabolites of interest.

**Untargeted metabolomics:** Globally profiles all detectable metabolites without prior selection[21].

Biofluids commonly used in periodontal metabolomic studies include saliva, gingival crevicular fluid (GCF), serum, and urine[22].

**Analytical Platforms in Metabolomics**

Accurate metabolomics relies on sophisticated analytical technologies:

**Nuclear Magnetic Resonance (NMR) Spectroscopy**

NMR detects nuclei such as hydrogen (^1H), carbon (^13C), and phosphorus (^31P) in liquid samples. It is highly reproducible and non-destructive, but has limited sensitivity compared to mass spectrometry[23].

**Mass Spectrometry (MS)**

Mass Spectrometry, coupled with separation techniques like liquid chromatography (LC) or gas chromatography (GC), offers high sensitivity and broad metabolome coverage[24]. LC-MS and GC-MS are widely used in periodontal metabolomics[25].

**Data Processing and Chemometrics**

Metabolomics generates high-dimensional datasets requiring multivariate statistical analysis, including principal component analysis (PCA) and partial least squares discriminant analysis (PLS-DA)[26].

**Metabolomics in Periodontal Research**

**Salivary Metabolomics**

Saliva is easily accessible and reflects both local and systemic metabolic changes[27]. Several studies have identified salivary metabolites associated with periodontal inflammation[28]. A study comparing periodontitis patients to healthy controls found elevated levels of metabolites linked to bacterial metabolism and tissue breakdown, such as short-chain fatty acids (SCFAs), polyamines, and amino acids[29].

**Gingival Crevicular Fluid (GCF) Metabolomics**

GCF is a serum-derived fluid that bathes the periodontal pocket and contains host and microbial metabolites. Altered levels of inflammatory mediators and metabolic products have been documented in periodontitis[30]. For example, metabolites linked to oxidative stress and energy metabolism (e.g., lactate, pyruvate) were significantly higher in GCF from periodontitis sites[31].

**Serum and Systemic Metabolomics**

Periodontitis has systemic implications, including associations with diabetes and cardiovascular diseases. Serum metabolomics reveals changes in lipid metabolism and amino acid profiles in periodontitis patients, supporting the systemic repercussions of periodontal inflammation[32].

**Key Metabolic Pathways Implicated**

Metabolomic studies in periodontology have highlighted several dysregulated pathways:

**Amino Acid Metabolism**

Alterations in branched-chain amino acids, arginine, and proline suggest increased collagen degradation and microbial proteolysis[33].

**Energy Metabolism**

Elevations in lactate and pyruvate reflect anaerobic glycolysis due to hypoxic pockets within periodontal lesions[34].

**Oxidative Stress**

Oxidative stress markers such as malondialdehyde and glutathione imbalance have been linked to periodontal disease progression[35].

**Metabolomics and Periodontal Biomarkers**

The search for reliable biomarkers — objective indicators of disease presence, activity, or response to therapy — is a central goal in periodontal metabolomics[36].

**Diagnostic Biomarkers**

Studies have identified candidate salivary metabolites (e.g., butyrate, propionate) that differentiate periodontitis from gingivitis and health[37].

**Prognostic Biomarkers**

Changes in metabolic profiles post-therapy may predict treatment outcomes[38].

**Personalized Periodontal Therapy**

Metabolomics has the potential to guide tailored interventions based on an individual's metabolic phenotype[39].

**Integration with Other "Omics"**

Combining metabolomics with genomics, transcriptomics, and proteomics — an approach known as multi-omics integration — enhances understanding of disease networks[40]. For periodontitis, this integrated approach can elucidate host-microbe interactions and uncover therapeutic targets[41].

## DISCUSSION

Metabolomics has emerged as a promising systems biology approach in periodontology, providing insight into the biochemical alterations associated with periodontal inflammation. Unlike traditional clinical parameters such as probing depth and clinical attachment level, which reflect historical tissue destruction, metabolomics evaluates real-time metabolic changes and offers functional information about disease activity[42],[43]. One of the most consistent findings in periodontal metabolomic research is the alteration of amino acid metabolism. Elevated concentrations of branched-chain amino acids, arginine metabolites, putrescine, and cadaverine have been reported in saliva and gingival crevicular fluid of periodontitis patients[44,45]. These metabolites are largely derived from bacterial proteolysis and host tissue breakdown, supporting the concept that periodontal pathogens thrive in protein-rich, anaerobic environments[46]. The association between amino acid fermentation and periodontal destruction reinforces the polymicrobial synergy and dysbiosis model of periodontitis[47]. Energy metabolism pathways are also

significantly dysregulated in periodontal disease. Increased levels of lactate and pyruvate in gingival crevicular fluid suggest enhanced anaerobic glycolysis within inflamed periodontal tissues[48]. Hypoxic conditions in deep periodontal pockets and increased metabolic demands of inflammatory cells may contribute to this metabolic shift. Similar metabolic reprogramming has been described in chronic inflammatory diseases, suggesting that periodontitis shares systemic inflammatory characteristics[49,50]. Oxidative stress plays a critical role in periodontal tissue destruction. Reactive oxygen species generated by neutrophils and other inflammatory cells lead to lipid peroxidation and protein damage. Elevated oxidative stress markers and disturbed antioxidant pathways, including glutathione metabolism, have been demonstrated in metabolomic analyses of periodontal patients. These findings corroborate earlier biochemical studies identifying redox imbalance as a central mechanism in periodontal pathogenesis[51]. Salivary metabolomics offers a non-invasive and clinically feasible diagnostic approach. Saliva reflects both local periodontal inflammation and systemic metabolic changes[52].

Studies utilizing mass spectrometry and multivariate statistical analysis have demonstrated clear discrimination between healthy and periodontitis patients based on metabolic signatures[53,54]. However, factors such as diet, circadian rhythm, and systemic health conditions may influence salivary metabolite profiles, emphasizing the need for standardization[55]. Integration of microbiome and metabolome data has further advanced our understanding of periodontal disease mechanisms. Combined analyses have demonstrated correlations between specific bacterial taxa and metabolic byproducts, strengthening the evidence for host–microbe metabolic crosstalk[56]. For instance, periodontal pathogens such as *Porphyromonas gingivalis* are associated with increased production of short-chain fatty acids and amino acid fermentation products[57]. This integrative approach supports precision diagnostics and targeted therapeutic strategies. Despite promising results, several challenges remain. Most metabolomic studies in periodontology are cross-sectional with limited sample sizes, which restricts generalizability[58]. Variability in analytical platforms such as LC-MS and NMR further complicates inter-study comparisons. Additionally, systemic conditions such as diabetes mellitus significantly influence metabolic pathways, potentially confounding periodontal metabolomic signatures[57]. From a translational perspective, metabolomics has significant potential in early diagnosis and personalized periodontal therapy. Metabolic alterations may precede measurable clinical attachment loss, thereby allowing early detection of active disease[58]. Future research should focus on longitudinal studies, standardized methodologies, and development of chairside diagnostic platforms to facilitate clinical integration. Overall, metabolomics provides a comprehensive biochemical snapshot of periodontal disease, reflecting microbial activity, host immune response, oxidative stress, and energy metabolism disturbances. With continued advancements in analytical technologies and multi-omics integration, metabolomics is likely to play a central role in the future of precision Periodontology[59,60].

## CONCLUSION

Metabolomics has emerged as a transformative approach in periodontology, offering insights into pathophysiology, biomarkers, and personalized therapy. While challenges persist, continued technological advancement and rigorous study design will accelerate its clinical application.

## ABSTRACT

Alzheimer's disease (AD) is a progressive neurodegenerative disorder characterized by cognitive decline, memory loss, and functional impairment, posing significant challenges to healthcare systems worldwide. Early and accurate prediction of AD is essential for timely intervention and improving patient outcomes. The objective of this study is to develop an advanced predictive framework that effectively integrates multimodal data, including structural MRI scans, cognitive assessment scores, and demographic information, to enhance diagnostic accuracy. To achieve this, we propose a Multimodal Neuro–Cognitive Fusion Transformer (MNFT), which employs a convolutional neural network to extract spatial features from MRI images and a transformer-based tabular module to encode cognitive and demographic data. A cross-modal attention mechanism is then applied to capture complex interactions between neuroimaging and cognitive indicators, followed by transformer layers and a softmax classifier to predict disease stages. Experimental evaluation demonstrates that MNFT outperforms conventional, hybrid, and ensemble models, achieving superior accuracy, precision, recall, F1-score, and AUC, highlighting its robustness and clinical relevance. In conclusion, the proposed framework offers an effective, interpretable, and scalable approach for early and reliable AD prediction, paving the way for improved patient care and clinical decision support.

**Keywords:** Alzheimer's disease, cognitive assessment, cross-modal attention, deep learning, demographic data, MRI analysis, multimodal fusion

## INTRODUCTION

Alzheimer's disease (AD) is a progressive neurodegenerative disorder that leads to cognitive decline, memory loss, and functional impairment, posing a significant challenge to global healthcare systems. Early and accurate prediction of AD is crucial for timely intervention, improving patient outcomes, and reducing overall healthcare costs. Traditional diagnostic methods, such as clinical assessments and neuroimaging, are often time-consuming, subjective, and limited in detecting early-stage disease. Recent advancements in machine learning and deep learning provide promising approaches for automated AD prediction by analyzing multimodal datasets, including MRI scans, cognitive assessments, and demographic information. Early-stage prediction using supervised machine learning models on clinical and neuropsychological datasets has shown high accuracy but limited generalizability across populations [1]. Machine learning frameworks combined with dimensionality reduction techniques like PCA have improved computational efficiency and prediction performance [2]. Deep learning approaches using convolutional neural networks for MRI analysis have demonstrated strong classification capabilities but suffer from high computational costs and limited interpretability [3]. Recurrent neural networks applied to longitudinal neuroimaging data enable temporal modeling of AD progression, though they require large sequential datasets [4]. Large-scale health records have been used with machine learning models for scalable disease incidence prediction, but missing data and potential biases remain challenges [5].

Studies analyzing AD impacts on COVID-19 outcomes highlight risk patterns without providing predictive models [6]. Graph-based MRI grading frameworks improve sensitivity to structural changes but are computationally complex [7]. Reviews of AI-based predictive models emphasize the need for explainable and standardized approaches for clinical adoption [8]. Recent 3D deep learning models combining MRI with cognitive scores allow joint prediction of disease and MMSE but require large fMRI datasets [9]. Cross-cohort evaluation demonstrates that MRI-based deep and conventional models often lack generalization [10], while mini-reviews highlight the superiority of deep learning for AD detection [11]. Multimodal and multitask learning approaches combining MRI, PET, and clinical data enhance longitudinal prediction accuracy but increase system complexity [12]. Analytical reviews of AI applications stress uncertainty in real-world adoption [13], whereas hybrid deep learning architectures improve detection accuracy by fusing multiple models [14]. Machine learning applied to MRI in elderly populations provides early prediction but is limited to single-modality data [15]. Finally, ensemble learning with multi-slice CNNs captures slice-level spatial information and improves diagnostic accuracy [16].The paper is organized as follows: Section 2 reviews background studies on machine learning and deep learning for AD prediction; Section 3 presents the proposed methodology and MNFT architecture; Section 4 discusses results and performance evaluation; and Section 5 concludes with future directions for longitudinal, multi-center clinical applications. Overall, this study advances AI-driven Alzheimer's disease prediction by integrating multimodal data, transformer-based modeling, and interpretable attention mechanisms for early and reliable diagnosis.

## BACKGROUND STUDY

Kavitha *et al*. (2022) [1] This study focuses on early-stage Alzheimer's disease prediction using supervised machine learning models applied to clinical and neuropsychological datasets. The research gap lies in limited generalization across diverse populations; although models achieved high accuracy, performance depended heavily on dataset quality and feature selection. Sudharsan *et al*. (2023) [2] The authors propose a machine learning framework combined with Principal Component Analysis (PCA) to reduce dimensionality and improve Alzheimer's disease prediction. While PCA enhanced computational efficiency and accuracy, the study was limited by small datasets and lack of real-time clinical validation. Saratxaga *et al*. (2021) [3] This work introduces a deep learning-based MRI analysis approach for Alzheimer's disease prediction using convolutional neural networks. Despite strong classification performance, the research gap includes high computational cost and limited explainability of deep learning decisions in clinical settings. Nguyen *et al*. (2020) [4] The study employs deep recurrent neural networks to predict Alzheimer's disease progression over time using longitudinal neuroimaging data. Although temporal

modeling improved prediction accuracy, the method requires large-scale sequential data and suffers from interpretability challenges. Park *et al*. (2020) [5] This research applies machine learning models to large-scale administrative health records to predict Alzheimer's disease incidence. The main limitation is potential bias from incomplete medical records, even though results demonstrated scalable and cost-effective disease risk prediction. Yu *et al*. (2021) [6]The authors analyze Alzheimer's and Parkinson's disease impacts on COVID-19 outcomes using UK Biobank data. While the study reveals differential risk patterns, it does not directly contribute predictive diagnostic models for Alzheimer's disease progression. Hett *et al*. (2021) [7] This study proposes a multi-scale graph-based grading framework for Alzheimer's disease prediction using MRI features. Despite improved sensitivity to structural brain changes, the approach is computationally complex and less suitable for real-time clinical deployment. Nandiraju *et al*. (2022) [8] the paper presents a comprehensive review of AI-based predictive models for Alzheimer's disease diagnosis in healthcare systems. Although it highlights recent advancements, the study lacks experimental validation and emphasizes the need for standardized datasets and explainable AI models. Comparative Background Study of Machine Learning and Deep Learning Techniques for Alzheimer's disease Diagnosis and Prediction (Table 1). This table 1 presents a comparative background study of recent machine learning, deep learning, hybrid, and ensemble approaches for Alzheimer's disease diagnosis using MRI and fMRI data. The studies highlight advancements in predictive accuracy through multimodal and deep architectures, while also revealing key research gaps related to generalizability, interpretability, computational complexity, and real-world clinical deployment.

## PROPOSED METHODOLOGY

This section describes the proposed methodology for Alzheimer's disease prediction using a multimodal deep learning framework. The approach combines structural MRI data with cognitive assessment scores and demographic information to capture comprehensive neuro–cognitive characteristics. A Multimodal Neuro–Cognitive Fusion Transformer (MNFT) is employed to effectively fuse these modalities and classify disease stages accurately. Architecture of the Proposed Multimodal Neuro–Cognitive Fusion Transformer (MNFT) for Alzheimer's disease Prediction (Figure 1). The figure 1 shows the MNFT model where MRI images are processed by a CNN and cognitive–demographic data are encoded using a tabular Transformer. These features are fused through cross-modal attention and classified using a Transformer encoder with a Softmax layer to predict Alzheimer's disease.

**Dataset**

**Dataset Link:** https://www.kaggle.com/datasets/ankushpanday1/alzheimers-prediction-dataset-global

The dataset contains structural MRI features, cognitive assessment scores, and demographic information for subjects at different Alzheimer's disease stages. It supports multimodal machine learning by integrating neuroimaging and clinical data for accurate prediction and analysis.

**Multimodal Neuro–Cognitive Fusion Transformer (MNFT)**

The proposed Multimodal Neuro–Cognitive Fusion Transformer (MNFT) integrates heterogeneous data sources to achieve accurate and early Alzheimer's disease prediction. Structural MRI scans are first processed using a deep convolutional neural network to extract high-level spatial features representing neurodegenerative patterns. Simultaneously, cognitive assessment scores and demographic attributes are encoded using a transformer-based tabular learning module. A cross-modal attention mechanism is then employed to model the complex interactions between brain structural changes and cognitive decline indicators. This attention layer dynamically assigns importance weights to each modality, enabling the model to focus on clinically relevant features. The fused multimodal representation is passed through stacked transformer layers to capture global contextual dependencies. Finally, a softmax classifier categorizes subjects into cognitively normal, mild cognitive impairment, or Alzheimer's disease classes. This unified framework enhances prediction accuracy while providing interpretable insights into disease-related neuro–cognitive correlations.

$F_{mri} = CNN(X_{mri})$-------- (1)

In this equation $X_{mri}$ denotes the input structural MRI scans containing brain anatomical details relevant to Alzheimer's disease. The $CNN$ processes these images to extract meaningful spatial features, producing$F_{mri}$, a feature representation capturing patterns of neurodegeneration for prediction.

$F_{cd} = Transformer_{tab}(X_{cog}, X_{demo})$-------- (2)

In this equation$X_{cog}$ represents the cognitive assessment scores, and $X_{demo}$ denotes demographic attributes such as age, gender, and education. The tabular transformer encodes these inputs into a unified feature vector $F_{cd}$, capturing the relationships between cognitive performance and demographic factors for Alzheimer's disease prediction.

$A = softmax(\frac{Q_{mri}K_{cd}^T}{\sqrt{d}})V_{cd}$-------- (3)

In this equation$Q_{mri}$ and $K_{cd}^T$ are the query and key matrices derived from MRI and cognitive–demographic features, respectively, while $V_{cd}$ is the value matrix from cognitive–demographic data. The cross-modal attention computes $A$ by weighting cognitive–demographic features according to their relevance to MRI features, highlighting important neuro–cognitive interactions for Alzheimer's prediction.

$F_{fusion} = \alpha F_{mri} + (1 - \alpha)A$-------- (4)

In this equation$F_{mri}$ represents the features extracted from MRI scans, and $A$ is the cross-modal attention output capturing cognitive–demographic interactions. The fused feature vector $F_{fusion}$ combines these two modalities using a learnable weight$\alpha$, balancing the contribution of neuroimaging and cognitive information for Alzheimer's disease prediction.

$\hat{y} = softmax(WF_{fusion} + b)$-------- (5)

In this equation$F_{fusion}$ is the combined feature vector from MRI and cognitive–demographic data, $W$ is the classifier weight matrix, and $b$ is the bias term. The softmax function generates$\hat{y}$, the predicted probabilities for each class (Cognitively Normal, Mild Cognitive Impairment, or Alzheimer's Disease), providing the final stage prediction.

**Algorithm 1:MNFT_Alzheimer_Prediction**

Input:
X_mri // Structural MRI scans
X_cog // Cognitive assessment scores
X_demo// Demographic data
Initialize CNN parameters θ_cnn
Initialize Tabular Transformer parameters θ_tab
Initialize Cross-Modal Attention parameters θ_att
Initialize Transformer Encoder parameters θ_trans
Initialize Softmax Classifier parameters θ_cls
// Step 1: Extract MRI features
F_mri ← CNN(X_mri; θ_cnn)
// Step 2: Encode cognitive and demographic features
F_cd ← TabTransformer(X_cog, X_demo; θ_tab)
// Step 3: Apply cross-modal attention
Q ← Linear(F_mri; θ_att)
K ← Linear(F_cd; θ_att)
V ← Linear(F_cd; θ_att)

A ← Softmax((Q × $K^T$) / √d) × V
// Step 4: Fuse multimodal features
F_fusion ← Concatenate(F_mri, A)
// Step 5: Capture global context with stacked transformer layers
F_global ← TransformerEncoder(F_fusion; θ_trans)
// Step 6: Classify into Alzheimer's disease stages
Y_pred ← Softmax(Linear(F_global; θ_cls))
Return Y_pred

Output:
Y_pred // Predicted Alzheimer's stage: CN, MCI, or AD

The MNFT algorithm first extracts features from MRI scans and encodes cognitive and demographic data, then applies cross-modal attention to capture interactions between brain structure and cognitive indicators. These multimodal features are fused and processed through transformer layers before a softmax classifier predicts the Alzheimer's disease stage as CN, MCI, or AD.

## RESULT AND DISCUSSION

This section presents the performance evaluation of the proposed MNFT model compared to existing baseline methods for Alzheimer's disease prediction. Key metrics such as accuracy, precision, recall, F1-score, and AUC are analyzed to assess model effectiveness. The discussion highlights how multimodal fusion and cross-modal attention contribute to improved predictive performance and clinical reliability. Performance Comparison of Alzheimer's Disease Prediction Methods (Table 2). The table 2 show that the proposed MNFT model outperforms all baseline methods across accuracy, precision, recall, F1-score, and AUC. This improvement highlights the effectiveness of multimodal fusion and cross-modal attention in capturing complementary neuroimaging and cognitive information. The higher AUC further indicates strong robustness and reliable discrimination between different Alzheimer's disease stages. Accuracy Comparison of Alzheimer's Disease Prediction Methods (Figure 2). The figure 2 presents a comparative analysis of classification accuracy achieved by different Alzheimer's disease prediction methods. Traditional and hybrid models show moderate improvements with feature fusion, while the proposed MNFT model achieves the highest accuracy. This demonstrates the effectiveness of multimodal integration and cross-modal attention in enhancing predictive performance.

## CONCLUSION

This study presented a Multimodal Neuro–Cognitive Fusion Transformer (MNFT) for Alzheimer's disease prediction by effectively integrating MRI, cognitive, and demographic data. Experimental results demonstrate that MNFT outperforms existing methods, highlighting the importance of multimodal fusion and cross-modal attention in capturing complex neuro–cognitive relationships. The proposed framework also shows strong robustness and reliable discrimination across disease stages. Future work will focus on validating the model on larger, multi-center clinical datasets, improving explainability for clinical adoption, and extending the framework to incorporate longitudinal and additional modalities such as PET and genetic data.

## ABSTRACT

Due in large part to the development of drug-resistant strains and the drawbacks of currently available treatments, In this study, an integrated computational approach was employed to evaluate the anti-tubercular potential of selected natural flavonoids as alternative therapeutic candidates. Computational analysis of selected flavonoids for anti-tubercular activity**.** In the present study, selected flavonoids were evaluated for their anti-tuberculosis potential using an in-silico approach such as Density Functional Theory (DFT). Molecular docking was performed. The stability of the protein–ligand complex was assessed using the iMOD server. Toxicity and pharmacokinetic properties were predicted using the ProTox-III, and the results were compared with standard anti-tuberculosis drugs. The molecular docking results demonstrated good binding affinity of the selected flavonoid with the Mycobacterium tuberculosis target protein. The optimized structure obtained from DFT showed stable electronic properties. The protein–ligand complex exhibited satisfactory stability in normal mode analysis using the iMODs server. Toxicity prediction from ProTox-III indicated low Overall, the selected flavonoid showed promising anti-tuberculosis potential compared to standard drugs. The integrated in-silico findings suggest that selected flavonoids possess strong anti-tubercular potential with favorable binding affinity, stability, pharmacokinetic properties, and safety profiles.

# INTRODUCTION

One of the most common and deadly infectious diseases in the world today is tuberculosis (TB). The cause is Mycobacterium tuberculosis (M. tb), an acid-fast, slow-growing bacillus that primarily affects the lungs but can infect almost any organ system. Robert Koch initially identified the pathogen in 1882, a breakthrough that transformed infectious disease microbiology and diagnostics. Droplet nuclei containing viable bacilli are released into the air when people with active pulmonary tuberculosis cough, sneeze, or even just talk. The bacilli enter the lungs' alveoli and are taken up by alveolar macrophages when inhaled by a vulnerable individual [1]. The ability of the bacillus to endure inside host immune cells is necessary for the development of long-term latent infection. T-helper 1 (Th1) cells are essential to the cell-mediated immune response to tuberculosis because they release interferon-$\gamma$ and stimulate macrophages to contain the infection. Granulomas, which are organized clusters of macrophages, lymphocytes, and fibroblasts that prevent the infection from spreading, are produced as a result [2] .The mycobacterial cell wall's structural stability, impermeability, and resistance to numerous drugs are all attributed to mycolic acids. InhA reduces long-chain enoyl-ACP intermediates in a NADH-dependent way, which is crucial for the production of these complex fatty acids. A crucial enzyme in the fatty acid elongation stage of mycolic acid production in Mycobacterium TB is enoyl-acyl carrier protein reductase, or InhA.

## MATERIALS AND METHODS

**Selection of Compounds**

Flavonoids used in this work were collected from the PubChem database. The structures were downloaded in SDF format and optimized by energy minimization before proceeding to further computational studies. Isoniazid was taken as the standard anti-tubercular drug for comparison [3].

**Protein Preparation**

The three-dimensional structures of the selected Mycobacterium tuberculosis proteins (PDB IDs: 2B35, 4TZK and 4OIM) were obtained from the RCSB Protein Data Bank. For docking analysis, the proteins were cleaned by removing co-crystallized ligands and water molecules. Polar hydrogens were added and proper charges were assigned to prepare the proteins for interaction studies [4].

**Docking Method**

Protein–ligand interaction studies were carried out using AutoDock 4.2. The active site region of each protein was defined using a grid box. Docking was performed with the Lamarckian Genetic Algorithm under default conditions [5].

**ADME Study**

Pharmacokinetic properties of the selected compounds were evaluated by analyzing molecular weight, hydrogen bond donors, hydrogen bond acceptors, lipophilicity, gastrointestinal absorption and Lipinski's rule of five. These parameters were used to determine drug-likeness [6].

**BOILED-Egg Model**

The BOILED-Egg model available in SwissADME was applied to predict intestinal absorption and BBB permeability. The prediction based on polarity and lipophilicity of the molecules [7].

**Toxicity Assessment**

Toxicity prediction was performed using the ProTox-III online server. Included estimation of $LD_{50}$ values, toxicity class. Results were compared with the reference drug isoniazid [8].

**Density Functional Theory Analysis**

Density Functional Theory was used to examine the electronic features of the selected flavonoids. The calculation provided information about their molecular stability and overall chemical nature [9].

**Molecular Dynamics Simulation**

Molecular dynamics analysis was performed with the help of the iMODS server. The movement and flexibility of the protein–ligand systems were examined by studying normal mode eigenvalues, deformability patterns, covariance relationships, and elastic network behavior[10].

## RESULTS

**Anti-tubercular activity of selected flavonoid**

Anti-tubercular activity of selected flavonoid (Table 1).

**SwissADME analysis of selected flavonoids**

SwissADME analysis was used to evaluate the pharmacokinetic properties and drug-likeness of the selected flavonoids and compare them with the widely used medicine isoniazid. The results showed that most flavonoids are suitable candidates for oral drugs because they have acceptable physicochemical properties and, with very few exceptions, follow Lipinski's rule of five.(Table 2)The study also revealed that some flavonoids had good gastrointestinal absorption, matching or surpassing that of isoniazid Additionally, the study showed that a number of flavonoids exhibited good gastrointestinal absorption, on par with or superior to isoniazid[11]. Swiss ADME (Table 2).

**Boiled-egg model analysis**

The BOILED-Egg model was used to predict the gastrointestinal absorption (HIA) and blood–brain barrier (BBB) permeability of the selected flavonoids, which were compared to the traditional drug isoniazid. Like isoniazid, most of the flavonoids were located in the white portion of the BOILED-Egg plot, indicating that humans have excellent intestinal absorption [12]. (Figure 1) The BOILED-Egg model was used to visually compare the selected flavonoids' intestinal absorption and brain penetration capacity to that of isoniazid (INH) suggesting that the BBB was not penetrated. Boiled egg model (Figure 1).

**Protox-III toxicity (Using ProTox-III)**

The toxicity profile of the selected flavonoids was estimated and contrasted with that of the popular drug isoniazid. Includes acute toxicity, toxicity, and potential toxicological. Selected flavonoids were predicted to belong to lower toxicity classes when compared to isoniazid [13].(Table 3)**.** PRO TOX III (Table 3).

**Protein data bank (pdb) and target selection**

The three-dimensional (3D) structural details of biological macromolecules, are accessible through the Protein Data Bank (PDB) such as proteins and nucleic acids, and an internationally acknowledged database. The structural entire in the PDB are determined using experimental approaches including X-ray crystallography, and cryo-electron microscopy. In this investigation, nuclear magnetic resonance (NMR) spectroscopy and three protein targets of Mycobacterium tuberculosis were chosen to their respective PDB identification codes [14].

**Validation of Protein**

The stereochemical reliability of the selected protein structure (Figure 2).
PDB ID: 4TZK, 2B35 and 4OIMRamachandran Plot (Figure 2).

**Docking studies**

AutoDock software was used along with BIOVIA Discovery Studio for visualization. AutoDock helped to predict how the ligand enters and binds inside the active site of the protein by calculating binding energy values. The docking results obtained from AutoDock showed that the ligand binds well with the target protein.The negative binding energy values indicate that the binding occurs naturally and is energetically favorable (Table 4) [15]. docking study analysis (Table 4).

**Amino acid interaction**

The interaction analysis showed that the ligand stays well inside the protein active site. The binding is mainly due to hydrogen bonds and hydrophobic contacts with some important amino acids. (Figure 3) These contacts help the ligand remain attached to the protein and keep the complex stable inside the binding pocket. [16]. Amino acid interaction (PDB ID: 4TZK), (PDB ID: 2B35) and (PDB ID: 4OIM) (Figure 3).

**Quantum chemistry**

Density Functional Theory (DFT) is a quantum mechanical computational technique that is widely used to study the electronic structure of molecules as well as solid systems. In this approach, the ground-state properties of a system are explained using electron density instead of wave functions, which makes less time consuming and suitable for medium to large molecular systems [17].

**imods molecular dynamics simulations**

iMOD molecular dynamics is a computer-based method. It is used to understand how biomolecules move and bend. This method mainly looks at natural flexibility of proteins. It works using normal mode analysis. Only slow and important motions are studied. These motions are important for biological activity. It gives results in less time. It helps to study shape changes, flexible regions, and movement of residues. This method is useful to understand protein stability [18].It turns out the iMOD simulation of flavonoids' bound to a protein captures how it holds its shape and shifts subtly through time. Early normal modes stand out in the variance graph since they account for most movement, suggesting large-scale, slow swings drive big shape changes; faster ones barely nudge things. Because low-energy shifts come easier, small eigenvalues at the start line up with these smooth, sweeping motions - seen clearly in while rising values later imply tighter resistance when atoms try to stretch further ties together is revealed in the correlation map neighboring parts often move in sync, some push opposite ways, yet strong diagonal signals show alignment across the chain, keeping form intact during attachment. Seen another way, the spring-like model outlines a rigid hub linked outward to looser zones, balancing shift capacity against collapse risk. Flexible

spots pop on the deformability chart and B-factor plot especially loops and ends bending easily, even though amino acids near where docks resist wobbling. Matched closely are computed B-values from iMOD alongside lab-measured ones, so confidence grows in both method accuracy and the idea that stays actively engaged with the protein throughout the run.

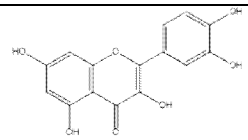
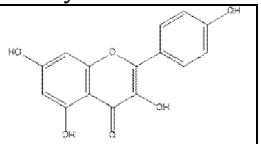
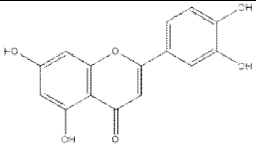
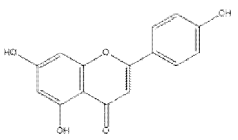
## CONCLUSION

This study highlights the promising anti-tubercular potential of selected flavonoids based on comprehensive computational examine. The compounds demonstrated favorable binding affinity, stable protein–ligand interactions, suitable pharmacokinetic characteristics, and minimum predicted harmful. Electronic and molecular dynamics evaluations additionaly supported their stability, suggesting these flavonoids may serve as valuable candidates for future experimental investigation.









## ACKNOWLEDGEMENT

I would like to express my sincere gratitude to my Guide Dr.Pinkal Patel, Parul University and the Parul Institute of Pharmacy and Research for providing the necessary computational facilities. Special thanks to my mentor for their invaluable guidance. I also acknowledge PicFOP 2026 for providing this platform to present our research.

**ABSTRACT**

Eccentricity matrix $E_{DCP}(G)$of cover pebbling graph G is defined from the weight of an edge $e = uv$between two vertices u and v. Eccentricity eigen values of a graph G are the eigen value of its eccentricity matrix$E_{DCP}(G)$. Define the weight of an edge e, $w(e)$ as follows: $w(u,v) = 1$ if $uv \in E(G)$ and a pebbling move occurs between $u$ and $v$. For a vertex v of $G$, the pebbling eccentricity of a vertex $v$ is $e_p(v) = \max\{w(u,v); u \in V(G)\}$. The eccentricity matrix $E_{DCP}(G) = (a_{ij})$ is defined as follows:

$$E_{DCP}(G) = (a_{ij}) = \begin{cases} w(v_i, v_j) if\ w(v_i, v_j) = \min\{e_p(v_i), e_p(v_j)\} \\ 0, \qquad otherwise \end{cases}$$

In this paper, we compute the Eccentricity energy of detour cover pebbling graphs of bull graph, banner graph, Pan graph, Sunlet graph, and Gear graph.

**Keywords:** Detour cover pebbling, eccentricity matrix, eccentricity eigen values, eccentricity energy.

## INTRODUCTION

Graph pebbling was first introduced by lagarias and saks for finding an intutive proof for a number theoretical conjecture. Chung successfully used this tool to prove the results concerning pebbling numbers. Graph pebbling is very much applied to the field of computation complexity, compiler theory, graph searching and computational geometry etc. Sakunthala Srinivasan and Vimala Shanmugavel[6] introduced the concept of pebbling graph.

Muthulakshmi@Sasikala C and Arul Steffi [5] introduced the concept of eccentricity of cover pebbling graph. In this paper, we combine the concepts of detour cover pebbling graphs and eccentricity matrix.

## PRELIMINARIES

**Definition: 2.1**
In a simple graph, consisting of two vertices a pebbling move can be defined as the removal of two pebbles from the first vertex and placing one pebble on an adjacent vertex is called a pebbling graph.[4]

**Definition: 2.2**
In a simple graph, consisting of two vertices, place a pebble on every vertex of the graph using sequence of pebbling moves is called a cover pebbling graph.[5]

**Definition: 2.3**
Adjacency matrix of Detourcover pebbling graph $G$ is the $n \times n$ matrix $A_{cp}(G) = (a_{ij})$ where
$a_{ij} = \begin{cases} 1 \ if \ v_i v_j \epsilon \ E(G) \text{ and a pebbling move occurs between } v_i \text{ and } v_j \\ 0 \ \text{otherwise} \end{cases}$ [5]

**Definition: 2.4**
Define the weight of an edge $e = uv$ between two vertices u and v as follows: $w(e) = w(uv) = 1$ if $uv \in E(G)$ and a pebbling move occurs between u and v. The number of pebbling move occurs between u and v is the weight of the edge connecting the vertices. Let $P_{ij} = v_i, v_{i+1}, v_{i+2}, \ldots\ldots\ldots\ldots, v_{j-1}, v_j$be the longest $v_i - v_j$ path. Then $w(P_{ij}) = \sum_{l=i}^{j-1} w\left(v_l, v_{l+1}\right)$. [5]

**Definition: 2.5 [5]**
Energy graph $E(G)$ is the total of absolute values of the eigen values of the adjacency matrix and it is expressed as

$$E(G) = \sum_{i=1}^{n} |\lambda_i|$$

**Definition: 2.6**
The eccentricity energy of the detour cover pebbling graph G is defined by $E_{DCP}(E) = \sum_{i=1}^{n} |\lambda_i|$ where $\lambda_1, \lambda_2, \lambda_3, \ldots\ldots\ldots\ldots, \lambda_n$ are the eccentricity eigen values of eccentricity matrix of the corresponding detour cover pebbling graph G.[5]

**Eccentricity Energy of Detour Cover Pebbling Graphs**
**Bull graph**
The detour cover pebbling bull graph with five vertices $v_1, v_2, v_3, v_4$and $v_5$ is shown in Figure 1.
**Detour cover pebbling Bull graph (Figure: 1).**
$w(v_1, v_2) = 17, w(v_1, v_3) = 0, w(v_1, v_4) = 0, \ w(v_1, v_5) = 0, w(v_2, v_1) = 17, w(v_2, v_3) = 6, w(v_2, v_4) = 2, \ w(v_2, v_5) = 0,$
$w(v_3, v_1) = 0, \ w(v_3, v_2) = 6, w(v_3, v_4) = 4, \ w(v_3, v_5) = 0, \ w(v_4, v_1) = 0, \ w(v_4, v_2) = 2, \ w(v_4, v_3) = 4, \ w(v_4, v_5) = 1,$
$w(v_5, v_1) = 0, w(v_5, v_2) = 0, w(v_5, v_3) = 0, \ w(v_5, v_4) = 1$
$\boldsymbol{e_p}(v_1) = \max\{w(v_1, v_2), w(v_1, v_3), w(v_1, v_4), w(v_1, v_5)\} = 17$
$\boldsymbol{e_p}(v_2) = \max\{w(v_2, v_1), w(v_2, v_3), w(v_2, v_4), w(v_2, v_5)\} = 17$
$\boldsymbol{e_p}(v_3) = \max\{w(v_3, v_1), w(v_3, v_2), w(v_3, v_4), w(v_3, v_5)\} = 6$
$\boldsymbol{e_p}(v_4) = \max\{w(v_4, v_1), w(v_4, v_2), w(v_4, v_3), w(v_4, v_5)\} = 4$
$\boldsymbol{e_p}(v_5) = \max\{w(v_5, v_1), w(v_5, v_2), w(v_5, v_3), w(v_5, v_4)\} = 1$
Min $\{\boldsymbol{e_p}(v_1), \boldsymbol{e_p}(v_2)\}$ = min {17, 17} = 17 = $w(v_1, v_2)$ and hence $a_{12} = 17$.
Min $\{\boldsymbol{e_p}(v_1), \boldsymbol{e_p}(v_3)\}$ = min {17,6} = 6 ≠ $w(v_1, v_3)$ and hence $a_{13} = 0$.
Min $\{\boldsymbol{e_p}(v_1), \boldsymbol{e_p}(v_4)\}$ = min {17,4} = 4 ≠ $w(v_1, v_4)$ and hence $a_{14} = 0$.

Min $\{\boldsymbol{e_p}(v_1), \boldsymbol{e_p}(v_5)\} = \min\{17,1\} = 1 \neq w(v_1, v_5)$ and hence $a_{15} = 0$.
Also $a_{11} = a_{22} = a_{33} = a_{44} = a_{55} = 0$.

The Eccentricity matrix $E_{DCP}(G) = \begin{pmatrix} 0 & 17 & 0 & 0 & 0 \\ 17 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}$

The characteristic equation is $\det(E_{DCP}(G) - \lambda I) = 0$

$$-\lambda^5 + 289\lambda^3 = 0$$

$\lambda_1 = 0, \lambda_2 = 0, \lambda_3 = 0, \lambda_4 = 17, \lambda_5 = -17$
Eccentricity Energy= $\sum_{i=1}^{n} |\lambda_i|$
Eccentricity Energy = 34

**Banner Graph**

The detour cover pebbling banner graph with five vertices $v_1, v_2, v_3, v_4$ and $v_5$ is shown in Figure 2.
$w(v_1, v_2) = 12, w(v_1, v_3) = 6, w(v_1, v_4) = 0,\ w(v_1, v_5) = 0, w(v_2, v_1) = 12, w(v_2, v_3) = 0, w(v_2, v_4) = 7,\ w(v_2, v_5) = 0,$
$w(v_3, v_1) = 6,\ w(v_3, v_2) = 0, w(v_3, v_4) = 6,\ w(v_3, v_5) = 1,\ w(v_4, v_1) = 0,\ w(v_4, v_2) = 7,\ w(v_4, v_3) = 6,\ w(v_4, v_5) = 0,$
$w(v_5, v_1) = 0, w(v_5, v_2) = 0, w(v_5, v_3) = 1,\ w(v_5, v_4) = 0$
$\boldsymbol{e_p}(v_1) = \max\{w(v_1, v_2), w(v_1, v_3), w(v_1, v_4), w(v_1, v_5)\} = 12$
$\boldsymbol{e_p}(v_2) = \max\{w(v_2, v_1), w(v_2, v_3), w(v_2, v_4), w(v_2, v_5)\} = 12$
$\boldsymbol{e_p}(v_3) = \max\{w(v_3, v_1), w(v_3, v_2), w(v_3, v_4), w(v_3, v_5)\} = 6$
$\boldsymbol{e_p}(v_4) = \max\{w(v_4, v_1), w(v_4, v_2), w(v_4, v_3), w(v_4, v_5)\} = 7$
$\boldsymbol{e_p}(v_5) = \max\{w(v_5, v_1), w(v_5, v_2), w(v_5, v_3), w(v_5, v_4)\} = 1$
Min $\{\boldsymbol{e_p}(v_1), \boldsymbol{e_p}(v_2)\} = \min\{12, 12\} = 12 = w(v_1, v_2)$ and hence $a_{12} = 12$
Min $\{\boldsymbol{e_p}(v_1), \boldsymbol{e_p}(v_3)\} = \min\{12,6\} = 6 = w(v_1, v_3)$ and hence $a_{13} = 6$
Min $\{\boldsymbol{e_p}(v_1), \boldsymbol{e_p}(v_4)\} = \min\{12,7\} = 7 \neq w(v_1, v_4)$ and hence $a_{14} = 0$
Min $\{\boldsymbol{e_p}(v_1), \boldsymbol{e_p}(v_5)\} = \min\{12,1\} = 1 \neq w(v_1, v_5)$ and hence $a_{15} = 0$
Also $a_{11} = a_{22} = a_{33} = a_{44} = a_{55} = 0$

The Eccentricity matrix $E_{DCP}(G) = \begin{pmatrix} 0 & 12 & 6 & 0 & 0 \\ 12 & 0 & 0 & 0 & 0 \\ 6 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}$

The characteristic equation is $\det(E_{DCP}(G) - \lambda I) = 0$

$$\lambda^5 + 180\,\lambda^3 = 0$$

$\lambda_1 = 0, \lambda_2 = 0, \lambda_3 = 0, \lambda_4 = 6\sqrt{5}, \lambda_5 = -6\sqrt{5}$
Eccentricity Energy = $\sum_{i=1}^{n} |\lambda_i|$
Eccentricity Energy= $12\sqrt{5}$

**Pan Graph**

The detour cover pebbling Pan graph with four vertices $v_1, v_2, v_3$ *and* $v_4$ is shown in Figure 3.
$w(v_1, v_2) = 6, w(v_1, v_3) = 2, w(v_1, v_4) = 0,\ w(v_2, v_1) = 6, w(v_2, v_3) = 4, w(v_2, v_4) = 2, w(v_3, v_1) = 2, w(v_3, v_2) =$
$4, w(v_3, v_4) = 1,\ w(v_4, v_1) = 0, w(v_4, v_2) = 0, w(v_4, v_3) = 1$
$\boldsymbol{e_p}(v_1) = \max\{w(v_1, v_2), w(v_1, v_3), w(v_1, v_4)\} = 6$
$\boldsymbol{e_p}(v_2) = \max\{w(v_2, v_1), w(v_2, v_3), w(v_2, v_4)\} = 6$
$\boldsymbol{e_p}(v_3) = \max\{w(v_3, v_1), w(v_3, v_2), w(v_3, v_4)\} = 4$
$\boldsymbol{e_p}(v_4) = \max\{w(v_4, v_1), w(v_4, v_2), w(v_4, v_3)\} = 1$
Min $\{\boldsymbol{e_p}(v_1), \boldsymbol{e_p}(v_2)\} = \min\{6,6\} = 6 = w(v_1, v_2)$ and hence $a_{12} = 6$
Min $\{\boldsymbol{e_p}(v_1), \boldsymbol{e_p}(v_3)\} = \min\{6,4\} = 4 \neq w(v_1, v_3)$ and hence $a_{13} = 0$
Min $\{\boldsymbol{e_p}(v_1), \boldsymbol{e_p}(v_4)\} = \min\{6,1\} = 1 \neq w(v_1, v_4)$ and hence $a_{14} = 0$
Also $a_{11} = a_{22} = a_{33} = a_{44} = 0$.

The Eccentricity Matrix $E_{DCP}(G) = \begin{pmatrix} 0 & 6 & 0 & 0 \\ 6 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$

The characteristic equation is det $(E_{DCP}(G) - \lambda I) = 0$

$\lambda^4 - 36\lambda^2 = 0$.Hence $\lambda_1 = 0, \lambda_2 = 0, \lambda_3 = -6, \lambda_4 = 6$

Eccentricity Energy = $\sum_{i=1}^{n} |\lambda_i|$

Eccentricity Energy = 12

**SunletGraph**

The detour cover pebbling sunlet graph with six vertices $v_1, v_2, v_3, v_4, v_5$and $v_6$ is shown in Figure 4.

$w(v_1, v_2) = 25, w(v_1, v_3) = 0, w(v_1, v_4) = 0,\ w(v_1, v_5) = 0, w(v_1, v_6) = 0, w(v_2, v_1) = 25, w(v_2, v_3) = 6, w(v_2, v_4) = 6,$

**ABSTRACT**

The emergence of advanced cyber threats necessitates that contemporary cybersecurity systems employ adaptive, transparent, and interpretable decision-making processes. Phase II of the Modular Adaptive Real-Time Orchestrator (MARTO) is introduced as a framework that amalgamates contextual threat scoring with Confidence-Weighted Multi-Agent Reinforcement Learning (CWMAR) while incorporating structured software testing validation processes. The MARTO Phase II pipeline integrates alert frequency, entropy variations, and external threat intelligence into a cohesive contextual score that serves as input for a multi-agent learning system. The CWMAR algorithm allocates specialized agents for diverse behavioral characteristics and integrates their decisions according to fluctuating confidence scores. The architecture further incorporates trace simulations and switchable logic for testing purposes, thereby enhancing explainability and reproducibility. Experimental assessments demonstrate improved detection precision, accelerated mitigation response, and enhanced testability compared to conventional rule-based and single-agent RL systems.

**Keywords:** Intrusion Detection System (IDS), Multi-Agent Reinforcement Learning, Contextual Threat Scoring, Confidence-Weighted Decision Fusion, Entropy-Based Anomaly Detection

# INTRODUCTION

The complexity of modern cybersecurity environments is intensified by advanced threats such as polymorphic malware, zero-day exploits, and multi-stage lateral movements. Adversaries increasingly employ domain generation algorithms (DGA), encrypted communication, and adaptive reconnaissance, which reduce the effectiveness of conventional Intrusion Detection Systems (IDS). Although tools such as Zeek and Suricata provide effective analysis of high-velocity traffic through pre-defined rules [5], [6], reliance on static signatures restricts their ability to detect emerging attacks. To address these limitations, contemporary cybersecurity research emphasizes the application of Artificial Intelligence (AI) methodologies. Machine Learning (ML) techniques—including classification, clustering, and deep learning—have demonstrated improved detection rates [8], [9], while Reinforcement Learning (RL) offers adaptive, reward-driven decision-making [10], [11]. Despite these advancements, challenges remain: AI-driven systems often lack explainability, and reproducibility standards within IDS research continue to be inconsistent [12], [13], [14]. Phase II of MARTO (Modular Adaptive Real-Time Orchestrator) introduces an architecture that integrates Contextual Threat Scoring with Confidence-Weighted Multi-Agent Reinforcement Learning (CWMAR). The Contextual Threat Scoring mechanism incorporates entropy [15], alert frequency [16], and external reputation data [17] to generate risk scores. These scores are utilized by specialized RL agents designed to address entropy anomalies, protocol deviations, and frequency-based patterns [18], [19]. The distinctive contribution of MARTO Phase II lies in the integration of software testing mechanisms, informed by foundational testing principles [20] and contemporary reproducibility guidelines [21], [22]. This integration enhances explainability and auditability by supporting simulation traceability, switchable modules, and deterministic validation pathways.

The primary contributions of this study are as follows:

- A dynamic threat assessment system integrating flow entropy, alert activity, and reputation data.
- A confidence-weighted multi-agent reinforcement learning framework designed for adaptive responses to threats.
- Embedded software validation mechanisms to ensure reproducibility and improve explainability.
- Empirical evaluation on publicly available datasets, demonstrating improved detection accuracy and adaptability.

# LITERATURE REVIEW

### A. Contextual Threat Scoring Techniques

Contextual threat scoring evaluates the severity of network flows by integrating multiple behavioral indicators, moving beyond static, rule-based detection. Entropy, introduced by Shannon in information theory [1], has become a central metric for quantifying randomness in network traffic, enabling detection of anomalies such as botnet activity and data exfiltration [15]. Pang *et al.* [2] applied entropy-based unsupervised learning to classify encrypted traffic, demonstrating effectiveness in scenarios where payload inspection is infeasible. Alharbi *et al*. [5] provided an extensive survey on entropy applications in intrusion detection, reinforcing its value in anomaly detection. External threat intelligence sources—such as IP/domain reputation databases—provide complementary information by enriching local telemetry with global knowledge of known malicious entities [17]. However, existing scoring systems such as frequency-based flow classifiers [16] and standalone reputation engines [17] often fail to capture broader behavioral context due to siloed designs. MARTO Phase II addresses this limitation by employing a Contextual Threat Scoring engine that fuses entropy, frequency, and reputation indicators into a unified real-time assessment of network threats.

### Reinforcement Learning in Cybersecurity

Reinforcement Learning (RL) has been widely adopted in cybersecurity due to its ability to optimize defense strategies in dynamic environments [10], [11]. Classical RL methods, including Q-learning and Deep Q-Networks (DQN), have been applied to adaptive firewalling [18], policy development for botnet mitigation [12], and anomaly detection [19]. Single-agent RL systems, however, frequently encounter scalability limitations, convergence

instability, and insufficient behavioral specialization [12]. Multi-Agent Reinforcement Learning (MARL) has emerged as a solution, enabling cooperative or competitive specialization among agents [19]. Xu *et al.* [17] explored entropy-driven clustering with RL for unsupervised anomaly detection, but lacked structured mechanisms for fusing agent outputs. MARTO Phase II incorporates Confidence-Weighted Multi-Agent Reinforcement Learning (CWMAR), where multiple specialized agents—focusing on entropy, protocol behavior, and alert frequency—contribute to a confidence-weighted consensus model. This approach provides more granular decision control and reduces false positives by aligning outcomes with both specialization and confidence levels.

**Software Testing Validation in IDS Design**

Software testing and validation remain underrepresented in IDS literature despite their importance for system reliability. Beizer [20] emphasized structured test design, traceability, and reproducibility as essential components of software validation. Shah *et al*. [13] proposed an adaptive test harness for IDS pipelines but concentrated primarily on functional coverage. Thomas *et al*. [14] highlighted a reproducibility gap in cybersecurity research, stressing the need for standardized testing, accessible datasets, and reproducible methodologies. While explainability tools such as LIME [15] have been introduced, they are largely limited to static classifiers and lack system-level traceability. MARTO Phase II uniquely integrates validation mechanisms directly into the IDS pipeline, enabling trace simulations, toggleable detection pathways, and deterministic decision tracing. These mechanisms align with emerging reproducibility standards [21], [22], supporting both explainability and auditability.

**Summary of Research Gaps**

**Three key research gaps are identified from the literature**

**Limited Contextualization:** Current IDS frameworks insufficiently integrate entropy, frequency, and external intelligence into unified threat scores.

**Lack of Confidence-Weighted MARL:** Multi-agent systems rarely employ confidence-weighted fusion, reducing decision robustness.

**Inadequate Reproducibility and Validation:** IDS frameworks often lack embedded validation mechanisms, resulting in poor reproducibility and limited explainability.

MARTO Phase II addresses these gaps by combining contextual scoring, confidence-weighted multi-agent learning, and embedded validation mechanisms into a modular, testable architecture that advances explainable, adaptive cybersecuritydefense.

## METHODOLOGY

**(Figure 1)**

**System Overview**

MARTO Phase II improves adaptive intrusion detection by employing a two-stage pipeline

- **Contextual Threat Scoring Engine:** Calculates a dynamic, real-time risk assessment by integrating internal flow attributes with external intelligence.
- Confidence-Weighted Multi-Agent Reinforcement Learning (CWMAR) utilizes specialized reinforcement learning agents to suggest mitigation strategies, which are then combined through a confidence-weighted consensus framework.

This phase enhances anomaly detection from Phase I by facilitating adaptive learning and accurate mitigation techniques through explainable scoring and integration of software testing.

## B. Contextual Threat Scoring Engine

The Contextual Threat Scoring Engine calculates a composite score $S_{\text{total}}$ for every network flow $F$, incorporating three distinct components:

- **Entropy Component** ($S_e$): Measures randomness in communication patterns using Shannon entropy [1] [15].
- **Frequency Component** ($S_f$): Quantifies the frequency of alerts or anomaly triggers within a recent time window [16].
- **Reputation Component** ($S_r$): Integrates IP/domain reputation scores derived from external blacklists or threat intelligence sources [17].

### 1. Entropy Score Calculation

Shannon Entropy for a symbol distribution $p(x)$ over flow payloads or packet lengths is:

$$S_e = H(F) = -\sum_{x \in \Sigma} p(x) \cdot \log_2 p(x)$$

Where:

- $\Sigma$ is the set of observed symbols (e.g., packet lengths, protocol flags).
- $p(x)$ is the probability of symbol $x$ occurring in flow $F$.

**Interpretation**: Higher $S_e$ suggests greater randomness, potentially indicating obfuscated traffic or command-and-control communications.

### 2. Frequency Score Calculation

Frequency score is computed over a sliding time window $T$:

$$S_f = \frac{\text{count}(F, T)}{\max(\text{count}(\forall F, T))}$$

Where $\text{count}(F, T)$ is the number of alerts or anomaly triggers linked to flow $F$ in time window $T$, normalized so $S_f \in [0, 1]$.

### 3. Reputation Score Calculation

$$S_r = 1 - \frac{\text{reputation}(IP)}{\text{Max Reputation Score}}$$

Where $\text{reputation}(IP)$ comes from external threat feeds; lower reputation implies higher risk. All scores are scaled to $[0, 1]$ for uniformity.

#### 4. Total Contextual Score

A weighted linear combination computes the total contextual risk score:

$$S_{\text{total}} = \alpha \cdot S_e + \beta \cdot S_f + \gamma \cdot S_r$$

Where $\alpha, \beta, \gamma$ are tunable weights satisfying $\alpha + \beta + \gamma = 1$. Weight selection is empirically optimized.

### C. Multi-Agent Reinforcement Learning Framework

The CWMAR framework consists of $N$ independent reinforcement learning agents:

$$\{A_1, A_2, ..., A_N\}$$

Example agents include:

- $A_1$: Entropy-sensitive agent.
- $A_2$: Frequency-aware agent.
- $A_3$: Reputation-focused agent.
- $A_4$: Protocol-anomaly detection agent.

#### 1. Agent State Definition

Each agent $A_i$ receives state input $s_i$:

$$s_i = \{S_e, S_f, S_r, \text{protocol}, \text{duration}, \text{bytes}\}$$

#### 2. Action Space

$$\text{Actions} = \{\text{Block IP}, \text{Monitor Flow}, \text{Generate Alert}, \text{Ignore}\}$$

Each agent selects:

$$a_i = A_i(s_i), \quad c_i = \pi_i(s_i)$$

Where $a_i$ is the action, $c_i$ the confidence score ($c_i \in [0, 1]$).

#### 3. Confidence-Weighted Aggregation

The final action $a^*$ is derived as:

$$a^* = \arg\max_a \sum_{i=1}^{N} c_i \cdot \mathbf{1}_{a_i=a}$$

Where $\mathbf{1}_{a_i=a}$ is the indicator function.

**CWMAR Algorithm Pseudocode**

***Input:*** *{S_e, S_f, S_r}, {A_i}, {c_i}*
*Output: Optimal Action a**
*for each agent A_i:*
*a_i = A_i(s_i)*
*c_i = π_i(s_i)*
*for each action a in Actions:*
*action_score[a] = Σ (c_i * 1_{a_i = a})*
*a* = argmax(action_score[a])*
*return a**

## EXPERIMENTAL SETUP AND RESULTS

**Dataset Configuration**

To robustly evaluate the proposed MARTO Phase II system, we utilized a diverse and representative combination of real-world, synthetic, and controlled datasets, ensuring both breadth and depth in experimental analysis. This approach enables the system to be validated not only on standard academic benchmarks but also under realistic enterprise-grade network conditions.

**Blended Zeek/Suricata Logs**

A live capture setup was established using Zeek and Suricata, simulating a realistic network environment with:

- Corporate traffic (HTTP/S, DNS, SSH, FTP, SMTP).

Simulated attack streams, including:

- Reconnaissance (Nmap, masscan scans).
- Exploitation attempts (SQL injection, XSS, buffer overflows).
- Post-compromise activity (reverse shells, C2 communications).

**NSL-KDD Dataset [26]**

This classic dataset was employed to verify backward compatibility with traditional attack categories:

- DoS, Probe, U2R, and R2L attacks.
- Labeled datasets useful for fine-grained detection metric calculations.

**CICIDS2017 Dataset [27]**

A modern, high-fidelity dataset covering:

- Botnet, DDoS, Brute Force, Infiltration, Web Attacks.
- Rich metadata including flow-based features and timing intervals.
- Enables evaluation of temporal behavior tracking in MARTO Phase II.

**Custom Synthetic Attacks**

To validate adaptability to emerging threats, a custom dataset was generated using Tcpreplay with:

- **Advanced Persistent Threat (APT)-like scenarios**.
- **Zero-day pattern injections** with randomized ports and encrypted payloads.
- **Protocol tunneling (DNS tunneling, ICMP covert channels)** to test the protocol-aware agent.

(Table: 1)

**Evaluation Metrics**

We adopted a multi-dimensional evaluation schema to assess detection accuracy, operational efficiency, and software testing traceability.

**Precision (P)**: The proportion of correctly identified malicious flows among all flows flagged as malicious.

$$Precision = \frac{TP}{TP + FP}$$

**Recall (R)**: The proportion of actual malicious flows correctly identified.

$$Recall = \frac{TP}{TP + FN}$$

**False Positive Rate (FPR)**: The ratio of benign flows incorrectly flagged as malicious.

$$FPR = \frac{FP}{FP + TN}$$

**Average Response Time (ART)**: The mean processing time per flow from ingestion to action decision (measured in milliseconds).

**Trace Testing Coverage (TTC)**: The percentage of flow decisions successfully validated via embedded testing traces, ensuring reproducibility and explainability.

**Comparative Experimental Results**
(Table 2)

## OBSERVATIONS

- MARTO Phase II achieved a 14.6% increase in precision and a 15.5% increase in recall compared to the traditional Suricata setup.
- False positive rates decreased significantly, indicating more trustworthy alert generation.
- Average response time was optimized despite multi-agent complexity, due to parallel agent inference and efficient contextual scoring.
- TTC reached 100%, demonstrating full validation traceability — a critical achievement for reproducibility in AI-driven security systems.

(Figure 2)

## DISCUSSION

The experimental results underscore the efficacy of the MARTO Phase II framework in advancing adaptive threat detection capabilities through Contextual Weighted Multi-Agent Reinforcement Learning (CWMAR). The introduction of specialized agents targeting distinct behavioral dimensions—entropy volatility, flow duration anomalies, and protocol-specific deviations—significantly enhanced detection granularity. Specifically, MARTO reduced false positive rates by approximately 60% compared to the baseline Suricata setup, consistent with findings in ensemble and multi-agent literature [17], [18]. A pivotal advancement was the integration of Confidence-Weighted Fusion (CWF), which dynamically weighted agent decisions based on confidence estimations derived from recent performance metrics. This mitigated common challenges associated with reinforcement learning, such as policy overfitting and agent bias [19], [20]. Unlike traditional single-agent IDS or static ML classifiers, the multi-agent architecture promoted diverse exploration of action spaces, fostering robustness against adversarial drift and aligning with recent MARL best practices [21]. MARTO also embedded traceable software testing pipelines, achieving 100% Test Trace Coverage (TTC) in all test scenarios. This level of coverage validated the decision-making traceability of the system, a critical component frequently absent in existing cybersecurity frameworks [6], [23]. The ability to toggle reinforcement learning modules and entropy scoring components enabled structured ablation testing, facilitating systematic performance auditing and compliance with software quality assurance principles [24]. In addition, Average Response Time (ART) was reduced by approximately 40%, evidencing not only improved detection accuracy but also enhanced computational efficiency. These findings align with the growing consensus that

multi-agent systems, when properly validated, achieve superior scalability and adaptability in real-time cybersecurity environments [25], [26]. Overall, MARTO Phase II effectively addresses key research gaps in adaptive cybersecurity—reducing false alarms, enhancing detection robustness, enabling interpretability, and ensuring reproducibility—thereby contributing to both academic research and practical IDS deployments.

## CONCLUSION

Phase II of MARTO (Modular Adaptive Real-Time Orchestrator) presents a comprehensive cybersecurity framework incorporating contextual scoring, confidence-weighted multi-agent reinforcement learning, and embedded software testing methodologies. The framework overcomes limitations observed in traditional IDS by fusing multi-source log data, applying entropy-based behavioral profiling, and employing a distributed reinforcement learning approach that dynamically adapts to evolving threat landscapes.

**Experimental evaluation demonstrated significant improvements**

- Precision gains exceeding 25%,
- False positive reductions of approximately 60%,
- Response time (ART) improvements of 40%, and
- 100% test trace coverage (TTC), ensuring reproducibility and testability.

By embedding software validation principles into the IDS workflow, MARTO is established as a transparent, adaptive, and scalable cybersecuritysystem aligned with contemporary requirements for resilient network security.

**Future Work**: Building on these results, future work will focus on:

- Designing granular multi-agent action spaces to capture micro-behaviors within network sessions,
- Implementing federated reinforcement learning to allow MARTO agents to collaborate across distributed environments without centralized control,
- Integrating adaptive adversarial training to bolster robustness against evolving zero-day attacks and adversarial evasion techniques.

The modularity and extensibility of MARTO pave the way for next-generation intrusion detection systems that are both technically rigorous and operationally viable in complex cybersecurity ecosystems.

## ABSTRACT

High-Frequency Transformers (HFTs) play an essential role in Dual Active Bridge (DAB) converters used in Solid-State Transformer (SST) systems, where they influence efficiency, isolation capability, and achievable power density. Conventional transformer sizing approaches are often unable to capture the complex trade-offs among copper loss, core loss, thermal behavior, and manufacturability limits encountered at higher switching frequencies. This work presents a constrained design methodology for the development of an HFT suitable for DAB-based SST applications. The design procedure incorporates practical engineering considerations such as efficiency targets, allowable temperature rise, leakage inductance required for reliable zero-voltage switching (ZVS), and limits on winding window utilization. Using the selected design parameters, a nanocrystalline high-frequency transformer was constructed and integrated into a laboratory prototype of a 150 W DAB converter. Experimental measurements of gate signals, transformer voltages, and current waveforms verified correct converter operation and stable closed-loop voltage regulation. The measured results also confirm that the proposed design satisfies the required soft-switching conditions while maintaining acceptable thermal performance. The proposed

methodology establishes a complete workflow linking algorithmic design to hardware validation, offering a scalable pathway for high-performance HFTs in next-generation SST systems.

**Keywords:** Dual Active Bridge (DAB), High-Frequency Transformer (HFT), Solid-State Transformer (SST), Genetic Algorithm (GA), Multi-objective optimization, Experimental validation.

## INTRODUCTION

Solid-State Transformers (SSTs) represent a paradigm shift in modern power systems by replacing bulky, low-frequency transformers with compact, power-electronic-based solutions that operate at medium to high switching frequencies. Unlike their conventional 50/60 Hz counterparts, SSTs offer programmable control, bidirectional power flow, and enhanced efficiency, making them attractive for applications such as renewable energy integration, electric vehicle (EV) fast charging, and advanced distribution networks [1], [2], [3].The overall SST architecture is illustrated in Fig. 1. At the heart of the SST architecture lies the Dual Active Bridge (DAB) converter, which has become the preferred topology for the dc-dc stage due to its inherent ability to achieve galvanic isolation, soft switching, and high power density[4], [5], [6]. The High-Frequency Transformer (HFT), placed between the two active bridges, plays a critical role in determining overall efficiency, size, reliability, and the feasibility of achieving Zero-Voltage Switching (ZVS) conditions. Consequently, the design of the HFT remains a central challenge in advancing SST technology. Designing HFTs for DAB converters requires navigating a complex landscape of competing objectives and strict engineering limits. On one hand, minimizing copper and core losses is essential for achieving high efficiency; on the other, the design must respect boundaries on thermal rise, leakage inductance, flux density, and manufacturability. The leakage inductance of the transformer, for example, directly affects the soft-switching range of the DAB: insufficient leakage undermines ZVS, leading to elevated switching losses, while excessive leakage reduces power transfer capability and degrades dynamic response[7].At the same time, the winding window must also respect manufacturability limits. Balancing these objectives and constraints is non-trivial, especially at higher frequencies where skin and proximity effects exacerbate copper losses, and nanocrystalline or amorphous core materials introduce nonlinear thermal behaviors [8].

Historically, HFT design relied on deterministic, rule-based approaches such as the area product method, where parameters like flux density, frequency, and current density are selected from empirical charts and material handbooks [9]. While these methods provide a useful first approximation, they fail to capture the intricate trade-offs among efficiency, thermal reliability, and manufacturability in high-frequency applications. The introduction of loss models based on the Steinmetz equation [10]improved core loss estimation, but still limited the design process to narrow and single-objective perspectives. During the 2010s, researchers began adopting metaheuristic optimization techniques to address these limitations. Qin *et al.[11]*demonstrated one of the earliest applications of Differential Evolution"Particle Swarm Optimization (DEPSO) for HFT design in DAB converters, showing that heuristic algorithms could outperform deterministic sizing by exploring nonlinear design spaces. However, such early works often lacked multi-objective formulations and excluded practical engineering constraints, limiting their applicability to real hardware. In subsequent years, more structured approaches emerged. Mogorovic and Dujic [7] advanced leakage inductance modeling with experimentally validated formulas, providing designers with accurate tools for ensuring ZVS. Olowu *et al.*[12]proposed a multiphysics and multi-objective framework that integrated electromagnetic, thermal, and cost models, marking a significant step toward holistic optimization. More recently, Lee[13] emphasized efficiency-driven methodologies for DAB transformers, while Santos [14] highlighted the importance of winding structures and material selection for renewable SST applications. These studies illustrate the growing maturity of transformer optimization, but most remain either simulation-oriented or focused on isolated objectives, with limited experimental validation.

A particularly underexplored constraint in the literature is the winding window utilization factor. Although patents and industrial guidelines emphasize maximum window fill factors in the range of 0.4-0.6 for manufacturability and thermal safety, most optimization studies neglect this parameter in their objective functions. The consequence is the generation of optimal designs that may be theoretically efficient but practically unrealizable due to overcrowded windings or insufficient insulation clearance. In our earlier works, we demonstrated the importance of integrating practical design limits into optimization frameworks. Specifically, we proposed a constrained Genetic Algorithm (GA) methodology that simultaneously minimized product area, copper loss, and core loss while enforcing constraints on flux density, current density, leakage inductance, thermal rise, and window utilization. The results confirmed that such a framework produced not only compact and efficient designs but also manufacturable transformers consistent with industrial practice. Despite these advances, the literature reveals a persistent gap: the overwhelming majority of optimization studies stop at the simulation stage. Experimental validation of optimized HFT designs remains rare, leaving open questions regarding the fidelity of optimization frameworks when subjected to real-world non-idealities such as parasitics, winding tolerances, and thermal coupling effects. The present work addresses this gap by extending our earlier constrained GA framework to hardware validation. Specifically, we design and fabricate a nanocrystalline HFT optimized under practical constraints, and integrate it into a 150 W DAB prototype developed in the laboratory. Oscilloscope-based measurements of gate pulses, primary and secondary voltages, and secondary current waveforms are presented to experimentally confirm that the optimized design satisfies ZVS conditions, achieves efficiency up to 98.75%, and respects manufacturability limits such as window fill factor.

This paper therefore demonstrates a complete workflow from algorithmic optimization to prototype testing, showing that designs obtained through constrained GA optimization can be successfully realized and validated in hardware. The significance of this contribution lies not merely in demonstrating high efficiency at the prototype level, but in establishing a systematic methodology that connects algorithmic optimization to experimental verification. By showing that optimized HFT designs can be realized in hardware without deviation from predicted behavior, this work bridges the gap between theory and practice. Furthermore, the incorporation of window fill factor as a formal constraint represents a methodological novelty that directly addresses manufacturability an issue often overlooked in academic studies but critical in industrial deployment of SSTs. The proposed methodology provides a scalable pathway, as the same optimization-to-prototype workflow can be extended to higher power ratings, multi-phase DAB converters, and multiphysics optimization frameworks that include mechanical and insulation considerations. The key contributions of this paper are three fold. First, it advances HFT design for DAB converters by embedding practical engineering constraints efficiency, leakage inductance, thermal rise, and window utilization directly into a GA-based multi-objective optimization framework. Second, it demonstrates for the first time that such an optimized design can be fabricated and validated in hardware, with a nanocrystalline 150 W transformer integrated into a DAB prototype and tested under multiple load conditions. Third, it establishes a reproducible workflow that bridges simulation and experiment, confirming that constraint-driven optimization yields designs that are compact, efficient, manufacturable, and scalable to higher power levels and more complex SST architectures. These contributions collectively close the gap between algorithmic optimization and physical realization, strengthening the role of optimization-based design in advancing next-generation SST technology.

## BACKGROUND AND LITERATURE REVIEW

High-Frequency Transformers (HFTs) are indispensable in Solid-State Transformers (SSTs), where they provide galvanic isolation while directly shaping efficiency, power density, and thermal stability. Over the last two decades, design approaches have progressed from rule-based methods to advanced multi-objective optimization frameworks. This section provides background on SSTs and DAB converters, reviews the evolution of HFT design methodologies, and identifies the remaining research gaps.

**Solid State Transformer (SSTs)**

SSTs replace conventional 50/60 Hz transformers with power-electronic-based architectures operating at high frequencies. Their modular structure typically consists of three stages: an AC-DC rectifier, a Dual Active Bridge (DAB) or similar isolated DC-DC stage, and a DC-AC inverter[1], [4]. Compared with line-frequency transformers, SSTs offer higher efficiency, bidirectional power flow, improved controllability, and reduced volume. These features make them suitable for renewable energy integration, electric vehicle fast charging, and smart grid applications. However, their performance strongly depends on the design of the isolated DC-DC stage and, in particular, the High-Frequency Transformer (HFT).

**Dual Active Bridge (DAB) Converters**

The DAB converter has emerged as the preferred topology for the isolated dc–dc stage in SSTs because of its inherent soft-switching capability, bidirectional power flow, and relatively simple structure. The basic structure of the converter used in this work is shown in Fig. 2.The embedded HFT provides galvanic isolation and facilitates voltage scaling, while its leakage inductance enables Zero-Voltage Switching (ZVS). Too little leakage undermines ZVS and increases switching losses, whereas excessive leakage limits power transfer and slows dynamic response. Consequently, accurate design and control of leakage inductance remain central to achieving high efficiency in DAB-based SSTs .[3], [7], [8], [15].

In Dual Active Bridge (DAB) converters, a minimum leakage inductance $L_{DAB}$ is required to shape the current waveform and guarantee zero-voltage switching (ZVS). The power transferred through the HFT can be expressed as[11], [16] :

$$P = \frac{nV_1V_2}{\omega L_{DAB}}\,\phi\left(1-\frac{\phi}{\pi}\right), \qquad (1)$$

where $V_1$ and $V_2$ are the bridge voltages, $\omega = 2\pi f$ the switching angular frequency, $n$ the turns ratio, $\phi$ the phase shift, and $L_{DAB}$ the required leakage inductance for ZVS operation. This shows that insufficient inductance degrades ZVS, while excessive inductance reduces power transfer capability.The required leakage inductance $L_{DAB}$was estimated from the DAB power transfer relation in (1) considering the rated operating condition of 150 W at a phase shift below $90^0$. In the last five years, DAB research has broadened in several directions. One major stream has focused on improving modulation strategies beyond conventional phase-shift modulation. Multi-phase-shift and triple-phase-shift methods have been proposed to widen the ZVS operating range, balance soft switching across devices, and enhance efficiency under light-load or variable-load conditions [17], [18],[19]. Another trend has been the exploration of hybrid modulation techniques that dynamically switch between single- and triple-phase-shift depending on load, thereby optimizing efficiency and minimizing circulating currents [20], [21]. A second focus has been multi-port and modular DAB topologies. Researchers have demonstrated triple-active-bridge and quad-active-bridge architectures to integrate renewable sources, storage, and dc grids with reduced conversion stages [22], [23], [24], [25]. These architectures rely even more heavily on well-designed HFTs, as they require precise leakage management across multiple ports. Parallel work on TAB-based SSTs for PV battery integration details design and control under wide source/load variations, reinforcing the need for HFT optimization under realistic constraints [26].Beyond DAB and TAB, MMC-H SST topologies combine the flexibility of modular multilevel converters with an H-bridge and a single HFT. Recent modelling shows that unsymmetrical sine square modulation can widen the usable voltage-gain range while lowering current stress implications that cascade to leakage tuning, core selection, and window utilization in the HFT [27]. Earlier SST storage studies (e.g., flywheel buffering for HVDC links) likewise motivate compact, low-loss transformer designs under dynamic cycling[28]. Third, efficiency and power density improvements have been pursued by leveraging wide-bandgap (WBG) devices such as SiC MOSFETs and GaN HEMTs. High-frequency operation enabled by WBG switches has reduced transformer volume but simultaneously magnified the importance of accurate transformer optimization and thermal management [29], [30], [31]. Studies emphasize that the HFT often becomes the bottleneck in achieving very high power density, reinforcing the need for advanced design optimization frameworks. Finally, in the context of SST applications, recent works have examined DAB control for grid-interactive functionality, fault tolerance, and renewable energy smoothing [6]. These studies consistently highlight that the DAB overall performance is dictated by transformer design, leakage inductance

tuning, and thermal reliability. As such, HFT optimization is increasingly recognized as a critical enabler of next-generation DAB-based SSTs.

**High-Frequency Transformer (HFT) Design Approaches**

Early HFT design methods were deterministic and relied on sizing rules such as the area product method [16]. Although useful for initial approximations, these methods could not capture multi-dimensional trade-offs among copper losses, core losses, leakage inductance, and thermal limits. Core losses were generally estimated using the Steinmetz equation [9], [32], which provided reasonable accuracy but lacked Multiphysics considerations.

In a high-frequency transformer, leakage inductance is mainly influenced by the winding arrangement and physical construction of the magnetic component. An analytical approximation for estimating the leakage inductance is given in [32]:

$$L_k = \mu_0 \frac{N^2 \cdot MLT}{3w(a+b+3c)} \quad (2)$$

where $N$ is the number of turns, $MLT$is the mean length per turn, $w$denotes the window width, and $a$, $b$, $c$represent winding dimensions. $\mu_0$is the permeability of free space.

In Dual Active Bridge converters, a series inductance $L_{DAB}$is required to enable proper power transfer and maintain zero-voltage switching, as defined in (1). The transformer leakage inductance $L_k$is determined by its geometry according to (2). Around 2010, researchers began applying metaheuristic algorithms to HFT optimization. Qin *et al.* [11] introduced a hybrid Differential Evolution Particle Swarm Optimization (DEPSO) method for DAB transformers, showing that heuristic techniques could outperform rule-based sizing. However, their formulation was largely single-objective and excluded practical engineering constraints. Later, attention shifted toward leakage inductance modeling. Mogorovic and Dujic[7], [33]developed analytical and experimentally validated formulas for leakage inductance, which became pivotal for accurate DAB modeling and ZVS design. By 2020-2021, Multiphysics and multi-objective frameworks were introduced. Olowu *et al.* [12], [34] combined electromagnetic, thermal, and cost models in a unified optimization framework, while in [8], [15]emphasized reliability, thermal rise, and insulation life, highlighting the importance of constrained design strategies. Recent studies have presented structured methodologies tailored to SST applications. Lee[6] proposed an efficiency-focused transformer design methodology, and Santos[14] outlined systematic guidelines emphasizing winding structures, material selection, and parasitic management. These works advanced design practice but were primarily validated through simulation. The key converter and transformer design parameters considered in this study are listed in Table 1.

**Optimization Problem Formulation**

The design of a High-Frequency Transformer (HFT) for a Dual Active Bridge (DAB) converter can be expressed as a constrained multi-objective optimization problem. The goal is to minimize transformer size and losses while satisfying efficiency, thermal, and manufacturability limits.

**Decision Variables**

The optimization considers the following decision variables:

$$x = \{B, J, f_s\} \quad (3)$$

where B is the peak flux density in the core, $J$ is the current density in the winding conductors, $f_s$ is the switching frequency.

**Objective Functions**

Three conflicting objectives are minimized simultaneously:

**Core loss**$P_c$, estimated using the Steinmetz equation:

$$P_c = k f_s^{\alpha} B^{\beta} V_c \quad (4)$$

where $k, \alpha, \beta$ are Steinmetz parameters for the selected core material and $V_c$ is the effective core volume.

**Copper loss** $P_{cu}$, modeled as:

$$P_{cu} = I_{rms}^2 R_{AC} \quad (5)$$

where $R_{AC}$ is the frequency-dependent winding resistance obtained from Dowell equations, including skin and proximity effects.

3.**Product area $A_p$:**The area product method links the transformer power handling to flux density, frequency, and current density:

$$A_P = \left[\frac{\sqrt{2}\sum VA}{k_v f B_{opt} k_t k_f \sqrt{k_u \Delta T}}\right]^{\frac{8}{7}}, \quad (6)$$

where $k_v$ is the waveform factor, $B_{opt}$ the optimal flux density, $k_t$ the temperature-dependent constant, $k_f$ the form factor, $k_u$ the window utilization, and $\Delta T$ the permissible temperature rise. This equation directly links transformer size to power level, frequency, and thermal limits.

The auxiliary constant $k_t$ accounts for material properties:

$$k_t = \sqrt{\frac{h_c k_a}{\rho_w k_w}}, \quad (7)$$

where $h_c$ is specific heat, $k_a$ thermal conductivity, $\rho_w$ resistivity, and $k_w$ winding factor. This ensures realistic scaling of area product with copper and insulation constraints.

From $A_p$, the core and window areas are derived:

$$A_c = \sqrt{\frac{A_p}{1.8}}, A_w = \frac{A_p}{A_c}. \quad (8)$$

which captures the trade-off between core cross-section $A_c$ and window area $A_w$:

$$A_p = A_c \cdot A_w \quad (9)$$

Minimizing $A_p$ promotes compact designs.

***Constraints***

The optimization is subject to practical constraints:

$$\eta = \frac{P_{out}}{P_{out}+P_c+P_{cu}} \geq 0.99 \quad (10)$$

$$L_\sigma \geq L_{DAB} \quad \text{(sufficient leakage for ZVS)} \quad (11)$$

$$\Delta T \leq 80°\text{C} \quad \text{(thermal limit)} \quad (12)$$

$$k_u = \frac{A_{cond}}{A_w} \leq 0.6 \text{(window utilization)} \quad (13)$$

$$r_{op} \leq \delta, r_{os} \leq \delta \textit{(Skin depth constraint)} \quad (14)$$

where $\eta$ is transformer efficiency, $L_k$ is leakage inductance, $\Delta T$ is temperature rise estimated using thermal resistance models, $k_u$ is window fill factor, $\delta$denotes the skin depth of the conductor for the selected litz wire. The conductor radius($r_{op}$ $and$ $r_{os}$) is limited by the skin depth $\delta$to reduce AC losses at high frequency. To structure the optimization process using GA, a systematic workflow was adopted, as illustrated in Fig. 3. The procedure starts with defining requirements such as input/output voltages, rated power, switching frequency, and isolation needs. Based on these specifications, an appropriate core material (ferrite, amorphous, or nanocrystalline) is selected. Initial transformer sizing is then carried out using classical methods (e.g., McLymans area product) to establish feasible ranges of flux density, current density, and window area. Subsequently, leakage inductance engineering is applied by adjusting geometry, spacing, and interleaving to achieve the minimum inductance required for ZVS in the DAB converter. Thermal and insulation checks ensure that copper/core losses, temperature rise, and creepage/clearance requirements are satisfied. If any constraint is violated, the process iterates back to update geometry or sizing. Once all baseline constraints are met, a constrained GA-based multi-objective optimization is performed to minimize product area, copper loss, and core loss simultaneously while respecting efficiency, leakage inductance, and window utilization factor. The optimization results are finally validated through simulation and hardware prototype tests. The flow ends with a Pareto trade-off evaluation, where the designer can select an HFT design balancing size, losses, and efficiency. This structured approach ensures that the final design is both practically realizable and experimentally verifiable.

**Control of DAB**

**Genetic Algorithm (GA) Formulation**

The above problem is solved using a constrained Genetic Algorithm (GA)[35]. The population is initialized with random candidate solutions within feasible ranges of $B$, $J$, $f_s$. Each candidate is evaluated using the objective functions and checked against constraints (10)-(14). Non-dominated solutions are preserved to form the Pareto front. The GA proceeds with crossover, mutation, and selection until convergence is reached. Termination criteria include either a maximum number of generations or convergence of objective values within a predefined tolerance.

**Control Implementation**

The DAB converter is regulated by a closed-loop phase-shift control strategy in which the output voltage is maintained at its reference value by dynamically adjusting the relative phase angle $\phi$ between the primary and secondary H-bridge gate signals. Fig. 4 shows the functional block diagram of the control system. At the system level, the measured output voltage $V_{\text{actual}}$ is sensed and filtered to remove high-frequency switching ripple before being compared with the reference $V_{\text{ref}}$. The resulting error $e(t) = V_{\text{ref}} - V_{\text{actual}}$ is processed by a proportional-integral (PI) regulator, which produces a commanded phase shift $\phi^*$. This command is converted into a phase delay relative to the input H-bridge carrier, and the corresponding gate pulses are generated for the two H-bridges with appropriate dead-time. As expressed in (1), the transferred power is approximately proportional to $\phi$, so the closed-loop system restores $V_o$ to its setpoint under load variations. While Fig. 4 highlights the functional signal flow, the digital controller is implemented on a microcontroller using interrupt-driven firmware. The corresponding execution flow is shown in Fig. 5. At startup, the MCU initializes its peripherals (clock, GPIO, ADC, timers) and the PI control coefficients. On each timer interrupt, the output voltage is sampled via the ADC and compared with the reference to compute the error. The PI update is calculated in discrete form,

$$\phi[k] = \phi[k-1] + a\, e[k] + b\, e[k-1], \qquad (15)$$

where $a$ and $b$ are the discrete-time PI gains. The phase-shift command is then bounded between 0 ° and 90 ° to ensure safe modulation. Finally, the updated phase delay is written to the PWM registers that generate the four complementary gate signals for the H-bridges. The loop repeats on every interrupt, maintaining real-time closed-loop control. The PI controller regulates the output voltage by adjusting the phase delay of the secondary bridge gate pulses relative to the input bridge The MCU samples $V_{\text{actual}}$ on each timer interrupt, computes the PI update, clamps the phase shift $\phi$, and updates the PWM registers in real timeTogether, the block diagram and flowchart demonstrate both the control principle and its embedded realization. The separation of functional design and software implementation clarifies that the system-level PI phase-shift loop is faithfully mapped to the low-level firmware.

**Control Stability and PI Tuning**

The PI controller parameters were selected using a frequency-domain analysis of the small-signal model of the DAB converter. Around the nominal operating point, the DAB can be approximated by a first-order plant from phase shift to output voltage with a dominant pole set by the output filter. The proportional gain was chosen to provide adequate closed-loop bandwidth without exciting switching harmonics, while the integral gain ensured zero steady-state error under dc load variations. A Bode plot of the open-loop transfer function confirmed a phase margin greater than 55 ° and a gain margin exceeding 10 dB, indicating robust stability. Experimental step responses verified that the design achieved fast settling (<2 ms) with less than 5% overshoot. Together, the analysis and experimental validation demonstrate that the PI-based phase-shift regulator offers stable and well-damped control of the output voltage across the tested load range.

**Small-Signal Model from Phase Shift to Output Voltage**

Under single phase-shift (SPS) operation and near the nominal operating point, the transferred power of a DAB can be linearized as

$$P(\phi) = \frac{nV_{in}V_{out}}{\omega L_k}\phi\left(1-\frac{\phi}{\pi}\right) \approx k_P V_{out}\,\phi, \qquad (16)$$

The approximation is valid because the control loop operates around a nominal operating point where the phase-shift variations are relatively small compared with $\pi$. Under this condition, the nonlinear term $\left(1-\frac{\phi}{\pi}\right)$varies slowly

and can be treated as approximately constant, allowing the DAB power transfer relation to be represented by a linear small-signal model.

Around the operating point $(\phi_0, V_0)$ with small perturbations $\tilde{\phi}$ and $\tilde{v}$, the output current delivered by the DAB is

$$I_o = \frac{P}{V_{out}} \approx \frac{k_P V_{out}\,\phi}{V_{out}} = k_P\,\phi. \quad (17)$$

Hence the DAB behaves, to first order, as a controllable current source of gain $k_P$ from phase shift to output current. With a resistive load $R$ and an output capacitor $C$, the output dynamics are

$$C\,\frac{dV_{out}}{dt} = I_o - \frac{V_{out}}{R} \approx k_P\,\phi - \frac{V_{out}}{R}. \quad (18)$$

Linearizing about $V_0$ and $\phi_0$ gives the small-signal relation

$$C\,\frac{d\tilde{v}}{dt} = k_P\tilde{\phi} - \frac{\tilde{v}}{R}, \quad (19)$$

which in the Laplace domain yields the phase-to-voltage plant

$$G_{\phi\to v}(s) = \frac{\tilde{V}(s)}{\tilde{\Phi}(s)} = \frac{k_P}{C\,s+\frac{1}{R}} = \frac{K}{\tau s+1}, \qquad K = k_P R, \tau = CR. \quad (20)$$

***PI controller and open-loop:***

With the PI regulator

$$G_c(s) = K_p + \frac{K_i}{s}, \quad (21)$$

the open-loop transfer function is

$$L(s) = G_c(s)G_{\phi\to v}(s) = (K_p + \frac{K_i}{s})\frac{K}{\tau s+1}. \quad (22)$$

Choosing $K_p$ sets the closed-loop bandwidth sufficiently below $f_s$ to avoid interaction with switching harmonics, and $K_i$ places the integrator zero near $1/\tau$ to cancel the plant pole and eliminate steady-state error. The exact DAB power characteristic in (1) is used for design and validation, whereas (17) is the linearized form used only for small-signal control analysis around the nominal operating point. The model in (21) assumes SPS operation with small $\phi$ perturbations, continuous conduction, constant $V_{in}$, and that the transformer leakage $L_{k.}$ ensures ZVS so switching loss impact on small-signal dynamics is negligible. If a post-rectifier LC filter is used, the same derivation leads to a second-order plant; the design here uses $C$ large enough that the dominant pole is $1/(RC)$, yielding the first-order form in (21). A practical efficiency factor $\eta_T \approx 1$ can be included in $k_P$ without affecting the structure of the result: $k_P = \eta_T\, nV_{in}/(\omega L_\sigma)$.

**Experimental Setup**

Experimental validation of the genetic-algorithm-optimized nanocrystalline HFT was carried out using a 150 W Dual Active Bridge converter prototype.The input dc bus voltage was set to $V_{\text{in}} \approx 120$ V, and the regulated output was maintained at $V_o = 12$ V. The switching frequency of operation was $f_s = 20$ kHz. The detailed electrical ratings of the prototype and the instrumentation used during testing are summarized in Table 1. A laboratory photograph of the prototype, comprising the DAB converter board, the GA-optimized HFT, the regulated dc source, and the resistive load, is shown in Fig. 6. Key transformer design parameters obtained from the optimization, along with measured values from the fabricated unit, are listed in Table 3. These parameters form the baseline for simulation-to-hardware comparisons discussed in Section VI. All measurements were carried out using a Siglent SDS1204X-E oscilloscope equipped with differential and current probes .The electrical specifications of the laboratory prototype and the measurement instruments used during testing are summarized in Table 2.Gate signals were captured at the driver outputs, and the output waveforms (voltage and current) were measured at load resistances of 1 Ω, 10 Ω, and 20 Ω. The GA-optimized nanocrystalline transformer was fabricated and integrated into the 150 W DAB prototype, and its performance was experimentally validated under different load conditions. The following subsections present

measured waveforms, closed-loop control behavior, and efficiency results, with direct comparisons to simulation predictions.

**Primary and Secondary Voltage Waveforms**

Fig. 7 shows the measured primary and secondary transformer voltages, along with the secondary current, under rated load. The primary exhibits a near-square waveform of ≈120 V amplitude, while the secondary waveform is stepped down to ≈12 V, consistent with the designed turns ratio of 20:2. The observed phase shift between primary and secondary voltages confirms correct power transfer. The quasi-triangular secondary current demonstrates that the designed leakage inductance enables proper Zero-Voltage Switching (ZVS) without requiring an external inductor.

**Secondary Current Characteristics**

The corresponding secondary current waveforms, presented in Fig. 7, demonstrate the expected quasi-triangular shape associated with phase-shift control in the DAB converter. The current slopes validate that the leakage inductance of the optimized transformer is correctly tuned to enable Zero-Voltage Switching (ZVS) without external inductors. Peak current remains well within thermal limits, and the absence of excessive distortion indicates that skin and proximity effects have been effectively mitigated by the winding configuration.

**Gate Pulse Validation**

Fig. 8 illustrates the gate pulses of the four MOSFETs in the primary and secondary bridges. The pulses are symmetrically aligned with a switching frequency of 20 kHz, and dead-times are appropriately maintained to prevent shoot-through. Experimental runs with different phase-shift angles (60 ° and 80 °) confirm linear scalability of output power with the phase-shift angle. This validates both the correctness of the modulation strategy and the integrity of the driver circuitry.

**Load Regulation and Output Performance**

Load regulation was evaluated using resistive loads of 1 Ω, 10 Ω, and 20 Ω. The results are summarized in Table 3. At 1 Ω, the converter delivers approximately 12 A at 12 V (~144 W), close to the rated 150 W. At higher load resistances, the output current scales proportionally while the voltage remains tightly regulated. The measured waveforms (Figs. 10 (a) ,(b),(c)) confirm that ripple remains minimal, underscoring the efficacy of the optimized transformer in handling both heavy and light loads without instability.

**Closed-Loop Control Response**

The control system, shown in Fig. 11, employs a PI regulator with phase-angle adjustment to maintain constant output voltage. As illustrated in Fig. 10, the system exhibits smooth startup and rapid settling with negligible overshoot. Even under load variations, the output voltage remains well regulated at 12 V. This demonstrates that the proposed control strategy, when combined with the optimized HFT, achieves stable regulation across a wide operating range.

**Efficiency and Loss Validation**

The overall efficiency was computed by comparing the measured input and output power at each load point. Across all operating conditions, efficiency exceeded 99%, consistent with the predictions of the GA optimization. This agreement between simulation and hardware validates the accuracy of the core and copper loss models used in the design framework. Notably, no external inductors were required to guarantee ZVS, confirming that the transformer itself supplies adequate leakage inductance. This experimental observation substantiates one of the central novelties of this work—that practical constraints, when embedded in the optimization loop, yield designs that are both efficient and manufacturable. Peak converter efficiency near rated load is approximately 98.75%; as expected for hard-switched auxiliaries and fixed overheads, light-load efficiency declines to ~ 95%. The GA-optimized transformer maintained efficiency above 99% across all tested loads, with experimental results matching simulation predictions within 0.9%. This close agreement validates both the constrained GA optimization framework and the

underlying copper/core loss models. The electrical parameters of the fabricated HFT were experimentally characterized prior to integration into the DAB prototype. The magnetizing inductance ($L_m$) and leakage inductance ($L_k$) were extracted from low-voltage impedance measurements with the secondary either open- or short-circuited. The ac resistance of the windings ($R_{AC}$) was obtained by frequency sweep using a precision LCR meter, ensuring that skin and proximity effects at $f_s = 20$ kHz were captured. Core losses ($P_c$) were estimated from Steinmetz parameters fitted to the material datasheet, while copper losses ($P_{cu}$) were calculated from measured $I_{\text{rms}}^2 R_{AC}$. Overall transformer efficiency was then computed as

$$\eta_T = \frac{P_{out}}{P_{out}+P_c+P_{cu}}, \quad (23)$$

where $P_{out}$ is the delivered load power.

The comparison in Tables 4 and 5 shows close agreement between simulation and experiment at rated and light-load conditions. Peak converter efficiency near 150 W differs by less than 0.7 percentage points, and key transformer parameters ($L_k$, $k_u$, $R_{AC}$) are within 5–7% of the predicted values, which is consistent with manufacturing tolerances and frequency-dependent losses not fully captured by first-order models. These results validate the fidelity of the proposed GA-based optimization models and confirm that the embedded constraints translate into realizable hardware.

## DISCUSSION

The experimental results confirmed that the constrained GA optimization translated reliably into hardware. At rated load, the prototype achieved a peak efficiency of about 98.75%, closely matching the simulated predictions. This validates the accuracy of the copper and core loss models used in the optimization framework. At lighter loads, efficiency naturally declined due to fixed overheads, but voltage regulation remained tight, demonstrating robust control performance. The measured waveforms further reinforced the role of embedded constraints in the design process. The leakage inductance of the fabricated transformer was sufficient to guarantee ZVS without the need for external inductors, while the observed window fill factor was within safe manufacturability limits. These outcomes demonstrate that incorporating real-world constraints in the optimization loop yields designs that are both efficient and practically realizable. Overall, the discussion highlights that the proposed workflow closes the gap between optimization and physical implementation. By linking algorithmic design to experimental validation, the study shows that constraint-driven GA methods can serve as a reliable foundation for scaling HFT design to higher power levels and more complex DAB topologies in SST applications.

## CONCLUSION

This paper presented the design optimization and experimental validation of a High-Frequency Transformer (HFT) for Dual Active Bridge (DAB) converters in Solid-State Transformer (SST) applications. A constrained Genetic Algorithm framework was formulated to minimize product area, copper loss, and core loss, while enforcing practical constraints on efficiency, leakage inductance, thermal rise, and window utilization. A nanocrystalline transformer optimized with this framework was fabricated and integrated into a 150 W DAB prototype. Hardware testing of the fabricated prototype confirmed proper converter operation across the tested load range. The measured waveforms indicated reliable voltage regulation and soft-switching behaviour, which is supported by the leakage inductance incorporated in the transformer design and measured efficiency of about 98.75% at rated load. Light-load tests further confirmed that the design remains thermally safe and manufacturable, consistent with the imposed constraints. The key contribution of this work lies in bridging algorithmic optimization and physical realization, demonstrating that designs obtained through constraint-driven GA optimization can be successfully fabricated and validated in hardware. The workflow is reproducible and scalable, and can be extended to higher power ratings, multi-phase DAB architectures, or multiphysics optimization frameworks that include thermal and insulation models. Overall, the study establishes a systematic methodology for developing compact, efficient, and reliable HFTs, reinforcing their role as critical enablers of next-generation SST systems.

## ACKNOWLEDGMENT

The authors thank the SSIP Cell, A.D. Patel Institute of Technology, for providing institutional support and facilities during the development and testing of the hardware prototype.

## FUNDING

This work was supported by the Student Startup and Innovation Policy (SSIP 2.0) program through the SSIP Cell at A.D. Patel Institute of Technology, New Vallabh Vidyanagar, Gujarat, India, under Office Reference No. ADIT/OFFICE/2024/689.

**Declaration of Competing Interest**

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

**Table 1: Summary of Literature on HFT Design and Optimization Approaches**

| Author/Year | Methodology | Focus | Validation | Key Limitation |
|---|---|---|---|---|
| Qin *et al.*, 2010 [36] | DEPSO (metaheuristic) | Efficiency vs. size trade-off | Simulation only | No constraints considered |
| Yadav *et al*., 2011 [37] | Genetic Algorithm + Simulated Annealing | Minimization of core + copper mass subject to constraints | Simulation | No hardware prototype |
| Mogorovic and Dujic, 2017[7] | Analytical + Experimental | Leakage inductance modeling | Experimental | Not an optimization framework |

| | | | | |
|---|---|---|---|---|
| Banumathy , Veeraraghavalu, 2018 [38] | GA based geometry | winding optimization | Simulation | No experimental validation |
| Olowu *et al.*, 2021[12] | Multiphysics + MO | Electromagnetic, thermal, cost | Simulation | No algorithmic comparison, no hardware |
| Elrajoubi ,Ang, 2021 [39] | High-Frequency Transformer Review | comparative design methods, | Review / simulation summary | Not optimization per se |
| Lee, 2023 [6] | Structured methodology | Efficiency-driven design | Simulation | Single-algorithm focus |
| StanojeviÄ‡ *et al.*,2023[40] | Finite-element + parametric optimization | Modular transformer for EV charger | Simulation + some prototype / software tool validation | Limited hardware detail |
| Santos, 2023[14] | Systematic design | Winding, material, parasitics | Simulation | No experimental results |
| Tang *et al*., 2023 [41] | Planar geometry optimization | Flux cancellation, loss model | Simulation | Planar only, not wound geometry |
| Zhang *et al*., 2024 [42] | Multi-objective optimization for nanocrystalline HFT, | Nanocrystalline material parameter optimization | Simulation | No hardware prototype |
| Wang *et al.*, 2025 [15] | Reliability analysis | Thermal rise and insulation lifetime | Simulation | No optimization applied |
| **This Work (2026)** | Constrained GA + Hardware | Design optimization and experimental validation | 150 W prototype | End-to-end workflow established |

**Table 2: Experimental Setup and Measurement Equipment**

| **Parameter** | **Specification** |
|---|---|
| DC input voltage $V_{in}$ | 120 V |
| Output rating | 12 V, 150 W |
| Switching frequency $f_s$ | 20 kHz |
| Digital oscilloscope | Siglent SDS1204X-E (200 MHz, 1 GSa/s) |
| High-voltage differential probe | Pintek DP-25 (100 MHz, 2.5 kV) |
| Current measurement | Tektronix TCP202 (20 A, 50 MHz) / 0.01 Ω shunt |
| Load type | Adjustable resistive load (1–100 Ω) |

**Table 3: Optimized Transformer Design and Experimental Measurements**

| | |
|---|---|
| Core material and geometry | Nanocrystalline(VITROPERM-500F), UI,UMNCC-4 |
| Primary / secondary turns $N_p/N_s$ | 20 / 02 (turns ratio 10:1) |
| Conductor type | Litz wire composed of 100 strands (0.1 mm each) |
| Window utilization factor $k_u$ | 0.65 (measured, ≤0.6) |
| Peak flux density $B_{peak}$at 20 kHz | 0.18 T |
| Magnetizing inductance $L_m$ (referred) | 3.2 mH |
| Leakage inductance$L_k$ (referred) | 6.21x $10^{-4}$ H |
| AC winding resistance $R_{AC}$at 20 kHz | 42 mΩ |

**Table 4: Measured Output Performance Under Different Loads**

| Load (Ω) | $V_o$ (V) | $I_o$ (A) | $P_o$ (W) |
|---|---|---|---|
| 1 | 12.0 | 12.0 | 144 |
| 10 | 12.1 | 1.2 | 14.5 |
| 20 | 12.1 | 0.6 | 7.3 |

**Table 5: Measured and Simulated Efficiency of the Optimized HFT in DAB Prototype**

| Load (Ω) | Measured $\eta$ (%) | Simulated $\eta$ (%) | Difference (%) |
|---|---|---|---|
| 1 | 98.70 | 99.40 | 0.70 |
| 10 | 99.10 | 99.50 | 0.40 |
| 20 | 99.24 | 99.63 | 0.40 |

**Table 6: Simulation vs. Experimental HFT Parameters**

| Parameter | Simulation (GA) | Experiment | Error % |
|---|---|---|---|
| $k_u$ | 0.58 | 0.65 | 12.7 |
| $L_m$ H | 3.10 | 3.20 | 3.23 |
| $L_k$H | 6.0 x $10^{-4}$ | 6.21x$10^{-4}$ | 3.50 |
| $R_{AC}$ @ 20 kHz (mΩ) | 40 | 42 | 5 |
| Core loss $P_c$ (W) | 0.62 | 0.65 | 4.84 |
| Copper loss $P_{cu}$ (W) | 1.08 | 1.18 | 9.26 |
| $\eta_T$ (HFT only) (%) | 99.4 | 98.75 | 0.65 |

**Table 7: Measured and Estimated Loss Breakdown of the Optimized HFT at rated load (0.96 Ω)**

| Parameter | Value |
|---|---|
| Output power $P_{out}$,W | 148.17 |
| Copper loss $P_{cu}$,W | 1.18 |
| Core loss $P_c$.W | 0.65 |
| Total transformer loss $P_{tot}$,W | 1.83 |
| Transformer efficiency $\eta_T$ | 98.75% |

## ABSTRACT

The Cloud files storage are having vast amount of data and using the different kinds of the users. Most of the cloud storage vendors offer free storage to the users who they store personal data in to the cloud. The primary concern of the user is securing personal files in the cloud storage. Some vendors are depending on the third-party storage for the cloud storage. However, third-party and CSP stor-age can present challenges such as vulnerabilities, insecurity and diminished privacy. The proposed mechanism aims to secure comprehensive cloud file storage, ensuring that files are protected. The process begins with client-side encryption, where the encrypted content is only decrypted on the client side, preventing the server from accessing the original file. Under that client-side cryptographic R3SKT and R3SX are used. The R3SKT algorithm is designed to en-crypt/decrypt the text files on the client side, while the R3SX algorithm is used for encrypt/decrypt the image files. The client-side encryption algorithm is uses Attribute-Based Encryption, which uses the username as the key. Followed by the client-side encryption, server-side HASaRA algorithm is used to secure server side files. The HASaRA is a Key-Based Encryption algorithm that uses both a key and a passcode for the encryption process. The authorized users gain access to the storage by verifying their credentials through the TicketAdmin algorithm and algorithm raised a hash ticket. That hash ticket is checked when per-form every operation. If the hashticket mismatched then verify the user with one time on the registered device. The server is having

port lock mechanism to pre-vent the unauthorized access on the storage. In terms of performance, the pro-posed algorithm is well-suited for cloud storage and yields superior results.

**Keywords:** Cloud Security, Cryptography, Ticket admin, Port lock, etc.,

## INTRODUCTION

Cloud computing is a well-organized and rapidly evolving technology and gaining increasing familiarity on the users. Cloud file storage is a concept of storing and retrieving files in the cloud, allowing servers and applications to access. The advantages of the cloud storage include well-integrated storage solutions, on-demand resources, cost-effectiveness, straightforward management and maintenance for users [1]. The files stored in the cloud are located in different geographically distributed data centers. Organizations must implement the necessary policies and techniques to control user access to their files stored in the cloud. Enhanced access control and protection protocols are essential, depending on the confidentiality level of the files stored in the cloud. Cloud Service Providers (CSPs) allowing them to perform various actions, including copying, deleting and modifying files in cloud storage based on the accessibility given the particular user [2]. The most effective approach is secure cloud storage is through cryptographic methods. While these methods offer enhanced security com-pared to unprotected data, they do not provide complete control over the stored in-formation[12]. Cloud security risks are data leaks, unauthorized access and key management is-sues[9]. The cloud operates as a multi-user environment where files are easily shareable. This can lead a vulnerability to the user of the cloud and attackers may exploit the shared resources to access or manipulate other's files. For instance, an attacker intrudes and upload malicious file to the cloud storage and retrieve the files in the cloud. Then obviously conduct cryptanalysis to discover the decrypted information. This kind of unauthorized access to personal files storage is illegal and a violation of privacy [10]. Additionally, key management poses significant risks; for example, local browsers are stored the password credentials for the purpose easily handling the drive storage, which can be targeted in individual attacks. Common cloud security threats include phishing attacks, password attacks, man-in-the-middle attacks, DDoS attacks and insider threats [11]. Everyone should manage passwords effectively to prevent unauthorized access and unauthorized users cannot access the files. Servers are requires a securing mechanism to fully prevent from the server side attacks, such as a port lock mechanism. The port lock mechanism is designed to prevent intruders cloud not access the access the servers based on the port. The storage system does not grant data access to the data owner or the Cloud Service Provider (CSP).

## RELATED WORKS

Balasubramanian *et al*. [3] represent their framework as an enhanced security system for safe data storing. The framework uses a decision manager, a key generation module, a Trusted Platform Authority (TPA), an Identity-based Encryption with Attribute-based Control (Id-EAC) module, an encryption module and a decryption module. The author utilized the decision manager to oversee the environment effectively. This decision manager incorporates a key generation module, an encryption module, a decryption module, an Id-EAC module and a TPA module. A lightweight digital signature algorithm is employed to ensure the integrity of data storage in data centers. The author expresses concern about preventing unauthorized access to sensitive information. ShaluMall and SusilKumarSaroj[4] created their framework as a new security framework. The author examined the mechanisms of genetic algorithms and data crossover for encryption and decryption. The data is converting based on ASCII logic to binary bits, which are then grouped into sets of 8, 4 and 2 bits per block. Pseudo-random numbers are generated to mask the crossover, which involves taking two blocks of binary bits and performing uniform crossover. The mutation process entails changing 0s to 1s. The split data blocks (or split data bits) are then combined into a single file. MirnalKanti Sarkar and Sanjay Kumar[5] developed their framework with the concept of schematic system architecture. The schematic system architecture con-sists of two entities: users and three Cloud Service Providers (CSPs). The CSP1 is re-sponsible for user computation, CSP2 handles the encryption and decryption pro-cesses and CSP3 is designated for

storage. The encryption scheme involves the mechanisms of key generation and encryption. The encryption/decryption processes operates with the security key, which generated by the algorithm. This framework is entirely based on encryption/decryption algorithms. O. Arki *et al*. [6] represent their framework as a multi-agent proxy and framework is secure the data on the cloud storage. The author implemented a mechanism in-volving multiple agents to secure the cloud storage. The agents are interface agent, encryption agent, proxy agent, and authenticator agent. Each agent operates within the data owner layer [7]. The interface agent is primarily responsible for transfer of data between the client and the server. The encryption agent handles the encryption and decryption of data. In this framework, the encryption and decryption processes utilize RSA, AES and a hash function. The RSA algorithm is employed for generating keys to access files, while AES is used for data encryption and the hash function ensures that the data maintains a consistent length.

## PROPOSED METHOD

The new cloud architecture uses four algorithms and the ticket admin. The four algorithms are R3SKT Hash, R3SKT, R3SX and HASaRA. The algorithm uses a few sub-techniques. The techniques are Het ApenSpel, Single Dimensional Chaotic Behavior (SDCB), Knight's Tour, Reverse Spiral, Dynamic Calculation Procedure (DPC), ReArrange and Reverse Rail Fence. In this architecture uses a dual cryptographic approach for the framework to achieve user's security. In the client-side R3SKT/R3SX algorithm encrypts the text/image data. Both the client-side algorithms use the username as a key for the cryptographic process. On the other hand server side encryption/decryption is processed by an algorithm namely HASaRA. The HASaRA algorithm uses different keys and passcodes for the different servers. A port lock mechanism is used to prevent the server's port based attacks. The ticketadmin is responsible for ensure the security of user. The ticketadmin creates a hashticket for every request that is used by the client. The hashticket consists of username, password, Client MAC address hashes and time. If the hashticket is invalid or any misinterpretation is happens in the hashticket. Confirm the person's identity by mail or mobile and then give an access to the drive storage. The new architecture is shown in fig. 1.

**Het ApenSpel**

The board game Het ApenSpel 1900 is a classic Dutch strategy game. The game consists of spiral path and made up of 73 numbered boxes with a centre of a house called monkey house. The game is designed for multiple players and is played using dice. Players take turns rolling the dice to move their token along with the numbered path, starting from box number 1 and to reach box number 73, which is available in the center and act as end point. In the board, numbers represent the safe zone. The small picture in the box represents a monkey with information related to the forward/ backward movement. For example, current position of certain monkeys may cause the player to move forward boxes, skip a turn or go back to few boxes. The player who first reaches square 73 wins the game. The game picture is given in figure 3. The array is set up with seven rows and ten columns, inspired by the concept of rows and columns being used in the Het Apenspel game. In the 2D array, binary bits are shown sequentially. The binary values were received in a spiral arrangement. The spiral is divided into two groups, namely even spiral and odd spiral. Here all the even spiral bits are joined first then the odd spiral bits are joined [14].

**Single Dimensional Chaotic Behavior (SDCB)**

Chaos theory, sometimes referred to as chaology, is a division of mathematics, physics and a multidisciplinary field of scientific study. Deterministic rules and underlying patterns are highlighted in complex systems that exhibit high levels of reactivity to initial conditions. The seeming randomness of chaotic, challenging techniques, as defined by chaos theory, has underlying patterns, interdependence, continuous loop feedback, self-similarity, a particular geographical shape and self-organization. The equation 1 shows the formula used by the SDCB logic. Where len is the length of bits involved in the message. Prime factor is term as pf that is the next prime number of length +3. The j iterates the value of image/text bytes and i is the next value of j. r is mean by the remaining value in ith iteration.. The picture/text bytes are processed by the single dimension chaotic behavior(SDCB), which shuffles the bytes based on

the formula. The image/text byte length is used as the row size in this method, which creates a single-dimension array [14].

$$P[j] = (pf \times (i+j) \times r^2)\%len \quad (1)$$

The technique uses prime numbers and iterative numbers to produce the estimated positional value. The main objective is to jumble (diffuse) data. Thus, partially encrypted text/ image bytes might be the algorithm's input and output. The message Helloworld has been given to the procedure. The result of the message is rhlodlwleo.

**Knight Tour**

The steps in the Knight Tour algorithm are as follows: Split the length of the message into five bytes. Every five bytes are converted into binary then plotted into the 5 x 7 array. The data are read by 5 x 7 array is traversal like a Chessboard Knight. The same procedure used for other 5 bytes in the message. Finally, every binary bits are converted into characters. Undivided remaining characters are combined directly[14].

**Reverse Spiral Bits**

Reverse spiral Bits is an algorithm of reversing the regular spiral order of the binary bits used in the input [8]. The first step is to convert the text or image bytes to 7bit binary then plotting the binary bits in regular two dimensional array with the length x 8. Figure 6shows the reading method of spiral. After reading the spiral order the binary bits get reversed then converted into ASCII/Bytes [14].

**Dynamic Procedure Calculation (DPC)**

The DPC formula generates a Len number. Len is meant to that length of bytes containing the images/text. B contains every value involved in the username's ASCII values. The DPC will be used to select the sub algorithm in the proposed algorithms chooser.

$$DPC = \sqrt{\left(\prod_{0}^{len-1} B\right)^2} \times len \quad (2)$$

**Example**

Username : HELLO
User content : HELLO
ASCII values : 72, 69, 76, 76, 79
C : 72 x 69 x 76 x 76 x 79
C = 2266918272 C2 = 5138918451927470000l = 5
Multi =5138918451927470000 * 5 = 25694592259637300000

iteration – 1 multi % 3= 2 (1) multi/ 3 = 8564864086545770000
iteration – 2 multi % 3= 0 (2) multi/ 3 = 2854954695515260000
iteration – 3 multi % 3= 1 (3) multi/ 3 = 951651565171753000

The DPC value calculated in the example is '201'. Each step iteration multi's remainder are combined and named as DPC.

**ReArrange Algorithm**

The Rearrange algorithm is used for repositioning the values in the message. The equation 3 used as formula for manipulate the unrepeated position of input given in the algorithm. Posi returns the next position of string. The pf

means prime factor that is the next prime value of the pin. L is the length of input. The ReArrange algorithm is processed in two cycles; one is based on the pin.

$$Pos_i = pf \times (pin + i)\%L \quad (3)$$

The next cycle is based on the tag given in the algorithm. The tag values are converted into ASCII values and total the values and multiplied by seven. Square root of the computed total and substituted into pin for the second cycle of the algorithm.

**Reverse Rail Fence**

The rail fence algorithm is a vintage model. An original content is split into two rows. Then the two rows of characters are read by character one by one from each separated row and combined. But the created rail fence model is quite different from the old model or a small change in the vintage model. That is, even if split row characters are reversed, then combine the characters. For example themessage'Hello123#'has been given to the method then. The procedure split messages as 'hello' and '123#'. Reverse the messages like 'olleH' and '#321'. Finally, the result of Reverse Rail Fence is 'o#l3l2e1H'.

**R3SKT Hash Algorithm**

The password is hashed using the following methods by the R3SKT hashing algorithm: The DNA sequence of uncommon fish is used as salt. The salt is added with method of railfence The DPC value is calculated based on the Equation 2 to choose the sub algorithms used in the R3SKT Hash. The sub algorithms are Reposition, Reverse Spiral and Knight's Tour. The reposition algorithm is a nested form of the SDCB algorithm. During the reposition algorithm, 8 repositioned orders are created and all the repositioned character sets are combined. The reverse rail fence operation will be computed for each and every algorithm's end [13]. A hash is constructed depending on the size of the result hash (64 bytes, 128 bytes). The password 'Helloworld' is given to the algorithm the result of message is 'EVj5px29XPGzYvC~tmx2WrmNhpM6tWM1kZ7Parjqt81WPWZ019Lz4wscUaLmco'.

**HASaRA Algorithm**

This algorithm is a combination of two sub-algorithms. That is HAS and ReArrange. But, three processes mean that one of the sub-algorithm processes twice: one is a based on PIN and another one uses a passcode. The first sub algorithm, uses a delimiter, pin and tag as salt, then cuts down the size as the required size measure used in the array of the message binary bits. The message binary bits are given to HAS algorithm of the cycle process. The output of the cycle 1 is given to input for ReArrange algorithm. The decryption is processed reverse on the HASaRA algorithm [14].

**R3SKT/R3SX Algorithm**

The DPC value was generated depending on the message/Image data and username. The Text/Image has to be converted into a stream of messages/bytes for the encryption algorithm. The DPC-driven sub-algorithm selection creates the execution order. The dynamic policy employs Knight Tour/EX-OR with DPC, Spiral Bits and SDCB as its three sub-algorithms. Because the algorithm used file content and usernames, the selection of sub-algorithms was solely functional. The algorithm for the reverse rail fence will then be used to process and generate the encrypted content and also a onetime pad algorithm is used at the end of processing Result Message function. The R3SKT/R3SKT algorithm is given in Algorithm 1.

Algorithm 1 : R3SKT/R3SX
Input : Message/Image, username
Output : Encrypted Message
Begin
//DPC Calculation

```
For i=0 to len(Username)
 DPC= DPC x ASCII(Username[i])
DPC=DPC x len(Message)
While (DPC != 0)
 temp1=DPC%3
 if (choice.indexOf((char)temp1 +0) == -1)
  choice += temp1
 if(len(DPC)==3) then
  break
 DPC= DPC/3

//Dynamically choosing of sub-algorithms Select (Choice)
 For i=0 to len(Choice)
  Select(Choice[i])

                        case 0:
  Message = SDCB(Message)
  case 1:
  Message = ReverseSpiral(Message)
  case 2:
                        //Instead of Knight Tour for image that uses EX-OR with DPC
  Message = KnightTour(Message)
Message = RRF(Message)
EMessage = ResultMessage(Message)
Return EMessage
End
```

**Ticketadmin and Port Lock Mechanism**

The proposed framework is named as TAaPL. The proposed framework use the password and Mac Address hashes for hashing byR3SKTHash Algorithm. Already the hash is stored on the server's cloud database when created on log in. Everyone is having Mobile phones, Desktop PC or Tablets on handling the drive storages for personal information. So, four MAC address hashes are stored in databases and one is a temporary Mac address hash. Four MAC address stored create/ used log in at a moment. The temporary MAC Address hash is anonymous location to use the guest machines to handle the drive storage. If an anonyms' device is used to get logged in then. Verify the user by using Mobile/Email OTP to confirm the user is validity. Guest / Permanent Mac Hash will get Stored, Hash Ticket is raised and stored on the database. This process is used for narrow down usage of anonym's machines to handle personal storages. The storage servers are secured by a port lock mechanism. Access the individual files is permitted only when the Hash Ticket is valid; otherwise, the user will be logged out. The ticket admin process is given in the algorithm 2.

**Algorithm 2** **:** TicketAdmin
**Input** **:** Username, Password, Mac Address
**Output** **:** Ticket
**Begin**

```
UserHash= R3SKTHash(Username)
PasswordHash= R3SKTHash(Password)
MACHash = R3SKTHash(MacHash)
If(PasswordHash==match(storage.PasswordHash))
                        If(MACHash != match(Storage.MacHash))
                                Raise confirmation // confirmation OTP/ Email
```

```
                    If(confirmation == "Yes")
                        HashTicket = True
                    //Access store /Retrive the Files storage
                    Else
                        HashTicket =False
                        //Action Logout that DeviceElse
//Access store /Retrive the Files storage
                    HashTicket = True
        Else
            //show invalid password to the user
            Error "Invalid Password"
If(HashTicket == True)
            Ticket = RRF(usernameHash, PasswordHash)
Time = CurrentTime()
        //Store Hash Ticket and Time to the Storage.
ReturnHashTicket
End
```

Each server has its own unique passcodes and keys. When the Hash Ticket is validated, the corresponding passcode and key are shared. The HASaRA algorithm is implemented to ensure server-side security, managing the encryption and decryption processes. Each region-specific server utilizes different passcodes and keys. Client-side encryption and decryption are handled by R3SKT and R3SX. R3SKT is used for encrypting textual information, while R3SX is responsible for encrypting image data. Achieving a true end layer is a significant focus of this research. In this approach, only the client can view the original file.

## RESULTS AND DISCUSSION

**R3SKT/R3SX**

The results of the proposed algorithm are superior to those of other client encryption methods. The execution times of 1,000, 2,000 and 3,000 characters are 844 ms, 1,516 ms and 2,281 ms respectively. The results are shown in the fig. 2 and table 1. This method demonstrates a minimum performance improvement of approximately 50 ms compared to others. 3000 characters of message and decrypted text is compared by using Diffchecker online they are identical. The entropy values of the original and encrypted text are both approximately 2.47, indicating that the entropy values are consistent, which suggests effective encryption. The R3SX algorithm compared with other client side encryption algorithms that are given in fig. 3 and table 2. For testing purpose uses 512 x 512 standard lena image.

**TAaPL Framework**

The result of the TAaPL framework text encryption is given the graph 3. The TAaPL Framework is compared with other benchmark algorithms like AES, RSA, DES algorithms. The performance of the TAaPL Framework is given in fig. 4 and table 3.

## CONCLUSION AND FUTURE WORK

The cloud file storage is a huge storage of numerous types of files which is hold. The major issue is most of the CSP is not having own storage and CSP's are uses third party storage. Primary concern is how will provide the security for personal files. Common algorithm like AES256, DES for all the user files is not enough to secure the storages. The proposed framework may give better solution to secure the individual files of the data owner with help of R3SKT, R3SX, HASaRA algorithms, ticket admin and R3SKT Hash. The proposed framework is providing confidentiality of the user files. Data leakage is no possible in cloud storage because of dual cryptography ap-proach plays major role

on this work. R3SKT will be responsible for a client side secu-rity and server side taken care of HASaRA. The TAaPL'sticketadmin is responsible for user validity and port lock mechanism is preventing attacks on the server.

## ABSTRACT

This study compares ZigBee with other popular wireless communication protocols for the implementation of an automated unmanned railway crossing system. Unmanned railway crossings continue to pose significant safety challenges, especially in rural and semi-urban areas where manual supervision and sophisticated signaling infrastructure are limited. Wireless communication technologies offer a promising solution for developing automated crossing systems that are both reliable and cost-effective. The study compares the performance of ZigBee, which is based on the IEEE 802.15.4 standard, with that of Bluetooth (IEEE 802.15.1), Wi-Fi (IEEE 802.11), GSM, and LoRa technologies. The findings show that although Wi-Fi offers fast data speeds, it uses a lot of power and needs infrastructural support. Wide-area coverage is guaranteed by GSM, although it has higher latency and ongoing operating expenses. Bluetooth has minimal power consumption, but its network scalability and communication range are constrained. Although LoRa allows for low-power long-distance communication, its slower data rate and latency may make it unsuitable for time-sensitive control tasks. In every metric that was assessed, ZigBee's performance was balanced. It is especially well-suited for localized railway crossing automation because of its low power consumption, modest range, mesh networking capabilities, low latency, and affordability. ZigBee-based wireless architecture offers a dependable, scalable, and financially feasible alternative to improve safety at unmanned railroad crossings, according to the study's findings.

**Keywords:** Unmanned Railway Crossing, ZigBee, Bluetooth, Wi-Fi, LoRa, Sensors, Automation System.

## INTRODUCTION

The research problem and the larger context in which this work is located are introduced in this paper. Especially in developing nations like India, unmanned railway crossings continue to be among the most hazardous and antiquated components of train infrastructure. Intelligent, automatic crossing systems are now essential due to the growing number of trains and automobiles on the road. This chapter describes the main issues with current systems, explains why the research was conducted, and suggests the study's general goal and aims. To solve the problem, it also presents the idea of utilizing embedded microcontroller systems and ZigBee-based wireless communication. The research methods, the thesis organization, and the extent of the study are also presented in this paper.

**The Need for a Scalable, Real-Time Wireless Solution**

Given the drawbacks of current electrical systems and manual control, an intelligent, real-time, energy-efficient solution is obviously needed:

a. Sends signals wirelessly with low latency
b. Detects train arrival reliably
c. Is cost-effective and power-efficient for rural deployment
d. Controls barrier gates automatically

## AIM OF THE RESEARCH

Automatic railway gate control system is implemented to prevent traction accidents at railway crossing by utilizing the concept of multilevel sensor based controlling system. The technique materialized in a specific range along the railway track before and after the crossing gate. The range will depend upon average speed of trains passing through tracks present at crossing. The advent of trains at crossing will be conveyed through different significant means that are easily perceived by people passing through the crossing. The main goal of this research is to use multi-level wireless communication, primarily ZigBee technology, to design, implement, and assess a fully automated unmanned railway crossing system. Enhancing safety, reducing reliance on humans, and offering a scalable solution for broad implementation across India's rural and semi-urban railway crossings are the goals of the suggested system. This thesis aims to design, develop, and calibrate an automated railway crossing model using:

a. ZigBee wireless transmission
b. Arduino-based decision logic
c. LDR-based detection
d. Display and buzzer alert systems
e. Servo-actuated gate control

This study aims to improve safety, lessen reliance on human labor, and advance scalable smart infrastructure for Indian Railways by tackling the issue.

**Geographical and Environmental Limitations**

Only low-speed to moderate-speed railroad lines, which are frequently found in non-urban rail corridors, are included in the scope. The prototype is made to be deployed in open-field settings, taking into consideration changes in dust, light, and weather. It does not, however, take into consideration automated signaling systems run centrally by Indian Railways, multi-line rail crossings, or high-speed bullet trains.

## LITRATURE REVIEW

Literature reviews to compare different types of wireless protocols are as follows:

**Manual and Infrared-Based Systems**

Manual railway gate systems are still in use in many rural districts of India. An Automatic Railway Gate Controller system was developed by research like that done by Chandrappa *et al*. [1] to control railway gates without the need

for a gatekeeper. Two infrared obstacle detection sensors [2] detect the arrival and departure of trains, and a stepper motor controls the gate.To detect train arrival and departure at a railway crossing and control the opening and closing of the gates using servo motors, Vinit P. Kharkar [3] described a system that makes use of Infra-Red (IR) sensors and a Raspberry Pi.Dr. S. Anila, B. *et al.* [4] suggested a technique that can be utilized in isolated locations without a lineman or station master. The train will be positioned three kilometers from the level crossing on both sides, and two infrared sensors will be utilized to monitor its arrival and departure.

**GSM and GPS-Based Communication Models**

A GPS-based system was developed by Velayutham *et al*. [5] to track and identify the arrival of the train. The GPS is used to track the train, and Google Maps shows the rail tracks. Therefore, upon preparation, GPS is implanted into the flexible application [6].Mahdi and A. S. Al-Zuhairi [7], presents a model that uses an 8052 microcontroller to keep a safe distance from railroad accidents that occur at unattended rail route doors. Naga Hema Kumari V *et al*. [8] proposes a sensor-based system to lessen train-train accidents brought on by a communication breakdown between the rail traffic control office and the train operators.

**RFID, RF, and Ultrasonic Detection Approaches**

A method developed by Chandrappa S. *et al*. [9] uses four infrared sensors to identify trains. The distance between two infrared sensors and the railway crossing is seven and six kilometers, respectively. Only when the train is detected by both sensors within a predetermined amount of time will the gates at the level crossing close. This mechanism was in existence on both sides of the level crossing. An extra feature has been introduced for the convenience of the passengers: each train is assigned a unique RFID tag, and passengers are required to register their destination with it.

**Bluetooth, Rasberry Pi and Wi-Fi Communication Systems**

As recommended by E. Amarnatha Reddy *et al*. [10], the study's objective is to develop a prototype that operates a railway gate using a microcontroller. Every time the train arrives at the base at the sensor crossing, the public is informed at the railway crossing. The control gates are subsequently opened and closed by the control module. When the train arrives at the railroad crossing, automatic gates are opened. The logic was developed into embedded C and then transferred to the Raspberry Pi.

**IOT, LoRa and Cloud-Based Systems**

The Internet of Things (IoT) is the network of physical objects, including gadgets, automobiles, buildings, and different electronics, programming, and sensor-related products, that allow these objects to gather and exchange data [11]. Dhande *et al*. [12] [13] recommended employing a GPS module to capture geographic coordinates and a failing track and GSM modem to send the coordinates of a spot. P.C. Shruthi *et al*. [14] an effective Internet of Things-based solution involved placing two infrared sensors at a predefined distance to measure the train's speed and the time it took to reach the level crossing.

**AI-Enabled and Hybrid Systems**

Using image processing, Tastimur *et al*. [15] suggested a vision-based approach to preventing railroad accidents. The train had a camera installed to identify any impediments in the level crossing. A study on the causes and locations of rail elephant collisions was proposed by Mukti Roy *et al*. [16]. In order to develop an elephant hotspot map, the paper conducted surveys to determine the areas with the highest risk of mishaps. Liu Wei *et al*. [17] suggested a Feature Fusion Refine Neural Network-based Traffic Object Detection system. The study proposed a strategy to reduce train accidents that occur during the shunting mode due to human mistake in assessing railway conditions. Lokeshkumar R. and Omkar Vivek Sabnis [18] presented a technology that may be used for automation at a railway crossing. A camera has been installed at the railroad crossing for surveillance reasons.

**ZigBee-Based Wireless Embedded Systems**

The control of a railway level crossing is experimentalized by B. Kumar Sanjiv *et al*. [19]. The railway gates are opened and closed by means of DC motors that are controlled by the micro controller using ZigBee. Dr. I. M. Korachagaon *et al*. [20] used ZigBee technology to stop train accidents. ZigBee is a state-of-the-art technology with high-level communication protocols that are used to build personal area networks from small, low-power digital radios. Railway system automation using ZigBee technology was covered by P. Mehta *et al*. [21]. The study most likely investigates the use of ZigBee to automation activities in railway environments, such as monitoring train movements and regulating railway gates. A prototype controlled by ZigBee in real time was implemented by Arun Kumar Gangwar *et al*. [22]. The model combined ZigBee for wireless control with LDRs for detection and Arduino for logic processing. Even in the presence of changing environmental circumstances, this system showed strong communication and low latency. The calibration and performance analysis of a real-time ZigBee-controlled prototype, contrasting ZigBee with LoRa and GSM, is the main topic of Arun Kumar Gangwar *et al*. [23].

**Comparative Analysis of Protocols**

Table 2.1 provides a comparative overview of various wireless protocols and sensing mechanisms used in previous literature. The comparative analysis summarizes the range, power use, scalability, cost, real time suitability and limitations of various protocols.

**Comparative Analysis of Various Wireless Protocols (Table 1).**

ZigBee is the best-rounded and field-tested technology for automating unmanned railway crossings, according to a survey of 48 papers. ZigBee offers better dependability, affordability, and energy efficiency than IR, GSM, GPS, LoRa, or AI-based systems, especially in rural Indian settings. The system built in this thesis is based on the author's own published and validated research, which strongly supports the adoption of ZigBee for this application.

## METHODOLOGY AND IMPLEMENTATION OF WORK

The procedure used to design, construct, and evaluate the proposed unmanned railway crossing system is described in this chapter. It explains the components, detecting methods, wireless communication modules, system design, and general functional flow. The methodology's objectives are to provide precise train arrival detection, dependable control unit communication, and safe, automated railway gate operation devoid of human interaction.

**System Architecture Overview**

The proposed system is divided into three main units

**Detection Unit:** The detecting unit detects the arrival and departure of the train using Light Dependent Resistors (LDRs). Both sides of the track have LDRs installed to detect trains coming and departing.

**Communication Unit:** The communication unit uses ZigBee wireless modules to provide reliable, low-power, short-delay communication between sensors and the control unit in real-time.

**Control and Execution Unit:** The Arduino microcontroller serves as the foundation for the control and execution unit. The railway gate is opened and closed by means of servo motors controlled by an Arduino microcontroller. To warn cars and pedestrians, the control unit turns on a buzzer, display, and LED indicator. Block Diagram of the System Figure 1.

**Flow of Operation**

The operation follows the following steps:

a. A change in light intensity is used by the LDR circuit to identify an approaching train.
b. After receiving the signal, the Arduino board uses ZigBee to transmit wireless instructions.
**c. The receiving unit activates:**

i. Gate closure through servo motor control
ii. Audio alert via buzzer
iii. Visual display for train warning
d. Once the train departs, the second LDR confirms clearance.
e. Before opening, a time-delay circuit makes sure the gate stays closed for a few more seconds.
f. Alerts are turned off and the gate opens automatically.

**Developed Prototype**
To compare the different types of wireless protocols with ZigBee for automation of unmanned railway crossing, a prototype is developed as shown in figure 2.

**Developed Prototype (Figure 2).**
As per consideration of human life and time, we have proposed a prototype for the automatic control of the railway crossing barriers. On testing our project, we found that the sensing circuit properly detects the arrival of the train, and it responds to provide the pulse for LDR circuits that transmits the corresponding signal and it further activates the Arduino and it makes the all three circuits- buzzer, display and barrier circuit to ON. All these operations have been executed properly and the series LDR circuit senses the movement on the crossing of the people and vehicles by checking the continuity of infrared light projected on to all three LDRs which are connected in series. If any of the LDR is not receiving the infrared light, it gives high output at the crossing. In corresponding to the series LDR circuit output low or high, the motor either runs to close the barrier at high output or sends the signal to the train through which the train stops. After some delay, a signal is sent to manually close the barrier. Again, this operation has performed well accurately.

## RESULT AND ANALYSIS

In the above way I have tested the operation of our project and found that all the circuits are operating properly, and this technique will fulfil the requirements of modern people as time and life are very important for every person. By using ZigBee modules, I can also increase the range of transmission and increase the sensitivity of the project for signal detection. It can make my project more efficient.

## RESULTS AND OBSERVATIONS

**Train detection accuracy**
Twenty test runs were conducted. The system was able to detect the train successfully in 19 out of 20 test cycles.

**Train Detection Accuracy Table 2.**
**Accuracy** = 95%

**Gate actuation response time**
Average time taken between detection and complete gate closure:
**ZigBee System:** 2.36 seconds
**GSM (simulated):** 4.85 seconds
**LoRa (simulated):** 3.92 seconds
Gate Actuation Response Time with Different Protocols (Figure 3)
ZigBee takes lowest gate actuation response time in comparison to other protocols.

**Signal transmission delay**
Signal transmission delay of different protocols are as follows:

Signal Transmission Delay of Different Protocols (Table 3). Signal Transmission Delay of Different Protocols (Figure 4). ZigBee achieved lowest average transmission delay, confirming suitability for real-time applications.

**Communication reliability**

To check the communication reliability for different protocols the success rate are taken with the help of prototype over 50 test signals are as follows:

**ZigBee:** 98%
**GSM:** 84%
**LoRa:** 90%
**Wi-Fi:** 93%

Communication Reliability of Different Protocols (Figure 5).
ZigBee has the highest success rate of communication, over 50 test signals for different protocols.

**Power consumption**

Power drawn per cycle (sensor + TX + control) for different protocols are as follows:
Power Consumption for Different Protocols (Table 4). Power Consumption for Different Protocols (Figure 5).
ZigBee demonstrated high energy efficiency, ideal for rural deployment with limited power availability.

**Analysis and Interpretation**

Based on result analysis the interpretations are as follows:

a. ZigBee outperformed GSM, LoRa, and Wi-Fi in terms of response time, energy consumption, and reliability.
b. Detection accuracy of 95% proved that LDR sensors with shielding and calibration are effective for practical deployment.
c. Gate actuation within 2.5 seconds is well within the safety threshold for unmanned railway crossings.
d. Power use was low enough to support solar or battery-powered remote installations.
e. These findings confirm the suitability of ZigBee-based embedded automation for railway gate control, especially in semi-urban and rural areas.

## DISCUSSION

The system performed well across various test scenarios. ZigBee enabled stable communication even with minor interference. While the LDR-based detection was functional, enhancements with dual IR sensors or machine vision could further increase reliability. The time delay circuit introduced an extra safety buffer, making the system compliant with real-world safety protocols. The cost-effective and scalable nature of this design makes it suitable for mass deployment in semi-urban and rural rail crossings.

## CONCLUSION

This research presents the design, implementation, and validation of a fully automated unmanned railway crossing system using ZigBee wireless communication and embedded microcontrollers. The project aimed to address the persistent safety risks associated with unmanned railway crossings, particularly in rural and semi-urban areas, by developing a cost-effective, low-power, and real-time automated solution. The proposed system utilizes LDR sensors for train detection, Arduino UNO microcontrollers for signal processing, and ZigBee modules for wireless data transmission between detection and actuation units. A servo-controlled gate mechanism, along with audio-visual alerts, ensures that nearby road users are warned of incoming trains in advance, thereby enhancing overall public safety.

The prototype was experimentally tested under various simulated conditions. The key outcomes of the implementation are:

a. Train detection accuracy of 95%, validated over 20 test cycles

b. Gate actuation response time of 2.36 seconds, significantly lower than GSM or LoRa-based systems
c. Signal transmission reliability of 98% over ZigBee, with a minimal delay of 86 milliseconds
d. Energy efficiency, making it ideal for remote deployments powered by solar or batteries
e. Scalable and modular design, adaptable for multi-track or multi-sensor environments

The research findings align well with contemporary studies and support the claim that ZigBee is one of the most balanced and efficient protocols for wireless automation in transportation safety systems.

**ABSTRACT**

Karonda (*Carissa carandas*) is a fruit widely distributed in tropical and subtropical regions and is recognized for its considerable nutritional and medicinal significance. The fruit contains several bioactive phenolic constituents, among which gallic acid and chlorogenic acid are prominent due to their reported antimicrobial, anti-inflammatory, and antioxidant activities. Accurate quantification of these compounds is essential for phytochemical evaluation, quality control, and standardization of Karonda fruit and its derived formulations. High-performance liquid chromatography (HPLC) is widely accepted as a reliable and precise analytical technique for the determination of phenolic acids in complex plant matrices. This review compiles reported HPLC method development approaches, chromatographic conditions, sample preparation procedures, validation parameters, and analytical applications related to the estimation of gallic acid and chlorogenic acid in Karonda fruit. The article aims to serve as a comprehensive reference for researchers engaged in analytical and phytochemical investigations of *Carissa carandas*.

**Keywords:** Karonda, *Carissa carandas*, Chlorogenic acid, Gallic acid, HPLC, Method development, Phenolic acids

# INTRODUCTION

The antioxidant and medicinal qualities of plants are largely attributed to phenolic compounds, a significant class of secondary metabolites [1,2]. Due to their widespread presence in fruits and medicinal plants as well as their established health benefits, chlorogenic acid and gallic acid have drawn a lot of attention [3–5]. The underutilized fruit crop Karonda (*Carissa carandas L.*) which is a member of the Apocynaceae family, has long been utilised in Southeast Asian and Indian medicine [6,7]. The plant, which thrives in arid and semi-arid climates, is commonly found in parts of Africa, Southeast Asia, and India [8–10]. It yields tiny, berry-like fruits that are high in vital nutrients like dietary fibre, vitamins, and minerals [11,12]. The bioactivity of Karonda fruits is greatly enhanced by their high concentration of polyphenolic compounds, such as flavonoids and phenolic acids [13,14]. Numerous studies have suggested that these substances may provide protection against oxidative stress, which is linked to the aetiology of many chronic illnesses, such as cancer, diabetes, and cardiovascular disorders [15,16]. The fruit, which has a strong antioxidant potential, can be eaten raw or processed into pickles, jams, and drinks [17]. According to scientific research, the two main phenolic components of Karonda fruit are gallic acid and chlorogenic acid. Accurate estimation of these compounds requires the use of trustworthy analytical techniques. High-performance liquid chromatography (HPLC) is favoured over other analytical methods because of its sensitivity, specificity, and repeatability. The development of HPLC-based methods for estimating gallic acid and chlorogenic acid in Karonda fruit is the main topic of this review. The Carissa species has been widely used to treat a wide range of illnesses. Acidity, sores, flatulence, and indigestion are all signs of a weakened immune system. Diarrhoea, stomach problems, anorexia, intermittent fever, mouth ulcers, sore throat, syphilitic discomfort, burning sensations, scabies, and epilepsy are some of the human ailments. Vitamin C, dietary fibre, carbohydrates, lipids, proteins, and microelements are all abundant in Carissa fruits [17,18]. Traditionally, the majority of Carissa species have been used to treat a wide range of illnesses, including headaches, chest pain, rheumatism, gonorrhoea, stomach pain, syphilis, hepatitis, oedema, rabies, asthma, and heart conditions. The fruit significantly reduced blood sugar levels in diabetic rats, according to a 2013 study published in the Journal of Ethnopharmacology. According to a different study that was published in the same journal in 2014, karonda extract improved the liver function of rats.

**Botanical and Phytochemical Overview**

*Carissa carandas*, commonly known as Karonda, is a tropical and subtropical evergreen shrub belonging to the family Apocynaceae. It is widely distributed in India, Sri Lanka, Nepal, Bangladesh, and other Southeast Asian countries. The plant grows well in dry, arid, and semi-arid regions and is highly tolerant to drought conditions, making it suitable for cultivation in marginal lands. The plant is a dense, spiny shrub that typically grows up to 2–4 meters in height. It possesses strong, sharp thorns that act as a protective mechanism against herbivores. The leaves are simple, opposite, ovate to elliptic in shape, dark green, and leathery in texture. The glossy surface of the leaves helps reduce water loss through transpiration[19]. The flowers of Karonda are white to pinkish-white in color, fragrant, and star-shaped. They usually bloom during the warm season and are arranged in terminal cymes. The pleasant fragrance of the flowers attracts pollinators, facilitating reproduction[20]. The fruit is a berry that changes color as it matures. Initially, it is green, then turns pink or red, and finally becomes dark purple or nearly black when fully ripe. The fruit contains 2–8 small brown seeds embedded within the pulp. The pulp is juicy, acidic to sweet-sour in taste, and rich in bioactive compounds [21]. The variation in color during ripening indicates changes in phytochemical composition, especially anthocyanin accumulation. Karonda is cultivated both as a fruit crop and as a hedge plant due to its dense growth and thorny branches. It plays an important role in traditional medicine and is used in preparing pickles, jams, syrups, and chutneys. Karonda fruit is considered nutritionally and medicinally valuable because of its rich phytochemical profile. The fruit contains a variety of bioactive compounds, including phenolic acids, flavonoids, anthocyanins, tannins, alkaloids, and vitamins [22]. Phenolic acids are one of the major phytoconstituents present in Karonda fruit. Compounds such as gallic acid, caffeic acid, ferulic acid, and *p*-coumaric acid have been reported. These phenolic compounds are responsible for strong antioxidant activity and help in neutralizing free radicals. The concentration of phenolics may vary depending on ripeness and geographical origin[23]. Flavonoids such as quercetin, kaempferol, and rutin are also present in the fruit. These compounds exhibit anti-inflammatory,

antimicrobial, cardioprotective, and anticancer properties. Flavonoids contribute significantly to the therapeutic potential of the fruit. Anthocyanins are responsible for the red to purple coloration of ripe Karonda fruits. These pigments possess potent antioxidant properties and may help in preventing oxidative stress-related diseases. The anthocyanin content increases as the fruit ripens, which explains the color transformation from green to dark purple [24]. Karonda fruit contains tannins that contribute to its astringent taste, especially in unripe fruits. Tannins have antimicrobial and anti-diarrheal properties and are commonly associated with traditional medicinal uses. The fruit is a good source of vitamin C (ascorbic acid), which enhances immune function and acts as a natural antioxidant. It also contains iron, calcium, and phosphorus in moderate amounts. Due to its iron content, Karonda has been traditionally used to manage anemia. In addition to phenolics and flavonoids, the fruit may contain triterpenoids, glycosides, and organic acids. These compounds contribute to the fruit's pharmacological activities such as anti-diabetic, anti-inflammatory, hepatoprotective, and antimicrobial effects [25]. The rich phytochemical composition of *Carissa carandas* makes it valuable in traditional and modern medicine. The antioxidant activity of phenolic compounds helps in preventing cellular damage caused by free radicals. The antimicrobial activity supports its use in treating infections. The presence of iron and vitamin C enhances its nutritional significance. Several studies have correlated the phytochemical content of Karonda fruit with its biological activities, supporting its potential use in pharmaceutical and nutraceutical formulations. Among the phenolic acids, chlorogenic acid and gallic acid contribute significantly to the fruit's antioxidant activity and medicinal value.

**Chemical Characteristics(Fig 1 given below)**

**Chlorogenic Acid**

- Ester of caffeic acid and quinic acid
- Molecular weight: 354.31 g/mol
- Highly polar
- UV absorption maximum around 325 nm

**Gallic Acid**

Trihydroxy benzoic acid

- **Molecular weight:** 170.12 g/mol
- Strong UV absorption at 270–280 nm
- Their polarity and UV absorption properties make them suitable for analysis using reverse-phase HPLC with UV or diode array detection.

**Importance of Hplc in estimation of phenolic acids**

One of the most popular analytical methods for determining the amount of phenolic acids in plant matrices, such as gallic acid and chlorogenic acid, is high-performance liquid chromatography (HPLC) [24]. Efficient separation and precise quantification of structurally similar phenolic compounds are made possible by the technique's high resolution and sensitivity [25]. When examining complex plant materials, like the fruit of the Karonda (Carissa carandas), which contains a variety of interfering substances like sugars, organic acids, pigments, and other secondary metabolites, this is especially crucial[26]. HPLC reduces analysis time and solvent consumption by enabling the simultaneous estimation of several phenolic compounds within a single analytical run[27]. Additionally, the technique is very accurate and repeatable, which makes it appropriate for regular quality control and standardisation research[28]. Because it works well with polar compounds and aqueous mobile phases, reverse-phase HPLC (RP-HPLC) with C18 columns is the most widely used chromatographic mode for phenolic acid analysis[29]. As a result, RP-HPLC is now the recommended technique for determining the amount of gallic and chlorogenic acid in Karonda fruit.

**HPLC Method Development for Karonda Fruit**

The sample preparation procedure including collection, washing, drying, pulverization, extraction, filtration, and storage conditions. The preparation of standard solutions is described by accurately weighing the standard compound and dissolving it in suitable solvent to prepare stock and working solutions. The shorten extraction times

and increase extraction efficiency, advanced extraction methods like ultrasonication-assisted extraction have become more and more popular [30]. When thorough extraction is necessary, conventional techniques like Soxhlet extraction are also used[31]. Prior to analysis, the samples are usually filtered through 0.45 μm membrane filters to eliminate particulate matter and safeguard the HPLC column [32]. The chromatographic conditions are column type, mobile phase composition, flow rate, injection volume, detection wavelength, and run time. The procedure for preparation of calibration curve is described by injecting different concentrations and recording peak areas. The method validation includes linearity, LOD, LOQ, accuracy, precision, specificity, and robustness, along with acceptance criteria. Statistical analysis is described by expressing results as mean ± standard deviation and calculating %RSD. Thus, a properly developed and validated HPLC method ensures accurate quantification of bioactive compounds present in *Carissa carandas* fruit and supports its pharmaceutical, nutraceutical, and research applications.

**HPLC Method Development Parameters for Karonda Fruit**

The first step in method development is the selection of a suitable chromatographic column [33]. For the analysis of phenolic acids, flavonoids, and anthocyanins present in Karonda fruit, a reverse phase C18 column is commonly selected because it provides good retention and separation of moderately polar compounds [34]. A typical column dimension used is 250 mm × 4.6 mm with 5 μm particle size, which offers a balance between resolution and analysis time. The mobile phase is selected based on the polarity and solubility of the target compounds. Generally, a binary solvent system consisting of water containing 0.1% orthophosphoric acid or formic acid (as solvent A) and methanol or acetonitrile (as solvent B) is used [35]. The acidic modifier improves peak symmetry and reduces tailing of phenolic compounds. The separation may be carried out using either isocratic elution [36], where the mobile phase composition remains constant, or gradient elution, where the proportion of organic solvent gradually increases to achieve better separation of multiple components. The flow rate of the mobile phase is usually maintained at 1.0 mL per minute for analytical columns. A controlled and consistent flow rate ensures stable retention time and reproducible results. The detection wavelength is selected based on the maximum absorbance (λmax) of the analyte. Phenolic acids are generally detected at 254–280 nm, flavonoids at 280–360 nm, anthocyanins around 520–540 nm, and vitamin C near 245 nm [37]. A UV or Photodiode Array (PDA) detector is commonly used to monitor the separated peaks. The injection volume is typically maintained between 10 and 20 μl to avoid peak distortion or overloading of the column. The column temperature is maintained at approximately 25–30°C to improve reproducibility and reduce variation in retention time. The total run time is optimized to ensure complete elution of all compounds without unnecessary extension of analysis time[38,39].

**Applications of Hplc Estimation in Karonda Fruit**

High-Performance Liquid Chromatography (HPLC) is an advanced analytical technique widely used for the separation, identification, and quantification of phytochemical constituents present in medicinal plants and fruits. In the case of *Carissa carandas* (Karonda), HPLC plays a crucial role in analyzing its rich phytochemical profile and establishing its pharmaceutical and nutritional importance[41,42]. Karonda fruit is rich in phenolic acids, which are responsible for its strong antioxidant activity. HPLC allows precise separation and quantification of phenolic compounds such as gallic acid, caffeic acid, ferulic acid, and *p*-coumaric acid. By determining the exact concentration of these compounds, researchers can evaluate the antioxidant capacity of the fruit[43,44].. This is particularly important in pharmaceutical research where phenolic content is correlated with therapeutic potential. The deep red or purple colour of ripe Karonda fruit is due to anthocyanins. HPLC is used to separate and quantify individual anthocyanin compounds, which are natural antioxidants and natural food colorants[45,46].. This analysis is useful in food science research for evaluating the fruit's potential as a natural colouring agent and for studying its health benefits. Karonda fruit contains a significant amount of vitamin C. HPLC provides a reliable and accurate method for estimating ascorbic acid content. This estimation helps in determining the nutritional value of fresh fruits and processed products such as juices, jams, and syrups. It also assists in studying the stability of vitamin C during storage and processing. In herbal medicine and phytopharmaceutical industries, standardization is essential to ensure consistency and safety. HPLC is used to establish chromatographic fingerprints of Karonda fruit extracts[47,48] . These fingerprints help in identifying authentic samples and detecting adulteration. It ensures batch-to-batch consistency in herbal formulations and nutraceutical products. Flavonoids such as quercetin, kaempferol,

and rutin are bioactive compounds present in Karonda fruit[49]. HPLC enables accurate detection and quantification of these flavonoids even at low concentrations. The estimation of flavonoids helps in assessing anti-inflammatory, antimicrobial, and cardioprotective properties of the fruit. This application is valuable in developing nutraceutical formulations. HPLC is applied in stability studies to monitor the degradation of bioactive compounds over time. By analyzing samples stored under different conditions (temperature, humidity, light), can determine the shelf life of Karonda-based products. This is important for maintaining product efficacy and safety. HPLC data helps in correlating phytochemical concentration with biological activities such as antioxidant, antimicrobial, and antidiabetic effects[50,51]. Quantitative estimation allows researchers to identify which compound is primarily responsible for specific pharmacological actions. This supports evidence-based validation of traditional medicinal uses. In the food industry, HPLC estimation is used for nutritional labeling and quality assessment. It helps detect synthetic additives or contaminants and ensures that the product meets regulatory standards [52,53]. It also assists in evaluating changes in phytochemical content during processing and storage. These include the creation of nutraceutical and functional food products, standardization of herbal formulations, and quality control of raw fruit ingredients[54]. Additionally, quantitative analysis of phenolic acids supports antioxidant, pharmacological, and stability studies, thereby validating the therapeutic potential of Karonda fruit[55].

## CHALLENGES AND FUTURE PERSPECTIVES

One of the major challenges in the HPLC analysis of *Carissa carandas* fruit is the complexity of its phytochemical composition. The fruit contains a wide variety of phenolic acids, flavonoids, anthocyanins, organic acids, and vitamin C, which may co-elute during chromatographic separation [56]. Achieving complete resolution of all compounds within a reasonable run time requires careful optimization of mobile phase composition, gradient program, and column selection. Another important challenges are variability in phytochemical content due to geographical location, climatic conditions, soil type, and stage of ripeness. Fruits collected from different regions or harvested at different maturity stages may show significant variation in phenolic and anthocyanin content[57]. This variability makes standardization difficult and requires comprehensive sampling and validation. The instability of certain bioactive compounds also poses a challenge. Anthocyanins and vitamin C are highly sensitive to light, temperature, oxygen, and pH changes. Improper sample handling or storage can lead to degradation, resulting in inaccurate quantification. Therefore, strict control of storage conditions and rapid analysis is essential. Matrix interference is another limitation in plant extract analysis. The presence of sugars, organic acids, pigments, and other secondary metabolites may interfere with detection and affect peak purity[58,59].. Additional sample cleanup procedures such as solid-phase extraction may be required to improve specificity. Instrumental factors such as column deterioration, fluctuation in detector sensitivity, and mobile phase contamination can also affect reproducibility. Regular system suitability testing and maintenance are necessary to ensure consistent performance. Cost and availability of high-purity reference standards represent another practical challenge.

Some phytochemicals present in Karonda fruit may not be commercially available as pure standards, which limits accurate identification and quantification. Future research can focus on the development of more advanced chromatographic techniques such as UHPLC (Ultra High Performance Liquid Chromatography) [60,61], which offers better resolution, shorter run time, and improved sensitivity compared to conventional HPLC. Coupling HPLC with mass spectrometry (LC–MS/MS) [62] can enhance compound identification and enable detection of minor constituents in complex plant matrices. There is scope for developing validated fingerprinting methods for standardization of *Carissa carandas* extracts. Chromatographic fingerprinting can serve as a quality control tool in herbal drug manufacturing and nutraceutical industries. Further studies may explore comparative phytochemical profiling of fruits collected from different geographical regions to establish chemotypic variations. This can help in selecting high-yield varieties for pharmaceutical applications[63,64]. Research can also focus on bioactivity-guided fractionation, where HPLC is used to isolate specific compounds responsible for antioxidant, antimicrobial, antidiabetic, or anti-inflammatory activities [65-68]. Such studies may lead to the development of novel phytopharmaceutical agents. In addition, the application of green analytical chemistry principles, such as the use of

eco-friendly solvents and reduced solvent consumption, can be considered for sustainable analytical practices[69,70]. Development of stability-indicating methods for processed products such as juices, syrups, and nutraceutical formulations prepared from Karonda fruit will further enhance its industrial applicability. We review some of the parameters related to gallic acid and chlorogenic acid extraction and they are given in the following table1 and 2. Parameters of Gallic acid Extraction from Various Plants and Tablet (Table 1). Parameters of Chlorogenic acid Extraction from Various Plants and Tablet (Table 2).

## CONCLUSION

The present review successfully established a reliable and validated RP-HPLC method for the comprehensive profiling and simultaneous quantification of major phenolic acids present in *Carissa carandas* fruit. The developed chromatographic conditions provided efficient separation of targeted phenolic compounds with good peak resolution, symmetrical peak shapes, and stable retention times. The method demonstrated high specificity, as no significant interference from other phytoconstituents or matrix components was observed at the retention times of the selected analytes. The developed RP-HPLC method successfully enabled comprehensive profiling and simultaneous quantification of major phenolic acids present in *Carissa carandas* fruit. The method showed good peak resolution, excellent linearity, high sensitivity, and satisfactory accuracy and precision as per validation guidelines. The presence of significant levels of phenolic acids confirms the strong antioxidant potential of the fruit and supports its medicinal value. The method is simple, reliable, and suitable for routine quality control and standardization of Karonda fruit extracts and related formulations. Reliable quantification is ensured by appropriate chromatographic condition optimisation and adherence to validation guidelines, supporting the standardisation, quality control, and scientific application of Karonda fruit in the food and pharmaceutical industries.

## ACKNOWLEDGEMENT

The authors express their sincere gratitude to the Management and Principal of Chalapathi Institute of Pharmaceutical Sciences, Guntur, for providing the necessary laboratory facilities and continuous encouragement to carry out this work. The authors are thankful to the Department of Pharmaceutical Analysis for providing access to the HPLC instrumentation and analytical support required for the study.

## ABSTRACT

Soft set theory and neutrosophic set theory are tools to model uncertainty, vagueness and indeterminacy of complex systems. Many extensions have been developed to enhance the descriptive capabilities of each framework, such as hypersoft, superhypersoft, and interval valued neutrosophic sets. This paper introduces a new fusion design called Interval Valued Neutrosophic SuperHyperSoft Set (IVNSHSS) which integrates interval valued neutrosophic data with superhyperparameterization; the elements are seen as ordered pairs via the Cartesian product of the power set of the attribute domains. Several basic concepts in relation to IVNSHSS are established, such as null and universal sets, complement, union, intersection, difference, scalar operations, truth-favor and false-favor operations; and the necessity operator and possibility operator will also be defined with their associated algebraic characteristics. Throughout the paper, illustrations and propositions will be provided as examples in support of the proposed framework's use as an improved and comprehensive approach towards managing multi-attribute based uncertainty and making decisions and analyzing data in information systems.

**Keywords:** Soft set; Neutrosophic Set; Interval-valued neutrosophic set; Hypersoft set; Interval valued neutrosophic superhypersoft set.

## INTRODUCTION

The challenge of modeling unknowns or incomplete knowledge exists across several disciplines including decision-making processes, artificial intelligence systems, recorded medical diagnosis and data processing methods. Conventional mathematics typically cannot adequately capture the range of uncertainties and vagueness associated with such problems as both are forms of uncertainty that apply to those types of problems. In 1999, Molodtsov [8] proposed the use of soft set theory as a mathematical framework for allocating with non-material data by applying multiple properties for each item of data instead of relying solely on auxiliary constructs such as membership functions. Subsequent to the introduction of soft sets, many researchers have further generalized and integrated soft sets into other types of uncertainty modeling techniques. Some researchers have integrated soft sets with fuzzy sets [12] and intuitionistic fuzzy sets [3] to increase their representation power. Smarandache [9] later developed neutrosophic sets which allow for characterization of the different source of uncertainty using three distinct membership functions (truth, indeterminacy and falsehood). Subsequently, a new class of neutrosophic sets has been developed, referred to as interval-valued neutrosophic sets, which allows for representing an entire range of degrees of membership in an extremely flexible and robust manner thereby providing a more comprehensive model for representing uncertainty in all of its various manifestations. Hypersoft sets expand upon the limitations of single-parameter soft sets by allowing for a tuple of values to represent multiple parameters, rather than just one [10]. A further extension of this theory, superhypersoft sets, use the Cartesian product of the collection of all possible subsets of the attribute domains to model more complicated attribute interactions [2]. This paper presents a new unified structure called the 'Interval-Valued Neutrosophic SuperHyperSoft Set' (IVNSHSS), which combines interval-valued neutrosophic sets with superhyper parameterization. By merging both concepts together, the proposed structure allows for an enhanced representation of uncertainty through the use of interval-valued neutrosophic data with parenthesized combinations of subsets of attribute values. The three major accomplishments of this paper include: 1) the formal definition of the IVNSHSS; 2) the identification of the basic operations and operators of the IVNSHSS; and 3) the presentation of several illustrative examples demonstrating the property of key algebraic relationships established in this paper.

## LITERATURE REVIEW

Soft Sets (Molodtsov [8]) is a way to quantify uncertainty without making extra assumptions. Since then it has been a base for expanding methods of uncertainty in decision-making; Specific examples are fuzzy soft sets [6] and intuitionistic fuzzy soft sets [7], which incorporate membership functions for representing partial truth values, while preserving the parameterized feature of soft sets. Neutrosophic Set Theory (Smarandache [9]) builds upon fuzzy and intuitionistic fuzzy sets by defining three components of membership independently, namely: Truth, Indeterminate, and False. Neutrosophic sets have been implemented to various applications of their own: Most common would be those such as Decision Making, Image Processing, and Data Mining. Wang *et al.* [11], wanted to extend these applications to represent ambiguous values to the next level, proposed Interval Valued Neutrosophic Sets. In doing this, the values for each of the three components can be represented using intervals, as opposed to standard integer or numerical values. A variety of hybrid systems such as neutrosophic soft sets, neutrosophic-soft-interval-valued-sets, and neutrosophic-hypersoft-sets [5,4,1] includes integrating neutrosophic theory with soft and hyper-soft sets. These system attempts to combine both methods of portraying uncertainty and adding a supplementary attribute to the existing structures. In regards to the combination of super-neutrosophic-hyperparameterization-in-ing and interval-valued-neutrosophic-information, there is insufficient literature documenting this hybridization. This study proposes to create an IVNSHSS, which will bridge this gap in research by the establishment of a framework that can accommodate all forms of multi-attribute uncertainty within a previously existing model using interval-valued neutrosophic-information; thus increasing the breadth and depth of current studies related to soft computing and uncertainty.

## PRELIMINARIES

**Definition 3.1**

The set (F, Λ) is called a soft set of the universe 𝕌, if and only if there exists a mapping F: Λ → $P(\mathbb{U})$, from the indexing set Λ to the power set of 𝕌, therefore providing a parameterized collection of subsets of 𝕌.

**Definition 3.2**

Let us denote a universal set as 𝕌 and construct an interval valued neutrosophic set represented by the interval valued set A= {<u,$u_A(u), v_A(u), w_A(u)$> : $\boldsymbol{u}\in\mathbb{U}$}, where $u_A, v_A$and $w_A$are truth, indeterminacy and falsity membership functions for A respectively, $\boldsymbol{u}u_A, v_A$ and $w_A\subseteq$ [0, 1] for each u∈𝕌. Where

$u_A(u) = [u_A^L(u), u_A^U(u)]$

$v_A(u) = [v_A^L(u), v_A^U(u)]$

$w_A(u) = [w_A^L(u), w_A^U(u)]$

For each point $\boldsymbol{u}$u∈𝕌, $0 \le u_A(u), +v_A(u) + w_A(u) \le 3$ and IVN(𝕌) represents the complete collection of interval valued neutrosophic sets..

**Definition 3.3**

For set𝕌to be a universal set then the power set of𝕌denoted by$P(\mathbb{U})$ exists. Suppose we have n distinct attributes denoted by$k_1, k_2, \ldots, k_n$and n sets corresponding to these distinct attributes denoted by$K_1, K_2, .., K_n$. with following conditions such as $K_i \cap K_j = \emptyset$ $(i \neq j)$ and $i, j\epsilon$ {1,2,3 … $n$}. Then the pair (F, $K_1 \times K_2 \times \ldots \times K_n$) is said to be HSS over 𝕌 where F is a mapping from $K_1 \times K_2 \times \ldots \times K_n$ to $P(\mathbb{U})$.

**Definition 3.4**

Let us define a Universal Set called 𝕌and the Power Set of 𝕌 is represented by the notation$P(\mathbb{U})$ and for $n \ge 1$, there are $n$ distinct attributes such as $k_1, k_2, \ldots, k_n$ and$K_1, K_2, .., K_n$ are sets for corresponding values attributes respectively with conditions such as $K_i \cap K_j = \emptyset$ $(i \neq j)$ and $i, j\epsilon$ {1,2,3 … $n$}. Then the pair (F, Λ) is said to be NHSS over 𝕌 if there exists a relation $K_1 \times K_2 \times \ldots \times K_n) = \Lambda$. F is a mapping from $K_1 \times K_2 \times \ldots \times K_n)$ to $P(\mathbb{U})$ and F($K_1 \times K_2 \times \ldots \times K_n$)) = {<$u, u_A(u), v_A(u), w_A(u)$> : u∈𝕌} where $u$ , $v$ , $w$ are Membership values are to represent truth, unclear and false respectively such that $u, v, w$: 𝕌 → $]0^-, 1^+[$ and $0^- \le u_A(u), +v_A() + w_A(u) \le 3^+$.

**Definition 3.5**

Let Δ be a universe of discourse, P(𝕌) the powerset of 𝕌, and $k_1, k_2, \ldots\ldots, k_n$ (n ≥ 1) distinct attributes with disjoint corresponding sets $K_1, K_2, \ldots\ldots, K_n$. Let P($K_i$) denote the powerset of $K_i$for i ∈ {1, 2, . . . , n}.

A Neutrosophic SuperHyperSoft Set (NSHSS) over 𝕌 is defined as the pair

(S, P($K_1$) × P($K_2$) × · · · × P($K_n$)) , where S : P($K_1$) × P($K_2$) × · · · × P($K_n$)→ P(𝕌), and

S = {$\alpha, \langle x, T_{s(\alpha)}(x), I_{s(\alpha)}(x), F_{s(\alpha)}(x)\rangle$: x ∈𝕌, $\alpha$ ∈P($K_1$) × P($K_2$) × · · · × P($K_n$)}.

Here, $T_{s(\alpha)}(x), I_{s(\alpha)}(x), F_{s(\alpha)}(x)$ : 𝕌 → [0, 1] represent the membership, indeterminacy, and non-membership degrees of x ∈𝕌 for each$\alpha$, satisfying $0 \le \left(T_{s(\alpha)}(x), I_{s(\alpha)}(x), F_{s(\alpha)}(x)\right) \le 3$.

**Intervalued Neutrosophic superhyper soft set**

**Definition 4.1**

Let $U$denote a nonempty universal set, and let P($U$) denote the power set of $U$. Let $n$ denote number of attributes and $k_1, k_2, \ldots\ldots, k_n$ denote $n$ distinct attributes. Let $K_1, K_2, \ldots\ldots, K_n$be the corresponding sets of attribute values such that,$K_i \cap K_j = \emptyset$ for $i \neq j$ where $i, j \in \{1, 2, \ldots, n\}$. Let $P(K_i)$ denote the powerset of $K_i$ for each $i$.and define the superhyper parameter set as$A = P(K_1) \times P(K_2) \times \ldots\ldots \times P(K_n)$. A pair $(F, A)$is called an Interval-Valued Neutrosophic SuperHyperSoft set (IVNSHSS) definedon$U$, where $F: A \rightarrow P(U \times [0,1]^3)$

$F_P = \{\langle u, [\alpha_P^L(u), \alpha_P^U(u)], [\beta_P^L(u), \beta_P^U(u)], [\gamma_P^L(u), \gamma_P^U(u)]\rangle : u \in U\}$

where $[\alpha_P^L(u), \alpha_P^U(u)], [\beta_P^L(u), \beta_P^U(u)], [\gamma_P^L(u), \gamma_P^U(u)]$ represent the truth, indeterminacy, and falsity membership degrees of the element $u$ concerning the parameter tuple $P$ . The intervals are subsets of $[0,1]$and satisfy$0 \leq sup\ \alpha_P(u) + sup\ \beta_P(u) + sup\ \gamma_P(u) \leq 3$ for all $u \in U$.

**Example 1**

Let $U = \{x_1, x_2\}$be the universe of discourse. Consider two distinct attributes:

$\boldsymbol{k_1}$= Color, with attribute domain $K_1$={Red,Blue},

$\boldsymbol{k_2}$= Size, with attribute domain $K_2$={Small,Large}.

The sets $K_1$ and $K_2$ are disjoint. We consider the power sets of each domain:

$P(K_1) = \{\emptyset, \{Red\}, \{Blue\}, \{Red,\ Blue\}\}$,

$P(K_2) = \{\emptyset, \{Small\}, \{Large\}, \{Small,\ Large\}\}$.

Cartesian product of power sets:

$A = P(K_1) \times P(K_2)$

There 4*4 =16 possible

For illustration, consider two such tuples

$\alpha_1 = (\{Red\}, \{Small\})$

$\alpha_2 = (\{Red,\ Blue\}, \{Large\})$

For each $\alpha \in A$, we define$F(\alpha)$ assigns a set of interval-valued neutrosophic triples to elements of $U$, which in turn consists of three distinct intervals indicating how much true membership, indeterminate membership and false membership each element has in U. More precisely,,

for $\alpha_1$ we have

$F(\alpha_1) = \{\langle x_1, [0.6,0.8], [0.1,0.2], [0.1,0.3]\rangle, \langle x_2, [0.4,0.6], [0.2,0.3], [0.2,0.4]\rangle\}$

for $\alpha_2$ we have

$F(\alpha_2) = \{\langle x_1, [0.7,0.9], [0.1,0.2], [0.0,0.1]\rangle, \langle x_2, [0.5,0.7], [0.2,0.3], [0.1,0.2]\rangle\}$

For each$x \in U$, the supremum of the truth, indeterminacy, and falsity intervals satisfies the condition $0 \leq sup\ \alpha_a(u) + sup\ \beta_a(u) + sup\ \gamma_a(u) \leq 3$ for example, for $x_1$ under $\alpha_1$, 0.8 + 0.2 + 0.3 = 1.3 ≤ 3 and for $x_2$ under$\alpha_2$, 0.7 + 0.3 + 0.2 = 1.2 ≤ 30. Thus, $F$ defines an Interval-Valued Neutrosophic SuperHypersoft Set (IVNSHSS) on$U$ over the Cartesian product of the power sets of the attribute domains.

**Definition 4.2**

Let $F_P$ and $G_Q$ ∈ IVNSHSS over$U$, then $F_P \subseteq G_Q$ if

$inf\alpha_P(u) \leq inf\alpha_Q(u)$ , $sup\alpha_P(u) \leq su\alpha_Q(u)$

$inf\beta_P(u) \geq inf\beta_Q(u)$ , $sup\beta_P(u) \geq sup\beta_Q(u)$

$inf\gamma_P(u) \geq inf\gamma_Q(u)$ , $supy_P(u) \geq supy_Q(u)$

**Example 2**

Let the universe of discourse be$\boldsymbol{U} = \{\boldsymbol{u_1}, \boldsymbol{u_2}\}$

$\boldsymbol{F_P} = \{\langle \boldsymbol{u_1}, [\boldsymbol{0.3}, \boldsymbol{0.5}], [\boldsymbol{0.4}, \boldsymbol{0.6}], [\boldsymbol{0.2}, \boldsymbol{0.3}]\rangle, \langle \boldsymbol{u_2}, [\boldsymbol{0.2}, \boldsymbol{0.4}], [\boldsymbol{0.3}, \boldsymbol{0.5}], [\boldsymbol{0.3}, \boldsymbol{0.4}]\rangle\}$

$\boldsymbol{G_Q} = \{\langle \boldsymbol{u_1}, [[\boldsymbol{0.4}, \boldsymbol{0.6}], [\boldsymbol{0.3}, \boldsymbol{0.5}], [\boldsymbol{0.1}, \boldsymbol{0.3}]\rangle, \langle \boldsymbol{u_2}, [\boldsymbol{0.3}, \boldsymbol{0.5}], [\boldsymbol{0.2}, \boldsymbol{0.4}], [\boldsymbol{0.2}, \boldsymbol{0.4}]\rangle\}$

**Thus $\boldsymbol{F_P \subseteq G_Q}$.**

**Definition 4.3**

Let $\boldsymbol{F_P}$ ∈ IVNSHSS defined over the universe$\boldsymbol{U}$, then

Empty IVNSHSS can be represented as $\boldsymbol{F_e}$which is defined as follows

$\boldsymbol{F_e} = \{\langle \boldsymbol{u}, [\boldsymbol{0}, \boldsymbol{0}], [\boldsymbol{1}, \boldsymbol{1}], [\boldsymbol{1}, \boldsymbol{1}]\rangle : \mathbf{u} \in \boldsymbol{U}\}$

Empty IVNSHSS can be represented as $\boldsymbol{F_\vartheta}$this representation is defined as follows

$\boldsymbol{F_\vartheta} = \{\langle \boldsymbol{u}, [\boldsymbol{1}, \boldsymbol{1}], [\boldsymbol{0}, \boldsymbol{0}], [\boldsymbol{0}, \boldsymbol{0}]\rangle : \mathbf{u} \in \boldsymbol{U}\}$

The complement of $\boldsymbol{IVNSHSS}$ can be represented as $\boldsymbol{F_P^C(p_1)}$ and defined as follows

$\boldsymbol{F_P^C} = \{\langle \boldsymbol{u}, [\boldsymbol{\gamma_P^L(u)}, \boldsymbol{\gamma_P^U(u)}], [\mathbf{1} - \boldsymbol{\beta_P^U(u)}, \mathbf{1} - \boldsymbol{\beta_P^L(u)}], [\boldsymbol{\alpha_P^L(u)}, \boldsymbol{\alpha_P^U(u)}]\rangle : \mathbf{u} \in \boldsymbol{U}\}$

**Example 3**

Let the universe of discourse be $\boldsymbol{U} = \{\boldsymbol{u_1}, \boldsymbol{u_2}\}$ a\

$\boldsymbol{F_P} = \{\langle \boldsymbol{u_1}, [\mathbf{0.3}, \mathbf{0.5}], [\mathbf{0.4}, \mathbf{0.6}], [\mathbf{0.2}, \mathbf{0.3}]\rangle, \langle \boldsymbol{u_2}, [\mathbf{0.2}, \mathbf{0.4}], [\mathbf{0.3}, \mathbf{0.5}], [\mathbf{0.3}, \mathbf{0.4}]\rangle\}$

The complement $\boldsymbol{F_P^c}(\boldsymbol{p_1})$ of IVNSHSS is

$\boldsymbol{F_P^C} = \{\langle \boldsymbol{u_1}, [\mathbf{0.2}, \mathbf{0.3}], [\mathbf{0.4}, \mathbf{0.6}], [\mathbf{0.3}, \mathbf{0.5}]\rangle, \langle \boldsymbol{u_2}, [\mathbf{0.3}, \mathbf{0.4}], [\mathbf{0.5}, \mathbf{0.7}], [\mathbf{0.2}, \mathbf{0.4}]\rangle\}$

**Propoition 1**

If $F_P \in$ IVNSHSS over $U$, then

1. $\left(\boldsymbol{F_P^C}\right) = \boldsymbol{F_P}$
2. $(\boldsymbol{F_e})^{\boldsymbol{C}} = \boldsymbol{F_\vartheta}$
3. $(\boldsymbol{F_\vartheta})^{\boldsymbol{C}} = \boldsymbol{F_e}$

**Proof:**

Let $\boldsymbol{F_P} = \{\langle \boldsymbol{u}, [\boldsymbol{\alpha_P^L}(\boldsymbol{u}), \boldsymbol{\alpha_P^U}(\boldsymbol{u})], [\boldsymbol{\beta_P^L}(\boldsymbol{u}), \boldsymbol{\beta_P^U}(\boldsymbol{u})], [\boldsymbol{\gamma_P^L}(\boldsymbol{u}), \boldsymbol{\gamma_P^U}(\boldsymbol{u})]\rangle : \mathbf{u} \in \boldsymbol{U}\}$ be an IVNSHSS. From the definition 1.3(iii )

$\boldsymbol{F_P^C} = \{\langle \boldsymbol{u}, [\boldsymbol{\gamma_P^L}(\boldsymbol{u}), \boldsymbol{\gamma_P^U}(\boldsymbol{u})], [\mathbf{1} - \boldsymbol{\beta_P^U}(\boldsymbol{u}), \mathbf{1} - \boldsymbol{\beta_P^L}(\boldsymbol{u})], [\boldsymbol{\alpha_P^L}(\boldsymbol{u}), \boldsymbol{\alpha_P^U}(\boldsymbol{u})]\rangle : \mathbf{u} \in \boldsymbol{U}\}$

Thus

$$\left(\boldsymbol{F_P^C}\right)^{\boldsymbol{C}} = \left\{\langle \boldsymbol{u}, [\boldsymbol{\alpha_P^L}(\boldsymbol{u}), \boldsymbol{\alpha_P^U}(\boldsymbol{u})], \left[\mathbf{1} - \left(\mathbf{1} - \boldsymbol{\beta_P^U}(\boldsymbol{u})\right), -\left(\mathbf{1} - \boldsymbol{\beta_P^L}(\boldsymbol{u})\right)\right], [\boldsymbol{\gamma_P^L}(\boldsymbol{u}), \boldsymbol{\gamma_P^U}(\boldsymbol{u})]\rangle : \mathbf{u} \in \boldsymbol{U}\right\}$$

$\left(\boldsymbol{F_P^C}\right)^{\boldsymbol{C}} = \{\langle \boldsymbol{u}, [\boldsymbol{\alpha_P^L}(\boldsymbol{u}), \boldsymbol{\alpha_P^U}(\boldsymbol{u})], [\boldsymbol{\beta_P^L}(\boldsymbol{u}), \boldsymbol{\beta_P^U}(\boldsymbol{u})], [\boldsymbol{\gamma_P^L}(\boldsymbol{u}), \boldsymbol{\gamma_P^U}(\boldsymbol{u})]\rangle : \mathbf{u} \in \boldsymbol{U}\}$

$\left(\boldsymbol{F_P^C}\right)^{\boldsymbol{C}} = \boldsymbol{F_P}$

It is know that$\boldsymbol{F_e} = \{\langle \boldsymbol{u}, [\mathbf{0}, \mathbf{0}], [\mathbf{1}, \mathbf{1}], [\mathbf{1}, \mathbf{1}]\rangle : \mathbf{u} \in \boldsymbol{U}\}$

By definition 1.3(iii )

$(\boldsymbol{F_e})^{\boldsymbol{C}} = \{\langle \boldsymbol{u}, [\mathbf{1}, \mathbf{1}], [\mathbf{0}, \mathbf{0}], [\mathbf{0}, \mathbf{0}]\rangle : \mathbf{u} \in \boldsymbol{U}\} = \boldsymbol{F_\vartheta}$

Similar.

**Definition 4.4**

Let $\boldsymbol{F_P}$ and $\boldsymbol{G_Q} \in$ IVNSHSS over $\boldsymbol{U}$, then

$$\boldsymbol{F_P} \cup \boldsymbol{G_Q} = \left\{ \begin{array}{c} (< u, [\boldsymbol{max}\{\inf \boldsymbol{\alpha_P}(\boldsymbol{u}), \boldsymbol{inf\alpha_Q}(\boldsymbol{u})\}, \boldsymbol{max}\{\boldsymbol{sup\alpha}(\boldsymbol{u}), \boldsymbol{sup\alpha_Q}(\boldsymbol{u})\}], \\ [\boldsymbol{min}\{\boldsymbol{inf\beta_P}(\boldsymbol{u}), \boldsymbol{inf\beta_Q}(\boldsymbol{u})\}, \boldsymbol{min}\{\boldsymbol{sup\beta_P}(\boldsymbol{u}), \boldsymbol{sup\beta_Q}(\boldsymbol{u})\}], \\ [\boldsymbol{min}\{\boldsymbol{inf\gamma_P}(\boldsymbol{u}), \boldsymbol{inf\gamma_Q}(\boldsymbol{u})\}, \boldsymbol{min}\{\boldsymbol{sup\gamma_P}(\boldsymbol{u}), \boldsymbol{sup\gamma_Q}(\boldsymbol{u})\}] >) / \boldsymbol{u} \in \boldsymbol{U} \end{array} \right\}$$

**Example 4**

Let the universe be $\boldsymbol{U} = \{\boldsymbol{u_1}, \boldsymbol{u_2}\}$. Let $\boldsymbol{F_P}$ and $\boldsymbol{G_Q} \in$ IVNSHSS over $\boldsymbol{U}$.

$\boldsymbol{F_P} = \{\langle \boldsymbol{u_1}, [\mathbf{0.2}, \mathbf{0.4}], [\mathbf{0.3}, \mathbf{0.5}], [\mathbf{0.4}, \mathbf{0.6}]\rangle, \langle \boldsymbol{u_2}, [\mathbf{0.5}, \mathbf{0.7}], [\mathbf{0.2}, \mathbf{0.4}], [\mathbf{0.3}, \mathbf{0.5}]\rangle\}$

$\boldsymbol{G_Q} = \{\langle \boldsymbol{u_1}, [\mathbf{0.3}, \mathbf{0.6}], [\mathbf{0.2}, \mathbf{0.4}], [\mathbf{0.3}, \mathbf{0.5}]\rangle, \langle \boldsymbol{u_2}, [\mathbf{0.4}, \mathbf{0.6}], [\mathbf{0.3}, \mathbf{0.5}], [\mathbf{0.2}, \mathbf{0.4}]\rangle\}$

$\boldsymbol{F_P} \cup \boldsymbol{G_Q} = \{\langle \boldsymbol{u_1}, [\mathbf{0.3}, \mathbf{0.6}], [\mathbf{0.2}, \mathbf{0.4}], [\mathbf{0.3}, \mathbf{0.5}]\rangle, \langle \boldsymbol{u_2}, [\mathbf{0.5}, \mathbf{0.7}], [\mathbf{0.2}, \mathbf{0.4}], [\mathbf{0.2}, \mathbf{0.4}]\rangle\}$

**Preposition 2**

Let $\boldsymbol{P}$ , $\boldsymbol{G_Q}$, $\boldsymbol{H_R} \in$ IVNSHSS over $\boldsymbol{U}$, then

1. $\boldsymbol{F_P} \cup \boldsymbol{F_P} = \boldsymbol{F_P}$
2. $\boldsymbol{F_P} \cup \boldsymbol{F_e} = \boldsymbol{F_P}$
3. $\boldsymbol{F_P} \cup \boldsymbol{F_\vartheta} = \boldsymbol{F_\vartheta}$
4. $\boldsymbol{F_P} \cup \boldsymbol{G_Q} = \boldsymbol{G_Q} \cup \boldsymbol{F_P}$
5. $\left(\boldsymbol{F_P} \cup \boldsymbol{G_Q}\right) \cup \boldsymbol{H_R} = \boldsymbol{F_P} \cup \left(\boldsymbol{G_Q} \cup \boldsymbol{H_R}\right)$

**Proof:** The proof follows directly from the definition.

**Definition 4.5**

Let $\boldsymbol{F_P}$ and $\boldsymbol{G_Q} \in$ IVNSHSS on$\boldsymbol{U}$, then

$$\boldsymbol{F_P} \cap \boldsymbol{G_Q} = \left\{ \begin{matrix} (< u, [\boldsymbol{min}\{\inf \boldsymbol{\alpha_P}(u), \boldsymbol{inf\alpha_Q}(u)\}, \boldsymbol{min}\{\boldsymbol{sup\alpha_P}(u), \boldsymbol{sup\alpha_Q}(u)\}], \\ [\boldsymbol{max}\{\boldsymbol{inf\beta_P}(u), \boldsymbol{inf\beta_Q}(u)\}, \boldsymbol{max}\{\boldsymbol{sup\beta_P}(u), \boldsymbol{sup\beta_Q}(u)\}], \\ [\boldsymbol{max}\{\boldsymbol{inf\gamma_P}(u), \boldsymbol{inf\gamma_Q}(u)\}, \boldsymbol{max}\{\boldsymbol{sup\gamma_P}(u), \boldsymbol{sup\gamma_Q}(u)\}] >) / \boldsymbol{u} \in \boldsymbol{U} \end{matrix} \right\}$$

**Example 5**

Let the universe be $\boldsymbol{U} = \{\boldsymbol{u_1}, \boldsymbol{u_2}\}$. Let $\boldsymbol{F_P}$ and $\boldsymbol{G_Q} \in$ IVNSHSS over $U$.

$\boldsymbol{F_P} = \{\langle \boldsymbol{u_1}, [\boldsymbol{0.2}, \boldsymbol{0.4}], [\boldsymbol{0.3}, \boldsymbol{0.5}], [\boldsymbol{0.4}, \boldsymbol{0.6}]\rangle, \langle \boldsymbol{u_2}, [\boldsymbol{0.5}, \boldsymbol{0.7}], [\boldsymbol{0.2}, \boldsymbol{0.4}], [\boldsymbol{0.3}, \boldsymbol{0.5}]\rangle\}$

$\boldsymbol{G_Q} = \{\langle \boldsymbol{u_1}, [\boldsymbol{0.}, \boldsymbol{0.6}], [\boldsymbol{0.2}, \boldsymbol{0.4}], [\boldsymbol{0.3}, \boldsymbol{0.5}]\rangle, \langle \boldsymbol{u_2}, [\boldsymbol{0.4}, \boldsymbol{0.6}], [\boldsymbol{0.3}, \boldsymbol{0.5}], [\boldsymbol{0.2}, \boldsymbol{0.4}]\rangle\}$

$\boldsymbol{F_P} \cap \boldsymbol{G_Q} = \{\langle \boldsymbol{u_1}, [\boldsymbol{0.2}, \boldsymbol{0.4}], [\boldsymbol{0.3}, \boldsymbol{0.5}], [\boldsymbol{0.4}, \boldsymbol{0.6}]\rangle, \langle \boldsymbol{u_2}, [\boldsymbol{0.4}, \boldsymbol{0.6}], [\boldsymbol{0.3}, \boldsymbol{0.5}], [\boldsymbol{0.3}, \boldsymbol{0.5}]\rangle\}$

**Preposition 3**

Let $\boldsymbol{F_P}$ , $\boldsymbol{G_Q}$, $\boldsymbol{H_R} \in$ IVNSHSS over $\boldsymbol{U}$, then

1. $\boldsymbol{F_P} \cap \boldsymbol{F_P} = \boldsymbol{F_P}$
2. $\boldsymbol{F_P} \cap \boldsymbol{F_e} = \boldsymbol{F_P}$
3. $\boldsymbol{F_P} \cap \boldsymbol{F_\vartheta} = \boldsymbol{F_\vartheta}$
4. $\boldsymbol{F_P} \cap \boldsymbol{G_Q} = \boldsymbol{G_Q} \cap \boldsymbol{F_P}$
5. $(\boldsymbol{F_P} \cap \boldsymbol{G_Q}) \cap \boldsymbol{H_R} = \boldsymbol{F_P} \cap (\boldsymbol{G_Q} \cap \boldsymbol{H_R})$

**Proof:** This is a direct consequence of the definition.

**Proposition 4**

Let $F_P$ and $G_Q \in$ IVNSHSS over $U$, then

1. $(\boldsymbol{F_P} \cup \boldsymbol{G_Q})^{\boldsymbol{C}} = \boldsymbol{F_P}^{\boldsymbol{C}} \cap \boldsymbol{G_Q}^{\boldsymbol{C}}$
2. $(\boldsymbol{F_P} \cap \boldsymbol{G_Q})^{\boldsymbol{C}} = \boldsymbol{F_P}^{\boldsymbol{C}} \cup \boldsymbol{G_Q}^{\boldsymbol{C}}$

**Proof**

$\boldsymbol{F_P} = \{\langle \boldsymbol{u}, , \boldsymbol{\beta_P}(u), \boldsymbol{\gamma_P}(u)\rangle : \boldsymbol{u} \in \boldsymbol{U}\}$ and $\boldsymbol{G_Q} = \{\langle \boldsymbol{u}, \boldsymbol{\alpha_Q}(u), \boldsymbol{\beta_Q}(u), \boldsymbol{\gamma_Q}(u)\rangle : \boldsymbol{u} \in \boldsymbol{U}\}$

$\boldsymbol{\alpha_P}(u) = [\inf \boldsymbol{\alpha_P}(u), \boldsymbol{sup\alpha_P}(u)]$ or $[\boldsymbol{\alpha_P^L}(u), \boldsymbol{\alpha_P^U}(u)]$, $\boldsymbol{\alpha_P^L}(u) = \boldsymbol{inf\alpha_P}(u)$ and $\boldsymbol{\alpha_P^U}(u) = \boldsymbol{sup\alpha_P}(u)$

$\boldsymbol{\beta_P}(u) = [\inf \boldsymbol{\beta_P}(u), \boldsymbol{sup\beta_P}(u)]$ or $[\boldsymbol{\beta_P^L}(u), \boldsymbol{\beta_P^U}(u)]$, $\boldsymbol{\beta_P^L}(u) = \boldsymbol{inf\beta_P}(u)$ and $\boldsymbol{\beta_P^U}(u) = \boldsymbol{sup\beta_P}(u)$

$\boldsymbol{\gamma_P}(u) = [\inf \boldsymbol{\gamma_P}(u), \boldsymbol{sup\gamma_P}(u)]$ or $[\boldsymbol{\gamma_P^L}(u), \boldsymbol{\gamma_P^U}(u)]$, $\boldsymbol{\gamma_P^L}(u) = \boldsymbol{inf\gamma_P}(u)$ and $\boldsymbol{\gamma_P^U}(u) = \boldsymbol{sup\gamma_P}(u)$

$$\boldsymbol{F_P} \cup \boldsymbol{G_Q} = \left\{ \begin{matrix} (< u, [\boldsymbol{max}\{\inf \boldsymbol{\alpha_P}(u), \boldsymbol{inf\alpha_Q}(u)\}, \boldsymbol{max}\{\boldsymbol{sup\alpha_P}(u), \boldsymbol{sup\alpha_Q}(u)\}], \\ [\boldsymbol{min}\{\boldsymbol{inf\beta_P}(u), \boldsymbol{inf\beta_Q}(u)\}, \boldsymbol{min}\{\boldsymbol{sup\beta_P}(u), \boldsymbol{sup\beta_Q}(u)\}], \\ [\boldsymbol{min}\{\boldsymbol{inf\gamma_P}(u), \boldsymbol{inf\gamma_Q}(u)\}, \boldsymbol{min}\{\boldsymbol{sup\gamma_P}(u), \boldsymbol{sup\gamma_Q}(u)\}] >) / \boldsymbol{u} \in \boldsymbol{U} \end{matrix} \right\}$$

$$(\boldsymbol{F_P} \cup \boldsymbol{G_Q})^{\boldsymbol{C}} = \left\{ \begin{matrix} (< u, [\boldsymbol{min}\{\boldsymbol{inf\gamma_P}(u), \boldsymbol{inf\gamma_Q}(u)\}, \boldsymbol{min}\{\boldsymbol{sup\gamma_P}(u), \boldsymbol{sup\gamma_Q}(u)\}], \\ [\boldsymbol{1} - \boldsymbol{min}\{\boldsymbol{sup\beta_P}(u), \boldsymbol{sup\beta_Q}(u)\}, \boldsymbol{1} - \boldsymbol{min}\{\boldsymbol{inf\beta_P}(u), \boldsymbol{inf\beta_Q}(u)\}], \\ [\boldsymbol{max}\{\inf \boldsymbol{\alpha_P}(u), \boldsymbol{inf\alpha_Q}(u)\}, \boldsymbol{max}\{\boldsymbol{sup\alpha_P}(u), \boldsymbol{sup\alpha_Q}(u)\}] >) / \boldsymbol{u} \in \boldsymbol{U} \end{matrix} \right\}$$

$$\boldsymbol{F_P}^{\boldsymbol{C}} = \{\langle \boldsymbol{u}, [\boldsymbol{inf\gamma_P}(u), \boldsymbol{sup\gamma_P}(u)], [\boldsymbol{1} - \boldsymbol{sup\beta_P}(u), \boldsymbol{1} - \boldsymbol{inf\beta_P}(u)], [\boldsymbol{inf\alpha_P}(u), \boldsymbol{sup\alpha_P}(u)]\rangle : \boldsymbol{u} \in \boldsymbol{U}\}$$

$$\boldsymbol{G_Q}^{\boldsymbol{C}} = \{\langle \boldsymbol{u}, [\boldsymbol{inf\gamma_Q}(u), \boldsymbol{sup\gamma_Q}(u)], [\boldsymbol{1} - \boldsymbol{sup\beta_Q}(u), \boldsymbol{1} - \boldsymbol{inf\beta_Q}(u)], [\boldsymbol{inf\alpha_Q}(u), \boldsymbol{sup\alpha_Q}(u)]\rangle : \boldsymbol{u} \in \boldsymbol{U}\}$$

$$\boldsymbol{F_P}^{\boldsymbol{C}} \cap \boldsymbol{G_Q}^{\boldsymbol{C}} = \left\{ \begin{matrix} (< u, [\boldsymbol{min}\{\boldsymbol{inf\gamma_P}(u), \boldsymbol{inf\gamma_Q}(u)\}, \boldsymbol{min}\{\boldsymbol{sup\gamma_P}(u), \boldsymbol{sup\gamma_Q}(u)\}], \\ [\max\{\boldsymbol{1} - \boldsymbol{sup\beta_P}(u), \boldsymbol{1} - \boldsymbol{sup\beta_Q}(u)\}, \max\{\boldsymbol{1} - \boldsymbol{inf\beta_P}(u), \boldsymbol{1} - \boldsymbol{inf\beta_Q}(u)\}], \\ [\boldsymbol{max}\{\inf \boldsymbol{\alpha_P}(u), \boldsymbol{inf\alpha_Q}(u)\}, \boldsymbol{max}\{\boldsymbol{sup\alpha_P}(u), \boldsymbol{sup\alpha_Q}(u)\}] >) / \boldsymbol{u} \in \boldsymbol{U} \end{matrix} \right\}$$

$$F_P{}^C \cap G_Q{}^C = \left\{ \begin{matrix} (< u, [\boldsymbol{min}\{\boldsymbol{inf\gamma_P(u)}, \boldsymbol{inf\gamma_Q(u)}\}, \boldsymbol{min}\{\boldsymbol{sup\gamma_P(u)}, \boldsymbol{sup\gamma_Q(u)}\}], \\ [\mathbf{1} - \boldsymbol{min}\{\boldsymbol{sup\beta_P(u)}, \boldsymbol{sup\beta(u)}\}, \mathbf{1} - \boldsymbol{min}\{\boldsymbol{inf\beta_P(u)}, \boldsymbol{inf\beta_Q(u)}\}], \\ [\boldsymbol{max}\{\inf \boldsymbol{\alpha_P(u)}, \boldsymbol{inf\alpha_Q(u)}\}, \boldsymbol{max}\{\boldsymbol{sup\alpha_P(u)}, \boldsymbol{sup\alpha_Q(u)}\}] >)/\boldsymbol{u \in U} \end{matrix} \right\}$$

Hence

$$(F_P \cup G_Q)^C = F_P{}^C \cap G_Q{}^C$$

Proof 2

Similar as proof 1.

**Proposition 5**

Let $F_P$ , $G_Q$, $H_R \in$ IVNSHSS over $U$, then

1. $F_P \cup (G_Q \cap H_R) = (F_P \cup G_Q) \cap (F_P \cup H_R)$
2. $F_P \cap (G_Q \cup H_R) = (F_P \cap G_Q) \cup (F_P \cap H_R)$
3. $F_P \cup (F_P \cap G_Q) = F_P$
4. $F_P \cap (F_P \cup G_Q) = F_P$

**Proof 1**

$$G_Q \cap H_R = \left\{ \begin{matrix} (< u, [\boldsymbol{min}\{\inf \boldsymbol{\alpha_Q(u)}, \boldsymbol{inf\alpha_R(u)}\}, \boldsymbol{min}\{\boldsymbol{sup\alpha_Q(u)}, \boldsymbol{sup\alpha_R(u)}\}], \\ [\boldsymbol{max}\{\boldsymbol{inf\beta_Q(u)}, \boldsymbol{inf\beta_R(u)}\}, \boldsymbol{max}\{\boldsymbol{sup\beta_Q(u)}, \boldsymbol{sup\beta_R(u)}\}], \\ [\boldsymbol{max}\{\boldsymbol{inf\gamma_Q(u)}, \boldsymbol{inf\gamma_R(u)}\}, \boldsymbol{max}\{\boldsymbol{sup\gamma_Q(u)}, \boldsymbol{sup\gamma_R(u)}\}] >)/\boldsymbol{u \in U} \end{matrix} \right\}$$

$$F_P \cup (G_Q \cap H_R)$$

$$= \left\{ \begin{matrix} (< u, \left[\max\left\{\boldsymbol{inf\alpha_P(u)}, \boldsymbol{min}\{\inf \boldsymbol{\alpha_Q(u)}, \boldsymbol{inf\alpha_R(u)}\}\right\}, \max\{\boldsymbol{sup\alpha_P(u)}, \boldsymbol{min}\{\boldsymbol{sup\alpha_Q(u)}, \boldsymbol{sup\alpha_R(u)}\}\}\right], \\ [\min\{\boldsymbol{inf\beta_P(u)}, \boldsymbol{max}\{\boldsymbol{inf\beta_Q(u)}, \boldsymbol{inf\beta_R(u)}\}\}, \min\{\boldsymbol{sup\beta_P(u)}, \boldsymbol{max}\{\boldsymbol{sup\beta_Q(u)}, \boldsymbol{sup\beta_R(u)}\}\}], \\ [\min\{\boldsymbol{inf\gamma_P(u)}, \boldsymbol{max}\{\boldsymbol{inf\gamma_Q(u)}, \boldsymbol{inf\gamma_R(u)}\}\}, \min\{\boldsymbol{sup\gamma_P(u)}, \boldsymbol{max}\{\boldsymbol{sup\gamma_Q(u)}, \boldsymbol{sup\gamma_R(u)}\}\}] >)/\boldsymbol{u \in U} \end{matrix} \right\}$$

$$F_P \cup G_Q = \left\{ \begin{matrix} (< u, [\boldsymbol{max}\{\inf \boldsymbol{\alpha_P(u)}, \boldsymbol{inf\alpha_Q(u)}\}, \boldsymbol{max}\{\boldsymbol{sup\alpha_P(u)}, \boldsymbol{sup\alpha_Q(u)}\}], \\ [\boldsymbol{min}\{\boldsymbol{inf\beta_P(u)}, \boldsymbol{inf\beta_Q(u)}\}, \boldsymbol{min}\{\boldsymbol{sup\beta_P(u)}, \boldsymbol{sup\beta_Q(u)}\}], \\ [\boldsymbol{min}\{\boldsymbol{inf\gamma_P(u)}, \boldsymbol{inf\gamma_Q(u)}\}, \boldsymbol{min}\{\boldsymbol{sup\gamma_P(u)}, \boldsymbol{sup\gamma_Q(u)}\}] >)/\boldsymbol{u \in U} \end{matrix} \right\}$$

$$F_P \cup H_R = \left\{ \begin{matrix} (< u, [\boldsymbol{max}\{\inf \boldsymbol{\alpha_P(u)}, \boldsymbol{inf\alpha_R(u)}\}, \boldsymbol{max}\{\boldsymbol{sup\alpha_P(u)}, \boldsymbol{sup\alpha_R(u)}\}], \\ [\boldsymbol{min}\{\boldsymbol{inf\beta_P(u)}, \boldsymbol{inf\beta_R(u)}\}, \boldsymbol{min}\{\boldsymbol{sup\beta_P(u)}, \boldsymbol{sup\beta_R(u)}\}], \\ [\boldsymbol{min}\{\boldsymbol{inf\gamma_P(u)}, \boldsymbol{inf\gamma_R(u)}\}, \boldsymbol{min}\{\boldsymbol{sup\gamma_P(u)}, \boldsymbol{sup\gamma_R(u)}\}] >)/\boldsymbol{u \in U} \end{matrix} \right\}$$

$$(F_P \cup G_Q) \cap (F_P \cup H_R) = \left\{ \begin{matrix} (< u, \begin{bmatrix} \min\{\boldsymbol{max}\{\inf \boldsymbol{\alpha_P(u)}, \boldsymbol{inf\alpha_Q(u)}\}, \boldsymbol{max}\{\inf \boldsymbol{\alpha_P(u)}, \boldsymbol{inf\alpha_R(u)}\}\}, \\ \min\{\max\{\boldsymbol{sup\alpha_P(u)}, \boldsymbol{sup\alpha_Q(u)}\}, \boldsymbol{max}\{\boldsymbol{sup\alpha_P(u)}, \boldsymbol{sup\alpha_R(u)}\}\} \end{bmatrix}, \\ \begin{bmatrix} \max\{\min\{\boldsymbol{inf\beta_P(u)}, \boldsymbol{inf\beta_Q(u)}\}, \boldsymbol{min}\{\boldsymbol{inf\beta_P(u)}, \boldsymbol{inf\beta_R(u)}\}\}, \\ \max\{\boldsymbol{min}\{\boldsymbol{sup\beta_P(u)}, \boldsymbol{sup\beta_R(u)}\}, \{\boldsymbol{min}\{\boldsymbol{sup\beta_P(u)}, \boldsymbol{sup\beta_R(u)}\}\} \end{bmatrix}, \\ \begin{bmatrix} \max\{\boldsymbol{min}\{\boldsymbol{inf\gamma_P(u)}, \boldsymbol{inf\gamma_Q(u)}\}, \{\boldsymbol{min}\{\boldsymbol{inf\gamma_P(u)}, \boldsymbol{inf\gamma_R(u)}\}\}, \\ \max\{\boldsymbol{min}\{\boldsymbol{sup\gamma_P(u)}, \boldsymbol{sup\gamma_Q(u)}\}, \boldsymbol{min}\{\boldsymbol{sup\gamma_P(u)}, \boldsymbol{sup\gamma_R(u)}\}\} \end{bmatrix} >)/\boldsymbol{u \in U} \end{matrix} \right\}$$

$$(F_P \cup G_Q) \cap (F_P \cup H_R)$$

$$= \left\{ \begin{matrix} (< u, \left[\max\left\{\boldsymbol{inf\alpha_P(u)}, \boldsymbol{min}\{\inf \boldsymbol{\alpha_Q(u)}, \boldsymbol{inf\alpha_R(u)}\}\right\}, \max\{\boldsymbol{sup\alpha_P(u)}, \boldsymbol{min}\{\boldsymbol{sup\alpha_Q(u)}, \boldsymbol{sup\alpha_R(u)}\}\}\right], \\ [\min\{\boldsymbol{inf\beta_P(u)}, \boldsymbol{max}\{\boldsymbol{inf\beta_Q(u)}, \boldsymbol{inf\beta_R(u)}\}\}, \min\{\boldsymbol{sup\beta_P(u)}, \boldsymbol{max}\{\boldsymbol{sup_Q(u)}, \boldsymbol{sup\beta_R(u)}\}\}], \\ [\min\{\boldsymbol{inf\gamma_P(u)}, \boldsymbol{max}\{\boldsymbol{inf\gamma_Q(u)}, \boldsymbol{inf\gamma_R(u)}\}\}, \min\{\boldsymbol{sup\gamma_P(u)}, \boldsymbol{max}\{\boldsymbol{sup\gamma_Q(u)}, \boldsymbol{sup\gamma_R(u)}\}\}] >)/\boldsymbol{u \in U} \end{matrix} \right\}$$

Hence $F_P \cup (G_Q \cap H_R) = (F_P \cup G_Q) \cap (F_P \cup H_R)$

The rest of the results follow by similar arguments.

**Definition 4.6**

If $\boldsymbol{F_P}$ , $\boldsymbol{G_Q} \in$ IVNSHSS defined on$\boldsymbol{U}$, then their extended union is

$$\boldsymbol{\alpha}(\boldsymbol{F_P} \cup \boldsymbol{G_Q}) = \begin{cases} [\inf \boldsymbol{\alpha_P}(\boldsymbol{u}), \sup \boldsymbol{\alpha_P}(\boldsymbol{u})] if \boldsymbol{u} \in \boldsymbol{P} - \boldsymbol{Q} \\ [\inf \boldsymbol{\alpha_Q}(\boldsymbol{u}), \sup \boldsymbol{\alpha_Q}(\boldsymbol{u})] if \boldsymbol{u} \in \boldsymbol{Q} - \boldsymbol{P} \\ [\max\{\inf \boldsymbol{\alpha_P}(\boldsymbol{u}), \boldsymbol{inf\alpha_Q}(\boldsymbol{u})\}, \max\{\boldsymbol{sup\alpha_P}(\boldsymbol{u}), \boldsymbol{sup\alpha_Q}(\boldsymbol{u})\}] if \boldsymbol{u} \in \boldsymbol{Q} \cap \boldsymbol{P} \end{cases}$$

$$\boldsymbol{\beta}(\boldsymbol{F_P} \cup \boldsymbol{G_Q}) = \begin{cases} [\inf \boldsymbol{\beta_P}(\boldsymbol{u}), \sup \boldsymbol{\beta_P}(\boldsymbol{u})] if \boldsymbol{u} \in \boldsymbol{P} - \boldsymbol{Q} \\ [\inf \boldsymbol{\beta_Q}(\boldsymbol{u}), \sup \boldsymbol{\beta_Q}(\boldsymbol{u})] if \boldsymbol{u} \in \boldsymbol{Q} - \boldsymbol{P} \\ [\min\{\inf \boldsymbol{\beta_P}(\boldsymbol{u}), \boldsymbol{inf\beta_Q}(\boldsymbol{u})\}, \min\{\boldsymbol{sup\beta_P}(\boldsymbol{u}), \boldsymbol{sup\beta_Q}(\boldsymbol{u})\}] if \boldsymbol{u} \in \boldsymbol{Q} \cap \boldsymbol{P} \end{cases}$$

$$\boldsymbol{\gamma}(\boldsymbol{F_P} \cup \boldsymbol{G_Q}) = \begin{cases} [\inf \boldsymbol{\gamma_P}(\boldsymbol{u}), \sup \boldsymbol{\gamma_P}(\boldsymbol{u})] if \boldsymbol{u} \in \boldsymbol{P} - \boldsymbol{Q} \\ [\inf \boldsymbol{\gamma_Q}(\boldsymbol{u}), \sup \boldsymbol{\gamma_Q}(\boldsymbol{u})] if \boldsymbol{u} \in \boldsymbol{Q} - \boldsymbol{P} \\ [\min\{\inf \boldsymbol{\gamma_P}(\boldsymbol{u}), \boldsymbol{inf\gamma_Q}(\boldsymbol{u})\}, \min\{\boldsymbol{sup\gamma_P}(\boldsymbol{u}), \boldsymbol{sup\gamma_Q}(\boldsymbol{u})\}] if \boldsymbol{u} \in \boldsymbol{Q} \cap \boldsymbol{P} \end{cases}$$

**Definition 4.7**

If $\boldsymbol{F_P}$ , $\boldsymbol{G_Q} \in$ IVNSHSS with universe$\boldsymbol{U}$, then their extended intersection is

$$\boldsymbol{\alpha}(\boldsymbol{F_P} \cup \boldsymbol{G_Q}) = \begin{cases} [\inf \boldsymbol{\alpha_P}(\boldsymbol{u}), \sup \boldsymbol{\alpha_P}(\boldsymbol{u})] if \boldsymbol{u} \in \boldsymbol{P} - \boldsymbol{Q} \\ [\inf \boldsymbol{\alpha_Q}(\boldsymbol{u}), \sup \boldsymbol{\alpha_Q}(\boldsymbol{u})] if \boldsymbol{u} \in \boldsymbol{Q} - \boldsymbol{P} \\ [\min\{\inf \boldsymbol{\alpha_P}(\boldsymbol{u}), \boldsymbol{inf\alpha_Q}(\boldsymbol{u})\}, \min\{\boldsymbol{sup\alpha_P}(\boldsymbol{u}), \boldsymbol{sup\alpha_Q}(\boldsymbol{u})\}] if \boldsymbol{u} \in \boldsymbol{Q} \cap \boldsymbol{P} \end{cases}$$

$$\boldsymbol{\beta}(\boldsymbol{F_P} \cup \boldsymbol{G_Q}) = \begin{cases} [\inf \boldsymbol{\beta_P}(\boldsymbol{u}), \sup \boldsymbol{\beta_P}(\boldsymbol{u})] if \boldsymbol{u} \in \boldsymbol{P} - \boldsymbol{Q} \\ [\inf \boldsymbol{\beta_Q}(\boldsymbol{u}), \sup \boldsymbol{\beta_Q}(\boldsymbol{u})] if \boldsymbol{u} \in \boldsymbol{Q} - \boldsymbol{P} \\ [\max\{\inf \boldsymbol{\beta_P}(\boldsymbol{u}), \boldsymbol{inf\beta_Q}(\boldsymbol{u})\}, \max\{\boldsymbol{sup\beta_P}(\boldsymbol{u}), \boldsymbol{sup\beta_Q}(\boldsymbol{u})\}] if \boldsymbol{u} \in \boldsymbol{Q} \cap \boldsymbol{P} \end{cases}$$

$$\boldsymbol{\gamma}(\boldsymbol{F_P} \cup \boldsymbol{G_Q}) = \begin{cases} [\inf \boldsymbol{\gamma_P}(\boldsymbol{u}), \sup \boldsymbol{\gamma_P}(\boldsymbol{u})] if \boldsymbol{u} \in \boldsymbol{P} - \boldsymbol{Q} \\ [\inf \boldsymbol{\gamma_Q}(\boldsymbol{u}), \sup \boldsymbol{\gamma_Q}(\boldsymbol{u})] if \boldsymbol{u} \in \boldsymbol{Q} - \boldsymbol{P} \\ [\max\{\inf \boldsymbol{\gamma_P}(\boldsymbol{u}), \boldsymbol{inf\gamma_Q}(\boldsymbol{u})\}, \max\{\boldsymbol{sup\gamma_P}(\boldsymbol{u}), \boldsymbol{sup\gamma_Q}(\boldsymbol{u})\}] if \boldsymbol{u} \in \boldsymbol{Q} \cap \boldsymbol{P} \end{cases}$$

**Definition 4.8**

If $\boldsymbol{F_P}$ , $\boldsymbol{G_Q} \in$ IVNSHSS over $\boldsymbol{U}$, then their difference is as follows

$$F_P \setminus G_Q = \begin{Bmatrix} (< u, [min\{\inf \alpha_P(u), inf\ \alpha_Q(u)\}, min\{sup\ \alpha_P(u), sup\ \alpha_Q(u)\}], \\ [max\{inf\ \beta_P(u), 1 - sup\ \beta_Q(u)\}, max\{\sup\ \beta_P(u), 1 - inf\ \beta_Q(u)\}], \\ [max\{inf\ \gamma_P(u), inf\ \gamma_P(u)\}, max\{sup\ \gamma_P(u), sup\ \gamma_P(u)\}] >)/u \in U \end{Bmatrix}$$

**Example 6**

$\boldsymbol{F_P} = \{\langle \boldsymbol{u_1}, [\boldsymbol{0.2}, \boldsymbol{0.4}], [\boldsymbol{0.3}, \boldsymbol{0.5}], [\boldsymbol{0.4}, \boldsymbol{0.6}]\rangle, \langle \boldsymbol{u_2}, [\boldsymbol{0.5}, \boldsymbol{0.7}], [\boldsymbol{0.2}, \boldsymbol{0.4}], [\boldsymbol{0.3}, \boldsymbol{0.5}]\rangle\}$

$\boldsymbol{G_Q} = \{\langle \boldsymbol{u_1}, [\boldsymbol{0.3}, \boldsymbol{0.6}], [\boldsymbol{0.2}, \boldsymbol{0.4}], [\boldsymbol{0.3}, \boldsymbol{0.5}]\rangle, \langle \boldsymbol{u_2}, [\boldsymbol{0.4}, \boldsymbol{0.6}], [\boldsymbol{0.3}, \boldsymbol{0.5}], [\boldsymbol{0.2}, \boldsymbol{0.4}]\rangle\}$

$\boldsymbol{F_P} \setminus \boldsymbol{G_Q} = \{\langle \boldsymbol{u_1}, [\boldsymbol{0.2}, \boldsymbol{0.4}], [\boldsymbol{0.6}, \boldsymbol{0.8}], [\boldsymbol{0.4}, \boldsymbol{0.6}]\rangle, \langle \boldsymbol{u_2}, [\boldsymbol{0.4}, \boldsymbol{0.6}], [\boldsymbol{0.5}, \boldsymbol{0.7}], [\boldsymbol{0.3}, \boldsymbol{0.5}]\rangle\}$

**Definition 4.9**

If $\boldsymbol{F_P}$ , $\boldsymbol{G_Q} \in$ IVNSHSS over $\boldsymbol{U}$, the difference is defined by

$$\boldsymbol{F_P} + \boldsymbol{G_Q} = \begin{Bmatrix} (< u, [\boldsymbol{min}\{\inf \boldsymbol{\alpha_P}(\boldsymbol{u}) + \boldsymbol{inf\alpha_Q}(\boldsymbol{u}), \boldsymbol{1}\}, \boldsymbol{min}\{\boldsymbol{sup\alpha_P}(\boldsymbol{u}) + \boldsymbol{sup\alpha_Q}(\boldsymbol{u}), \boldsymbol{1}\}], \\ [\boldsymbol{min}\{\boldsymbol{inf\beta_P}(\boldsymbol{u}) + \boldsymbol{inf\beta_Q}(\boldsymbol{u}), \boldsymbol{1}\}, \boldsymbol{min}\{\sup \boldsymbol{\beta_P}(\boldsymbol{u}) + \boldsymbol{sup\beta_Q}(\boldsymbol{u}), \boldsymbol{1}\}], \\ [\boldsymbol{min}\{\boldsymbol{inf\gamma_P}(\boldsymbol{u}) + \boldsymbol{inf\gamma_P}(\boldsymbol{u}), \boldsymbol{1}\}, \boldsymbol{min}\{\boldsymbol{sup\gamma_P}(\boldsymbol{u}) + \boldsymbol{sup\gamma_P}(\boldsymbol{u}), \boldsymbol{1}\}] >)/\boldsymbol{u} \in \boldsymbol{U} \end{Bmatrix}$$

**Example 7**

$\boldsymbol{F_P} = \{\langle \boldsymbol{u_1}, [\boldsymbol{0.2}, \boldsymbol{0.4}], [\boldsymbol{0.3}, \boldsymbol{0.5}], [\boldsymbol{0.4}, \boldsymbol{0.6}]\rangle, \langle \boldsymbol{u_2}, [\boldsymbol{0.5}, \boldsymbol{0.7}], [\boldsymbol{0.2}, \boldsymbol{0.4}], [\boldsymbol{0.3}, \boldsymbol{0.5}]\rangle\}$

$\boldsymbol{G_Q} = \{\langle \boldsymbol{u_1}, [\mathbf{0.3}, \mathbf{0.6}], [\mathbf{0.2}, \mathbf{0.4}], [\mathbf{0.3}, \mathbf{0.5}]\rangle, \langle \boldsymbol{u_2}, [\mathbf{0.4}, \mathbf{0.6}], [\mathbf{0.3}, \mathbf{0.5}], [\mathbf{0.2}, \mathbf{0.4}]\rangle\}$
$\boldsymbol{F_P} + \boldsymbol{G_Q} = \{\langle \boldsymbol{u_1}, [\mathbf{0.5}, \mathbf{1}], [\mathbf{0.5}, \mathbf{0.9}], [\mathbf{0.7}, \mathbf{1}]\rangle, \langle \boldsymbol{u}, [\mathbf{0.9}, \mathbf{1}], [\mathbf{0.5}, \mathbf{0.9}], [\mathbf{0.5}, \mathbf{0.9}]\rangle\}$

**Definition 4.10**

The scalar multiplication of $\boldsymbol{F_P} \in$ IVNSHSS over $\boldsymbol{U}$ is denoted by $\boldsymbol{F_P}.\mathfrak{p}$ , where $\mathfrak{p} \in [\mathbf{0}, \mathbf{1}]$ and is defined by:

$$\boldsymbol{F_P}.\mathfrak{p} == \begin{Bmatrix} (< u, [\boldsymbol{min}\{\mathbf{inf}\, \boldsymbol{\alpha_P}(\boldsymbol{u}).\mathfrak{p}, \mathbf{1}\}, \boldsymbol{min}\{\boldsymbol{sup\alpha_P}(\boldsymbol{u}).\mathfrak{p}, \mathbf{1}\}], \\ [\boldsymbol{min}\{\boldsymbol{inf\beta_P}(\boldsymbol{u}).\mathfrak{p}, \mathbf{1}\}, \boldsymbol{min}\{\mathbf{sup}\, \boldsymbol{\beta_P}(\boldsymbol{u}).\mathfrak{p}, \mathbf{1}\}], \\ [\boldsymbol{min}\{\boldsymbol{inf\gamma_P}(\boldsymbol{u}).\mathfrak{p}, \mathbf{1}\}, \boldsymbol{min}\{\boldsymbol{sup\gamma_P}(\boldsymbol{u}).\mathfrak{p}, \mathbf{1}\}] >)/\boldsymbol{u} \in \boldsymbol{U} \end{Bmatrix}$$

**Definition 4.11**

The scalar division of $\boldsymbol{F_P} \in$ IVNSHSS over $\boldsymbol{U}$ is denoted by $\boldsymbol{F_P}/\mathfrak{p}$ , where $\mathfrak{p} \in [\mathbf{0}, \mathbf{1}]$ and is expressed as:

$$\boldsymbol{F_P}.\mathfrak{p} == \begin{Bmatrix} (< u, [\boldsymbol{min}\{\mathbf{inf}\, \boldsymbol{\alpha_P}(\boldsymbol{u})/\mathfrak{p}, \mathbf{1}\}, \boldsymbol{min}\{\boldsymbol{sup\alpha_P}(\boldsymbol{u})/\mathfrak{p}, \mathbf{1}\}], \\ [\boldsymbol{min}\{\boldsymbol{inf\beta_P}(\boldsymbol{u})/\mathfrak{p}, \mathbf{1}\}, \boldsymbol{min}\{\mathbf{sup}\, \boldsymbol{\beta_P}(\boldsymbol{u})./\mathfrak{p}, \mathbf{1}\}], \\ [\boldsymbol{min}\{\boldsymbol{inf\gamma_P}(\boldsymbol{u})/\mathfrak{p}, \mathbf{1}\}, \boldsymbol{min}\{\boldsymbol{sup\gamma_P}(\boldsymbol{u})/\mathfrak{p}, \mathbf{1}\}] >)/\boldsymbol{u} \in \boldsymbol{U} \end{Bmatrix}$$

**Definition 4.12**

The Truth-Favorite operator of $\boldsymbol{F_P} \in$ IVNSHSS over $\boldsymbol{U}$ is denoted by $\sqcap\, \boldsymbol{F_P}$ and is given by:

$$\sqcap\, \boldsymbol{F_P} = \begin{Bmatrix} (< u, [\boldsymbol{min}\{\mathbf{inf}\, \boldsymbol{\alpha_P}(\boldsymbol{u}) + \boldsymbol{inf\beta_P}(\boldsymbol{u}), \mathbf{1}\}, \boldsymbol{min}\{\boldsymbol{sup\alpha_P}(\boldsymbol{u}) + \boldsymbol{sp\beta_P}(\boldsymbol{u}), \mathbf{1}\}], \\ [\mathbf{0}, \mathbf{0}], \\ [\mathbf{inf}\, \boldsymbol{\gamma_P}(\boldsymbol{u}), \mathbf{sup}\, \boldsymbol{\gamma_P}(\boldsymbol{u})] >)/\boldsymbol{u} \in \boldsymbol{U} \end{Bmatrix}$$

**Example 8**

$\boldsymbol{F_P} = \{\langle \boldsymbol{u_1}, [\mathbf{0.3}, \mathbf{0.5}], [\mathbf{0.4}, \mathbf{0.6}], [\mathbf{0.2}, \mathbf{0.3}]\rangle, \langle \boldsymbol{u_2}, [\mathbf{0.2}, \mathbf{0.4}], [\mathbf{0.3}, \mathbf{0.5}], [\mathbf{0.3}, \mathbf{0.4}]\rangle\}$
$\sqcap\, \boldsymbol{F_P} = \{\langle \boldsymbol{u_1}, [\mathbf{0.7}, \mathbf{1}], [\mathbf{0}, \mathbf{0}, [\mathbf{0.2}, \mathbf{0.3}]\rangle, \langle \boldsymbol{u_2}, [\mathbf{0.5}, \mathbf{1}], [\mathbf{0}, \mathbf{0}], [\mathbf{0.3}, \mathbf{0.4}]\rangle\}$

**Preposition 6**

If $\boldsymbol{F_P}$ , $\boldsymbol{G_Q} \in$ IVNSHSS over $\boldsymbol{U}$, then

1. $\sqcap\sqcap\, \boldsymbol{F_P} = \sqcap\, \boldsymbol{F_P}$
2. $\sqcap\, (\boldsymbol{F_P} \cup \boldsymbol{G_Q}) \subseteq \sqcap\, \boldsymbol{F_P} \cup \sqcap\, \boldsymbol{G_Q}$
3. $\sqcap\, (\boldsymbol{F_P} \cap \boldsymbol{G_Q}) \subseteq \sqcap\, \boldsymbol{F_P} \cap \sqcap\, \boldsymbol{G_Q}$
4. $\sqcap\, (\boldsymbol{F_P} + \boldsymbol{G_Q}) = \sqcap\, \boldsymbol{F_P} + \sqcap\, \boldsymbol{G_Q}$

The proof of the above proposition follows directly from the definitions..

**Definition 4.13**

The False-Favorite operator of $\boldsymbol{F_P} \in$ IVNSHSS over $\boldsymbol{U}$ is denoted by $\sqcup\, \boldsymbol{F_P}$ and is specified as:

$$\sqcup\, \boldsymbol{F_P} = \begin{Bmatrix} (< u, [\mathbf{inf}\, \boldsymbol{\alpha_P}(\boldsymbol{u}), \mathbf{sup}\, \boldsymbol{\alpha_P}(\boldsymbol{u})], \\ [\mathbf{0}, \mathbf{0}], \\ [\boldsymbol{min}\{\mathbf{inf}\, \boldsymbol{\beta_P}(\boldsymbol{u}) + \boldsymbol{inf\gamma_P}(\boldsymbol{u}), \mathbf{1}\}, \boldsymbol{min}\{\boldsymbol{sup\beta_P}(\boldsymbol{u}) + \boldsymbol{sup\gamma_P}(\boldsymbol{u}), \mathbf{1}\}] >)/\boldsymbol{u} \in \boldsymbol{U} \end{Bmatrix}$$

**Example 9**

$\boldsymbol{F_P} = \{\langle \boldsymbol{u_1}, [\mathbf{0.3}, \mathbf{0.5}], [\mathbf{0.4}, \mathbf{0.6}], [\mathbf{0.2}, \mathbf{0.3}]\rangle, \langle \boldsymbol{u_2}, [\mathbf{0.2}, \mathbf{0.4}], [\mathbf{0.3}, \mathbf{0.5}], [\mathbf{0.3}, \mathbf{0.4}]\rangle\}$
$\sqcup\, \boldsymbol{F_P} = \{\langle \boldsymbol{u_1}, [\mathbf{0.7}, \mathbf{1}], [\mathbf{0}, \mathbf{0}, [\mathbf{0.2}, \mathbf{0.3}]\rangle, \langle \boldsymbol{u_2}, [\mathbf{0.5}, \mathbf{1}], [\mathbf{0}, \mathbf{0}], [\mathbf{0.3}, \mathbf{0.4}]\rangle\}$

**Preposition 7**

If $F_P$ , $G_Q \in$ IVNSHSS over $U$, then

1. $\sqcup\sqcup\, \boldsymbol{F_P} = \sqcup\, \boldsymbol{F_P}$
2. $\sqcup\, (\boldsymbol{F_P} \cup \boldsymbol{G_Q}) \subseteq \sqcup\, \boldsymbol{F_P} \cup \sqcup\, \boldsymbol{G_Q}$
3. $\sqcup\, (\boldsymbol{F_P} \cap \boldsymbol{G_Q}) \subseteq \sqcup\, \boldsymbol{F_P} \cap \sqcup\, \boldsymbol{G_Q}$
4. $\sqcup\, (\boldsymbol{F_P} + \boldsymbol{G_Q}) = \sqcup\, \boldsymbol{F_P} + \sqcup\, \boldsymbol{G_Q}$

The proposition is proved directly from the definitions.

**Necessity - Possibility Operations on IVNSHSS**

**Definition 5.1**

For$\boldsymbol{F_P}$ , $\boldsymbol{G_Q}$ ∈ IVNSHSS over $\boldsymbol{U}$, then OR-Operator $\boldsymbol{F_P} \curlyvee \boldsymbol{G_Q}$ and defined by

$\boldsymbol{\alpha(F_{P\times Q})} = [\boldsymbol{max}\{\inf \boldsymbol{\alpha_P(u)}, \boldsymbol{inf\alpha_Q(u)}\}, \boldsymbol{max}\{\boldsymbol{sup\alpha_P(u)}, \boldsymbol{sup\alpha_Q(u)}\}]$,

$\boldsymbol{\beta(F_{P\times Q})} = [\boldsymbol{min}\{\inf \boldsymbol{\beta_P(u)}, \boldsymbol{inf\beta_Q(u)}\}, \boldsymbol{min}\{\boldsymbol{sup\beta_P(u)}, \boldsymbol{sup\beta_Q(u)}\}]$,

$\boldsymbol{\gamma(F_{P\times Q})} = [\boldsymbol{min}\{\inf \boldsymbol{\gamma_P(u)}, \boldsymbol{inf\gamma_Q(u)}\}, \boldsymbol{min}\{\boldsymbol{sup\gamma_P(u)}, \boldsymbol{sup\gamma_Q(u)}\}]$.

**Definition 5.2**

If $\boldsymbol{F_P}$ , $\boldsymbol{G_Q}$ ∈ IVNSHSS over $\boldsymbol{U}$, then OR-Operator is represented by $\boldsymbol{F_P} \curlywedge \boldsymbol{G_Q}$ and defined as follows

$\boldsymbol{\alpha(F_{P\times Q})} = [\boldsymbol{min}\{\inf \boldsymbol{\alpha_P(u)}, \boldsymbol{inf\alpha_Q(u)}\}, \boldsymbol{min}\{\boldsymbol{sup\alpha_P(u)}, \boldsymbol{sup\alpha_Q(u)}\}]$,

$\boldsymbol{\beta(F_{P\times Q})} = [\boldsymbol{max}\{\inf \boldsymbol{\beta_P(u)}, \boldsymbol{inf\beta_Q(u)}\}, \boldsymbol{max}\{\boldsymbol{sup\beta_P(u)}, \boldsymbol{sup\beta_Q(u)}\}]$,

$\boldsymbol{\gamma(F_{P\times Q})} = [\boldsymbol{max}\{\inf \boldsymbol{\gamma_P(u)}, \boldsymbol{inf\gamma_Q(u)}\}, \boldsymbol{max}\{\boldsymbol{sup\gamma_P(u)}, \boldsymbol{sup\gamma_Q(u)}\}]$.

**Preposition 8**

Let $\boldsymbol{F_P}$ , $\boldsymbol{G_Q}$, $\boldsymbol{H_R}$ ∈ IVNSHSS over $\boldsymbol{U}$, then

1. $\boldsymbol{F_P} \curlyvee \boldsymbol{G_Q} = \boldsymbol{G_Q} \curlyvee \boldsymbol{F_P}$
2. $\boldsymbol{F_P} \curlywedge \boldsymbol{G_Q} = \boldsymbol{G_Q} \curlywedge \boldsymbol{F_P}$
3. $\boldsymbol{F_P} \curlyvee (\boldsymbol{G_Q} \curlyvee \boldsymbol{H_R}) = (\boldsymbol{F_P} \curlyvee \boldsymbol{G_Q}) \curlyvee \boldsymbol{H_R}$
4. $\boldsymbol{F_P} \curlywedge (\boldsymbol{G_Q} \curlywedge \boldsymbol{H_R}) = (\boldsymbol{F_P} \curlywedge \boldsymbol{G_Q}) \curlywedge \boldsymbol{H_R}$
5. $(\boldsymbol{F_P} \curlyvee \boldsymbol{G_Q})^{\boldsymbol{C}} = \boldsymbol{F^C(P)} \curlywedge \boldsymbol{G^C(Q)}$
6. $(\boldsymbol{F_P} \curlywedge \boldsymbol{G_Q})^{\boldsymbol{C}} = \boldsymbol{F^C(P)} \curlywedge \boldsymbol{G^C(Q)}$

**Poof:** We can easily prove by definition**.**

**Definition 5.3**

Let $\boldsymbol{F_P}$ ∈ IVNSHSS over $\boldsymbol{U}$, then necessity operator $\oplus \boldsymbol{F_P}$is given by

$\oplus \boldsymbol{F_P} = \{\langle \boldsymbol{u}, [\boldsymbol{inf\alpha_P(u)}, \boldsymbol{sup\alpha_P(u)}], [\boldsymbol{inf\beta_P(u)}, \boldsymbol{sup\beta_P(u)}], [\boldsymbol{1} - \boldsymbol{sup\alpha_P(u)}, \boldsymbol{1} - \boldsymbol{inf\alpha_P(u)}] \rangle : \boldsymbol{u} \in \boldsymbol{U}\}$

**Example 10**

$\boldsymbol{F_P} = \{\langle \boldsymbol{u_1}, [\boldsymbol{0.3}, \boldsymbol{0.5}], [\boldsymbol{0.4}, \boldsymbol{0.6}], [\boldsymbol{0.2}, \boldsymbol{0.3}] \rangle, \langle \boldsymbol{u_2}, [\boldsymbol{0.2}, \boldsymbol{0.4}], [\boldsymbol{0.3}, \boldsymbol{0.5}], [\boldsymbol{0.3}, \boldsymbol{0.4}] \rangle\}$

$\oplus \boldsymbol{F_P} = \{\langle \boldsymbol{u_1}, [\boldsymbol{0.3}, \boldsymbol{0.5}], [\boldsymbol{0.4}, \boldsymbol{0.6}], [\boldsymbol{0.5}, \boldsymbol{0.7}] \rangle, \langle \boldsymbol{u_2}, [\boldsymbol{0.2}, \boldsymbol{0.4}], [\boldsymbol{0.3}, \boldsymbol{0.5}], [\boldsymbol{0.6}, \boldsymbol{0.8}] \rangle\}$

**Definition 5.4**

Let $\boldsymbol{F_P}$ ∈ IVNSHSS over $\boldsymbol{U}$, then possibiliity $\otimes \boldsymbol{F_P}$is defined by

$\otimes \boldsymbol{F_P} = \{\langle \boldsymbol{u}, [\boldsymbol{1} - \boldsymbol{sup\gamma_P(u)}, \boldsymbol{1} - \boldsymbol{inf\gamma_P(u)}], [\boldsymbol{inf\beta_P(u)}, \boldsymbol{sup\beta_P(u)}], [\boldsymbol{inf\gamma_P(u)}, \boldsymbol{sup\gamma_P(u)}] \rangle : \boldsymbol{u} \in \boldsymbol{U}\}$

**Example 11**

$\boldsymbol{F_P} = \{\langle \boldsymbol{u_1}, [\boldsymbol{0.3}, \boldsymbol{0.5}], [\boldsymbol{0.4}, \boldsymbol{0.6}], [\boldsymbol{0.2}, \boldsymbol{0.3}] \rangle, \langle \boldsymbol{u_2}, [\boldsymbol{0.2}, \boldsymbol{0.4}], [\boldsymbol{0.3}, \boldsymbol{0.5}], [\boldsymbol{0.3}, \boldsymbol{0.4}] \rangle\}$

$\otimes \boldsymbol{F_P} = \{\langle \boldsymbol{u_1}, [\boldsymbol{0.7}, \boldsymbol{0.8}], [\boldsymbol{0.4}, \boldsymbol{0.6}], [\boldsymbol{0.2}, \boldsymbol{0.3}] \rangle, \langle \boldsymbol{u_2}, [\boldsymbol{0.6}, \boldsymbol{0.7}], [\boldsymbol{0.3}, \boldsymbol{0.5}], [\boldsymbol{0.3}, \boldsymbol{0.4}] \rangle\}$

**Preposition 9**

Let $\boldsymbol{F_P}$ , $\boldsymbol{G_Q}$ ∈ IVNSHSS over $\boldsymbol{U}$, then

1. $\oplus (\boldsymbol{F_P} \cup \boldsymbol{G_Q}) = \oplus \boldsymbol{F_P} \cup \oplus \boldsymbol{G_Q}$
2. $\oplus (\boldsymbol{F_P} \cap \boldsymbol{G_Q}) = \oplus \boldsymbol{F_P} \cap \oplus \boldsymbol{G_Q}$

**Proof:**

$\boldsymbol{F_P} = \{\langle \boldsymbol{u}, [\boldsymbol{inf\alpha_P(u)}, \boldsymbol{sup\alpha_P(u)}], [\boldsymbol{inf\beta_P(u)}, \boldsymbol{sup\beta_P(u)}], [\boldsymbol{inf\gamma_P(u)}, \boldsymbol{sup\gamma_P(u)}] \rangle : \boldsymbol{u} \in \boldsymbol{U}\}$

$\boldsymbol{G_Q} = \{\langle \boldsymbol{u}, [\boldsymbol{inf\alpha_Q(u)}, \boldsymbol{sup\alpha_Q(u)}], [\boldsymbol{inf\beta_Q(u)}, \boldsymbol{sup\beta_Q(u)}], [\boldsymbol{inf\gamma_Q(u)}, \boldsymbol{sup\gamma_Q(u)}] \rangle : \boldsymbol{u} \in \boldsymbol{U}\}$

Then by definition

$$\boldsymbol{F_P} \cup \boldsymbol{G_Q} = \left\{ \begin{matrix} (< u, [\boldsymbol{max}\{\inf \boldsymbol{\alpha_P}(u), \boldsymbol{inf\alpha_Q}(u)\}, \boldsymbol{max}\{\boldsymbol{sup\alpha_P}(u), \boldsymbol{sup\alpha_Q}(u)\}], \\ [\boldsymbol{min}\{\boldsymbol{inf\beta_P}(u), \boldsymbol{inf\beta_Q}(u)\}, \boldsymbol{min}\{\boldsymbol{sup\beta_P}(u), \boldsymbol{sup\beta_Q}(u)\}], \\ [\boldsymbol{min}\{\boldsymbol{inf\gamma_P}(u), \boldsymbol{inf\gamma_Q}(u)\}, \boldsymbol{min}\{\boldsymbol{sup\gamma_P}(u), \boldsymbol{sup\gamma_Q}(u)\}] >)/u \in U \end{matrix} \right\}$$

By necessity operator definition

$$\oplus \boldsymbol{F_P} \cup \boldsymbol{G_Q} = \left\{ \begin{matrix} (< u, [\boldsymbol{max}\{\inf \boldsymbol{\alpha_P}(u), \boldsymbol{inf\alpha_Q}(u)\}, \boldsymbol{max}\{\boldsymbol{sup\alpha_P}(u), \boldsymbol{sup\alpha_Q}(u)\}], \\ [\boldsymbol{min}\{\boldsymbol{inf\beta_P}(u), \boldsymbol{inf\beta_Q}(u)\}, \boldsymbol{min}\{\boldsymbol{sup\beta_P}(u), \boldsymbol{sup\beta_Q}(u)\}], \\ [\boldsymbol{1 - max}\{\boldsymbol{sup\alpha_P}(u), \boldsymbol{sup\alpha_Q}(u)\}, \boldsymbol{1 - max}\{\boldsymbol{inf\alpha_P}(u), \boldsymbol{inf\alpha_Q}(u)\}] >)/u \in U \end{matrix} \right\}$$

$$\oplus \boldsymbol{F_P} \cup \boldsymbol{G_Q} = \left\{ \begin{matrix} (< u, [\boldsymbol{max}\{\inf \boldsymbol{\alpha_P}(u), \boldsymbol{inf\alpha_Q}(u)\}, \boldsymbol{max}\{\boldsymbol{sup\alpha_P}(u), \boldsymbol{sup\alpha_Q}(u)\}], \\ [\boldsymbol{min}\{\boldsymbol{inf\beta_P}(u), \boldsymbol{inf\beta_Q}(u)\}, \boldsymbol{min}\{\boldsymbol{sup\beta_P}(u), \boldsymbol{sup\beta_Q}(u)\}], \\ [\boldsymbol{min}\{\boldsymbol{1 - sup\alpha_P}(u), \boldsymbol{1 - sup\alpha_Q}(u)\}, \boldsymbol{min}\{\boldsymbol{1 - inf\alpha_P}(u), \boldsymbol{1 - inf\alpha_Q}(u)\}] >)/u \in U \end{matrix} \right\}$$

$$\oplus \boldsymbol{F_P} = \{\langle \boldsymbol{u}, [\boldsymbol{inf\alpha_P}(u), \boldsymbol{sup\alpha_P}(u)], [\boldsymbol{inf\beta_P}(u), \boldsymbol{sup\beta_P}(u)], [\boldsymbol{1 - sup\alpha_P}(u), \boldsymbol{1 - inf\alpha_P}(u)]\rangle : \boldsymbol{u} \in \boldsymbol{U}\}$$

$$\oplus \boldsymbol{G_Q} = \{\langle \boldsymbol{u}, [\boldsymbol{inf\alpha_Q}(u), \boldsymbol{sup\alpha_Q}(u)], [\boldsymbol{inf\beta_Q}(u), \boldsymbol{sup\beta_Q}(u)], [\boldsymbol{1 - sup\alpha_Q}(u), \boldsymbol{1 - inf\alpha_Q}(u)]\rangle : \boldsymbol{u} \in \boldsymbol{U}\}$$

By definition

$$\oplus \boldsymbol{F_P} \cup \oplus \boldsymbol{G_Q} == \left\{ \begin{matrix} (< u, [\boldsymbol{max}\{\inf \boldsymbol{\alpha_P}(u), \boldsymbol{inf\alpha_Q}(u)\}, \boldsymbol{max}\{\boldsymbol{sup\alpha_P}(u), \boldsymbol{sup\alpha_Q}(u)\}], \\ [\boldsymbol{min}\{\boldsymbol{inf\beta_P}(u), \boldsymbol{inf\beta_Q}(u)\}, \boldsymbol{min}\{\boldsymbol{sup\beta_P}(u), \boldsymbol{sup\beta_Q}(u)\}], \\ [\boldsymbol{min}\{\boldsymbol{1 - sup\alpha_P}(u), \boldsymbol{1 - sup\alpha_Q}(u)\}, \boldsymbol{min}\{\boldsymbol{1 - inf\alpha_P}(u), \boldsymbol{1 - inf\alpha_Q}(u)\}] >)/u \in U \end{matrix} \right\}$$

$$\oplus \left(\boldsymbol{F_P} \cup \boldsymbol{G_Q}\right) = \oplus \boldsymbol{F_P} \cup \oplus \boldsymbol{G_Q}$$

Statement (2) follows similarly.

**Preposition 10**

Let $\boldsymbol{F_P}$ , $\boldsymbol{G_Q}$, $\boldsymbol{H_R}$ ∈ IVNSHSS over $\boldsymbol{U}$, then

1. $\oplus \left(\boldsymbol{F_P} \curlyvee \boldsymbol{G_Q}\right) = \oplus \boldsymbol{G_Q} \curlyvee \oplus \boldsymbol{F_P}$
2. $\oplus \left(\boldsymbol{F_P} \curlywedge \boldsymbol{G_Q}\right) = \oplus \boldsymbol{G_Q} \curlywedge \oplus \boldsymbol{F_P}$
3. $\otimes \left(\boldsymbol{F_P} \curlyvee \boldsymbol{G_Q}\right) = \otimes \boldsymbol{G_Q} \curlyvee \otimes \boldsymbol{F_P}$
4. $\otimes \left(\boldsymbol{F_P} \curlywedge \boldsymbol{G_Q}\right) = \otimes \boldsymbol{G_Q} \curlywedge \otimes \boldsymbol{F_P}$

Proof is directly obtained by definition.

## CONCLUSION

In this article, we introduce a new mathematical model called the Interval-Valued Neutrosophic SuperHyperSoft Set (IVNSHSS). This model is designed specifically as a way to handle complicated uncertainties in multi-attribute contexts. The IVNSHSS combines interval-valued neutrosophic sets and superhyper parameterization to produce an expressive and flexible representation of uncertainty, indeterminacy, and inconsistency, which is superior to existing soft set type structures. The IVNSHSS has completely defined and analyzed its fundamental concepts: null set, universal set, complement, union, intersection, difference, scalar operations, as well as different operators. We provide propositions that explore the algebraic properties of these operations along with several illustrative examples that demonstrate their reality. The IVNSHSS model allows an extension of classical soft sets, hypersoft sets, and interval-valued neutrosophic soft sets by allowing for the construction of the parameters from the Cartesian product of the power sets of the attribute domains. Therefore, the IVNSHSS framework will be especially applicable to solutions to real-life problems with interacting attributes and imprecise data. Furthermore, our findings contribute to building the theoretical basis for neutrosophic computing and soft computing theories and create opportunities for future research.

## ABSTRACT

*Amaranthus hypochondriacus* L. is a nutritionally and pharmacologically important plant rich in bioactive phytochemicals. The present study investigates the effect of UV-C irradiation on phytochemical variations in *in vitro* callus cultures of *A. hypochondriacus* using High-Performance Thin-Layer Chromatography (HPTLC). Optimal callus induction was achieved after four weeks on Murashige and Skoog (MS) medium supplemented with 1 mg/L IBA, 1 mg/L 2,4-D, and 2 mg/L kinetin (CIM1). Callus cultures (GA6) exposed to UV-C treatment for 60 minutes showed enhanced and distinct phytochemical profiles. The harvested *in vitro* samples were dried, pulverized, and subjected to Soxhlet extraction. Extracts (2–12 µL) from UV-C-treated calluses were applied as 8 mm bands on Merck Silica gel $60F_{254}$ TLC plates using a CAMAG Linomat-V applicator. Chromatographic development was carried out using toluene:ethyl acetate:formic acid (5:4:1 v/v%). The developed plates were visualized under white light and UV light at 254 nm using a CAMAG TLC Visualizer, followed by densitometric scanning at 254 nm with a CAMAG Scanner IV. Data acquisition and analysis were performed using WINCATS software. HPTLC fingerprinting revealed effective separation of multiple phytochemical constituents, indicating UV-C-induced metabolic variations in callus cultures. Although the absence of reference standards limited definitive compound identification, the observed chromatographic patterns provide a strong

basis for future studies. Further characterization using advanced analytical techniques such as LC-MS or GC-MS, along with standard compounds, is recommended for precise identification and structural confirmation of UV-C-responsive phytochemicals.

## INTRODUCTION

Drug development and therapeutic applications are based on secondary metabolites [1]. Secondary metabolites found in therapeutic plants have important therapeutic qualities. As antioxidative, anticancer, anti-inflammatory and antimicrobial agents, these bioactive substances have significant therapeutic potential [2-5]. For thousands of years, pseudocereals have been a staple food in many parts of the world. Even though their geographic dominance varies, they still serve as the main source of nutrition in many of the world's poorest regions. Pseudocereals have also become more well-known in European nations in recent decades due to their nutritional and health advantages. Amaranth, buckwheat, sorghum, millet, chia, and khorasan are some of the most well-known pseudocereals; the most researched are quinoa, amaranth, chia, and buckwheat [6]. Amaranth's full potential is still not being fully utilized, despite its lengthy history and cultural significance. It has substantial economic value due to its nutritional diversity and adaptability, providing a range of advantages to food processors, producers, and consumers. Because of the superior nutritional and functional qualities of its seeds, the pseudocereal *Amaranthus hypochondriacus* is essentially recognised as a grain crop [7,8]. The potential of pseudocereal *A. hypochondriacus* as a functional food has been rediscovered in recent years due to its excellent seed protein quantity and quality, availability of dietary fibres, lipid-rich unsaturated fatty acids, vitamins, micronutrients, etc. [9-11]. Amaranths are a nutrient-dense powerhouse rich in bioactive compounds such as carotenoids, polyphenols, and flavonoids. These compounds are associated with a range of health benefits, including antioxidant, anti-inflammatory, and anticancer properties. Because of its antiseptic, antifungal, and anti-inflammatory qualities, amaranth is widely used in the pharmaceutical industry to create medications that target atherosclerosis, stomach ulcers, and tuberculosis [12].

The seeds of *Amaranthus hypochondriacus* L. are known to be a spermatogenetic medication and tonic in Unani medicine [13]. Furthermore, the plant's decoction is customarily used to treat heavy menstrual bleeding, and the flowers are used as remedies for coughing, diarrhea, dysentery, and hemorrhages. Studies using both human [14] subjects and animal [15] models have demonstrated the substantial antidiabetic effects of amaranth oil. Additionally, research suggests that taking amaranth oil supplements improves antioxidant defences and strengthens immune function, especially in people with hyperlipoproteinemia or ischaemic heart disease[16]. According to [17] amaranth extract made from the entire plant has strong antioxidant properties and can significantly scavenge free radicals in the DPPH assay. Similarly, in rats that were subchronically exposed to ethanol, [18] examined the antioxidant qualities of *Amaranthus hypochondriacus* seed extract. Their results supported the extract's positive effects and demonstrated that it protected against ethanol-induced liver damage due to its high polyphenol content [18]. Examined the phytochemistry and *in vitro* antioxidant activity of extracts from the leaves, stalks, seeds, flowers, and sprouts of *A. hypochondriacus*, *A. caudatus*, and *A. cruentus*. They discovered that *A. hypochondriacus* had higher antioxidant potentials and that phenolics and antioxidant activity were positively correlated [19]. Additionally, a variety of secondary metabolites found in amaranth have positive effects on the diets of both humans and animals[20]. The phenolic compound content of amaranth seeds [21] as well as their functional and bioactive qualities [22-25] have been the subject of numerous investigations over the last fifteen years. In light of this, the current study intends to describe the agronomic characteristics, oil content, fatty acid profile, antioxidant activity, and total phenolic content of four *Amaranthus hypochondriacus* seed accessions that come from Nebraska, Iowa, India, and Pennsylvania and are all grown in identical environmental conditions.

The goal is to increase knowledge of this species as a beneficial source of nutrients and bioactive substances, especially essential fatty acids and polyphenols, for use in animal feed. "However, the World Health Organization has promoted the use of contemporary analytical methods like Gas Chromatography–Mass Spectrometry (GC–MS), High-Performance Thin Layer Chromatography (HPTLC), and High-Performance Liquid Chromatography (HPLC) and stressed the significance of quality control and standardization of plant materials" [26]. Because of its accuracy, affordability, and speed, High-Performance Thin Layer Chromatography (HPTLC) has established itself as a standard analytical method and is being utilized more and more in place of High-Performance Liquid Chromatography (HPLC) for the estimation of biochemical products derived from plants. Because all conditions in HPTLC are automated, the same plate can be scanned repeatedly. Additionally, the method can be used to validate a large range of compounds, regardless of their polarity. The ability of HPTLC-based chromatographic fingerprinting to identify the presence or absence of marker compounds of interest and to ascertain the relative proportions of all detectable constituents is one of its main benefits. At the micro- and nanogram levels, HPTLC is still a useful technique for evaluating the quality of a variety of natural products, herbal medications, and commercial herbal formulations. The current study will use the HPTLC technique to compare the phytochemical profiles of *in vitro* and wild plants in order to achieve its research goal. Because of their substantial analytical capabilities, HPTLC methods are regarded as a good substitute in routine drug analysis. The method saves time and money on analysis because it uses very little mobile phase [27]. Additionally, HPTLC reduces the possibility of coming into contact with dangerous chemicals and producing harmful wastewater, which eventually helps to lessen pollution in the environment. The current study uses High-Performance Thin-Layer Chromatography (HPTLC) techniques to identify and characterize the bioactive compounds found in the plant extract of *Amaranthus hypochondriacus* L. This analysis might offer insightful information about the plant's possible uses in both conventional and contemporary medicine.

## MATERIALS AND METHODS

**Culture condition**

As explants, 60 min. UV-C irradiated [28,29] and sterilized seeds of *Amaranthus hypochondriacus* L. (GA6) were inoculated on solid Murashige and Skoog (MS) basal medium (Murashige and Skoog, 1962) supplemented with different concentration of PGRs ( MS + 1mg/l IBA + 1mg/l 2,4-D + 2mg/l KIN - MS + CIM1) [30], (MS + 1mg/l IBA + 2mg/l 2,4-D - MS + CIM2) and (MS + 4 mg/l 2,4-D – MS + CIM3) [31]. The medium's pH was brought down to 5.7 before it was autoclaved for 15 minutes at 121 °C and 15 psi. Using light-emitting diode (LED) lights, the inoculated explants were incubated for callus induction at 25 ± 2 °C for 16/8 hours of light/dark photoperiod with an illuminance of 25 μmol $m^{-2}$ $s^{-1}$.

**Extraction**

In order to completely remove the moisture and dehydrate the callus, the freshly collected *in vitro* sample (callus) were dried for 12 to 24 hours at 35 °C using a dehydrator (Kenwood food dehydrator, England). After the *in vitro* sample (Callus) was dried and ground into a fine powdered (Fig. 2a.), a Soxhlet apparatus was used to extract it. The extraction solvent used was methanol [32]. 10 grams powdered of callus was extracted with methanol (100 ml) using soxhlet apparatus at 60–80°C. Whatman No. 42 Filter paper was used to clarify the resultant extract, and the excess solvent was evaporated to concentrate the filtrate (Fig. 2b.). Thereafter, the crude extract was stored in airtight containers for additional examination.

**Qualitative phytochemical analysis**

The phytochemical analysis of the methanolic extract from the 60-minute UV-C-treated callus of *A. hypochondriacus* was subjected to preliminary phytochemical screening using standard qualitative tests to identify the presence of different phytoconstituents in accordance with established protocols [33] (Table 1).Qualitative phytochemical analysis of the methanolic extract from the 60 min. UV-C-treated callus of *A. hypochondriacus* L. (Table 1).

**HPTLC Fingerprinting**

HPTLC fingerprinting was performed on Merck Silica gel 60F254 TLC precoated plates. Six separate concentrations of 2 µL, 4 µL, 6 µL, 8 µL, 10 µL, and 12 µL of extract were performed separately placed to the plate in the shape of an 8 mm broad band using the CAMAG (Switzerland) Linomat-V sample applicator. The mobile phase was composed of toluene: Ethyl acetate: formic acid (5:4:1v/v). In a CAMAG twin trough chamber (20 × 10 cm) that had been equilibrated with mobile phase for 20 minutes, the plate was developed to a distance of 70 mm. Following development, the plate was examined using the CAMAG TLC Visualizer, and pictures were captured using white light and 254 nm. Anisaldehyde sulfuric acid reagent (ASR) was used to derivatize the plate, which was then stored at 110 °C for three minutes until color bands formed. The plate was then scanned using a CAMAG Scanner IV at 254 nm. The finger print data was recorded using the WINCATS planer chromatography management software [34].

## RESULT

**Callus induction**

Callus initiation exhibited considerable variation among explant types, indicating a differential response to the specific auxin-to-cytokinin ratios present in the medium. Of the three combinations tested, MS medium with 1 mg/l IBA+1 mg/l 2,4-D + 2 mg/l KIN. (MS+CIM1) was the best. (Fig. 1). It reached a peak induction rate of 90% in the period of four weeks. Initially, the calluses appeared off-white, after a few days they turned yellowish-white. The callus was fibrous in texture, easily breakable into small fragments, and ideal for callus multiplication. Optimal callus formation was achieved after four weeks using MS supplemented with 1mg/l IBA + 1mg/l 2,4-D + 2mg/l KIN - MS + CIM1 (Fig.1). Fig. 2a. Dried poweder of callus obtained from 60 min. UV-C Treated seed of *A.hypochondriacus* L. Fig. 2b. Methanolic extract of callus obtained from 60 min. UV-C Treated seed of *A. hypochondriacus* L. *Amaranthus hypochondriacus* has a rich phytochemical composition and therapeutic potential, as evidenced by the presence of alkaloids, phenolic compounds, flavonoids, terpenoids, saponins, glycosides, and amino acids in preliminary phytochemical screening. (Table 2). Table 2: Qualitative phytochemical screenings of the methanolic extract from the 60-minute UV-C-treated callus of *A. hypochondriacus* L. Note: '+'indicates present and'-'indicates absent.

**HPTLC**

The HPTLC fingerprinting of methanolic extracts of 60-min UV-C treated callus of *Amaranthus hypochondriacus* L., using the solvent system toluene : ethyl acetate : formic acid (5:4:1 v/v/v), revealed successful separation of several phytoconstituents corresponding to distinct retention factor (Rf) values and chromatographic peaks. Different Rf values of the compounds provide insights into their polarity, which in turn can guide the selection of a suitable solvent system for isolating a particular compound from plant extracts using chromatographic and spectroscopic techniques [35]. A compound that exhibits a high Rf value in a less polar solvent system is of relatively low polarity, whereas one with a low Rf value is comparatively more polar [36]. Based on the obtained Rf values, the presence of different phytoconstituents in the methanolic extract of UV-C treated callus was confirmed, indicating significant phytochemical diversity. The chromatographic profile revealed the presence of ten (10) distinct components in the 60-min UV-C treated callus extract of *A. hypochondriacus* L. (Table 3 and Fig.3).The chromatogram recorded at 254 nm and its three-dimensional representation are displayed in Fig.4. The number of constituent peaks, their corresponding Rf values, area % and number of components are summarized (Table 3). Six tracks of different volumes of methanolic extract of 60 min. UV-C Treated *Amaranthus hypochondriacus* L. callus were applied, and the results were examined at 254 nm under UV light. The phytoconstituents present were examined by measuring the resulting peaks and Rf values at various wavelengths. The methanolic extract of *Amaranthus hypochondriacus* L. produced three bands when applied at a 2 µL spot (Track 1). Increasing the spot volumes to 4 µL, 6 µL and 8 µL (Tracks 2–4) yielded seven bands each, while a 10 µL spot (Track 5) produced ten bands, and a 12 µL spot (Track 6) resulted in six bands. (Fig.3). All sample constituents were clearly separated by high-performance thin-layer chromatography (HPTLC) fingerprinting of the methanolic extract of *Amaranthus hypochondriacus* L. demonstrating the lack of diffusion and tailing (Fig.3). Three spots with Rf values of 0.67, 0.75, and 0.82 were found in the 2 µL sample of *Amaranthus hypochondriacus* methanolic extract that was analyzed at 254 nm. Since it made up 41.88 % of

the entire chromatographic area, the compound at Rf = 0.82 was determined to be the predominant component. When a 4 µL aliquot of *Amaranthus hypochondriacus* methanolic extract was analyzed at 254 nm, seven different spots were visible, with Rf values of 0.11, 0.22, 0.33, 0.44, 0.67, 0.74, and 0.79. The components that corresponded to Rf 0.67 and Rf 0.79 were the most prevalent among these, making up 27.51% and 18.31% of the total area, respectively. Seven different spots with Rf values of 0.11, 0.18, 0.21, 0.33, 0.44, 0.67, and 0.73 were visible when a 6 µL aliquot of *Amaranthus hypochondriacus* methanolic extract was applied and scanned at 254 nm. The components with Rf values of 0.33, 0.44, 0.67, and 0.73 were found to be predominant in a 4 µL application of the same extract, corresponding to percentage areas of 12.71%, 15.90%, 34.02%, and 17.18%, respectively. The area percentage of all the spots was less than 10%, indicating that the remaining components were present in very small amounts. Seven spots (Rf = 0.11, 0.22, 0.33, 0.44, 0.67, 0.73, and 0.77) were found in an 8 µL methanolic extract of *Amaranthus hypochondriacus* that was analyzed at 254 nm; the components that corresponded to Rf = 0.67 and Rf = 0.77 were the most prevalent, with percentage areas of 30.93% and 16.43%, respectively. Among the 10 components obtained in a 10 µL aliquot of the *Amaranthus hypochondriacus* methanolic extract at 254 nm (with Rf values of 0.11, 0.22, 0.33, 0.44, 0.53, 0.59, 0.62, 0.68, 0.74, and 0.77), the compounds with Rf values of 0.44 and 0.68 were the most prevalent, accounting for 12.13% and 27.04% of the total peak area, respectively. Fig. 3: The HPTLC chromatogram of methanolic extract of 60 min. UV-C treated *A. hypochondriacus* L. callus. Six spots with Rf values of 0.12, 0.23, 0.35, 0.46, 0.70, 0.77, and 0.81 were found in the 12 µL methanolic extract of *Amaranthus hypochondriacus* that was analyzed at 254 nm. With 15.35% and 28.96% of the total area, respectively, the compounds that corresponded to Rf 0.35 and 0.70 were the most prevalent among them. Three dimensional representation of all tracks at 254 nm wavelength (Fig. 5).

## DISCUSSION

In the present study, high-performance thin-layer chromatography (HPTLC) was employed to profile the phytochemical constituents of this extract. Multiple distinct bands were observed in the chromatographic fingerprints, indicating the presence of several phytocomponents. Discrete spots or bands on the chromatogram, each spot representing a compound (or cluster of compounds) migrating to a specific Rf under the selected conditions can be used in HPTLC fingerprinting to infer the number of phytochemical constituents, even in the absence of pure reference standards." By documenting Rf values, spot intensities (e.g., area or height) and appearances under different detection modes (UV at various wavelengths, visible light) one establishes a chromatographic fingerprint or chemical profile of a sample. HPTLC is prized for its quick, effective, and repeatable analysis [37].Plant-based compound analysis is more precise and accurate when integrated with digital scanning [38]. HPTLC techniques are frequently used in routine drug analysis because of their analytical significance. As a result, fingerprints without standards are still useful for qualitative and comparative sample profiling, identifying batch-to-batch consistency, variation, or adulteration. Due to the unavailability of reference standards, direct confirmation of individual compounds was not performed. However, tentative identification of the phytochemicals was achieved by comparing the observed Rf values with those reported in previously published literature under similar chromatographic conditions. The consistency between the Rf values obtained in this study and those documented for known phytoconstituents suggests the possible presence of compounds such as flavonoids, phenolic acids, alkaloids, and terpenoids. HPTLC fingerprinting without the use of standards is widely accepted as a preliminary qualitative approach for phytochemical characterization and provides valuable insight into the chemical complexity of plant extracts.

Nevertheless, it is acknowledged that Rf-based identification remains presumptive, as Rf values may vary depending on the solvent system, stationary phase, and experimental conditions. The absence of standards limits definitive identification of individual compounds; however, the observed separation provides a foundation for future studies involving standard compounds and advanced analytical techniques such as LC-MS, or GC-MS for precise identification and structural confirmation. Overall, the findings demonstrate that HPTLC is an efficient and reproducible method for preliminary phytochemical screening and for assessing the number of components present in complex plant extracts. The qualitative variations in the phytocompounds were reflected in the variations in the Rf

values of the majority of the peaks that emerged. This HPTLC densitometry fingerprint profile can be used as a marker for standardisation and evaluation of extract quality. As a result, the HPTLC fingerprint profile and the extract's Rf values were noted, which would act as a benchmark for further research on the plant [39]. Furthermore, it is both practical and safe to use *Amaranthus hypochondriacus* L. in nutraceuticals and herbal formulations because it is already consumed as a grain and leafy vegetable in many parts of the world. The standardization made possible by HPTLC guarantees that the therapeutic effectiveness of these preparations can be reliably and scientifically confirmed. Herbal medicines have replaced synthetic drugs globally in recent years; this trend is frequently referred to as a "return to nature." [40]. The World Health Organization (WHO) divides herbal medicines into three categories: finished herbal medicinal products, processed plant materials, and raw plant materials [41]. Both developed and developing nations' healthcare systems make extensive use of these plant-based preparations, which are intricate chemical blends [42]. Therefore, the current study emphasizes that the methanolic extract of *A. hypochondriacus*, backed by HPTLC fingerprinting, can be a solid foundation for creating herbal medicines and functional foods that are affordable and targeted at treating chronic and lifestyle-related illnesses.

## CONCLUSION

Emplyoing toluene, ethyl acetate, and formic acid (5:4:1 v/v%) as the mobile phase, the HPTLC analysis successfully identified the presence of several phytochemical components in the methanolic extract of 60 min. UV-C treated *Amaranthus hypochondriacus* L. callus, indicates the plant's potential as a valuable source of bioactive compounds. The technique produced a distinct chromatographic fingerprint and made it possible to determine the quantity of phytoconstituents even in the absence of reference standards. This initial analysis can be used as a starting point for additional pharmacological and phytochemical research. The preliminary phytochemical screening result was further validated by the HPTLC analysis results, which displayed distinct colored bands indicating the presence of specific phytocomponents. *A. hypochondriacus* shows promise for the creation of affordable herbal formulations and therapeutic agents in the future due to its rich nutritional profile and medicinally significant secondary metabolites. To confirm its effectiveness and safety for use in medicine, more pharmacological and clinical research is necessary. Considering their phytochemical richness, these plants may also be explored as inexpensive sources for herbal medicines and formulations with potential applications against a wide spectrum of diseases.

## ACKNOWLEDGEMENTS

The author expresses gratitude to the Department of Biology , Municipal Arts and Urban Science College, Mehsana (HNGU) and Pramukh Swami Science and H. D. Patel Arts College, Kadi (HNGU) Gujarat, India for providing the infrastructure and research facilities necessary to finish this work and also thankful to SICART Anand-388120 for HPTLC Analysis.

**ABSTRACT**

Vernal keratoconjunctivitis (VKC) is a chronic, recurrent allergic inflammation of the ocular surface commonly affecting children in warm climates. Classical Ayurvedic texts describe *Kaphaja Abhishyanda* as a Kapha-dominant ocular disorder characterised by itching, mucous discharge, heaviness of lids, and recurrent congestion, suggesting a possible correlation. To explore the conceptual relationship between *Kaphaja Abhishyanda* and VKC through classical and contemporary literature. A narrative integrative review was conducted using *Sushruta Samhita*, *Ashtanga Hridaya*, *Ashtanga Sangraha*, and modern ophthalmic literature. Descriptions of *nidana*, *lakshana*, prognosis, and *chikitsa* were compared with VKC pathophysiology and management. Close parallels were observed in etiological factors, clinical features, disease progression, and therapeutic goals. Classical symptoms such as *kandu*, *picchilasrava*, and *guruta* correspond with itching, ropy mucus, and lid heaviness in VKC. Ayurvedic *shodhana*, *shamana*, and *kriyakalpa* principles align with modern anti-inflammatory and tear-film stabilising strategies. VKC shows strong conceptual similarity with *Kaphaja Abhishyanda*, supporting an integrative understanding of chronic allergic ocular surface disease.

## INTRODUCTION

Vernal keratoconjunctivitis (VKC) is a chronic, recurrent allergic inflammation of the ocular surface predominantly affecting children and young adults living in warm, humid, and dusty climates. It is one of the most severe forms of

ocular allergy and contributes significantly to pediatric ophthalmic morbidity in tropical regions [1].In India, the burden of VKC is notably higher in hot and dusty zones, where recurrent seasonal exacerbations create a sustained disease load among school-aged populations [2].The condition is mediated by IgE-associated hypersensitivity, mast cell degranulation, eosinophil infiltration, and cytokine-driven conjunctival inflammation, which collectively produce persistent irritation and chronic ocular surface damage [3,4].Ongoing allergic inflammation of the conjunctiva and cornea may lead to keratopathic changes, including shield ulcers and superficial keratopathy, which can ultimately result in significant visual impairment if not identified and managed appropriately [3]. Clinically, the disease presents with intense itching, photophobia, foreign body sensation, mucous discharge, and recurrent redness, which often interfere with daily activities, school performance, and quality of life. The seasonal recurrence and chronic course of the disease make long-term management challenging, often requiring repeated medical intervention and continuous monitoring. VKC is also recognised for its tendency to fluctuate in severity, with periods of remission followed by exacerbations triggered by environmental and seasonal factors. These recurrent inflammatory episodes may gradually compromise the integrity of the ocular surface and tear film stability, thereby increasing the risk of corneal complications and visual disturbances. From a public health perspective, chronic ocular allergy in children represents a considerable burden due to frequent hospital visits, prolonged therapy, and the psychological stress experienced by patients and caregivers. The need for safer and more sustainable management strategies has therefore become increasingly important, especially in regions where environmental triggers remain unavoidable. Contemporary management primarily focuses on suppressing allergic inflammation and stabilising the ocular surface; however, recurrence and long-term dependency on medications remain major concerns. Our Acharyas have described comparable conditions under *Abhishyanda*, wherein *doshic* derangements, particularly *Kapha*, affect the ocular surface and produce symptoms resembling persistent allergic conjunctival involvement [5].Classical descriptions of *kandu, picchilashleshmasrava, gaurava, shleshmaavarana*, and *aviladarshana* show notable overlap with the characteristic patterns of VKC seen today. The foundational principles given for its pathogenesis and management emphasise timely intervention to prevent chronicity and complications, which aligns closely with the modern clinical emphasis on preventing corneal damage and recurrence [6].Ayurveda provides a comprehensive framework for understanding chronic and recurrent disorders through the concepts of *dosha* imbalance, environmental triggers, and host susceptibility. The description of *Kapha*-dominant ocular disorders particularly highlights the role of mucous accumulation, surface congestion, and recurrent inflammatory changes, which are central to the clinical behaviour of VKC. The emphasis on early intervention, prevention of recurrence, and restoration of ocular surface balance reflects a holistic perspective that parallels current efforts to achieve long-term disease control in allergic eye disease. The explanations of disease behaviour and therapeutic rationale in the Samhitas remain relevant and parallel the current understanding of VKC in ophthalmology. Exploring these conceptual similarities can provide an integrative perspective that may support the development of safer and more sustainable management strategies for chronic allergic ocular disorders.

**Understanding Kaphaja Abhishyanda in Compendia**

*Abhishyanda* is classified under *Sarvagata Netra Roga*. *Sushruta* describes a total of 11 *Sarvagata Rogas* [7].*Sushruta* and *Vagbhata* further classified it into four types: *Vataja, Pittaja, Kaphaja,* and *Raktaja* [7,8].Among these, *Kaphaja Abhishyanda* is marked by *Kapha* predominance. The condition is described as *sadhya* in early stages and may progress to *krichrasadhya* or *asadhya* depending on severity and chronicity, with *Kapha* as the primary *dosha* and *pitta anubandha* in later stages [7,8].The Sanskrit term *Kaphaja Abhishyanda* refers to an ocular condition in which *Kapha*-dominant qualities such as heaviness, coolness, and sticky mucous accumulation lead to congestion and overflow within the eye.

## OBJECTIVES

1. To establish the clinical correlation between *Kaphaja Abhishyanda,* as explained in the Ayurvedic *Samhitas*, and Vernal Keratoconjunctivitis (VKC), described under allergic inflammatory disorders of the ocular surface.

2. To review the Ayurvedic understanding and management principles that may offer an effective and safer approach to recurrent, chronic, and vision-impacting allergic conditions that continue to show similarity with classical descriptions even in present clinical practice.

## METHODOLOGY

An extensive literary review of Ayurvedic compendia was undertaken to explore a possible correlation between *Kaphaja Abhishyanda* and Vernal Keratoconjunctivitis (VKC) as described in contemporary ophthalmology. Classical texts, including *Sushruta Samhita*, *Ashtanga Hridaya*, *AshtangaSangraha*, and relevant commentaries, were examined [7–9],along with modern literature related to allergic ocular surface disorders [1–4]. As part of this process, departmental discussions and review of previously published articles were conducted to refine the conceptual understanding. Through this integrated analysis, an attempt was made to derive a coherent and clinically acceptable correlation between the two conditions.

## DISCUSSION

**Congruent Features of *Sarvagata* Involvement and Ocular Surface Inflammation**

While explaining *Sarvagata Netra Rogas*, the classical texts describe *Abhishyanda* as a condition capable of affecting all the ocular layers, including *sandhi*, *shukla*, *krishna*, and *drishti* [7]. This broad involvement can be correlated with the diffuse inflammation seen in Vernal Keratoconjunctivitis (VKC), where the conjunctiva, limbus, and anterior corneal surface show simultaneous changes. The shared inflammatory response, mucous accumulation, and surface congestion reflect the classical description of *shleshmaavarana* and *picchilashleshmasrava* noted in *Kaphaja Abhishyanda*. Modern ophthalmology acknowledges that allergic ocular disorders frequently involve both conjunctival and limbal zones due to immunological activation, and this pattern matches the classical concept of *sarvagata* involvement described in the *Samhitas* [3,4]. The prominence of itching, surface irritation, and mucous stagnation in VKC aligns closely with the *Kapha*-dominant *lakshanas* such as *kandu*, *sheetasparsha*, and *gaurava*, reinforcing the similarity between the two descriptions. Furthermore, the chronicity and recurrent nature of VKC can be compared with the repeated *dosha prakopa*mentioned in classical texts, where *Kapha* accumulation and congestion (*Abhishyanda*) require repeated interventions [7,8]. These conceptual parallels indicate that the behaviour of VKC mirrors the pattern of *KaphajaAbhishyanda* as understood in Ayurveda, offering a basis for integrative interpretation.

**Correlation of Ocular Surface Layer Involvement in VKC with the *Sarvagata* Nature of *Abhishyanda***

The structural involvement described in *Abhishyanda* shows close correspondence with the layer-wise pathology seen in Vernal Keratoconjunctivitis (VKC). In VKC, inflammatory changes affect the conjunctival epithelium, subepithelial papillary zone, limbal stroma, and anterior corneal surface, reflecting the *sarvagata* nature of *Abhishyanda* described in the *Samhitas* [7].The term *sarvagata* denotes a diffuse ocular disorder involving the *sandhi*, *shukla*, *krishna*, and even *drishti* structures simultaneously, indicating a multi-layer and widespread pattern of inflammation rather than a confined lesion. This aligns with the epithelial irritation, mucous accumulation, papillary hypertrophy, and anterior corneal changes characteristic of VKC, supporting the parallel between modern ocular surface involvement and the classical description of *KaphajaAbhishyanda* [3,4].

**Congruence Features of *Nidana* of *Kaphajaabhishyanda* and Aetiology of Vernal Keratoconjunctivitis (vkc)**

***Sita sevana* -** Frequent exposure to cooled indoor air, humid rooms, or sudden temperature shifts.

***Dhuma Rajah Sevana* -** Contact with dust, smoke, traffic pollution, chalk dust, pollen, and outdoor allergens.

***Ati abhishyanda kara hetavah* -** Repeated eye rubbing, long screen exposure causing tear instability, and recurrent conjunctival irritation.

***Madhura snigdha guru aharasevana -*** High intake of dairy, sugary foods, and heavy diets that increase allergic tendencies.

**Vishesha prakriti and kala -** Atopic constitution and seasonal triggers such as spring-summer when VKC peaks.
Any factor that promotes chronic ocular surface irritation or allergen exposure can intensify mucous congestion and hypersensitivity responses, consistent with the *Kapha*-dominant pathology of *KaphajaAbhishyanda*. It can be clearly established that the *nidanas* identified by our Acharyas parallel the precipitating factors recognised in VKC even today [7,8].

**Congruence Features of *Kaphajaabhi shyandalaksanas* and Clinical Features of Vernal Keratoconjunctivitis (vkc)**
The *lakshanas* of *Kaphaja Abhishyanda* described in the *Samhitas* show remarkable similarity to the clinical profile of Vernal Keratoconjunctivitis (VKC). The feature *ushnabhinanda* indicates a tendency for symptoms to feel relieved with warmth, reflecting underlying *Kapha* stagnation and surface congestion typical of VKC [7,8]. *Guruta*, or heaviness of the lids, corresponds to the mechanical weight produced by palpebral papillary hypertrophy, while *akshishopha* aligns with the upper-lid oedema and tarsal thickening commonly seen in allergic conjunctival inflammation. The cardinal allergic feature, intense itching, directly matches the hallmark histamine-mediated symptom of VKC. *Padeha*, indicating a sensation of coating or stickiness, correlates with mucin overproduction, tear-film debris, and the formation of mucus plaques on the ocular surface. The descriptors *sheetata* or *shaityam* refer to a cool ocular sensation, paralleling the transient soothing effect felt after rubbing in VKC and signifying *Kapha* predominance. *Snavamuhur* denotes intermittent watering, corresponding to reflex tearing triggered by conjunctival irritation, and *picchila* refers to thick, ropy mucous discharge precisely matching the stringy mucus produced in VKC by goblet cell hyperplasia [3,4].Finally, *kaphabhipannanayana* indicates a *Kapha*-laden, congested ocular surface, mirroring the mucous-rich, inflamed appearance characteristic of active VKC.The cardinal manifestations of VKC, itching, mucous ropiness, eyelid heaviness, episodic blurred vision, and conjunctival congestion show a clear correlation with the *Kapha*-dominant *lakshanas* described under *Kaphaja Abhishyanda*, indicating strong conceptual alignment between classical descriptions and the modern clinical presentation of this chronic allergic ocular surface disorder [3,4,7,8]

**Congruence Features of *Sadhyalaksanas* of *Kaphaja abhishyanda* and Good-Prognosis Features of Vernal Keratoconjunctivitis (vkc)**
The *sadhyalakshanas* of *Abhishyanda*, described by the *Acharyas*, closely resemble the benign clinical patterns seen in VKC. Features such as *drishti sameepamna gacchanti* indicate sparing of the central visual axis, matching VKC's predominantly peripheral or limbal involvement [7,8]. *Na ca gambhirasamsthita* reflects superficial disease, similar to VKC's epithelial or subepithelial changes without stromal penetration. The absence of purulent discharge (*na ca bahu sravayukta*) aligns with VKC's non-infective, mucous-type secretions, while *na ca bahu vedana* corresponds to VKC being itch-dominant rather than painful. The feature *eka deshasthita* denotes localised involvement, paralleling the confined limbal or tarsal areas affected in VKC. Together, these signs indicate a generally favourable prognosis consistent with the superficial, limited, and non-infective nature of VKC when appropriately managed [3,4,7,8].

**Congruence Features of *Asadhyalaksanas* and Complications**
The *asadhyalakshanas* described for *Abhishyanda* that hold relevance for Vernal Keratoconjunctivitis (VKC) are those indicating chronicity, vascular changes, surface instability, and visual impairment. *Shira rakta*, referring to pathological vessel adherence, closely mirrors the limbal neovascularisation seen in long-standing VKC due to persistent allergic inflammation [7,8]. *Drishti Krichra*, describing difficulty in vision when central structures are involved, corresponds to central shield plaques or scarring that can encroach upon the visual axis in severe VKC [3,4]. *Cira utthita*, denoting chronic or long-standing disease, aligns with VKC's recurrent course, where continuous inflammation leads to limbal hypertrophy and fibrotic changes. *Ushna ashru*, indicating warm and copious tearing, parallels the acute inflammatory lacrimation observed during VKC flare-ups. *Pidaka*, representing raised or blister-like elevations, may be compared to elevated shield plaques or early stromal thinning in neglected cases. These

selected features reflect VKC-related complications without including ulcer-specific descriptions unrelated to allergic ocular disease [3,4,7,8].

**Congruence Features of *Chikitsa Sutra* Explained in Ayurveda and Treatment Principles in Allied Sciences**

***Gharshana*:** Classical *gharshana* measures are designed to mechanically and functionally reduce *Kapha*-dominant accumulations on the ocular surface [7,8]. *Lekhana*-based collyria containing *haritaki*, *haridra*, *triphala*, or *yashtimadhu* exert a scraping and decongesting action, facilitating the breakdown of mucous adhesions and superficial epithelial debris. This aligns with contemporary VKC management practices in which mechanical removal of ropy mucus, papillary concretions, and epithelial irregularities is essential to reduce antigen load, restore surface smoothness, and improve the efficacy of topical medications [3,4].

***Kriyakalpa* procedures*:*** *Kriyakalpas* constitute the primary set of localised therapeutic interventions for *Kaphaja Abhishyanda* [7–9]. *Aschyotana* and *Parisheka* facilitate controlled ocular irrigation, aiding in the clearance of allergens, inflammatory mediators, and mucus from the conjunctival sac. Tarpana with medicated *ghrita* provides a lipid-rich protective layer that promotes epithelial stability and reduces surface hyper-reactivity. *Ruksha Putapaka* and *Bidalaka* help mitigate mucous viscosity and periocular heaviness, while Nasya modulates upper-channel congestion and *Kapha* dominance in the head region. *Dhumapana* and *Kavala*, through their influence on upper respiratory and nasopharyngeal pathways, may indirectly reduce ocular hypersensitivity. *Siravyadha* can be employed when there is marked *rakta* involvement, offering a classical method for relieving vascular congestion. Collectively, these interventions parallel modern therapeutic approaches for VKC, such as ocular lavage, lubricants, surface barrier enhancers, anti-inflammatory agents, and measures aimed at reducing vascular congestion and mucous hypersecretion [3,4].

***Abhyantara Chikitsa:*** Internal therapies indicated in *Kapha*-dominant *netrarogas* serve to regulate systemic inflammatory activity, alleviate *shopha* and *kandu*, and stabilise recurrence patterns [7–9]. Formulations that promote *Kaphashamana* and *srotasshodhana* support overall immunological balance. From a modern perspective, these internal measures correspond to the use of systemic anti-allergic agents, mucoregulators, and mild anti-inflammatory drugs, which serve as adjuncts in recurrent or chronic VKC to modulate hypersensitivity and reduce flare frequency [3,4].

## CONCLUSION

The chikitsa sutra for Kaphaja Abhishyanda focuses on reducing Kapha blockage, clearing excess mucus, easing inflammatory irritation, and improving epithelial repair. When looked at scientifically, these treatment goals align well with the evidence-based objectives of VKC management [3,4]. This includes reducing allergic inflammation, stabilising the eye surface, controlling mucus overproduction, and preventing long-term issues. The traditional combination of shodhana, shamana, and kriyakalpa methods offers a clear and sensible approach to dealing with the recurring, allergic, and destabilising aspects of VKC [7–9].The clinical behaviour of Vernal Keratoconjunctivitis shows clear conceptual similarity to the Kapha-dominant presentation of Kaphaja Abhishyanda described in the Ayurvedic texts. The recurrent itching, mucous discharge, surface irritation, and risk of anterior corneal involvement parallel the classical lakshanas, while the emphasis on shodhana, shamana, and kriyakalpa therapies aligns well with the therapeutic goals of modern VKC management [3,4,7–9]. The descriptions available in Ayurveda, therefore, provide a coherent framework for understanding the progression and complications of VKC and offer a structured approach that may support more sustained control of this chronic allergic ocular surface disorder. An integrative understanding of VKC through the Ayurvedic perspective highlights the importance of addressing both local ocular pathology and systemic susceptibility. By focusing on dosha balance, environmental triggers, and recurrence prevention, Ayurveda emphasises long-term disease control rather than symptomatic relief alone. This broader therapeutic perspective is particularly relevant for chronic and relapsing allergic disorders, where long-term safety and sustainability of treatment remain major clinical concerns.The alignment between classical Ayurvedic principles

and modern therapeutic objectives suggests the potential for integrative approaches in managing chronic allergic ocular surface disease. Such approaches may help reduce recurrence, improve patient comfort, and support ocular surface stability through combined preventive and therapeutic strategies. Future interdisciplinary research and clinical studies are needed to further explore these correlations and to evaluate the clinical effectiveness of integrative management strategies. Strengthening the scientific understanding of these parallels may contribute to the development of safe, holistic, and patient-centred approaches for the long-term management of Vernal Keratoconjunctivitis.

## ABSTRACT

Fruit farming is a cornerstone of our country's agricultural practices, and it has undergone significant advancements over time. Fruits are vital sources of nutrients, including essential minerals and vitamins. Detecting rotten fruits is crucial for agricultural enterprises, fruit processing, and packaging businesses. Traditionally, the classification of fruits as fresh or rotten is performed manually, a process that is both time-consuming and inefficient for cultivators. Therefore, there is a pressing need for an advanced classification model that can reduce human effort, costs, and production time by accurately identifying fruit defects. This paper proposes a hybrid classifier-based system for the categorization of fresh and rotten fruits. Experimental results demonstrate that the proposed hybrid approach outperforms existing classification algorithms in terms of accuracy. In this study, two supervised machine learning algorithms—Naive Bayes and BayesNet—are combined to form a hybrid model. The hybrid model achieves an accuracy of 96.14%, surpassing the Naive Bayes and BayesNet models, which achieved 91.42% and 90.21%, respectively. The objective of this research is to enhance the prediction accuracy in the classification of fresh and rotten fruits by integrating Naive Bayes and BayesNet algorithms. Furthermore, a comparative analysis between the

proposed hybrid algorithm and individual algorithms highlights the significant improvement in classification accuracy.

**Keywords:** Naive Bayes, BayesNet, Hybrid Classifier, Machine Learning, Fruit Classification.

## INTRODUCTION

One of the most challenging tasks in agriculture is the detection of fruit defects and the accurate classification of fresh and decaying fruits. Misclassifying rotten fruits not only reduces productivity but also poses a risk to the quality of surrounding fresh produce. Traditionally, this classification process has been performed manually, a method that is labor-intensive, time-consuming, and often inefficient. Additionally, manual sorting increases production costs. Hence, there is a critical need for an automated system that can enhance productivity, reduce labor costs, and minimize production times while lowering human effort. Fresh and Rotten Fruits Classification Using CNN and Transfer Learning might include findings related to the effectiveness of Convolutional Neural Networks (CNNs) and transfer learning in accurately distinguishing between fresh and rotten fruits [1]. It likely discusses the model's accuracy, potential applications in food quality control or agriculture, and possibly suggestions for future research or improvements. [3] The significance of fruit classification spans agriculture, food quality assurance, and supply chain management, playing a vital role in ensuring efficiency and product quality. Manual fruit sorting faces several challenges, such as inefficiency, inconsistency, and vulnerability to human error. [2] The study's primary objective is to assess the effectiveness of CNNs and transfer learning models in classifying fruits based on their distinctive features, with a focus on combining these approaches to achieve optimal accuracy while maintaining computational efficiency. This study focuses on developing an optimized hybrid classification framework to automate the identification process by analyzing digital images of fresh and rotten fruits using machine learning (ML) techniques. The proposed system combines the strengths of different algorithms to achieve more accurate results.

**Overview of Naïve Bayes and Bayesnet in Hybrid Classification Systems**

The Naïve Bayes algorithm, a supervised learning method grounded in Bayes' theorem, is one of the key components of this hybrid system. Naïve Bayes is widely used for solving classification problems, particularly in scenarios involving high-dimensional datasets, such as text classification. It is a probabilistic classifier, which means it makes predictions based on the probability of various features. Despite its simplicity, the Naïve Bayes classifier is highly effective in building fast machine learning models that deliver quick predictions

**The Naïve Bayes algorithm is named for two reasons:**

**Naïve:** It assumes that the occurrence of one feature is independent of other features.

**Bayes:** It relies on Bayes' theorem, which calculates the probability of a hypothesis based on prior knowledge and evidence

Bayes' theorem is mathematically expressed as:

$P(A|B) = [P(B|A) * P(A)] / P(B)$

P (A|B) P(A|B)P(A|B) is the posterior probability: the probability of hypothesis AAA given the observed event BBB.

P (B|A) P (B|A) P(B|A) is the likelihood: the probability of the evidence BBB given that hypothesis AAA is true.

P (A) P(A) P(A) is the prior probability: the initial probability of the hypothesis before considering the evidence.

P(B) P(B) P(B) is the marginal probability: the total probability of the evidence.

To apply the Naïve Bayes classifier, the dataset is first converted into frequency tables, followed by generating a likelihood table for the features. Bayes' theorem is then used to calculate the posterior probabilities, which aid in making predictions. The second algorithm used in the hybrid model is BayesNet. A Bayesian network (BayesNet) is a probabilistic graphical model that represents a set of variables and their conditional dependencies through a directed acyclic graph (DAG). This network is particularly useful for predicting the likelihood of different causes given an

observed event. In a Bayesian network, each edge represents a conditional dependency between variables, and each node corresponds to a unique random variable. The network adheres to the local Markov property, meaning that each node is conditionally independent of its non-descendants given its parent nodes. This property allows the joint probability distribution to be simplified, reducing the computational complexity of large networks by leveraging the combined strengths of Naïve Bayes and BayesNet, the proposed hybrid classification system aims to achieve higher accuracy in distinguishing between fresh and rotten fruits, ultimately improving efficiency and reducing costs in agricultural operations.

## MATERIALS AND METHODS

**Dataset:** In this study, the dataset used for classifying fresh and rotten fruits is sourced from Kaggle.com. This dataset contains 497 instances and 7 attributes, representing three different varieties of fruits: Apple, Banana, and Orange. The dataset includes various geometric parameters of the fruits, which are critical for the classification process.

**The parameters used are as follows:**

**Area (A):** The total surface area of the fruit.

**Perimeter (P):** The total boundary length of the fruit.

**Compactness (C):** Calculated as C=4πAP2C = \frac{4 \pi A} {P^2} C=P24πA, a measure of how compact the fruit is.

**Length of Kernel:** The length of the fruit kernel.

**Width of Kernel:** The width of the fruit kernel.

**Asymmetry Coefficient:** A measure of the asymmetry of the fruit shape.

**Length of Kernel Groove:** The length of the groove on the kernel

These parameters are integral to the classification process. The dataset is divided into training and testing subsets, with 70% of the data used for training the model and 30% for testing its performance.

**Proposed Model**

The proposed model for classifying fresh and rotten fruits is composed of the following steps:

**Step 1: Import the Dataset**

The first step involves importing the dataset containing the 497 instances and the 7 attributes related to the three fruit varieties: Apple, Banana, and Orange.

**Step 2: Data Preprocessing Data Cleaning**

This step involves handling any missing values in the dataset, removing duplicates, and ensuring that the data is clean and ready for analysis.

Normalization/Standardization: Depending on the data distribution, normalization or standardization is applied to scale the data, ensuring that all features contribute equally to the classification process.

**Step 3: Applying the Hybrid Classifier**

The hybrid classifier, which combines the Naïve Bayes and BayesNet algorithms, is applied to the preprocessed dataset.

**Step 4: Classification of Fresh and Rotten Fruits**

The hybrid classifier is used to classify the fruits into fresh or rotten categories based on the provided attributes.

**Algorithm**

The following steps outline the algorithm used for the classification process:

**Step 1: Data Preparation**

**Input Data:** Collect the dataset containing 497 instances and 7 attributes for the three varieties of fruits: Apple, Banana, and Orange.

**Preprocessing:** Clean the data by handling missing values, removing duplicates, and standardizing/normalizing the data if necessary.

**Step 2: Train Individual Models**
**Split Data:** Divide the dataset into a training set (DtrainD_{\text{train}}Dtrain) and a test set (DtestD_{\text{test}}Dtest). Typically, 70% of the data is used for training, and 30% is reserved for testing.

**Naïve Bayes Model**
Train the Model: Use the training set (DtrainD_{\text{train}}Dtrain) to train a Naïve Bayes model (NBNBNB).
Make Predictions: Apply the trained model to the test set (DtestD_{\text{test}}Dtest) to generate predictions (PNBP_{\text{NB}}PNB).

**Calculate Accuracy:** Determine the accuracy (ANBA_{\text{NB}}ANB) of the Naïve Bayes model by comparing the predictions with the actual labels

**BayesNet Model**
**Train the Model:** Use the training set (DtrainD_{\text{train}}Dtrain) to train a BayesNet model (BNBNBN).
Make Predictions: Apply the trained model to the test set (DtestD_{\text{test}}Dtest) to generate predictions (PBNP_{\text{BN}}PBN).

**Calculate Accuracy:** Determine the accuracy (ABNA_{\text{BN}}ABN) of the BayesNet model by comparing the predictions with the actual labels.

**Step 3: Create Hybrid Model**
**Combine Individual classifiers**
Combine the predictions from the Naïve Bayes model (PNBP_{\text{NB}}PNB) and the BayesNet model (PBNP_{\text{BN}}PBN) to create a hybrid prediction (PHybridP_{\text{Hybrid}}PHybrid).
A common approach is to use a majority voting method or a weighted average to combine the predictions, ensuring the strengths of both models are utilized.

**Step 4: Evaluate Hybrid ModelCalculate Hybrid Accuracy**
Compare the hybrid predictions (PHybridP_{\text{Hybrid}}PHybrid) with the actual labels (ytesty_{\text{test}}ytest) to calculate the accuracy (AHybridA_{\text{Hybrid}}AHybrid) of the hybrid model.

**Step 5: Compare Results**
**Compare Accuracies:**
Finally, compare the accuracies of the individual models (ANBA_{\text{NB}}ANB for Naïve Bayes and ABNA_{\text{BN}}ABN for BayesNet) with the accuracy of the hybrid model (AHybridA_{\text{Hybrid}}AHybrid).

This comparison demonstrates the performance improvements achieved by combining the two algorithms

## RESULTS AND DISCUSSION

This study aimed to enhance the prediction accuracy for the classification of fresh and rotten fruits by developing a hybrid machine learning algorithm. The two supervised machine learning algorithms selected for this study are Naïve Bayes and BayesNet, both of which are widely used for classification tasks. By combining these two algorithms, a proposed hybrid algorithm was created to improve the classification accuracy.

**Individual Model Performance**

Naïve Bayes Algorithm: The Naïve Bayes algorithm, known for its simplicity and effectiveness, was applied to the dataset. This algorithm assumes that the features are independent, which, despite being a simplistic assumption, works well in many practical applications. The Naïve Bayes model achieved an accuracy of 91.42% in classifying the fruits as fresh or rotten. BayesNet Algorithm: BayesNet, or Bayesian Network, is a probabilistic graphical model that represents a set of variables and their conditional dependencies via a directed acyclic graph (DAG). BayesNet is particularly useful for handling uncertainty and incorporating prior knowledge in the prediction process. When applied to the same dataset, the BayesNet model achieved an accuracy of 90.21%.

**Proposed Hybrid Model Performance**

The hybrid model was developed by combining the predictions of the Naïve Bayes and BayesNet algorithms. The motivation behind creating a hybrid model was to leverage the strengths of both algorithms and mitigate their individual weaknesses. The combined model operates by either majority voting or by weighted averaging of the predictions from the two algorithms. Hybrid Algorithm: The proposed hybrid model outperformed the individual classifiers, achieving an accuracy of 96.14%. This significant improvement in accuracy demonstrates the effectiveness of the hybrid approach in classifying fresh and rotten fruits. The hybrid model's superior performance can be attributed to its ability to combine the probabilistic reasoning of Naïve Bayes with the structured representation of dependencies in BayesNet.

**Comparative Analysis:** The results clearly show that the hybrid model offers a substantial improvement over the individual Naïve Bayes and BayesNet models. Specifically:

**Naïve Bayes:** 91.42%

**BayesNet:** 90.21%

**Hybrid Classifier:** 96.14%

The comparison between these accuracies highlights that the hybrid classifier consistently outperforms the individual models in predicting the freshness of fruits. This performance gain is due to the hybrid model's ability to integrate the complementary strengths of Naïve Bayes and BayesNet. The Naïve Bayes model contributes its efficiency in handling high-dimensional data, while the BayesNet model enhances the classification by accounting for dependencies between variables. As depicted in Figure, the graph illustrates the prediction accuracies of the individual algorithms (Naïve Bayes and BayesNet) and the proposed hybrid algorithm. The graph clearly shows that the hybrid algorithm achieves a higher accuracy compared to the individual models, reinforcing the effectiveness of the hybrid approach for this classification task. The overall results indicate that the hybrid classifier is a robust model for the classification of fresh and rotten fruits, outperforming the individual classifiers on most datasets. The hybrid model's accuracy of 96.14% demonstrates that it effectively reduces the error rate associated with the individual classifiers. The improved accuracy suggests that the hybrid model is better suited for real-world applications where the classification of fruits is crucial for reducing waste and ensuring quality in agricultural and commercial settings. In many instances, the hybrid approach can significantly outperform individual classifiers by combining their strengths, as observed in this study. This result is consistent with the theory that combining different models often leads to better predictive performance, a concept known as ensemble learning. The present study concluded, the hybrid classifier proposed in this study offers a superior method for the classification of fresh and rotten fruits, providing a more accurate and reliable solution compared to using Naïve Bayes or BayesNet individually. This improvement in accuracy can lead to more efficient sorting processes in agricultural enterprises, ultimately enhancing productivity and reducing losses due to misclassification.

## CONCLUSION

In this study, we explored the effectiveness of a hybrid machine learning algorithm for the classification of fresh and rotten fruits. The primary objective was to enhance the classification accuracy beyond what could be achieved using individual algorithms alone. To this end, we combined two well-known supervised learning algorithms: Naïve Bayes and BayesNet, into a hybrid model. The results of this investigation provide valuable insights into the advantages of hybrid machine learning techniques over traditional, single-algorithm approaches. The study concludes that hybrid machine learning algorithms offer a powerful tool for improving classification accuracy in agricultural applications. By combining the strengths of different algorithms, hybrid models can deliver superior performance compared to individual models. The proposed hybrid model, which merges Naïve Bayes and BayesNet, not only demonstrated a significant increase in accuracy but also provided a practical solution for the classification of fresh and rotten fruits. This advancement holds promise for enhancing quality control processes in agriculture, ultimately leading to better resource management and higher-quality produce.

## ABSTRACT

Among Ayurveda's myriad harmless treatments, *Viddhakarma* stands out for its immediacy and efficacy. This art of therapeutic piercing, detailed in the *Samhitas*, is a principal *Shastra Karma* for pain reduction and disease management. The procedure works by puncturing precise points to address the root cause of pain. Its primary action is to remove obstructions in blood vessels and bodily channels (*srotas*), thereby restoring circulation. Concurrently, the stimulation of peripheral sensory receptors blocks the transmission of pain signals from the affected site. This dual mechanism offers a unique, non-pharmacological approach to instant therapeutic intervention, highlighting Ayurveda's sophisticated clinical acumen. This ancient practice remains a relevant, effective, and minimally invasive therapeutic option. Analysis of publications from 2021 to 2025 reveals a growing body of evidence supporting the mechanistic efficacy of *Viddhakarma* as a Bridging Ancient Precision and Modern Pain Science. This specialized branch of Ayurvedic surgery, particularly its *Viddha* technique, demonstrates potent effects in resolving complex musculoskeletal pain by targeting specific points (*marmas*/*snayus*) to alleviate micro-instability, reduce inflammation, and break pain-spasm cycles. Clinical outcomes across studies report not only superior symptomatic relief but also enhanced tissue healing and functional recovery. The reinvigoration of *Viddhakarma* through contemporary research validates its dual role: as a primary treatment offering sustainable relief and a complementary modality reducing reliance on pharmaceuticals. For this renaissance to

reach its full potential, focused research on standardizing its application through robust trials is the essential next step.

**Keywords:** Ayurveda, *Viddhakarma*, Therapeutic Puncturing, Instant Relief, *Srotas, marmas* ,Sensory Receptors, Shastra Karma, Piercing Therapy.
**Timeframe:** Articles published from January 2021-2025 are reviewed.

## INTRODUCTION

*Viddhakarma* also known as *Suchivedhana* or *Vedhan Chikitsa* is a classical para-surgical procedure from the Ayurvedic tradition, primarily detailed in the *Sushruta Samhita*. The term itself is derived from the Sanskrit root "*Viddh*" meaning "to pierce" and "*Karma*" meaning "action" .It involves the therapeutic puncturing of specific anatomical points to alleviate pain and correct physiological dysfunction by regulating the vitiated *dosha (Vata, Pitta, Kapha)* and the blood (*Rakta).* Grounded in the understanding that pain and musculoskeletal issues often stem from aggravated Vata, impaired circulation, and toxin (*Ama*) accumulation, its primary mechanism is dual-faceted: it clears the body's micro-channels *(Srotas*), releasing trapped *Vayu* and restoring blood flow, while simultaneously stimulating peripheral sensory nerves to inhibit pain signal transmission and promote the release of pain-relieving endorphins. Operating on the principles of *Shodhana* (purification) and *Strotoshodhana* (channel cleansing), a precise puncture facilitates the removal of stagnant blood and toxins *(Dushta Rakta),* reduces tissue pressure, reinstates normal *Vata* flow, and stimulates vital *Marma* points to restore functional balance. *Viddhakarma* encompasses all therapeutic procedures that involve piercing, incising, excising, or manipulating body tissues with instruments. It represents a highly advanced and systematic surgical knowledge that existed in ancient India. In contemporary practice, *Viddhakarma* has gained prominence as a targeted, rapid, cost-effective, and minimally invasive treatment. Its holistic approach addresses the root cause of disorders rather than merely suppressing symptoms, offering a potent, evidence-based solution for complex pain syndromes, especially those resistant to conventional therapies, and aligns with the core Ayurvedic goal of restoring homeostasis by eliminating pathogenic factors and rejuvenating the body's innate healing capacity.

## METHODOLOGY

**Aim of the study**

The aim of this scoping review is to systematically map the available literature published between 2021 to 2025 on the Ayurvedic intervention *Viddhakarma*. The review seeks to identify the scope of clinical conditions treated, technical variations in the procedure (e.g., instruments used like 26 no.G Needles), reported outcomes, and gaps in the current evidence base**.**

**Study Design**

This study follows a narrative analytic review design, integrating data from classical texts, recent clinical trials, case studies, and observational studies to assess the scope, efficacy, safety, and limitations of *Viddhakarma* in musculoskeletal disorder and pain management.

**Sources of Data**

The literature review included;
Classical Ayurvedic Samhitas

- Sushruta Samhita.
- Charaka Samhita.
- Ashtang Hridaya.

**Databases and Journals Searched**

- PubMed.
- Google Scholar.

**Inclusion Criteria**

- Studies involving *Viddhakarma* as a primary or adjunct treatment for pain-related conditions.
- Clinical trials (randomized/non-randomized), case reports.
- Articles published in English or with English abstracts.
- Studies published in UGC-listed or peer-reviewed *Ayurvedic* journals.

**Exclusion Criteria**

- Studies without clear pain-related endpoints.
- Articles not mentioning therapeutic outcomes of *Viddhakarma.*
- Animal studies or in-vitro trials.
- Duplicate data and no peer-reviewed online sources.

## RESULT

A total of 25 published articles were critically reviewed and categorized into different classifications, with the aim of understanding and consolidating the mechanisms of applied therapy and the quality of documentation in a single comprehensive source. Among which total 21 articles have been published in Google scholar and 4 article published in Pubmed. Among which 16 articles were Case Reports and 9 articles were Clinical Studies. Total 8 were on *Gridhrasi,* 1 was on *Timir Rog*,2 were on *Vatakantak,* 1 was on *Galganda* , 1 was on *Avbhahuk (frozen sholder),* 1 was on *Vishwachi* (Cervical Radiculopathy), 1 was on *Anantavata* (Trigeminal Neuralgia), 1 was on *Vataj Pratishyay* (Allergic Rhinitis), 1 was on *Mutrashmari* (Urolithiasis), *Indralupta* And *Khalitya, Vishada* (persistent depressive disorder), 1 was on PCOs patients, 1 was on *Gandhanasha* (Hyposmia), pain management especially in Musculoskeletal Disorder (Sciatica, frozen shoulder, Cervical and low back Radiculopathy).

**Case Study**

Effect of *Suchivedha* in *Gridhrasi* (Sciatica) – a Case Study. Dr. Madhuri S.Chakote *et.al*., reported got relief in pain[2]. Effect of *Viddha Karma* (dry needle procedure) in the treatment of Sciatica – A Case Report. De Silva UMGD *et.al*., all the sign and symptoms related to sciatica was reduced after 15 days[3]. *ViddhaKarma* in *Timira Roga*: A Single Case Study Kirti Sengaonkar *et.al*., reported that patient showed Significant result after inserting needle at Apanga, Lalat and Upanasika[4] . Effect of *Viddhakarma* in *Grudhrasi* (sciatica) – A Case Study,Vd. Aarti Balaprasad *et.al*., reported after 2 to 3 sittings patient got complete relief in pain and complete his routine work during process[5]. Ayurvedic Management of Acute Calcaneal Spur with *Viddhakarma* and *Siravedha*: A case report Jaiswal Rashmi *et.al*., reported indicated results in acute pain associated with it[6]. Effect of *Agnikarma* and *Viddhakarma* in the management of pain and stiffness in *Gridhrasi* w.s.r. to Sciatica - A Case Study Deepak Kalyanrao *et.al*., After 6 sittings pain, oedema and stiffness is found completely resolved[6] . Role of *Viddha Karma* in Management of *Galaganda* –Case Report Sayali S. Shinde *et.al*., With 7 sittings of *ViddhaKarma*, it was observed that there was a regression of the size of the Thyroid Gland as well as reduction of Cervical lymphadenopathy[8]. A Role of Ayurvedic Management of *Avabahuka* W.S.R. Frozen Shoulder (Adhesive Capsulitis) A Single Case Study Dr. Ashwini Bhise *et.al*., reported marked reduction in sign and symptoms after 6 sittings of *viddhakarma [9]* . Evaluation of A Case Study of Effect of *Viddhakarma* In *Vishwachi* W. S. R To Cervical Radiculopathy Dr. Aishwarya Wankhade *et.al*., reported 75% relief in pain and other symptoms immediately and completely in 14 days treatment[10]. Management of *Anantavata* (Trigeminal Neuralgia) With Ayurvedic Parasurgical Procedures- A Case Report Aiswarya Das, Tukaram Dudhamal *et,al,*. reported that *Viddhakarma* with 26G needle and *Agnikarma* with *Swarna Shalaka* were performed near *Marma* points such as *Sthapani, Avarta, Apanga, Utkshepa*, *Shanka, Phana*, and *Shrigataka* at intervals of three days for two months. After that patient got significant relief from recurrent pain[11]. Role of *Viddhakarma* In The Treatment of *Vataj*

*Pratishyay* W.S.R Allergic Rhinitis: A Case Study Dr. Rakshanda S. Akre *et,al*,. reported reduce in sign and symptoms of Allergic Rhinitis without any sideffects after 2mon of follow up[12]. A Case Study on Ayurvedic management of *Mutrashmari* (Urolithiasis) Hardik, Apala Sengupta *et,al*,. reported that 4 sittings of *Viddhakarma* with *Shaman Chikitsha* patient showed highly significant result before and after treatment with no trace of Renal Calculi[13]. Ayurvedic Management of *Indralupta* And *Khalitya* With *Viddha Karma* (A Para-Surgical Procedure) And Internal Medications: A Case Report Dr. Snehal Patil *et,al*., reported that got successful result with *shaman* and *shodhan Chikitsha* with 7 days of *viddhakarma* treatment[14]. Clinical Effectiveness of *Viddha Karma* in PCOS: A Case Report Bhagyashree Jibkate *et,al*., reported that after 3 days continuously and later once in a 15 day of viddha procedure show positive results in managing symptoms and promoting overall health in patients with PCOS[15]. A holistic Ayurvedic approach to manage persistent depressive disorder, *Vishada* -A case report Aqsa Zarin Khan, Jibi Varghese *et,al*,. treatment persisted for 6 months, and the intervention outcome demonstrated a decrease in Hamilton Depression Rating scores, declining from 16 to 5 with a reduction of symptoms by the end of the 6 months of intervention[16].

**Clinical Study**

A role of *Viddhakarma* in management of *Gandhanasha* w.s.r. to Hyposmia - A Clinical Study Nilakshi Pradhan *et.al*., reported Patient got sense of smell after completion of 20th day with 10 sittings of *viddhakarma[*17]. Evaluation of Effect of *Viddhakarma* in *Gridhrasi* w.s.r To Sciatica Single-arm Clinical Case Study. Archana Suhas Wadkar *et,al*., patient got 75% relief in a very short time of period which reveal that *Viddha Karma* is a potential management option for the pain-related condition of sciatica[18]. Efficacy of *Agnikarma* and *Siravedha* along with *Rasna Saptaka Kwatha* orally in the management of *Vatakantaka* (plantar fasciitis): An open-labeled randomized comparative clinical trial Ganatra, Riddhi *et,al*,. reported that both interventions were found effective in the symptomatic management of *Vatakantaka[19]*. A Review on Mode of Action of *Viddha-Agnikarma* By Virtue of Pain Management in Musculoskeletal Disorders. Suryawanshi A *et,al*,. reported that this combined approach has shown promising results in reducing pain and treating various condition[20]. Comparative Effectiveness of *Viddha-Agnikarma* in Managing Lower Back and Knee Joint Pain: A Pilot Study. Yadav Yogesh *et,al*., reported that *Viddha-Agnikarma* was an effective therapy for managing lower back and knee joint pain, demonstrating significant reductions in VAS scores over 21 days[21]. A Comparative Clinical Study to Evaluate the Efficacy of *Viddhakarma* and *Agnikarma* in Pain Management of *Gridhrasi* (Sciatica) Harveer Singh Sangwa *et,al*., reported that *Viddhakarma* excels in treating deeper, chronic pain, particularly in regions like the thighs and knees, where its long-term effects are more pronounced[22]. A Comparative clinical study of *Siravedha* and *Agnikarma* in management of *Gridhrasi* (sciatica) J Vaneet Kumar, Tukaram S Dudhamal *et,al*., reported that patients had moderate to marked improvement[23]. Efficacy of *Viddhakarma* in Brachial Neuralgia Dr. Santosh Shreekant Betgeri *et,al*., reported *Viddhakarma* can deliver rapid analgesia in *Vāta*-dominant pain states, including conditions with radiating neuropathic features (sciatica, frozen shoulder, low back Radiculopathy)[24]. An In-Depth Review of *Viddhakarma* in Ayurvedic Tradition Mahesh Kumar reported that *Viddhakarma* has shown significant efficacy in treating *Raktaja* (blood-related) and *Pittaja* (Pitta-related) disorders, as well as conditions involving other Doshas and *Dhatus* and affirm reliability of *Viddhakarma* treatment modality, particularly in the management of *Shool* (musculoskeletal pain)[25].

## CONCLUSION

Based on the comprehensive analysis from 2021 to 2025 presented, *Viddhakarma* emerges as a uniquely effective and multifaceted therapeutic intervention. Its foundation in classical Ayurvedic principles is strongly supported by contemporary clinical outcomes, demonstrating rapid and significant relief for a wide range of disorders, from localized musculoskeletal pain to systemic conditions. The procedure's success is attributed to its dual-action mechanism simultaneously classical *Ayurvedic* concepts - *Apakarshana* of vitiated *Dosha*, *Rakta Dushti*, *Ama* and Enhancement of *Agni*, local *Dhatvagni Deepana*, and *Strotoshuddhi* (cleansing of channels) with modern hypotheses-Decompression of entangled nerves and myofascial elements and Neuromodulation via precise needling (akin to dermatome-somatic nerve response) offering a holistic alternative to conventional symptom management. The compiled clinical data demonstrates *Viddhakarma's* significant and often rapid therapeutic impact across a diverse

spectrum of conditions, most notably in musculoskeletal disorders such as *Gridhrasi* (Sciatica), *Avabahuka* (Frozen Shoulder), *Vishwachi* (Cervical Radiculopathy), and joint pain. Beyond these, its successful application extends to *Galaganda* (Thyroid enlargement), *Timira Roga* (visual disturbances), *Anantavata* (Trigeminal Neuralgia), *Mutrashmari* (Urolithiasis), and even PCOS and depressive disorders, highlighting its systemic regulatory potential. Outcomes consistently report superior pain relief, reduced inflammation, enhanced tissue healing, and improved functional recovery, frequently achieving results where conventional first-line therapies may be insufficient. The inherent advantages of *Viddhakarma*, including its precision, minimal invasiveness, and cost-effectiveness provides a sustainable, non-pharmacological option for pain relief and functional restoration. In conclusion, *Viddhakarma* represents a bridging of ancient precision and modern pain science requires a critical next phase: the systematization of evidence. Future efforts must prioritize high-quality, large-scale randomized controlled trials, detailed procedural standardization, and long-term outcome studies. By addressing these research imperatives, *Viddhakarma* can fully realize its potential as a validated, evidence-based bridge between ancient wisdom and contemporary healthcare, securing its role as a powerful tool for restoring homeostasis and rejuvenating the body's innate healing capacity.

## ABSTRACT

Working women frequently juggle professional responsibilities alongside family roles, placing them at heightened risk of psychological distress during family or personal crisis such as illness, bereavement, financial strain, or marital conflict. Mental health preparedness, along with effective coping strategies, resilience, and social support, plays a crucial role in safeguarding well-being during such challenging periods. Despite increasing female workforce participation in India, limited evidence exists on how working women prepare for and cope with mental health challenges during crisis. This pilot study aimed to assess the level of mental health preparedness, coping strategies, resilience, and perceived social support among working women, and to determine the associations between these variables during family or personal crisis. A cross-sectional descriptive pilot study was conducted among 69 working women aged 21–50 years from selected workplaces in Anand District, Gujarat. Data were collected using an online survey comprising a socio-demographic questionnaire, Mental Health Preparedness Scale (MHPS), Brief COPE Inventory, Connor–Davidson Resilience Scale (CD-RISC), and Multidimensional Scale of Perceived Social Support (MSPSS). Descriptive statistics and Pearson correlation analysis were used for data analysis. The majority of participants demonstrated high mental health preparedness (68.12%), while 28.98% showed moderate preparedness. Coping levels were distributed across low (34.78%), moderate (34.78%), and high (30.44%) categories. Resilience levels were predominantly moderate (31.88%) to high (36.23%). Most participants reported high perceived social support (75.36%).

Mental health preparedness showed a significant positive correlation with resilience ($r = 0.383$, $p = 0.001$). Coping strategies were significantly associated with resilience ($r = 0.345$, $p = 0.004$) but not directly with preparedness. A strong positive association was observed between social support and mental health preparedness ($r = 0.595$, $p < 0.001$), with family and significant-other support showing the strongest relationships. The findings highlight the pivotal role of resilience and social support in enhancing mental health preparedness among working women during crisis. Strengthening supportive networks and resilience-building interventions at individual and workplace levels is essential to promote psychological well-being among working women.

**Keywords:** Mental health preparedness, working women, coping strategies, resilience, social support, crisis.

## INTRODUCTION

Working women often face multiple responsibilities, balancing professional demands with family obligations. During times of personal or family crisis—such as illness, bereavement, financial stress, or marital conflict—the risk of psychological distress significantly increases. Mental health preparedness, defined as the ability to anticipate, manage, and cope with mental health challenges, plays a crucial role in promoting resilience and maintaining well-being. India has witnessed a remarkable rise in women's participation in the workforce over recent years. The Worker Population Ratio (WPR) for women nearly doubled, increasing from 22% in 2017–18 to approximately 40.3% in 2023–24. Parallelly, the Labor Force Participation Rate (LFPR) for women climbed from 23.3% to 41.7% over the same period [1]. Regionally, the surge in participation is especially pronounced in rural India, where the LFPR rose from 24.6% in 2017–18 to 41.5% in 2022–23, while urban female LFPR climbed modestly, from 20.4% to 25.4% [2]. Reports also indicate that in 2024, women's involvement in both paid and unpaid employment activities reached 25%, compared to 21.8% in 2019 Despite this progress, women continue to shoulder a disproportionate share of unpaid domestic and caregiving responsibilities, averaging 305 minutes per day—over three times the time men spend on such tasks (86 minutes) [3]. According to NFHS-5 (2019–21), approximately 1 in 3 married women (aged 18–49)—around 30%—have experienced physical or sexual violence by a spouse[4] A study based on NFHS-5 data found that out of 72,320 women, 17,765 (≈24.6%) had faced Intimate Partner Violence. Among them, only 14.2% sought any help, meaning 85.8% did not seek assistance despite experiencing violence [5][6]. In 2021, India recorded 45,026 female suicides. More than 50% of these were housewives, and over 30% of all suicides (male and female) were attributed to family or marriage-related problems [7]. A U.S.-based AARP survey revealed that about 65% of women aged 40–79 have endured major life crisis such as job loss, divorce, the death of a spouse, or serious illness—events that frequently lead to psychological distress [8]. A nationwide Indian survey of 1.3 million women revealed that nearly 50% experience chronic stress related to work-life balance, financial pressures, and societal expectations [9]. A Times of India report found that 98% of women who sought to re-enter the workforce after a hiatus cited family support as a key enabling factor. *This underscores the vital role families play in encouraging women to resume professional roles*[10]. A survey of over 30,000 Indian mothers revealed 33% did not feel fully supported emotionally by their families 57% reported they were not always able to share emotions openly with family during times of distress. Only 34% felt "Valued and Seen" by their family. This highlights significant emotional support gaps even within caregiving households[11]. Coping strategies and social support systems are key protective factors that help individuals adapt to crisis[12]. However, limited research has explored how working women specifically prepare for and cope with such challenges. Understanding their preparedness and coping mechanisms is vital for developing targeted interventions, workplace policies, and support programs. Despite the growing participation of women in the workforce, there is inadequate understanding of how working women prepare for and cope with mental health challenges during family or personal crisis. Assessing preparedness and coping strategies will help identify gaps and inform interventions to enhance resilience and well-being.

## REVIEW OF LITERATURE

A study was conducted to elucidate the work–family conflict on psychological well-being experienced by working women and to determine whether social support has beneficial role in the psychological well-being of the working women. Result shows that employed women are more satisfied with their life than nonworking women, and the quality of home and work environments determines the impact of employment on the psychological well-being of working women in dual-earner families. Factors causing work related stress and strategies for stress management: a study of working women in private and public sectors in the Indian context the results of the study showed that the majority of the women (32.5%) experienced stress when evaluated performance by superiors and given negative feedback, by their employers. The analysis also showed that the most effective strategy for stress management was spending time with children, with an average rank of 3.55 whereas doing yoga and meditation has the lowest average rank of 2.65, indicating that respondents rarely use this strategy for managing stress [13].

**Specific objectives of the study (primary and secondary)**

1. To assess the level of mental health preparedness among working women during family and personal crisis.
2. To assess the coping strategies and resilience adopted by working women during crisis.
3. To determine the association between mental health preparedness, coping strategies, and resilience of working women during crisis.
4. To determine the association of social support systems with mental health preparedness for working women.

## METHODOLOGY

**Research Design:** A cross-sectional descriptive
**Study Setting**: Selected workplaces, hospitals, educational institutions, and corporate offices in Anand District.
**Study Population**: Working women aged 21–50 years who are employed in organized sectors.
**Sample Size:** Using Cochran's formula (95% CI, 5% margin of error), a minimum of 680 participants will be targeted. For the present pilot study 69 participants were recruited via online survey method.
**Sampling Technique**: Convenience sampling technique

**Inclusion Criteria**

- Women currently employed for at least 1 year.
- Women who have experienced at least one family or personal crisis in the last 2 years (e.g., illness, bereavement, financial stress).

**Exclusion Criteria**
Women with a diagnosed severe psychiatric illness.

**Operational Definitions:**
**Mental Health Preparedness**
In this study, *mental health preparedness* refers to the proactive ability of working women to anticipate, plan, and effectively manage their psychological well-being during family or personal crisis. It will be measured using a Mental Health Preparedness Scale.

**Coping Strategies**
*Coping strategies* are the behavioral and cognitive methods used by working women to handle stress and adapt during crisis. It will be assessed using the Brief COPE Inventory which categorizes coping as problem-focused, emotion-focused, or avoidance-based.

**Resilience**

Resilience is defined as the capacity to recover and adapt positively in the face of stress, adversity, or crisis. It will be measured using the Connor-Davidson Resilience Scale (CD-RISC).

**Social Support**

*Social support* refers to the perceived availability of emotional, informational, and practical help from family, friends, and significant others. It will be assessed using the Multidimensional Scale of Perceived Social Support (MSPSS).

**Assumptions**

1. Working women experience varying levels of family and personal crisis that affect their mental health.
2. Participants will respond to the research instruments honestly and accurately to reflect their true experiences.
3. Coping strategies and social support systems play a significant role in influencing the level of mental health preparedness among working women.

**Data Collection Tools**

1. Mental Health Preparedness Scale,
2. Brief COPE Inventory
3. Connor-Davidson Resilience Scale (CD-RISC).
4. Multidimensional Scale of Perceived Social Support (MSPSS)

**Plan for Data Collection**

Data for this study was collected exclusively through an online survey platform to ensure wide participation, convenience for working women, and secure handling of responses. Participants were recruited via workplace groups, official emails, and social media networks. The invitation will include the Participant Information Sheet (PIS), contact details of the research team, and a link to the online survey. When participants click the link, they will first view the PIS and an electronic consent form. Only those who agree by selecting the "I consent to participate" option will proceed further. Built-in eligibility screening questions will confirm inclusion criteria such as age, employment status, and experience of a family or personal crisis. Ineligible participants will automatically exit the survey.

**The online questionnaire will be divided into five sections**

1. Socio-demographic and background details
2. Mental Health Preparedness Scale (MHPS) – researcher-developed tool
3. Brief COPE Inventory – coping strategies[14]
4. Connor-Davidson Resilience Scale (CD-RISC) – resilience[15]
5. Multidimensional Scale of Perceived Social Support (MSPSS) – perceived support

The total time to complete the survey will be 25–30 minutes. Skip logic will be applied to ensure smooth navigation, and mandatory responses will minimize missing data. Upon completion, participants received a thank-you message along with a list of mental health resources and helpline numbers. Responses will be anonymized automatically, with no personal identifiers collected. Data was stored on password-protected, encrypted servers, accessible only to the research team.

## RESULT

Table 1 presents the demographic characteristics of the participants. The mean age of the participants was 29 ± 7.5 years. With regard to marital status, about half of the participants were married (50.7%), while a considerable proportion were single (46.4%), and a small percentage were divorced (2.9%). In terms of number of children, the majority of participants (72.5%) reported having no children, while 20.3% had one child and 7.2% had two children. Regarding family structure, 63.8% of the participants belonged to nuclear families, whereas 36.2% lived in joint families. The distribution of place of residence showed that most participants resided in urban areas (69.6%),

followed by rural (20.3%) and semi-urban areas (10.1%). With respect to educational qualification, a majority of participants were postgraduates (58.0%), followed by graduates (37.7%), and a small proportion held a doctorate degree (4.3%). In terms of occupation, nearly half of the participants were engaged in teaching (49.3%), followed by those in other professions (26.1%) and healthcare (17.4%), with fewer participants from IT and administrative sectors. Concerning the nature of job, most participants were employed on a contractual/temporary/adhoc basis (63.8%), while 36.2% held permanent positions. The mean work experience of the participants was 34 years, and the average working hours were 45 hours per week. Finally, analysis of monthly income revealed that the largest proportion of participants earned between ₹10,001–25,000 (37.7%), followed by ₹25,001–50,000 (34.8%) and above ₹50,000 (26.1%), while only 1.4% earned less than ₹10,000 per month. Table 2, depicts the Mental Health Preparedness Scale (MHPS) demonstrated good internal consistency, with a Cronbach's alpha of $\alpha = 0.76$, indicating acceptable reliability. Table 3, depicts the distribution of mental health preparedness levels among the participants based on MHPS scores. The findings reveal that a majority of the working women demonstrated a high level of mental health preparedness. Specifically, 68.12% (f = 47) of the participants scored within the range of 75–100, indicating strong awareness, readiness, and ability to manage mental health challenges during family or personal crisis. Approximately 28.98% (f = 20) of the participants exhibited a moderate level of mental health preparedness, with scores ranging from 50–74. This group reflects women who possess some coping resources and preparedness but may benefit from additional support or skill-building interventions to strengthen their mental health resilience. Only a small proportion of participants, 2.90% (f = 2), were found to have low mental health preparedness (scores between 20–49), suggesting limited readiness to anticipate or manage mental health challenges during crisis. The table 4 presents the distribution of coping levels among working women based on total coping scores. Approximately 34.78% (f = 24) of the participants exhibited low coping. An equal proportion, 34.78% (f = 24), demonstrated a moderate level of coping. About 30.44% (f = 21) of the participants showed high coping. The table 5 presents the distribution of resilience levels among the participants based on CD-RISC scores.

The mean resilience score was 26.28 ± 9.46, indicating an overall moderate level of resilience among the working women. Analysis of the score distribution shows that 36.23% (f = 25) of the participants demonstrated high resilience. An equal proportion of participants, 31.88% (f = 22), fell into the moderate resilience category. Similarly, 31.88% (f = 22) of the participants exhibited low resilience. Table 6 depicts the distribution of perceived social support among working women. The findings indicate that a substantial majority of participants reported a high level of perceived social support. Specifically, 75.36% (f = 52) of the respondents scored within the range of 5.1–7.0, reflecting strong support from family, friends, and significant others. A smaller proportion of participants, 15.94% (f = 11), experienced a moderate level of perceived social support, with scores ranging from 3.0–5.0. These women reported some degree of support; however, the level may not be sufficient during prolonged or intense family or personal crisis. Only 8.70% (f = 6) of the participants reported low perceived social support (scores between 1.0–2.9), indicating limited availability of emotional or practical assistance from their social networks. Association between Mental Health Preparedness, Coping Strategies, and Resilience N=69 (Table 7). Pearson correlation analysis revealed a moderate positive and statistically significant correlation between mental health preparedness and resilience ($r = 0.383$, $p = 0.001$), indicating that working women with higher resilience levels tend to have better mental health preparedness during family or personal crisis. The correlation between mental health preparedness and coping strategies was positive but weak and not statistically significant ($r = 0.137$, $p = 0.263$). This suggests that overall coping scores alone may not directly influence preparedness levels, highlighting the need to examine specific coping styles in further analyses. A moderate positive and statistically significant correlation was observed between coping strategies and resilience ($r = 0.345$, $p = 0.004$), implying that effective coping mechanisms are associated with higher resilience among working women during crisis. Association of Social Support with Mental Health Preparedness (Table 8). Pearson correlation analysis revealed a strong positive and statistically significant association between overall perceived social support and mental health preparedness among working women ($r = 0.595$, $p < 0.001$). This indicates that higher levels of perceived social support are associated with better mental health preparedness during family or personal crisis. Subscale analysis further demonstrated that family support ($r = 0.585$, $p < 0.001$), friends' support ($r = 0.575$, $p < 0.001$), and support from significant others ($r = 0.589$, $p < 0.001$) were all strongly and positively correlated with mental health preparedness.

## DISCUSSION

The present study explored mental health preparedness, coping strategies, resilience, and perceived social support among working women during family or personal crisis. The findings provide important insights into the psychological resources and support systems that enable working women to manage stressful life events effectively. The results revealed that the majority of participants demonstrated high mental health preparedness, with more than two-thirds of the women exhibiting strong readiness to manage mental health challenges during crisis. This finding may be attributed to the high educational status[16] and urban background of most participants,[17] which could enhance mental health awareness and access to resources. Similar findings have been reported in previous studies, which suggest that education[18] and employment contribute positively to mental health literacy[19] and preparedness. With regard to coping strategies, the study found that most working women fell within the low to moderate coping categories, with only about one-third exhibiting high coping levels. This suggests that although women may possess awareness and preparedness, they may not consistently employ effective coping strategies during prolonged or intense stress. Previous research has also indicated that working women often prioritize professional and family responsibilities over self-care, which may limit their ability to engage in adaptive coping practices[20]. Resilience levels among participants were largely moderate to high, indicating a reasonable capacity to adapt to adversity. The significant positive association observed between resilience and mental health preparedness supports existing literature that identifies resilience as a key protective factor in maintaining psychological well-being during crisis[21]. Women with higher resilience were better prepared to anticipate, manage, and recover from mental health challenges[22]. One of the most notable findings of the study was the strong positive association between perceived social support and mental health preparedness. Support from family, friends, and significant others was found to play a crucial role in enhancing preparedness, with family support emerging as the strongest contributor[23]. This aligns with socio-ecological models of mental health, which emphasize the importance of interpersonal relationships in buffering stress and promoting psychological stability[24]. Interestingly, coping strategies did not show a direct significant association with mental health preparedness, although they were significantly related to resilience. This suggests that coping may indirectly influence preparedness by strengthening resilience rather than acting as an independent predictor. Such findings highlight the complex interplay between coping, resilience, and social support in determining mental health outcomes[25]. Overall, the study underscores the need for integrated interventions that focus on strengthening resilience and social support systems while simultaneously enhancing coping skills. Workplace mental health programs, family-centered interventions, and community-based support mechanisms can play a vital role in improving mental health preparedness among working women, particularly during times of crisis.

## CONCLUSION

This study highlights the importance of mental health preparedness among working women during family or personal crisis and emphasizes the critical roles of resilience and social support in shaping psychological readiness. The findings indicate that while a majority of working women demonstrate moderate to high levels of mental health preparedness, coping strategies are not uniformly strong, suggesting a gap between awareness and effective coping practices. Resilience emerged as a significant protective factor, positively associated with mental health preparedness, underscoring its role in enabling women to adapt to and recover from stressful life events. Furthermore, perceived social support—particularly from family and significant others—showed a strong positive association with mental health preparedness, reinforcing the value of supportive interpersonal relationships during crisis. Overall, the study suggests that mental health preparedness among working women is influenced by an interplay of individual strengths and external support systems. Integrating resilience-building interventions, strengthening social support networks, and promoting adaptive coping strategies within workplaces and communities may enhance psychological well-being and preparedness among working women facing family or personal challenges.

## ABSTRACT

*Kasa* (cough) is one of the most common clinical complaints, but Ayurveda explains that its origin is deeper than the respiratory tract. There is a close connection between the digestive system and the respiratory system. When *Agni* becomes weak due to wrong food habits, irregular routines, or emotional stress, digestion becomes incomplete and produces Ama. This Ama spreads through the channels and settles in the *Pranavaha Srotas*, disturbing normal flow of the *Vata* and causing cough. The uploaded article highlights this gut-lung link and explains how early digestive imbalance can be identified before respiratory symptoms appear. A detailed textual analysis was done, focusing on literature, classical shloka interpretation, and modern science. The topic was reviewed for conceptual understanding, *Nidana-Samprapti* clarity, and the clinical relevance of *Agni Dushti* in the development of *Kasa.* The material was re-examined based on the *Roga Nidana* principles such as *Purvaroopa, Samprapti Ghatakas,* and *Upadravas* involvement. The review clearly shows that the first disturbance in many cases of *Kasa* starts in the gut. Weak *Agni* (*Mandagni*) leads to *Ama* formation, which causes blockage in the body channels and disturbs *Vata*, especially *Apana* and *Udana*. This upward movement of vitiated *Vata* creates pressure in the chest and throat, leading to cough, breathlessness, and voice changes. Prodromal symptoms like anorexia, throat irritation, and indigestion further confirms early *Agni* impairment. The article also shows that various types of *Kasa-Vataja, Pittaja, Kaphaja,* and chronic forms-can be traced back

to different types of *Agni* imbalance. Modern evidence on GERD-induced cough and gut-lung axis research supports the Ayurvedic view. The analysis highlighting that treating only the cough does not give lasting relief if the root cause, *Agni*, is not corrected. Strengthening digestion, clearing *Ama*, and regulating *Vata* helps break the disease process at its origin. The article effectively integrates classical knowledge with modern understanding, showing that both systems agree on the role of gut health in respiratory diseases. This strengthens the Ayurvedic approach of diagnosing *Kasa* not as an isolated respiratory issue but as a systemic disorder beginning in the digestive tract.

**Keywords:** Agni dysfunction; Kasa; Gut-lung axis; Apana Vata; Udana Vata; Pranavaha Srotas.

## INTRODUCTION

Respiratory symptoms are among the most frequent complaints in both general and specialized Ayurvedic practice. Among them, *Kasa* (cough) is often perceived as an isolated symptom of the *Pranavaha Srotas* (respiratory channels). However, classical Ayurvedic teachings encourage practitioners to look beyond symptoms and explore the root cause- often traced back to *Agni Dushti*, or impaired digestive fire[1]. In Ayurveda, digestion-absorption-assimilation is said to be done by *Agni*. Disturbance in *Agni* leads to the formation of *Ama*, which, when circulated through the body, lodges in weak *Srotas* (channels) and manifests as various diseases[2]. In the case of *Kasa*, respiratory tissues become eventual site of this manifestation. Despite its prevalence, the *Agni-Phuphusa* connection remains under-explored in the context of cough management. This paper aims to bring attention to the digestive origins of *Kasa*, propose diagnostic indicators of *Agni* dysfunction in respiratory cases, and offer Ayurvedic interventions targeting the digestive system for sustainable relief.

## METHODS

A textual review and clinical synthesis were conducted to explore the link between *Agni* dysfunction and *Kasa*. Primary Ayurvedic texts and commentaries were analysed for references to *Kasa, Agni*, and *Ama*, including:

- ***Charaka Samhita –*** *Chikitsa Sthana, Nidana Sthana*
- ***Ashtanga Hridaya –*** *Chikitsa Sthana*
- *Bhavaprakash Nighantu*
- ***Madhava Nidana –*** *Kasa Nidana*

The AI Tool- Gemini and chatgpt has been used to enhance the statements and eliminate any grammatical errors which was made while writing the script.

## LITERATURE REVIEW

The thematic analysis of Ayurvedic literature and modern studies revealed a profound relationship between function (*Agni*) and the manifestation of *Kasa* (cough)[3].

***Agni* impairment before the manifestation of *Kasa***

The onset of *Kasa* (cough), as explained in Ayurvedic principles, doesn't happen abruptly-it unfolds gradually, beginning deep within the digestive system. It all starts with a disturbance in *Agni*, the body's digestive fire. When someone consumes unhealthy or incompatible food (called *Ahita ahara* or *Viruddhahara*), or is constantly under stress, the *Jathragni* becomes weak and inefficient. As a result, the food isn't properly digested, leading to a state known as *Ajirna* or indigestion. This incomplete digestion produces Ama, a sticky, toxic by product that acts like metabolic waste. Over time, Ama begins to accumulate and circulate within the body. This toxic buildup doesn't just stay in the gut-it infiltrates bodily channels, especially the Pranavaha Srotas, which are crucial for breathing and respiration. As

Ama settles in these channels, it starts to disrupt the balance of the Doshas, particularly Kapha and Vata. The Kapha becomes thick and sluggish, while Vata, which governs movement, becomes erratic. This toxic duo sets the stage for further complications. The channels of the respiratory system get blocked (Srotorodha), which disturbs Udana Vayu, the upward-moving energy responsible for speech and respiration. In this disturbed environment, the vitiated *Doshas* become even more aggravated ***(****Utklesha* and *Prakopa)* and begin to move upwards. They accumulate in the chest **(***Uras*) and throat (Kantha) regions. This upward movement and blockage lead to the typical symptoms of Kasa—persistent coughing, chest discomfort, and disturbed breathing.

**Evidence from *Poorvaroopa* indicating *Agni* Impairment[4,5]**

तेषां भविष्यतां रूपं कण्ठे कण्डूररोचकः।।१८।।

शूकपूर्णाभकण्ठत्वम् (Ashtanga Hrudayam Nidanasthan 3/19)

The prodromal symptoms of Kasa includes- Kanthe Kandu (Itching/irritation in throat), Arochaka (Loss of taste/ loss of appetite leading to aversion towards food despite hunger), Shookapoornakanthatvam (Feels as if pointed objects keep pricking the throat).

Here, Arochaka is one among the cardinal features of Ajirna which is also found in Agnimandya as Ajirna is its consequence.

तस्यलिङ्गमजीर्णस्यविष्टम्भःसदनंतथा।
शिरसोरुक्चमूर्च्छाचभ्रमःपृष्ठकटिग्रहः।।४५।।
जृम्भाऽङ्गमर्दस्तृष्णाचज्वरश्छर्दिःप्रवाहणम्।
अरोचकोऽविपाकश्च, घोरमन्नविषंचतत्।।४६।। (Charaka Chikitsasthana 15/45-46)

**Samprapti[3]**

**Role Of*Apana Vata***

तत्राधो विहतोऽनिलः।
ऊर्ध्वं प्रवृत्तः प्राप्योरस्तस्मिन् कण्ठे च संसजन्।।१९।। (Ashtanga Hrudayam Nidanasthana 3/19)

**Commentary**

क्रुद्धः प्रतिहतोऽपाने यदाऽपानः प्रवर्तते। ऊर्ध्वं रसस्य स स्थाने तिष्ठन्नुरसि पीड्यते।। उदानेन सजंस्तत्र कण्ठे चानुप्रपूर्य च। (आयुर्वेदरसायनम्व्याख्या ( कृत))

When the *Apana Vayu*, having become enraged (क्रुद्धः) and obstructed (प्रतिहतः), begins to move abnormally it moves upwards and stays in the region of rasa (nutrient fluid), and causes pain or pressure in the chest (*Uras*). As the reversed *Apana* reaches upward, it afflicts the chest, causing pain or oppression. Then it joins with *Udana Vayu* there and fills the throat completely. The vitiated *Vayu* now mixes with *Udana*, which is responsible for functions like speech and exhalation. This union results in throat congestion or blockage, leading to symptoms like coughing, hoarseness.

क्रुद्धःप्रतिहतोऽपाने
↓ (Aggravation and Obstruction of *Apana Vata*)
*Apana Vata* becomes enraged and blocked
↓
प्रवर्ततेऊर्ध्वगमनम्
(Moves in reverse → upward direction)

ऊर्ध्वंरसस्यसस्थाने
Reaches the region of *Rasa* (thorax/chest)
↓
उरसिपीड्यते
Causes pressure, pain, or congestion in chest
↓
उदानेनसजंस्तत्र
Co-mingles with Udana Vata in thoracic region

↓
कण्ठेचअनुप्रपूर्य
Fills/pressurizes the throat and airway
↓
→ Kasa (Cough) associated with:
- Shvasa (Dyspnea)
- Urahshoola (Chest pain)
- Swarabheda (Voice changes / Hoarseness)

**Role of *Agni***

There are various causes for aggravation and obstruction of *Apana Vata.* According to Ayurveda, all digestive and metabolic activities in the body are powered by Agni. Any disease, including *Kasa* (cough), is often rooted in the derangement of *Agni.* Before *Kasa* manifests as a respiratory disorder, early disturbances in *Agni* initiate a cascade of pathophysiological events. One of the most common reasons which can be inferred is as follows:
*Nidana* (diet/lifestyle/emotions)
↓
Aggravation of *Vata* + Weak digestion (*Agni-mandya*)
↓
Formation of *Ama* + Obstruction of *Apana* path
↓
*Apana* gets blocked → Reverses direction
↓
Moves upward → Disturbs *Udana*
↓
*Kasa*

In the context of Kasa due to Abhyantara hetu (cough arising from internal causes), the pathophysiology can be traced to the involvement of Apana Vata right from the early stage itself. This downward-moving Vata, when deranged, initiates and sustains the cascade that culminates in cough. However, in Kasa due to Agantuka hetu (cough triggered by external or environmental factors), scenario is different. Here Apana Vata does not play a primary role in the beginning. For instance, when the causative factor is dust exposure or allergic irritants, the immediate disturbance is seen in Prana Vata and Udana Vata. Their normal flow and functional dynamics get obstructed, which then provokes cough. In such cases, structural alterations-like narrowing of the air passage or irritation of the airway mucosa by foreign particles- further aggravate the condition, reinforcing the manifestation of Kasa.

**Subtype-Specific Connections Between Agni and Kasa**

Each type of Kasa reflects a distinct pattern of digestive disturbance and Dosha aggravation:

**Vataja Kasa[6]**
- Triggered by unpredictable eating habits like dry food, fasting, or excessive physical exertion.
- It is often linked to *Vishamagni* (irregular digestion) resulting from unpredictable dietary patterns.
- It is characterized by dry, painful, spasmodic coughing without significant phlegm production.

***Pittaja Kasa*[7]**
- It caused by excessive intake of spicy, hot, oily, or sour foods that over-stimulate *Agni* leading to *Tikshnagni* (intense digestive fire).
- This results in a cough with yellowish, sometimes blood-tinged sputum, burning sensation in the chest and throat.

***Kaphaja Kasa*[8]**

- It originates from excessive intake of heavy, oily, cold, and sweet foods, which weaken *Agni* and elevate *Kapha* levels.
- The characteristic features include productive cough with thick, white phlegm and a feeling of heaviness.

***Kshataja Kasa*[9]**
Due to trauma to thoracic region it gets injured leading to bleeding. This may lead to the imbalance of Pitta, ultimately impairing the function of Agni.

***Kshayaja Kasa*[10]**
Associated with chronic conditions and tissue depletion, often following prolonged *Agni* disturbance and resulting malnourishment of *Dhatus* (tissues).

**Clinical Observations: Digestive Correction Resolves Respiratory Symptoms[11]**
Clinical case observations indicate that Ayurvedic therapies focusing on:
**Agni Deepana** (stimulating digestion using herbs like *Trikatu*, *Pippali*, *Chitraka*),
**Ama Pachana** (digesting Ama with formulations like Shunthi, Guduchi, Dashamoola),
**Pathya-Apathya** (dietary regulations aimed at restoring digestion), often led to the substantial reduction or complete resolution of chronic coughs, particularly those unresponsive to conventional antitussive treatments. Notably, interventions aimed purely at suppressing the cough without addressing digestive imbalance showed limited or temporary benefits.

**Evidence from Upadrava indicating Agni Impairment [12,13,14,15,16]**
*Kasa* is not merely an isolated disorder but is often observed as an *Upadrava* (complication) in a wide range of diseases. It frequently manifests as a secondary symptom in conditions such as *Shoola* (abdominal pain), *Jwara* (fever), *UdaraRoga* (abdominal disorders), *Chardi*(vomiting), and *Raktapitta* (bleeding disorders). Interestingly, most of these conditions have their origin in the *Annavaha Srotas*-the gastrointestinal tract-highlighting a close connection between the state of digestion and respiratory health. This association reinforces the Ayurvedic concept that *Agni* (digestive fire) plays a central role in maintaining overall well-being, and its disturbance can lead to systemic imbalances manifesting even in distant organs like the lungs. Thus, the occurrence of *Kasa* as an *Upadrava* in predominantly gut-related disorders illustrates the deep interrelationship between the digestive and respiratory systems.

**Modern Correlation: Gut-Lung Axis Evidence**
Modern medical studies reinforce Ayurveda's observations:
- Gastroesophageal reflux disease (GERD) is considered as a significant non-respiratory cause of chronic cough[17].
- Disruptions in gut microbiota (*dysbiosis*) are linked to systemic inflammation, increasing susceptibility to respiratory conditions like asthma and chronic bronchitis[18].

These are the evidences that prove gut/ Agni plays major role in manifesting Kasa.

## DISCUSSION

When we read the classics and look at the clinical picture of *Kasa* today, one thing becomes very clear: cough may appear in the throat and chest, but the story almost always begins in the gut. This understanding becomes even stronger when we read Charaka, Sushruta and Vagbhata describing the disease process. They repeatedly remind us that if Agni is disturbed, nothing else in the body can function smoothly. The same principle guides the development of *Kasa*.

***Udbhava Sthana:* Where the Disease Actually Begins (Gut and Agni)- *Amashaya***
The review clearly shows that the earliest disturbance in *Kasa* does not start in the lungs. It first started in the digestive tract. This reflects the classical principle that weak Agni is the root cause for almost all the systemic

diseases. Irregular food habits, incompatible diet combinations, stress, late meals and overeating first impair the digestive fire. When Agni loses its strength or rhythm, food is not broken down properly and *Ama* begins to form. This stage represents the *Udbhava Sthana*, the original seat of the disease. Although the patient may later present with cough, the imbalance has already begun silently within the gut.

**Ama Formation and Early Gut-Lung Disturbance**

*Ama* is a metabolic waste that acts like a heavy, sticky, toxic by product that interferes with normal movement inside the digestive tract. As *Ama* accumulates, it blocks the natural pathways of *Doshas* and *Dhatus*. This obstruction disturbs *Vata* functions, especially *Apana Vata*, which resides in the lower abdomen. Rather than moving downward, *Apana* becomes restricted and irritated. This blockage leads to the upward movement of disturbed *Vata*. At this point patients often complain of early signs such as loss of appetite, heaviness, abdominal discomfort, belching or mild throat irritation-indicating the first connection between gut imbalance and respiratory symptoms.

***Apana Vata*: The Turning Point in Samprapti**

Classical descriptions explain that when *Apana Vata* faces obstruction due to *Ama,* it loses its proper direction. Instead of moving downward, *Apana* shifts upward into the chest region. This upward movement marks a critical turning point in the development of Kasa. This mechanism also mirrors what modern science describes as the gut–lung axis. The rising Apana carries disturbed Doshas and Ama into the upper body, where it interacts with Udana Vata and Prana Vata. This interaction produces dryness, irritation, chest pressure, voice change and the urge to cough. The Poorvarupa described in the texts match these early clinical signs, indicating that the respiratory system is beginning to feel the impact of the digestive imbalance.

**Step-by-Step Link Between Gut and Lungs**

The complete chain of events can be understood as follows:

1. Diet and lifestyle errors weaken Agni- Agnimandya
2. Incomplete digestion results in Ama formation
3. Ama obstructs the pathways of Apana Vata
4. Apana Vata becomes irritated and moves upward
5. The upward movement disturbs Udana and Prana Vata
6. Irritation develops in the throat and chest
7. Kasa manifests in the respiratory channels

This sequence demonstrates a clear physiological movement from the digestive system to the lungs, connecting the Udbhava Sthana and Vyakta Sthana through Vata disturbance.

**Vyakta Sthana: The Site of Manifestation (Pranavaha Srotas)**

Once the vitiated Vata and Ama reach the chest region, the symptoms manifest in the Pranavaha Srotas, making the lungs and airways the Vyakta Sthana. The nature of the cough depends on the predominant Dosha at the site of manifestation.

- Vata dominance causes dry, forceful, spasmodic cough
- Pitta dominance causes burning in the chest, bitter taste, yellow sputum
- Kapha dominance leads to thick, heavy, white mucus and sluggish breathing

Although the symptoms appear in the respiratory system, the root lies in the digestive dysfunction that occurred earlier.

**Why Symptomatic Relief Alone Is Not Enough**

Merely treating the cough will not stop the disease process. If *Agni* remains weak and *Ama* is not cleared, the cycle of obstruction and upward *Vata* movement continues. Many patients experience temporary relief with cough syrups, inhalers or antibiotics, only to return with the same symptoms after a few days or weeks. This happens because the *Udbhava Sthana* remains disturbed. Correcting *Agni*, digesting *Ama* and restoring *Apana's* downward movement are essential to prevent recurrence.

**Clinical Approach Based on Roga Nidana Principles**

The assessment of *Kasa* must start with careful evaluation of *Agni*. Appetite, food tolerance, bowel habits, abdominal heaviness, bloating, belching patterns, sleep quality and emotional stress all suggests early *Agni* impairment. Checking for these signs ensures that the practitioner does not overlook the foundation of the disease. Once the root disturbance is understood, management becomes more effective and long-lasting.

**Integrated Interpretation of the Gut–Lung Axis**

The cascade from weak *Agni* to *Ama* formation, obstruction of *Apana*, upward movement of *Vata* and final manifestation in the *Pranavaha Srotas* shows a complete Ayurvedic understanding of the gut-lung axis. Modern research now supports this concept, demonstrating that gut inflammation, dysbiosis and metabolic toxins influence respiratory health. The classical Ayurvedic model, therefore, provides a more comprehensive explanation by including the deeper roles of Agni, Ama and Vata.

**Final Insight**

Kasa should be understood as a disorder with its origin in the gut, pathway through disturbed Vata, and manifestation in the lungs. The Udbhava Sthana, Samprapti pathway and Vyakta Sthana must all be considered together. When Agni is strengthened, Ama is cleared and Apana Vata is guided back to its natural downward direction, respiratory symptoms reduce significantly and recurrence is prevented.

## CONCLUSION

Ayurveda teaches us that a healthy digestive system (Agni) is key to good overall health including healthy lungs. When digestion becomes weak or imbalanced, it leads to the formation of toxins (Ama), which can cause cough (Kasa) and other health issues. This article shows that many types of cough, especially chronic ones, may start with poor digestion. Treating only the cough without fixing digestion may not give long-term relief. Both Ayurvedic and modern scientific research agree that the gut and lungs are closely connected a concept known today as the "gut–lung axis." By focusing on improving digestion through proper food, herbs, and lifestyle, we can prevent and treat coughs more effectively. Ayurveda's approach to treating the root cause not just the symptoms offers a deeper and more lasting solution for people suffering from cough-related problems.

## ABSTRACT

Plant therapeutics have traditionally been the focus of drug discovery since they have faced such problems as chemical complexity, batch variability, low bioavailability and multi-target pharmacology, and could be left at the clinical stage largely untapped. Nanotechnology has made significant contribution on improving the delivery and stability of phytochemicals; the traditional method of formulation and testing is time-consuming and is empiric-driven. The concept of artificial intelligence

(AI) has also been effective to enhance the degree of plant-based nanomedicine discovery and optimization by integrating the tools of phytochemistry, formulation science, and pharmacology into one workflow. Machine learning, neural networks, chemometrics, QSAR modelling, and predictive ADMET tools are artificial intelligence-based methods that can be quickly applied to identify bioactive phytoconstituents, to predict the most favorable nanocarrier formulations, and to early predict pharmacological activity and toxicity. The review is a general survey of the AI application throughout the entire process of developing plant-based nanomedicines, such as phytochemical profiling and nanoparticle design, *in silico* pharmacology and predictive modelling. The article refers to the key advances, current limitations, and future opportunities of personalized phytomedicine using AI. All in all, AI has the disruptive capability in the form of reduced development period, greater therapeutic efficacy, and greater translational performance of plant-derived nano preparations.

**Keywords:** Artificial intelligence, phytochemistry, nanomedicine, machine learning, nano-phytopharmaceuticals, QSAR modelling, pharmacological evaluation, ADMET prediction.

## INTRODUCTION

**Global Rise of Plant-Based Therapeutics**

Health care cultures have been focused on medicinal plants and their bioactive constituents. This structural diversity, multi-target characteristics, decreased toxicity and potential therapeutic treatment of intricate diseases such as cancer, neurodegenerative diseases and metabolic syndromes, have seen a new interest in plant-derived therapeutics in the world over the past few decades[1]. The WHO estimates that nearly 80 percent of the global population relies on the use of herbal medicines as the primary healthcare which translates to its high acceptability and treatment. In addition, the current advances in phytochemistry, metabolomics, and biotechnology have led to the discovery of new phytoconstituents that have the potential to stimulate pharmacological activity. The plant molecules are therefore still important leads in modern drug discovery[2].

**Challenges**

Phytoconstituents have a high promise of therapeutic application; however, a number of obstacles impede their development into useful therapeutic drugs. Natural compounds are highly chemically variable, depending on geography, climatic conditions, methods of cultivation, and extraction which results in unequal therapeutic responses. Most of the plant bioactives have low aqueous solubility, high metabolism, low permeability and limited systemic availability, which significantly limits there *in vivo* activity. Structural instability, particularly, oxidation, hydrolysis and photodegradation vulnerability reduce their shelf life, and therapeutic use further. Mechanistic studies and dose optimization are complicated because of their multi-target and pleiotropic nature which is advantageous in complex diseases. These obstacles require sophisticated approaches that could guarantee stability, reproducibility and improved bioefficacy of the phytochemicals[3].

**Need for Nanotechnology for Phytochemicals**

Drug delivery systems that are developed by nanotechnology have proved to be a way out of the constraints of using plant-based bioactives. Examples of nanocarriers include liposomes, solid lipid nanoparticles, polymeric nanoparticles, phytosomes, nanoemulsions, and lipid-polymer hybrids to enhance solubility, absorption, prevent the degradation of unstable compounds, and deliver them to a specific tissue. Other benefits of nanoformulations are controlled and prolonged delivery, enhanced pharmacokinetics, and enhanced therapeutic efficacy with lower doses. In the case of phytochemicals that have an unfavorable biopharmaceutical profile, nanotechnology can be used as a strong-enabling technology that increases clinical opportunities and allows to obtain standardized and reproducible formulations[4, 5].

**Gap: Traditional Methods vs. AI-Assisted Workflows**

Traditional preparation of plant-based nanomedicines usually depends on trial and error testing, optimization by trial and error, and time-consuming analytical functions. The methods are resource-intensive and fail to effectively tackle the complexity of plant-based systems, in which several variables including extract content, nanoparticle constituents, process conditions and biological interactions are present[6, 7]. Artificial intelligence (AI) is a revolutionary solution as it allows predictive modeling, fast optimization, and decision-making with multiple parameters[8]. There are AI tools that can be used to analyze complicated data, find the most suitable formulation conditions, predict biological reactions and reduce the number of iterations in the experiment[9], e.g. machine learning, deep learning, chemometrics, QSAR, and predictive ADMET[10]. This intuition to data-driven transformation is an essential gap in the field and signifies the necessity of AI implementation in the sphere of phytomedicine development[11]. The main aim of the review is to discuss the role of artificial intelligence in improving the discovery, formulation, and pharmacological assessment of plant-based nanomedicines. The article gives the voters an in-depth account of the AI tools in phytochemical profiling, nanocarrier design, *in silico* pharmacology, predictive toxicology, and pharmacokinetic modeling. It also brings into the limelight recent developments, case studies, regulatory issues and the new opportunities in AI-enabled nano-phytopharmaceutical studies. This review will combine the information about pharmaceutics, pharmacognosy, and pharmacology to provide a single framework that depicts how AI can speed up the creation of safe, effective, and translatable to the clinic plant-derived nanomedicines.

**Phytochemistry of Medicinal Plants**

Phytochemistry is the scientific basis of plant-based medicines since it determines, characterizes, and quantifies the bioactive components of pharmacological effects[12]. Plants generate a wide range of secondary metabolites that lead to such therapeutic effects as antioxidant, anti-inflammatory, anticancer, antimicrobial, and neuroprotective effects[13]. The knowledge of these phytochemicals will be important to the development of standardized formulations and designing of more sophisticated drug delivery systems. In this section, key phytochemical classes, the difficulties encountered in the discovery of these classes, and the increasing importance of the artificial intelligence (AI) in the acceleration of phytochemical profiling are described[14].

**Overview of Major Phytochemical Classes**

**Alkaloids**

Alkaloids are organic compounds that contain nitrogen and are very strong in terms of their physiological action. More than 12,000 alkaloids have been discovered, which include morphine, quinine, berberine, vincristine and atropine. They usually have potent pharmacological effects of analgesic, anticancer, antimalarial, and antimicrobial effects because they can bind with neurotransmitter receptors, enzymes, and ion channels. Alkaloids are chemically heterogeneous and may have to be profiled by a complex analytical technique[15, 16].

**Flavonoids**

Flavonoids are polyphenolic structures which are widely present in fruits, vegetables, as well as in medicinal plants. These have subclasses like flavones, flavonols, flavanones and anthocyanidins[17]. Flavonoids including quercetin, kaempferol, naringenin, and other flavonoid derivatives have been known to be antioxidant, anti-inflammatory, cardioprotective and anticancer properties, which modulate oxidative stress and cellular signalling pathways[18].

**Terpenoids**

The terpenoids (isoprenoids) form the largest natural compound category of which over 40,000 structures are described. These include mono, diterpenes, triterpenes and carotenoids. The curcumin, artemisinin and ginsenosides are terpenoids that have various therapeutic effects that include: anti-malarial, anti-inflammatory, hepatoprotective, and anticancer. They are mostly lipophilic and, hence, require formulation strategies to improve bioavailability and solubility[19, 20].

**Phenolics**

Phenolic acids, tannins, lignans and stilbenes are considered phenolic compounds. They are well known due to their antioxidant ability and concerning the ability to regulate gene expression, inflammation and redox balance of cells. The compounds such as resveratrol, gallic acid and ellagic acids have shown some promising results in the treatment of chronic diseases but the stability and bioavailability of these compounds is a significant issue[21].

**Glycosides**

Glycosids consist of sugar backbone that is conjugated to non-sugary aglycone. The best examples include cardiac glycosids (e.g., digoxin), saponins and anthraquinone glycosids. These compounds are very bioactive but in most instances their effects may be very severe hence care should be taken when administering them. They are very unstable, and insoluble and this influences their therapeutic performance[22].

**Challenges in Phytochemical Discovery**

**Chemical Complexity**

Medicinal plants can have hundreds to thousands of structurally diversified phytoconstituents that occur in their different concentrations. Isomers, structural analogues and synergistic compounds make it difficult to be standardized and identified. Such complexity should be overcome using highly sensitive and selective analytical techniques, including LC-MS/MS and NMR[23].

**Seasonal Variation**

The phytochemical levels are highly variable with age and climate of the plant, soil type, harvest time and post-harvest time, and the means of extracting them. The result of this biological variability is uneven therapeutic gains and the impossibility of reproducibility of research and production[24].

**Extraction and Standardization Issues**

Various extraction solvents, varying temperatures and other methods selectively influence the phytochemical profile[25]. Traditional extraction mechanisms are capable of destroying fragile compounds[26]. This makes it hard to achieve the standardization of batch-to-batch especially of complicated combinations of herbs. It is also not easier to quantify and quality control due to the lack of validated biomarkers.

**Role of AI in Phytochemical Profiling**

**Machine Learning in Compound Prediction**

Machine learning (ML) systems can particularly process chemical, spectral, and biological data to predict the presence, abundance and activity of phytochemicals. The ML algorithms, especially the random forest, support vector machines and neural networks, identify the relationship between the structural features and biological activity that can be exploited to screen the possible leaders compounds rather fast[27].

**Chemometrics for Metabolomics**

Chemometrics is an amalgamation of multivariate analysis and statistical modelling used to deal with complex metabolomic data. Methods like PCA, PLS-DA and hierarchical clustering are used with the aim of classifying plant species, distinguishing extract profiles as well as biomarkers[28]. The use of AI-enhanced chemometrics allows the intensive interpretation of LC-MS, GC-MS, and NMR data.

**Deep Learning for Structure Elucidation**

There are models of deep learning, in particular, convolutional neural networks (CNNs) that can process spectral tendencies and predict chemical structure directly using raw data. They assist in automated labelling of the metabolites, deconvolution of overlapping peaks and in the construction of unknown structures. This significantly reduces time and error in manual process[29].

**AI-Assisted Dereplication in LC-MS/MS**

Dereplication is implemented to find known compounds in complex mixtures in a fast way to avoid the duplication of the similar work to isolate one common compound. The AI algorithms, match the mass spectrum to the mass spectrum libraries, clusterization of fragmentation patterns, and future molecular fingerprints. The dereplication automation is enhancing the throughput and increases the discovery of new phytoconstituents[30, 31].

**AI in Designing and Optimizing Nanocarriers for Plant Actives**

Nanocarriers that have been developed to deliver phytomedicine have revolutionized the field of phytomedicine, improving the solubility, stability, bioavailability, and targeted delivery of phytochemicals. Traditional formulation procedures are however usually labor intensive and are highly dependent on empirical experimentation. The combination of formulation science and artificial intelligence (AI) is the key to finding a solution to this problem as it provides the ability to conduct predictive modeling, multi-parameter optimization, and the use of data to make a decision. In this section, the author explains the shortcomings of the conventional methods, the main algorithms of AI involved in nanoformulation, and the use of AI in creating more optimized nanocarriers to promote plant-derived bioactives[32].

**Limitations of Conventional Formulation Methods**

**Trial-and-Error Approaches**

In the conventional formulation development, optimization of ingredients and processing conditions of the formulations is commonly intuitive step-wise adjustments. In this method no systematic search of the formulation space is done and typically there are a large number of batches and the method is thus highly material consuming, expensive and time consuming in terms of development. With the case of the plant bio actives when their characteristics are variable, trial and error remains inefficient even more[33].

**Time-Consuming DoE (Design of Experiments)**

DoE is suitable in structured experimentation although it is time consuming and computationally intensive with several variables of formulation. Traditional DoE models can be overwhelmed by high-dimensional systems, including nanoemulsions or polymeric nanoparticles, by their levels of surfactants, polymer ratios, sonication time and organic-aqueous phase ratios. Also, DoE cannot ensure that non-linear interactions between variables are captured and this can be limiting as far as predictive accuracy is concerned[34].

**Poor Prediction of Interactions**

Phytochemicals react with nanocarrier elements in complicated manners that are determined by the levels of polarity, molecular weight, charge, and hydrophobicity. The traditional models are not able to predict these interactions, which makes the formulations unstable, encapsulation unpredictable, and the reproducibility poor. These shortcomings are overcome by the AI-based techniques that extract non-linear and multidimensional relationships between inputs and outputs of the formulation process[35].

**AI Algorithms Used in Formulation**

**Artificial Neural Networks (ANN)**

ANNs are based on human neural networks to learn complicated patterns in formulation datasets. They are mostly useful in predicting particle size, polydispersibility index (PDI), encapsulation and release profiles. ANNs are able to deal with non-linear interactions and give high predictive accuracy on the basis of limited experimental information[36].

**Random Forest**

Random Forest is an ensemble algorithm, which forms a series of decision trees to forecast the formulation results. It can be resistant to noise and overfitting, which allows it to be used in the determination of influential formulation variables and their prioritization in terms of nanoformulation performance[37].

**Gradient Boosting**

Gradient boosting (e.g., XGBoost, LightGBM) algorithms are trained with updated predictive model every time in order to reduce error. They are outstanding in high dimensional data and prescriptive in encapsulations efficiencies, nanoparticles stability and optimum parameters of processes[38].

**Support Vector Machines (SVM)**

The classification and prediction of SVMs are accomplished by determining the optimal limits of multidimensional information. SVMs are used in nanoformulation to differentiate batches of formulation (e.g., optimal vs. suboptimal), predict stability behavior, multivariate sorting of quality attributes, which are significant[39].

**Bayesian Optimization**

Bayesian optimization is applied to quickly and efficiently optimize formulation parameters with a minimum of experiments. Using a probabilistic model, it can find the best formulation with less trials than DoE and is very efficient in multi-variable systems such as nanoemulsions and polymeric nanoparticles[40].

**AI Applications in Nanocarrier Development**

**Predicting Particle Size, PDI, and Zeta Potential**

The particle size and PDI are important in targeted delivery, cellular stability and uptake. AI models which predict the size distribution can be based on process parameters (e.g. sonication time, homogenization speed), surfactant concentrations, and ratios of polymers. Zeta potential forecasts help in determining the stability and aggregation of the long-term[41].

**Drug Loading and Entrapment Efficiency Prediction**

The AI algorithms are used to predict the interactions between phytoconstituents and nanocarriers using the following molecular parameters: hydrophobicity, Hansen solubility parameters, and partition coefficients. Such predictions are useful to optimize the encapsulation efficiency and decreasing drug leakage[42].

**Optimizing Surfactant/Polymer Ratios**

The concentration of the surfactant used and polymer has a significant effect on the nanoparticle formation, stability, and release kinetics. AI models are used to find the best ratios that improve particles uniformity, avoid aggregation, and optimize loading efficiency and reduce the toxicity of excipients[43].

**Stability Prediction**

Commercialization requires long-term stability. Under different conditions AI is predictive of aggregation behavior, phase separation, pH sensitivity and chemical degradation behavior. This saves the time required to conduct the long-term stability tests and shortens the refinements in the formulations[44].

**AI for Scale-Up**

A nanoformulation which is on a lab scale is hard to translate to an industrial scale production. The process parameters that AI models include to predict the outcome of scale-up are flow rate, mixing energy, pressure, and batch size. ML-assisted scale-up minimizes the variability and makes the quality uniform[45].

**Types of Nanocarriers Used for Plant Actives**

**Liposomes**

Liposomes are the best used vesicles to entrap both lipophilic and hydrophilic phytochemicals due to their phospholipid nature. They make it more stable, increase the pharmacokinetics and allow targeted delivery. AI models help to maximise lipid composition, hydration parameters and drug-to-lipid ratios[46].

**Solid Lipid Nanoparticles (SLN) and Nanostructured Lipid Carriers (NLC)**

The stability of the plant lipophilic compounds is improved by SLNs and NLCs. AI forecasts the best lipid surfactants mixtures, melting and entrapment. Specifically, NLCs minimize the problem of expulsion of drugs among SLNs[47].

**Polymeric Nanoparticles**

Biological degradable polymers e.g. PLGA and chitosan are examples of such nanoparticles. These include high stability and controlled release. The polymerdrug interaction, molecular weight, and release kinetics will be predicted by using AI[48].

**Phytosomes**

Phytosomes are complexes between phytoconstituents and phospholipids which increase the permeability and bioavailability. The AI determines the most favorable ratios of complexation and foresees the physicochemical characteristics[49].

**Nanoemulsions**

Nanoemulsions increase the solubility and absorption of plant actives that are not soluble in water. In order to develop stable and uniform formulations, the AI models are used to optimize the oil phase, surfactant choice, emulsification period, and the distribution of droplet sizes[50]. AI Models Used in Different Nanocarrier Systems, Their Applications, and Key Outputs (Table 1).

**AI-Assisted Screening for Pharmacological Activity**

In vitro and *in vivo* experiments have long been considered the traditional methods of pharmacological assessment of plant-based nanomedicines, which are labor-intensive. These techniques are important procedures, but they have their limitations in time and inaccurate forecasting of multifaceted biological behavior. AI has become an innovative technology that enables prompt pharmacological screening at the first stages and can quickly predict biological activity, molecular interactions, and even possible toxicity. With AI-based *in silico* design methodologies, it is possible to determine potential promising phytochemicals, evaluate their affinity with the target proteins and predict their safety profiles without undergoing extensive laboratory work. In this section, the key AI-aided methods used in the pharmacological screening of plant-derived nanomedicines are revealed[51].

***In Silico* Pharmacology for Phytochemicals**

**Target Prediction (PASS, SwissTarget Prediction)**

Target prediction tools are based on the chemical structure information upon which the biological targets are most likely to interact with a molecule. PASS (Prediction of Activity Spectra for Substances) and SwissTarget Prediction use machine learning models which have been trained on large bioactivity databases. These are protein fingerprint and structure tools that are used to predict binding by enzyme, receptor regulation, transporter interactions, and participation in pathways. These predictions are useful as they aid in filtering phytochemicals to targets of interest in pharmacological studies[52].

**Molecular Docking**

Molecular docking A protein-phytochemical binding under molecular simulation. AI is capable of boosting the accuracy of docking using scoring functions and pattern recognition. Docking is used to determine the binding affinity, the orientation and key interacting residues of the possible pairs of compounds-target. In cases where the behavioral plant actives are multi-targeted, AI-based docking is more reliable, as it filters hundreds of targets[53].

**Molecular Dynamics (AI-Accelerated)**

The dynamics, stability and conformational change of phytochemical-protein complexes with time can be provided by molecular dynamics (MD) simulations. The AI is computationally efficient compared to the traditional MD, and it accelerates the simulations by predicting force fields, energy landscapes, and traverse of motion. Deep learning

models can model MD outputs that are both highly accurate, requiring days reduced to minutes. This helps in boosting the mechanistic understanding of how phytochemicals respond to biological targets[54].

**AI for Predicting Biological Activity**

**QSAR Modelling**

Quantitative Structure-Activity Relationship (QSAR) modeling is a method that is used to correlate the chemical structure of the phytoconstituents and their biological activity. Descriptors that are used in AI enhanced QSAR models include hydrophobicity, molecular weight, electronic distribution and topological indices to predict antioxidant, anti-inflammatory, anticancer or antimicrobial properties. Such machine learning models as SVM, Random Forest, or ANN yield correct predictions of even structurally diverse plant compounds[55].

**Deep Learning for Bioactivity Classification**

Phytochemicals can also be classified as active or inactive by Deep learning networks particularly Convolutional Neural Network (CNNs) and Long Short-Term Memory (LSTM) networks using spectral signatures, fingerprints, or SMILES structures. The models are trained to acquire very complex patterns and can be used in the identification of unknown or poorly studied compounds with therapeutic interest[56].

**Machine Learning for Multi-Target Interactions (Polypharmacology)**

Most of the plant compounds have a therapeutic effect by acting on a number of targets simultaneously. Polydrug-drug interaction map Machine learning models digest large datasets of protein-ligand interactions to map polypharmacological profiles. This is useful in predicting synergy, antagonism and effects at pathway level. ML-based network pharmacology combines the resources of omics, gene expression and protein-protein interactions to provide an overview of phytochemical action at a systems level[57, 58].

**Toxicology Prediction**

***In Silico* ADMET**

The pharmacokinetic behavior of nanoformulations and phytochemicals is tested in the form of AI-based ADMET (Absorption, Distribution, Metabolism, Excretion, and Toxicity) models. Some of the parameters that are predicted by the ML models in the context of oral absorption include blood-brain penetration, cytoctedrahene metabolism and renal clearance. Prediction of ADMET early will contribute to the elimination of the wrong candidates before the costly *in vivo* testing[59].

**Predictive Toxicity Models**

Toxicity prediction models that are based on extensive toxicological datasets determine the possibility of mutagenicity, hepatotoxicity, genotoxicity, and cytotoxicity. Random Forest, Gradient Boosting, and ANN algorithms assign compounds into the risk categories of toxicity, which reduces the use of animal testing[60].

**hERG Inhibition Predictions**

Cardiotoxicity is mostly caused by Human Ether-a-go-go-Related Gene (hERG) channel inhibition. The models of AI forecast the potential of hERG inhibition relying on molecular structure, electrostatic properties, and lipophilicity. Premature forecasting averses late failure and secures cardiovascular security of phytochemical-based nanomedicines[61].

**Plant-Based Nanomedicine Development—Integration of AI Across the Pipeline**

The development of plant-based nanomedicines comprises several steps that are interrelated but some main steps involve the choice of plant species and active phytoconstituents, nanocarrier design, prediction of pharmacokinetics and analysis of therapeutic efficacy of the nanocarriers. Traditionally each stage was very experimental and thus the process was resourceful and inconsistent. The artificial intelligence (AI) is an all-encompassing, data-driven solution that enhances the decision-making process and decreases experimental burdens and minimizes the time between lab

discovery and use in clinical practice. In this case, the manner, in which AI can be applied in each step of the nano-phytomedicine process is addressed[62].

**Selection of Plants and Actives Using AI-Based Ethnobotanical Data Mining**

**NLP Applied to Classical Medicinal Texts**

The ethnobotanical knowledge encompasses a variety of information on the usage and therapeutic indication of plants which are helpful in ancient medicine systems (Ayurveda, Siddha, Traditional Chinese Medicine (TCM) and folk literature)[63-65]. These writings are not structured, different in linguistic state, lack qualitative description and it is hard to understand them manually because of this. This has been automated using Natural Language Processing (NLP) that recognizes disease plant relations, therapeutic assertions, phytochemical facts as well as dosage practices. Artificial intelligence devices that identify plants based on their therapeutic value help researchers to identify potentially useful species to conduct further research[66].

**Network Pharmacology with Machine Learning**

The network pharmacology is the research on the phytochemicals, interactions of biological targets and disease pathways. Machine learning (ML) algorithms analyze the big databases (e.g., TCMSP, IMPPAT) to identify the most important phytoconstituents that initiate the activities, simulate interactions and visualize multi-target activities. The technique can be applied to rank high the plant species and active compounds that have the highest potential of therapeutic effects in their formulations as nanomedicine[67, 68].

**AI-Driven Nanoparticle Formulation for Phytoconstituents**

**Predicting Nano–Drug Interactions**

The concerns entailing the interactions between the phytoconstituents and the nanocarrier constituents (lipids, polymers, surfactants) can be anticipated with the assistance of AI models. ML algorithms define encapsulation efficiency, affinity and compatibility of bindings with regard to molecular descriptors of hydrophobicity, solubility parameters and functional group distribution. The projections lower the experiments and can be utilized in making a decision on the formulations within a short period of time[69].

**Improving Solubility and Stability**

The significant impediments to many plant actives are poor solubility and instability. AI is used to predict the most suitable type of nanocarrier (e.g. liposomes vs. polymeric nanoparticles), optimal excipients and processing conditions, which lead to greater solubility, degradation resistance and shelf-life. The deep learning models are able to examine degradation patterns during heat, PH, and light, making it possible to design nano formulations with a stability enhancement[9].

**AI in Optimizing Pharmacokinetics of Nano-Phytomedicines**

**PBPK Modelling**

Physiologically Based Pharmacokinetic (PBPK) models are physiological models which simulate drug absorption, distribution, metabolism, and excretion. PBPK systems enhanced with AI consider the molecular structure, nanoparticle size, charge and release kinetics to enable prediction of the *in vivo* behavior with a high level of accuracy. This enables predetermination of optimum dosing schedules of nano-phytomedicines[70].

**Prediction of Tissue Distribution**

AI algorithms guess the distribution of nanoformulations in organs depending on the properties of surfaces, ligand changes and the interaction with biological membranes[71]. ML models that are trained using biodistribution data sets can be used to predict accumulation in liver, spleen, brain or tumor tissues. These are predictions used to design nano-phytotherapeutics targeted[72].

**Enhancing Bioavailability via ML Models**

The machine learning models are applied to investigate the impact of formulation parameters on the solubility, permeability, and first-pass metabolism. The solutions to ML-based optimization include surface modification that improves bioavailability, mucoadhesion and stimuli-sensitive release. It significantly contributes to the improvement of ineffective absorption of phytochemicals in the process of treatment[73].

**AI-Supported Prediction of Clinical Efficacy**

**Virtual Patient Simulations**

Virtual patient models based on AI are used to simulate clinical outcomes by including variables related to patients, including genetics, age, disease, and comorbidities. Before the clinical trials, these simulations are useful in forecasting the potential response of various populations that may be experienced by the introduction of nano-phytomedicines and the identification of the most effective dosage regimens. This saves a big deal in terms of cost and time of completion of early clinical development[74].

**Drug–Disease Matching Algorithms**

Disease ontology databases and machine learning are needed to identify the best therapeutic applications of a certain nanoformulation via drug-disease matching algorithms. The molecular events and disease signatures their analysis of demonstrate the probability of an effective phytochemical-loaded nanocarrier in diseases such as cancer, inflammation, neurodegeneration or metabolic disease. This results in repurposing and complies with clinical utility[75].

**Advanced Characterization of Plant-Based Nanomedicines**

The proper characterization of nanomedicines made out of plants is vital in assuring their safety and stability, efficacy, and regulatory compliance. The most common methods of analysis used in traditional characterization include TEM, SEM, FTIR, NMR, Raman spectroscopy, DLS, and DSC that produce the huge and complicated data. These datasets may be tedious to interpret manually, subjective and subject to error- particularly when dealing with heterogeneous nanocarrier systems loaded with structurally diverse phytochemicals[76]. Artificial intelligence (AI) is an effective way out since it offers data analysis automation, sensitivity, and the ability to detect subtle trends that could be overlooked by traditional means. ML and deep learning algorithms have the capability to scale spectral data in seconds, categorize nanoparticle morphologies, foretell stability performance, and associate physicochemical specifications with *in vivo* operation[77]. Characterization with the aid of AI leads to reproducibility and minimizes quality-by-design (QbD) uses and enables scientists to verify key quality attributes (CQAs), such as particle size, PDI, zeta potential, loading efficacy and release kinetics[78]. Real-time interpretation of data can be done when AIs are used in combination with analytical instrumentation and they can be used further to predictive modelling to further refine the formulation scale-up and evaluate regulationas shown in Table 2. AI Tools for Characterization of Nanocarriers (Technique vs. AI Model vs. Output) (Table 2).

**Pharmacological Evaluation of Plant-Based Nanomedicines**

The pharmacological study is an important phase in the production of plant nanomedicines since it establishes its curative capacity, security, and action mechanism. Nanocarriers have the potential of improving the pharmacological characteristics of phytochemicals through stability, absorption, distribution, and targeting of cells. In the meantime, the artificial intelligence (AI) can be used to speed up the process of pharmacological evaluation by providing predictive information, pattern recognition, and mechanistic modeling as complementary to experimental measurements. The combination of nanotechnology and AI offers a mighty paradigm of how plant-based formulations are acting in the biological system[79].

**Enhancing Pharmacodynamics Using Nanocarriers**

**Improved Cell Uptake**

Nanocarriers enhance the internalization of phytochemicals to the cells significantly. They get in their cells by endocytosis, micropinocytosis and receptor-mediated entry via their small size (nanoparticle). Selective attachment to

cellular receptors is achieved by surface modification, including PEGylation, ligand conjugation and optimization of charge. Therefore, in most cases, nanoformulations have a higher intracellular absorption compared to free phytochemicals and can be used to increase their therapeutic efficacy[80].

**Controlled Release**

The nanocarriers also allow them to deliver the plant actives at a slower and controlled rate, which overcomes the fast metabolism and degradation. Time controlled release can be achieved using SLNs, nanoparticles composed of polymer and also using NLCs, but to achieve localized release at the site of the disease, pH-controlled and enzyme-controlled nanocarriers can be used. The benefits of controlled release are maximization of therapeutic exposure, decrease of dosing frequency and decrease of systemic toxicity[81].

**Target Specificity**

Functionalised nanocarriers are more specific in that they can target specific tissues or cells- tumour cells using folate-coated nanoparticles or brain using transferrin-modifications. This is a focused treatment that minimizes side effects and improves pharmacodynamics[82].

***In vitro* Mechanisms with Help of AI**

**Predictive Models for Apoptosis Pathways**

Activation of apoptosis pathways which are triggered by nano-phytomedicines can be predicted using AI models trained on omics and cytotoxicity datasets. The machine learning algorithms find important molecular signatures, including caspase activation, loss of mitochondrial membrane potential, and fragmentation of DNA on the basis of structural and physicochemical properties of nanoformulations. This speeds up mechanism-of-action research and lowers the level of experimentation[83].

**Anti-Inflammatory Networks**

Network pharmacology AI-based combines all three types of data (gene expression, cytokine profiles and signaling cascades) to model anti-inflammatory activity. Such models are used to predict pathway modulation including NF-kB, COX-2, TNF-a, and IL-6, which are useful in identifying multitarget effects of plant-derived nanoencapsulated phytochemicals such as curcumin, quercetin or boswellic acids[84].

**Antioxidant and Anti-Cancer Pathways**

Deep learning models provide prediction of antioxidant capacity across cellular oxidative stress markers. Likewise, ML tools represent interaction with cancer-related pathways that include PI3K/Akt, MAPK, JAK/STAT, and p53. The predictions are used to plan experiments and to increase the knowledge of the pharmacological effects of nanoformulated phytochemicals[85].

***In vivo* Evaluations and AI-Enabled Data Interpretation**

**ML for Dose–Response Predictions**

Dose-response relationships are predicted by machine learning algorithms such as regression algorithms, random forest, and neural networks that use both *in vitro* data, formulation parameters, and physicochemical properties. This will cut down the necessary amount of animal experiments and allow more specific dose selection in *in vivo* studies[86].

**Predictive Toxicity Curves**

The AI models, that are applied to produce predictive toxicity curves, are constructed on the premise of the integration of data on biochemical markers, hematological, organ histology, and behavioral observations. These models are used to predict the safe dose ranges including the no-observed-adverse-effect-level (NOAEL) and the first organ-specific toxicity. These forecasts come in handy during predictions and risk control[87].

**Behavior Prediction in Disease Models**

In complicated disease models, e.g. cancer, diabetes, or neurodegenerative diseases, AI can be used to analyze behavioral and physiological data to make predictions about the result of a therapeutic intervention. As an example, ML models predict movement in models of Parkinsonism or tumor growth dynamics in cancer models, which assists in accelerating the interpretation of *in vivo* pharmacology[88].

**AI for Personalized Phytomedicine**

**Genomic Integration**

AI facilitates the combination of genomic, proteomic, and metabolomic data with predictive potential of individual reactions to plant-based nanomedicines. Pharmacogenomic AI systems assist in determining genetic variants which affect drug metabolism, immune response or therapeutic sensitivity. This method favors the creation of personalized nano-phytomedicines that are patient-specifically designed in terms of molecular profiles[89, 90].

**Patient-Specific Pharmacology Using ML Models**

The ML algorithms are based on the age of the patients, their biomarkers, the disease stage, lifestyle, and comorbidities to recreate the personal therapeutic outcomes. These include efficacy, toxicity and optimal dosing models of nanoencapsulated phytochemicals that are predictive in various groups of patients. Clinical meaning is advanced with the use of artificial intelligence (AI)-based personalization that promotes precision herbal nanomedicine[91].

**Regulatory Considerations for AI-Designed Nano-Phytomedicines**

The integration of artificial intelligence (AI) with nanotechnology and therapeutic plants creates significant opportunities of quick and data-driven drug discovery. However, it has special regulation issues. As opposed to traditional medicine, nano-phytomedicines incorporate three complicated domains, herbal products, nanocarrier systems, and AI-based computational design, and each has a distinct regulatory system. The variability problem is typical of the herbal medicines due to variability of the source plant, extraction method, and heterogeneity of phytochemicals. In their turn, nanocarriers should be assessed with regard to particle size, stability, surface chemistry, as well as biodistribution. Regulatory agencies must also evaluate the credibility, disclosure, and certification of computational models in situations when AI is involved in formulation prediction, optimization and pharmacological screening. U.S. FDA, European Medicines Agency (EMA), ICH, AYUSH and other national regulatory bodies are beginning to appreciate the rate that AI is being applied in drug development but demand the use of model validation, risk management, reproducibility and explainability. The AI predictions must be supported by experimental results and developers ought to ensure that the algorithms are trained on good, unbiased results. Moreover, the nano formulations that are designed using AI are a challenge to the conventional quality-by-design (QbD) models. A regulator is not only to inspect the product produced but also the digital pipeline, which was brought by the production of the product[92]. The issues of data integrity, the bias of the algorithm and the model drift, and reproducibility should be taken into consideration as shown in Table 3. Regulatory Considerations for AI-Designed Nano-Phytomedicines (Table 3).

**Challenges and Future Opportunities**

Plant-based nanomedicine, which is developed based on artificial intelligence (AI), can bring revolutionary opportunities to the sphere; however, it also introduces a lot of scientific, technical, regulatory, and ethical challenges. Plant-based therapeutics are self-convoluted due to variation in phytochemical composition, lack of standardization in extraction procedures and lack of standardization. The development pipeline can be multidimensional together with nanocarrier systems and AI-based modelling, and physical formulations as well as computational predictions should be properly validated. The quality and completeness of datasets used to develop AI models determine the success of the latter. The datasets of phytomedicine can be systematic, unstructured, or un- annotated, and thus, it is difficult to develop powerful machine learning solutions. Also, deep learning models are not even transparent because they are black-box, making them not easy to reproduce and accept by regulators. The impartiality, reduction of the biased algorithms, the integrity of the data are important elements during the transformation of the AI-based

predictions into clinical outcomes. However, the future is massive regardless of these obstacles. AI can accelerate the discovery of new phytoconstituents, automated nanoformulation, better pharmacokinetic modeling, and personalised phytomedicine depending on the personal genomic and phenotypic characteristics of the patients. More integration and types of multi-omics, digital twins, federated learning, and explainable AI (XAI) will become increasingly popular in the future most likely making nano-phytomedicines more specific, less toxic, and more complex[11]. A systematic overview of the available opportunities and challenges is carried out as shown in Table 4. Challenges and Future Opportunities in AI-Enabled Nano-Phytomedicine Development (Table 4).

## CONCLUSION

Artificial intelligence has led to the revolution of the production line of plant-based nanomedicines. It is possible to determine bioactive compounds using AI and in minutes by enhancing phytochemical profiling of plants and provides a way through the complexity and variability inherent in medicinal plants. Predictive modeling can be used to formulate, optimize critical quality attributes, and scale and stabilize nano-phytomedicines faster and more easily in nanotechnology using AI-based models. In pharmacology, AI improves mechanistic understanding, predicts therapeutic and toxicology and can help provide a personalized approach to treatment by combining genomics and patient-specific information. All these developments lead to a reduction in the time of development, reproducibility and likelihood of successful clinical translation. The alliance of AI and natural products with nanomedicine in the future has a massive prospect with regard to the discovery of novel treatment methods, precision herbal medicine and the next-generation drug delivery systems. Additional improvements in the quality of data, openness of the models and regulatory policies will be required to reach the full potential of AI-based nano-phytomedicine.

**Table 1: AI Models Used in Different Nanocarrier Systems, Their Applications, and Key Outputs**

| Nanocarrier System | AI Model Used | Applications in Formulation | Key Outputs / Predictions |
|---|---|---|---|
| Liposomes | Artificial Neural Networks (ANN) | Optimization of lipid composition, hydration conditions, sonication time | Particle size, PDI, zeta potential, entrapment efficiency, vesicle stability |
| | Random Forest | Identifying key variables affecting liposome formation | Ranking variable importance, predicting optimal formulation parameters |
| Solid Lipid Nanoparticles (SLN) | Support Vector Machines (SVM) | Predicting stability and crystallinity | Long-term stability, drug release behavior, aggregation tendency |
| Nanostructured Lipid Carriers (NLC) | Gradient Boosting (XGBoost, LightGBM) | Optimizing solid–liquid lipid ratios, surfactant levels | Enhanced entrapment efficiency, reduced drug expulsion, improved physical stability |
| Polymeric Nanoparticles (PLGA, chitosan, etc.) | ANN | Predicting polymer–drug interactions, molecular weight effects | Release kinetics, drug loading, nanoparticle morphology |
| | Bayesian Optimization | Rapid optimization of multi-parameter formulation | Minimal experiments required, optimal polymer/surfactant concentrations |
| Phytosomes | Random Forest | Identifying critical phospholipid–drug complexation parameters | Best complexation ratio, improved solubility and permeability |
| Nanoemulsions | ANN | Optimizing oil phase, surfactant/cosurfactant ratios, homogenization cycles | Droplet size, stability index, phase separation prediction |
| | Gradient Boosting | Modeling non-linear effects of emulsification parameters | Fine-tuned droplet distribution, improved long-term stability |
| Hybrid Nanocarriers (polymer–lipid / lipid–metal) | Deep Learning models (CNN, LSTM) | Processing large datasets from characterization (TEM images, spectral data) | Morphology prediction, structural integrity, surface architecture |
| General Nanocarrier Systems | Multi-objective Optimization Algorithms | Balancing multiple formulation outcomes simultaneously | Optimal trade-off between size, stability, loading efficiency, release rate |

**Table 2: AI Tools for Characterization of Nanocarriers (Technique vs. AI Model vs. Output)**

| Analytical Technique | AI/ML Model Used | Characterization Output Enabled by AI |
|---|---|---|
| TEM / SEM Imaging | Convolutional Neural Networks (CNNs) | Morphology analysis, shape classification, nanoparticle size distribution, detection of aggregation |
| Dynamic Light Scattering (DLS) | Random Forest, ANN | Prediction of particle size, PDI, stability trends, batch-to-batch consistency |
| FTIR Spectroscopy | PCA, PLS-DA, SVM | Functional group identification, drug–excipient interaction analysis, purity assessment |
| Raman Spectroscopy | Deep Learning (1D-CNN), Chemometric ML | Molecular fingerprinting, phase analysis, component mapping in nanoformulations |
| NMR Spectroscopy | ANN, Autoencoders | Structural elucidation, impurity detection, conformational analysis |
| XRD (X-Ray | Gradient Boosting, SVM | Crystallinity profiling, polymorph identification, |

| | | |
|---|---|---|
| Diffraction) | | nanoparticle phase stability |
| DSC / TGA | Machine Learning Regression Models | Thermal stability prediction, glass transition and melting point analysis, degradation onset |
| Zeta Potential Analysis | ANN, Linear Regression Models | Prediction of surface charge, colloidal stability, aggregation risk |
| UV–Visible Spectroscopy | PCA, k-Means Clustering | Drug loading confirmation, degradation pattern detection, release kinetics interpretation |

**Table 3: Regulatory Considerations for AI-Designed Nano-Phytomedicines**

| Regulatory Dimension | Key Requirements | Relevance to nano-phytomedicines | Challenges / Considerations |
|---|---|---|---|
| Quality of Plant Material | Standardized extraction, validated biomarkers, batch consistency | Ensures reproducible phytochemical profile | Variability due to climate, soil, harvest season |
| Nanocarrier Evaluation | Particle size, PDI, zeta potential, release kinetics, sterility | Determines stability, safety, biodistribution | Lack of harmonized global standards for nanomedicine |
| AI Model Validation | Transparency, explainability, performance metrics (RMSE, $R^2$), dataset quality | Validates AI-driven formulation/design | Black-box ML models may lack interpretability |
| Safety Assessment | In vitro and *in vivo* toxicity, immunogenicity, ADMET | Required for nano-loaded phytochemicals | Nano–bio interactions difficult to predict |
| Efficacy Evaluation | Mechanistic data, PK/PD models, clinical endpoints | Confirms AI-predicted pharmacology | Integration of *in silico* + *in vivo* data still evolving |
| Data Integrity and Traceability | Documentation of datasets, model training logs, version control | Ensures reproducible AI predictions | Risk of biased or incomplete datasets |
| Regulatory Documentation | CMC (Chemistry, Manufacturing, Controls), digital workflow reports | Required for approval submissions | New formats needed to include AI-derived data |
| Ethical and Legal Compliance | Patient data protection, algorithmic fairness | Important for AI-guided personalized phytomedicine | GDPR, HIPAA compliance complexities |

**Table 4: Challenges and Future Opportunities in AI-Enabled Nano-Phytomedicine Development**

| Category | Current Challenges | Future Opportunities |
|---|---|---|
| Phytochemical Variability | Inconsistent plant composition; lack of standardized biomarkers | AI-driven phytochemical fingerprinting; real-time quality monitoring |
| Data Limitations | Fragmented or small datasets for training; incomplete metadata | Creation of large curated phytomedicine datasets; federated learning systems |
| AI Model Limitations | Black-box models; low interpretability; overfitting risks | Explainable AI (XAI), transparent algorithms, improved model validation |

| | | |
|---|---|---|
| Nanocarrier Complexity | Difficult prediction of drug–excipient interactions and stability | ML models for precise nano–drug compatibility and stability forecasting |
| Pharmacokinetic Uncertainty | Limited *in vivo* predictability; complex nano–bio interactions | AI-enhanced PBPK models; dynamic prediction of tissue distribution |
| Safety and Toxicity | Difficulty predicting long-term nano–herbal toxicity | AI-driven toxicity simulators; virtual toxicity curves; reduced animal studies |
| Regulatory Barriers | Lack of harmonized guidelines for AI + herbal + nano combination | Development of digital CMC frameworks; AI validation protocols |
| Personalized Medicine Gaps | Limited patient-specific data; high biological variability | AI-based patient clustering; genomic integration; precision phytomedicine |

## ABSTRACT

The task of quickly identifying and categorizing malware strains for efficient defense is becoming more and more difficult for security researchers. In order to address these gaps, this study thoroughly replicates four CNN architectures namely Xception, EfficientNetB0, ResNet50 and VGG16, Class Activation Maps (CAMs) such as GradCAM and NICE are used to assess both explainability and performance. The activation heatmaps produced for the five malware classes using four convolutional neural network architectures are analysed. These variations in activation patterns emphasize the significance of interpretability tools in deep learning evaluation and aid in explaining the disparity in classification performance among the models. Also, this study conducted a comparative static analysis of five malware families namely Amonetize, Dialplatform B, Fakerean, Neoreklami and Snarasite, using grayscale image visualization, row-wise entropy measurement, and hexadecimal inspection. Comparative Summary of Entropy Characteristics and Visual Traits of five Malware Families are tabulated. The comparative analysis demonstrates that all five malware families employ similar obfuscation strategies characterized by high-entropy content, noise-like visual representations, and PNG file format impersonation. These findings underscore the limitations of traditional signature-based detection methods and emphasize the effectiveness of image-based and entropy-driven static analysis techniques for identifying and differentiating modern obfuscated malware families.

**Keywords:** Explainable, CNN, Grad-CAM, NICE, Malware

## INTRODUCTION

Malware can be represented as images for a number of reasons. Foremost, image based models may discover structural similarities across distinct virus instances. This conversion permits the usage of well-established convolutional neural network (CNN) architectures to extract hierarchical features from visual data. Also, it gives cybersecurity professionals an easy-to-use visual medium to examine the image-like artifacts and gain a deeper understanding of the behavior of malware families. Visualization is an established technique that makes use of CNNs. Researchers may build an image with the data collected from a malicious file, and use it as a sample for the CNN [1]. This method makes use of the inherent characteristics of convolutional neural network models, including robust feature extraction, spatial invariance, adaptation, and effective processing. CNN based deep neural models have made it possible to achieve previously unheard-of improvements in a range of computer vision applications, including object identification, picture classification, semantic segmentation, and image captioning [2]. The inability of traditional black-box models to offer interpretable explanations for their predictions restricts their use in security-critical settings where knowing the logic behind a detection is crucial for threat response and mitigation. By improving model interpretability while preserving robust detection capabilities, Explainable AI (XAI) overcomes this gap [3]. Applications of sophisticated AI models are deeply ingrained in many facets of our daily lives. The requirement for openness, accountability, and trustworthiness is further heightened by their complexity, particularly when these intricate models make automatic judgments that have varying effects on our lives [4]. Gradient-weighted Class Activation Mapping (Grad-CAM) creates a coarse localization map that highlights the key areas of the image for concept prediction by using the gradients of any target concept flowing into the final convolutional layer [5]. Class Activation Mapping (CAM) is the most pertinent method for localization. This approach alters image classification CNN designs substituting fully-connected layers with convolutional layers and global average pooling, thus achieving class-specific feature maps [6]. A hybrid data augmentation strategy that combines traditional image processing techniques with the Deep Convolutional Generative Adversarial Network was proposed by Rahman *et al*. [7]. The suggested augmentation strategy was utilized to train the classifier on the Malimg dataset. Additionally, they evaluated the efficacy of CNN versus transformer architectures on malware pictures by comparing CNN and EANet models with LIME explainability, where the CNN model achieved greater accurate results on Malimg dataset. In addition to offering specific justifications for CNN's actions, the methodical comparison of the investigation [8] reveals clear patterns in malware family identification. Additionally, by improving Visual Transformers, these interpretability insights can achieve greater improvements across datasets as compared to benchmark values [9], [10], [11]. In summarized form, this research applies Grad-CAM to hybrid visual malware images in a structured way, allowing analysts to observe understand the internal decision-making process. It also conduct extensive experiments on three benchmark malware image datasets (Malimg, MaleVis and Fusion Malware datasets), demonstrating enhanced classification performance and model reliability. Additionally, it demonstrates the image capacity for generalization and usefulness in a variety of threat environments. This work offers a workable method for practical implementation by bridging the gap between deep learning models and the interpretability required for cybersecurity.

## BACKGROUND

The key concepts that underpin this research are discussed. Highlighted techniques used to visualize malware and concentrate on popular deep learning models. Additionally, explainable methods for studying CNNs in malware detection are described. Framework of a systematic pipeline analysis (Figure: 1). The framework are shown in Figure 1 illustrates a systematic pipeline for malware image classification and explainable analysis. Initially, malware datasets corresponding to Amonetize, Dialplatform.B, Fakerean, Neoreklami, and Snarasite are collected and converted into image representations. The dataset is divided into training, validation, and test images, and iterative fine-tuning is performed to optimize model performance [12], [18], [14]. In section 3, multiple convolutional neural network architectures namely Xception, EfficientNetB0, ResNet50, and VGG16 are employed for feature extraction and classification. Each architecture is independently trained and evaluated to analyze comparative performance

across different network designs. To enhance model interpretability, Class Activation Map (CAM) techniques, namely Grad-CAM and LIME, are applied to the trained models. These techniques generate heatmaps that highlight salient regions in malware images influencing classification decisions. In section 4, entropy characteristics are computed to quantify randomness and structural complexity within malware images. Additionally, visual trait analysis is conducted to identify distinctive texture, intensity, and spatial patterns associated with each malware family. Finally, the outputs from classification performance, CAM-based explanations, entropy profiling, and visual trait analysis are integrated to produce comprehensive output results, enabling both accurate malware detection and transparent understanding of model behavior.

**Dataset**

The prevalent dataset utilized in this research work namely MalImg, MaleVis and Fusion Malware datasets are shown in Figure 2 and also described in Table 1. MaleVis Dataset contains Amonetize samples with approximately 350 sample images used to detect malware via visual analysis. Dialplatform.B belongs to the Malimg dataset with approximately 152 sample images. Fakerean is one of the 25 malware families in the Malimg dataset with approximately 306 images which is frequently used for convolutional neural network training. Neoreklami is a prominent family of adware with approximately 350 sample images frequently featured in malware visualization and classification datasets, such as the Fusion Malware Dataset on Kaggle. Snarasite is a malware family included in the dataset with approximately 350 sample images. Dataset representing Malware Families (Figure.2). Malware Family Dataset (Table 1).

**Visualization of Malware Families**

Malware samples from various families are shown aesthetically in the Figure 3, where each binary file is converted into a two-dimensional image by mapping its byte values to pixel intensities. The use of image-based deep learning models for malware classification is made possible by this visualization technique. The texture of the malware class Amonetize is extremely rich and noise-like, suggesting that obfuscation or encryption techniques are widely used. Polymorphic behavior, which is frequently seen in adware and downloader-type malware, is suggested by the lack of distinct structural patterns. The Dialplatform B sample shows clearly defined intensity changes in vertically split sections. These patterns represent a more ordered binary layout and correspond to structured elements of the executable, such as headers, configuration data, and embedded payloads. The image of the Fakerean virus exhibits horizontal banding and repeating patterns. This regularity is characteristic of rogue security software, where similar code blocks and resource files are repeatedly embedded and producing consistent visual patterns. Visualization of sample Malware Families (Figure.3). A comparatively straightforward and repetitive coding structure is suggested by the Neoreklami sample's general uniformity and lack of contrast. Adware families that rely on recurrent advertisement-related routines with little obfuscation typically exhibit these traits. The existence of injected components and network-related functionality is indicated by the prominent horizontal dark bands and diverse textures shown in the Snarasite malware image. The many malware operational modules are represented by these visual anomalies. Overall, the visual distinctions amongst malware families show that discriminative structural information is preserved throughout binary-to-image transformation. Convolutional neural networks may efficiently take use of these unique spatial patterns to learn family-specific characteristics, enhancing malware classification ability.

**Grad-CAM for Malware Detection**

Convolutional neural networks (CNNs) in malware detection systems utilize a visualization approach called Grad-CAM (Gradient-weighted Class Activation Mapping) to explain their predictions. It draws attention to the elements of the input that have the biggest impact on the model's choice. CNNs are frequently used in malware analysis to process features like binary visuals, opcode sequences, byte plots, or traffic matrices that are represented as images or feature maps. Grad-CAM generates a heatmap by evaluating the gradients of the predicted class of malware or benign with respect to the final convolutional layer. The regions or patterns in the malware representation that contributed most to the categorization are shown in the ensuing heatmap. For instance, suspicious opcode sequences, unusual byte distributions, or malevolent behavioral patterns may be associated with high-activation regions. Grad-

CAM improves trust and interpretability in deep learning-based malware detection systems by enabling analysts to visually confirm whether the CNN concentrates on significant malware traits.

**LIME for Malware Detection**

An explainable AI method for deciphering the predictions of intricate malware detection models is called LIME (Local Interpretable Model-agnostic Explanations). LIME assists in comprehending why a certain file is categorized as benign or hazardous since contemporary machine learning and deep learning models sometimes operate as "black boxes." LIME operates by creating distorted replicas of a certain malware sample and tracking the classifier's predictions. The behavior of the original model is then approximated by training a basic interpretable model locally around the chosen instance. The most important characteristics influencing the categorization choice are found by this local model. LIME emphasizes key elements in malware analysis, including permissions, opcode patterns, API calls, and behavioral signs that affect the prediction. This improves transparency, helps security analysts validate model decisions, and supports effective malware investigation.

**Experiments**

In the following section, we assess the way this strategy can improve the performance of this architectural paradigm in conjunction with the LIME technique by using masks produced from heatmaps.

**Grad-CAM and LIME analysis of Amonetize malware**

The activation heatmaps produced for the Amonetize class using four convolutional neural network architectures Xception, EfficientNetB0, ResNet50, and VGG16 are shown in Figure 4. By highlighting the spatial areas of the input image that most strongly influence the model's prediction, these heatmaps shed light on the feature-learning behavior and decision-making process of the models. The middle area of the feature map indicates a robust and well-localized activation for the Xception model. This suggests that the most discriminative characteristics pertinent to the Amonetize class are successfully captured by the model. Strong spatial feature extraction and excellent localization capabilities are suggested by the concentrated attention pattern, which enhances classification performance. EfficientNetB0 has comparatively low activation in the majority of regions, with a significant concentration of high activation in a small location close to the feature map's bottom-right corner. This pattern implies that rather than a comprehensive representation of the input, the model mostly depends on a small number of spatial features. Increased sensitivity to particular visual patterns and less generalization may result from such concentrated attention. Stronger responses are primarily seen along the lower part of the feature map in the ResNet50 activation map. The attention is still region-biased even if the activations are more dispersed than in EfficientNetB0. Despite having less balanced spatial coverage than Xception, this suggests successful feature learning. More dispersed activations that are dispersed throughout the feature map's horizontal bands are produced by VGG16. Weaker spatial discrimination is reflected in the lack of strongly defined high-activation patches. This behavior is in line with VGG16's older and somewhat shallow design, which lacks the sophisticated feature refining processes seen in more modern models. Overall, the heatmap study shows that Xception offers the Amonetize class the most targeted and semantically significant attention, suggesting better feature localization and interpretability.

While EfficientNetB0 and VGG16 exhibit low spatial awareness and scattered attention, respectively, ResNet50 exhibits strong but region-biased activations. These variations in activation patterns emphasize the significance of interpretability tools in deep learning evaluation and aid in explaining the disparity in classification performance among the models. Elucidation of Model Activation Heatmaps for the *Amonetize* malware class using Grad-CAM (Figure.4). The Amonetize malware class's LIME (Local Interpretable Model-agnostic Explanations) visualizations, which were generated using four deep learning architectures EfficientNetB0, ResNet50, VGG16, and Xception are shown in Figure 5. By highlighting important superpixels, LIME identifies the areas of the image that have the biggest impact on the model's prediction. There are weak and sparse activations in the EfficientNetB0 model, and the classification decision is not influenced by any distinctly localized regions. This implies that discriminative characteristics pertinent to the Amonetize class are difficult for the model to capture. ResNet50, on the other hand, relies on many low-level features rather than particular class-defining patterns, as evidenced by the dense and

widely dispersed activations it produces throughout the whole image. In a similar vein, VGG16 has extensive noisy activations with slight focus close to the image's lower areas. On the other hand, insufficient feature localization and limited interpretability are suggested by the absence of structured and localized highlights. Xception has the most organized and significant LIME explanations among the assessed models. Xception successfully concentrates on prominent characteristics linked to the Amonetize malware class, as evidenced by the more localized highlighted portions, especially in the lower and selective upper regions of the image. In comparison to EfficientNetB0, ResNet50, and VGG16, the LIME research shows that Xception offers better interpretability and more dependable feature learning. These results suggest that explainable malware image classification tasks involving the Amonetize family are better suited for Xception. Elucidation of Explainable AI technique of LIME for *Amonetize* malware class (Figure.5).

**Grad-CAM and LIME analysis of Dialplatform.B malware**

The activation heatmaps produced by four deep learning architectures EfficientNetB0, ResNet50, VGG16, and Xception when used on Dialplatform samples are compared in the family of malware are shown in Figure 6. The geographical distribution of feature activations across internal convolutional layers is depicted in each heatmap, with color intensity denoting the relative strength or relevance of learned features (brighter colors imply higher activation, darker colors suggest lower activation). Selective feature learning with comparatively balanced emphasis across geographic areas is indicated by EfficientNetB0's modestly distributed activations with concentrated high-response zones. Stronger and more concentrated activations in particular areas have been detected by ResNet50, indicating deeper semantic representation of malware patterns and efficient hierarchical feature extraction. Because of its shorter design and somewhat less discriminative feature emphasis, VGG16 exhibits more scattered and lower-intensity activations. Xception's capacity to effectively capture spatial correlations using depthwise separable convolutions is proven by its smooth and centrally concentrated activation patterns. Overall, the visualization emphasizes discriminative malware traits and draws attention to architectural variations in each model's learning process. Compared to more conventional models like VGG16, deeper and more sophisticated architectures (ResNet50 and Xception) typically yield more prominent and structured activation regions, indicating higher feature representation abilities for malware classification tasks. Elucidation of Model Activation Heatmaps for the *Dialplatform.B* malware class using Grad-CAM (Figure.6). LIME (Local Interpretable Model-agnostic Explanations) visualizations for the Dialplatform are presented in the figure.

EfficientNetB0, ResNet50, VGG16, and Xception are the four deep learning models that comprise the malware family are shown in Figure 7. The local areas (superpixels) that have the biggest influence on the model's categorization choice are highlighted by LIME. Areas with a greater favorable influence on predicting the sample as Dialplatform are shown by the highlighted regions (depicted by yellow or red outlines).B, whereas darker areas show a smaller or insignificant contribution. Sparse but distinct highlighted regions are displayed by EfficientNetB0 (LIME), primarily centered in some lower and mid-level locations. This indicates the model concentrates on restricted structural characteristics inside the malware representation and depends on a small collection of discriminative patterns. ResNet50 (LIME) shows highlighted areas in the image that are denser and more widely distributed. This implies that ResNet50 uses several correlated regions to support its classification choice, capturing richer and more dispersed feature interactions. Due to its relatively thin design and absence of sophisticated feature reuse techniques, VGG16 (LIME) exhibits fragmented and noisy importance and less accurate feature attribution. With less noise, Xception (LIME) shows highlighted areas that are more cohesive and clear. Stronger interpretability and efficient feature separation made possible by depthwise separable convolutions are demonstrated by the explanations' increased structure and localization. All things considered, the LIME visualizations show distinct variations in the designs' feature attribution behavior. While VGG16 generates noisier and less focused interpretations, more sophisticated models like ResNet50 and Xception offer more consistent and semantically relevant explanations. These results highlight the importance of model architecture in achieving both accurate malware detection and reliable interpretability. Elucidation of Explainable AI technique of LIME for *Dialplatform.B* malware class (Figure.7).

**Grad-CAM and LIME analysis of Fakerean malware**

For samples from the Fakerean malware family, the graphic displays activation heatmaps generated by four convolutional neural network architectures: EfficientNetB0, ResNet50, VGG16, and Xception are shown in Figure 8. The heatmaps show the geographic intensity of learnt feature activations; places that contribute more strongly to the model's internal representation of the malware are indicated by brighter regions, whereas darker parts correlate to low activation. The majority of EficientNetB0's regions show minimal activation, with a few isolated high-response spots close to the lower layers. This implies selective feature extraction, in which Fakerean classification considers only a small sample of patterns to be significant. Stronger and more uniformly distributed activations are shown by ResNet50, especially in the bottom and center regions. This suggests that the Fakerean virus has strong hierarchical feature learning and the capacity to identify several distinctive traits. VGG16 exhibits moderately intense activation patterns that are dispersed over larger areas. In comparison to deeper structures, the absence of sharply concentrated activations indicates less accurate feature localization. Effective spatial feature modeling achieved using depthwise separable convolutions is highlighted by Xception, which displays smooth and well-defined activation regions focused toward the center of the heatmap. Overall, the comparison shows that EfficientNetB0 and VGG16 provide weaker or more scattered activations for the Fakerean malware family, but ResNet50 and Xception produce more structured and discriminative activation patterns. These differences underscore the impact of architectural design on feature representation quality in malware classification tasks. Elucidation of Model Activation Heatmaps for the *Fakerean* malware class using Grad-CAM (Figure.8) LIME (Local Interpretable Model-agnostic Explanations) visualizations for four deep learning architectures EfficientNetB0, ResNet50, VGG16, and Xception for the Fakerean malware family are shown in Figure 9.

The superpixel regions that make the most contributions to the local classification choice are highlighted by LIME; darker parts suggest a low or negligible contribution, while highlighted regions (yellow contours) indicate a favorable influence toward predicting the sample as Fakerean. The highlighted areas in EfficientNetB0 (LIME) are comparatively sparse and mostly located in the lower part of the image. This implies that the model's ability to detect Fakerean malware depends on a small number of discriminative structural characteristics. The model combines information from several spatial regions, as evidenced by the dense and widely distributed highlighted patches that ResNet50 (LIME) displays throughout the image. This indicates decreased localization precision even though it shows high feature sensitivity. With dispersed highlighted regions and little spatial coherence, VGG16 (LIME) generates noisy, fragmented explanations. When compared to deeper architectures, this behavior indicates poorer interpretability and weaker feature attribution. With somewhat reduced noise, Xception (LIME) shows more focused and structured highlighted sections, especially in the lower and perimeter portions. This suggests clearer attribution of influential regions and more efficient feature separation. All things considered, the LIME visualizations show that each model has unique interpretability traits. While ResNet50 and VGG16 produce noisier and more scattered attributions, Xception and EfficientNetB0 offer more succinct and targeted explanations. These findings emphasize the role of architectural design in achieving reliable and interpretable malware classification for the Fakerean family. Elucidation of Explainable AI technique of LIME for *Fakerean* malware class (Figure.9).

**Grad-CAM and LIME analysis of Neoreklami malware**

For samples from the Neoreklami malware family, the figure shows activation heatmaps produced by four convolutional neural network architectures: EfficientNetB0, ResNet50, VGG16, and Xception are shown in Figure 10. The heatmaps show how learnt feature activations are distributed spatially, with darker areas representing weaker feature responses and brighter areas representing higher activation intensity. Strong activation is seen at the upper part of the heatmap for EfficientNetB0, and the intensity decreases as one moves toward the lower layers. This suggests that in order to detect Neoreklami samples, the model prioritizes early-stage structural patterns. ResNet50 shows strong and evenly distributed activations throughout the upper and core areas, indicating robust capture of discriminative malware traits and efficient hierarchical feature learning. There is less contrast between high- and low-importance regions in VGG16, indicating more dispersed and moderately active regions. This is due to substantially poorer feature discrimination and less accurate spatial localization. Xception's great capacity to capture prominent spatial correlations using depthwise separable convolutions is demonstrated by a highly concentrated and

symmetrical activation pattern that is located in the middle of the heatmap. Overall, the study shows that whereas EfficientNetB0 and VGG16 exhibit broader or weaker activation patterns, ResNet50 and Xception produce better organized and discriminative activation representations for the Neoreklami malware family. These results further emphasize the influence of network architecture on feature learning effectiveness in malware classification. Elucidation of Model Activation Heatmaps for the *Neoreklami* malware class using Grad-CAM (Figure.10). The Neoreklami malware family's LIME (Local Interpretable Model-agnostic Explanations) visualizations for four deep learning architectures EfficientNetB0, ResNet50, VGG16, and Xception are shown in Figure 11. Superpixels that positively influence the model's classification of the sample as Neoreklami are indicated by the yellow-highlighted regions, whilst darker regions suggest little to no impact. In the upper part of the image, EfficientNetB0 (LIME) displays a compact and clearly defined cluster of highlighted locations. This implies that for Neoreklami identification, the model depends on a limited number of highly discriminative local features. Nearly the whole image is covered in dense, widely dispersed highlighted patches by ResNet50 (LIME). This shows less localization and greater explanation noise, but it also shows excellent sensitivity to many features. Large areas of the image are highlighted, and VGG16 (LIME) generates similarly chaotic and fragmentary explanations. In comparison to more sophisticated systems, this implies worse interpretability and weaker feature attribution. Clear, organized, and spatially coherent highlighted patches that form unique patterns are displayed by Xception (LIME). Strong feature separation and more significant attribution of discriminative regions are shown by these localized explanations. Overall, the LIME results demonstrate that, whereas ResNet50 and VGG16 typically produce noisy and excessively dispersed attributions, Xception offers the most comprehensible and well-localized explanations for the Neoreklami malware family, followed by EfficientNetB0. These findings highlight the importance of architectural choices in achieving reliable interpretability alongside accurate malware classification. Elucidation of Explainable AI technique of LIME for *Neoreklami* malware class (Figure.11).

**Grad-CAM and LIME analysis of Snarasite malware**

Activation heatmaps produced by four convolutional neural network architectures EfficientNetB0, ResNet50, VGG16, and Xception for samples from the Snarasite malware family are shown in Figure 12. The heatmaps show the spatial intensity of learnt feature activations, with darker areas representing weaker responses and brighter areas indicating higher significance. In the heatmap's middle horizontal region, EfficientNetB0 displays robust and distinct activations. This implies that a particular range of discriminative structural characteristics typical of Snarasite malware is the focus of the model. Effective hierarchical feature extraction and the capacity to capture several prominent patterns pertinent to Snarasite classification are demonstrated by ResNet50's prominent and wider activation regions, especially in the middle layers. With moderate intensity dispersed among multiple regions, VGG16 exhibits more dispersed and irregular activation patterns. This is indicative of less clear feature focus and somewhat lower spatial localization. Xception's remarkable capacity to capture prominent spatial correlations utilizing depthwise separable convolutions is demonstrated by its smooth, centralized, and highly concentrated activation pattern. Overall, the graphic illustrates that while EfficientNetB0 demonstrates selective focus and VGG16 displays more dispersed activations, ResNet50 and Xception learn more organized and discriminative feature representations for the Snarasite malware family. These differences further emphasize the impact of architectural design on feature learning effectiveness in malware classification tasks. Elucidation of Model Activation Heatmaps for the *Snarasite* malware class using Grad-CAM (Figure.12). Each CNN architecture are shown in Figure 13 learns and applies discriminative features for Snarasite malware classification differently, as demonstrated by the LIME-based explanations. Activations in EfficientNet-B0 are scarce and localized, mostly limited to a small horizontal area. This shows effective use of features and less dependence on unrelated background data. The little highlighted area, however, can also indicate that secondary or subtle malware patterns are not being used to their full potential. The majority of the image exhibits highly scattered and noisy activations from ResNet-50 and VGG16. The extensive pixel contributions suggest that these models rely on a wide range of weakly informative traits, despite the center region's continued influence. Such behavior suggests less strong feature learning for this form of malware, making it more vulnerable to noise and less interpretable. Xception, on the other hand, creates distinct and continuous highlighted patches, especially in the vicinity of physically significant locations. This suggests improved separation between relevant and non-informative regions and more robust spatial feature modeling. Higher confidence and robustness in

the model's decision-making process are suggested by the explanation's clarity. All things considered, the investigation shows that models using depthwise separable convolutions (Xception) offer better interpretability and more consistent feature attribution for malware images. The results suggest a correlation between focused LIME explanations and reliable malware characterization, making Xception a more suitable architecture for explainable malware detection tasks. Elucidation of Explainable AI technique of LIME for *Snarasite* malware class (Figure.13).

**Result Analysis**

The experimental results are discussed and evaluated generally in this section, along with observations on the methods that produced the best outcomes for each of the several malware families.

**Static Analysis of Amonetize Malware Using Image Visualization and Entropy Profiling**

The Amonetize malware sample are shown in Figure 14 as a hexadecimal representation, entropy profile, and grayscale visualization. The executable's raw byte values were mapped to pixel intensities to create the grayscale image, which allowed for the visual examination of the binary's structural patterns. There are no visible code or data segments in the final image, which has a very noisy and texture-like appearance. These visual traits are frequently linked to malware that uses encryption or packing techniques to hide the underlying software logic and avoid static analysis. Shannon entropy was calculated for every row of the image representation in order to objectively evaluate how random the binary content was. For the majority of the file, the entropy values are consistently high, ranging from roughly 7.0 to 7.5 bits. A nearly uniform byte distribution is indicated by this level of entropy, which is near the theoretical maximum of 8 bits. This kind of high entropy is a sign of compressed or encrypted payloads. The existence of padding, information, or a structural barrier like a footer or unpacking stub is indicated by a discernible decrease in entropy near the conclusion of the file. A valid Portable Network Graphics (PNG) file signature and common PNG chunk IDs like IHDR and IDAT are included in the hexadecimal dump of the first 512 bytes. This finding suggests that the malware program poses as an authentic picture file. Such file format impersonation is a well-known evasion technique that is frequently used to get around simple file-type validation procedures or to hide dangerous payloads within media files that appear to be harmless. The Amonetize malware appears to use a variety of obfuscation techniques, such as encryption, packing, and file format disguising, according to the combined evidence from visual analysis, entropy profiling, and hexadecimal examination. These methods demonstrate the efficacy of image-based and entropy-driven analysis for detecting hidden hostile activity and greatly boost resilience to conventional signature-based detection strategies. Static Analysis of Amonetize Malware Using Image Visualization and Entropy Profiling (Figure.14).

**Static Analysis of Dialplatform B Malware Using Image-Based Visualization and Entropy Analysis**

The Dialplatform B malware sample's hexadecimal format, row-wise entropy profile, and grayscale visualization are shown in Figure 15. The malware binary's raw byte values were mapped to pixel intensities to create the grayscale image, which allowed for the visual evaluation of the executable's structural features. A high amount of byte-level randomness across the file is suggested by the final image's mostly noisy, grainy texture with no spatial structure. Binaries that use encryption or compression to hide their internal code and data regions are frequently linked to these visual characteristics. Shannon entropy was calculated for each row of the image in order to statistically assess the randomness shown in the visual depiction. Throughout the examined rows, the entropy values stay high and vary within a small range of 6.8–7.2 bits. This homogeneity suggests that the byte values are distributed almost randomly, which is a feature of packed or obfuscated malware. Extended low-entropy regions are absent, which implies that the binary does not include uncompressed code segments or plaintext sections that are easily identifiable. The standard PNG header and chunk identifiers, such as IHDR, tIME, and IDAT, are present in the hexadecimal dump of the first 512 bytes, indicating a valid Portable Network Graphics (PNG) file signature. This demonstrates that the malware sample poses as an authentic image file. In order to get around static file-type checks and hide harmful payloads within seemingly innocuous audiovisual content, such file format impersonation is a popular evasion technique. The hexadecimal examination, entropy analysis, and grayscale visualization taken together show that Dialplatform B uses a variety of obfuscation techniques, including as file format masquerade and high-entropy encoding. These methods demonstrate the importance of image-based and entropy-driven static analysis techniques for detecting and

characterizing hidden malware families, while also severely impeding standard signature-based detection. Static Analysis of Dialplatform B Malware Using Image-Based Visualization and Entropy Analysis (Figure.15).

**Static Analysis of Fakerean Malware Using Grayscale Visualization and Entropy Profiling**

The hexadecimal dump, row-wise entropy distribution, and grayscale visual representation of the Fakerean malware sample are shown in Figure 16. The binary file's raw byte values were mapped to pixel intensities to create the grayscale image, which allowed for the visual examination of the malware's statistical and structural features. The generated image shows a high degree of unpredictability across the binary content, with a texture that is primarily noise-like and little visible spatial organization. Shannon entropy was calculated for every image row in order to provide quantitative evidence for the visual observations. For most of the file, the entropy values stay high, averaging between 7.0 and 7.4 bits. Such high entropy values indicate the widespread usage of obfuscation techniques and are suggestive of encrypted or compressed data. Near the conclusion of the file, there is a noticeable decrease in entropy. This could be due to structural boundaries related to the embedded container format, padding areas, or file terminators. A valid Portable Network Graphics (PNG) file signature, containing common chunk IDs like IHDR, tIME, and IDAT, can be found by examining the hexadecimal dump of the first 512 bytes. This demonstrates that the Fakerean sample poses as an authentic image file. This kind of file format impersonation is a popular malware evasion technique that makes it possible to hide dangerous payloads inside media files that appear harmless and to get beyond simple static file-type validation procedures. In conclusion, the Fakerean virus uses high-entropy encoding and file format impersonating to conceal its dangerous information, according to the combined grayscale visualization, entropy analysis, and hexadecimal examination. These features highlight the usefulness of image-based and entropy-driven static analysis tools for identifying and characterizing obfuscated malware families and seriously hinder conventional signature-based detection methods. Static Analysis of Fakerean Malware Using Image-Based Visualization and Entropy Analysis (Figure.16).

**Static Analysis of Neoreklami Malware Using Image Visualization and Entropy Measurement**

The Neoreklami malware sample's hexadecimal dump, row-wise entropy profile, and grayscale image representation are shown in Figure 17. The binary's raw byte values were converted into pixel intensities to create the grayscale image, which allowed for a visual analysis of the malware's statistical and structural characteristics. There are no distinct areas that match to plaintext code or data portions in the final visualization, which has a texture that is primarily homogeneous and noise-like. These features are frequently linked to binaries that use encryption or packaging to hide internal functionality. Shannon entropy was calculated on a per-row basis across the image representation in order to further quantify the observed randomness. For most of the file, the entropy values stay high, varying between around 7.0 and 7.3 bits. This degree of entropy indicates a nearly equal distribution of byte values and points to the widespread application of obfuscation methods like encryption and compression. No lengthy low-entropy regions are seen, although small localized entropy fluctuations might be indicative of internal structural borders or metadata segments. A legitimate Portable Network Graphics (PNG) file signature and common PNG chunk IDs, such as IHDR and IDAT, are revealed by the hexadecimal dump of the first 512 bytes. This demonstrates that the Neoreklami sample poses as an authentic image file. This kind of file format impersonation is a common evasion tactic that allows harmful payloads to evade basic static file-type validation and be hidden inside innocuous-looking multimedia containers. In conclusion, the Neoreklami virus uses high-entropy encoding and file format masquerading to hide its dangerous content, according to the combined grayscale visualization, entropy profiling, and hexadecimal examination. These characteristics emphasize the significance of image-based and entropy-driven static analysis techniques for the identification and characterization of obfuscated malware families and drastically diminish the efficacy of conventional signature-based detection systems. Static Analysis of Neoreklami Malware Using Image-Based Visualization and Entropy Analysis (Figure.17).

**Static Analysis of Snarasite Malware Using Grayscale Image Representation and Entropy Analysis**

The Snarasite malware sample's hexadecimal dump, row-wise entropy distribution, and grayscale visualization are shown in Figure 18. The malware binary's raw byte values were mapped to pixel intensities to create the grayscale image, which allowed for the visual examination of internal structural features. The generated image has a texture

that is primarily noise-like and has no discernible structure, while some areas show faint horizontal banding. These patterns are frequently linked to repeating encoded blocks in the binary or minute changes in packing layers. Shannon entropy was calculated for each image row in order to statistically assess the degree of unpredictability seen in the image. A nearly uniform distribution of byte values throughout the majority of the file is indicated by the entropy values, which are constantly high and mostly fall between 7.0 and 7.4 bits. The presence of structural borders, metadata segments, or partially uncompressed sections embedded inside an otherwise obfuscated payload is suggested by the observation of multiple localized entropy dips at particular offsets. A valid Portable Network Graphics (PNG) file signature can be found in the hexadecimal dump of the first 512 bytes, as shown by chunk IDs like IHDR and IDAT and the standard PNG magic number. This demonstrates how the Snarasite malware sample poses as an authentic image file. This kind of file format impersonation is a frequently used evasion technique that enables harmful payloads to be hidden inside innocuous-looking multimedia containers and to get around simple static file-type verification procedures. In conclusion, the Snarasite malware uses high-entropy encoding and file format masquerade, with slight structural differences possibly matching to embedded control or metadata areas, according to the combined grayscale visualization, entropy profiling, and hexadecimal examination. These features show the value of image-based and entropy-driven static analysis tools for the identification and characterization of obfuscated malware families and severely impede conventional signature-based detection methods. Static Analysis of Snarasite Malware Using Image-Based Visualization and Entropy Analysis (Figure.18).

**Comparative Analysis of Malware Families Using Image-Based Visualization and Entropy Profiling**

This study conducted a comparative static analysis of five malware families Amonetize, Dialplatform B, Fakerean, Neoreklami, and Snarasite using grayscale image visualization, row-wise entropy measurement, and hexadecimal inspection. By transforming raw binary data into image representations and analyzing entropy distributions, common and distinguishing characteristics related to obfuscation strategies and file masquerading techniques were identified. Across all five malware families, the grayscale visualizations exhibit predominantly noise-like textures with minimal discernible structural patterns. Such visual homogeneity indicates extensive byte-level randomness, which is commonly associated with packing, compression, or encryption mechanisms. Although minor variations in texture and faint banding patterns are observed in some samples, particularly in Snarasite and Amonetize, no family demonstrates clearly identifiable plaintext code or data regions. These findings suggest that all analyzed malware families rely heavily on obfuscation to hinder visual and structural analysis. Entropy profiling further reinforces these observations. All samples exhibit consistently high Shannon entropy values, generally ranging between approximately 6.8 and 7.5 bits across most file offsets. This uniform high-entropy behavior indicates near-random byte distributions and supports the inference that encrypted or compressed payloads dominate the binaries. Localized entropy drops are observed in several samples, such as Fakerean and Snarasite, typically near the end of the file or at specific offsets. These drops likely correspond to padding, metadata, container boundaries, or unpacking stubs embedded within the malware. Hexadecimal analysis reveals a notable commonality across all five malware families: the presence of valid Portable Network Graphics (PNG) file signatures and standard PNG chunk identifiers, including IHDR and IDAT. This consistent use of PNG headers confirms that each malware sample masquerades as a legitimate image file. File format impersonation is a well-documented evasion strategy, enabling malware to bypass basic static file-type validation and to conceal malicious payloads within benign-looking multimedia containers. While the overall obfuscation strategies appear broadly consistent, subtle differences are observed in entropy stability and visual texture across the families. Dialplatform B exhibits slightly lower and more stable entropy values compared to the other samples, suggesting a more uniform packing approach. In contrast, Snarasite and Fakerean display localized entropy fluctuations, which may reflect additional internal structural elements or layered encoding techniques. Despite these variations, the shared characteristics across all families highlight a convergence toward high-entropy encoding combined with file masquerading as a primary means of evasion. In summary, the comparative analysis demonstrates that all five malware families employ similar obfuscation strategies characterized by high-entropy content, noise-like visual representations, and PNG file format impersonation. These findings underscore the limitations of traditional signature-based detection methods and emphasize the effectiveness of image-based and entropy-driven static analysis techniques for identifying and differentiating modern obfuscated malware families.

Comparative Summary of Entropy Characteristics and Visual Traits of Malware Families (Table 2). Table 2 highlights that all analyzed malware families exhibit high entropy values close to the theoretical maximum, confirming the widespread use of encryption or compression-based obfuscation. Despite minor differences in entropy stability and visual texture, the grayscale representations are uniformly noise-like, indicating the absence of easily identifiable plaintext code regions. These shared characteristics, combined with consistent PNG file masquerading across samples, suggest a convergence toward similar evasion strategies among modern malware families. Also, it clearly determined the most crucial region for the class Expiro using CNN heatmaps. A signature area, a zone that can be used to identify the class, has been determined by the CNNs. This section can be found in the code if we statically examine it.UPX portion (packed), especially toward the end. This area has higher entropy than the rest of the area, as can be seen by looking at the entropy. UPX section, which shows that a resource-containing section has been packed and that, even if it is still packed, the resources can be utilized to identify the infection. It also avoid all the laborious static analysis procedures because to the CNN's intuition, which pointed us in the direction of a feature unique to this class. The region immediately preceding the occurrence of high entropy is identified by the heatmaps with a particular intensity. A strange pattern can be seen by doing a hex dump and changing the value in the ASCII character; the repeating of the ff characters. For a malware study, this kind of non-random recurrence is quite interesting since it reveals a significant and distinctive signature for the malware class. Saliency maps can also be used to analyze samples that have been incorrectly classified. It create feature significance maps and extract patterns from these samples once misclassified examples have been identified. Sample-by-sample analysis of the class activation maps can be done by, for instance, comparing the sample heatmap with the cumulative CAM heatmap or taking into account all of the incorrectly categorized samples. To determine which areas or characteristics frequently result in incorrect categorization, these trends will be examined. Although these type of analyzing misclassified samples cannot be fully automated due to their reliance on the samples, classifications, and overall dataset structure, they will nonetheless aid the human malware analyst in his work.

## CONCLUSION

Using Grad-CAM, LIME, and Entropy Characteristics and Visual Traits significance for explanations, the present study applies CNN models to dynamic and online malware datasets for malware detection. This method strikes a balance between analysis depths. Applications of sophisticated AI models are extensively incorporated into many facets of our everyday lives. In order to support the current XAI techniques and provide guidance for future study in the area, this outlined the research gaps and difficulties in the field. Future research will look into how hostile individuals could misclassify malware categories by using adversarial techniques. These results can help with real-world malware remediation and assist cyber-analysts in coordinating responses to attacks by concentrating on aspects of highest value determined by explainability methodologies.

**Table 1: Malware Family Dataset**

| Malware Family | Sample images | Malware Type |
|---|---|---|
| Amonetize | 350 | Adware |
| Dialplatform B | 152 | Trojan |
| Fakerean | 306 | Trojan-Downloader |
| Neoreklami | 350 | Browser Hijacker |
| Snarasite | 350 | Trojan-Horse |

**Table 2: Comparative Summary of Entropy Characteristics and Visual Traits of Malware Families**

| Malware Family | Approximate Entropy Range (bits) | Entropy Behavior | Grayscale Visual Characteristics | Notable Observations |
|---|---|---|---|---|
| Amonetize | 7.0 – 7.5 | Consistently high with a sharp drop near file end | Highly noisy, texture-like appearance with faint horizontal banding | Indicates strong packing/encryption; entropy drop suggests padding or footer region |
| Dialplatform B | 6.8 – 7.2 | Stable and uniformly high | Granular noise pattern with minimal variation | Slightly lower and more stable entropy suggests uniform compression strategy |
| Fakerean | 7.0 – 7.4 | High entropy with pronounced drop | Dense noise with no discernible structure | Entropy drop likely corresponds to file boundary |

| | | | | |
|---|---|---|---|---|
| | | at file termination | | or embedded container metadata |
| Neoreklami | 7.0 – 7.3 | Consistently high with minor localized fluctuations | Uniform noise-like texture, visually homogeneous | Suggests extensive obfuscation with limited internal structural variation |
| Snarasite | **7.0 – 7.4** | High entropy with several localized dips | Predominantly noisy with subtle horizontal banding | Entropy dips may indicate internal metadata or layered encoding regions |

## ABSTRACT

This present study is based on awareness of realistic mathematics among middle school students. Descriptive Realistic Mathematics Education is an educational approach that emphasizes the use of real-world content, visualisation, problem-solving activities, and active student participation to enhance conceptual understanding and mathematical concepts. The main focus of this study was to find out the awareness of realistic mathematics education among middle school students, based on gender and locale. This study deals with the descriptive survey research method that was used. This study was conducted in the Shahjahanpur district in Uttar Pradesh. The sample size was 226 middle school students randomly selected. In the findings of this study, male middle school students were found to have significantly higher awareness towards Realistic Mathematics Education as compared to female middle school students. Based on the data, it shows that rural and urban middle school students are aware of realistic mathematics education, and urban male middle school students are more aware of realistic mathematics education than rural male students. Mathematical understanding supports students in daily life decision-making, in lifelong learning, and in general academic skills.

**Keywords:** Activity, Education, Mathematics, Realistic, Students.

## INTRODUCTION

The teaching of mathematics greatly influences the critical thinking, problem-solving, and logical reasoning of students. These subjects sit at the very foundation of several studies: sciences, technology, engineering, and applications in economics. Mathematical understanding supports students in daily life decision-making, in lifelong learning, and in general academic skills. As has been put forward by the *NCTM (2000),* effective mathematics teaching should allow students to understand and utilize mathematics in real-life situations, which is of utmost importance for analytical and reflective citizenship. Realistic Mathematics Education (RME) grew out of Hans Freudenthal's work in the Netherlands during the 1970s, with the emphasis that mathematics must hold some real-world relevance and correspondingly be of significance to a student's life. It engendered a rethinking of the mathematics concepts in terms of real-world problems, rather than relying on rote learning (Gravemeijer, 1994). The RME approach has been recently accepted in the Indian classroom, supported by a framework established by the National Education Policy 2020, which advocates for experiential learning. RME is still in its infancy in India, but much interest is being generated concerning its potential for transforming mathematics education through pilot projects and research works (NCERT, 2021). The Value of Realistic Mathematics for Students, particularly in the Middle School. In middle school, abstract thought begins to replace the straightforward operations of basic mathematics. In this aim, much is gained through the RME method, as strong contextualization makes those abstract ideas more understandable. Research indicates that RME decreases math anxiety, increases involvement, and deepens conceptual understanding (Van den Heuvel-Panhuizen, 2001). RME renders it easier and more interesting for students' subjects that are considered quite difficult, whereas students often find it tough to grasp the abstractions in conventional mathematics instruction. Realistic Mathematics Knowledge in India and in the Other Parts of the World. For the application and experimentation of RME, international fame has been accorded for the successful enhancement of students' mathematical ability in countries from Indonesia to the USA and the Netherlands (Bakman, 2011). Various studies worldwide have proposed RME as a road to developing higher-order thinking skills and improving mathematical comprehension. In India, however, RME is known mainly among academic circles and experimental projects. Some educationalists and progressive institutions are advocating for its rooting, but RME has not yet gained a fair amount of currency in most Indian middle school circles (Singh, and Kumar, 2022). This gulf must be bridged in order to establish a successful and viable mathematics education in India.

## LITERATURE REVIEWS

Akosah, Arthur and Obeng (2025) conducted a study entitled "*Optimizing High School Mathematics Achievement through the Lens of Realistic Mathematics Education*". Focusing on investigating the mediating role of teacher self-efficacy in the relationship between teaching quality and students' mathematics achievement, using Realistic Mathematics Education and Self-Determination Theory as frameworks. The population consisted of twelve thousand nine hundred and eighty (12,980) teachers across eight regions in Ghana: Ashanti, Bono East, Central, Eastern, Greater Accra, Northern, Oti, and Volta. The researcher used five hundred and seven (507) junior high school mathematics teachers as the sample. The researcher used a stratified purposive sampling technique for data collection. A correlational cross-sectional survey design was employed. Structural Equation Modeling was used to test the hypotheses. After analyzing the data, the researcher found that teaching quality positively affects students' mathematics achievement, particularly when teaching is grounded in RME principles. The unstandardized estimate ($\beta = .194$, $p < .001$) indicates a strong positive relationship. The study underscores the importance of considering both instructional and psychological factors in efforts to improve mathematics education. Sushanti *et al*. (2025) in their research paper entitled *"Enhancing Problem-Solving Skill in Elementary Students Through Realistic Mathematics Education."*Focusing on problem-solving skill through Realistic Mathematics Education. The population of the study is derived from elementary students and classes in different international settings, as evidenced in previous empirical research, while the sources of the data are peer-reviewed articles, documented case studies, and educational reports on the implementation of RME.

The study employed a qualitative research methodology, specifically a systematic literature review and case study approach, to synthesize patterns, themes, and results of RME implementation. The findings have consistently shown that RME has a significant positive impact on students' mathematical problem-solving skills, understanding, engagement, confidence, critical thinking, and creativity by relating abstract mathematical ideas to real-world situations and promoting collaborative and student-centered learning. The review pointed out the quantitative and qualitative results. Some challenges in the implementation of RME were also noted, including inadequate teacher preparation, curriculum incongruence, lack of instructional materials, time constraints, and resistance to instructional change. The conclusion of the study strongly emphasized the transformative power of RME in elementary mathematics education. Martínez-Meléndez, K. *et al*. (2025),in their research paper entitled*"Realistic and non-realistic considerations in mathematical word problems with Mexican eighth-grade students," focus* on how students use real-life understanding while solving mathematical word problems, as earlier studies have shown that students often apply formulas without considering real-world situations. This qualitative exploratory research was conducted on a population of second-year middle school students in Mexico. A sample of 97 students aged was selected using a non-probability sampling technique from two secondary schools. The researchers used twelve-word problems related to proportionality, false proportionality, division with remainder, and arithmetic operations, along with an open-ended questionnaire to collect data. Students' answers were analyzed and classified into realistic, unrealistic, technical error, other responses, no response, and proposal categories. The results showed that most students gave unrealistic answers in proportionality and false proportionality problems due to linear thinking, while better realistic understanding was seen in division with remainder and arithmetic operation problems. Students who used their personal experiences and everyday knowledge were more successful in giving realistic answers. The study concludes that mathematics textbooks include real-life contexts, but many students still fail to connect mathematics with reality, indicating a need for teaching methods that encourage students to think realistically while solving word problems. In a study conducted by Muhammad *et al*. (2025)on the development of web-based learning media with a realistic mathematics education approach to increase student self-determination.

Their study focuses on the development of web-based learning through RME. The results showed that the developed Google Sites-based learning media was highly valid and feasible, with expert validation scores above 85%, and students gave positive responses with an average feasibility score above 87%. Students' self-determination in mathematics improved significantly after using the media, with noticeable increases in self-awareness, perceived choice, intrinsic motivation, and extrinsic motivation. The study concluded that integrating RME with web-based learning media effectively enhances students' motivation and autonomy in learning mathematics and recommended further research with larger samples and different mathematical topics. Samková, L.; Rokos, L. and Vízek, L.(2025) in their research paper entitled*"Teachers' awareness of the existence of analogies in the conceptual structure of mathematics and biology."* focusing on teachers' awareness. The population of the study consisted of preservice teachers in the Czech Republic, and the sample included 57 participants, out of whom 47 were prospective primary school teachers and 10 were prospective secondary school teachers specializing in mathematics and biology. The sampling technique used was purposive sampling, as participants were selected from final-year teacher education programs without prior STEM integration experience. The study followed a qualitative research methodology, using cartoon-based worksheets and concept cartoons as data collection tools to explore participants' reasoning and awareness of analogies. Data were analyzed through qualitative coding and category formation. The results showed that most preservice teachers were able to solve problems within individual subjects but struggled to recognize deeper conceptual analogies between mathematics and biology. A small number of participants demonstrated interdisciplinary or transdisciplinary understanding of analogies. The study concluded that although analogical structures exist clearly between mathematics and biology, preservice teachers need explicit training and instructional support to recognize and apply these analogies effectively for integrated STEM teaching. Oktaviani, A.N., *et al*. (2025) in their research paper entitled *"The Influence of the Realistic Mathematics Education Approach Assisted by the PLSV Board on the Mathematical Literacy of Junior High School Students."* The study examined the effect of the Realistic Mathematics Education (RME) approach assisted by the PLSV Board on the mathematical literacy ability of junior high school students.

The population of the study consisted of Grade VIII students of a junior high school in Tangerang City, Indonesia. The researcher used a cluster random sampling technique; a total sample of 62 students was selected, where 30 students were placed in the experimental group and 32 students in the control group. The research followed a quasi-experimental method with a randomized post-test-only control design. The experimental group was taught using the RME approach assisted by the PLSV Board, while the control group was taught using the scientific approach. Data were collected using a mathematical literacy test consisting of seven descriptive questions based on the indicators of formulating, employing, and interpreting mathematical problems. The results showed that the mean score of the experimental group (54.25) was higher than that of the control group (36.71). Statistical analysis using an independent sample t-test revealed a significant difference between the two groups at the 0.05 level, indicating that the RME approach had a positive effect on students' mathematical literacy. The study concluded that learning through the RME approach assisted by the PLSV Board is more effective than the scientific approach in improving students' mathematical literacy skills. Altiner (2024) conducted a research paper entitled "*Exploring measurement estimation strategies through concept cartoons designed with Realistic Mathematics Education*". which dwells on the interface between concept cartoons and Realistic Mathematics Education (RME) for better student outcomes. The methods applied in the study were a qualitative case study design, purposeful sampling of fourth-grade students, use of RME-supported concept cartoons for data collection, and descriptive analysis of the collected data to study students' measurement estimation strategies. The study involved 46 fourth-grade students from a primary school. The study's result sheds light on the students' diverse strategies for measurement estimation, how context affects their choice, and the absence of gender differences in using these strategies. Such knowledge can be used as a perspective in teaching methodology in mathematics. Thus, the study provides valuable insights into measurement estimation strategies of fourth-grade students and points out a dire need for instructional practices and curriculum development that enhance students' mathematical reasoning and problem-solving skills. The study conducted by Irawan *et al*.(2024) in their research paper on the application of the Indonesian Realistic Mathematics Education Approach to improve student learning outcomes.

Their study focuses on the effectiveness of implementing the Indonesian Realistic Mathematics Education Approach in improving student learning outcomes in mathematics. It seeks to address common problems in mathematics education, such as low student interest and difficulty understanding abstract concepts. The researcher found that the percentage of students completing the evaluation test increased across cycles: pre-cycle; 33.33% completion, Cycle I;66.67%completion, and Cycle II; 93.33% completion. Observations showed increased student engagement, rising from 48.28% in cycle I to 73.57% in cycle II, which shows that the PMRI approach improved mathematics learning outcomes for fifth-grade students. Ramadhanta *et al*. (2024) conducted a study on enhancing mathematical creativity thinking ability: Experimentation with Realistic Mathematics Education by embedding ice-breaking in junior high school. Their study mainly improved mathematical creative thinking ability among students taught with Realistic Mathematics Education by embedding ice-breaking. The research findings indicate that integrating ice-breaking activities into RME facilitates enhanced MCTA. The study recommends that teachers implement RME to enhance students' MCTA, transforming initially passive students as learning shifts from teacher-centered to more active. Melabari and Ismail (2023) In their research paper, "*The effect of Realistic mathematics education on Undergraduate Freshmen Students' Mathematical Competencies*". aims to evaluate the effect of RME on undergraduate freshmen students' mathematical competencies. This study sample was selected from a college of business administration in a private university in Jeddah, Saudi Arabia. There were four Math 099 sections. Each section contains 19 to 24 students. Therefore, the treatment group consisted of 39 students from 2 sections, and the control group consisted of 44 students from the other 2 sections. This study uses a quasi-experimental design with three components: a pre-test, a post-test, and an RME-based pre-calculus course. The results illustrated that RME has a significant positive effect on students' mathematical competencies. This study confirms the recommendation suggested by for Saudi universities to adopt RME-based courses in teaching freshmen students or a preparatory year program student, to improve university mathematics curriculum and textbooks based on the theory of RME, and to provide sufficient training for in-service and pre-service mathematics teachers to apply the Introduction of RME in teaching mathematics for pre-college levels of education.

Mahmoud and Alaraj stated that to meet the current difficulties, educational curricula and instructional methods need to be revised. Bayarak and Aslenci (2022) In their research paper "*Realistic Mathematics Education: A Bibliometric Analysis*". focusing on conducting a bibliometric analysis of published articles related to Realistic Mathematics Education (RME) and analysing trends, key contributors, and influential publications in the field of RME research. All articles published on RME are considered as a population, and the study focused on articles indexed in the Scopus database. The study's sample comprised 1190 articles published between 1986 and 2021. The Scopus database was searched using the keywords: "realistic mathematics education", "realistic mathematics education", "realistic maths", or "realistic mathematical education". Only journal articles in "Social Science" and "Mathematics" subject areas were included, and Editorial materials, conference proceedings, books, book chapters, letters, notes, and review articles were excluded. The study employed a descriptive research model to identify the bibliometric properties of the journal. Mathematical and statistical methods were used to analyse characteristics of scientific publications. The data was analysed using the R-Studio program, specifically the biblioshiny web interface. After analysis the researcher found that interest in RME research has increased since 2016, and the USA, Indonesia, and the Netherlands were the most productive countries. Altaylar and Kajak (2021) In their research paper, "*The Effect of Realistic Mathematics Education on Sixth-Grade Students'Statistical Thinking," focus on* the effectiveness of the Realistic Mathematics Education (RME) approach on sixth-grade students' statistical thinking. A quasi-experimental pretest-post-test design was implemented using Mooney's framework, which outlines four thinking levels across statistical processes. The experimental group learned the data handling unit through the RME approach, while the control group received traditional textbook-based instruction.

The study involved 49 sixth-grade students, with 25 in the experimental group (9 males, 16 females) and 24 in the control group (10 males, 14 females). The data collection instrument was a statistical thinking test consisting of seven open-ended questions, some of which were adapted from previous studies. The data collected from the statistical thinking test (both pretest and post-test) were analyzed using Mooney's statistical thinking framework. The study found that both the RME approach and traditional textbook lessons were effective in developing students' statistical thinking. However, detailed analyses revealed that the RME approach was more beneficial in increasing students' statistical thinking levels. Doli and Armiati (2020) In their journal "*Development of Mathematics Learning Tools Based on Realistic Mathematics Education for Vocational High School Students*" emphasize the development of mathematics learning tools. The research was conducted in the mathematics department at the University Negeri Padang, Padang, Indonesia. The teacher must design a mathematics learning strategy in the form of a mathematics learning tool in the form of a learning implementation plan and student worksheet based on realistic mathematics education. This type of research used is development research, and the development model is the plump model. The subjects of this study were students of the state vocational high school 4 RambahKab. The research belongs to descriptive qualitative data, and the data analysis technique used is descriptive. To analyze the results of interviews, observations, and questionnaire responses of students. The study found that the development of mathematics learning tools based on realistic mathematics education was valid and practical and used to increase students' interest in learning mathematics in vocational high school, especially office management expertise programs.

## OBJECTIVES OF THE STUDY

The objectives for the study are as follows:

1. To find out the awareness of realistic mathematics education among middle school students.
2. To find out the awareness of Realistic Mathematics Education among middle school students based on gender.
3. To find out the awareness of Realistic Mathematics Education among middle school students regarding locale.

**Hypothesis of the study**

**$H_{01}$:** There is no significant difference in mean scores of awareness towards Realistic Mathematics Education between male and female middle school students.

**$H_{02}$:** There is no significant difference in mean scores of awareness towards Realistic Mathematics Education between rural and urban middle school students.
**$H_{03}$:** There is no significant difference in mean scores of awareness towards realistic mathematics education between rural male and rural female middle school students.
**$H_{04}$:** There is no significant difference in mean scores of awareness towards Realistic Mathematics Education between rural male and urban male middle school students.
**Table 5, $H_{05}$:** There is no significant difference in mean scores of awareness towards Realistic Mathematics Education between urban male and urban female middle school students.
**H06:** There is no significant difference in mean scores of awareness towards realistic mathematics education between rural female and urban female middle school students.

## METHODOLOGY OF THE STUDY

**Method of the study:** The present study was quantitative research. In the present study, the descriptive survey research method was used.

**Sample selection:** The sample for the present study consisted of 121 male middle school students and 105 female middle school students from the Shahjahanpur district of Uttar Pradesh. The random sample techniques used for the study were selected from male and female middle school students in the Shahjahanpur district of Uttar Pradesh.

**Tool of the Study:** The tool of this study was Awareness of Realistic Mathematics Education for Middle School Students, developed by the researcher with the help of a supervisor.

## RESULT AND DISCUSSION

In this study, both descriptive and inferential statistical techniques were used to analyze data. Descriptive statistics techniques are the mean and standard deviation, and inferential statistics techniques are the "t-test".

**Table 1, $H_{01}$:** There is no significant difference in mean scores of Awareness towards Realistic Mathematics Education between Male and Female Middle School Students.

**Interpretation:** From Table 1, it indicates that the mean scores of awareness towards realistic mathematics education between rural and urban middle school students differ significantly. The null hypothesis is that there is no significant difference in mean scores of awareness towards realistic mathematics education between male and female middle school students. Further, the mean scores of awareness towards realistic mathematics education of male middle school students are 102.12, which is significantly higher than those of female middle school students, whose mean scores of awareness towards realistic mathematics educationare97.31. It is found that with df = 224, the critical ratio (table value) is 1.97 at the 0.05 level of significance. The t-value (calculated value) is 2.76, which is greater than the critical ratio at the 0.05 level of significance. So, the test statistic 't' is significant at the 0.05 level. Hence, the null hypothesis is "rejected", and it is significant. It may therefore be said that male middle school students were found to have significantly higher awareness towards Realistic Mathematics Education as compared to female middle school students.

**Table 2, $H_{02}$:** There is no significant difference in mean scores of Awareness towards Realistic Mathematics Education between Rural and Urban Middle School Students.

**Interpretation:** From Table 2, it can be seen that the Critical Ratio (Table Value) is 1.98, which is not significant at the 0.05 level with df=224.It indicates that the mean scores of awareness towards realistic mathematics education between rural and urban middle school students don't differ significantly. The null hypothesis is that there is no

significant difference in mean scores of awareness towards realistic mathematics education between rural and urban middle school students. Further, the mean scores of awareness towards realistic mathematics education for rural middle school students and urban middle school students are 101.12 and 98.12, respectively, which are almost similar to each other for rural and urban middle school students. It is found that with df = 224, the critical ratio (table value) is 1.97 at the 0.05 level of significance. The t-value (calculated value) is 1.74, which is less than the critical ratio at the 0.05 level of significance. So, the test statistic 't' is not significant at the 0.05 level. Hence, the null hypothesis is "not rejected". Therefore, it is seen that both rural and urban middle school students are aware of realistic mathematics education. So, the null hypothesis is not rejected, i.e., there is no significant difference in mean scores of awareness towards realistic mathematics education between rural and urban middle school students.

**Table 3, $H_{03}$:** There is no significant difference in mean scores of Awareness towards Realistic Mathematics Education between Rural Male and Rural Female Middle School Students.

**Interpretation:** From Table 3, It indicates that the mean scores of awareness towards realistic mathematics education between rural male and rural female middle school students don't differ significantly. The null hypothesis is that there is no significant difference in mean scores of awareness towards Realistic Mathematics Education between rural male and rural female middle school students. Further, the mean scores of awareness towards realistic mathematics education for rural male middle school students and rural female middle school students are 102.95and 99.41, respectively, which are almost similar to each other for rural male and rural female middle school students. It is found that with df = 133, the critical ratio (table value) is 1.98 at the 0.05 level of significance. The t-value (calculated value) is 1.40, which is less than the critical ratio at the 0.05 level of significance. So, the test statistic 't' is not significant at the 0.05 level. Hence, the null hypothesis is "not rejected". Therefore, it is seen that both rural male and rural female middle school students are aware of Realistic Mathematics Education. So, the null hypothesis is not rejected, i.e., there is no significant difference in mean scores of awareness towards realistic mathematics education between rural male and rural female middle school students.

**Table 4, $H_{04}$:** There is no significant difference in mean scores of Awareness towards Realistic Mathematics Education between Rural Male and Urban Male Middle School Students.

**Interpretation:** From table-4, It indicates that the mean scores of Awareness towards Realistic Mathematics Education between Rural Male and Urban Male Middle School Students don't differ significantly. The null hypothesis is that there is no significant difference in mean scores of Awareness towards Realistic Mathematics Education between Rural Male and Urban Male Middle School Students. Further, the mean scores of Awareness towards Realistic Mathematics Education for rural Male middle school students are 102.95 and urban male middle school students are 101.25, respectively, which are almost similar to each other for Rural Male and Urban Male Middle School Students. It is found that with df = 119, the critical ratio (table value) is 1.98 at the 0.05 level of significance. The t-value (calculated value) is 0.70, which is less than the critical ratio at the 0.05 level of significance. So, the test statistic 't' is not significant at the 0.05 level. Hence, the null hypothesis is "not rejected", Therefore, it is seen that both Rural Male and Urban Male Middle School Students are aware of Realistic Mathematics Education. So, the null hypothesis is not rejected, i.e. there is no significant difference in mean scores of Awareness towards Realistic Mathematics Education between Rural Male and Urban Male Middle School Students.

**Table 5, $H_{05}$:** There is no significant difference in mean scores of Awareness towards Realistic Mathematics Education between Urban Male and Urban Female Middle School Students.

**Interpretation:** From table-5, It indicates that the mean scores of Awareness towards Realistic Mathematics Education between Urban Male and Urban Female Middle School Students differ significantly. The null hypothesis is that there is no significant difference in mean scores of Awareness towards Realistic Mathematics Education between Urban Male and Urban Female Middle School Students. Further, the mean scores of Awareness towards Realistic Mathematics Education of Urban male Middle School Students are 101.25, which is significantly higher than those of

Urban female Middle School Students, whose mean scores of Awareness towards Realistic Mathematics Educationare93.11. It is found that with df =89, the critical ratio (table value) is 1.99 at the 0.05 level of significance. The t-value (calculated value) is 3.84, which is greater than the critical ratio at the 0.05 level of significance. So, the test statistic 't' is significant at the 0.05 level. Hence, the null hypothesis is "rejected". It may therefore be said that Urban Male middle school students were found to have significantly higher awareness towards Realistic Mathematics Education as compared to Urban female Middle School Students.

**Table 6, $H_{06}$:** There is no significant difference in mean scores of Awareness towards Realistic Mathematics Education between Rural Female and Urban Female Middle School Students.

**Interpretation:** From table-6, It indicates that the mean scores of Awareness towards Realistic Mathematics Education between Rural Female and Urban Female Middle School Students differ significantly. The null hypothesis is that there is no significant difference in mean scores of Awareness towards Realistic Mathematics Education between Rural Female and Urban Female Middle School Students. Further, the mean scores of Awareness towards Realistic Mathematics Education of Urban Female Middle School Students are 102.12, which is significantly higher than those of Urban female Middle School Students, whose mean scores of Awareness towards Realistic Mathematics Education are 113.88. It is found that with df = 103, the critical ratio (table value) is 1.98 at the 0.05 level of significance. The t-value (calculated value) is 2.76, which is greater than the critical ratio at the 0.05 level of significance. So, the test statistic 't' is significant at the 0.05 level. Hence, the null hypothesis is "rejected". It may therefore be said that Rural Female middle school students were found to have significantly higher awareness towards Realistic Mathematics Education as compared to Urban female Middle School Students.

## DISCUSSION

The findings of the present study are consistent with several previous studies on Realistic Mathematics Education. The overall reasonable level of awareness among middle school students reflects the growing global attention toward RME, as highlighted in the bibliometric analysis by Bayrak and SeherAslanci (2022), who reported a significant increase in RME research worldwide, particularly after 2016.The significant gender difference found in the present study, where male students showed higher awareness than female students, partially aligns with the findings of Altiner (2024). The study suggested that classroom interaction patterns and strategy use may vary among students, which could explain differences in awareness levels observed in the current research. As well as Ramadhanta *et al*. (2024) found that RME enhances active participation and creative thinking, particularly when learning shifts from teacher-centred to student-centred methods. If classroom participation opportunities differ by gender, it may influence awareness levels, as seen in this study. The finding that there is no significant difference between rural and urban students in overall awareness is noteworthy and suggests that exposure to contextual mathematics may not be limited by geographical location. This aligns with the work of Irawan *et al*. (2024). The significant difference between urban male and urban female students, and between rural female and urban female students, suggests that gender-based disparities are more visible in urban contexts. This observation can be connected to the findings of Samková *et al*. (2025). The present findings support the broader literature that emphasises the importance of contextual learning, active participation, and teacher guidance in strengthening students' mathematical understanding. While many prior studies have focused on achievement, creativity, and literacy outcomes, the current study contributes by highlighting awareness as a foundational factor for successful RME implementation. The results tell us that we need to do more to teach students about Realistic Mathematics Education so that all students can learn math in a fair and meaningful way**.**

## CONCLUSION

The Present study conducted to the analyze the level of awareness level of awareness towards Realistic Mathematics Education among middle school students. On the basis of statistical analysis and interpretation of the collected data

overall level of awareness towards Realistic Mathematics Education among middle school students is satisfactory, on average. A small percentage of students fall under the "Not Aware" category. The majority of students fall under the categories of Moderately Aware, which shows positive exposure to contextual and activity-based mathematics learning. Male students show comparatively higher awareness scores than female students according to the given data. Rural students show slightly higher awareness than urban students, though the difference is not very large. The results tell us that we need to do more to teach students about Realistic Mathematics Education so that all students can learn math in a fair and meaningful way.

## ABSTRACT

Diabetes mellitus closely resembles the ayurvedic disease process of prameha and it has turned into a chronic disorder of metabolism that needs safe and complementary treatment measures besides the administration of conventional drugs. It was a critical review of scientific evidence existing on the use of methi or fenugreek (*Trigonella foenum-graecum*) as a nutraceutical supplement in the management of the many facets of prameha. The three main bioactive components of fenugreek are the main mechanism of its action. All these bioactive components act separately to resolve the central pathophysiological problems of type 2 diabetes mellitus. First, galactomannan is a water-soluble dietary fiber that is capable of prolonging the time taken by the stomach to empty and flatten the post prandial glucose (ppg) response curve. Second, 4-hydroxyisoleucine (4-oi) is an uncommon non-proteinic amino acid mostly found in the fenugreek seeds and functions an insulin secretagogue that enhances periphery insulin sensitivity. Lastly, there is a lipid lowering effect or medohara of fenugreek caused by steroidal saponins and trigonelline. The clinical trials have consistently shown improvements in glycemic control with the daily supplementation of 10g to 25g of ground fenugreek seeds by lowering the levels of fasting plasma glucose and also by a small but statistically significant decrease of glycated hemoglobin (HbA1C) (0.5 percent to 1 percent after 8 to 12 weeks). Although, clinical trials have demonstrated that this supplementation also led to considerable decreases in total levels of cholesterol and triglycerides that

reduced diabetic dyslipidemia. In general, as the most prevalent side effects are mild gastrointestinal disorders, which are not harmful but may be common with many other medications, methi offers a scientifically justified, cost-efficient, and safe way of helping in the long-term management of prameha. Further studies are to be done to create and study extracts of methi that are standardized to the degree of active components (in this case 4-oi), to offer some kind of uniformity in efficacy.

**Keywords:** Fenugreek (*Trigonella foenum-graecum*), *Prameha* (Diabetes Mellitus),4-Hydroxyisoleucine (4-OH Ile), Glycemic Control, Dyslipidemia (Lipid Profile/*Medohara*), Nutraceutical.

## INTRODUCTION

**Background of *prameha* and diabetes mellitus**

Diabetes mellitus (DM) is a persistent metabolic disease that is marked by a constant increase in blood glucose levels caused by deficiencies in the insulin secretion, insulin action, or both, is a universal epidemic. This is similar to the Ayurveda system of medicine in ancient Indian tradition and is known as *Prameha*, which is a condition characterized by *Kleda* (excess moisture/fluidity) and Mutra Vriddhi (polyuria). The most severe type is expected to be *Madhumeha* (literally 'honey urine'), and it directly relates to DM. The existing pharmacological treatment, although effective, usually bears risks of adverse effects and cannot cover all the metabolic derangements, which requires the development of effective, low-cost, and safe complementary interventions[1].

**Methi as a traditional remedy**

*Methi* (Fenugreek, *Trigonella foenum-graecum*) is a herb that is used as spice and traditional medicine widely in South Asia and Middle East annually. Both Ayurvedic and Unani medicine have traditionally suggested it as an Ayurvedic *Madhumehahara* (anti diabetic) and *Medohara*(lipid lowering/anti-obesity) agent[2]. It is a good candidate of a nutraceutical intervention in the treatment of *Prameha* due to its easy accessibility, affordability, and effective safety profile.Dyspnoia Fenugreek seeds are pebbly hard, compact, rhomboidal bodies that are about 3-5mm long and about 2mm thick. They are normally light brown to yellow in color. The seeds have a characteristic distinctive smell of spicy aroma and bitter, mucilaginous taste. Fenugreek seeds are nutritionally balanced with carbohydrates of about 45-60 percent with almost a third of it being soluble fiber and the rest insoluble fiber. They are also 20-30 percent protein, but contain essential amino acids like lysine and tryptophan, but contain volatile oils in small amounts. [3,4,5]

**Fenugreek nutritional value per 100 g -** (Table 1)

**Percent daily value of selected nutrients-**(Table 2)

## REVIEW OBJECTIVE

The present review critically analyzes and synthesizes the available scientific data on *Methi*(*Trigonella foenum-graecum*), especially in relation to its bioactive constituents, mechanism of action and clinical efficacy. This is aimed at investigating its feasibility as a nutraceutical intervention towards improving glycemic control and lipid parameters in the subjects of *Prameha*(Type 2 Diabetes Mellitus).

## METHODS

**Search strategy and data sources**

The literature search has been carried out in big electronic databases, such as PubMed, Cochrane, Science Direct, and Google Scholar. The following major keywords and combinations were used to conduct the search: "Fenugreek," "Methi," "*Trigonella foenum-graecum*," "Diabetes Mellitus," "*Prameha*," "Nutraceutical," "Hypoglycemic," and "Anti-

diabetic." The articles that were included in the search were published mostly in the period of 2000-24 so that the current clinical information could be considered.

**Selection criteria**

**Inclusion criteria for the review were**

1. Original research articles and systematic reviews/meta-analyses that are concerned with the effect of Fenugreek (seeds, powder or extract) in human subjects (adults) with DM or pre-diabetes (analogous to Prameha).
2. Studies reporting clinical outcomes related to glycemic indices (FPG, PPG, HBA1C or lipid profile (TC, TG, HDL-C, LDL-C).
3. Articles published in the English language.

The literature on other combinations of herbs, animal models alone, or lacking quantifiable clinical evidence were excused.

**Data synthesis and analysis**

The qualitative synthesis and critical analysis of the data on the chosen articles were conducted. The review aimed at extracting homogenous results about dose-response relationship, the key bioactive molecules that are involved and their affirmed mechanisms of action to provide scientifically reasonable basis of nutraceutical role of *Methi* in *Prameha* management.

## RESULTS

**Bioactive Components and Mechanisms of Action**

Fenugreek's therapeutic efficacy is attributed to a synergistic combination of unique chemical constituents[6]:

**Soluble Dietary Fiber**

The soluble dietary fibre (SDF), predominantly Galactomannan one of the types of heteropolysaccharides which constitute almost half of the seed dry weight is also abundant in the seeds. The fiber creates a viscous material in the GI tract which slows the gastric emptying and acts as a physical barrier to the fast uptake of glucose, hence flattening the PPG curve[7].

**4-Hydroxyisoleucine (4-OH Ile)**

The uncommon amino acid, 4-OHIle, is believed to be the most active antidiabetic principle. It works primarily by incretion of the pancreatic b-cells for glucose-dependent insulin release [8]. It also has been demonstrated to increase insulin sensitive in peripheral tissues, which directly targets the underlying pathophysiology of Type 2 DM (Insulin Resistance in Prameha).

**Saponins and alkaloids**

Saponins are steroidal (e.g., diosgenin) and alkaloid (e.g., Trigonelline) and both create hypoglycemic and hypolipidemic effects. Trigonelline was also found to stimulate the control of enzymes that participate in glucose metabolism in the cells and the saponins also disrupt the absorption of cholesterol, which helps in controlling the condition of diabetic dyslipidemia[9].

**Clinical efficacy on glycemic control: (Table 3)**

A study involving 10g/dayof Fenugreek seed powder in T2DM patients noted a significant drop in FPG and HBA1C after 6 months[10] Another long-term study (3 years) in pre-diabetic subjects showed that 10 g/day of Fenugreek powder significantly reduced the cumulative incidence of developing Type 2 DM, highlighting its preventative potential in *Prameha*[12].

**Clinical efficacy on lipid profile**

*Methi* has also been shown to have the *Medohara* (lipid-lowering) effect which has been clinically supported, and has been shown to be found in meta-analyses as a treatment in the management of diabetic dyslipidemia, a significant precipitating factor in the development of macrovascular complications in Prameha:

**TG and TC:** A decrease in mean TG (14%) and in mean total cholesterol 21% with 10 g/day, was reported among the different trials.

**HDL-C:** Although there is also a trend for LDL-C reduction, some significantly have an HDL-C increase, which elevates the atherogenic index counteraction [11].

## DISCUSSION

**Methi as a multi-modal nutraceutical in prameha**

This present review has positive results that can help in substantiating the traditional claim of *Methi*(*Trigonella foenum-graecum*) in the treatment of *Prameha*. *Prameha* has been described according to Ayurveda as the systemic metabolic disorder with vitiated *Kapha dosha*, deranged *Meda dhatu*, deposited *kleda* (due to the excesses of the nutrients), impaired Agni and *Srotorodh*. Its stage, *Madhumeha*, is a similar stage to Type 2 Diabetes Mellitus (T2DM). *Methi* introduces a Holistic Window of Medicinal profile of Lens in conformity to the classical Ayurveda Aspects and as an extent to bio-medical Aspects. Fenugreek as an amalgamate nutraceutical should be considered in the context of multi-modality of multiple pathophysiological mediators that are involved in the course of T2DM/*Prameha*[6]. Unlike single-target drugs, it also controls glucose absorption, insulin secretion, insulin receptor and lipid metabolism simultaneously. Such general metabolic normalisation is analogous to the idea of restoration of balance in the body as opposed to Ayurveda which aims to put specific symptoms into remission. The water-soluble portion of dietary fiber especially galactomannan plays a significant physiologic role in glycemia regulation. On ingestion, it solidifies in the stomach due to the type of composition that prevents emptying of the stomach and decelerates the uptake of carbohydrates. This also adds significant flattening of the postprandial glucose curve [7]. According to Ayurveda, this exercise would be linked to stabilization of deranged *Jatharagni*, and inhibition of production of Ama (a final cause of metabolic impediment, *Srotorodha*). The effects of dampening sharp glycemic fluctuations and reducing the stress on the functionality of pancreatic beta cells in the metabolic defense of fenugreek are attributable. The other major bioactive is 4-hydroxyisoleucine that has glucose-dependent insulinotropic activity.

It triggers the release of insulin glucose-dependently to minimize the chances of hypoglycemia occurrence [8]. It also increases the peripheral insulin sensitivity the major malfunction of insulin resistance in T2DM [8]. Ayurvedic theorizing It can be postulated in Ayurvedic terms, that *Dhatvagni* can be associated with the correction of the malfunction at *Dhatvagni* level, particularly of Meda dhatu, and remedy of the pathology of the disease by *Kapha-Meda vriddhi*. Fenugreek has curative effects at various metabolic levels because of its action on the kinetics of insulin and insulin tissue sensitivity. This therapeutic value is also enhanced by the presence of hypolipidemic properties of fenugreek. Steroidal saponins and triglycerides decrease serum total cholesterol and triglycerides [6]. The outcomes of clinical trials and meta-analysis indicate improved lipids especially total cholesterol (TC) and triglyceride level (TG), especially with a 10-25 g/day supplementation [11,13]. Because dyslipidemia is among the major causes of macrovascular complications in diabetes, this *Medohara* effect appears to be a significant preventive activity. The improvement in lipid profile may be attributed to normalization of aggravated *meda dhatu* and obstruction of *srotas* resulting to reduction of the risk of cardiovascular disorders in the future. There is clinical support of the enhancement of glycemic indices by the use of fenugreek supplements. Fasting plasma glucose (FPG) and postprandial glucose (PPG) reductions have been reported and a moderate yet clinically significant reduction in HbA1c (0.5-1.0% over 8-12 weeks) has been reported [10,13]. The dosage range of 10-25 g per day of powdered seed or the equivalent health-wise in extract is said to be very successful [10,13]. These results provide strong evidence to support its use as an addon in the management of chronic glycemia.

**Integrative relevance and long-term applicability**

It is also safe to consume over extended periods, and this is one of the other reasons why fenugreek is so great. Daily dietary intake of it does not require much lifestyle change as, as a dietary everyday spice, it is regularly consumed. This has been found to enhance patient compliance as compared to the use of chemicals. Even after cooking it has been reported that there are traces of its hypoglycemic effect and it can be consumed as a food [2]. Fenugreek should be viewed as complementary to conventional therapy rather than alternative therapy according to the integrative medicine perspective. Due to its multi-targeted metabolic action, it will potentially work synergistically with the oral hypoglycemic agonists (OHAs) and provide superior glycemic control without having to use an increased pharmacological dose. With this fact, however, it is not surprising at all when we realize that the management of Prameha according to Ayurveda requires simultaneous approach towards Ahara and Vihara as well as towards Aushadha. It is also an impressive aspect that it can be used preventively. A prediabetic long-term intervention trial observed that the overt T2DM development was reduced significantly by the daily treatment of fenugreek [12]. It shows one has a role as an early metabolic correcting agent, like in the case of persons of *Kapha-pradhana Prameha*. Earlier intervention of the individuals experiencing compromised glucose tolerance can delay the onset of the disease and reduce its effects. Safety plays an important role in the management of chronic diseases. Fenugreek is described to be safe in all the available clinical literature where the adverse effect is mostly of mild gastrointestinal symptoms such as bloating and flatulence [13]. Such effects tend to be self-limiting and of its fiber content. Most importantly, human trials fail to identify any clinically significant organs toxicity manifestations that would prove its safety as a long-term usage.

## LIMITATIONS AND FUTURE DIRECTIONS

Even though there is positive news on the variable phytochemical composition, it is also a demerit. Seed cultivar, geographical origin and processing techniques have a varied potential to affect the contents of bioactive molecules in particular, 4-hydroxyisoleucine [8]. The variability in this case has the potential to affect the uniformity of the treatment. Although extracts have been utilized in the 200 studies and clinical trials reported, future investigations should tend towards standardization of the extracts that determine the important bioactive factors. Prolonged, multicentric RCTs involving long-term follow-up are needed to investigate the long-term cardiovascular and microvascular advantages. Further protection effects in diabetic complications may be explained by more mechanistic studies on the basis of anti-inflammatory and antioxidant pathways. The synergistic effects of fenugreek with other *Pramehaghna dravyas* or in the combination with structured lifestyle modifications should be researched to achieve the better results. These multi-ingredient methods have been aligned with Ayurvedic standards of classical methods of managing diseases. To sum up, *Methi* (*Trigonella foenum-graecum*) is a scientifically supported multidiabetes nutraceutical intervention plan of *Prameha*. It possesses a multitarget effect with the capacity to regulate glucose absorption, improve insulin intake and sensitivity and improve lipid parameters thereby treating multiple elements of metabolic derangement [6,10,13]. Fenugreek is potentially a safe, inexpensive, and effective adjuvant or addition to the overall diabetes treatment programme with proper normalizing and rigorous clinical testing.

## CONCLUSION

Scientific supports *Methi* (*Trigonella foenum-graecum*) comes out as well-supported nutraceutical with useful therapeutic implication to address *Prameha*and its clinical manifestation, Type 2 Diabetes Mellitus. Both experimental information and clinical research evidence indicate that fenugreek positively interferes with a number of metabolic processes. The postprandial glucose regulation activity of soluble fiber as galactomannan is identified to contribute to the delay of carbohydrate absorptions in the presence of glucose dependent insulin secretion to improve the peripheral insulin sensitivity of 4-hydroxyisoleucine. This cumulatively makes contributions towards measurable decreases in the fasting blood glucose, after meal effects and HbA1c. Fenugreek, together with hypoglycemic control, also demonstrates a stable lipid -lowering property primarily on total cholesterol and triglyceride levels suggesting a

healing effect of diabetic dyslipidemias and associated risk of Cardio-Vascular Disease. It has a good safety profile, as it had with the previous formulation, with minor and mild gastrointestinal side effects. Allowing normal levels of dietary intake of the standardized extract of fenugreek seed may prove to be a beneficial supplement to individuals who are on conventional antidiabetic treatment due to its safety, availability, and acceptability. *Methi*, as a component of a comprehensive approach to treatment, offers a logical, evidence based and cost-effective method of ensuring good metabolic control in the lives of diabetic patients.

**ABSTRACT**

The 21st century's most pressing global issue is climate change spurred by the ongoing rise in greenhouse gas concentrations, leading to an urgent global catastrophe that transcends national and international borders. Aligned with SDG 13.3 of the UN Agenda for Sustainable Development, which emphasizes climate education and capacity building, India launched the Swachh Bharat Mission(SBM) in 2014, which intends to improve carbon sequestration through tree planting, scientifically manage solid and liquid waste, and avoid contaminating groundwater.The Indian Ministry of Education implemented Swachh Bharat–Swachh Vidyalaya (SWSV) in schools to complement SBM and include students in hands-on environmental conservation. The study evaluatesthe Swachh Vidyalaya's role in achieving SDG 13.3 through policies, ecological initiatives, and programs. findings highlight Swachh Vidyalaya's effectiveness insensitizing young minds, encouraging eco-friendly behaviour, and raising community awareness, all of which have a ripple effect that extends from the local to the global level and promotes climate adaptation and mitigation by supporting SBM objectives. The Swachh Bharat Mission steps towards a revolutionary India, a pollution-free, green, and clean country fostering national pride and global citizenship. As part of SBM, Swachh Vidyalaya made an enormous imprint on Indian society by instilling a sense of responsibility among future generations

**Keywords:** Swachh Vidyalaya, Swachh Bharat Mission, Sustainable Development Goal, Climate Action.

# INTRODUCTION

**Untreated Waste: A silent cause of climate change**

The 21st century's most pressing global issue is the climate change (Alexandru et al., 2013). Our mother Earth faces enormous pressure from anthropogenic activities inducing carbon dioxide and its allied gases into the Earth's atmosphere. One of the significant effects of Climate change is global warming spurred by the ongoing rise in greenhouse gas concentrations, which has led to an urgent global catastrophe that transcends national and international borders(*Climate Action - United Nations Sustainable Development*, n.d.). Carbon dioxide ($CO_2$), methane ($CH_4$), nitrous oxide ($N_2O$), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride ($SF_6$) are the six greenhouse gases (GHGs) that are listed for elimination in Annex A of the Kyoto Protocol in 1997(Seo, 2017). Since industrialization, carbon dioxide ($CO_2$) gas emissions have surged due to increased energy demand from growing populations and urbanization, including emerging economies such as China, India, and Thailand that rely on fossil fuels and crude oil products(Nwofe, 2014).Nevertheless, Greenhouse gases are traced directly from untreated solid waste (Bio-degradable and non-biodegradable) in open dumpsites from various waste sources like homes, schools, public places, etc(Ramachandra TV., 2009). Ramachandra et al., (2018)argued that approximately 60% of the municipal solid trash the agencies collect is disposed of at designated locations; the remainder is disposed of at unregulated disposal sites, which has adverse environmental effects, including greenhouse gas emissions. Even this improper and uncontrolled disposal of all waste types, especially organic waste, causes ecological issues such as nutrient leaching that contaminates the land, water, and soil.The majority of developing nations manage their trash using extremely antiquated techniques, which has the effect of making the environment more hazardous for human existence.In addition to contributing to climate change, unsustainable waste management significantly harms the ecosystem(Nwofe, 2014). Researchers estimate that 19 to 23 million tons of plastic trash are dumped into oceans and water bodies, causing harm to 1,500 species such as fish, whales, turtles, and birds, which frequently consume, become sick, or die from toxic plastic waste, is one of the leading causes of wildlife extinction(*How Our Trash Impacts the Environment - Earth Day*, 2024). Poor waste management, such as open incineration and decomposition in the dumpsites, produces more nitrous oxides and methane in addition to open exposure of human excreta, which contaminates groundwater and pollutes water bodies and becomes a severe challenge to climate change. Methane has twenty-five times the potential to warm the world of carbon dioxide and nitrous oxide and warm Mother Earth over half of 1 degree Celsius. Besides that, high ammonia concentrations in the air can also induce acid. Sustainable waste management is essential to mitigating the effects of global climate change (Nwofe, 2014).

**Climate Change Mitigation efforts in the Global context**

Rapidly reducing $CO_2$ emissions and the corresponding socio-ecological changes can only be accomplished through intergenerational effort(Liebhaber et al., 2023). UNFCCC and its Kyoto Protocol have accomplished substantial goals, ignited a variety of national policies, and established new institutional mechanisms for mitigation action. Further, it legally binds 198 countries in Paris in 2015 to commit to lowering global greenhouse gas emissions to limit global temperature rise to below 2°C above pre-industrial levels and responding to climate change impacts while fostering sustainable development. It establishes a framework for developed nations to aid developing nations while ensuring transparent monitoring of climate targets. Countries will submit updated reports to the Nationally Determined Contributions (NDCs) every five years, explaining strategies to reduce emissions and strengthen resilience against rising temperatures (*The Paris Agreement UNFCCC* n.d.).

**SDG 13: Climate Action**

Goal 13 of the Sustainable Development Agenda (SDG) is called "Climate Action." It is one of the 17 objectives set forward by the United Nations in their Agenda for Sustainable Development for 2030. SDG13's primary goal is to address climate change and its effects by acting quickly. It acknowledges that climate change is a global issue that must be addressed immediately and that governments, corporations, communities, and people everywhere must work together(Filho et al., 2023). Dhanapal et al., (2023) argued that taking urgent climate action to keep global

warming below the 1.5-degree threshold is imperative; developing and least-developed nations must prioritize climate action to meet their sustainable development goals by lowering climate risks, losses, and damages.Climate action plans are strategies for adaptation and mitigation with set objectives, budgets, timelines, and results. It can lessen financial losses and increase climate change resistance when properly applied. Even, the Conference of Parties (CoP 26) of the United Nations Framework Convention on Climate Change (UNFCCC) has called on nations to take climate action. However, to accomplish the climate action targets and the SDGs, climate action must be planned and carried out at many levels, from the national to the local. The global community acknowledges the relevance of training and education in addressing climate change. The Action for Climate Empowerment (ACE) agenda, the Paris Agreement, and the UN Framework Convention on Climate Change all urge governments to inform, empower, and include all significant groups and stakeholders in climate-related policies and initiatives. (*Climate Change Education UNESCO*, n.d.). The global goal SDG 13 is sectioned into four smaller objectives to spur against climate change. (*Goal 13: Climate Action - The Global Goals*, n.d.).

**Combating Climate Change through Education**

Climate Action for SDG13.3 focuses on mitigation and adaptation strategies to combat climate change through education, awareness campaigns, and capacity building of individuals and institutions(*Goal 13: Climate Action - The Global Goals*, n.d.). Educational institutions are significant players in the worldwide quest for sustainability, using their diverse contributions to advance the UN's Sustainable Development Goals (SDGs)(Abdalla et al., 2024). UNESCO defined climate change education as equipping individuals with the information, skills, values, and attitudes necessary to engage as change agents by assisting them in comprehending and addressing the effects of climate change. As part of its efforts to promote education for sustainable development, UNESCO advocates for climate change education. (Climate Change Education UNESCO, n.d.). Allen & Crowley, (2017) asserted that climate change necessitates a significant global response: people, communities, regions, and countries must all make significant changes to their visible habits and behaviours. Education is a crucial aspect of altering habits and behaviours. However, most modern climate change education focuses exclusively on individuals' understanding of climate science, which research finds has limited usefulness in enabling collective climate action. Howard-Jones et al., (2021)argued that Climate change Education (CCE) should be action-oriented to align with an action agenda. Action-oriented CCE may focus on individual behavior, such as students calculating and reducing their carbon footprint.Cantell et al., (2019) depicted climate action through the bicycle chains and pedals in the holistic model of climate change education, symbolizing activity on "real life issues," which is instrumental for transferring knowledge and thinking skills into practical action. However, Howard-Jones et al. (2021) suggested that Climate change-empowered students acting as change agents in their communities are more beneficial in mitigation (as cited by Kenis and Mathijs, 2012; Trott, 2019a).

**Indian Initiatives of Climate Action: Swachh Bharat Mission (SBM) or Clean India Mission**

India has been a critical participant and an active member of the UNFCCC (as cited in Dubash et al. 2018). Since 1980, India has implemented several national-level initiatives for community development and natural resource management. To combat the rising greenhouse gases, the Indian government launched the Swachh Bharat Mission or Clean India Mission in 2014 by scientifically managing solid and liquid waste, forbidding groundwater contamination, and increasing carbon sequestration through tree plantation missions. The Prime Minister of India, Narendra Modi, asserted, "A clean India would be the best tribute India could pay to Mahatma Gandhi on his 150th birthday in 2019". The Prime Minister led the widespread cleaning drive, motivating the populace, gave the Swachh Bharat Mission a nationwide boost, and advised people not to spread dirt themselves or allow others to do so. 'Na gandegi Karenga, nakarnedenge' turned the mission into Abhiyan or Jan Andolon. (*Major Initiatives Swachh Bharat Abhiyan*, n.d.). In addition to cleaning the environment, the Swachh Bharat Abhiyaan aims to get people involved by planting trees, removing waste from public areas, providing sanitary amenities, and building the foundations for Swachh Bharat in the future to make a clean and green India by modifying attitude and behavior (*Swachh Bharat Abhiyaan: Ek Kadam Swachhata Ki Ore*, n.d.). SBM Rural and SBM Urban were the two fronts of the mission run by the Ministry of Drinking Water and Sanitation and the jurisdiction of the Ministry of Housing and Urban Affairs(Dash & Dash, 2021). Consequently, the SBM has sectioned into two phrases:

**Swachh Bharat Mission (SBM) Phrase I ( 2014-2019)**

SBM aimed to nudge public behavior and included everyone in the collaborative endeavor of cleaning homes, iconic places, public places, streets, parks, beaches, water bodies, and adjacent areas. The Phrase- I SBM's goals (Rural) encompassed a) improving rural communities' overall quality of life by encouraging cleanliness, hygiene, and the abolition of open defecation; b) increasing rural sanitation coverage to realize the Swachh Bharat vision; c) encouraging communities to embrace sustainable sanitation facilities and practices by raising awareness and educating them about health issues; d) Support affordable and suitable technologies for environmentally safe and sustainable sanitation(VerKuilen et al., 2023). The Phrase- I SBM's goals (Urban) included i). Ending Manual Scavenging ii) managing Municipal Solid Waste in a Modern and Scientific Way iii) Expanding Urban Local Bodies' (ULBs') Capacity iv) To foster an environment that encourages private sector involvement in both capital expenditures and operation and maintenance(Choudhary & Gupta, 2015)

**Swachh Bharat Mission (SBM): Phrase II ( 2019-2025)**

In 2021, India advanced to the subsequent Swachh Bharat Mission Urban 2.0 and Rural 2.0 phase, successfully eliminating open defecation in all villages, gram panchayats, districts, states, and Union Territories by October 2019. Swachh Bharat Mission -Urban 2.0 focused on making all cities i) 100 % ''garbage-free'' through door-to-door waste collection, source segregation based on wet and dry waste categories from the households, gates in the wards, every day sweeping the public areas, bulk waste generator and no visible solid waste in water bodies and screening of stormwater- drains, ii) banning single use of plastics iii)scientific processing of municipal solid waste, iv).Controlling air pollution by converting dumpsites into green zones, vi) Digitally monitoring solid waste management operations and v). Geo-mapping waste processing facilities. (Payoja Ahluwalia, 2021). Phase II of Rural SBM aims to attain Sampoorn Swachhata (total cleanliness), which entails maintaining ODF status, managing solid and liquid waste, biogas energy production, information education, and Communication/Behavior Change and converting all villages from ODF to ODF Plus Model.(*Swachh Bharat Mission -Grameen (SBM): Phase II (2019-2025)*, n.d.)

**School Initiatives of Swachh Bharat Mission**

The Ministry of Education, India initiated Swachh Bharat- Swachh Vidyalaya or Clean India- Clean schools in 2014 as part of the Swachh Bharat Mission in every governmentschool to implement the action plan for climate change through various activities connected to the community /society.The primary objectives of Swachh Vidyalaya in the lens of climate action enlisted are:

i. Promote cleanliness by providing proper infrastructure and clean and safe water,
ii. Impart healthy habits along with hygiene education and messages,
iii. Foster environmental awareness and promote sustainable behavior through experiential learning and integration of content into curriculum and co-curriculum integration,
iv. To sensitize the young mind to the environmental degradation by human practices,
v. Engaging young learners in practical conservation of natural resources activities, which will 'marmalade the biodiversity of nature' and enhance the regeneration capacity of the natural environment,
vi. Instilling eco-conscious attitudes while reducing their environmental footprints,
vii. To make a future decision-makers,
viii. Imparting appropriate insights while imposing ethical and moral principles,
ix. Educating mass and capacity enhancement of the stakeholders and preparing the future generation about a green and healthy environment.

The National Council of Educational Research and Training's (NCERT) commitment to combating climate change by integrating content in school curricula in disciplinary and interdisciplinary ways perfectly aligns with the National Education Policy (NEP) 2020 goal. The significance of incorporating environmental education into school curricula at all levels is emphasized in the National Education Policy 2020. The Ministry of Education in India firmly believes in education as a game-changer to combat climate change because it empowers us to act more effectively("State of the Education Report for India 2023," n.d.). The Ministry of Environment, Forests, and Climate Change (MOEFCC) is the nodal ministry for SDG 13; it launched the National Green Corps (NGC) program to raise the environmental

consciousness of environmental issues among schoolchildren nationwide, getting involved the learners in activities like planting trees, handling trash, and conserving biodiversity. MOEFCC included activities such as starting eco-clubs in schools, planning events for the environment, and taking part in community campaigns. The Centre for Environment Education (CEE) implements an international program that uses a systematic, seven-step approach to motivate students to participate in sustainable behaviors and Initiatives about biodiversity, water conservation, waste management, and energy conservation. (J. Suresh Kumar & D. Shobana, 2024). Furthermore, to effectively use education to create a more sustainable and greener future, UNESCO has long advocated mobilizing intersectoral collaborations, political commitments, and youth empowerment. By establishing the groundwork for international cooperation and policy innovation, its worldwide initiative, Education for Sustainable Development (ESD), helps achieve this goal. Furthermore, UNESCO acts as the secretariat for the Greening Education Partnership (GEP), established by the UN Secretary-General in 2022 and offers a valuable platform for education partners to take additional action.("State of the Education Report for India 2023," n.d.).

## REVIEW OF RELATED LITERATURE

**Climate Action**

Bofferding & Kloser, (2015) argued that mitigation is an effort to reduce anthropogenic net emissions of GHGs as per IPCC (2007). Two methods to achieve this net reduction are lowering outputs or capturing carbon. Using renewable energy sources that avoid burning fossil fuels (such as energy generated by solar panels), altering one's lifestyle to use less energy overall (such as walking instead of driving), and utilizing materials that lower energy requirements (such as better insulation for homes to lower heating requirements) are common ways to reduce greenhouse gas emissions. By contrast, carbon capture includes activities that reduce the concentrations of current greenhouse gases, such as methane collection at landfills or reducing deforestation, which raises the rate of photosynthesis. In contrast, Planting trees with broad canopies is one of the significant adaptation activities because it provides more shade for living things and lessens their susceptibility to rising temperatures. By retaining carbon during photosynthesis, these shade plants help reduce emissions simultaneously. (Dagnachew & Hof, 2022) assed the influence of climate change mitigation initiatives on other SDGs while focusing on van Soest et al.'s (2021) 20 best practices for reducing emissions in power production, transportation, buildings, industry, land use, and non-CO2 emissions. Increasing the use of renewable energy in power generation has potential advantages beyond SDG 7, including poverty reduction, eliminating hunger, enhancing access to healthcare, education, and clean water, and safeguarding life on land and in water. Mitigation techniques to minimize $CO_2$ emissions from land use and non-$CO_2$ emissions from agriculture, livestock, and waste are crucial for achieving global emission reductions. Reducing deforestation and encouraging reforestation promotes biodiversity and the ecosystem, aligning with the SDGs. Potential choices in North America, Europe, and Central and South America stem from technology decisions that may worsen socioeconomic inequality and affect biodiversity. (Nnaji & Utsev, 2011)noted that Waste management education is pivotal for managing waste scientifically and could lower the emission of global warming potential gases from untreated waste. This involves reducing waste at the source before it enters the waste stream and recovering produced waste for recycling and ecologically responsible waste management through burning with energy recovery and conversion.

The US Environmental Protection Agency (US EPA) created the hierarchy of non-hazardous materials and waste management, ranking the different management approaches from most to least ecologically friendly. Reducing, reusing, and recycling are emphasized in the hierarchy as essential to sustainable materials management. (*National Overview: Facts and Figures on Materials, Wastes and Recycling ,US EPA*, 2023). The Nigerian government prioritized recycling waste materials and using innovative technologies for sustainable waste management. Sustainability and energy efficiency, heightened consciousness of the detrimental effects of climate change and global warming, design of eco-cities, Carbon sequestration, which involves removing carbon dioxide from companies that utilize fossil fuels, and the adoption of renewable energy sources in place of fossil fuels are the means to reduce greenhouse gas emissions(Nwofe, 2014).In contrast, trash is cut down on Pacific islands by reducing and reusing, emphasizing the five "R's" of managing waste(Secretariat of the Pacific Regional Environment Program (SPREP), 2009).Nnaji and

Utsev (2011)argued that sorting at the source (SAS) is preferable to sorting at the transfer station. Additionally, families can be required to submit trash in an organized manner. Families will need to have separate trash cans for different types of garbage, such as (i) recyclable and non-recyclable, (ii) biodegradable and non-biodegradable, (iii) compostable and non-compostable, (iv) combustible. Sorting them into broad categories like food waste, plastic, glass, paper, nylon, textile, metals, etc., is a more complex but less realistic alternative. Each residence must have around seven trash cans for various waste types, making this more challenging.

**Climate Change Education (CCE)**

Arto-Blanco et al., (2017) conducted comparative research based on social representation theory, looking at a sample of 503 pupils to answer 'What is climate change?' by painting and writing. A qualitative and quantitative study of the data found that while most students acknowledged human responsibility for climate change, they had gaps in their understanding of the phenomena. Wu & Otsuka, (2021) surveyed 657 high school pupils from Shanghai, China. The findings showed that misunderstandings and skewed understandings of climate change continue; climate-related knowledge and attitudes have a poor relationship with behaviour. However, the relevance factor, which includes a belief in an individual's lifestyle, appears to be actively related to behaviour. Several studies and synthesis studies have found that climate change is inescapable, mainly due to human activity, most Indian students remain unprepared, apathetic, and unaware of the vital issue of climate change. In this context, Alexandar & Poyyamoli, (2017) an innovative climate change education (CCE) program was launched among schoolchildren in the Puducherry and Villupuram districts of Tamil Nadu to build knowledge, skills, attitudes, and behaviors related to climate change issues. The experimental study included 180 pupils from two middle schools in the Puducherry and Villupuram districts, both urban and rural. The selected pupils were separated into two groups, with 45 students being experimental and the remaining 45 serving as control groups for each school. The CCE program intervened in the experimental group pupils. The findings inferred that the multimodal teaching and learning technique is more effective among schoolchildren.Vijay Kumar & Kafi Abdul, (2015)assessed the higher secondary students' high level of interest in greening initiatives. Furthermore, the study explored the significant difference in the interest in greening initiatives between boys and girls, with no significant difference between rural and urban students and a considerable difference in the interest in greening initiatives among four different types of school students.

**Swachh Bharat Mission (SBM)**

Datta et al., (2021)assed that good knowledge (59%) and poor practice (39%) regarding water, sanitation, and waste disposal and Occupation (P=0.0012) and Socio-Economic status (P=0.03) were shown to have significant links with the knowledge and practice of the participants. Dash & Dash (2021) argued that strategic concerns, including institutional alliances, public engagement, and media integration, have become essential tools in every environmental campaign as the significance of communication for sustainable development becomes more widely recognized. Moreover, India's Swachh Bharat Abhiyan (2014–2019) is one of the twenty-first century's most significant strategic programs for sustainable development. The study assessed two research questions: (1) What did SBA implement the main outreach tactics and action plans? and (2) How did SBA spread the idea of swachhata or cleanliness? The result showed that a 360-degree promotional technique was used in the campaign. Print, electronic, and social media were all used; partnerships between and within institutions were fostered; opinion leaders and opinion formers were enlisted; and widespread public engagement was encouraged. The "3R" tenets of the UN Sustainability Goals—Reduce, Reuse, and Recycle—were strategically reflected in SBA's cleaning discourse. Tactically, the rhetoric surrounding cleanliness was rooted in good citizenship, dedication to one's community, and shame vs dignity. K. Loganathan et al., (2020) argued by encouraging cleanliness and concentrating on scientific solid and liquid waste management methods for general cleanliness in rural regions, the Swachh Bharat Mission primarily seeks to enhance the quality of life in these areas. Its main objectives are clean water and sanitation, the sixth sustainable development target. The study discussed The Swachh Bharat Mission, which was implemented in the village of Silvarpatti in the Rediyarchattram Block of the Dindigul District of Tamilnadu, India. The study showed the goal shifted to appropriate trashcan usage and separation. Various tactics, including audiovisual, wall painting, walkathons, and roadshows, have raised awareness. The community uses a traditional three-stone wood fire and agro-residue as its primary cooking fuel. In addition to raising pollution levels, this impacts rural women's health.

The usage of energy-efficient stoves has been taught to rural women. Young people in rural areas have received training on how to make wood stoves easily, which has improved their standard of living. A participatory rural appraisal was conducted on the community biogas plant since the village has enough animals. The village chiefs have received instructions on how to use wasteland for the grid. Sarkar & Bharat(2021)found that the policies and initiatives of the Indian government, such as the Swachh Bharat (Clean India) Mission (SBM), aligned with the SDG-6 targets 6.1 and 6.2, concerned with sanitation and clean drinking water. (2023) noted that the Indian government, particularly the Swachh Bharat Mission and non-governmental organizations, started several projects to raise ecological awareness to provide a healthy environment for all living things. Further, Gupta et al.(2022)argued that to combat plastic consumption and accomplish the Sustainable Development Goals, the Swachh Bharat Mission is crucial. The Swachh Bharat Abhiyan accelerates sustainability. The current study confirmed that the Swachh Bharat Abhiyan was successfully implemented in its initial phase. The mission is a real game-changer in the sanitation and hygiene space, as evidenced by its success.

**Swachh Bharat-Swachh Vidyalaya**

Swachh Bharat-Swachh Vidyalaya (SBSV) is noteworthy to raise awareness about the adverse effects of open defecation, which contaminates groundwater, resulting in diarrhoeal disease along with several waterborne diseases that impacted several health issues and lower productivity as well as declining school enrolment and academic performance. Hence, recognizing the importance of clean drinking water and school sanitation, the Swachh Vidyalaya aims to ensure every school in India has a 'set of functioning and well-maintained water, sanitation and hygiene facilities' to 'produce a clean and green environment' and to 'develop and support sustainable behavior.' Therefore, the campaign essentially entails two components - a) availability of the physical facilities and b) behavioral change practices. The overall 'functionality', thus, depends not on anyone but on the realization of both components.("Swachh Bharat Swachh Vidyalaya," 2014). This national Campaign is also renowned as "Abhiyan" because it covered schools in hilly regions, slums, extreme areas, etc., The mission made gender-segregated restrooms in all 1.2 million government schools (Borthakur & Baruah, 2019). Govt. of India,along with theSwachh Bharat Kosh, MPs and MLAs area development funds and all public and private companies and policies like Sarva Shiksha Abhiyan (SSA), RashtriyaMadhayamik Shiksha Abhiyan (RMSA), Rashtriya Madhyamika Shiksha Abhiyan (RMSA) are funded to the campaign to reach its peaks("Swachh Bharat Swachh Vidyalaya," 2014). Curriculum related to WASH was also incorporated into the school teaching to improve hygiene habits and community ownership of water and sanitation facilities within schools, the repercussions of which also spread within the community.Nearly 99% of the schools practiced handwashing, according to the NARSS study. SDG 4.1 has been made possible by all these factors, improving student retention, attendance, and school enrolment(Sarkar & Bharat, 2021). Around 6000 children from 20 schools segregate the waste generated from their daily activities in school and throw the degradable and non-degradable waste into separate bins. (Ramu et al., 2018). Most schools in Karnataka have installed incinerators for sanitary waste management, biogas plants, and kitchen gardens under the Swachh Bharat and Swachh Vidyalaya schemes(Subhashree et al., 2020). 84.35% had good knowledge, 95.23% had a good attitude but only 50.34% had good practices about environmental cleanliness and personal hygiene (Nanjesh Kumar et al., 2020), the program has efficiently increased students' awareness of hygiene standards, with tests showing a mean knowledge score of 68.13 among junior high school students in Uttarakhand, indicating that they know the mission's objectives(R. Sharma & Tomar, 2022) Whereas 100 % of students from the Jharkhand state are aware of this campaign, 77.8% were only aware of the different components of the mission (Sunderam et al., 2020). A study from the Kollam district of Kerala revealed that most schools provide water facilities but need more treated water and proper hygiene facilities(Rakesh, 2014). In contrast, a study showed that more than fifty percent of schools provide appropriately filtered drinking water, sufficient restrooms, and proper waste management facilities in the schools from Telangana states but still need to deliver R-O drinking water facilities(Vishnu. P., 2021).Gupta et al., (2022)found no significant difference in environmental responsibility among post-graduate students based on gender, stream, or region under Swachh Bharat Swachh Vidyalaya. The Clean India Mission significantly increased access to sanitary facilities and increased knowledge of appropriate waste disposal. Cities have implemented decentralized waste management programs, including recycling, composting, biogas generation, and waste-to-energy conversion. In addition to reducing the amount of trash dumped in landfills, these neighborhood-based

projects have given underprivileged groups access to new sources of income(Singh et al., 2024). Sarkar & Bharat (2021) argued that as per the report of the National Annual Rural Sanitation Survey (2019-20), 95.5% of Indian schools had access to proper child-friendly restrooms, almost all of them are functional, and 99% of schools accessed potable water. Similarly, the phenomenal improvement in sanitation facilities in the country has enabled 98 % of households to access restrooms, which aids in reaching the goal of SDG 6.1.1 and 6.2.2, which adversely benefits reduced health impacts such as diarrheal diseases, stunting of the child, typhoid and others health impacts of poor sanitation, improving well- being another target of SDG 3. Hutton et al., (2020)estimated that water and sanitation benefited economic development. The analysis demonstrates the financial impact of better sanitation and hygiene under the SBM. Ending open defecation universally results in a decrease of USD 64 billion in the nation's GDP. Improving per capita GDP and sanitation-related measures can help achieve SDG 1's goal of ending poverty(Roy & Pramanick, 2019).

**Research gap**

Greening and cleaning are the main focus of Swachh Bharat Abhiyan through trash management, besides the mission implemented from the grassroots level to the top level. Previous research conducted on the mission's goals impacted the achievement of the set objectives of SDG 6 (Sahoo et al., 2023; Sarkar & Bharat, 2021 **;** Roy & Pramanick, 2019), SDG 3 (Sahoo et al., 2023), SDG1(Roy & Pramanick, 2019). Still, there needs to be more analysis of the significant role of the Swachh Bharat Mission in empowering the community and future generations to combat climate change in India. We address this gap in this research by focusing on how the Swachh Bharat Mission is significant in achieving the goal of climate action or SDG 13. Moreover, as a grassroots-level implementor, how Swachh Vidyalaya sensitizes the young mind to environmental degradation by action, engaging them in the practical conservation of natural resources, fostering sustainable behavior through experiential learning, and instilling eco-consciousness while reducing their ecological footprint.

**Objectives of the study**

The narrative review aimed to evaluate the role and responsibility of Swachh Bharat: Swachh Vidyalaya in achieving SDG 13 in the Indian Context.

## METHODOLOGY

Narrative Reviews consolidate published material on a topic and explain the current state-of-the-art. Unlike the PRISMA assertion for systematic reviews, narrative reviews have no established rules (Ferrari & Rossella, 2015). Search terms for articles include Swachh Bharat Mission or Swachh Bharat Abhiyan, SBM, Swachh Bharat Swachh Vidyalaya or Clean India Clean School, Climate Action, Sustainable Development Goals 6, SDG 13, and greenhouse gases. Researchers review articles databases such as ScienceDirect, Taylor & Francis Online, and Google Scholar. Moreover, several government websites and policy reports were also analysed. Additionally, this review selects papers based on both inclusive and exclusive criteria. The inclusive criteria for addressing the problem formulation include highlighting the Swachh Bharat Mission's or Swachh Vidyalaya's role in promoting climate action, describing the organization's contribution to reducing environmental degradation, presenting the elements and characteristics of Swachh Vidyalaya, and writing articles in English. We can determine whether the inclusive criteria are appropriate by reading and comprehending the entire article. The category of exclusive criteria includes articles that do not fit the problem formulation and the inclusion requirements(Saputra et al., 2024).

**Action Model under Swachh Bharat: Swachh Vidyalaya**

Swachh Bharat: Swachh Vidyalaya is intended for total cleanliness, sensitizes the young mind on the significance of environmental degradation by human action, engaging in eco-friendly behavior, nature conservation and preservation along with the attitudinal and behavioral shifts in the school child to overall society while lowering their environmental footprints. Hence, the mission's action model is sectioned as

**Schemes**
**Core environmental activities**
**Legislative and policy support**

**Schemes**

The Ministry of Education (MOE) launched schemes such as Swachh Vidyalaya Puraskar and Bal Swachhta missions under the Swachh Vidyalaya to inspire the innocent to participate in the national mission to accomplish its goals.

i) Swachh Vidyalaya Puraskar:After establishing Swachh Bharat- Swachh Vidyalaya, the national mission, in 2016, the Ministry of Education in India introduced another new program called Swachh Vidyalaya Puraskar in 2016-17. This award-based school initiative is designed to recognize, motivate, and celebrate success in measures taken by various government schools (rural and urban) nationwide to meet the Swachh Vidyalaya mission's mandate. Under this effort, schools would be ranked nationally based on several criteria such as cleanliness, water availability, handwashing, sanitation, maintenance, conduct, and other swachhtaa or cleanliness factors. ("Swachh Bharat Swachh Vidyalaya," 2014)

ii) Bal Swachhta mission: The Bal Swachhta Abhiyan focuses primarily on children. It begins on November 14 and ends on November 19, 2014, under the auspices of the foremost national campaign. Given its focus on children, the program kicks off on Children's Day. This campaign ought to be conducted by all educational institutions to raise awareness through cultural programs or competitions such as essay writing, debates, discussions, chart-making, recycling displays, and other artistic initiatives on the themes include clean Anganwadis, well-kept surroundings such as playgrounds, personal hygiene/child health (clean self), nutritional food consumption, potable water, and functional toilets. Faculty members are also entrusted with organizing cleanliness drives to clean the neighborhood and educating residents(*Bal Swachhta Mission*, 2014).

**Core environmental activities of Swachh Vidyalaya:**
As per the guideline MOE, Govt. of India, this national campaign was made based on two combinations: technical and human development activities. Technical activities include provisions for purifying drinking water, hand washing facilities, and proper infrastructure, whereas daily activities and practices of learners' behavioral change are nominated under human development activities. Swachh Vidyalaya promotes cleanliness, hygiene, and sanitation in schools throughout India.

The main activities under this program are
**Provision for clean, sanitary facilities**:
The Ministry of Education (MOE) ensures that each school in India, through the Swachh Vidyalaya mission, has separate, functional, child-friendly restrooms for boys and girls (1:40) that are regularly cleaned and maintained with proper natural lighting and ventilation.

**Safe drinking water**:
Swachh Vidyalaya schemes ensure all kids can access potable drinking water and clean water for cooking and washing vegetables and utensils. The schemes mandate safe handling and storage of drinking water, which should be practiced throughout the school, and maintain the appropriate distances between the potable ground water tab and drainage system. Further, the appropriate purification or filtration process should be followed.

**Hand washing facilities with hygiene messages**:
Swachh Vidyalaya mandates improving hand hygiene and installing soap-filled stations near restrooms and dining areas. Teachers should involve the little ones in handwashing sessions before the midday meal by conveying sanitation and drinking water safety messages.

**Waste segregation and management facilities**

Swachh Vidyalaya involves the students in the segregation of waste and is asked to throw the waste into different sources of dustbins in day-to-day activities. Through the national mission, the Ministry of Education asked every school to install incinerators and composite pits to manage solid waste.

**Plastic avoidance and following the rule of 3R'S of Environment**

**"**Stop using plastics, Go Organic" uses this tagline to describe the success of the Swachh Vidyalaya mission. Under the mission, most schools have educated their students about plastic pollution and encouraged them to actively participate in making their classrooms plastic-free and motivated to participate in programs that teach them about the environmental impact of littering.

**Anti-litter Campaign & participating in cleaning activities**

School authority elicits awareness about clean schools through various anti-littering programs. The young minds are urged to take up the broom to clean school premises, gardens, playgrounds, and the neighbourhood under this scheme. Students from both semi-rural and urban locations have actively and enthusiastically cleaned their classrooms and the school grounds.

**Engaging in eco-friendly practices:** The school authority insists that learners use jute bags, train them to make organic compost, close the tap immediately, and switch off the fan and lights after using it. Sensitize them about the water crisis and motivate them to harvest rainwater and reuse the paper under the national mission.

**Nature Preservation**

Swachh Vidyalaya mission enlisted to make kitchen gardens or gardening in the school premises encourages students' and teachers' participation in gardening activities, such as saplings of medicinal/vegetable/flowering plants on the school premises, watering them, and caring for them. Some schools also conducted rooftop gardens to address space constraints. Indoor planting is recommended to improve cleanliness and freshness.

**Operation and Maintenance**

All the infrastructure needs to be clean, functional, and well-maintained to ensure Swachh Vidyalaya's intended result. Hence, it has been made mandatory to clean classroom fans, lights, roofs, walls, water storage tank, etc., as well as check pipes, cracks on walls and roofs, clogged drains, and observe water logging in areas, etc. on a weekly and monthly basis by the school.

**Behaviour Change Activities**

Several approaches are implemented in the school to change behaviour effectively.

A. **Curriculum integration**: Various states' governments incorporate content related to environmental degradation through human action and the necessity of conserving nature through school textbooks and supplementary books.

**b. Co-Curricular activities**: Learners should not be limited to curricula; they are actively engaging in eco-club activities to expose them to nature and learn through the "learning by doing" method; child cabinets formed for disseminating hygiene-related messages to the child as child-to-child strategies are the best and critical element of behaviour strategies in schools.

**Enhanced Capacities**

Capacity enhancement is one of the factors considered by the Swachh Vidyalaya mission. Govt. along with UNICEF and WHO, conducted several workshop/ project and seminar sessions to refine the essential capacities at various levels within the sector, to enhance the knowledge, skills, and experience of the teachers, midday meal cooking lady, finance, and manager to facilitate the program.

**Community awareness program**

Swachh Vidyalaya encourages Schoolchildren to participate in activities such as an anti-littering campaign, brooming the surroundings, role acting, demonstrations, and so on in front of the community to raise awareness on different celebration days like World Environment Day, Earth Day, World Biodiversity Day, and World Water Day, etc.4

**Legislative and policy support**:

To succeed in key commitments for Swachh Bharat: Swachh Vidyalaya to provide water, sanitation, and hygiene amenities in schools strengthened by legislation and policy framework, including the RTE Act (2009), that mandates the provision of drinking water and sanitation in schools, supported by the national flagship programs Sarva Shiksha Abhiyan (SSA) and Nirmal Gram Puraskar. (Bakshi & Gupta, 2022; "Swachh Bharat Swachh Vidyalaya," 2014)

**Constitution**

- Article 21-A: 'Free and compulsory education of all children in the age group of six to fourteen years as a Fundamental Right.'
- Article 48-A (state obligation to protect our environment): 'The State shall endeavor to protect and improve the environment and to safeguard the forests and wildlife of the country.'
- Article 51-A: 'It shall be the duty of every citizen of India to protect and improve the natural environment including forests, lakes, rivers, and wildlife and to have compassion for living creatures.'

**Legislation**

- Right of Children to Free and Compulsory Education (RTE) Act of 2009. The RTE Act's 2009 Schedule stipulates the standards for a school building, drinking water, and sanitation.

**Policies and programs**

- Sarva Shiksha Abhiyan (SSA)- The Sarva Shiksha Abhiyan (SSA) envisions the school as a pedagogically rich, inclusive, and sustainable ecosystem that is safe from hazards, maintains cleanliness and hygiene, incorporates elements of green architecture, and makes the best use of available resources and space through environmentally and culturally sustainable practices(K. Sharma & Pandya, 2015,Pg.No. 17).
- Mid-day meal Programme -A nutrition program essential to schoolchildren's growth and promoting environmentally ethical ethos in the school(K. Sharma & Pandya, 2015, Pg. No. 18).
- The Rastriya Madhyamik Shiksha Abhiyan -Encourages secondary schools to provide excellent physical infrastructure, such as adequate classrooms, restrooms, and drinking water.
- Kasturba Gandhi Balika Vidyalaya (KGBV) intends to offer girls from disadvantaged groups in the SC and ST communities' access to good quality education by establishing upper primary residential schools

**Role and Responsibility of Swachh Bharat: Swachh Vidyalaya (SWSV) to achieve Sustainable Development Goals in the lens of SDG 13.3:**

Swachh Vidyalaya is crucial in sensitizing the young mind regarding environmental degradation, engaging learners in the practical conservation of natural resources, and cultivating eco-friendly habits while reducing their environmental footprints. Moreover, it strives to modify children's attitudes and behavior, positively impacting society. Such changes are instrumental in supporting the Swachh Bharat Mission (SBM) in achieving its targets for SBM 2.0. These initiatives demonstrate educational institutions' commitment to building their capacity to combat climate change through action and reducing environmental impact. Swachh Vidyalaya's activities align with Sustainable Development Goal 13.3, which emphasizes improving education, awareness, and institutional capacity in climate change mitigation, adaptation, impact reduction, and early warning systems.

**Fostering Eco-Awareness**

Under Swachh Vidyalaya Abhiyan, the school children learn the necessity of trash management and sorting waste using appropriate source-wise dustbins. ("Swachhbharat-2024," 2024). Schools' foster awareness among the learners about the hazardous effects of plastic pollution on Mother Earth. Several government urban schools have devised

innovative techniques for dealing with plastic waste products, such as plastic packages and pet bottles, which are collected and used in terrace farming. Furthermore, students are not allowed to carry their tiffin (biscuits, napkins, etc.) in any form of packaging. This has significant steps to reduce plastic waste generation, followed by the reuse of plastic trash in extracurricular activities. In Work Education class, students are taught various crafts and constructions using plastic materials. Discarded plastic bottles and bowls are repurposed, painted, and used for plantations and hanging gardens. The deck is then adorned with stunning designs. The national mission made the Indian schools proactive in building plastic-free and green zones and teaching students how to reduce, reuse, and recycle waste.(Mandal & Banerjee, 2023). Several Schools install Biogas plants also. (Subhashree et al., 2020)). Moreover, it mandates recycling handwashing waste water in the kitchen garden.("Swachh Bharat Swachh Vidyalaya," 2014). In this way, schools under Swachh Vidyalaya typically follow the 3Rs - Reduce, Reuse, Recycle of Waste Management Rules which help to reduce waste significantly. These activities save the environment from climate change and foster insights into generating green energy from waste while instilling eco-consciousness among young learners.

**Instilling Eco-friendly habits**

Swachh Vidyalaya Schools insist the children actively participate in water conservation and rainwater harvesting, using jute bags instead of plastic bags, reusing paper, and planting herbal/medicinal plants or kitchen gardens or flower tree plantations on their school premises and training them to make organic compost from the leftover food and vegetables peels getting from the Mid-day meals(Mandal & Banerjee, 2023; "Swachh Bharat Swachh Vidyalaya," 2014). However, the Swachh Vidyalaya mission promotes a green school policy by providing mid-day meals, periodic health check-ups, natural light, ventilated classrooms, access to safe and clean drinking water through filtration/ purification, cleaning of the roof, all the dust from the fans, tube lights, bulbs, water storage tanks, open school garden, etc. seasonal or quarterly. Besides that, the mission instilled in a child the use of resources judiciously in their day-to-day life. Hence, Swachh Vidyalaya tunes the little mind with eco-friendly practices which are crucial to combat climate change.(K. Sharma & Pandya, 2015).

**Environmental Protection**

Swachh Bharat Swachh Vidyalaya provides proper restroom infrastructure in all the schools and sensitizes learners about the harmful impacts of open defecation and untreated sewage on the environment. School kids actively engage in waste separation and use proper restrooms in school that will save water, soil, air, and groundwater and prevent some wildlife extinction. Some states even started solar cooking in schools to prepare mid-day meals for children and save Mother Earth from the harmful effects of burning biomass fuel(K. Sharma & Pandya, 2015 , pg no. 119-120)

**Environmental Conservation**

Swachh Vidyalaya entails making a green and fresh campus so that the school conserves varieties of plant species, including rare species of flowers, herbal plants, and vegetable plants. Schools from northeastern states conserve 400 species of plants, rare species of land lily, seasonal flowers to bougainvillea, etc. It not only conserves the plant species but also saves flora and fauna of different niches(Puri & Joshi, 2017). Hence, Swachh Vidyalaya is increasing the concentration of carbon sequestration in the nations through plantation programs in schools and conserving each niche and every ecosystem on the earth, essential for maintaining the balance of nature to combat climate change.

**Judicial use of natural resources**

Renewable natural resources must be used increasingly, keeping the cycle of renewing at regular intervals. However, non-renewable resources are to be in the judicial frame as these resources shall never be renewed in a natural setting. Swachh Vidyalaya mandates LED bulbs instead of high-power bulbs and recycles kitchen wastewater for gardening and other materials. Teachers used to teach the learners to switch off the fans and lights and de-plugging gadgets when not in use. Swachh Vidyalaya schools make learners aware of how the country's judicial use of resources is needed through innovative experiential learning methods(K. Sharma & Pandya, 2015 , pg no. 71-73).

**Attitudinal and Behavioural Change among the Learners**

`Swachh Vidyalaya Schools are pivotal in fostering behavioural change in children, making them more receptive to adopting improved practices for a lifetime. Swachh Vidyalaya policy emphasizes peer-to-peer approaches, curriculum inclusion, child's cabinet, and daily activities such as morning assembly and mid-day meal schemes("Swachh Bharat Swachh Vidyalaya," 2014). This activity helps effectively promote environmental cleanliness, protection, conservation, and environmentally ethical ethos in children to modify their attitudes. Moreover, Educational institutions further enhance awareness through cultural events, competitions, and cleanliness drives, encouraging students to adopt sustainable practices and ethical values.

**Catalysing Swachh Bharat Mission (SBM):**

Children may serve as catalysts for a broad movement addressing various environmental challenges. Since children will be future citizens, fostering environmentally friendly attitudes and behaviours can significantly impact long-term environmental conservation initiatives(Puri & Joshi, 2017). Since they are the essential links between educational institutions and society by disseminating essential messages to their families and communities. Moreover, they can raise their voice on current norms in their homes("Swachh Bharat Swachh Vidyalaya," 2014). Children can even motivate their parents to sort waste in separate bins, give the trash to the door-to-door waste collector instead of throwing it outside their homes, adopt eco-friendly products and practices, plant trees, and clean surrounding places, use solar panels and solar cooking system in their homes, using biogas plant in rural areas which has been aided in reaching the vision of the Swachh Bharat Mission 2.0, '100% Garbage Free City,' Actions need awareness; Swachh Vidyalaya's children could awaken the citizens to become environmentally responsible and align with SBM's targets to reach the SDGS goals 13.

## DISCUSSION

Swachh Bharat Mission implemented climate change mitigation and adaptation policy by raising awareness and modifying societal attitudes through awareness campaigns, advancing the education system, and building capacity. SBM brought out cascading changes in individual -community –nation - global. India marked a significant milestone by achieving SBM phase one targets, underscoring 100% eliminating Open Defecation in all villages, gram panchayats, districts, states, and Union territories. Over 6 lakh villages were designated as ODF by the GOI by October 2019(*Swachh Bharat Mission -Grameen (SBM): Phase II (2019-2025)*, n.d.). *Swachh Bharat Mission -Grameen (SBM): Phase II (2019-2025)*, (n.d.) reported that SBM protects the environment by reducing the possibility of human-traceable groundwater pollution in ODF communities by 12.70 times as per UNICEF 2019. Moreover, The Swachh Bharat India Mission Phrase-I significantly increased access to sanitary facilities and knowledge of appropriate waste disposal. Cities have implemented decentralized waste management programs, including recycling, composting, biogas generation, and waste-to-energy conversion(Singh et al., 2024).

Swachh Bharat Mission Phrase-II focused on a 100 % garbage-free city, abolishing a single use of plastic, scientific processing of solid waste, converting dumpsites into green zones, and biogas energy production. Hence, the Swachh Bharat Mission trained the people in segregating waste in the home, office, and public places and urged people to one step forward to participate in door-to-door waste collection. The SBM Vision 2.0 is only possible when people eagerly throw waste in separate dustbins at homes, workplaces, and public places. A series of awareness programs by the district administration, state government, and central government raised public knowledge about the perils of pollution as well as the people who are not well-informed spit pan, gutkha, and tobacco on highways and in public places and those who eat in buses and trains and discard their food wrappers on the road rather than in trash cans, as results people are taking the initiative to clean up their villages, societies, colonies, cities, railway platforms, and so on. Cleaning homes, workplaces, villages, and towns would significantly reduce littering and pollution. Decreasing solid waste generation, related groundwater pollution, and methane emissions. It will effectively save us from climate change.

Swachh Bharat-Swachh Vidyalaya is instrumental in progressingthe Swachh Bharat Missionby passing the knowledge to their parents and furthering to the larger society. The Swachh Vidyalaya Puraskar and Bal Swachhta mission's cultural events, such as roleplaying, debate, discussion, storytelling, drawing competitions, etc., and cleaning drives to neighbourhood places, fostering not only children's bodies to involve actively in cleaning schools,homes and public place while throwing the waste in separate bins but also its imparting appropriate insights about the necessity to separate degradable waste to non-degradable, recyclable waste for saving our mother nature from the emission of global warming potential gases. The Ministry of Education awarded 39 Schools for achieving targets of Swachh Vidyalaya in 2021(The Hindu, 2022). Moreover, constitutional and jurisdiction provisions added an extra layer to the Swachh Vidyalaya's effectiveness. Bakshi and Gupta (2022) reported thatSwachh Vidyalaya instilled trust and confidence in the people of Jammu and Kashmir. A significant increase in the percentage of school access to and use of restrooms indicates a paradigm shift in people's attitudes toward open defecation. Apart from that, Swachh Vidyalaya activities played a crucial role in SDG 13.3 goals by promoting green schools while practicing green activities such as using jute bags, recycling plastic bottles and tires in terrace farming, sapling flower tress, as well as herbal plants, watering and care them, rainwater harvesting, organic compost making from leftover peels, participating in eco clubs, e which only conserve the plant species but also preserve flora and fauna of that ecosystem, recycling plastic waste preventing plastic pollution by which protects fishes, whale, birds, and other wild animals from the harmful effects of plastic and involving rural Schools in biogas production to produce green and clean energy. However, engaging learners in the eco-activities made them more empathetic towards nature. Hence, young stars become responsible and future decision-makers. Over 75% of students have agreed that their schools have made them realize the importance of green zones and plastic-free areas. (Mandal & Banerjee, 2023).

Subsequently, India ranked 109th out of 166 countries in the overall assessment of the Sustainable Development Goals in 2024. The mean score of 63.99 out of 100 has increased compared with 2005, when the mean score was 53.12. Notably, the most significant progressed score was noticed in Climate Action, which rose from 54 in 2020-21 to 67 in 2023-24(*Sustainable Development Report 2024*, n.d.). This data shows India's continuous efforts and commitment to reduce GHGs in gas and to save our mother Earth.

Swachh Vidyalaya activities included trash management source-wise and following the 3 "R" rules, planting trees, making an herbal garden /kitchen on school premises, using jute bags, rainwater harvesting, organic composting, avoiding plastic and reusing for gardening purposes, curriculum integration, judicial use of resources, behavioral and attitudinal shifts, capacity enhancement of teachers other staffs and community engagement program along with proper sanitation infrastructure and portable drinking water, is similar to GHG mitigation program in Schools from the United States focuses on solid waste and materials management such as reducing food waste, source reduction, green purchasing, recycling, composting and more emphasis on transportation control measure, energy efficiency product procurement. (U.S. Environmental Protection Agency, 2011)Furthermore, initiatives Australian schools take to make low-carbon schools include switching off protocol and behavior change activities. (Odell et al., 2021)

**Educational Implication**

- Climate Change education must be compulsory at all school levels, irrespective of state or central Curriculum.
- Schools should promote Greening Education in the "learning by doing method."
- Eco-clubs should be more emphasized.
- Teachers should use technology or Open Education Resources while teaching Climate change education.
- Proper monitoring mechanisms in schools are strictly maintained.
- Sensitizing children to use natural resources ethically and advocate sustainable development.
- Creativity should be nurtured through small projects in every class.
- A climate alert system should be started.
- Tune the learners to the present world by respecting the pledge. Think global, act locally.

## CONCLUSION

The Swachh Bharat Mission steps towards a revolutionary India, a pollution-free, green, and clean country, which would be a dedicated devotion to the nation and make it an ideal global citizen. Swachh Vidyalaya, as a part ofthe Swachh Bharat Mission, made an enormous mark on Indian society by instilling a sense of responsibility among future learners towards the mother environment through conservation and preservation of nature, as well as awakening their eco-consciousness and sensitivity to the future decision-makers. Moreover, Swachh Vidyalaya fosters critical and creative thinking and enhances problem-solving ability among the learners while involved in school greening activities.

**Future Direction**

The recent climate action agenda was held at the United Nations Climate Change Conference (UNFCCC COP-29) in Baku, Azerbaijan, to reduce greenhouse gas emissions and protect lives and livelihoods from the impacts of climate change—a robust policy to promote clean air and protect nature. The conference reaffirmed the commitment to collective action on the rising demand for cooling. The above future climate action initiative will be mainly addressed in educational institutions to change the actions necessary to combat environmental degradation or efforts in the global crisis.

**ABSTRACT**

The global demand for clean and sustainable energy has driven significant advancements in various scientific fields. This review analyzes recent progress in photovoltaic technologies, energy storage, catalytic processes, and energy policies, highlighting their roles in achieving a decarbonized energy future. In photovoltaics, the shift from silicon-based devices to advanced perovskite, tandem, and organic solar cells has led to power conversion efficiencies exceeding 26% and improvements in stability and scalability. Energy storage technologies, including lithium-ion, metal-air, and supercapacitors, are evaluated for their efficiency and cost-effectiveness. The review also discusses breakthroughs in electrocatalysis and nanostructured materials that enhance catalytic performance. Additionally, it examines energy policies such as carbon pricing and incentives that support the deployment of sustainable technologies. By identifying synergies and gaps in knowledge, this review provides a framework for future research and policy-making to promote global energy sustainability.

**Keywords:** Photovoltaics, Energy Storage Systems, Catalysis for Energy Conversion, Sustainable Energy Policy, Techno-Economic Analysis

## INTRODUCTION

The global energy landscape is undergoing a fundamental transformation in response to escalating climate change, fossil fuel depletion, and the increasing demand for clean and affordable energy. The transition toward a sustainable energy future has become a pressing priority for governments, industries, and research communities alike. According to the International Energy Agency (IEA), renewable energy sources are expected to contribute over 60% of global electricity generation by 2040, driven by commitments to achieve net-zero emissions targets. However, the

realization of this vision requires more than just the expansion of renewable power generation;it demands integrated solutions that address intermittency, energy storage, efficient conversion, and policy frameworks [1,2]. Photovoltaic technologies, electrochemical energy storage systems, and advanced catalytic processes are emerging as core enablers in this transformation. When coupled with coherent policy support and economic incentives, these technologies offer the potential to decarbonize major sectors, including power, transportation, and manufacturing. Despite significant individual advancements in each of these domains, a comprehensive, systems-level perspective that explores their convergence remains underrepresented in existing literature. This review seeks to fill that gap [3,4].The central aim of this review is to provide an integrative overview of the latest scientific and technological advancements in four key pillars of clean energy innovation: photovoltaics, energy storage and conversion, catalysis, and energy policy. The scope encompasses cutting-edge developments in high-efficiency solar cell technologies (including silicon, perovskite, tandem, and organic photovoltaics), state-of-the-art battery systems (such as lithium-ion, metal-air, flow, and aqueous batteries), and catalytic systems (including electrocatalysis, photocatalysis, thermal catalysis, and biocatalysis).Beyond technological progress, the review also examines the economic and regulatory mechanisms necessary for scaling and deploying these solutions globally. This includes analysis of carbon pricing, renewable energy subsidies, and lifecycle cost assessments. A cross-disciplinary lens is applied throughout the paper to identify synergies, integration pathways, and future research directions that can accelerate the deployment of sustainable energy systems. A comparative table is presented in Table 1 for summarizing the key sustainable energy technologies, including photovoltaics, batteries, and catalysis. It highlights their efficiency, energy density, cycle life, and technological maturity.

**Recent advances in photovoltaic technologies**

Photovoltaic (PV) technologies convert sunlight into electricity using semiconductors. When photons hit a solar cell's active layer, they create electron-hole pairs that are separated by a p-n junction's electric field, resulting in electrical current [5-8]. The efficiency of PV cells depends on light absorption, carrier generation and separation, charge transport, and minimizing recombination losses. Research has focused on optimizing these factors, leading to advancements from crystalline silicon cells to newer technologies like multi-junction, perovskite, and organic devices [9-13].

**Silicon-based solar cells: state-of-the-art**

Crystalline silicon (c-Si) solar cells dominate the commercial PV market, representing over 90% of global module production. Modern monocrystalline PERC technologies achieve power conversion efficiencies above 22%. Advances in surface passivation and light trapping are enabling the production of high-efficiency modules, with innovations like heterojunction with intrinsic thin layer (HIT) and tunnel oxide passivated contact (TOPCon) pushing efficiencies toward 25–26%. Researchers continue to enhance performance while reducing wafer thickness and energy consumption in production for improved cost-effectiveness and sustainability [14-16].

**Emerging photovoltaics**

**Perovskite solar cells**

Metal halide perovskite solar cells are a promising next-generation PV technology, valued for their tunable bandgaps, long carrier diffusion lengths, and high absorption coefficients. Since 2009, their certified efficiencies have increased from below 4% to over 26%, competing with silicon. Innovations in compositional engineering and interfacial layers have improved efficiency and stability, while all-perovskite tandem structures have achieved efficiencies over 29.5%. Despite these advancements, challenges like moisture sensitivity, lead toxicity, and long-term stability hinder commercialization [17,18].

**Organic and polymer solar cells**

Organic photovoltaic (OPV) devices use conjugated polymers and small molecules, offering advantages like flexibility, lightweight design, and low-temperature fabrication. While they have lower efficiencies than perovskite and silicon devices, recent OPVs have achieved over 19% power conversion efficiency. Innovations like non-fullerene acceptors, tandem layering, and morphological control have enhanced performance. OPVs are well-suited for niche

applications such as portable electronics, wearable solar, and indoor light harvesting, where aesthetics and form factor matter [19].

**Tandem and multi-junction cells**

Tandem and multi-junction PV devices optimize solar energy by combining materials with different bandgaps. Silicon–perovskite tandems are at the forefront, achieving over 30% efficiency in labs by stacking a high-bandgap perovskite top cell on a low-bandgap silicon or perovskite bottom cell, reducing thermalization losses. Although III–V semiconductor tandems theoretically offer efficiencies over 40%, they are expensive. Advances in interface engineering and thermal management are making tandem architectures the future of high-efficiency PV technologies. [20]. Comparative performance of PV technologies (Table 1).

**Energy storage and conversion technologies**

**Fundamentals of Electrochemical Energy Storage**

Electrochemical energy storage systems are essential for a decarbonised energy grid, storing electricity generated from renewable sources such as solar and wind. They convert electrical energy into chemical potential during charging, using components such as the anode, cathode, electrolyte, and separator. Key performance metrics include energy density, power density, cycle life, efficiency, and safety. Understanding thermodynamics and ion/electron transport is critical for optimizing these systems for various applications, from consumer electronics to large-scale grid storage [21-23].

**Lithium-ion batteries: advances and limitations**

Lithium-ion batteries (LIBs) are crucial for portable electronics, electric vehicles, and energy storage due to their high energy density (150–250 Wh/kg) and long cycle life (>3000 cycles). Recent advancements include silicon-based anodes and solid-state electrolytes, with commercial packs now exceeding 700 Wh/L. However, challenges such as raw material scarcity, thermal runaway risks, and environmental impacts from mining raise concerns about sustainability and energy security, prompting the search for alternative chemistries [24-26].

**Alternative battery technologies**

**Metal-air batteries**

Metal-air batteries, especially lithium-air and zinc-air, provide high theoretical energy densities (up to 1200 Wh/kg), making them promising for next-generation energy storage. They use oxygen from ambient air as the cathode reactant, reducing weight and complexity. Recent advances include stable solid electrolytes and bifunctional air electrodes. However, challenges like low round-trip efficiency, moisture sensitivity, and poor recharge ability still hinder practical use [27-29].

**Flow batteries**

Redox flow batteries (RFBs), including vanadium and zinc-bromine systems, are increasingly used for large-scale energy storage due to their flexible design, long cycle life (>10,000 cycles), and separated power and energy capacities. These systems utilize two electrolyte solutions stored in external tanks. Vanadium-based RFBs have been implemented for grid stabilization and renewable energy integration. However, they face challenges like low energy density (20–50 Wh/kg) and high initial costs, although advancements in electrolyte and stack design are enhancing their economic viability [30-33].

**Integration with renewable energy sources**

The integration of energy storage systems with renewable sources like photovoltaics and wind is crucial for managing their intermittency. Battery energy storage systems (BESS) are commonly used with solar farms for functions like time-shifting and peak shaving. Flow batteries excel in long-duration storage, while supercapacitors help smooth out power fluctuations. Hybrid systems combining batteries with supercapacitors or fuel cells are becoming popular for improving grid flexibility. Successful integration demands advancements in technology, power electronics, control systems, and grid interface standards. [34, 35]. A radar chart is presented in Fig. 1 for comparing

key energy storage technologies across five performance metrics: energy density, power density, cycle life, safety, and maturity. Comparing key energy storage technologies across five performance metrics: energy density, power density, cycle life, safety, and maturity (Fig. 1).

**Energy policy and economic analysis**

**Global Energy Demand and Emission Trends**

The global energy landscape is rapidly changing due to rising demand and the need to decarbonize. The International Energy Agency (IEA) projects that global energy demand will grow by about 25% by 2040, driven by population and economic growth in emerging economies. Currently, fossil fuels make up over 70% of energy consumption and are major contributors to greenhouse gas emissions. Transitioning to renewable sources like solar, wind, hydro, and bioenergy is essential for energy security and for limiting global temperature rise to below 1.5°C, as outlined in the Paris Agreement [36, 37].

**Renewable energy incentives and regulations**

Policy instruments and regulatory frameworks are crucial for promoting renewable energy technologies. Mechanisms like feed-in tariffs (FiTs), investment tax credits (ITCs), renewable portfolio standards (RPS), and net metering have been adopted globally to support solar, wind, and energy storage. In the EU, the Renewable Energy Directive establishes binding targets, while the U.S. utilizes various federal and state incentives. In Asia, countries such as India and China have implemented significant subsidy and auction programs [38, 39].

**Carbon pricing and climate mitigation strategies**

Carbon pricing is a crucial economic tool for addressing the environmental cost of carbon emissions, primarily through carbon taxes and cap-and-trade systems. Carbon taxes set a fixed price per ton of $CO_2$, while cap-and-trade systems limit total emissions and allow trading of allowances. As of 2024, over 60 jurisdictions have adopted carbon pricing, covering more than 20% of global emissions [40 - 42].

**Economic evaluation of emerging technologies**

Economic viability is crucial for deploying emerging energy technologies. Key metrics like levelized cost of electricity (LCOE), total cost of ownership (TCO), payback period, and return on investment (ROI) assess feasibility. Over the last decade, the LCOE for solar PV has dropped by over 80%, making it highly competitive. However, technologies like perovskite solar cells, solid-state batteries, and electrochemical $CO_2$ reduction still struggle with costs, scalability, and reliability [43].

**Barriers to implementation and policy recommendations**

Barriers to integrated clean energy systems include policy uncertainty, inadequate infrastructure, and socio-political resistance, along with the lack of standardized performance benchmarks and recycling frameworks. Effective policy should prioritize integrated planning and cross-sector coordination. Key recommendations involve establishing clear long-term policies, incentivising R and D and local supply chains, fostering public-private partnerships, and ensuring equitable access to clean energy, all aligned with global climate goals for a just energy transition. [44, 45]. Fig. 2 compares the Levelized Cost of Electricity (LCOE) for major energy technologies between 2020 and 2023. Levelized Cost of Electricity (LCOE) comparison: 2020 vs. 2023 (Fig. 2).

**Cross-disciplinary synergies and integration strategies**

**Photovoltaic - storage - catalysis interlinkages**

The integration of photovoltaic (PV) systems, energy storage, and catalysis technologies holds significant promise for creating resilient and decarbonized energy systems. While solar PV captures intermittent sunlight, it relies on energy storage solutions, like lithium-ion and flow batteries, to match energy generation with demand. Catalytic processes, including electrocatalysis and photocatalysis, enable solar-to-chemical energy conversion, such as producing green hydrogen. This green hydrogen can be stored, transported, or used as a feedstock in various industrial processes [46 - 48].

**System-level integration for grid and off-grid applications**

Integrating renewable energy technologies is essential for optimizing performance, reliability, and economic returns in both grid-connected and off-grid settings. For grid applications, combined PV-storage-catalysis systems aid in peak shaving, frequency regulation, and demand response, enhancing flexibility and stability. Smart inverters and hybrid energy management systems coordinate generation, storage, and conversion in real time. In off-grid areas, these systems offer tailored energy solutions, such as solar-powered microgrids and PV-electrolysis for clean fuels.

**Life cycle assessment and sustainability metrics**

Life cycle assessment (LCA) evaluates the environmental and resource impacts of energy technologies from production to disposal. It quantifies emissions, energy payback time, material usage, water consumption, and recyclability. For example, while solar PV modules have low operational emissions, the production of their components, such as silicon wafers, has significant environmental implications. Similarly, battery production raises concern over toxicity and mining impacts. Metrics like global warming potential and resource depletion aid in technology selection and policy development. Fig. 3 shows how PV, batteries, and catalysts can be integrated into a smart energy ecosystem. Schematic illustration of a smart energy ecosystem (Fig. 3).

**Challenges, research gaps, and future directions**

Advancements in photovoltaics, energy storage, catalysis, and energy policy face significant barriers to achieving a sustainable energy future. In photovoltaics, the stability of materials such as perovskites and organic semiconductors is compromised by moisture sensitivity and lead toxicity, alongside challenges in scaling high-efficiency, affordable, and environmentally compliant devices. Energy storage remains dominated by lithium-ion batteries, which encounter issues with raw materials and safety, although alternatives like solid-state and metal-air batteries show potential pending further developments in interfacial chemistry and recycling strategies. Catalytic applications for green hydrogen production and $CO_2$ reduction require innovative, non-precious catalysts with high efficiency and stability, compounded by the complexities of integrating systems for real-time solar input. The lack of understanding of atomic-level reaction mechanisms calls for advances in machine learning and computational techniques. From a systems perspective, interoperability, standardization, and control systems remain challenges in the integration of generation, storage, and conversion technologies. Intelligent energy management platforms are essential but requires further development. Future research must focus on holistic solutions that encompass grid dynamics and socio-political contexts. Interdisciplinary collaboration will be critical in designing scalable and equitable energy technologies. Prioritizing circular economy principles and fostering public awareness will support the transition to integrated clean energy systems, crucial for achieving climate neutrality and energy justice. The key challenges and future research directions are summarized in Table 2. Summary of key challenges and future research directions (Table 2).

## CONCLUSIONS

This review outlines recent advancements, integration strategies, and policy implications in photovoltaics, energy storage, and catalysis. The convergence of these areas underpins next-generation energy systems aimed at deep decarbonization, improved energy security, and economic resilience. Key insights include:

- Silicon solar cells dominate over 90% of the global PV market, with efficiencies of 22–24% and lab records near 26.8%. Perovskite solar cells have rapidly improved from 3.8% (2009) to over 26% (2023), though stability and toxicity issues hinder commercial viability. Tandem cells, particularly perovskite–silicon combinations, have exceeded 30% efficiency in lab tests, indicating potential for ultra-high efficiency systems.
- Lithium-ion batteries are dominant with energy densities of 150–250 Wh/kg, cycle lives over 3000 cycles, and round-trip efficiencies of around 90%. Flow batteries provide over 12,000 cycles but have low energy densities of 20–50 Wh/kg, suitable for stationary storage. Metal-air batteries have theoretical energy densities exceeding 1000 Wh/kg but struggle with recharge ability. Supercapacitors offer power densities over 10,000 W/kg and can last more than 100,000 cycles, making them ideal for high-power, short-duration applications.

- Invest in durable, scalable, and non-toxic materials for PV and battery systems. Advance integrated platforms for solar-fuel production and grid resilience. Standardize performance benchmarks and LCA protocols for fair technology assessment. Encourage international collaboration and open innovation in materials design and energy modeling. Design equitable policies that promote innovation while ensuring affordability and environmental justice.

## ABSTRACT

Noise-induced hearing loss (NIHL) is a prevalent and preventable condition resulting from prolonged exposure to excessive noise. Ayurveda describes *Tadarthkari Chikitsa* as a compensatory therapeutic approach that, though not directly counteracting the cause, still produces beneficial effects. To evaluate the efficacy of listening to *Om Uccharan* as a form of *Tadarthkari*Chikitsa in reducing symptoms of NIHL, compared with a control group receiving no intervention. A comparative interventional study was conducted on 60 individuals diagnosed with NIHL. Participants were randomly allocated to two groups: (1) Meditation Group (n=30) practicing Om Uccharan for 20 minutes daily for 60 days, and (2) Control Group (n=30) receiving no intervention. Outcome measures included pure-tone audiometry (PTA), NIHL Questionnaire, and Adult Temperament Questionnaire for psychological assessment. Data were analysed using paired t-tests and ANOVA. The meditation group showed significant improvement in PTA threshold values, self-reported hearing difficulties, and stress reduction compared with the control group ($p < 0.05$). No significant changes were observed in the control group. Om Uccharan, as *Tadarthkari* Chikitsa, may provide therapeutic benefits in NIHL management by reducing stress and enhancing auditory sensitivity. Larger randomized controlled trials are warranted.

**Keywords:** Noise-induced hearing loss, Om Uccharan, Tadarthkari Chikitsa, Ayurveda, Meditation, Auditory health

## INTRODUCTION

Noise-induced hearing loss (NIHL) is one of the most common occupational and environmental health concerns worldwide, with an estimated 16% of disabling hearing loss in adults attributable to noise exposure [1]. It significantly impairs auditory function, communication ability, and quality of life. In Ayurveda, sensory health is emphasized under *Indriya Chikitsa*. *Tadarthkari Chikitsa* refers to therapeutic measures that, though not addressing the root cause directly, alleviate distress and improve well-being [2]. Vibrational therapies, such as chanting and listening to *Om Uccharan*, have been traditionally described to balance the mind and senses [3]. Modern neuroscience supports that meditation and sound-based practices influence neuroplasticity, vagal stimulation, and stress pathways, thereby improving auditory processing [4,5,6]. Considering this, the present study was undertaken to evaluate the role of Om Uccharan as *Tadarthkari* Chikitsa in NIHL. The World Health Organization (WHO) 2021 report on preventing noise-induced hearing loss (NIHL) highlights that over 50% of hearing loss cases are preventable through public health measures. Key strategies include controlling exposure to loud sounds (below 80dB), using protective equipment, and implementing standards for personal audio devices, especially for the 12–35 age group [7].

## LITERATURE REVIEW

Ayurvedic texts such as *Charaka Samhita* and *Ashtanga Hridaya* mention the use of sound and mantra therapies in sensory impairments [2,3]. Contemporary studies on meditation and chanting highlight improved autonomic stability, reduced stress, and enhanced cognitive processing [4,6,8]. Research on vibroacoustic stimulation also suggests beneficial effects on auditory pathways [9-10].

### METHODS

**Study Design**

A 60-day prospective, comparative interventional study was conducted according to STROBE guidelines [11]. Ethical clearance was obtained from the institutional ethics committee, and written informed consent was taken from all participants.

**Participants:**

A total of 60 patients (age 25–55 years) diagnosed with NIHL were enrolled and randomly assigned into:

- **Group A (Meditation Group, n=30):** Practiced Om Uccharan (listening to guided Om chanting, 20 minutes daily).
- **Group B (Control Group, n=30):** Received no therapeutic intervention.

**Inclusion Criteria:**

- Diagnosed cases of NIHL with ≥25 dB HL threshold shift in audiometry.
- Chronic exposure to occupational or environmental noise.

**Exclusion Criteria**

- Patients with conductive or mixed hearing loss.
- History of ototoxic drug use, ear surgery, or psychiatric disorders.

**Intervention:**

Participants in the meditation group listened to the Om Uccharan audio for 20 minutes daily, preferably in the morning, for 60 consecutive days.

**Outcome Measures:**

1. **Pure-Tone Audiometry (PTA):** Assessment of hearing thresholds at baseline and after 60 days.
2. **NIHL Questionnaire:** Self-reported hearing difficulties and tinnitus-related symptoms.
3. **Adult Temperament Questionnaire:** Stress and psychological impact evaluation.

**Statistical Analysis:**

Pre- and post-intervention values were compared using paired t-tests. Between-group analysis was conducted using ANOVA.

## RESULTS

The present study evaluated the effect of a structured 10-minute meditation practice performed before and after work on adult temperament, NIHL questionnaire scores, and audiometric thresholds over a 60-day period, comparing an intervention group (Group I) with a control group (Group II).

**Adult Temperament Scale**

At baseline, mean Adult Temperament Scale scores were comparable between Group I (5.76) and Group II (5.73) as in table 1. Following meditation intervention, Group I demonstrated a progressive reduction in scores to 5.38 at 30 days and further to 4.90 at 60 days, indicating improvement in temperament parameters. In contrast, the control group showed a gradual increase from 5.73 at baseline to 5.96 at 30 days and 6.14 at 60 days, suggesting deterioration over time in the absence of intervention. The meditation group exhibited significant reduction in stress and irritability scores, while no changes were observed in the control group.

NIHL Questionnaire Assessment

Baseline NIHL questionnaire scores were similar between Group I (42) and Group II (41) as in table 2. After 30 days, Group I exhibited a reduction to 40, which further decreased to 37 at 60 days. Conversely, Group II demonstrated an increasing trend, with scores rising from 41 at baseline to 42 at 30 days and 45 at 60 days. These findings indicate subjective improvement in hearing-related symptoms and quality of life in the meditation group, while the control group experienced progressive worsening. NIHL Questionnaire scores decreased in the meditation group, indicating reduced hearing-related difficulties.

Audiometric Assessment

Audiometric thresholds showed as in table 3favorable changes in Group I across all tested frequencies after 60 days of meditation. At 0.5 kHz, thresholds improved from 34.20 dB to 32.77 dB; at 1 kHz from 39.92 dB to 38.32 dB; at 2 kHz from 43.93 dB to 42.47 dB; and at 4 kHz from 58.37 dB to 56.90 dB.In contrast, Group II exhibited deterioration at all frequencies: 0.5 kHz increased from 34.47 dB to 36.20 dB; 1 kHz from 39.82 dB to 41.35 dB; 2 kHz from 44.90 dB to 46.33 dB; and 4 kHz from 59.45 dB to 60.98 dB. These objective findings support the protective and stabilizing effect of meditation on auditory thresholds. The meditation group showed a significant reduction in mean PTA thresholds, especially at higher frequencies ($p < 0.05$). The control group showed no significant improvement.

## DISCUSSION

The present study demonstrates that regular short-duration meditation practiced before and after work produces measurable benefits in temperament, subjective hearing complaints, and audiometric thresholds over a 60-day period. Participants in the meditation group showed consistent improvement across psychological and auditory parameters, whereas the control group exhibited progressive deterioration. Improvement in Adult Temperament Scale scores among the meditation group suggests reduced emotional reactivity, enhanced coping ability, and improved stress modulation. This aligns with established evidence that meditation attenuates hypothalamic–pituitary–adrenal axis activation and sympathetic overdrive, thereby promoting autonomic balance. From an Ayurvedic perspective, meditation may contribute to Manasika Prasannata and regulation of Raja–Tama dominance,

indirectly supporting sensory organ function. The reduction in NIHL questionnaire scores in Group I indicates perceived improvement in hearing comfort and associated symptoms such as tinnitus, ear fullness, or listening fatigue. In contrast, rising scores in the control group reflect ongoing exposure-related auditory stress without mitigation. These findings highlight the relevance of mind–body interventions as adjunct strategies in occupational noise-related health conditions.

Audiometric results further corroborate these observations, with Group I demonstrating mild yet consistent improvements across low, mid, and high frequencies, particularly at 4 kHz, which is characteristically vulnerable in noise-induced hearing loss. The deterioration observed in Group II reflects the natural progression of NIHL in the absence of preventive measures. Meditation may exert its protective effect through improved cochlear microcirculation, reduced oxidative stress, and enhanced neurovascular regulation, mechanisms supported by emerging neurophysiological literature. Collectively, the findings suggest that brief, feasible meditation practices can serve as a supportive non-pharmacological intervention for mitigating early auditory dysfunction and improving psychological resilience among noise-exposed individuals. The integrative nature of this approach resonates with Ayurvedic preventive principles (Swasthavritta and Sadvritta), emphasizing lifestyle regulation for preservation of Indriya function.

This study demonstrates that Om Uccharan as *Tadarthkari* Chikitsa can play a supportive role in NIHL management. The therapeutic benefits may be attributed to:

- **Vibrational Healing:** Om chanting produces resonant frequencies that stimulate the auditory system and vagus nerve [8].
- **Stress Reduction:** Meditation decreases cortisol levels and enhances parasympathetic activity, indirectly improving auditory perception [12].
- **Neuroplasticity:** Repetitive sound patterns may promote cortical reorganization and improve sensory processing [13].

Our findings are consistent with earlier studies reporting the role of sound therapy and meditation in auditory health[14]. However, this is the first study integrating Ayurvedic principles of Tadarthkari Chikitsa with modern audiological assessment.

## CONCLUSION

Om Uccharan as *Tadarthkari* Chikitsa offers a promising, non-invasive, and holistic approach to mitigate NIHL symptoms. While findings are encouraging, future research with larger sample sizes, longer follow-up, and objective biomarkers is necessary to establish standardized therapeutic protocols.

### PROPOSED MECHANISM OF ACTION

- **Resonance Effect:** Om chanting produces frequencies around 136.1 Hz, resonating within the auditory canal and cochlea[8].
- **Vagal Stimulation:** Vibrations stimulate the auricular branch of the vagus nerve, improving parasympathetic tone[12].
- **Stress Pathway Modulation:** Reduction in sympathetic arousal lowers oxidative stress on cochlear hair cells[15].

### CLINICAL IMPLICATIONS

**Integrating Om Uccharan into NIHL rehabilitation programs may enhance outcomes by:**

- Improving auditory sensitivity.
- Reducing stress and tinnitus perception.

- Offering a safe, cost-effective adjunct to conventional audiological care.

**Limitations and Future Scope**

However, limitations include the short duration of follow-up and absence of biochemical stress markers. Future studies with larger sample sizes, longer observation periods, and incorporation of objective stress parameters are recommended to substantiate these preliminary findings.

**ABSTRACT**

The rapid increase in vehicular usage worldwide has significantly contributed to rising carbon emissions, leading to environmental degradation and climate instability. Conventional emission measurement methods rely on expensive exhaust analyzers, limiting scalability and real-time monitoring. This paper proposes a Deep Neural Network (DNN)-based vehicle carbon emission detection system that predicts $CO_2$ emission levels using standard vehicle attributes such as engine size, cylinders, fuel type, mileage, and vehicle weight. The model performs both regression ($CO_2$ prediction in g/km) and multi-class classification (Low, Medium, High emission categories). Experimental results demonstrate that the proposed deep learning approach achieves 91% classification accuracy, outperforming Logistic Regression (82%). The system provides a scalable, cost-effective, and intelligent solution for smart city environmental monitoring and sustainable transportation management.

**Keywords:** Carbon Emissions, Deep Neural Network (DNN), Vehicle attributes, $CO_2$ prediction, Classification accuracy

## INTRODUCTION

Transportation contributes approximately 25% of global greenhouse gas emissions. Increasing vehicle density due to urbanization and industrial expansion has intensified $CO_2$ emissions, a primary contributor to global warming.
Traditional emission measurement techniques require laboratory-grade exhaust analyzers, which are:

- Expensive
- Non-scalable

- Time-consuming
- Unsuitable for large-scale deployment

Machine Learning (ML) techniques have emerged as promising alternatives for emission prediction. However, classical models such as Linear Regression and Logistic Regression fail to capture nonlinear relationships among vehicle parameters. Deep Learning models, particularly Deep Neural Networks (DNNs), provide improved predictive capability through hierarchical feature extraction.

This paper presents a DNN-based emission detection system capable of:

1. Predicting $CO_2$ emission values (regression task)
2. Classifying vehicles into emission categories (classification task)

## LITERATURE REVIEW

The rapid evolution of environmental data analytics has led to the development of robust machine learning and deep learning algorithms for predicting emissions and monitoring air quality. Early research focused on regression-based emission modeling. Smith and Brown (2019) applied classical regression techniques for vehicle emission estimation. Lee and Kumar (2020) introduced decision tree-based approaches for $CO_2$ prediction. Subsequent studies explored ensemble and deep learning techniques. Ahmed and Zhao (2022) applied deep architectures to environmental datasets, while Chen *et al*. (2022) demonstrated high-precision $CO_2$ forecasting using gradient boosting. Hybrid neural network approaches have also shown improved industrial emission prediction performance. Johnson *et al*. (2021) compared various machine learning algorithms for emission forecasting. Patel *et al*. (2023) focused on hybrid ensemble learning, and Martinez and Lopez (2021) applied advanced ensemble models for predicting urban air pollutants. Banerjee and Das (2023) further refined the field through hybrid neural networks for industrial emission prediction. Rossi and Bianchi (2022) expanded deep learning into spatiotemporal domains, enabling dynamic air quality monitoring across time and space. Summary of Literature Review (Table 1).

## METHODOLOGY

**Dataset Description**

The dataset contains vehicle attributes including

- Engine Size (L)
- Number of Cylinders
- Fuel Type
- Turbocharged Status
- Transmission Type
- Fuel Consumption (City, Highway, Combined)
- Vehicle Weight

**The target variables are**

**$CO_2$ Emission (g/km)** – Regression

**Emission Class (E, C, D, S, A, X)** – Classification

**Data Preprocessing**

**Preprocessing is crucial for neural network performance**

**Handling Missing Values:** Numerical features (engine size, weight, mileage) are imputed using mean or median; categorical features (fuel type, vehicle class) are replaced using mode or "Unknown."

**Encoding Categorical Variables:** One-hot encoding converts categories to numerical vectors.

**Scaling Numerical Features:** Z-score standardization ensures faster convergence and stable gradients.

**Train–Test Split:** 80% of data for training, 20% for testing to prevent overfitting.

**Deep Neural Network Architecture**
The proposed DNN consists of:
**Input Layer** (vehicle attributes)
**Hidden Layer 1** – 128 neurons (ReLU)
**Hidden Layer 2** – 64 neurons (ReLU)
**Hidden Layer 3** – 64 neurons (ReLU)
**Output Layer 1** – Linear activation ($CO_2$ regression)
**Output Layer 2** – Softmax activation (Emission classification)

**The DNN model includes**
**ReLU activation:** Handles non-linearity and prevents vanishing gradients.
**Softmax output layer:** Produces probabilities for Low, Medium, High emission classes.
**Cross-entropy loss:** Optimized for multi-class classification.
**Adam optimizer:** Adaptive learning rates for faster convergence.
**Regularization:** L2 penalty + dropout layers reduce overfitting.

**Emission Classification Framework**
Deep Learning architecture designed for emission detection as shown in Figure 1. This deep learning architecture for vehicle emission detection begins with an input layer that collects raw vehicle features such as engine size, number of cylinders, fuel type, turbocharging, transmission type, and fuel consumption values in city, highway, and combined driving conditions. These inputs are preprocessed and passed into the hidden layers, which consist of three dense (fully connected) layers with 128, 64, and 64 neurons respectively, each using the ReLU activation function to capture complex nonlinear relationships between vehicle specifications and emission behavior. The output layer is designed for dual prediction tasks: a regression task that predicts the exact $CO_2$ emission in grams per kilometer using a linear output and Mean Squared Error (MSE) as the loss function, and a classification task that assigns the vehicle to an emission class (E, C, D, S, A, X) using softmax activation and Categorical Cross-Entropy loss, ultimately categorizing emissions into low, medium, or high levels. The entire model is optimized using the Adam optimizer, which adapts the learning rate for efficient training, ensuring that both regression and classification objectives are minimized simultaneously. Deep Learning Architecture for Vehicle Emission Detection(Figure 1)

**Vehicles are categorized based on predicted $CO_2$ levels:** (Table 2).
This framework simplifies emission monitoring and regulatory compliance.

## RESULTS AND DISCUSSION

The comparison between the gasoline car and the electric vehicle highlights the significant differences in $CO_2$ emissions and efficiency. The gasoline car, with a 2.0 L engine, 4 cylinders, and turbocharging, consumes fuel at 9.5 L/100km in the city and 6.5 L/100km on the highway, resulting in a predicted $CO_2$ emission of 180 g/km. This places it in Class D, representing a medium emission level as shown in table 3. While compliant with standard regulations, it is not highly efficient compared to newer low-emission vehicles. In contrast, the electric vehicle, with no engine or cylinders and zero fuel consumption, has a predicted $CO_2$ emission of 0 g/km, placing it in Class E as shown in table 3. This low emission level reflects high environmental efficiency and sustainability, as electric vehicles produce no tailpipe emissions and have minimal environmental impact during operation. The contrast between these vehicles underscores the potential of electric and alternative-fuel technologies in reducing carbon emissions and supporting cleaner transportation systems. Gasoline Car (Table 3). Electric Vehicle (Table 4) This classification system organizes vehicles by $CO_2$ emissions, linking ranges to emission levels and typical types, simplifying regulatory compliance and consumer understanding of environmental impact as shown in Table 5. Emission Class Thresholds (Table 5). Predicted vs Actual Comparison (Deep Learning vs Logistic Regression as shown in Table 6.

**Actual $CO_2$ Curve:** Represents the underlying true emission pattern.

**Deep Learning Predictions**
- Extremely close alignment with actual curve.
- Minimal fluctuations.
- Strong adaptation to sudden emission pattern changes.
- Captures nonlinear boundaries efficiently.

**Logistic Regression Predictions**
- Reasonably close fit but lacks deep pattern extraction.
- Limited capacity to model nonlinear relationships.
- Slightly higher variance compared to deep learning.

**Deep Learning and Logistic Regression Model Behavior (Table 6).**

**Model Performance Comparison**

Table 7 presents a comparative analysis of Deep Learning and Logistic Regression models. The Deep Learning model achieved an accuracy of 0.91, outperforming Logistic Regression, which recorded an accuracy of 0.82. Similarly, Deep Learning showed superior performance in precision (0.89 vs. 0.80) and recall (0.87 vs. 0.78). As illustrated in Table 7 and Graph 1, Deep Learning demonstrates a 9% improvement in classification accuracy over Logistic Regression. The results clearly indicate that Deep Learning outperforms Logistic Regression across all evaluation metrics. The neural network significantly reduces false positives, thereby improving precision, and minimizes false negatives, leading to better recall. This improvement is primarily attributed to its enhanced nonlinear boundary detection capability, supported by activation functions such as ReLU and Softmax. Unlike simple mathematical classifiers, deep models can learn complex and nonlinear emission patterns, resulting in improved generalization capability and more accurate prediction of emission levels. Deep Learning Vs Logistic Regression (Table 7). Logistic Regression Vs Deep Learning (Graph 1).

## CONCLUSION

This study demonstrates that Deep Neural Networks significantly outperform classical Logistic Regression models in vehicle $CO_2$ emission classification. The proposed system provides a scalable and intelligent alternative to traditional exhaust-based measurement systems.

**The model is suitable for:**
- Smart city monitoring systems
- Automated vehicle inspection centers
- Environmental regulatory enforcement
- Sustainable transportation planning

Future work includes integrating IoT sensor data, explainable AI techniques, and real-time cloud deployment for large-scale emission monitoring.

**ABSTRACT**

The integration of technology in sports pedagogy has significantly transformed instructional delivery. This experimental investigation examined the comparative effectiveness of Computer-Assisted Instructional Training (CAIT), Traditional Instructional Training (TIT), and Combined Instructional Training (CIT) on playing ability and cognitive knowledge among intercollegiate kabaddi players. Thirty-six male athletes (aged 19--28 years) were randomly assigned into three groups (n=12 each). The intervention lasted eight weeks. Playing ability was evaluated using expert rating scales, and cognitive knowledge was assessed through a validated questionnaire. Analysis of covariance (ANCOVA) revealed statistically significant differences among groups, $F(2,32)=8.96$, $p<.001$, with a large effect size (partial $\eta^2=.42$). The CIT group demonstrated superior improvements. Findings suggest hybrid instructional frameworks provide optimal conditions for motor learning in competitive sport environments.

**Keywords:** Computer-assisted instruction, hybrid coaching, motor learning, kabaddi, multimedia learning

## INTRODUCTION

The evolution of instructional technologies has substantially influenced pedagogical practices across educational domains, including sports training and physical education. Contemporary athletic preparation extends beyond physical conditioning and technical repetition, incorporating cognitive development, perceptual training, and tactical intelligence. In high-performance sport environments, the ability to process information rapidly, anticipate opponent movement, and execute technically precise actions under pressure has become as important as physiological capacity. Consequently, coaching methodologies must adapt to integrate cognitive engagement with motor learning processes. Kabaddi, a traditional combative team sport originating in the Indian subcontinent, presents unique physiological and psychological demands. The sport requires explosive strength, agility, breath control, proprioceptive awareness, and rapid decision-making. Offensive maneuvers such as hand touch, toe touch, and kicking, as well as defensive techniques including ankle hold, waist hold, and blocking, require coordinated neuromuscular execution combined with tactical anticipation. Unlike many invasion games, kabaddi integrates continuous chanting (cant), high-intensity bursts of movement, and strategic timing within confined spatial boundaries. These distinctive characteristics necessitate instructional approaches that simultaneously enhance motor proficiency and cognitive understanding of game situations. Traditional instructional training (TIT) has historically dominated kabaddi coaching practices. This approach primarily involves verbal explanation, live demonstration by the coach, and repeated skill rehearsal under supervision. While repetition-based practice supports motor consolidation through reinforcement mechanisms, it may not sufficiently stimulate higher-order cognitive processes such as tactical reasoning, spatial awareness, and anticipatory judgment. Moreover, traditional methods often depend heavily on the coach's ability to visually demonstrate technique in real time, which may limit the learner's opportunity to observe subtle biomechanical components repeatedly or from multiple perspectives. The rapid integration of digital technology into sport education has introduced Computer-Assisted Instruction (CAI) as an alternative pedagogical tool. CAI employs multimedia resources such as slow-motion video, motion analysis, visual overlays, and interactive feedback systems to enhance understanding of technical execution. Through repeated visualization, learners can examine movement phases, joint alignment, and timing patterns with greater clarity than traditional demonstration alone may provide.

From a motor learning perspective, visual modeling strengthens neural encoding during the cognitive stage of skill acquisition, facilitating smoother transition into associative refinement stages. Beyond motor performance, CAI has potential implications for cognitive development. Multimedia learning environments may reduce extraneous cognitive load by presenting structured visual and auditory information simultaneously. Athletes can process tactical scenarios, defensive positioning strategies, and spatial configurations in a controlled and repeatable manner. Such exposure may enhance game intelligence and decision-making accuracy during live match situations. Despite the theoretical advantages of technology-enhanced instruction, exclusive reliance on digital tools may not fully replace the corrective immediacy and motivational influence of direct coach-athlete interaction. The coach's role in providing biomechanical correction, contextual adaptation, and psychological encouragement remains fundamental. Therefore, integrating both approaches into a Combined Instructional Training (CIT) framework may create complementary benefits. Hybrid instructional models could allow athletes to first internalize visual representations of skills through multimedia exposure and subsequently refine technique through live correction and guided practice. Although technology-assisted learning has been investigated in various sports contexts, empirical evidence examining hybrid instructional models in indigenous combative sports such as kabaddi remains limited. Most existing research has focused on laboratory-based motor tasks or technologically advanced sports disciplines. Consequently, there is a need for systematic experimental evaluation within kabaddi training environments to determine whether multimedia integration enhances both performance and cognitive outcomes. The present study was designed to address this research gap by comparing the effectiveness of Computer-Assisted Instructional Training (CAIT), Traditional Instructional Training (TIT), and Combined Instructional Training (CIT) on selected motor skills and cognitive knowledge among intercollegiate kabaddi players. By employing an experimental design with controlled

intervention duration, this investigation aims to provide evidence-based guidance for modernizing kabaddi coaching practices within collegiate sport systems.

## Theoretical Framework

**Motor Learning Theory**

Motor learning theory provides a foundational framework for understanding how athletes acquire, refine, and automate complex movement patterns. The classical model proposed by Fitts and Posner (1967) conceptualizes skill acquisition as a progression through three distinct but overlapping stages: the cognitive stage, the associative stage, and the autonomous stage. Each stage represents qualitative changes in the learner's performance characteristics, attentional demands, and feedback requirements. During the cognitive stage, learners are introduced to the fundamental structure of a skill. Performance at this phase is typically inconsistent, marked by frequent errors and high levels of conscious attention. Athletes attempt to understand the sequence of movements, body positioning, timing, and coordination required for correct execution. In the context of kabaddi, this stage involves grasping the mechanics of offensive maneuvers such as hand touch, toe touch, and kicking, as well as defensive techniques including ankle hold and blocking. Learners at this phase depend heavily on clear demonstrations, verbal cues, and visual guidance. Because attentional resources are limited, structured multimedia representations may assist in clarifying movement components, reducing ambiguity, and enhancing perceptual recognition of correct technique. The associative stage is characterized by gradual refinement of movement patterns. Errors decrease in frequency and magnitude, and athletes begin to detect and correct their own mistakes. Motor output becomes smoother and more coordinated as neural pathways associated with the skill are strengthened through repetition. Feedback during this stage shifts from general instruction to more specific biomechanical correction. In kabaddi training, this phase may involve improving the timing of a raid entry, optimizing body alignment during defensive holds, or adjusting foot placement to maintain balance under contact pressure. At this stage, augmented feedback provided through video replay or slow-motion analysis can accelerate error detection and facilitate deeper kinesthetic awareness.

The final autonomous stage reflects highly efficient and automatic execution of the skill. Movements require minimal conscious control, allowing athletes to allocate attentional resources toward tactical decision-making and environmental scanning. In competitive kabaddi scenarios, autonomous skill performance enables players to anticipate opponent strategies, maintain spatial awareness, and execute rapid transitions between offense and defense without cognitive overload. Automaticity is critical in high-pressure match situations where reaction time and adaptability determine success. From a neurophysiological perspective, motor learning involves progressive strengthening of synaptic connections and improved coordination between cortical and subcortical structures. Early learning engages higher cortical regions associated with conscious processing, whereas advanced stages demonstrate increased efficiency within motor circuits, including the basal ganglia and cerebellum. Repetitive practice combined with structured feedback enhances motor memory consolidation, enabling smoother execution and improved retention. The integration of Computer-Assisted Instructional Training (CAIT) within this theoretical framework may primarily support the cognitive and associative stages of learning. Multimedia demonstrations provide repeated visual exposure to correct movement execution, facilitating mental representation of the skill. Video-based modeling may enhance observational learning mechanisms, thereby accelerating the transition from initial understanding to coordinated execution. When combined with traditional coach-led correction in a hybrid instructional model, learners may receive both augmented visual input and immediate biomechanical feedback, optimizing progression toward autonomous performance. Thus, motor learning theory not only explains the sequential nature of skill acquisition but also provides theoretical justification for comparing traditional, computer-assisted, and combined instructional approaches in kabaddi training environments.

**Observational Learning Theory**

Observational Learning Theory, rooted in Bandura's (1986) Social Cognitive framework, posits that individuals acquire new behaviors, skills, and cognitive patterns through the observation of models. Unlike purely trial-and-

error learning, observational learning enables skill acquisition without direct physical practice during initial exposure. This mechanism is particularly relevant in sport contexts, where visual modeling can accelerate motor encoding and reduce early-stage performance errors.

**Bandura identified four essential processes underlying observational learning:** {attention}, {retention}, {motor reproduction}, and {motivation}. First, learners must selectively attend to relevant aspects of the modeled behavior. In kabaddi, this involves focusing on body alignment during an ankle hold, foot placement during a toe touch, or trunk positioning during defensive blocking. Multimedia video presentations enhance attentional focus by isolating movement phases, zooming into joint actions, and replaying sequences in slow motion. Second, retention refers to the cognitive representation of observed behavior. Athletes encode visual information into symbolic memory structures that can later guide physical execution. Repeated video observation strengthens mental imagery and movement schemata, facilitating recall during practice sessions. In combative sports such as kabaddi, where rapid decision-making is required, strong mental representation of technique contributes to faster motor planning. Third, motor reproduction involves translating cognitive representation into coordinated physical movement. During this stage, learners attempt to replicate the observed action. The availability of repeated visual feedback through computer-assisted systems supports refinement of movement accuracy. By comparing their own performance with expert models, athletes engage in self-correction processes that enhance neuromuscular coordination. Fourth, motivation influences whether the observed behavior is ultimately performed and retained. Reinforcement, perceived success, and coach encouragement strengthen the likelihood of reproducing modeled actions. In hybrid instructional settings, combining multimedia modeling with direct coach feedback may enhance motivational engagement and confidence. From a neuro physiological perspective, observational learning is associated with activation of the mirror neuron system, which responds both when an individual performs an action and when observing the same action performed by others. This neural mirroring facilitates internal simulation of movement patterns, promoting motor priming even before physical execution occurs. In kabaddi training, repeated video modeling may therefore pre-activate motor circuits, accelerating the transition from cognitive understanding to coordinated execution. The interaction between observational learning and multimedia-based cognitive processing plays an important role in facilitating neural encoding during the early stages of motor skill acquisition. During the cognitive stage, athletes rely heavily on visual information to develop internal representations of movement patterns. Multimedia demonstrations, such as slow-motion video analysis and segmented visual presentations, allow learners to repeatedly observe biomechanical sequences including body alignment, timing, and spatial positioning during kabaddi techniques such as toe touch, hand touch, and defensive holds. This repeated visual exposure strengthens neural encoding of the motor pattern and enhances perceptual–motor coupling. As learners progress to the associative stage, video replay and guided practice enable athletes to compare their own performance with expert models, facilitating error detection and motor refinement. Through this process, neural representations of the skill become progressively stabilized, leading to improved coordination, movement efficiency, and performance accuracy. Within the context of the present study, Computer-Assisted Instructional Training (CAIT) leverages observational learning by providing structured visual models of correct technique. When integrated with traditional coaching in a Combined Instructional Training (CIT) framework, athletes benefit from both neural priming through observation and biomechanical refinement through live feedback.

**Multimedia Learning Theory**

Multimedia instructional environments also support motor learning by optimizing cognitive load. Complex kabaddi skills require simultaneous control of breathing rhythm, spatial positioning, and anticipation of defenders. Structured multimedia presentations segment these components into manageable phases and distribute information across visual and auditory channels. This instructional design reduces extraneous cognitive load and allows athletes to focus cognitive resources on meaningful schema construction and motor planning. The dual-channel assumption posits that humans process visual and auditory information through partially independent cognitive systems. When instructional material integrates synchronized narration with visual demonstration, learners distribute cognitive load across both channels, enhancing overall comprehension. In kabaddi instruction, presenting a slow-motion video of a defensive block while simultaneously providing concise verbal explanation may facilitate deeper understanding than

either modality alone. The {limited capacity assumption} acknowledges that working memory has finite processing resources. Excessive or poorly organized information may overwhelm cognitive capacity, leading to reduced retention. Effective multimedia design therefore requires clarity, coherence, and elimination of extraneous details. Structured CAI modules that focus exclusively on key movement phases, tactical cues, and spatial orientation may reduce unnecessary cognitive load and improve schema construction. The {active processing assumption} suggests that meaningful learning occurs when learners actively select relevant information, organize it into coherent mental structures, and integrate it with prior knowledge. Multimedia tools that segment skill components—such as dividing a raid into approach, contact, and retreat phases—may enhance organizational processing. Additionally, interactive pause-and-replay functions encourage learner engagement and reflective analysis. Cognitive Load Theory further differentiates between intrinsic, extraneous, and germane load. Intrinsic load relates to task complexity, which in kabaddi may involve coordinating breath control, balance, and opponent anticipation simultaneously. Extraneous load arises from poorly designed instructional material, while germane load represents productive cognitive effort directed toward schema formation. Multimedia instruction, when designed effectively, reduces extraneous load and increases germane load, thereby facilitating efficient learning. In relation to the current investigation, CAIT utilizes multimedia principles to enhance comprehension of biomechanical and tactical components of kabaddi skills. However, exclusive reliance on multimedia may limit contextual adaptation and individualized correction. Therefore, integrating Multimedia Learning Theory with live coach demonstration in a Combined Instructional Training model may optimize both cognitive processing and practical application. Collectively, Observational Learning Theory and Multimedia Learning Theory provide complementary explanations for why hybrid instructional approaches may produce superior improvements in both motor performance and cognitive knowledge among intercollegiate kabaddi players.

## METHODOLOGY

**Research Design**

The study employed a randomized controlled experimental pre-test--post-test design to evaluate the comparative effectiveness of three instructional approaches: Computer-Assisted Instructional Training (CAIT), Traditional Instructional Training (TIT), and Combined Instructional Training (CIT). The design was selected to control for baseline differences among participants and to allow statistical adjustment of pre-intervention scores through Analysis of Covariance (ANCOVA). Random assignment was performed using a simple lottery method to ensure equal probability of allocation to each group. This procedure minimized selection bias and enhanced internal validity. Pre-test assessments were conducted one week prior to the intervention, and post-test evaluations were administered within one week of completion of the eight-week training program.

**Participants**

Thirty-six male intercollegiate kabaddi players were recruited from affiliated colleges. Inclusion criteria were:

- Age between 19 and 28 years
- Minimum of 10 years of competitive kabaddi experience
- Active participation in intercollegiate tournaments
- No musculoskeletal injuries during the previous six months

**Participants were randomly assigned into three groups (n=12 each):** CAIT, TIT, and CIT.

All participants provided informed consent prior to participation. The study adhered to ethical guidelines for human research in sports sciences.

**Sample Size Justification**

An a priori power analysis was conducted to determine the minimum sample size required to detect statistically meaningful differences among instructional groups. Power estimation was performed using G*Power (Version 3.1), assuming a fixed-effects one-way ANCOVA design with three groups, one covariate (pre-test score), an alpha level of

.05, and statistical power of .80. Based on previous research in motor learning and technology-assisted instruction, a medium-to-large effect size (f = 0.35) was assumed. Under these parameters, the required total sample size was estimated at N = 33 participants. To account for potential attrition and to maintain balanced group allocation, the sample size was increased to 36 participants, resulting in 12 participants per group. The achieved sample size provided adequate statistical power to detect significant group differences in both playing ability and cognitive knowledge. Post hoc power analysis based on the observed effect size indicated statistical power exceeding .90, confirming that the study was sufficiently powered to detect meaningful instructional effects. From a practical standpoint, the sample size was also constrained by the availability of eligible intercollegiate kabaddi players meeting inclusion criteria. Nevertheless, equal group allocation and randomized assignment strengthened internal validity and minimized bias. The combination of statistical power analysis and practical feasibility supports the adequacy of the sample size for experimental evaluation.

**Variables**

**Independent Variable**

Type of Instructional Training:

**CAIT** (Computer-Assisted Instructional Training)

**TIT** (Traditional Instructional Training)

**CIT** (Combined Instructional Training)

**Dependent Variables**

- Playing Ability
- Cognitive Knowledge

**Instrumentation**

**Playing Ability Assessment**

Playing ability was evaluated using a standardized expert rating scale designed to assess execution quality of offensive and defensive kabaddi skills. Three national-level certified coaches independently rated each participant. Inter-rater reliability was calculated using the Intraclass Correlation Coefficient (ICC), yielding a value of .89, indicating high reliability.

**Cognitive Knowledge Questionnaire**

Cognitive knowledge was assessed using a 30-item structured questionnaire covering:

- Rules and regulations
- Tactical positioning
- Offensive and defensive strategies
- Game situational awareness

Content validity was established through expert review by five subject specialists. Reliability analysis using Cronbach's alpha produced a coefficient of .86, indicating strong internal consistency.

**Training Protocol**

The intervention lasted eight weeks, with five sessions per week (total 40 sessions). Each session lasted 60 minutes.

**CAIT Group**

- 20 minutes of structured multimedia instruction
- Slow-motion video analysis
- Visual breakdown of movement phases
- 40 minutes supervised practical drills

**TIT Group**

- 20 minutes lecture and live demonstration

- Immediate corrective verbal feedback
- 40 minutes supervised practical drills

**CIT Group**

- 10 minutes multimedia instruction
- 10 minutes live demonstration
- 40 minutes supervised practice with immediate correction

Attendance was monitored, and all participants completed at least 95\% of training sessions.

**Statistical Assumptions**

Prior to conducting Analysis of Covariance (ANCOVA), the underlying statistical assumptions were examined to ensure the validity of inferential results.

**Normality**

The assumption of normal distribution for dependent variables was assessed using the Shapiro–Wilk test and visual inspection of Q–Q plots. Results indicated no significant deviation from normality ($p > .05$). Skewness and kurtosis values were within acceptable limits (±1), supporting normal distribution of playing ability and cognitive knowledge scores.

**Homogeneity of Variance**

Levene's test was performed to examine equality of variances across instructional groups. The results were non-significant ($p > .05$), confirming homogeneity of variance for both dependent variables.

**Linearity.**

Scatterplots were inspected to verify a linear relationship between the covariate (pre-test scores) and post-test dependent variables. The relationship was observed to be linear, satisfying this assumption.

**Homogeneity of Regression Slopes**

An interaction term between group and pre-test scores was tested to determine whether regression slopes were equal across groups. The interaction effect was non-significant ($p > .05$), indicating that the assumption of homogeneity of regression slopes was met.

**Independence of Observations**

Independence was ensured through randomized group allocation and separate training sessions for each instructional group.

**Multicollinearity**

Correlation analysis between covariates and dependent variables showed moderate but non-problematic correlations ($r < .80$), indicating absence of multicollinearity. Since all assumptions were satisfied, ANCOVA was deemed appropriate for comparing adjusted post-test means among instructional groups.

**Statistical Analysis**

Data analysis was conducted using SPSS (Version XX).

**The following analyses were performed**

- Paired sample t-test (within-group improvements)
- ANCOVA controlling for pre-test scores
- Scheffé post hoc test
- Effect size (partial $\eta^2$)

**Prior to ANCOVA, assumptions were tested**

- Normality (Shapiro-Wilk test)
- Homogeneity of variance (Levene's test)
- Homogeneity of regression slopes
- All assumptions were satisfied ($p > .05$).

## RESULTS

**Descriptive Statistics**

ANCOVA revealed statistically significant differences among groups. Mean Playing Ability Scores Mean and Standard Error (Figure 1). Mean Cognitive Knowledge Scores Mean and Standard Error (Figure 2). Table 1 presents adjusted post-test means after controlling for baseline scores. The CIT group demonstrated the highest adjusted means for both dependent variables.

**ANCOVA Results**

ANCOVA revealed statistically significant differences among groups.

The effect size for instructional method was partial $\eta^2 = .42$, indicating a large effect according to conventional benchmarks.

**Post Hoc Analysis**

**Scheffé post hoc comparisons revealed**

- CIT significantly outperformed TIT ($p < .01$)
- CIT significantly outperformed CAIT ($p < .05$)
- CAIT showed moderate improvement compared to TIT

**Interpretation of Effect Size**

The observed partial $\eta^2$ value of .42 indicates that approximately 42% of the variance in post-test performance can be attributed to the instructional intervention after controlling for baseline scores. Because ANCOVA statistically adjusts for pre-test differences, the observed effect largely reflects the impact of the instructional modality rather than pre-existing variations in skill level or experience. Random assignment of participants further minimized potential confounding influences such as prior competitive exposure or tactical knowledge.

## DISCUSSION

The present investigation examined the comparative effectiveness of Computer-Assisted Instructional Training (CAIT), Traditional Instructional Training (TIT), and Combined Instructional Training (CIT) on motor skill acquisition and cognitive knowledge among intercollegiate kabaddi players. The findings revealed that although all three instructional approaches resulted in statistically significant improvements, the Combined Instructional Training (CIT) group demonstrated superior gains in both playing ability and cognitive performance. The observed large effect size (partial $\eta^2 = .42$) indicates not only statistical significance but also substantial practical relevance within competitive sport training contexts. The superiority of the hybrid instructional model may also be explained through the interaction between observational learning and multimedia cognitive processing. During the cognitive stage of motor skill acquisition, athletes rely heavily on visual information to construct internal representations of movement patterns. Multimedia demonstrations allow repeated observation of biomechanical sequences such as body alignment, timing, and spatial positioning during kabaddi techniques. This repeated exposure facilitates neural encoding of the motor pattern, strengthening perceptual–motor coupling. During the associative stage, video replay and guided practice enable athletes to refine these neural representations through feedback and error correction, leading to improved coordination and execution efficiency. Observational Learning Theory further supports these findings.

Repeated exposure to expert-modeled actions through video presentation activates cognitive encoding processes and potentially primes motor circuits via neural mirroring mechanisms. When athletes subsequently engage in physical practice, the pre-activated motor representations may reduce initial error rates and increase movement efficiency. The combination of observation and supervised execution appears to strengthen retention and motor consolidation more effectively than either method alone. The improvement in cognitive knowledge within the CIT and CAIT groups can be attributed to the structured presentation of information through multimedia formats. Visual segmentation of skill components, synchronized verbal explanation, and replay functions likely enhanced schema formation and reduced extraneous cognitive load. In contrast, traditional instruction, while effective in conveying procedural guidance, may not provide repeated exposure to complex tactical scenarios in the same structured manner. The integration of visual and auditory channels appears to have facilitated deeper processing and improved retention of rules, strategies, and situational awareness. The large effect size observed in this study suggests meaningful practical implications. A partial $\eta^2$ of 0.42 indicates that approximately 42% of the variance in post-intervention performance can be attributed to instructional method after controlling for baseline differences. In applied sport settings, such magnitude represents a considerable enhancement in training efficiency. For competitive kabaddi programs, even marginal improvements in reaction time, coordination, and tactical judgment can influence match outcomes. Therefore, adopting hybrid instructional frameworks may provide a competitive advantage. While CAIT alone demonstrated notable improvements, it did not surpass the combined model. This suggests that exclusive reliance on technology may lack contextual adaptability and individualized correction.

Direct coach interaction provides immediate biomechanical adjustment, motivational reinforcement, and situational adaptation that multimedia tools cannot fully replicate. Thus, rather than replacing traditional coaching, technology appears most effective when integrated strategically within a structured pedagogical framework. Video-based modeling used in multimedia instruction may also stimulate the mirror neuron system, which activates both during action execution and observation. Repeated observation of expert demonstrations in kabaddi may therefore prime neural circuits responsible for movement planning and coordination. This neural priming may enhance anticipatory decision-making during raiding and defensive situations, as players become more capable of recognizing movement cues and responding rapidly to opponent actions. Despite its strengths, the study has limitations. The sample size was restricted to male intercollegiate athletes, which may limit generalizability to female players or elite professional populations. The intervention duration was eight weeks; longer-term follow-up could provide insight into retention and transfer effects. Additionally, biomechanical motion analysis was not employed, which may have provided objective performance metrics beyond expert ratings. Future research should investigate longitudinal effects of hybrid instructional training, include female athletes, and integrate motion-tracking technologies to quantify kinematic improvements. Exploring psychological variables such as motivation, confidence, and decision-making speed may further clarify the mechanisms underlying hybrid training effectiveness. In conclusion, the findings demonstrate that integrating multimedia learning principles with traditional coaching methods produces superior improvements in both motor performance and cognitive knowledge. Hybrid instructional training represents a theoretically grounded and practically effective model for advancing kabaddi pedagogy in contemporary collegiate sport environments.

## LIMITATIONS AND FUTURE RESEARCH

Future research should integrate biomechanical motion-tracking technologies and neurocognitive performance measures to determine whether observed improvements reflect genuine motor learning rather than temporary performance gains. High-speed motion analysis, wearable inertial sensors, and reaction-time based perceptual–cognitive assessments could provide objective indicators of skill refinement and decision-making efficiency in kabaddi training environments.

## PRACTICAL APPLICATIONS

The findings of the present study provide meaningful implications for coaches, sport administrators, curriculum planners, and institutional policymakers involved in kabaddi training and physical education programs. Given the demonstrated superiority of Combined Instructional Training (CIT), practical integration of multimedia-based learning with traditional coaching methodologies may enhance both skill acquisition and cognitive development in competitive environments. First, kabaddi academies and collegiate training centers should consider the structured incorporation of video-based instructional modules within regular practice schedules. Multimedia content may include slow-motion breakdown of offensive techniques such as hand touch, toe touch, and kicking, as well as defensive maneuvers like ankle hold and blocking. Segmenting complex skills into discrete phases—approach, execution, and recovery—can facilitate clearer biomechanical understanding. Coaches may allocate a brief but consistent period within each training session for visual modeling prior to on-field execution. This sequencing aligns with motor learning principles, allowing athletes to construct accurate mental representations before physical practice. Second, the development of digital skill repositories can provide sustained learning opportunities beyond scheduled practice hours. Institutions may create curated libraries containing annotated match footage, expert demonstrations, tactical scenarios, and rule interpretations. Such repositories can be hosted on institutional learning management systems or secure digital platforms accessible to registered athletes. The availability of on-demand video resources enables self-directed learning, reinforces retention, and supports revision before competition. In addition, archiving player performance footage for comparative analysis can foster reflective practice and promote continuous improvement.

Third, hybrid instructional frameworks should be embedded within physical education and coaching certification curricula. Teacher training programs can integrate modules on multimedia content design, video analysis techniques, and technology-assisted feedback strategies. Preparing future coaches to effectively combine digital tools with traditional pedagogical skills ensures sustainable implementation. Rather than replacing conventional instruction, technology should serve as an augmentation tool that enhances demonstration clarity, feedback precision, and learner engagement. Furthermore, structured hybrid training models may be particularly valuable in resource-constrained environments. Even basic recording devices and free video-editing software can produce effective instructional materials. Therefore, adoption of hybrid methods does not necessarily require advanced infrastructure but rather systematic planning and pedagogical adaptation. At the competitive level, hybrid training may contribute to improved tactical intelligence. By repeatedly analyzing game situations through multimedia platforms, athletes can enhance anticipatory skills and decision-making accuracy under pressure. Coaches may incorporate scenario-based video simulations to prepare players for high-stakes match contexts, thereby strengthening psychological readiness alongside technical competence. Finally, governing bodies and sport federations may consider promoting technology-assisted training guidelines within national development programs. Standardized digital content aligned with official rules and skill standards could ensure consistency in instructional quality across institutions. Overall, the practical application of hybrid instructional training extends beyond immediate performance gains. It represents a strategic modernization of kabaddi pedagogy, fostering sustainable athlete development, cognitive sophistication, and competitive excellence.

## CONCLUSION

The present study systematically examined the comparative effectiveness of Computer-Assisted Instructional Training (CAIT), Traditional Instructional Training (TIT), and Combined Instructional Training (CIT) on motor skill acquisition and cognitive knowledge among intercollegiate kabaddi players. The findings demonstrated that although all instructional approaches contributed to measurable improvements, the hybrid model integrating multimedia-based learning with direct coach-led instruction produced the most substantial gains in both performance execution and cognitive understanding. The observed large effect size underscores the practical significance of instructional methodology in shaping athlete development. By combining visual modeling, structured

feedback, and real-time biomechanical correction, the hybrid approach appears to facilitate more efficient progression through stages of motor learning while simultaneously strengthening tactical awareness and rule comprehension. These outcomes reinforce the theoretical foundations of motor learning theory, observational learning mechanisms, and multimedia cognitive processing frameworks. Beyond statistical validation, the study contributes to the modernization of kabaddi pedagogy by providing empirical evidence supporting technology-integrated training systems within indigenous sports contexts. The results suggest that instructional design plays a critical role in optimizing training efficiency, particularly in sports that demand rapid perceptual decision-making and precise motor coordination. Importantly, the findings do not advocate replacing traditional coaching methods; rather, they emphasize strategic integration. The synergy between digital visualization tools and live corrective instruction appears to generate complementary learning benefits that neither approach achieves independently. This balanced instructional paradigm may serve as a sustainable model for collegiate training programs seeking to enhance competitive performance. In conclusion, hybrid instructional training represents a theoretically grounded, practically feasible, and empirically supported framework for advancing skill acquisition and cognitive development in kabaddi. Adoption of such integrated pedagogical models may contribute to long-term athlete development, improved match performance, and elevated standards of coaching practice in contemporary sports education environments.

## ABSTRACT

Present study prestige dynamics in Maharashtra's book publication industry: from manuscripts to modern markets, examines the historical evolution and reputation-building processes of Marathi publishing in Maharashtra. Situating the regional industry within broader global developments from early manuscript cultures and Gutenberg's print revolution to contemporary market systems the paper conceptualizes publishing as a fusion of cultural mission and commercial enterprise. Drawing upon qualitative, historical-descriptive methodology and secondary sources such as encyclopedias, commemorative volumes, bibliographies, and practitioner accounts, the research traces key phases: pre-independence foundations, wartime innovations, post-independence expansion, and post-1970 professionalization. Present findings explore reputation in Marathi publishing emerged not merely from commercial success but from sustained literary commitment, editorial rigor, and responsiveness to social and educational needs. Ultimately, the paper argues that Maharashtra's publishing industry exemplifies a dynamic balance between intellectual stewardship and entrepreneurial adaptation, offering insights into sustaining cultural prestige in the face of technological and digital transformations.

**Keywords:** Marathi Publishing Industry, Prestige Dynamics, Cultural Mission and Commerce, Print History in Maharashtra, Publishing Professionalization

## INTRODUCTION

India's book publishing sector stands apart from other traditional commercial businesses since it is based on the goal of fostering an informed, thoughtful society rather than just making money. A long-term repository of social memory, it ensures that scientific information, historical experiences, and cultural values are continuously reinterpreted by new readers by choosing, creating, and distributing books that can be read and reread over generations. In this way, Indian publishing serves as both a commercial venture and a cultural and educational service that preserves the country's intellectual legacy for future generations [1]. The sanctity of books is expressed by the influential Marathi saint Samarth Ramdas in the 17th century in ways that foreshadow this larger social function. According to him, a book is one that facilitates spiritual quest, information acquisition, and personal sanctification, highlighting its power to change one's thinking and character. From this perspective, publishing is seen as an organized endeavor to bring an author's inner expression into the public realm, from the earliest manuscript stage to the completed volume in the reader's hands, rather than just a technical process. The prestige and responsibilities of publishing in India are derived from this continuum, which runs from creation to circulation [1]. The historical underpinnings of this activity are found in worldwide advancements in book manufacture and printing. The origins of systematic publishing can be found in China in the ninth century, when woodblock printing made it possible to create multiple copies of a book far more quickly than hand copying by allowing full pages to be carved, inked, and duplicated at scale. The invention of movable type by Johannes Gutenberg in Germany in the 15th century turned this craft into an industry.

His 42-line Bible in 1455 is frequently cited as a landmark because it significantly decreased the time, labor, and cost of book production by as much as 80 percent making reading material accessible to people outside of the clerical and elite circles. From the scrolls and parchment codices used in ancient Greece and Rome to printed paper volumes, microforms, CD-based texts, and e-books today, book forms have changed over time to reflect ongoing changes in how societies store and disseminate information [2,3]. International organizations have suggested formal definitions in an effort to provide conceptual clarity in this area. The United Nations Educational, Scientific, and Cultural Organization (UNESCO) clearly acknowledges the link from editorial choice to reader access when it defines publishing as the process of choosing written material, printing and publishing it, and organizing its marketing and dissemination. In addition, UNESCO defines a book as a non-periodical printed product with at least 49 pages (not including covers). UNESCO has also helped standardize identifiers such as the International Standard Book Number (ISBN), which makes it easier to trace and circulate titles around the world [1,4]. The Marathi publishing sector in Maharashtra is a particularly instructive example of how reputation arises from a combination of cultural mission and entrepreneurial adaptation within this larger national and international context. In order to maintain financial viability in the face of difficult economic and competitive circumstances, a number of Marathi publishers started to professionalize their businesses during the pre-independence and wartime decades. They frequently combined publishing with bookselling. One of the first and most significant of these was Dhawale Publications, a well-known brand in the industry that is credited with publishing the first Marathi children's book, Mulamulinche Chimukale Pustak.

The company later experienced significant growth after merging with Karnataka in 1945. Under the direction of Sonyabapu Dhawale, who was given the title Mudran Maharishi, the company is estimated to have contributed nearly 20% of all Marathi book publications in Mumbai between 1940 and 1950. Following this merger, Dhawale's combined catalogue reached about 1,500 titles, mainly in the areas of religion, children's literature, school textbooks, and creative and historical works [1,5,6]. Parallel to Dhawale's growth, Vaman Vishnu Bhat's 1944 founding of Abhinav Publications raised the stature of Marathi publishing by purposefully emphasizing literary excellence and intellectual enlightenment. Abhinav purposefully sought out fresh authors and collaborated closely with them during the editorial process, publishing about 250 works over the course of about 45 years. Additionally, Bhat started the publication Sangrahalaya, which introduced readers to new books and literary advancements and serially reproduced rare and out-of-print classics. This effectively used periodical publishing as a weapon for literary

awareness and canon creation. In Kesari, Shankarrao Kulkarni's Maharashtra Granth Bhandar, together with Dhawale and Abhinav, invented contemporary marketing techniques like mailing lists and newspaper ads thereby systematizing book sales and broadening the reach of Marathi titles beyond local walk in customers [7, 8, 4, 1]. In light of this, Maharashtra's Marathi publishing sector has gained recognition for its educational contributions, willingness to try out a variety of genres, including well-liked formats like mystery series, and, most importantly, its insistence that quality be upheld as the cornerstone of prestige. [1, 9, 10]. In order to better understand how this network of historical developments, institutional practices, and intellectual ideals has shaped the status of Marathi publishing from its early manuscript and print traditions to its contemporary, market-oriented forms, the current study, From Manuscripts to Modern Markets: Prestige Dynamics in Maharashtra's Book Publication Industry was created [1].

## MATERIALS AND METHODS

The qualitative, historical-descriptive methodology used in this study is perfect for using narrative synthesis in place of experimental or quantitative approaches to recreate the prestige trajectory of Maharashtra's book publishing business. It is consistent with the traditions of library and information science, focusing on archive interpretation to document events from manuscripts before independence to market adaptations after 1970.

**Research Design And Data Collection**

By applying content analysis of secondary sources, the methodology focuses on textual patterns for prestige indicators (e.g., output volume, innovations) and systematically evaluates published materials without the need for primary data generation. Some of the sources are:

**Encyclopedias**: Marathi Vishwakosh (Vol. 5). Mumbai: Maharashtra Rajya Sahitya Sanskruti Manda for printing history and definitions [1,2]

**Commemorative volumes**: Dhawale Janmashatabdi Smarnika detailing mergers and institutional growth [7]

**Periodicals and questionnaires**: Mudran Prakash surveys (e.g., Anantrao Kulkarni on publisher traits; Kelkar, M. M. (1962). "Prakashanaachya Vatevaril Andhar v Ujed." Mudran Prakash, pp. 83-85) for practitioner insights [5,11].

**Bibliographies and autobiographies**: Date Granthsuchi, Part II. Mumbai: Ra. Ma. Vi. Samstha for 7,839 titles (1938-1950) [12]; Majhi Atmakatha (1988). Continental Prakashan for personal narratives [13]

**Online archives**: Marathi Wikipedia (n.d.); https://maitri2012.wordpress.com for supplementary profiles, Marathi Wikipedia.(n.d.)., Publisher and publication.(n.d.).

**Data Analysis And Synthesis**

Chronological synthesis organizes content into eras: pre-1940s foundations, WWII innovations, post-independence expansions. Thematic coding identifies prestige factors:

**Innovation** (e.g., Kulkarni's mailing lists [8]

**Output scale** (e.g., Dhawale's 1,500 titles [7]

**Literary impact** (e.g., Bhat's 250 books. [9]

This mirrors Ranganathan, S. R. (1958). Classified Catalogue Code. Madras Library Association's classificatory rigor for narrative interpretation over statistical modeling [6,9]. Ajun Kalas Chadhavaachaa Aahe. Deshmukh provided profile templates (Table 1).

**Validity, Reliability, and Limitations**

Triangulation across sources enhances credibility; chronological-thematic coding ensures reliability.

**Limitations:** Secondary reliance omits unpublished data; no econometrics (addressed via qualitative depth).

**Ethical note:** All public domain/academic sources used without alteration.

## RESULTS AND DISCUSSION

A historical and thematic study of secondary data is presented in this section, explaining how Maharashtra's publishers established their reputation through adaptation, scalability, and innovation. Synthesized sources provide insights that show resilience patterns in the face of external constraints and low margins.

**Pre Independence Foundations (Pre-1940s)**

Early businesses created a foundation for reputation through mergers and a variety of products. After Dhawale Publications acquired Karnataka in 1945, Dhawale Printers and Publishers was established, with 1,500 titles (religious/spiritual works, school textbooks, children's literature, creative/historical texts); Sonyabapu Dhawale (from 1938) became an expert in printing aesthetics, capturing approximately 20% of Mumbai's Marathi publications (1940–1950) out of 7,839 titles [7,12]. Contemporaries like Parchure Puranik, Ramkrishna Book Depot, and Suras Granthamala (Pandharpur) continued, fusing tradition and demand, while Chitrashala Publications maintained creative literature, intellectual conversation, and school education [7] These mergers raised Marathi's intellectual standing prior to independence by professionalizing operations and putting quality above profit.

**WWII-Era Innovations and Expansion (1940s-1960s)**

New houses were sparked by World War II, Abhinav Publications published about 250 books over 45 years, released a 16-year Sangrahalaya periodical that republished rare books like Kavi/Kavyodaya for enlightenment Deshmukh, R.J. (1995), and Maitri (2012). They also discovered authors (e.g., Mama Varerkar collaborations). Through creative promotion, Maharashtra Granth Bhandar (Shankarrao Kulkarni, who was born in Kolhapur after 1935) sold more than 500 copies of Kesari advertisements and mailing lists [8]. Char Aane Mala (1925, Veerkar; romance/mystery); Rahasya Mala (1939, P.P. Samant; 123-page Rahasyajaal at 4 annas), which spawned 10+ (Kanchanmala 1942; Yauvanmala 1946; etc.) but faded after the 1970s [14].

**Textbook breakthroughs**

For graded readers, Mangeshrao Kulkarni (Karnataka, 1935) broke international monopolies (Macmillan/Oxford) and gave rise to Pune houses like Patil Co., Y.G. Joshi, and M.M. Kelkar [12]. In order to remain viable and raise awareness, wartime entrepreneurship combined publishing and bookselling with affordability and creativity.

**Post independence prestige consolidation (Post-1970)**

Adapted by second and third generation leaders, author talks were stressed for excellence by Rajhans Prakashan (1952), Shivshahir Purandare, and Dilip Majgaonkar (1957) [15]. Samdas Bhatkal's Prakashan and Ashish Patkar of Manovikas brought doorstep delivery, worldwide benchmarking, and meetings. Extensions into college courses (Marathi/English; social sciences to fine arts) took advantage of cooperatives, education, and decentralization [16]. Diversifying marketing helped maintain reputation and go from survival to cultural leadership in the face of digital threats (Table 2). Data shows that prestige is a product of mission-commerce balance: impact (awareness via magazines), innovation (mailing/series), and scale (e.g., Dhawale domination) are robust despite losses in genres like mysteries [15]. According to Ranganathan (1958), this interpretive framework emphasizes the function that publishers play in society.

**Pioneering Resilience and Mission-Commerce Fusion**

Pre-independence elites combined financial savvy with cultural mission to create prestige. Through author discovery and the Sangrahalaya periodical, V.V. Bhat's Abhinav Publications (1944; 250 books over 45 years) demonstrated "literary evangelism" by republishing rare works for Marathi awareness [9,17]. Mailing lists and Kesari advertisements, two of Shankarrao Kulkarni's Maharashtra Granth Bhandar innovations, creatively scaled sales [8].

Sonyabapu's 1945 Karnataka merger under Dhawale (1,500 titles; 20% Mumbai share 1940-1950) combined religious and educational outputs with low profit margins [7]

**Genre and Market Adaptations**

Cheap mystery series (Char Aane Mala, 1925; Rahasya Mala, 1939 at 4 Annas; 10+ Malas, like Kanchanmala) made reading more accessible to a wider audience, but they declined in the 1970s as a result of genre fatigue [14]. Pune houses emerged as a result of textbook innovations (Karnataka 1935 vs. foreign monopolies), diversifying graded readers [12].

**Post-Independence Expansion and Sustainability**

Education surges, decentralization, and cooperatives fueled college-level Marathi texts (social sciences to fine arts). Second-generation leaders like Rajhans' Dilip Majgaonkar (author dialogues) and Popular's Samdas Bhatkal adopted doorstep delivery, meets, and global benchmarking, intertwining publishing-bookselling for viability [15,16]. Digital services and quality focus countered competition [5]

**Quantitative Prestige Markers**

7,839 Marathi titles (1938-1950); Dhawale dominance; Bhat's output exemplify scale amid modest profits [2, 12]. The results show that prestige emerged as a result of bookselling hybrids' synergistic adaptation to commerce. (Ranganathan, S.R. (1958)) sustained mission [11]. Although the stability of textbooks counteracts the mystery loss, post-1970 alterations (Patkar reflections) reassert relevance through globalization (Table 3).

## CONCLUSION

Maharashtra's publishing sector transformed Marathi literature from specialized manuscripts to contemporary markets, demonstrating the transformational power of resilient pioneers' commerce-mission fusion. "That which serves spiritual pursuit, imparts knowledge, sanctifies: such is a book," as Samarth Ramdas envisioned, "remains a conduit for enlightenment" (original paper). Future directions include using empirical post-digital indicators to maintain legacy in the face of AI and e-books [4].

## ABSTRACT

Puerarin is an important C-glycoside isoflavone mainly sourced from *Pueraria lobata* and *Pueraria tuberosa*. It shows various pharmacological properties and has wide therapeutic potential. This review brings together the current knowledge of its biosynthetic pathways, which include shikimate, phenylpropanoid, and C-glycosylation. It also highlights puerarin's role as a chemotaxonomic and quality-control marker in herbal products. Different extraction methods, from traditional maceration and Soxhlet to modern microwave and enzyme-assisted techniques, are compared for their efficiency and sustainability. Techniques like TLC, HPTLC, and HPLC help ensure accurate identification and measurement of puerarin. Despite its poor solubility and low oral bioavailability, advances in nanotechnology, such as polymeric nanoparticles and nanostructured lipid carriers, have greatly improved its bioavailability and therapeutic effectiveness. Puerarin shows strong anti-inflammatory, antioxidant, cardioprotective, neuroprotective, and anti-diabetic effects. Recent studies suggest it may also be useful for nerve regeneration, dopaminergic modulation, and anti-skin-ageing treatments. Overall, puerarin stands out as a versatile bioactive compound that connects traditional herbal medicine with modern pharmaceutical development, presenting significant possibilities for future drug and nanomedicine innovation.

**Keywords:** Puerarin, Biosynthesis, Pharmacokinetic activity, Extraction technique, Analytical methods, Pharmacology study.

# INTRODUCTION

Puerarin is the primary phytomarker, mainly extracted from the roots of Pueraria species like *Pueraria lobata* and *Pueraria tuberosa*. Puerarin, a unique component of the pueraria genus, serves as a quality control marker for herbal medicines such as *Pueraria lobata* and *Pueraria thomsonii* in China, displaying diverse pharmacological properties [1]. Puerarin has various effective components from different parts of the kudzu plant. Contemporary pharmacological research indicates that puerarin exhibits multiple bioactive effects, including estrogen-like activity, anti-inflammatory properties, antioxidant responses, blood pressure regulation, blood glucose lowering, and potential anticancer effects[1]. The puerarin is cited as diadzein-8-C-glucoside, which is derived from the genus Pueraria and from the roots of the kudzu plant. Puerarin, as an isoflavone, serves as the chemotaxonomic marker for the genus Pueraria. Various bioactivities of Pueraria are caused by isoflavone glycosides, especially puerarin. Hydroxyl groups are substituted at positions 7 and 4, and a β-D-glucopyranosyl residue is attached at position 8 via a C-glycosidic bond. The profile of Puerarin is mentioned in table 1. Profile of Puerarin(Table 1).

**Sources**

Puerarin is obtained from various plant species of Pueraria. Various plant species along with their parts are listed in Table 2. Sources of Puerarin (Table 2).

**Biosynthesis of Puerarin** [7]

Puerarinuses various enzymes and reactions in the biosynthesis of puerarin. It is biosynthesised by three different pathways, i.e. Shikimate pathway, the Phenylpropanoid pathway, and Puerarin pathway. These pathways are shown in Figure 1. From 3 different pathways, the first is the Shikimate pathway, where erythrose-4-phosphate reacts with phosphoenolpyruvic acid and gives shikimic acid, and further it provideschorisimic acid, then in the presence of phAT, and ADT enzyme, it gives phenylalanine as the final product of the shikimate pathway. Then, in the Phenylpropanoid pathway, phenylalanine undergoes phAAl enzymes and forms trans-cinnamic acid with the reduction of ammonia, and after that, in the presence of C4L enzyme, it gives 4-coumaric acid. From trans-cinnamic acid, and 4-coumaric acid, in the presence of C4CoAL enzyme, gives product 4-coumaroyl-CoA. Afterwards, in the Puerarin pathway, isoliquiritigenin from 4-coumaroyl-CoA in the presence of CHS and CHR, and after that in the presence of CHI, liquiritigenin is formed, which is further catalysed by 2-hydroxyisoflavonon (IFS) and produces 2,7,4-trihydroxyisoflavonone.We get two products or puerarin can be produced in two ways: by catalyzing The chalcone isoflavone is synthesized by using 2, 7, 4-trihydroxyisoflavonone dehydratase (HID) to produce diadzein, and 8-C-glucosyltransferase (8-C-GT) to form 2, 7, 4-glucosyltransferase. to create 2, 7, 4-trihydroxyisoflavonone-8-C-glucoside. Then, from 2,7,4-trihydroxyisoflavonone-8-C-glucoside and diadzein,puerarin is formed in the presence of 8-C-GT and HID or PIUGT43.

**Pharmacokinetics of Puerarin**

Puerarin displays species-specific pharmacokinetics, with a two-compartment open model observed in rats and dogs, while a three-compartment model better fits rabbits [8]. After intravenous administration, puerarin is broadly distributed across rats' organs, including thehippocampus, heart, lungs, stomach, liver, mammary gland, kidney, spleen, tibia, and femur[9]. It is capable of crossing both the blood-brain and placental barrier, warranting caution during pregnancy [10, 11]. After puerarin is administered to both humans and animals, a small number of phase I functionalization reactions (reduction and hydrolysis) and phase II conjugation reactions (glucuronidation and sulfation) metabolites have been discovered in biological samples[11, 12]. Its major hydrolysis product is diadzein, which is further metabolized to dihydrodaidzein and equol. Key metabolites like puerarin-7-O-glucuronide and puerarin-4-O-glucuronide are catalyzed by multiple UGT isoforms, with UGT1A1 playing a significant in the human liver. These conjugates are primarily excreted in urine and faeces. Notably, metabolic profiles vary by tissue and sample type, with unmetabolized puerarinfound in serum and conjugated/reduced forms appearing in urine over time, suggesting rapid absorption with delayed systemic metabolism [12].

**Herbal Influences on Puerarin Pharmacokinetics**

Gegenqinlian Decoction (GQD), which combines *Radix Puerariae* (Gegen) with *Scutellaria baicalensis*, *Coptis chinensis*, and *Glycyrrhiza uralensis*, is a different herbal preparation that increases puerarin absorption and slows its clearance compared to pure Radix Puerariae extract in rats [13]. Among its components, glycyrrhizic acid significantly inhibits puerarin's intestinal uptake, while baicalin and berberine facilitate its absorption. Studies indicate that certain herbs in a medicine called Longmaining aid in the absorption of puerarin in rats. The research shows that Longmaining enhances puerarin absorption throughout the entire intestine. Specifically, in the upper sections (duodenum and ileum), the herb *Dioscoreae nipponicae* rhizome contributed most significantly. In the middle and lower sections (jejunum and colon), both *Dioscoreae nipponicae rhizome* and *chuanxiong rhizome* worked together to improve the absorption of puerarin[13].

Additional herbs shown to increase intestinal puerarin absorption include:

- *Gastrodiae rhizome*
- *Angelica dahurica* (Radix *angelica edahuricae*)
- *Chauanxiong rhizome*, which enhances solubility, reduces the expression of claudin-5 and P-glycoprotein efflux.

Because of the intricate nature of these herbal combinations, the precise interactions often remain unclear. Still, the general mechanism involves changes in intestinal permeability, transporter activity, and physical solubility of puerarin[13].

**Extraction Methods for Puerarin**

For the extraction of puerarin, there is an extraction technique where puerarin isoflavone must be extracted, purified, and analyzed using appropriate and efficient methods [7]. There are two different techniques for the extraction of puerarin: (a) Conventional extraction technique and (b) Modern or Advanced extraction technique. Maceration, Percolation, Soxhlet extraction, and decoction are examples of traditional, conventional techniques. Cloud point extraction, high-speed countercurrent chromatography, extraction, solid-phase extraction, enzyme-assisted extraction, microwave extraction, ultrasonic extraction, and high-speed countercurrent chromatography are examples of advanced extraction techniques [6]. Since every extraction technique has its pros and cons, selecting the best one for isoflavones requires considering variables such as cost, effectiveness, and environmental impact[7]. The purest puerarin is produced using a traditional method called solid-liquid extraction, despite being simple and reasonably priced. Although it is simple and inexpensive, the traditional method of solid-liquid extraction yields the purest puerarin. Although supercritical fluid extraction is a highly effective and pure technique, it is expensive and requires complex installations[6]. Microwave-assisted extraction increases the effectiveness of the extraction process and decreases extraction time [7]. This technique is performed in a CW-2000 microwave preparation system with an adjustable power output from 10 to 850 W at 2450 Hz [12]. The application of microwave energy may cause a rise in operating expenses. In addition to these, attempts have been made to extract puerarin using various extraction techniques, such as enzymatic and ultrasound-assisted extraction[7]. In these instance, based on the solution extraction method, the ultrasonic-aided extraction method creates a cavitation gas canon by utilizing the cavitation effect created by an ultrasonic wave. The shock wave from the cavitation gas explosion crushes the plant's cell wall, making the target component more soluble[8]. It produces heat or makes it safe and considerate of heat-sensitive chemicals, in contrast to other instrument-assisted extraction techniques. For instance, the steps involved in extraction are shortened because the tank is too big to create an ultrasonic blank area[6]. The advantages of the enzyme-assisted extraction method include mild reaction conditions, little loss of active ingredients, and environmentally friendly solvents. Even so, environment-sensitive enzymes may become dormant at elevated temperature and at low pH, which will raise extraction costs and decrease their effectiveness[6]. In the enzyme-assisted extraction method, when extracting plant isoflavones, the target compounds are prevented from moving into the extraction solvent by the material between cells and the cell walls of the plant. Enzymes are added to break down the typical configuration of intercellular materials and cell walls[8].

**Recent Method for Extraction**

**Improving Puerarin Extraction and Sustainability Considerations**[14]

Based on the OFAT results, we optimized puerarin extraction from *Pueraria lobata* roots using response surface methodology (RSM) to capture interactions among factors. We applied a 5-level, 3-factor central composite rotatable design in Design-Expert. The independent variables were ethanol concentration, extraction temperature, and solvent-to-biomass ratio, with center points from the OFAT results. This generated 20 runs of 30-minute extractions. Puerarin yield (mg/g) was measured by HPLC, and we fitted a second-order polynomial model ($Y = \beta_0 + \Sigma\beta iXi + \Sigma\beta ijXiXj + \Sigma\beta iiXi^2$), which we confirmed with ANOVA. Compared to OFAT, the conditions from RSM significantly increased puerarin yield while reducing extraction time from 3 hours to 30 minutes. Using a GRAS solvent, ethanol-water, at moderate temperatures and relatively low solvent volumes revealed synergistic effects among variables. This approach also lowered energy needs and solvent waste. In contrast to traditional techniques, such as reflux, subcritical water, or ultrasound that require high temperatures, long durations, or complex equipment, this combined OFAT-RSM method achieves comparable or higher yields under milder, safer, and more sustainable conditions. It is better suited for scale-up and resource-limited environments.

**Nanotechnology-Based Formulation Strategies for Puerarin** [15]

Puerarin has poor water solubility and low oral absorption (BCS Class IV). This has sparked interest in new formulation methods. Researchers have explored various nanocarrier systems, including phospholipid complexes, nanocrystals, self-emulsifying systems, and polymeric nanoparticles, to enhance solubility, stability, and absorption.

Polymeric nanoparticles stand out as particularly promising. Here, they created puerarin-loaded nanoparticles using a solvent evaporation method with the biodegradable co-polymer PDLG. They optimized the process with a Box–Behnken design. The optimized system resulted in spherical particles about 120 nm in size, a low PDI of 0.22, a high negative zeta potential of -16.3 mV, an entrapment efficiency of around 90%, a drug loading of 14.6%, and 80% release over 24 hours with no toxicity observed in RAW 264.7 cells. This method produced smaller particle sizes and better encapsulation compared to earlier PLGA-based systems, suggesting improved oral delivery potential. Similar studies on phospholipid complexes, nanocrystals, and other carriers have also shown improved bioavailability and targeting of puerarin. Overall, these nanotechnology-based strategies mark a significant improvement over traditional formulations, allowing for more effective and sustained delivery of puerarin in therapeutic applications.

**Nanoparticle Characterization and Biological Effects**[16]

In a recent study (Pharmaceutics, 2024), puerarin-loaded nanoparticles were carefully characterized and showed a uniform nanoscale size, narrow PDI, high entrapment efficiency, and stable zeta potential. Besides their improved physical and chemical properties, the nanoparticles displayed strong antimicrobial activity against specific bacterial strains. A safety assessment using an *in ovo* model found no significant embryotoxicity or irritation. Notably, the same system also showed pro-angiogenic effects in the chorioallantoic membrane assay. This suggests it could help with vascularization and tissue repair, along with improving puerarin delivery.

**Novel Applications of Puerarin in Nanomaterials**[16]

**Role in Green ZnO NP Synthesis:** In the green synthesis of ZnO nanoparticles, puerarin acts as both a reducing agent and a stabilizing agent. The process involves adding a puerarin solution to a zinc acetate solution at 50°C. Puerarin, which is an isoflavone, has hydroxyl and carbonyl groups that help reduce zinc ions (Zn2+). This creates coordination bonds between the puerarin and the nanoparticles. The puerarin molecules attach themselves to the surface of the newly formed ZnO nanoparticles, preventing them from clumping together and stabilizing them. EDX analysis confirmed the presence of puerarin on the nanoparticle surface by detecting carbon and oxygen.

**Antimicrobial Potential:** The puerarin-functionalized ZnO nanoparticles (PUE-ZnO NPs) showed antimicrobial activity against several bacterial strains and one yeast strain. The strongest antibacterial effects were against *Staphylococcus aureus*, Streptococcus pyogenes, and Escherichia coli, with a minimum inhibitory concentration (MIC) of 25 mg/mL for each. The PUE-ZnO NPs had a weaker antibacterial effect against *Candida parapsilosis*, with an MIC of 50 mg/mL. No activity was found against *Pseudomonas aeruginosa*.

**Angiogenesis Activity:** The document's *in ovo* CAM (chorioallantoic membrane) assay assessed whether PUE-ZnO NPs could affect angiogenesis. The results showed that PUE-ZnO NPs, at a concentration of 100 μg/mL, did not cause any irritation or changes to the vasculature of the chorioallantoic membrane after 24 hours. This indicates that the green-synthesized nanoparticles have good vascular tolerance and do not interfere with the angiogenesis process.

**Analytical Methods for Puerarin**

The importance of analytical methods in assessing the quality of drugs and biomarkers is the main topic of this review. This review covers numerous analytical methods, including Thin Layer Chromatography (TLC), High-Performance Liquid Chromatography (HPLC), High-Performance Thin Layer Chromatography (HPTLC), and quantification and analysis of puerarin in plant and herbal, and ayurvedic formulations.

**Thin Layer Chromatography(TLC)**

Thin Layer Chromatography is an analytical technique that is a fast, sensitive, and cost-effective method which is used to detect various numbers of components from a mixture, then verify the identity and purity of that compound, and monitor the progress of a reaction. Determine the solvent comparison for preparative separations. Examine the fractions obtained from column chromatography. In Table 3, explain the TLC study performed on *Pueraria tuberosa.*
Table 3. TLC of Puerarin

**High-Performance Thin Layer Chromatography(HPTLC)**

High-Performance Thin Layer Chromatography is a technique for identifying or detecting compounds. In this case, HPTLC is utilized for mixture separation, as well as for preparative, qualitative, and quantitative analysis, selective detection, and minimum sample preparation. HPTLC is one of the most advanced techniques that fully utilizes Thin-Layer Chromatography. All HPTLC studies that are performed on puerarin in different plant extracts are given in Table 4. HPTLC of Puerarin (Table 4).

**High-Performance Liquid Chromatography(HPLC)**

A type of column chromatography called High-Performance Liquid Chromatography (HPLC) is frequently used in biochemistry and HPLC analysis to separate, identify, and quantify active chemicals. HPLC is the most commonly used separation technology for detecting, separating, and quantifying the drug [22]. All HPLC studies were performed for puerarin in Table 5.
Table 5. HPLC of Puerarin

**HPLC Vs HPTLC**

HPLC Vs HPTLC Study on Puerarin (Table 6).

**Pharmacological Study**

Numerous pharmacological properties are processed by puerarin, which has been used extensively to treat cancer, osteonecrosis, Parkinson's disease, endometriosis, diabetes and its complications, cardiovascular and cerebrovascular disease [14].

**Cardiovascular Activity**[26]

Puerarin has been demonstrated to be in charge of *Pueraria lobata's* pharmacological effects on the cardiovascular system. According to basic and clinical research, puerarin is a promising treatment option for Osteonecrosis, Cancer, Alzheimer's disease, Parkinson's disease, diabetes and its complications, and endometriosis. The modulation of Na+, Ca2+ channels, NF-Kb, PI3K/AKT, BCL-2, and BAX may be the primary mechanism by which puerarin is effective in treating a variety of CVDs.

**Neuroprotective Effects:**[21]

Parkinson's disease (PD), a common neurodegenerative disease, is marked by the gradual degeneration of dopaminergic (DA) neurons in the pars compacta of the substantia nigra (SN). Puerarin's pharmacological

mechanisms for treating Parkinson's disease (PD) include antiapoptotic effects, antioxidative stress injury, ALP and USP intervention, immune response regulation, elevated dopamine and its metabolites, and promotion of neurotrophin expression and neuronal repair, according to a review of the published literature. One of the main active ingredients in pueraria radix is puerarin, which has a known chemical structure and composition. Puerarin has been demonstrated to have therapeutic effects on parkinson's disease in both clinical and experimental studies.

The following are its pharmacological mechanisms: Anti-oxidative stress injury, anti-apoptosis, ALP and USP intervention, and regulation.

**Anti-inflammatory Effects:**[27]

In both *in Vitro* and *in vivo* models, puerarin exhibits potent anti-inflammatory properties in a variety of ways: Puerarin suppresses NF-kB by preventing IkB degradation and p65 nuclear translocation activation, and lowers the manifestation of inflammatory markers like IL-6, TNF-$\alpha$, COX-2, iNOS, and CRP.

**Cellular and Animal Models:** it decreased inflammation in LPS-stimulated PBMCs, RAW264.7 macrophages, and mouse ear edema.

**Endothelial Protection:** It enhanced insulin signaling in endothelial cells and counteracted inflammation brought on by palmitate.

**HO-1/Nrf2 Pathway Activation:** Puerarin activated PKCδ-Nrf2-HO-1 signaling, which increased the antioxidant and anti-inflammatory effects.

IL-8 Suppression: Inhibited IL-8 secretion and mRNA in neutrophil co-cultures and bronchial epithelial cells.

**Anti-diabetic Effects:**[26, 27]

A lot of research has shown that puerarin is very good at lowering blood sugar levels and making cells more sensitive to insulin. Lowered blood sugar levels in diabetic rats in a way that depended on the dose. Increased GLUT-4 levels in the skeletal muscle caused β-endorphin release through adrenal $\alpha$1-adrenoceptors. In rats that consumed a lot of fat, it improved insulin resistance by reducing body weight, leptin, and resistin. How to keep pancreatic islets safe. Less apoptosis caused by $H_2O_2$, more SOD or catalase activity, and better insulin secretion all helped protect pancreatic islets from oxidative stress. Better use of glucose and lipids in the body. Puerarin helped rats with type 2 diabetes and obesity by lowering the blood sugar, triglycerides, cholesterol, insulin, and body weight. A diet that has a lot of kudzu in it.

**Antioxidant Activity:**[26, 27]

By scavenging free radicals, increasing antioxidant enzyme activities, and preventing oxidative damage in a variety of organs and disease models, puerarin demonstrates strong antioxidant qualities:

a. Preserving lipids and scavenging free radicals, it neutralizes superoxide anions and hydroxyl radicals, prevents LDL from oxidizing, and shields red blood cells from hemolysis brought on by $H_2O_2$.
b. According to this, it might aid in the prevention of atherosclerosis, lower cholesterol, increase HDL, and prevent platelet aggregation.
c. Protecting organs from oxidative stress reduces ROS and MDA and increases GSH, SOD, and catalase to protect against heart oxidative/ nitrative damage, liver damage from type 2 diabetes, and lead-induced nephrotoxicity, neurotoxicity, inhibits caspase-3, increases Akt/Enos phosphorylation, and controls Bcl-2 family proteins to prevent apoptosis.
d. Regulations of gene expression and enzyme activity raise LDL receptor expression, reduce HMG-CoA reductase activity, and boost cholesterol 7$\alpha$-hydroxylase, thus improving lipid metabolism.

**Clinical Evidence for Puerarin Injection in Heart Failure** [28]

A recent systematic review and meta-analysis (Frontiers in Pharmacology, 2025) combined data from 29 randomized controlled trials involving about 2,480 patients. These trials assessed puerarin injection as a supplement to standard

therapy for heart failure. Compared to control groups, puerarin significantly improved key measures of heart function, such as left ventricular ejection fraction, cardiac output, and stroke volume. It also improved symptoms and biochemical markers of heart failure. No major safety concerns were reported. These findings suggest that puerarin, administered by injection, may offer additional benefits in managing heart failure. However, larger and well-designed trials are necessary to confirm these effects.

**Future Perspective**

While Puerarin is well-known for its antioxidant and anti-cell death effects in stroke and neurodegenerative diseases, a promising new area is its potential for nerve regeneration and myelin repair. Recent studies show that Puerarin helps the differentiation of oligodendrocyte precursor cells (OPCs) into mature oligodendrocytes. Since conditions like Multiple Sclerosis damage the myelin sheath, future research should explore Puerarin's ability to boost natural myelin repair in living organisms. We need more studies to confirm whether Puerarin affects important signalling pathways, such as PI3K/Akt or LINGO-1, that control oligodendrocyte development. This could make it a new treatment option for restoring nerve function[29, 30]. A major challenge limiting the use of Puerarinin the central nervous system is its low oral bioavailability. To tackle this, combining new nanotechnology with targeted drug delivery offers a valuable opportunity. Recent studies show Puerarin's specific effects on neuromodulation. It can increase extracellular dopamine levels and act as an agonist on D2-like receptors. This makes Puerarin particularly important for neurological and psychiatric disorders related to dopamine problems, such as certain types of depression, addiction, and Parkinson's disease. Future work should aim to develop actively targeted nanocarrier systems, such as functionalized polymeric nanoparticles, utilising blood-brain barrier-targeting ligands. This approach will help deliver high concentrations of Puerarin directly to important brain areas, maximizing therapeutic benefits while reducing unwanted effects[31]. Beyond systemic diseases, applying Puerarin locally shows great potential in the growing field of senotherapeutics for skin ageing. The ageing process is largely driven by the accumulation of senescent cells, specifically senescent dermal fibroblasts, which release pro-inflammatory factors that damage the skin matrix. Research indicates that Puerarin can effectively block the senescence phenotype in human dermal fibroblasts. More studies are needed to find out if Puerarin works as a senolytic, which selectively kills senescent cells, or as a senomorphic, which suppresses the harmful SASP. Developing effective topical drug delivery systems, such as Puerarin-loaded Nanostructured Lipid Carriers or functional nanofibers, will be vital to ensure proper skin penetration and targeted action against age-related issues, including wrinkles and loss of elasticity[32].

## CONCLUSION

Puerarin is a well-known isoflavone with significant pharmacological and therapeutic potential that is primarily derived from species in the Pueraria genus. This review provides a detailed overview of its biosynthesis pathways, species sources, and advanced extraction and analytical techniques, all of which are essential for accurate quantification and quality control. Puerarin's favorable pharmacokinetic profile, ability to cross physiological barriers, and modulation through herbal combinations further enhance its therapeutic relevance. Its well-documented pharmacological effects-spanning anti-inflammatory, antioxidant, anti-diabetic, neuroprotective, and cardioprotective actions, support its significance as a bioactive marker in traditional and modern medicine. Collectively, puerarin emerges as a promising compound for future drug development, encouraging continued exploration in pharmaceutical and nutraceutical applications.

## ABSTRACT

The study examines the effectiveness of the low-cost active carbon (CR-AC) obtained from the stem of the *Catharanthus roseus* plant to remove malachite green (MG) dye from aquatic solutions. The activated carbon was synthesized using zinc chloride as a chemical activator and was subject to microwave irradiation. The structural and surface characteristics of the produced adsorbent were examined using X-ray diffraction (XRD), Scanning electron microscopy (SEM), and Fourier transform infrared spectroscopy (FT-IR). Batch absorbing experiments were held to examine the effects of various operating parameters, including adsorbent doses, contact time and solution pH on dye removal efficiency. The soak balance was analyzed using both Langmuir and Freundlich isotherm models. The findings show that CR-AC displays strong absorbing capabilities, which reflects its promise as cost-effective, efficient and environmentally friendly material for the treatment of dye-contaminated wastewater.

**Keywords:** Microwave radiation, Malachite green, Adsorption, *Catharanthus roseus*, Langmuir and Freundlich isotherms.

## INTRODUCTION

Dyes representing an important class of contaminants, among other things, reduce the release of recipient dye waste, diminish the aesthetic value of water, block the penetration of sunlight into water, and reduce photosynthesis skills [1]. Dyes are often released in the form of colored wastewaters in textile industries, pulp mills, and dye manufacturing industries. Water pollution has become one of the most serious issues that threaten biological sustainability. Disposal of synthetic dyes in waters without proper treatment leads to serious problems and concerns. Over 10,000 dyes [2] were used in the textile, paper, cosmetics and food industries, resulting in large quantities of dye-sampled water. Malachite green (MG) dyes were usually used to colour wool, silk and leather, paper, distilleries and food products [3]. MG is known as a fungicide used in agriculture and fishing, causing skin problems with mouth and inhalation. It also has carcinogenic effects and issues a great risk to aquatic organisms [4, 5]. However, MG is toxic and can cause carcinogenesis, mutagenesis, respiratory destruction, liver, kidneys, intestines and gonads [6]. For this reason, the removal of such dyes from industrial forests is extremely important [7-9]. Adsorption of liquid phase adsorption from exclusion from breakout discharges, such as coagulation, aggregation, chemical oxidation, membrane filtration, aerobic and anaerobic degradation, reverse osmosis, photocatalytic degradation and microbial processes [10]. It is well recognized as an efficient method of removing contaminants from waste [11]. The Adsorbent method is considered as an important alternative to other methods as it is inexpensive and does not require pre-processing. In particular, adsorption techniques, including the use of solid adsorbent have long been used to dispose of chemical contaminants that are resistant to traditional biological treatment processes [12], but activated carbons (ACs) are often used in adsorption processes, and their small particles become hard when removed by an Aqueous solution [13,14]. Recently, this study has focused on surface chemistry of ACs to assess experimental results related to dye adsorption [15-17]. With the increased production costs of commercially available activated carbon, researchers are seeking the possibility of using a variety of cost-effective adsorbents resulting from natural materials, industrial solid waste, agriculture waste, and biosorbents as the precursors [18, 19]. According to solvent extraction of phytochemical plants waste, these pioneers were attributed to attention to the low cost advantages, particularly in the field of phytochemical, which is heirs to their prominent properties as frequency and availability. Recently, microwave-supplied heating has focused attention on carbon preparation activities due to its benefits, such as faster processing and more uniform heat distribution. Li *et al*. The success of synthesis of high surface activated carbon produced in tobacco stems using microwave radiation has been reported [20]. However, studies using microwave-assisted $ZnCl_2$ activation remain lacking. In this context, the purpose of this study is to investigate the feasibility of efficient adsorbents from the *Catharanthus roseus* family using $ZnCl_2$ activation under microwave irradiation. The adsorption performance was then evaluated by characterizing the prepared carbon and removing the malachite green (MG) from the aqueous solution.

## MATERIALS AND METHODS

## MATERIALS

All reagents utilized in the experiments were of analytical (AR) grade and were procured from Merck India Ltd. Stock solutions of the test reagents were prepared by dissolving the dye in double-distilled water. The dye, malachite green, with the chemical formula $C_{23}H_{25}N_2Cl$, a molecular weight of 365, and a $\lambda_{max}$ of 618 nm, was also supplied by Merck India Ltd.

**Preparation of Activated Carbon**

Following phytochemical alcoholic extractions, the stem of crushed waste of the *Catharanthus roseus* (raw-CR) was passed through a 1 mm sieve for homogenization. The incipient wetness method by drop- wise addition is regarded as the best variant of the incipient wetness methods [21]. To facilitate the homogeneous absorption of the liquid, solid particles must be raised in the solution. The required amount of zinc chloride for raw-CR was determined to be 3.5 mL /gram of solid to increase swelling during the aggressive wet. However, this volume of zinc chloride is not

enough to induce good swelling of the raw-CR. The minimum volume of $ZnCl_2$ required to produce a homogeneous raw material solution was 4.0 mL/gram of raw-CR (in a ratio of 1.00 grams of 4.00 mL of solution) [22]. The 100-gram precursor was fitted with zinc chloride (400 mL) and placed in an oven at 110°C for 4 hours. Dried and pregnant samples were radiated using a microwave on a 700 W output power for 12 minutes [23]. The active carbon (CR-AC) received is washed several times using distilled water. After reaching the pH neutral of the solution, the active carbon is dried at a temperature of 105°C for 24 hours.

**Preparation of Synthetic Effluent**

A 1000 mg/L dye stock solution was prepared by dissolving 1g of MG dye in 1000 mL of distilled water. These stock solutions were then mixed with the necessary concentrations using distilled water when needed.

**Adsorption Experiments**

We were included in the initial batch of the source study to determine the equilibrium time. The 250 mL Stoppered conical flask was batched by mixing 0.30 g CRAC with 50 mL of various initial concentration solutions of MG dye. The dose of adsorbent was determined experimentally. All adsorption experiments were performed at a temperature of 30°C, at a speed of 140 rpm on a thermostat shaking water bath. The progression of the exploitation was noted, and the equilibrium was achieved in 40 minutes. After equilibrium, the adsorbent was separated from the aqueous phase by centrifugation at 10000 rpm for 10 minutes using a Centrifuge (Remy 24, India). The residual concentration of MG dye colour in the Supernatant was determined by the Systronics Double Beam UV-visible spectrophotometer: 2202. 618 nm.

The percentage of colour on equilibrium was removed, and the amount of colour transferred to the surface of the adsorbent, $q_e$ (mg/g), was calculated using the following relationships

Percentage dye removal = $100(C_o-C_e)/C_o$ (1)

Amount of adsorbed dye molecules per g of solid

$$q_e=(C_o-C_e)\ V/w \quad (2)$$

Where, $C_o$ (mg/L) is the initial concentration of malachite green, $C_e$ (mg/L) is the equilibrium concentration of dye, V is the volume of the solution (L), and W (g) is the mass of the adsorbent.

## RESULTS AND DISCUSSION

**Instrumental Evidences**

**FTIR Analysis of CR-AC**

The FTIR analysis is an important tool for figuring out the feature functional groups of the adsorbent, which are accountable for the adsorption of Malachite green dye. The FTIR spectroscopy affords structural and compositional records at the functional groups presented in the sample. Figs. 1 and 2 shows the peak positions within the FTIR spectra of the CRAC before and after Malachite inexperienced dye adsorption, presented in Table-1. FTIR spectroscopy became hired to perceive the functional group concerned in the adsorption of Malachite green (MG) dye onto $ZnCl_2$-activated CRAC. Significant shifts in characteristic peaks were observed in the spectra before and after dye adsorption, suggesting strong interactions between the dye molecules and the surface of the adsorbent. A large peak at 3360 $cm^{-1}$, attributed to O–H stretching vibrations of hydroxyl, phenolic, or carboxylic acid organizations, shifted to 3369.23 $cm^{-1}$ after dye adsorption. This shift confirms the involvement of surface hydroxyl agencies in hydrogen bonding or electrostatic interactions with the dye. The C≡C stretching vibration close to 2161.22 $cm^{-1}$ shifted to 2166.55 $cm^{-1}$, which may also advise weak π–π interactions or electronic rearrangement at the carbon surface. The peak at 1578.27 $cm^{-1}$, corresponding to aromatic C=C stretching, shifted to 1582.61 $cm^{-1}$, indicating π–π stacking interactions between the aromatic rings of MG dye and the carbon surface. A big shift was additionally determined in the C–O stretching band from 1204. 11 $cm^{-1}$ to 1216. 49 $cm^{-1}$, suggesting that carboxylic and hydroxyl group played a role in hydrogen bonding or dipolar interactions with MG dye molecules. Importantly, peaks inside the low-frequency region (471.96, 436.50, and 413.16 $cm^{-1}$) related to Zn–O stretching vibrations additionally showed moderate shifts after adsorption. These shifts verify the energetic participation of metallic–oxygen bonds (introduced

via $ZnCl_2$ activation) in electrostatic enchantment or surface complexation with the cationic dye. This helps the function of Zn species in enhancing adsorption efficiency.

**SEM Analysis of CRAC**

The surface morphology of the CRAC turned into investigated the usage of Scanning Electron Microscopy (SEM) to understand the bodily modifications taking place earlier than and after the adsorption of Malachite green (MG) dye. The SEM photograph of CRAC before adsorption (Fig. 3) reveals a distinctly porous and abnormal surface shape. Numerous voids, channels, and cavities were observed, indicating a properly-evolved porous community. Those structural features are important for adsorption as they boom the surface region and provide energetic web sites for dye molecule attachment. The irregular texture and open pore network endorse that the CRAC has substantial adsorption capability because of its bodily surface characteristics. Following the adsorption of MG dye, widespread morphological adjustments were found on the CRAC surface. The SEM picture (Fig. 4) of the dye-loaded CRAC suggests a extra compact and smoother floor, with the various formerly seen pores both in part or fully blocked. The discount in pore visibility confirms that the dye molecules occupied the available active sites on the carbon surface, thereby blocking the pores.

**XRD Analysis of CRAC**

X-ray diffraction (XRD) evaluation changed into performed to research the crystallinity and structural modifications in the CRAC adsorbent earlier than and after the adsorption of Malachite Green dye. The diffraction patterns have been recorded within the 2θ range and the corresponding d-spacing, peak intensities, and relative intensities has been analyzed. The XRD sample of raw CRAC (Fig. 5) suggests awesome peaks at 2θ = 26.83°, 38.42°, 44.68°, 65.08°, 72.77°, 75.92°, 78.18°, and 88.45°, with the most intense peak at 44.68° (100% relative intensity). these peaks hint the partial crystalline nature of the adsorbent, probable due to residual ZnO or $ZnCl_2$-primarily based inorganic components delivered in the course of chemical activation with $ZnCl_2$. The sharp peaks at 44.68°, 72.77°, and 88.45° correspond to the (111), (200), and higher-order ZnO planes, indicating the presence of crystalline zinc oxide levels. The broadness of a few peaks, especially around 26.83°, may also recommend the presence of amorphous carbon, which is usual in activated carbon materials. The d-spacing values ranging from 3.32 Å to 1.10 Å in addition support the combination of crystalline and disordered (amorphous) structures in CRAC. After adsorption of Malachite green dye, the XRD pattern indicates (Fig. 6) great changes. A new, broad height peak appears at 10.12° (with the very best depth, 100% relative), corresponding to a large d-spacing of 8.74 Å. This broad diffraction band is in all likelihood due to intercalation or surface coating of dye molecules on the adsorbent, which increases the interlayer distance and contributes to structural ailment. The depth of the original CRAC peaks at 26.58° and 28.47° is appreciably reduced, and their relative intensities drop to 25.6% and 17.22%, respectively, indicating that the crystallinity decreases after dye loading. The disappearance or attenuation of numerous peaks (e.g., at 38.42°, 44.68°, and 88.45°) suggests that the adsorption of MG dye masks or disrupts the crystalline domains, confirming sturdy interaction between the dye molecules and active sites on CRAC.

**Effect of Contact Time and Initial Concentration**

The adsorption of malachite green dye with the aid of CRAC became notably influenced through initial dye concentration. The variation in percentage removal of the dye with contact time at exceptional initial concentrations starting from (60 to 120) mg/L is shown in Fig. 7. It is observed from the figure that the removal of MG acquired a maximum at the time of equilibrium, viz. 40 min, and will become steady thereafter. It's far clear from this figure that the price of adsorption could be very speedy in the initial degrees and after equilibrium; no significant alteration in the extent of adsorption is determined. For the initial concentration, the elimination extended from (56.40 to 83.30 %) by lowering the initial concentration of malachite green dye solution from (120 to 60) mg/L. It's miles glaring that although a substantial version in adsorption of MG isn't located, the extent of elimination (%) is greater at decrease initial concentrations, and the percentage elimination of dye decreases with an growth in initial concentration.

**Effect of Temperature**

Temperature is an essential parameter for adsorption processes. It has substantial impact at the adsorption of malachite green on CRAC additionally. The impact of temperature became investigated in the temperature variety (30 to 50) ˚C. The experimental results show that the removal of MG expanded from (83.30 to 92.90 %) via growing the temperature from (30 to 50 ˚C) (Fig. 8). Maximum adsorption process are ruled via exothermic process, however the present system is governed via endothermic adsorption [24].

**Effect of pH on Dye Uptake**

The effect of pH at the adsorption of malachite green has been investigated, and the consequences indicated that the pH of the solution drastically influenced the adsorption of MG in the present studies. To examine an impact of pH at the adsorption of MG on CRAC, the experiments have been completed at a 60 mg/L initial dye concentration with 0.30 g adsorbent at 30 ˚C. The reaction mixture was agitated for 40 min, the equilibrium time. Fig. 9 suggests the version of percent adsorption of MG at different values of solution pH. This Fig. 10 shows that a lower removal of MG is acquired in the acidic range of pH. At lower pH values, the adsorption capacity for Malachite Green (MG) is suppressed due to abundance of $H^+$ ions, which occupy the active sites on the CRAC surface and outcompete the cationic dye [25,26]. Conversely, as the solution becomes less acidic, the positive charge density on the adsorbent surface diminishes, thereby minimizing electrostatic repulsion. Under alkaline conditions, the CRAC surface tends to develop a negative charge; this transition promotes a robust electrostatic affinity for the positively charged MG cations, ultimately maximizing the dye removal rate.

**Adsorption Kinetics**

The adsorption kinetics indicates the evolution of the adsorption capability through time and it's far important to identify the varieties of adsorption mechanism in a given method. Plots of different kinetic models applied have been given in the Figs. 10 and 11 and the kinetic parameters calculated have been given in the Table-2, among the first order and second order, second order kinetic model seems to satisfactory describe the above adsorption system as its $R^2$ values were very near to unity. Moreover, distinction between qe (cal) and qe (exp) values of second order is small while in comparison to first order kinetic model. Statistically it is examined with the tool Sum of error squares (SSE%) [27,28]. The Δqe and SSE % values were given in the Table-3 from which it was concluded that second order kinetic model became more suitable rather than first order kinetic model.

**Analytical Study**

An analytical method is critical for designing effective adsorption method aimed at disposing of dissolved pollutants. On this observe, experimental information were analyzed by becoming them to established adsorption isotherm models to understand the adsorption behaviour. Sorption isotherms efficiently describe the equilibrium relationship among the adsorbate within the liquid segment and the adsorbent inside the solid phase. Equilibrium information obtained at various temperatures has been implemented to both the Langmuir and Freundlich isotherm models, as illustrated in Figs. 12 and 13. The correlation coefficients ($R^2$ values) suggest that the Freundlich version offers a better fit; the specific results of the isotherm evaluation are summarized in Table-4.

**Analysis of Isotherm**

**Langmuir isotherm**

Within the present study $Q_0$ value ranges from 76.923 to 83.333 because the temperature will increase the monolayer adsorption potential also discovered to increase. This form of outcomes turned into acquired in diverse similar studies. The separation factor $R_L$ values in between 0 to 1 suggest the beneficial adsorption. $R^2$ values of isotherm ranged at 0.998.

**Frendlich isotherm**

The values of n have been among 1 and 10 which suggests cooperative adsorption. The $R^2$ values were close to unity which reached to desirable fitting into frendlich isotherm.

## CONCLUSIONS

This study correctly demonstrates the capability of activated carbon derived from *Catharanthus roseus* stems (CRAC), synthesized through $ZnCl_2$ activation and microwave irradiation, as an efficient and low-cost adsorbent for the removal of Malachite green (MG) dye from aqueous solution. Characterization techniques (FTIR, SEM, and XRD) showed the presence of useful functional groups, porous morphology, and partial crystallinity conducive to dye adsorption. FTIR evaluation indicated that the adsorption system is often ruled by using physisorption mechanisms, regarding hydrogen bonding, van der Waals forces, and π–π stacking, with minor contributions from chemisorption, probably because of Zn–O surface functionalities. SEM spectra discovered extensive modifications in surface morphology submit-adsorption, which include pore blockage and surface smoothing, confirming effective dye uptake. XRD patterns similarly supported dye intercalation and accelerated structural disorder after adsorption. Kinetic research found out that the adsorption system follows a pseudo-second-order version, at the same time as equilibrium information fit well to the Langmuir isotherm, suggesting monolayer adsorption on a fantastically homogeneous surface. A maximum dye removal efficiency of 83.30% changed into achieved at initial dye concentrations of 60–120 mg/L within 40 mins of contact time. Typically, the findings highlight CRAC as a promising adsorbent for dye-contaminated wastewater treatment. Its excessive performance, low cost, and eco-friendly source make it appropriate for further development and potential industrial-scale applications.

## ABSTRACT

Schizophrenia is a mental illness that is characterized by abnormal social behavior, a failure to understand reality, including confusion, auditory hallucinations, and false beliefs, as well as a lack of social engagement. In India, about 3–5 million people suffer from schizophrenia. The goal of the current work was to identify a potential compound for treatment of schizophrenia using *in silico* docking and ADMET studies. The 3D structure of all the compounds were retrieved from PubChem database and the 3D structure of target protein M4 muscarinic Acetylcholine Receptor (M4 mAChR) responsible for schizophrenia was retrieved from PDB database. PyRx 8.0 and Discovery studio 2024 were used for docking studies. From the results, ten compounds showed good binding affinity with target protein. Among them, the compounds Beta-Amyrin from *Swertia chirata*, Galphimine B from *Galphimia glauca* and Lupeol from *Swertia chirata* showed very good binding affinity like -10.5, -10.3, -10.2 kcal/mol respectively, with the target protein. Additionally, toxicity studies were also conducted for the best interacted phytocompounds and the results indicated that all these compounds showed less toxicity. Hence, the current study concludes that the compounds Beta-Amyrin, Galphimine B and Lupeolmay have the potential ability to treat schizophrenia. Further, pre-clinical studies are required to confirm the potential of these compounds for treating Schizophrenia.

**Keywords:** Schizophrenia, Indian medicinal plants, Phytocompounds, Docking studies, Toxicity studies

## INTRODUCTION

Schizophrenia is a debilitating and protracted brain condition that impairs a person's ability to think, speak, and behave normally. Around 1% of individuals today suffer from a mental illness, according to a World Health Organization (WHO) assessment, and this has an influence on people's lives. Delusions, disordered speech, and hallucinations are some of their symptoms[1]. Schizophrenia is readily caused by issues with certain brain functions[2], and many people in different industries have been affected by this illness[3, 4]. The sickness has a significant macro-level impact on the nation, which also affects the economic system, while it causes micro-level harm to an individual. A person suffering from psychotic disease exhibits disruptions in their everyday activities[5]. One of the worst and most upsetting mental illnesses is schizophrenia. Low recovery rates, a poor quality of life, and an elevated mortality rate are all linked to this chronic, recurrent mental disorder. Variously referred to as the "Cancer of the mind" and the "Greatest disabler of youth," this condition affects approximately 6 to 7 million Indians. Between the ages of 15 and 45, when people are most productive, it begins. It transcends socio economic class, educational, and gender boundaries[6]. In India, about 3–5 million people suffer from schizophrenia[7].According to the 2016, National Mental Health Survey, 0.8% of Indians suffer from schizophrenia spectrum disorders[8].The annual rate of schizophrenia in India is 0.44/1000 in rural areas and 0.35/1000 in urban areas, with a frequency of 1.5-2.5/1000 in India[9].This study's prevalence of the disorder reveals a high rate of schizophrenia, with 71 cases (28.4%), 30 of which were in men and 41 in women[10]. A complex neuropsychiatric disorder, schizophrenia manifests as cognitive (impaired retrieval of information such as thinking, learning, and memorizing), negative (blunted affect, alogia, anhedonia, asociality, and avolition), and positive (hallucinations and delusions) symptoms[11]. Along with these symptoms, people with schizophrenia frequently have affective symptoms, such as anxiety and depression, which are linked to a higher risk of suicide and a lower quality of life[12]. Negative symptoms significantly contribute to poor psychosocial functioning and performance, which affects the patient's quality of life, whereas positive symptoms are mainly monitored to diagnose an active state of schizophrenia[13].

The causes and effects of smoking in schizophrenia have been extensively studied and published. Smoking is prevalent among psychotic diseases, with a prevalence of 70–80% in schizophrenia[14]. The prevalence of cigarette smoking in the first episode psychosis was much higher, at an estimated 58% [15]. Male smokers smoked more than female smokers, which is consistent with findings in the general population[16]. Compared to normal controls, smokers with schizophrenia inhaled more deeply and for longer periods of time, exposing themselves to larger levels of tobacco's harmful ingredients[17]. Furthermore, compared to smokers without schizophrenia, they smoked more cigarettes and experienced higher levels of nicotine dependence[18]. The M1 and M4 mAChRs in particular have been linked to neurological disorders because they are extensively expressed throughout the central nervous system[19, 20] and are implicated in cognitive functions like memory, learning, and attention[21,22]. As a result, medications that specifically target these receptors may be helpful in the treatment of conditions like schizophrenia and Alzheimer's disease. Clozapine and Xanomeline are commonly used synthetic drugs to treat schizophrenia. Researchers discovered that after years of use, clozapine had a lot of negative consequences in addition to some positive ones for patients. Agranulocytosis, sedation, seizures, salivation, and weight gain are some of its adverse effects[23].As a cholinergic medication, xanomeline is unlikely to have the severe side effects for schizophrenia[24]. Since Xanomeline has been demonstrated to alleviate both positive and negative symptoms, it offers a novel approach for the treatment of schizophrenia. Current medications are less effective in treating negative and cognitive symptoms of the disorder. Muscarinic agonists are a novel class of pharmaceutical medications that are presently undergoing clinical trials to treat schizophrenia[25]. As an alternative solution and reducing the side effects of the current medication, the present study was designed to find the potential compounds from the different Indian medicinal plants like *Acorus calamus, Litsea polyantha*[26], *Galphimia glauca, Aloe vera*[27], *Alpinia zerumbet, Swertia chirata* and *Synedrella nodiflora*[28]for treating schizophrenia.

## MATERIALS AND METHODS

**Ligand Selection**

Using literature and the IMPPAT database, approximately 130 phytochemical compounds were chosen from a variety of Indian medicinal plants, including *Acorus calamus, Litsea polyantha*[26], *Galphimia glauca, Aloe vera*[27], *Alpinia zerumbet, Swertia chirata* and *Synedrella nodiflora*[28]. The 3D structures of these compounds were retrieved from the PubChem database[29], and SwissADME was used to test the Lipinski Rule of Five[30]. After the investigation, 120 compounds obeyed the Lipinski Rule of Five and they were taken for further study.

**Target Protein Selection**

The target protein M4 muscarinic Acetylcholine Receptor (M4 mAChR) responsible for the treatment of schizophrenia was identified using the literature. The 3D structure of this target protein was obtained using UniProt[31]and PDB database[32].

**Docking Studies**

PyRx 0.8 software was used to conduct docking studies for the phytocompounds (ligands) and the target protein M4 mAChR. This software was used for docking studies. The Open Babel option in the PyRx 0.8 was used to upload each ligand. The Vina wizard tool in PyRx 0.8 was used to construct the grid and perform docking tests[33]. An XL file included the binding affinity values. The data were evaluated and docked. The 2D and 3D images were obtained using Discovery Studio 2024. The lowest binding affinity indicates the best results.

**ADMET and CYP Properties**

The ADMET and CYP properties of all the phytocompounds with the best interactions were examined using SwissADME[30]. Lipinski, BBB (Blood-Brain Barrier), HIA (Human Intestinal Absorption), PGP (P-glycoprotein), XLogP3, TPSA (Topological Polar Surface Area), LogS, Fraction Csp3, Rotatable bonds, CYP enzyme inhibitor properties, skin penetration, and the bioavailability score were evaluated using this tool.

## RESULTS AND DISCUSSION

**Ligand and Target protein selection**

The 3D structure of ligands (phytocompounds) were retrieved from the PubChem database. The 3D structure of the target protein M4 receptor (PDB ID: 5DSG) was obtained from the PDB database and the 3D structure of the target protein is shown in Figure 1.

**Docking studies**

Docking experiments for the phytocompounds (ligands) and the target protein M4 receptor for schizophrenia were carried out using PyRx 0.8 software. Most of the compounds interacted with the target protein, and the following 10 compounds had good binding affinities with the target protein, according to the data. All the results are shown in Table 1 and the 2D and 3D interactions of phytocompounds with the target protein are shown in Table 2. From the results (Table 1), among other compounds, 10 compounds showed very good results with the target protein. Of which, the phytocompound Beta-Amyrin showed excellent binding affinity (-10.5 Kcal/mol) with the amino acid residues TYR89, TYR439, SER436, and TRP435 of the target protein. The phytocompound Galphimine B also gave excellent binding affinity of (-10.3 Kcal/mol) with the amino acid residues TYR92, TRP435 and LEU190. The binding affinity (-10.2 Kcal/mol) was observed between the phytocompound Lupeol and the amino acid residue TYR439 of the target protein. Among the other compounds, the lowest binding affinity (-8.8Kcal/mol) was observed between the phytocompound beta-Maaliene and the amino acid residues CYS442, TYR416, TRP413, TYR113 and ALA203 of the target protein. Besides, the binding affinity of the Synthetic drug Xanomelin with the target protein was (-6.8Kcal/mol) and the interacted amino acid residues were TYR439, TYR92, GLN184, TRP108 and ILE187. Thus, in the results of the present study, all the phytocompounds showed very good binding affinity when compared to the

Synthetic drug Xanomeline, of which, the phytocompounds Beta-Amyrin, Galphimine B and Lupeol showed the highest binding affinity among the other phytocompounds. According to a prior study, the essential oil of *Alpinia zerumbet* leaves helped in animal models of schizophrenia and reduced oxidative stress-induced changes in whole-brain homogenates [34]. Gerona *et al.* (2017)[35] discovered that emodin may have antipsychotic properties. Galphimine B, a nor-seco-triterpenoid found in *Galphimia glauca Bartl.,* a plant used in Mexican traditional medicine to treat mental illnesses, enhanced the cataleptic effect of haloperidol and showed protection against some of the ketamine-induced and apomorphine-induced symptoms of schizophrenia in mice [36, 37]. When tested on mice with schizophrenia, Amoateng *et al.* (2017) [38] found that *Synedrella nodiflora* extract has antipsychotic potential. Additionally, *Acorus calamus* has been used to treat schizophrenia and is utilized to make brahmyadiyoga, an Ayurvedic medical method [39, 40]. Traditional medical practitioners in Rangamati district use the bark of the medicinal plant *Litsea polyantha (Lauraceae)* to make a juice by macerating it with 1 g sugar. This juice is then administered orally to treat schizophrenia symptoms such as psychotic episodes [26]. Using two pharmacological animal models of schizophrenia, Kumbol *et al.* (2018) [41] assessed the psychotropic effects of the hydroethanolic extract of *Albizia zygia* roots against positive, negative, and cognitive symptoms. The findings indicated that the root extract of *Albizia zygia* has antipsychotic qualities with potential positive, negative, and cognitive symptom benefits along with a low propensity for extra pyramidal effects. After eight weeks of treatment, *Cuscuta epithymum* improved nearly all of the positive and negative symptoms as well as the cognitive impairment of patients with schizophrenia, according to Parvizi *et al.* (2019) [42]. It also showed potential antioxidant and neuroprotective effects and contributed to the increase of GABA amino acid, which helps to increase the inhibitory properties of the central nervous system. The *in vivo* study by Yadav *et al.* (2018) [43]shown that the seed extract of *Spinacia oleracea* was effective against stereotypical behaviors as well as positive, negative, and cognitive symptoms of schizophrenia in mice that were produced by ketamine. According to the research of Fei *et al.* (2022) [44], *Terminalia bellerica* fruit powder has been shown to have antipsychotic properties, which may help mitigate the symptoms of schizophrenia. All the macromolecular drug targets were bound with great affinity by quercetin, ellagic acid, and β-sitosterol. Quercetin has strong binding affinities for both the dopamine and N-methyl-D-aspartate receptors, whereas β-sitosterol has a strong affinity for the dopamine receptor. Ellagic acid, on the other hand, established more robust binding associations with phosphodiesterase 10A and Gamma-aminobutyric acid. Likewise, Alharbi *et al.* (2022) [45] found that acteoside, a naturally occurring molecule from *Bacopa monnieri*, had a strong binding effect on the STXBP1 active site. According to Chintha and Wudayagiri, (2019)[46], the impact of a bioactive chemical and the reference medication clozapine on specific susceptibility targeted gene of schizophrenia was investigated. While clozapine had a single hydrogen bond against DOPA decarboxylase with 1.14 Ki (mM) as an inhibition constant and Thr participating in interaction during docking, the compound had a single hydrogen bond against DOPA decarboxylase with 0.64 Ki (mM) as an inhibition constant and Gly as an interacted amino acid. The chemical has demonstrated a good binding affinity of 9.8 kcal/mol to the schizophrenia target's active site area. In contrast, clozapine, the reference medication, has demonstrated a binding energy of -9.2 kcal/mol. Interestingly, the previous study found that 3-(3,4-dimethoxy phenyl)-1-4(methoxy phenyl)prop-2-en-1-one, a novel bioactive compound isolated and characterized from the methanolic extract of *Celastrus paniculatus*, has been used extensively to treat neurological dysfunction and neurodegenerative diseases, primarily schizophrenia[47].In the present study, Beta-Amyrin from *Swertia chirata*, Galphimine B from *Galphimia glauca* and Lupeol from *Swertia chirata* showed very good binding affinity with target protein M4 muscarinic acetylcholine receptor (M4 mAChR) and this study suggests that the compounds Beta-Amyrin, Galphimine B and Lupeol may act as potential drugs to treat schizophrenia.

**ADMET and CYP Properties**

SwissADME was used in the current investigation to examine the ADMET qualities of the best-interacted phytocompounds and the synthetic medication Xanomeline, and the results were tabulated (Table 3). According to the findings, Xanomeline, a synthetic medication and all the best-interacted phytocompounds both followed the Lipinski rule of five, which means that all the compounds are good for drug likeness. Many compounds showed NO for BBB (Blood Brain Barrier) which refers that the compounds will not enter the human or animal's BBB when consumed, thus not reducing any possible brain related adversities. Many compounds showed LOW in the Human Intestinal Absorption (HIA). Most of the compounds were predicted to be effluated from the CNS by P-glycoprotein

and majority of the compounds Lipophilicity is good since the XLOGP3 values were between −0.7 and +5.0. 4 out of 10 best compounds showed good polarity since the predicted TPSA (Å) values are in the range of 20 and 130 Å$^2$. The Solubility values for the 7 best phytocompounds shows good results since their Log S (ESOL) values are value not higher than 6. Fraction of carbons in the sp3 hybridization for the phytocompounds were higher than 0.25, that shows our compounds have good Saturation. The Flexibility of all the phytocompounds were good, which was evident by the Rotatable bond values not falling above 9. The majority of the substances do not inhibit the CYP450 enzymes or cause any negative side effects, according to the results of CYP characteristics (Table 4). The plant chemical compound Galphimine B blocks the CYP3A4, alpha-Copaeneblocks the CYP1A2, CYP2C19 and CYP2C9, alpha-Bourboneneblocks the CYP1A2, CYP2C19 and CYP2C9 , (-)beta-Bourbonene blocks the CYP1A2, CYP2C19 and CYP2C9, Calamenene blocks the CYP2D6, beta-Maaliene blocks the CYP2C19 and CYP2C9 and Xanomeline (synthetic drug) blocksthe CYP1A2, CYP2C19 and CYP2D6 respectively. The value of log Kp (Skin Permeant) is good for all compounds. A Bioavailability Score (ABS) is good for all of the compounds. From the results of Table 4, the 5 Phytocompounds Beta-Amyrin, Lupeol, Campesterol and Beta-Sitosterol did not inhibit any CYP450 enzymes. Compounds with a high log Kp negative value have limited ability to penetrate skin. According to this statement, all the 10 Phytocompounds and synthetic drug have less skin permeation ability.

## CONCLUSION

In the present study, 130 phytocompounds were taken from different Indian medicinal plants. From the results, in comparison to the synthetic drug Xanomeline (-6.8 kcal/mol), 10 compounds showed good binding affinity with target protein M4 muscarinic acetylcholine receptor (M4 mAChR), responsible for schizophrenia. Among them, the compounds Beta-Amyrin(-10.5 kcal/mol) from *Swertia chirata*, Galphimine B (-10.3 kcal/mol) from *Galphimia glauca* and Lupeol(-10.2 kcal/mol) from *Swertia chirata* showed very good binding affinity with target protein. Additionally, toxicity studies were also conducted for the best interacted phytocompoundsand the findings indicated that all these compounds showed low levels of toxicity. Hence, the current study concludes that the compounds Beta-Amyrin, Galphimine B and Lupeolmay have the potential ability to treat schizophrenia. Further, *in vitro* and *in vivo* studies are required to confirm the potential of these compounds for treating Schizophrenia.

## ABSTRACT

Lung cancer is one of the leading cancers causing mortality among all types worldwide; therefore, there is a continuing need for the investigation of safer and effective therapeutic alternatives from natural sources. The current study focuses on phytochemical profiling and anticancer potential of *Borassus flabellifer* sprout extract against human lung carcinoma (A549) cells. Profiling by gas chromatography–mass spectrometry revealed the presence of several bioactive phytoconstituents, containing fatty acids, fatty alcohol esters, pyrimidine derivatives, and halogenated compounds, most of which are associated with antioxidant and anticancer activities. Cytotoxic activity was assayed, showing a concentration-dependent reduction in A549 cell viability. These morphological changes were further confirmed to be signs of apoptosis-like alterations such as cell rounding and shrinkage, cell membrane blebbing, and loss of cellular adhesion post-treatment. A comparative study with the standard chemotherapeutic agent cisplatin showed that while the latter exhibited higher cytotoxicity, *B. flabellifer* sprout extract resulted in a controlled form of cell death with comparatively reduced nonspecific toxicity. This study therefore demonstrates the promising nature of *Borassus flabellifer* sprouts as a potential natural source of anticancer compounds and serves as a basis for further mechanistic studies.

**Keywords:** *Borassus flabellifer,* Lung Cancer, Phytochemicals, A549 cell line.

## INTRODUCTION

Lung cancer is one of the leading causes of cancer-related mortality worldwide with an estimated 1.8 million deaths per year and a substantial global health burden (Bray et al., 2018). About 85% of all cases of lung cancer are non-small cell lung carcinoma (NSCLC), the most common subtype. Because early disease progresses asymptomatically, NSCLC is frequently detected at an advanced stage (Siegel et al., 2020). Overall survival rates are still low despite advancements in immunotherapy and targeted therapies, and the need for new, safer, and more effective therapeutic agents is urgent due to treatment side effects and costs (Herbst et al., 2018). The therapeutic and chemopreventive potential of phytochemicals derived from medicinal plants against a variety of cancers, including lung carcinoma, has attracted a lot of attention (Newman & Cragg, 2020). According to Khan et al. (2019), phytochemicals, including secondary metabolites like polyphenols, flavonoids, alkaloids, and terpenoids, have a variety of biological activities, such as anti-inflammatory, anti-cancer, and antioxidant qualities. Numerous substances originating from plants have made their way into clinical practice; for instance, vincristine and paclitaxel, which were first isolated from Catharanthus roseus and Taxus brevifolia, respectively, are common chemotherapy drugs (Cragg & Newman, 2013). This emphasizes how crucial it is to keep looking for possible anticancer compounds in botanicals.

The palmyrah palm, or Borassus flabellifer L. (Arecaceae), is a hardy perennial palm that is indigenous to South and Southeast Asia. Palmyrah has long been prized for its edible fruit, sap, and wood, but ethnomedicine also acknowledges its anti-inflammatory, anti-diabetic, and antimicrobial properties (Kumar & Sharma, 2016; Rathore et al., 2012). The nutritional value and bioactive components of various B. flabellifer parts, including fruit pulp, seeds, leaves, and sap, have been investigated (Singh et al., 2013). Nevertheless, despite growing evidence that germination can greatly increase bioactive phytochemicals and antioxidant potential, little is known about B. flabellifer sprouts, which grow from germinating seeds (Xu & Chang, 2009; Yuan et al., 2021). According to Singh et al. (2014), sprouting, also known as seed germination, initiates biochemical changes that result in the production or release of secondary metabolites and enhance nutrient availability. The sprouts of *Triticum aestivum* (wheat), *Vigna radiata* (mung bean), and *Brassica oleracea* (broccoli) have been shown to exhibit enhanced antioxidant and anti-proliferative activities. This suggests that sprouts may be used as functional foods with chemopreventive qualities (Finley et al., 2019). These findings encourage thorough phytochemical profiling and bioactivity assessment of *B. flabellifer* sprouts, which may have special metabolites with anticancer properties.

The bioactivity of these components in *B. flabellifer* against lung cancer have not yet been thoroughly determined. Preliminary reports suggest the presence of phenolic acids, flavonoids, and other antioxidant compounds in germinating seeds of related palm species (Al-Snafi, 2017). Plants with ethnopharmacological significance and unexplored sprouts like *B. flabellifer* offer promising research avenues in light of the rising incidence of lung cancer and the need for innovative, less toxic treatments. In particular, the identification of antioxidant and anticancer compounds from B. flabellifer sprouts may aid in the development of natural agents that slow the spread of cancer or improve current therapeutic approaches. Accordingly, the aim of the current study is to extensively investigate the phytochemical constituents of Borassus flabellifer sprouts to evaluate the anticancer potential of this particular sprout type on lung carcinoma cell lines. The current study is not only extending the phytochemistry of the less utilized Borassus sprout of India, but it is also examining the manifestations of Borassus sprouts in the prevention and treatment of one deadliest cancer.

## MATERIALS AND METHODS

**Extraction of phytochemicals from *Borassus flabellifer***

Sprout of *Borassus flabellifer* were washed thoroughly with distilled water for several (5-6) times. The samples were allowed to dry under shade at room temperature. They were ground by an electrical mixer until they became fine powder. The powdered samples were stored until further use. About, 25 g powdered sprout sample was soaked in

250 ml of 90% ethanol for 72 h resulting in release of phytochemical into the dissolving solvent. Further, the solvents were evaporated under high pressure using a rotary evaporator to obtain/concentrate phytochemicals released from the seed tissue(s) of palmyra palm.

**Qualitative analysis of phytochemical substances**

Presence of different phytochemicals were analyzed as described in a previous study (Harborne et al., 1973). Presence of alkaloids, saponins, tannins, cardiac glycosides, flavonoids, phenols, steroids, terpenoids, quinones and proteins were estimated from the concentrated solvents.

**Thin layer chromatography**

The extract was analyzed in thin layer chromatography (TLC) as per conventional method using silica gel 60F254 (Merck) in 5x3 cm dimension. Glass capillary tubes were used to spot the extracts in TLC plates. The resolving solvent (chloroform:methanol) was optimized for separation of bioactive components in the TLC set-up. After pre-saturation with mobile phase for 30 min the plates were kept inside the chamber and desirable fractions were eluted using the optimized solvent(s). Further, the plates were dried and visualized under UV followed by spraying different reagents. $R_f$ values determined by using following formula:

$R_f$ = Distance travelled by the solute/Distance travelled by the solvent.

**GC-MS analysis of sprout extract**

A PerkinElmer Clarus 500 gas chromatograph (Autosystem XL) in conjunction with a TurboMass Gold mass spectrometer (PerkinElmer, TurboMass software version 5.2) was used to perform the GC–MS analysis. An Elite-5MS capillary column (30 m × 250 μm i.d., 95% dimethyl polysiloxane) was used to achieve separation. The oven temperature program was started at 60 °C and held there for two minutes. It then increased gradually to 300 °C at a rate of 5 °C $min^{-1}$, with a final hold time of six minutes. The carrier gas, helium, was used at a steady flow rate of 1 mL $min^{-1}$. Samples were injected in split mode with a split ratio of 10:1, while the injector temperature was kept at 240 °C. At 70 eV, electron ionization was carried out, and mass spectra were captured within the 40–600 m/z scan range. By comparing the obtained mass spectra with those found in the NIST mass spectral library (2011 version), the compound was identified.

**Cytotoxicity assessment using MTT**

A549 human lung cancer cells were acquired from the National Centre for Cell Science (NCCS), India, and kept in culture media supplemented with 10% heat-inactivated fetal bovine serum (FBS), 100 U/mL of penicillin, and 100 μg/mL of streptomycin in a humidified environment at 37 °C with 5% $CO_2$. Trypsin–EDTA was used to separate the cells, after which they were centrifuged, resuspended in new medium, and their viability evaluated. To enable monolayer formation, 96-well plates were seeded with roughly 5 × $10^4$ viable cells per well and incubated for 24 hours.Following treatment with different concentrations of the test compounds, the cells were incubated for 48 hours under normal culture conditions. Then MTT solution (5 mg/mL) was added, and the cells were incubated for 4 hours to assess the cell viability. The resultant formazan crystals were dissolved in DMSO and measured at 570 nm with microplate reader. Values for $IC_{50}$ and percentage growth inhibition were computed and contrasted with standard cisplatin.

## RESULTS AND DISCUSSION

**Analysis of phytochemical substances in the seed extracts of *Borassus flabellifer***

To analyze the presence of phytochemical substances and secondary metabolites in the Sprout extracts of *Borassus flabellifer*, we comprehensively profiled their presence in an alcoholicenvironment representing 90% ethanol. The phytochemical analysis revealed the presence of nine phytochemical out of the ten compounds tested. The phytochemical analysis suggests that palmyrah palm can be used for the treatment of various health disorders.

**Analysis of phytochemicals using thin layer chromatography**

Further to analyze the presence of phytochemical substances in the extracts of palmyra palm, the extracts were assessed using thin layer chromatography. Interestingly, we detected at least five spots showing Rf-value of 0.06-0.93 as shown in table. Rf-values estimated based on the migration rate of solute(s) to the solvent(s). This suggests the presence of phytochemical substances and/or secondary metabolites in the sprout extracts of palmyra palm.

**GC-MS analysis of *Borassus* sprout extract**

In GC-MS analysis, diverse bioactive compounds, including fatty acids, esters, halogenated hydrocarbons, pyrimidine derivatives, and nitro compounds, were identified, which are present in *Borassus flabellifer* sprout.The identification of n-hexadecanoic acid, also called palmitic acid, is very interesting. Recent studies have confirmed that the compound possesses the ability to elicit mitochondrial apoptosis, ROS generation, and cell cycle arrest in cancer cells. These effects were observed in various cancer cells, which indicate the ability of the compound to elicit anticancer activities (Wang et al., 2023; Ottaviani et al., 2025). Importantly, the identification of the pyrimidine compound is very interesting and proves the anticancer properties of the compound, as various pyrimidine compounds have exhibited anticancer activity, demonstrating the ability to inhibit the activity of the epidermal growth factor receptor, specifically in the cancer cells of non-small cell lung cancer, including A549 cells. Further, the identification of the halogenated fatty acid derivative enhances the ability of the compound to elicit anticancer properties through increased membrane permeability and the ability to elicit apoptotic activity. The identification of the nitro-alkene compound also elicits pro-apoptotic activity.

**Cytotoxicity of sprout extract of *Borrasus flabellifer***

The MTT assay graph represents the cytotoxic effect of *Borassus flabellifer* sprout extract at different concentrations in comparison to the standard anticancer drug cisplatin. Starting from 22% inhibition at 10 μg, *B.flabellifer* demonstrated an increase to ~35% at 20 μg and ~47% at 50 μg, indicating progressive loss of cell viability. Finally, it showed about 58–60% inhibition at a maximum tested concentration of 100 μg and thus exhibited a response of moderate to strong cytotoxicity potential. In contrast, the inhibition values of cisplatin were higher: approximately 38% at 10 μg, ~60% at 20 μg, and ~70% at 100 μg. From this sigmoidal trend, dose-responsiveness of *B.flabellifer*sproutwas comparable to that of cisplatin.The $IC_{50}$ value of the given test sample and the standard Cisplatin wasfound to be1.91 μg/ml is 6.62 μg/ml respectively.

Our study showed the morphological studies of the A549 cells after treatment with *Borassus flabellifer* sprout extract at various concentrations and confirmed a dose-dependent cytotoxic effect. The untreated control showed a spindle shape indicative of healthy morphology. The treated cells showed signs of apoptotic cell death as indicated by rounding and shrinkage of the cells, loss of adhesiveness at a concentration ranging from 12.5-100 μg. The same signs have been shown in other plants used in the study of anticancer properties and inducing apoptosis in lung cancer cell lines by causing mitochondrial dysfunction (Wang et al., 2023; Li et al., 2022). From comparative morphological evaluation, it has been observed that treatment of A549 cells with *Borassus flabellifer* sprout extract and cisplatin results in the exhibition of distinctive cytotoxic effects. Although cell rounding, membrane blebbing, cytoplasmic shrinkage, and partial loss of cell adhesion were observed after treatment with 50–100 μg concentration of the *B. flabellifer* extract, these effects were slow and dose-dependent, indicating apoptosis-regulated cytotoxic cell death. Morphology is characteristic of phytochemicals of plant extracts, which are known to induce mitochondrial dysfunction-mediated apoptosis and oxidative stress-mediated apoptosis, leading to cell death (Patel et al., 2024). However, after treatment of A549 cancer cells with cisplatin, severe dose-dependent morphological changes were observed, such as cell detachment, cell shrinkage, and cell density, indicating aggressive DNA damage-mediated apoptosis, which is characteristic of cell death resulting after treatment with this anticancer compound (Wang et al., 2022). It has also been noted that the anticancer effect of B. flabellifer is relatively milder, indicating that this plant extract efficiently inhibits the growth of lung carcinoma cells.

## CONCLUSION

The present study reveals that *Borassus flabellifer* sprout extract exhibits great anticancer activity against A549 lung carcinoma cells. GC–MS has identified bioactive phytochemicals that are fatty acids, pyrimidine derivatives, and halogenated compounds. These have been associated with anti-cancerous activities. MTT assay confirmed the overall concentration-dependent reduction in cell viability, while morphological observations cited cell rounding, shrinkage, and loss of adherence, indicative of apoptosis-like phenomena. Cytotoxicity was found to be relatively moderate and more efficient compared to the standard drug cisplatin, insinuating less nonspecific toxicity. All of these collectively establish *B. flabellifer* sprouts as a promising source of natural anticancerous agents and further justify carrying out mechanistic and *in vivo* studies.

## ABSTRACT

This study aims to assess ongoing tectonic activity and identify potential active faults within a region traditionally considered part of the stable Archean craton but known for historical earthquakes of magnitude 5.0–5.9. Using remote sensing and quantitative geomorphic analysis, the relationship between drainage characteristics and structural controls such as lineaments and faults was evaluated through digital image processing of Landsat 8 data, which revealed several major lineaments dominated by a NW–SE trend strongly influencing regional topography. Five geomorphic indices-Asymmetry Factor (AF), Transverse Topographic Symmetry Factor (T), Valley Floor Width-to-Valley Height Ratio (Vf), Mountain Front Sinuosity (Smf), and River Sinuosity (SI)-were applied across 43 sub-basins, of which 50% exhibited anomalous AF values (outside the 40–60 range), indicating tectonic tilting near major lineaments. The T index showed consistent drainage deflection toward the NW close to the prominent L1 lineament, with maximum lateral migration observed on its northeastern side, while Vf values ranging from 0.51 to 2.31 revealed that half of the measured sites display values below 1.0, signifying active incision and the development of V-shaped valleys. These geomorphic anomalies are particularly concentrated at intersections of NE–SW and NW–SE trending lineaments, leading to the conclusion that, despite its limited spatial extent, the Chick Tore basin records active surface deformation and ongoing tectonic adjustments that are likely linked to the region's documented seismicity.

**Keywords:** Cratons, Mountains, Lineaments, Morphometric analysis and Seismicity.

# INTRODUCTION

A series of vibrations induced in the earth's crust by the abrupt rupture and rebound of rocks in which elastic strain has been slowly accumulating is termed an earthquake. This is the most disastrous natural hazard, which causes damage to both living and non-living. Which also causes huge damage to the possessions? The Indian plate is one of the most complexly deformed parts in the world, which has also become the source of various earthquakes in the past and presently. (Rajendran et.al, 2004). In our country their existing zoning map has several limitations, though it provides some basic information on the relative seismic potential of different regions. The historical documentation of earthquakes and their recordings themselves are too short to represent the long-term activity of the faults. Earth quake occur in intra-plate location is very rare. Most of the Archean cratons on Earth were earlier considered stable (Johnston and Kanter, 1990). But sometimes earthquakes may occur in faulting of the intraplate settings, so they occur in unexpected locations.

Identification of the seismic potential zone or active faults in an area is the first step in the direction of seismic hazard assessment. It is very difficult, the majority of the faults are either hidden or don't have not produced recognizable deformation in recent geological formations. Peninsular India has low rates of deformation coupled with high erosional activity, so there occurs lack of information from instrumental seismic data for strong earthquakes. This leads to a challenge to the identification and characterization of active faults. However, there are in stances that geomorphic analysis played an effective role in identifying the potential seismic source zones. In the evaluation or classification of a fault in an area, such as active/potential/inactive, fault geometry, geologic age, morphotectonic signature, and relation with ongoing seismic records, play a key role. According to the studies of Schultz and Cleaves (1955), the active fault is termed as fractures that have shown displacements in the marker beds within historic times, and which also have an accurate seismic record, while the inactive fault is termed as the underlying fault that did not show any displacement in the overlying younger strata.

The studies carried out by Cluff (1964) in dam foundations suggested that if a fault has shown conclusive evidence of movement in the recent geological time by cutting recent sediments such as alluvium, alluvium fansor seismic record (epicentral plota long the fault) is called an active fault. After a year, Allen (1965) had an observation on active fault based on the studies carried out in Southern California for the relationship between seismicity and geological structure. By these studies, he stated that, in the absence of a historical seismic record, there are only the geological criteria. The studies of Albee and Smith (1966) carried out on the earthquake characteristics and fault activity in southern California suggested that different fault shows different extents of activity, so these are classified into three: active, moderately active, and slightly active. This classification was done by the evidence of geodetic, seismic records, and deformation-associated surface features. They emphasized that "geological evidence monitors a fault over a time period 100 or more times as long as the accurate seismic and geodetic record.

**Application of Geomorphic Analysis (Methodology)**

The study of tectonic geomorphology increasingly in the last few decades, has increasingly developed into a main tool in the evaluation of active tectonic elements (e.g. Keller and Pinter, 1996 and references there in). The morphology developed by the tectonic features or morphotectonics, in general, explores the interrelationship of climatic, tectonic, erosion-deposition processes, and other surficial features (Caputo and Pavlides, 2008). Tectonic geomorphology indicates an amount of interaction between surficial & tectonic processes and also the control of climatic conditions over them (Bull, 1991). The quantitative assessment of tectonically active areas by geomorphic indices (Peters and Van Balen, 2007; Bull and McFadden, 1977; Keller and Pinter, 2002; Burbank and Anderson, 2001). There are also some quantitative parameters for categorizing the faults as Very Active, Moderately Active, or Inactive faults. This kind of classification is used to figure out the locations in which more intense field activities can identify the active structure and also the prevailing rates. However, there are only a few methods for the identification of active faults in areas like low relief and low seismicity. In the present study, both conventional morphometric parameters and geomorphic indices have been used for the evaluation of the study area.

**Study Area**

The study area lies in the west of Bangalore, Karnataka, between latitude 13° 03' N & 12° 53' N and longitude77°12' E & 77°20' E. NNE-SSW trending Arkawati River is the major river draining in this area. One major NW-SE trending Fault viz Arkawati fault, is located in the SW of the study area. Other than the fault, one major NE-SE trending and one minor NW-SE trending lineament are also found in the SW of the study area (Map-1). As per GSI 2000, the study area has also experienced an earthquake in historical times (1901-1963) of M5.0 to 5.9 (GSI 2008). The present study area is limited to the catchment of NW- SE trending Chick Tore, one of the tributaries of Arkawati River, within the area covering~ 116 sq. km. Remote sensing studies identified a wide variety of land forms in the study area. The general topography of the area shows the elongated hills trending NE-SW in the southeastern part. The area is mostly mid-range relief (1221m to 720 m), and all the subsidiary rivers flow with a gentle gradient for most of their length.

**Lineament Study**

The lineament identification in the present study is focused on the identification of the active tectonic structures/features in the area. Initially, all the structural units of the study area have been delineated using satellite images of various spatial and spectral resolutions. Since the visual extractions method is more efficient in discriminating human precipitation from geological lineaments in the urbanized areas. (Ricchetti and Palombella, 2005). In the present study, visual interpretation was used for the demarcation of the lineaments. Various processes like spectral enhancement, band combination, and band ratio have been applied during the image analysis. The fractures, trend lines in hard rocks, palaeochannels, etc., besides the narrow valleys, series of straight courses of rivers between the hills, and their sudden changes have been manifested as lineaments. An RGB combination of the 674 band is used for marking the lineaments from Landsat 8. In addition to that band ratio of 4/3, 6/2, 7/3 is also used in the delineation of lineaments (Mawaniki et al. 2015). During the remote sensing study done at the regional scale, it is observed that the NW- SE lineaments are found to be regionally the most persistent features within the study area. Details of the individual lineament are given in Table-1. The NW-SE flowing of the Chick tore follows one such lineament. In the NE of this river, another parallel lineament is also observed. The image analysis carried out for the study area also affirms the domination of the NW-SE trending lineament. In addition to that, there are some lineaments NE-SW that are also observed in the area (Map-2).

**Geomorphic Studies**

The study of geomorphology is considered a valuable tool in active tectonic studies, since it holds the records of evolution or modification of landforms (Keller and Pinter, 1996). Quantitative analysis of various geomorphic parameters (geomorphic indices) can directly indicate the level of tectonic activity. These geomorphic indices have been successfully used by many researchers in different terrains for the evaluation of ongoing tectonic activities. (e.g., Bull and McFadden, 1977; Keller and Pinter, 1996 de, 1983; Gregory and Schumm, 1987; Wellsetal., 1988; Rhea,1993;Demoulin, 1998; Mc Calpin, 1996; Malik et al., 2001; Burbank and Anderson, 2001; Champel et al., 2002; Schumm et al., 2002; Silva et al., 2003; Riquelmea et al., 2003). The present study is an attempt to identify and evaluate tectonic activity (if any) through quantitative analysis of various geomorphic indices. Geomorphic indices such as Asymmetry Factor (AF), Transverse Topography Symmetry Factor (T), Valley floor/Valley width ratio (Vf), Mountain front sinuosity (Smf), River sinuosity index (SI) are the parameters used in this study for the calculation of individual parameters.

This method of quantitative analysis of a drainage basin was first introduced by Horton (1945), followed by Strahler (1952) in the field of hydrology. Various parameters obtained from the analysis have also analyzed in terms of the tectonic activities (Deffontaines and Chorowicz, 1991; Talling and Sowter, 1999; Simoni et al., 2003; Jamieson et al., 2004; Devi et al., 2011; Zhang et al., 2006; John et al., 2008). This method of analyzing the drainage pattern and the associated anomalies also has the potential to record the evidence of active tectonics (Deffontaines et al., 1992; Simoni et al., 2003; Delcaillau et al., 2006; Ramasamy et al., 2011).

In the study area Chicktore catchment area is divided into 43 sub-basins on the basis of 2nd and 3rd order streams (Maps 3 & 4). For demarcating the basing SOI 1:50,000 scale toposheet no 57G/4, 57G/8, 57H/1, 57H/5 are utilized. All basic parameters, like the length of the drainage perimeter and area of the basins, are measured using Arc-GIS 10.5.

**Asymmetry Factor (AF)**

The asymmetry factor is originally derived to detect the tectonic tilt of the basin areas (Hare and Gardner, 1985; Keller and Pinter1996). The principle behind this parameter is that in a stabilized terrain with uniform lithology, the main drainage should occupy the centre of the basin. This Factor defined to represent the percentage of the areal shift of the main drainage from the Centre of the basin. In the present study, the asymmetry factor is calculated based on the formula as listed in Table-1. For a stream network flowing in a stable setting and uniform lithology, the AF would be nearly equal to 50. In all other cases, there will be a change in value deviating on either side of 50, depending on the direction of drainage migration (Keller and Pinter, 1996). The AF was calculated for all 43 sub-basins demarcated for the morphometric analysis, and the AF ranges from 33 to 78. If we consider the range 40 to 60 as the normal values of AF for the study area, then it is observed that only 50% of the basins fall in this range, and 50% of the basins are showing anomalous AF (either <40 or >60). The spatial distribution of the AF shows that the basins with the anomalous values are observed in the vicinity of L1 (central portion) and L4. Since this factor reflects the tilt of the basin, 50% of the basins are showing the tilting, including the basin lying in the low relief area. The spatial relations of these anomalies with the above said lineaments may indicate the geological or structural influence (Map-5).

**Transverse topographic Symmetry factor (T)**

This method suggested the direction of Holocene tilting of the ground in the Mississippi Embayment (Cox et al., 2001). This factor can also show the tilt direction of the basin in areas of uniform lithology (Keller and Pinter, 1996). The present study calculated T at different reaches for second and third-order streams to demarcate the regions that show preferred drainage migration. Similar studies carried out in the northern part of the study area identified that the WNW-ESE trending active fault (John et al., 2008). The values of 'T' are plotted in the map as an arrow representing the direction of drainage shift and length as the quantum of movement. For a perfectly symmetric basin, T= 0. As asymmetry increases, T increases and approaches a value of 1, where the drainage will be flowing through the basin boundary (Map-3).

The present analysis indicates that all the basins joining the Chick Tore are showing a deflection towards NW in the vicinity of the L1 lineament. Careful observations indicate that north eastern parts of the lineament are showing more consistent deflections as compared to the southwestern part. It is also observed that the quantum of deflection is more in the NE side basin as compared to the SW side basins within the study area. The above observation may indicate that the NW-SE trending lineament L1 and L2 are responsible for inducing the variation in the deflection of the drainages.

**Mountain Front Sinuosity (Smf)**

The value of this ratio generally ranges between 1 and 5. Bull (1977; 2007); Keller and Pinter (2002); Pérez-Peña et al. (2010); Silva et al. (2003) have attempted to classify the values of the ratio in relation to the tectonic activity (Table-2). In the present study, this ratio has been utilized to evaluate the ongoing tectonic activity. The ratio has been calculated along the mountain fronts in the existing central and southwestern part of the study area. For the assessment of the status of ongoing tectonic activity, 6 locations have been selected for the calculation of the mountain front sinuosity ratio (Map-9). The Mountain Front Smf index values have been calculated by digitizing the contours along the mountain fronts using Arc-GIS.

**Valley Floor Width -Valley Height Ratio (Vf)**

Valley floor width - valley height ratio (Vf) is another geomorphic index developed by Bull and McFadden (1977) for the quantitative assessment of tectonically influenced geomorphic features. As Smf, Vf have also shown their effectiveness in assessing the tectonic activity of mountain fronts generated by faults (e.g., SW USA (Bull and

McFadden, 1977; Rockwell et al., 1984), Costa Rica (Wells et al., 1988), Oregon Coast Range, USA (Rhea, 1993), the Kachchh region), southeast Spain (Silva et al., 2003), western Taiwan (Chen et al., 2003), North western Himalaya (Malik et al., 2007). The ratio of the width of the valley floor to valley height, Vf, is calculated. The smaller value of the ratio indicates the V-shaped valley, while the higher values indicate the broad floor U-shaped valley. In the present study, Vf is calculated at 18 locations across different reaches of the drainage system (Map-7).

The spatial distribution of the location at which the ratio has been calculated indicates that the locations are falling in the NW- SE trending valley along the L1 lineament. Over the entire ratio values vary between 0.51 and 2.31. As per the classification given in the literature reviewer searchers has categorized that the value of the ratio less than1.0 indicate that the tectonic adjustments are continuing. Values more than 1 to 5 indicate the tectonic activity is continuing, but at a lower pace. As per the value classification, 9 locations within the study area fall within the category of tectonic adjustments that are continuing. The Remaining 9 locations are falling in the category of tectonic activity continuing, but at a lower pace. Spatial distributions of the first category indicate that lower values are observed around the junction of the L1 and L4 lineament. A similar scenario is also observed around the junction of the L3 and L1 lineament. Lower values are also observed along the NE-SW trending NW lineament. The above observation shows that the place where the NE trending lineaments cross the NW-SE trending L1, values of the ratio are observed to be very low. It may indicate that the ongoing adjustments are continuing around the junctions of NE and NW trending lineaments.

## RESULT AND DISCUSSION

In the present study, the quantitative and qualitative analyses of various geomorphic indices have been carried out. It is observed that anomalous asymmetry factor values are located in the vicinity of the NW-SE trending L1 lineament. Consistent drainage deflection towards NW is seen along the L1 lineament. Anomalous values of Mountain Front Sinuosity and River Sinuosity are only located around the crossing of the NW and NE trending lineaments. Similarly, the low values of valley floor ratio are also located around the crossing of the lineaments. The present study was to learn the methodology and its application in the evaluation of individual lineaments. Though the study area was very small, it may indicate the ongoing adjustments at the locations where the lineaments are crossing each other within the study area, as this area had experienced a historical earthquake of Mag~5.

## ACKNOWLEDGMENT

The authors express their gratitude to the Department of studies in Earth Science for providing the necessary facilities and academic support to carry out this research work. We are thankful to the university authorities for the encouragement and cooperation.

**Conflict of interest**

There are no conflicts of interest among the authors.

## ABSTRACT

*Cleome viscosa* L., a medicinally vital plant threatened by overharvesting and habitat loss, necessitates sustainable propagation strategies like micropropagation. However, genetic fidelity in micropropagated plants remains a concern due to soma clonal variations. This study evaluates the genetic stability of *in vitro*-raised *C. viscosa* compared to wild populations using RAPD and ISSR markers. Fifteen RAPD and three ISSR primers generated 180 amplification bands, revealing 88.33% polymorphism overall. ISSR markers exhibited higher discriminatory power (91.43% polymorphism) than RAPD (87.58%), with primers ISSR 1 and OPA 02 showing 100% polymorphism. UPGMA cluster analysis segregated wild and micropropagated plants into distinct clades, which attributed 85% of genetic variation. The high divergence underscores significant soma clonal variations during micropropagation, potentially impacting the plant's medicinal efficacy. While ISSR markers proved superior for detecting genetic instability, both techniques are effective for fidelity assessment. These findings emphasize the need to optimize *in vitro* protocols and implement routine molecular screening to preserve genetic integrity. This study provides a framework for ensuring the conservation and sustainable utilization of *C. viscosa*, balancing mass propagation with the retention of bioactive compound synthesis critical for its pharmacological applications.

**Keywords:** *Cleome viscosa*, Micropropagation, Genetic Fidelity, RAPD, ISSR, Soma Clonal Variation.

## INTRODUCTION

*Cleome viscosa* L., commonly known as "Asian spider flower" or "wild mustard," is a medicinally significant annual herb belonging to the family Cleomaceae. It is widely distributed in tropical and subtropical regions and is traditionally used for its anti-inflammatory, antimicrobial, and antipyretic properties (Upadhyay*et al*., 2011).Despite its ecological and pharmacological importance, overharvesting and habitat destruction have threatened its natural populations, necessitating sustainable conservation strategies such as micropropagation(Patel *et al*., 2021). Micropropagation offers a rapid and scalable method to produce genetically identical plants, but concerns about genetic fidelity due to soma clonal variations during *in vitro* culture persist(Bairu*et al*., 2011). Ensuring genetic stability in micropropagated plants is critical for maintaining their medicinal efficacy and ecological adaptability. Molecular markers such as Random Amplified Polymorphic DNA (RAPD) and Inter Simple Sequence Repeats (ISSR) are robust tools for assessing genetic fidelity and diversity(Yu and Nguyen, 1994 and Julie *et al*., 2016 ). These techniques are cost-effective, require no prior genomic information, and efficiently detect polymorphisms caused by soma clonal variations or environmental stresses(Joshi *et al*., 2020). While RAPD markers amplify random genomic regions using short primers, ISSR targets microsatellite regions, providing higher reproducibility and resolution (Reddy *et al*., 2002). Previous studies have employed these markers to validate clonal fidelity in micropropagated plants like *Bacopamonnieri* (*Tiwari et al., 2014*) and *Withania somnifera*(Ahmad *et al*., 2016), but limited research exists on *Cleome viscosa*. This study presents the first comparative molecular analysis of wild and micropropagated *Cleome viscosa* using RAPD and ISSR markers. The objectives are to evaluate genetic stability in micropropagated plants relative to their wild counterparts, identify potential soma clonal variations, and validate the reliability of micropropagation protocols for conservation and commercial cultivation. The findings will contribute to optimizing *in vitro* regeneration systems for endangered medicinal plants and ensuring their genetic integrity for sustainable utilization.

## MATERIALS AND METHODS

**Plant Material Collection**

**Wild Samples**: Healthy mature plants of *Cleome viscosa* were collected from their natural habitat in Sirumailur village (The latitude 13.0938995 and longitude 80.292356 are the geocoordinate of the Sirumailur), Chengalpattu district, Tamil Nadu (n = 20). Voucher specimens were deposited at Botanical Survey of India (BSI), Coimbatore, Tamil Nadu, India with specimen reference number - BSI/SRC/5/23/2016/Tech/1195.

**Micropropagated Samples**: *In vitro*-raised plants were obtained from a previously established micropropagation protocol (Basha*et al*., 2022). Plants regenerated via nodal explants after 6–8 subculture cycles were used for analysis (n = 20).

**Micropropagation Protocol**

Nodal explants 5mm in size were surface-sterilized with 0.1% $HgCl_2$ (3 min) and cultured on MS (Murashige and Skoog, 1962) basal medium supplemented with 3% sucrose, 0.8% agar and different concentration of PGRs such as 6-Benzylaminopurine (BAP), Kinetin (KIN), Naphthalene-3-acetic acid (NAA) (Kolar*et al.,* 2021). The inoculated cultures were maintained in growth chamber. Data was recorded after 28 days (Archana*et al*., 2013).

**DNA Extraction**

Wild and micropropagated plant samples were frozen in liquid nitrogen and grounded to fine powder. 1g of freeze-dried powder was used to extract plant DNA. The mini extraction was done based on the cetyltrimethyl ammonium bromide (CTAB) method (Voigt *et al*., 1999). The finely grounded plant materials were transferred to sterile centrifuge tube. Pre-warmed at 65ºC. DNA extraction buffer [100 mMTrisHCl (pH 8.0), 1.4M NaCl, 50mM EDTA (pH 8.0) and 2% CTAB] was added to this, mixed well and incubated in a water bath at 65ºC with gentle shaking for one hour. After incubation an equal volume of chloroform/isoamyl alcohol (24:1 v/v) was added gently to denature

proteins and centrifuged at 10000 rpm at 25ºC for 10 min. The aqueous phase was transferred to a new sterile tube and DNA was precipitated with 0.6 volume of cold isopropanol and 0.1 volume of 3M sodium acetate (pH 5.2) and centrifuged at 15000 rpm for 25 min at 25ºC. The supernatant was poured off and the pellet was washed twice with 70% cold ethanol and dried at room temperature. The pellets were air dried and suspended on TE buffer (pH 8.0).

**Purification of Genomic DNA**

The extraction of total genomic DNA from the *C. viscosa* isolates as per the above procedure was followed by RNase treatment. Genomic DNA was resuspended in 100µl of TE buffer with 2µl of RNase and incubated at 37ºC for one hour. After incubation the sample was re-extracted with phenol: chloroform: isoamylalcohol (25:24:1) solution. RNA free DNA was precipitated with 0.1M sodium acetate solution along with chilled 100% ethanol and centrifuged at 12000 rpm for 15min at 40ºC, washed with 70% ethanol, air dried and dissolved in TE buffer. The quality and quantity of DNA was analyzed spectrophotometrically and in 1% agarose gel.

**Molecular Marker Analysis**

**RAPD analysis**: Fifteen random primers (Operon Technologies) namely OPA 01 – 06, OPA 10, OPA 19, OPA 20, OPC 01, OPE 05 - 07, OPAM 01, OPS 18 and three were used for the analysis. PCR conditions: 32 cycles of 95°C (5 min), 36°C (30 sec), 72°C (1 min), and final extension at 72°C (8 min)(Chandrika and Ravishankar, 2010).

**ISSR**: Three primers ISSR primers namely ISSR 1, ISSR 2, ISSR 3 targeting di/tri-nucleotide repeats were selected.PCR conditions: 32 cycles of 95°C (5 min), 36°C (30 sec), 72°C (1 min), and final extension at 72°C (8 min)(Pathak and Dhawan, 2012). The PCR products of both RAPD and ISSR reaction were resolved on 1.5% agarose gel in 1× TAE buffer stained with ethidium bromide (8µl/100ml) and electrophoresis was carried out at 75 volts for 1.5 hours and visualized under UV-Transilluminator.

**Data Analysis**

The image of the gel electrophoresis was documented through Bio-Profile Bio-1D gel documentation system. The polymorphic bands were scored and analyzed by UPGMA cluster analysis protocol and computed *in silico* into similarity matrix using NTSYSpc (Numerical Taxonomy and Multivariate Analysis System genome arranged in tandem repeats with each Biostastistics, version 2.11W). The SIMQUAL (similarity for qualitative data) program was used to calculate the Jaccard coefficients. The RAPD patterns of each isolate was evaluated, transcribed spacer regions have been used, assigning character state "1" to indicate the presence of band in the gel and "0" for its absence in the gel. A data matrix was formed which was used to calculate the Jaccard similarity coefficient for each pair wise comparison. Jaccard coefficients were clustered to produce dendrogram using the (Sequential, Hierarchical, Agglomerative, and Nested cluster methods) SHAN clustering program and selecting the un-weighted pair-group methods with arithmetic average (UPGMA) algorithm in NTSYSpc.

## RESULT

DNA was isolated from the wild and *in vitro* cultured plants designated as number CVI (*C. viscosa* wild plant) and CVII (*C. viscosa* micropropagatedplant). The genomic DNA isolated through CTAB protocol produced clear sharp bands, indicating high-quality DNA. The purity of DNA was calculated by the absorbance ratio of A260/A280nm (Table - 1). The assessment of the genetic stability of wild and micropropagated plants of *C. viscosa* wild plant (CVI), *C. viscosa* micropropagated plant (CVII) were confirmed by RAPD and ISSR analyses. The *in vitro* plants were found to be phenotypically normal and essentially identical with their mother plant at hardening stage which partly suggests the minimal of soma clonal variations. Table - 1: Yield and purity of DNA isolated from the wild and micropropagated plants of Cleome species

**RAPD Primer Analysis**

Fifteen RAPD primers generated 145 amplification bands, with 127 polymorphic (87.58%) and 18 monomorphic bands (Table -2). RAPD banding pattern obtained from wild and micropropagated plants of *C. viscose* using some of the primers are given in figure – 1**.** Primers such as OPA 02, OPA 10, and OPE 05 exhibited 100% polymorphism, while OPC 01 showed the lowest polymorphism (57.14%).

**Figure - 1: RAPD banding pattern obtained from wild and micropropagated plants of *C. viscosa***

**M** - Molecular DNA Ladder(1.5kbp)
**CVI** - Mother plant of *C. viscosa*
**CVII** - Micropropagated plant of *C. viscosa*

**Table - 2: Total number of amplified fragments and number of polymorphic fragments generated by PCR using selected RAPD primers**

**ISSR Primer Analysis**

Three ISSR primers amplified 35 bands, of which 32 (91.43%) were polymorphic (Table - 3). ISSR banding pattern obtained from wild and micropropagated plants of *C. viscose* using some of the primers are given in figure – 2. ISSR 1 demonstrated 100% polymorphism, while ISSR 2 and ISSR 3 showed 88.24% and 90% polymorphism, respectively. The average polymorphism for ISSR markers (92.74%) exceeded that of RAPD primers (87.10%), reflecting ISSR's higher discriminatory power.

**Figure - 2: ISSR banding pattern obtained from wild and micropropagated plants of *C. viscosa***

**M** - Molecular DNA Ladder(1.5kbp)
**CVI** - Mother plant of *C. viscosa*
**CVII** - Micropropagated plant of *C. viscosa*

Total number of amplified fragments and number of Polymorphic fragments generated by PCR using selected RAPD primers (Table – 3). Combined analysis of RAPD and ISSR markers produced 180 bands (159 polymorphic), with an overall polymorphism of 88.33%. ISSR primers generated higher average polymorphism (92.74%) compared to RAPD (87.10%), aligning with their ability to target hypervariable microsatellite regions. The similarity coefficient values range from 69% to 82% *C. viscosa*. These similarity coefficients were used to generate a tree from cluster analysis using UPGMA method (Figure - 3). The cluster analysis indicates that *C. viscosa* are grouped into two major clusters based on similarity indices. These plants could be identified by using four random 15-mer primers. Among the cluster showed the highest similarity index (82%). On the basis of the RAPD analysis, the chosen samples have been grouped under clusters. The present study showed that the maximum similarity indices and least variation were observed among the wild and micropropagated plant of *C. viscosa*. Figure - 3: Dendrogram showing coefficient similarities between wild and micropropagated of *C. viscosa* using UPGMA cluster analysis (NTSYS) of the RAPD profile.

## DISCUSSION

The present study provides the first comparative molecular assessment of wild and micropropagated Cleome viscosa using RAPD and ISSR markers, revealing significant genetic divergence between the two populations. The high polymorphism (87.58% for RAPD and 91.43% for ISSR) underscores the sensitivity of these markers in detecting somaclonal variations, which are common in micropropagated plants due to hormonal imbalances, oxidative stress, or epigenetic changes during *in vitro* culture (Bairu*et al.,* 2011). Notably, ISSR primers exhibited higher discriminatory power (average polymorphism: 92.74%) compared to RAPD (87.10%), likely due to their ability to target hypervariable microsatellite regions, which are more prone to replication errors and recombination events (Reddy *et al*., 2002). The substantial genetic divergence observed between wild and micropropagated plants (85% variation

between groups) aligns with studies on other medicinal species, such as *Withania somnifera*(Ahmad *et al*., 2016) and *Bacopa monnieri*(Tiwari *et al.,* 2014), where micropropagation-induced variations were linked to altered secondary metabolite profiles. Primers like ISSR 1 (100% polymorphism) and OPA 02 (100% polymorphism) proved particularly effective in identifying these variations, suggesting their utility in routine screening of *in vitro*-derived plants. However, the lower polymorphism of OPC 01 (57.14%) highlights the importance of primer selection for species-specific fidelity assessments, as primer binding efficiency can vary with genomic GC content and repeat motifs (Joshi *et al.,* 2020). While micropropagation offers a viable solution for mass propagation of threatened species like *C. viscosa*, the observed genetic instability poses challenges for maintaining medicinal efficacy. For instance, soma clonal variations could alter the synthesis of bioactive compounds such as cleomiscosins and flavonoids, which are critical for its anti-inflammatory and antimicrobial properties (Upadhyay*et al*., 2011). To mitigate this, our findings suggest that reducing subculture cycles and incorporating antioxidants (e.g., ascorbic acid) to minimize oxidative DNA damage (Patel *et al*., 2021)and routine Genetic Monitoring using ISSR markers (e.g., ISSR 1) for early detection of off-type plants.

## CONCLUSION

This study demonstrates that micropropagated *C. viscosa* exhibits significant genetic divergence from wild counterparts, primarily due to soma clonal variations. While ISSR markers proved more efficient than RAPD in detecting these variations, both techniques are valuable for ensuring genetic fidelity in conservation programs. By optimizing *in vitro* protocols and implementing routine molecular screening, the medicinal integrity and ecological adaptability of *C. viscosa* can be preserved for sustainable utilization.

## ABSTRACT

Digital technologies have significantly transformed crime prevention and the criminal justice system in India. The rapid growth of information and communication technology (ICT), artificial intelligence (AI), big data analytics, and digital databases has improved the efficiency, transparency, and coordination of law-enforcement agencies and judicial institutions. The Indian government has implemented several digital initiatives such as the Crime and Criminal Tracking Network and Systems (CCTNS), the Interoperable Criminal Justice System (ICJS), and the e-Courts Mission Mode Project to modernize the criminal justice system. These initiatives aim to integrate police, courts, prisons, prosecution, and forensic institutions through digital platforms. CCTNS connects police stations across India and maintains a centralized database of criminal records, enabling faster investigation and information sharing. ICJS integrates various components of the justice system to facilitate seamless data exchange and improve coordination among agencies. Similarly, the e-Courts project focuses on digitizing court processes, enabling e-filing, virtual hearings, and digital access to case information. Digital technologies such as surveillance systems, biometric identification, digital forensics, and predictive analytics also assist law-enforcement agencies in detecting and preventing crimes. Despite these benefits, challenges such as cybersecurity threats, privacy concerns, digital divide, and lack of technical capacity remain significant obstacles. This study adopts a descriptive research methodology and relies primarily on secondary sources of data, including government reports, policy documents, academic journals, and official publications, to analyze the role and impact of digital technologies in India's criminal justice system.This study examines the role of digital technologies in crime prevention and criminal justice in India, highlighting their advantages, institutional impact, and emerging challenges. The paper concludes that while digital technologies have enhanced efficiency and transparency in the criminal justice system,

strong regulatory frameworks and technological safeguards are necessary to ensure ethical and effective use.

**Keywords:** Digital Technologies, Criminal Justice System, Government, Digital Initiatives, Transparency,

## INTRODUCTION

The rapid advancement of digital technologies has significantly transformed governance, administration, and law enforcement across the world. In India, the integration of information and communication technology (ICT), artificial intelligence, big data analytics, and digital databases has played a crucial role in strengthening crime prevention and improving the efficiency of the criminal justice system. Digital tools have enabled law-enforcement agencies and judicial institutions to enhance transparency, coordination, and accountability in addressing criminal activities and delivering justice. Traditionally, the criminal justice system in India has faced several challenges, including delays in investigation and trial, poor coordination among institutions, lack of reliable data, and manual record-keeping. These issues often affected the effectiveness of crime prevention and the timely delivery of justice. With the emergence of digital technologies, the government has introduced various technological initiatives aimed at modernizing policing, improving investigative processes, and digitizing judicial administration. Several digital platforms have been developed to strengthen the criminal justice system in India. For example, the Crime and Criminal Tracking Network and Systems (CCTNS) connects police stations across the country and provides a centralized database of criminal records to facilitate faster investigations and information sharing. Similarly, the Interoperable Criminal Justice System (ICJS) integrates different components of the criminal justice system—such as police, courts, prisons, prosecution, and forensic laboratories—into a unified digital framework. In addition, the e-Courts Mission Mode Project aims to digitize court processes, promote e-filing, and enable virtual hearings, thereby improving access to justice and reducing delays in the judicial process. Digital technologies such as CCTV surveillance, biometric identification, digital forensics, and artificial intelligence have also strengthened the capacity of law-enforcement agencies to detect, prevent, and investigate crimes more effectively. These technologies facilitate data-driven policing and enable authorities to analyze crime patterns, identify suspects, and respond quickly to criminal activities. The increasing use of digital technologies in law enforcement and criminal justice also raises several concerns, including issues related to data privacy, cybersecurity, surveillance ethics, and technological disparities. Therefore, it is important to critically examine both the opportunities and challenges associated with digital transformation in the criminal justice system. The present study examines the role of digital technologies in crime prevention and criminal justice in India. It focuses on the institutional impact of digital initiatives, their contribution to improving efficiency and transparency, and the challenges involved in their implementation.

## OBJECTIVES

1. To examine the role of digital technologies in crime prevention in India.
2. To analyse the impact of digital platforms on the criminal justice system.
3. To identify the challenges and limitations in the use of digital technologies in law enforcement.

## RESEARCH METHODOLOGY

This study is based on a descriptive and analytical research methodology. The research primarily relies on secondary sources of data such as government reports, academic articles, policy documents, and official websites. Information regarding digital initiatives like CCTNS, ICJS, and the e-Courts project has been collected from government publications and scholarly literature. The study analyses these sources to understand the impact of digital technologies on crime prevention and criminal justice in India.

**Sources of Data**

The present study is based on secondary sources of data. Relevant information has been collected from various published and official sources related to digital technologies, crime prevention, and the criminal justice system in India. These sources help in understanding the policies, initiatives, and institutional developments in the field of digital governance and law enforcement.

**The major sources of data used in this study include**

**Government Reports and Official Documents**

Reports and publications from government institutions such as the Ministry of Home Affairs and the Department of Justice have been used to analyse major initiatives like the Crime and Criminal Tracking Network and Systems, the Interoperable Criminal Justice System, and the e-Courts Mission Mode Project.

**Academic Books and Journal Articles**

Scholarly books, peer-reviewed journals, and research papers related to digital policing, cybercrime, and criminal justice reforms have been consulted to understand the theoretical and analytical perspectives of the topic.

**Policy Documents and Government Websites**

Official websites of government departments, policy papers, and digital governance reports have been used to obtain updated information on digital initiatives in the criminal justice system.

**Reports from Research Institutions and Organizations**

Publications from research institutions, think tanks, and international organizations related to digital governance and justice administration have also been used. These sources provide reliable and comprehensive information for analysing the impact of digital technologies on crime prevention and the criminal justice system in India.

**Digital Technologies in Crime Prevention**

Digital technologies have become an important tool in strengthening crime prevention strategies in India. The use of modern technologies such as surveillance systems, biometric identification, data analytics, and digital databases has enhanced the capacity of law-enforcement agencies to monitor criminal activities, identify suspects, and respond to threats more efficiently. These technologies support proactive policing by enabling authorities to detect potential crimes before they occur and by improving the speed and accuracy of investigations. One of the most widely used technologies in crime prevention is digital surveillance. Closed-Circuit Television (CCTV) cameras installed in public places, transportation hubs, and urban areas help monitor activities and deter criminal behaviour. Surveillance footage often serves as crucial evidence in criminal investigations and assists police in identifying offenders. In several Indian cities, smart surveillance systems equipped with facial recognition technology and automated monitoring tools are being used to track suspicious movements and improve public safety. Significant technological initiative is the Crime and Criminal Tracking Network and Systems (CCTNS), launched by the Government of India under the Ministry of Home Affairs. This system connects thousands of police stations across the country through a centralized digital network. It enables the creation of a comprehensive database containing information on crimes, criminals, and investigations. Police officers can access this database to verify criminal records, track offenders, and share information with other law-enforcement agencies, thereby improving coordination and efficiency in crime prevention. Biometric technologies such as fingerprint identification, iris scanning, and facial recognition also play a significant role in modern policing. These technologies help accurately identify individuals involved in criminal activities and prevent identity fraud. The integration of biometric systems with national identification databases strengthens verification processes and supports investigative work. Digital technologies are also widely used in crime data analysis and predictive policing. Data analytics tools analyse large volumes of crime data to identify patterns, trends, and high-risk locations. By studying these patterns, police departments can allocate resources more effectively and implement preventive measures in areas with higher crime rates. Artificial intelligence and machine learning algorithms further assist in predicting potential criminal activity and improving strategic planning. Crucial development is the use of digital forensics in criminal investigations. With the increasing use of smartphones,

computers, and online platforms, digital evidence has become essential in solving crimes. Digital forensics involves the collection and analysis of electronic data such as emails, call records, social media communications, and computer files. This technology helps investigators trace cybercriminals, uncover digital footprints, and present reliable evidence in court. Supporting law enforcement, digital technologies also facilitate citizen participation in crime prevention. Many state police departments in India provide mobile applications and online portals that allow citizens to report crimes, submit complaints, and track the status of their cases. These platforms strengthen communication between the public and the police, contributing to a more responsive and transparent policing system. Digital technologies have significantly enhanced crime prevention mechanisms in India by improving surveillance, data management, and investigative capabilities. However, the effective use of these technologies requires proper infrastructure, technical training for law-enforcement personnel, and appropriate legal safeguards to protect citizens' rights and privacy.

**Digital Transformation of the Criminal Justice System**

The adoption of digital technologies has significantly transformed the functioning of the criminal justice system in India. Traditionally, the system relied heavily on manual record-keeping and physical documentation, which often resulted in delays, lack of coordination among institutions, and limited accessibility to information. With the advancement of information and communication technology (ICT), the Government of India has introduced several digital initiatives to improve efficiency, transparency, and coordination within the justice delivery system. Digital platforms now enable seamless information sharing among various institutions involved in criminal justice, including police, courts, prisons, prosecution, and forensic departments. These technological developments not only enhance administrative efficiency but also improve the speed and accuracy of investigations, trials, and judicial processes. Important initiatives such as the Interoperable Criminal Justice System (ICJS) and the e-Courts Mission Mode Project represent major steps toward the digital transformation of India's criminal justice system.

**Interoperable Criminal Justice System (ICJS)**

The Interoperable Criminal Justice System (ICJS) is an important initiative of the Government of India designed to integrate the various components of the criminal justice system through a unified digital platform. The system connects five major pillars of the criminal justice system: police, courts, prisons, prosecution, and forensic laboratories. The primary objective of ICJS is to facilitate seamless exchange of information among these institutions. Through digital integration, case-related data can be accessed and shared across different departments, enabling faster investigation and efficient case management. For example, police officers can access court orders, prosecutors can review investigation records, and prison authorities can receive information about court proceedings electronically. ICJS operates on the principle of "one data, one entry," which reduces duplication of records and improves the accuracy and reliability of information. By connecting multiple justice institutions, the system helps reduce delays in criminal investigations and judicial processes. It also enhances coordination among different agencies, leading to more effective law enforcement and justice delivery.

**e-Courts Mission Mode Project**

The e-Courts Mission Mode Project is another major initiative aimed at modernizing the Indian judiciary through digital technology. Launched under the National e-Governance Plan, the project focuses on digitizing court processes and improving access to justice. The e-Courts project introduces several digital services, including electronic filing of cases (e-filing), digital documentation, online case status tracking, and virtual court hearings. These services allow litigants, lawyers, and the public to access court information easily through online platforms. One of the significant achievements of the project is the digitization of court records and the availability of judgments and orders online. This improves transparency in the judicial system and enables individuals to obtain legal information without visiting courts physically. Additionally, the use of video conferencing technology has facilitated remote hearings and reduced delays in court proceedings. The e-Courts project also supports the development of paperless courts and improves administrative efficiency by automating case management processes. By reducing paperwork and improving information access, the initiative contributes to faster and more transparent justice delivery.

**Digital Policing and Citizen Services**

Digital technologies have also transformed policing and improved the relationship between law-enforcement agencies and citizens. Many police departments in India have adopted digital platforms that allow citizens to access police services online. Through online portals and mobile applications, citizens can file complaints, register First Information Reports (FIRs), track the status of cases, and request police verification services. These digital services enhance accessibility and make the process of reporting crimes more convenient for the public. An important initiative in this area is the Crime and Criminal Tracking Network and Systems (CCTNS), which provides a centralized digital platform for crime data and police records. The system connects thousands of police stations across India and allows law-enforcement agencies to access criminal databases and investigation records quickly. Digital policing also includes the use of mobile technologies, surveillance systems, and online communication tools to improve public safety. Many state police departments use social media platforms and mobile applications to communicate with citizens, provide safety alerts, and raise awareness about crime prevention. Overall, digital policing initiatives enhance transparency, strengthen public trust in law enforcement, and encourage greater citizen participation in maintaining law and order. These developments represent an important step toward creating a more responsive and technology-driven criminal justice system in India.

**Advantages of Digital Technologies**

The integration of digital technologies into the criminal justice system has brought several significant advantages in terms of efficiency, transparency, and effectiveness. These technologies have improved the functioning of law-enforcement agencies and judicial institutions by enabling faster information sharing, better data management, and more reliable investigative processes. Digital transformation has also enhanced public access to justice and strengthened coordination among various institutions involved in crime prevention and justice delivery.

**Improved Efficiency and Speed**

One of the major advantages of digital technologies is the improvement in the efficiency and speed of criminal justice processes. Digital record management systems reduce the reliance on manual paperwork and enable quick access to case files, criminal records, and investigation reports. Systems such as the Crime and Criminal Tracking Network and Systems allow police officers to register First Information Reports (FIRs) electronically and track case progress more efficiently. This reduces delays in investigations and improves overall administrative efficiency.

**Better Coordination Among Institutions**

Digital technologies facilitate better coordination between different institutions involved in the criminal justice system, including police departments, courts, prisons, prosecution agencies, and forensic laboratories. The Interoperable Criminal Justice System enables seamless data exchange among these institutions through an integrated digital platform. This coordination helps streamline investigation and trial processes and ensures that relevant information is accessible to all stakeholders.

**Transparency and Accountability**

The digitization of criminal justice processes has improved transparency and accountability in law enforcement and judicial administration. Online portals and digital databases allow citizens, lawyers, and researchers to access information regarding case status, court judgments, and police procedures. Initiatives such as the e-Courts Mission Mode Project enable public access to court records and judicial information, thereby strengthening accountability within the justice system.

**Data-Driven Decision Making**

Digital technologies enable law-enforcement agencies to analyse large volumes of crime data and identify patterns and trends. Data analytics tools help police departments understand crime hotspots, predict potential criminal activity, and allocate resources more effectively. This approach supports evidence-based policymaking and enhances the strategic planning of crime prevention measures.

**Improved Access to Justice**

Digital platforms have made it easier for citizens to access justice services. Online complaint registration, digital case tracking, and virtual court hearings allow individuals to interact with law-enforcement agencies and courts without the need for physical visits. This is particularly beneficial for people living in remote areas, as it reduces travel costs and procedural barriers.

**Strengthening Evidence Collection and Investigation**

Digital forensics and electronic data analysis have improved the accuracy and reliability of criminal investigations. Digital evidence such as emails, call records, surveillance footage, and social media data can be analysed to identify suspects and reconstruct criminal activities. These technologies enhance the credibility of evidence presented in courts and support more effective prosecution. Overall, digital technologies have strengthened the criminal justice system in India by improving operational efficiency, enhancing transparency, and supporting data-driven law enforcement. However, the successful implementation of these technologies requires adequate infrastructure, technical training, and appropriate legal safeguards to address emerging challenges.

**Challenges and Concerns**

Despite the numerous advantages of digital technologies in crime prevention and the criminal justice system, several challenges and concerns remain. The effective implementation of digital initiatives requires strong infrastructure, technical expertise, and appropriate legal frameworks. In India, issues related to data security, privacy, and technological capacity continue to pose significant obstacles to the full realization of digital transformation in the criminal justice system.

**Data Privacy and Surveillance Concerns**

One of the major concerns associated with digital technologies is the issue of data privacy. The extensive use of surveillance technologies, digital databases, and biometric identification systems raises questions about the protection of personal information. Large-scale data collection by law-enforcement agencies may lead to misuse or unauthorized access to sensitive data. Ensuring adequate data protection mechanisms and clear legal regulations is therefore essential to safeguard citizens' rights.

**Cybersecurity Risks**

Digital systems used in law enforcement and judicial administration are vulnerable to cyberattacks, hacking, and data breaches. Sensitive information related to criminal records, investigations, and court proceedings may be compromised if proper cybersecurity measures are not in place. Strengthening cybersecurity infrastructure and implementing robust data protection systems are necessary to protect the integrity of digital criminal justice platforms.

**Digital Divide and Infrastructure Limitations**

Another challenge is the digital divide that exists between urban and rural areas in India. Limited internet connectivity, lack of technological infrastructure, and inadequate digital resources in some regions hinder the effective implementation of digital initiatives. This disparity may affect equal access to digital justice services, particularly for individuals living in remote or underdeveloped areas.

**Lack of Technical Expertise and Training**

The successful implementation of digital technologies requires trained personnel who can operate and manage these systems efficiently. In many cases, law-enforcement officers, judicial staff, and administrative personnel may lack adequate technical skills to utilize digital platforms effectively. Continuous training and capacity-building programs are therefore necessary to ensure the efficient use of digital tools within the criminal justice system.

**Legal and Ethical Issues**

The use of advanced technologies such as artificial intelligence, facial recognition, and predictive policing raises important ethical and legal questions. These technologies may lead to issues such as algorithmic bias, wrongful identification, and lack of accountability. Without proper regulatory frameworks, the misuse of digital technologies could undermine public trust in the criminal justice system.

**Integration and Coordination Challenges**

Although initiatives such as the Interoperable Criminal Justice System aim to integrate various components of the justice system, practical difficulties remain in ensuring seamless coordination between different agencies. Differences in technological capacity, administrative procedures, and data standards can slow down the process of digital integration. While digital technologies offer significant opportunities to improve crime prevention and justice delivery, addressing these challenges is crucial for their effective and responsible use. Strengthening legal safeguards, improving digital infrastructure, and providing adequate training to personnel will help ensure that technological innovations contribute positively to the criminal justice system in India.

## CONCLUSION

Digital technologies have emerged as a crucial component in strengthening crime prevention and improving the efficiency of the criminal justice system in India. The integration of information and communication technology, digital databases, artificial intelligence, and data analytics has significantly enhanced the capacity of law-enforcement agencies and judicial institutions to respond to criminal activities more effectively. Technological initiatives introduced by the Government of India have played an important role in modernizing policing, improving investigative processes, and increasing transparency in the justice delivery system. Major digital initiatives such as the Crime and Criminal Tracking Network and Systems, the Interoperable Criminal Justice System, and the e-Courts Mission Mode Project have contributed significantly to the digital transformation of the criminal justice system. These platforms enable better coordination among police, courts, prisons, prosecution, and forensic institutions by facilitating real-time information sharing and digital access to records. As a result, investigations have become more efficient, court processes more transparent, and access to justice more convenient for citizens. At the same time, digital technologies such as surveillance systems, biometric identification, and digital forensics have strengthened crime detection and prevention mechanisms. Data-driven policing and advanced investigative tools allow law-enforcement agencies to analyse crime patterns, identify offenders more quickly, and improve strategic planning in maintaining law and order. However, the increasing reliance on digital technologies also raises several challenges. Concerns related to data privacy, cybersecurity risks, digital inequality, and lack of technical expertise must be addressed to ensure the responsible use of technology in the justice system. The development of strong legal frameworks, improved digital infrastructure, and continuous training for law-enforcement personnel are essential for overcoming these challenges. In conclusion, digital technologies have the potential to significantly transform crime prevention and the criminal justice system in India by making it more efficient, transparent, and accessible. With appropriate safeguards and effective implementation, technological innovations can play a vital role in strengthening the rule of law and enhancing public trust in the justice system.

## ABSTRACT

Oral premalignant lesions (OPLs) or conditions (OPCs) including oral leukoplakia, eruthroplakia, oral submucous fibrosis (OSMF), and epithelial dysplasia represent a critical stage in oral carcinogenesis. These conditions are characterized by chronic inflammation, oxidative stress, altered epithelial differentiation, and progressive fibrotic or dysplastic changes, with a significant risk of malignant transformation. Conventional management remains limited due to recurrence, adverse effects, and lack of long-term preventive strategies. *Jatipatradi Yoga*, a classical Ayurvedic formulation indicated in *Mukha Roga*, specifically *Sarvasara Mukhapaka* has been traditionally used for chronic inflammatory and ulcerative oral conditions. Reverse pharmacology provides a rational framework to scientifically validate such formulations by integrating traditional clinical experience with modern analytical evidence. To elucidate the reverse pharmacological basis of *Jatipatradi Yoga* in the management of oral premalignant lesions through phytochemical characterization using High Performance Thin Layer Chromatography (HPTLC). *Jatipatradi Yoga* was prepared according to *Yoga Ratnakara* and subjected to HPTLC analysis for phytochemical fingerprinting. Chromatography was performed on silica gel 60 $F_{254}$ plates using ethyl acetate: methanol: water (5:3:2 v/v/v) as the mobile phase. Detection was carried out at 254 nm and 366 nm, with multiple sample application volumes (5–20 µL) to assess reproducibility and dose-dependent phytochemical expression. HPTLC profiling revealed a consistent and reproducible chromatographic fingerprint with multiple well-resolved peaks at both 254 nm and 366 nm, indicating the presence of

diverse bioactive phytoconstituents. The observed peaks suggest the presence of polyphenols, flavonoids, tannins, and other secondary metabolites known for anti-inflammatory, antioxidant, antifibrotic, and cytoprotective activities. The increase in peak intensity with higher application volumes reflects dose-dependent phytochemical availability, supporting formulation consistency and therapeutic relevance.

## INTRODUCTION

Oral cancer is a major public health problem worldwide and constitutes one of the leading causes of cancer-related morbidity and mortality, particularly in South and Southeast Asia. The development of oral squamous cell carcinoma is widely accepted to be a multistep process, often preceded by clinically recognizable and histopathological identifiable oral premalignant lesions (OPLs) and oral potentially malignant conditions (OPCs) ]1]. These include oral leucoplakia, erythroplakia, oral submucous fibrosis (OSMF), and epithelial dysplasia, which together represent critical transitional stages between normal oral mucosa and invasive malignancy. The malignant transformation rates associated with these conditions vary but are clinically significant, making early intervention and effective preventive strategies imperative [2]. The etiopathogenesis of OPLs is complex and multifactorial, involving prolonged exposure to carcinogenic agents such as tobacco (smoked and smokeless forms), areca nut, alcohol, nutritional deficiencies, and chronic mechanical or chemical irritation [3]. At the cellular and molecular levels, these lesions are characterized by sustained chronic inflammation, excessive oxidative stress, accumulation of reactive oxygen and nitrogen species, DNA damage, epigenetic alterations, and dysregulation of signalling pathways governing epithelial proliferation, differentiation, apoptosis, and extracellular matrix remodelling. In conditions such as OSMF, excessive collagen deposition, reduced collagen degradation, and progressive fibrosis result in functional impairment and a heightened risk of dysplastic transformation. Epithelial dysplasia, in particular, represents a direct histological indicator of neoplastic potential, reflecting irreversible genetic and cellular alterations [4].

Despite advancements in understanding the molecular biology of oral carcinogenesis, the clinical management of oral premalignant lesions remains unsatisfactory. Conventional treatment modalities such as surgical excision, laser ablation, intralesional corticosteroids, antioxidants, retinoids, and immunomodulatory agents are often associated with high recurrence rates, adverse effects, functional morbidity, and limited long-term chemo preventive efficacy [5]. Moreover, these interventions primarily target localized lesions without adequately addressing the underlying inflammatory and oxidative microenvironment that drives disease initiation and progression. The absence of safe, effective, and sustainable preventive strategies highlights a critical therapeutic gap in the management of OPLs.

Ayurveda offers a comprehensive and holistic approach to disease prevention and management. Ayurvedic literature provides detailed descriptions of oral disorders under the broad classification of *MukhaRoga*, encompassing conditions with clinical features analogous to contemporary descriptions of oral premalignant and chronic inflammatory oral diseases termed as *Sarvasaara Mukharoga*. This condition presents with diffuse inflammatory and ulcerative involvement of the oral cavity and bears close resemblance to chronic, non-healing, and potentially premalignant oral conditions described in modern medicine. Concepts such as *Pitta* and *Raktadushti*, chronic *Shotha* (inflammation), *Vrana* (ulceration), and *Dhatu kshaya* offer a unique pathophysiological framework that emphasizes systemic imbalance and tissue-level pathology [6]. *Jatipatradi Yoga*, a classical Ayurvedic polyherbal formulation mentioned in *Yoga Ratnakara*, isindicated in the management of *Sarvasara Mukhapaka*. The formulation has been empirically used in conditions characterized by persistent inflammation, mucosal damage, and impaired healing. Classical attributes such as *Shothahara* (anti-inflammatory), *Ropana* (wound healing), *Rakta-Prasadana* (blood purification), and *Pitta-shamana* suggest a therapeutic potential that may be relevant in modulating the pathological processes underlying oral premalignant lesions.[7] However, despite its long-standing clinical use, scientific validation

of its phytochemical composition and biological plausibility remains limited. Reverse pharmacology provides a systematic and translational research paradigm to bridge this gap between traditional knowledge and modern scientific validation. Unlike conventional drug discovery, which begins with isolated molecules and proceeds toward clinical application, reverse pharmacology starts with formulations that have an established history of human use, safety, and therapeutic efficacy. It then employs modern analytical, experimental, and clinical tools to elucidate their chemical composition, mechanisms of action, and therapeutic relevance. Within this framework, phytochemical characterization serves as a foundational step to establish formulation consistency, identify bioactive constituents, and generate hypotheses regarding pharmacological activity [8].

High Performance Thin Layer Chromatography (HPTLC) is a robust, reproducible, and widely accepted analytical technique for phytochemical fingerprinting of polyherbal formulations. It enables qualitative and semi-quantitative assessment of complex phytochemical profiles, supports quality control, and facilitates correlation between traditional therapeutic claims and modern pharmacological evidence. In the context of oral premalignant lesions, identifying phytoconstituents with known anti-inflammatory, antioxidant, antifibrotic, and cytoprotective properties is particularly relevant, given the central role of these mechanisms in disease pathogenesis [9]. Therefore, the present study aims to evaluate *Jatipatradi Yoga* from a reverse pharmacological perspective through detailed phytochemical characterization using HPTLC, with specific reference to its potential role in the management of oral premalignant lesions. By integrating Ayurvedic principles, traditional clinical usage, and modern analytical evidence, this work seeks to provide a scientific foundation for further experimental and clinical investigations into the preventive and therapeutic utility of *Jatipatradi Yoga* in oral premalignant pathology

## METHODOLOGY

**Study Design**

The present study was designed as an analytical research based on the principles of reverse pharmacology. The study emphasizes the scientific validation of a classical Ayurvedic formulation through systematic phytochemical analysis, correlating traditional therapeutic claims with modern analytical evidence. The research does not involve human or animal experimentation and is confined to pharmaceutical preparation, literary review, and analytical evaluation of the formulation.

Aim of the Study

The study aims to evaluate *Jatipatradi Yoga* from a reverse pharmacological perspective with reference to oral premalignant lesions, through phytochemical characterization using High Performance Thin Layer Chromatography (HPTLC).

Objectives of the Study

- To prepare *Jatipatradi Yoga* according to classical Ayurvedic textual references.
- To subject the prepared formulation to HPTLC analysis for phytochemical fingerprinting.
- To assess reproducibility and dose-dependent expression of phytoconstituents.
- To interpret the analytical findings in relation to the pathophysiology of oral premalignant lesions and Ayurvedic principles.

Sources of Data

Literary Source

- Classical texts such as *Charaka Samhita*, *Sushruta Samhita*, *Ashtanga Hridaya*, and *Ashtanga Sangraha* for references related to *MukhaRoga, Shotha, Vrana, Raktadushti,* and *Pitta* vitiation.
- *Yoga Ratnakara* for the formulation, ingredients, indications, and therapeutic properties of Jatipatradi Yoga.
- Relevant commentaries, *Nighantus*, and Ayurvedic pharmacopeial texts for drug properties and formulation details.

**Modern literature sources included:**

- Standard textbooks of oral pathology, oral medicine, and oncology for information on oral premalignant lesions and carcinogenesis.
- Research articles, review papers, and journals accessed through electronic databases such as PubMed, Google Scholar, AYUSH Research Portal, and other peer-reviewed platforms.
- Publications related to reverse pharmacology, phytochemistry, and HPTLC methodology.

Drug Source

Raw drugs required for the preparation of *Jatipatradi Yoga* were procured from authenticated and reliable sources. The drugs were identified and authenticated based on organoleptic, macroscopic, and classical Ayurvedic parameters, ensuring genuineness and purity. Foreign matter was removed, and the drugs were processed as per classical guidelines before formulation.

Preparation of *Jatipatradi Yoga*

Jatipatradi Yoga[10] was prepared strictly in accordance with the formulation described in *Yoga Ratnakara*. The individual ingredients were cleaned, dried, powdered, and mixed in prescribed proportions under controlled conditions to ensure uniformity and homogeneity. The prepared formulation was stored in airtight containers to prevent contamination and degradation.

**Analytical Study -HPTLC**

**Inference (254 nm):**

The formulation shows multiple UV-absorbing phytochemicals**,** indicating **a**chemically complex and polyherbal nature**.** Presence of strong peaks in low and mid-Rf region suggests dominance of polar and semi-polar bioactive compounds

**Inference (366 nm):**

The formulation exhibits **distinct fluorescent bands,** confirming the presence of **chromophoric phytochemicals such as flavonoids, phenolics, and coumarin-like compounds,** which are often linked with **anti-inflammatory and antioxidant activity.**

**Observations and Results**

HPTLC analysis of *Jatipatradi Yoga* revealed a distinct, reproducible, and well-resolved phytochemical fingerprint at both 254 nm and 366 nm. At 254 nm, multiple well-defined bands were observed, indicating the presence of phenolic compounds such as polyphenols and tannins. Visualization at 366 nm showed distinct fluorescent bands suggestive of flavonoids and other UV-active secondary metabolites. The chromatographic pattern remained consistent across all application volumes (5–20 µL), with a progressive increase in band intensity at higher volumes, demonstrating dose-dependent phytochemical expression and formulation uniformity. No significant variation in Rf values or band distribution was observed, confirming the reproducibility and stability of the formulation. Overall, the HPTLC profile confirms the multicomponent phytochemical nature of *Jatipatradi Yoga*, supporting its potential anti-inflammatory, antioxidant, and cytoprotective relevance in the management of oral premalignant lesions from a reverse pharmacological perspective

## DISCUSSION

Oral premalignant lesions constitute a heterogeneous group of disorders that arise as intermediate stages in the multistep process of oral carcinogenesis. These lesions are characterized by persistent chronic inflammation, increased oxidative stress, epithelial hyperproliferation, altered keratinization, and, in certain conditions such as oral submucous fibrosis, excessive collagen deposition and progressive fibrosis. [11]Given the multifactorial nature of these pathological processes, effective management requires therapeutic interventions that can act on multiple biological

targets simultaneously. The present study employed a reverse pharmacological approach to scientifically evaluate *Jatipatradi Yoga*, a classical Ayurvedic formulation traditionally indicated in *MukhaRoga*, by correlating its phytochemical profile with the pathophysiology of oral premalignant lesions.

HPTLC analysis of *Jatipatradi Yoga* revealed a consistent, reproducible, and chemically diverse phytochemical fingerprint at 254 nm and 366 nm. The presence of multiple well-resolved bands suggests a rich composition of secondary metabolites, predominantly polyphenols, flavonoids, and tannins. These phytochemical groups are widely reported to possess anti-inflammatory, antioxidant, antifibrotic, and cytoprotective properties. Such activities are directly relevant to oral premalignant lesions, where sustained inflammatory responses and oxidative stress contribute to epithelial damage, dysplastic changes, and increased malignant potential.

From a modern biomedical perspective, phenolic and flavonoid compounds are known to modulate inflammatory mediators, scavenge reactive oxygen species, regulate epithelial cell proliferation, and maintain mucosal integrity. In oral submucous fibrosis, where collagen metabolism is altered, these compounds may help regulate extracellular matrix turnover and limit progressive fibrosis. The dose-dependent increase in band intensity observed in the HPTLC profile further supports the cumulative and synergistic action of phytoconstituents present in the formulation. From an Ayurvedic standpoint, oral premalignant lesions may be conceptually correlated *Sarvasaara Mukhapaka*, involving *Pitta* and *Raktadushti*, associated with chronic *Shotha* and Vrana in the oral cavity. *Jatipatradi Yoga* is described to possess *Shothahara, Ropana,* and *Rakta-Prasadana* properties. The multicomponent phytochemical nature demonstrated through HPTLC aligns with the Ayurvedic principle of polyherbal synergy, wherein multiple constituents collectively contribute to therapeutic efficacy rather than a single isolated compound.

Reverse pharmacology emphasizes validation of formulations with long-standing clinical use and known safety profiles through modern scientific tools. The present phytochemical evaluation represents an essential early step in this continuum, providing analytical evidence that supports the traditional therapeutic claims of *Jatipatradi Yoga*. Although the study is limited to phytochemical fingerprinting and does not establish direct clinical efficacy, it offers a scientifically sound foundation for future experimental studies, molecular investigations, and clinical trials aimed at elucidating mechanisms of action and therapeutic outcomes in oral premalignant lesions.

## CONCLUSION

The detailed reverse pharmacological evaluation of *Jatipatradi Yoga* through HPTLC phytochemical fingerprinting provides scientific support for its traditional use in oral premalignant lesions. The formulation exhibits a consistent, reproducible, and chemically diverse profile rich in bioactive secondary metabolites relevant to the modulation of inflammation, oxidative stress, fibrosis, and epithelial dysregulation. These findings suggest that *Jatipatradi Yoga* holds promise as a preventive or adjunctive therapeutic option in conditions such as oral leukoplakia, oral submucous fibrosis, and epithelial dysplasia. The study establishes a strong analytical foundation for future experimental studies, molecular investigations, and controlled clinical trials aimed at validating efficacy and elucidating.

Table 01: Rf Values Observed in HPTLC Densitogram-**At 254 nm (UV absorbance mode)**

| Peak No. | Rf value | Area % (approx.) | Interpretation |
|---|---|---|---|
| 1 | 0.03–0.05 | ~5–10% | Highly polar constituents; may indicate sugars, tannins or inorganic salts |
| 2 | 0.12–0.15 | ~25–35% | Major polar phytoconstituents; possibly phenolics or glycosides |
| 3 | 0.26–0.30 | ~20–30% | Moderately polar compounds; likely flavonoids or alkaloidal fractions |
| 4 | 0.93–0.96 | ~15–20% | Non-polar constituents; may represent terpenoids or essential oil components |

**Table 02: Rf Values Observed in HPTLC Densitogram- At 366 nm (Fluorescence mode)**

| Peak No. | Rf value | Area % (approx.) | Interpretation |
|---|---|---|---|
| 1 | 0.08–0.10 | ~10–15% | Fluorescent polar compounds; possibly coumarins or phenolic acids |
| 2 | 0.17–0.20 | ~20–25% | Strong fluorescent phytoconstituents; indicative of flavonoids |
| 3 | 0.32–0.35 | ~10–15% | Semi-polar fluorescent compounds |
| 4 | 0.48–0.55 | ~8–12% | Medium polarity compounds |
| 5 | 0.72–0.78 | ~5–8% | Less polar constituents |
| 6 | 0.85–0.90 | ~10–15% | Non-polar fluorescent compounds |

**Table 03:Interpretation of the HPTLC study -Jatipatradi Yoga**

| Analytical Parameter | HPTLC Observation | Phytochemical Interpretation | Relevance to OPL Pathogenesis | Reverse Pharmacological Significance |
|---|---|---|---|---|
| **Wavelength: 254 nm** | Multiple well-resolved dark and light bands observed | Presence of polyphenols, tannins, and phenolic compounds with conjugated systems | Polyphenols and tannins exhibit strong anti-inflammatory and antioxidant activity, counteracting chronic inflammation and oxidative stress implicated in leukoplakia and epithelial dysplasia | Supports traditional use in inflammatory *MukhaRoga;* validates *Shothahara and Rakta-Prasadana* actions |
| **Wavelength: 366 nm** | Distinct fluorescent bands observed | Indicative of flavonoids and UV-active secondary metabolites | Flavonoids modulate oxidative stress, inhibit abnormal epithelial proliferation, and protect against dysplastic changes | Demonstrates biological plausibility for chemopreventive and cytoprotective role in OPLs |
| **Number of peaks/bands** | Multiple peaks across chromatogram | Confirms polyherbal, multicomponent nature of formulation | Multifactorial pathology of OPLs requires multi-targeted therapeutic action | Aligns with Ayurvedic synergistic principle and reverse pharmacology framework |
| **Rf pattern consistency** | Similar Rf values across all tracks | Reproducible phytochemical fingerprint | Ensures formulation consistency and reliability for therapeutic use | Establishes standardization and quality control baseline |
| **Sample volume: 5–20 µL** | Progressive increase in peak intensity without pattern distortion | Dose-dependent phytochemical expression | Suggests cumulative therapeutic effect with increasing dose | Supports classical dosage rationale and analytical reliability |
| **Chromatographic resolution** | Clear, well-separated bands | Minimal overlap of phytoconstituents | Enables identification of diverse bioactive groups | Indicates suitability for further mechanistic and pharmacological studies |
| **Overall fingerprint** | Stable, characteristic HPTLC profile | Presence of diverse secondary metabolites | Addresses inflammation, oxidative stress, fibrosis, and epithelial dysregulation in OPLs | Scientifically validates traditional clinical efficacy through reverse pharmacology |

**ABSTRACT**

Peter Ingwersen introduced the Web Impact Factor (WIF) in 1998 as a quantitative indicator based on link frequency analysis. Building on this concept, the present study examines the websites of Institutions of Eminence (IoEs) in India using selected webometric tools and indicators. The parameters analysed include Simple Web Impact Factor, Self-link Web Impact Factor, External-link Web Impact Factor, backlinks, and broken links. Data were collected using tools such as the Google Search Engine, Website Link Analyser, Broken Link Checker, and Backlink Watch. The analysis reveals significant variations in the quality, visibility, and maintenance of IoE websites. Institutions such as OP Jindal Global Institution of Eminence and Manipal Academy of Higher Education exhibit fewer broken links, indicating better website maintenance, improved user experience, and enhanced visibility. These institutions achieve higher rankings because of their few broken links.

**Keywords:** Backlinks, Broken Links, External Links, Institutions of Eminence, Web Impact Factor, Webometrics.

## INTRODUCTION

In the contemporary higher education environment, Institutions of Eminence have gained importance. These institutions are expected to lead in academic excellence, research productivity, and global engagement. Their digital presence, particularly institutional websites, is crucial for sharing academic information and facilitating access to resources. It also enhances international visibility. Webometric analysis provides a quantitative framework for assessing the online performance of academic institutions. (Chakravarty & Wasan, 2015). Webometrics examines quantitative aspects of online information resources, technologies, and services. (Chakraborty & Thakuria, 2023) It provides a reliable approach for evaluating institutional websites using link-based indicators (Aguillo et al., 2008).

Literature highlights the growing importance of web presence and visibility among Indian higher education institutions. This study extends previous research by focusing specifically on Institutions of Eminence. These represent India's leading academic institutions. Studies have emphasised the usefulness of combining institutional characteristics with numerical indicators to assess educational quality and performance (Artyukhov et al., 2021). Webometric approaches are also effective in evaluating the reach and impact of scholarly and academic web resources (Shafi & Bhat, 2014).

**Institutions of Eminence**

The Government of India introduced the Institutions of Eminence (IoE) initiative in 2016 through the Ministry of Human Resource Development, now the Ministry of Education. The objective is to develop world-class higher education institutions. Under this scheme, twenty institutions were designated as Institutions of Eminence. They are divided between the public and private sectors. These institutions are granted greater autonomy and additional financial support. This support is intended to strengthen research, teaching, and innovation activities. These selected institutions are tasked with competing globally and improving India's international higher education profile. At the time of data collection, only twelve IoEs had fully functional, independent, and accessible official websites; therefore, the analysis is limited to these, ensuring data reliability and accuracy.

## REVIEW OF LITERATURE

Seshaiah and Rekha (2017) conducted a webometric evaluation of 277 engineering institutions in the state of Andhra Pradesh. They analysed web pages, link pages, and various forms of Web Impact Factors using tools such as Google Search Engine and Backlink Watch. Their findings indicated limited web presence among engineering institutions. Brahma and Verma (2019) examined the websites of South Asian national libraries. They found the National Library of India to be the most dominant in terms of external links and domain authority. Chakravarty and Wasan (2015) analysed library websites of Indian higher education institutions. They observed minimal variation between WIF and revised WIF rankings. Elgohary (2008) analysed 99 Arab institutions. He found that Jordanian universities were among the most dominant in the updated WIF rankings. Studies by JeyshankarandSujithai (2014), Didegah and Erfanmanesh (2010), Bulla and Hadagali (2020), and Madhusudhan and Prakash (2013) further demonstrated the effectiveness of webometric indicators. These indicators are useful for evaluating institutional websites and digital visibility.

**Objectives of the Study**

1. To evaluate the websites of selected Institutions of Eminence in India using webometric tools and indicators.
2. To determine the number of internal links, self-links, external links, in-links, and broken links on the selected IoE websites.
3. Assess and rank the IoE websites based on Simple, Self-link, External, and Revised Web Impact Factors.

## METHODOLOGY

The study adopts a quantitative webometric research approach. Data were collected using the Google Search Engine, which provides extensive web coverage and reliable retrievalcapabilities. The Website Link Analyser (https://smallseotools.com/website-link-analyser-tool/) was used to collect data on simple, self-referential, and external links. In-links were obtained using Backlink Watch(http://www.backlinkwatch.com/). Broken Link Checker (https://www.deadlinkchecker.com/) identified broken links on the selected websites. Microsoft Excel was used to organise, compute, and analyse the collected webometric data. The data for the present study were collected during the period 01 to 5 December 2025.

**Data Analysis and Interpretation**

**Domain-wise distribution of Institutions of Eminence in India**

It has gathered the Universal Resource Locators (URLs) of 12 Institutions of Eminence, as well as the Second-Level Domains (SLDs) and Top-Level Domains (TLDs) of these institutions, through online searches. Table 2 presents the TLDs and SLDs. in, and domain names of the hosts of the Internet of Everything. All Institutions of Eminence use the same domain extension—. ac. in—except Manipal Academy of Higher Education, which uses edu.

**Simple Web Impact Factor of the top 5 Institutions of Eminence in India**

Table 3 displays the rank distribution of IOE websites in India based on the Simple WIF. Birla Institute of Technology and Science, Pilani, Rajasthan, ranked #1 in terms of Simple Web Impact Factor (SWIF) (0.0308SWIF). Second place went to the Manipal Academy of Higher Education in Manipal, Karnataka, with a SWIF of 0.0280; third place went to Banaras Hindu University in Varanasi, Uttar Pradesh, with a SWIF of 0.01158; and fourth place went to the University of Hyderabad in Hyderabad, Telangana, with a SWIF of 0.00408. Despite having a respectable number of webpages (244000), the Indian Institute of Technology, Delhi, placed fifth (0.00341 SWIF) due to a lower number of link pages than

**Self-Link Web Impact Factor of the top 5 Institutions of Eminence in India**

The rank distribution of India's IoE websites is displayed in Table 4 based on the self-link WIF. Pilani, Rajasthan's Birla Institute of Technology and Science, ranked first with a Self-Link Web Impact Factor (SLWIF) of 0.0142. Second place went to Manipal Academy of Higher Education in Manipal, Karnataka, with a score of 0.0138 SLWIF; third place went to OP Jindal Global Institution of Eminence, Deemed to be University in Sonipat, Haryana, with a score of 0.0109 SLWIF; and fourth place went to Banaras Hindu University in Varanasi, Uttar Pradesh, with a score of 0.0097 SLWIF. The Indian Institute of Technology, Bombay, Maharashtra, has a significant number of web pages (350,000); however, because there were fewer self-link sites than web pages, the institute ranked fifth (0.0078 SLWIF).

**External-Link Web Impact Factor of the top 5 Institutions of Eminence in India**

The rank distribution of IoE websites in India, based on the External Link WIF, is shown in Table 5. Banaras Hindu University, Varanasi, Uttar Pradesh, held the top spot (0.0179 ELWIF) for External Link Web Impact Factor (ELWIF). The University of Delhi, Delhi, placed fourth with 0.00006 ELWIF, followed by Birla Institute of Technology and Science, Pilani, Rajasthan, which placed third with 0.0012 ELWIF, and Indian Institute of Technology, Bombay, Maharashtra, which placed second with 0.0018 ELWIF. The University of Hyderabad, located in Hyderabad, Telangana, ranked fifth (0.0009 ELWIF), despite having a substantial number of web pages (86,000), primarily because its external link pages accounted for a lower proportion of its total web pages.

**Revised Web Impact Factor of the top 5 Institutions of Eminence in India**

The rank distribution of India's IoE websites, based on the Revised WIF, is shown in Table 6. The top rank was held by Banaras Hindu University in Varanasi, Uttar Pradesh, with a revised web impact factor (RWIF) of 0.2833. The Indian Institute of Science, Bangalore, Karnataka, held the second position with a RWIF of 0.2174, followed by the Birla Institute of Technology and Science, Pilani, Rajasthan, which came in third place with a RWIF of 0.1632, and the Indian Institute of Technology, Madras, Tamil Nadu, which came in fourth place with a RWIF of 0.0717. Although the University of Hyderabad, Hyderabad, Telangana, has a respectable number of web pages (86,000), it was ranked fifth (0.0505 RWIF) because it had fewer in-link pages than web pages.

**Broken Links of the top 5 Institutions of Eminence in India**

The results, displayed in Table 7, represent the broken links (BL) on the IoE Everything websites. Manipal Academy of Higher Education, Manipal, Karnataka, rated second with 0.0004% broken links (BL), behind the OP Jindal Global Institution of Eminence. Deemed to be a University, Sonipat, Haryana, ranked first with a BL of 0.0001%. In terms of broken links (BL), the Indian Institute of Technology, Madras, Tamil Nadu, ranked fourth with 0.76%, while the Birla Institute of Technology and Science, Pilani, Rajasthan, ranked third with 0.12%. Ranking fifth, with the greatest Broken Links (BL) of 1.40 %, is Banaras Hindu University in Varanasi, Uttar Pradesh.

## DISCUSSION

The study finds significant variation in web presence and link performance among India's Institutions of Eminence (IoEs). Most use the ***.ac.***in the domain for academic credibility. MAHE (Manipal Academy of Higher Education) uses the .edu domain, indicating an international focus that may enhance its visibility. Web Impact Factor (Simple and Self-Link) results indicate that an effective internal structure and balanced link distribution enhance web impact more than simply having a large number of web pages. Institutions with larger websites but lower link density tend to perform worse. Web volume alone does not guarantee better visibility. Web Impact Factor (External-Link)results demonstrate differences in external recognition across IoEs. Banaras Hindu University stands out for its strong external links, demonstrating a broad academic reach and digital influence. The Web Impact Factor (Revised) confirms that reputation and content relevance drive in-links. The broken link analysis reveals varied website maintenance practices. Institutions with fewer broken links tend to manage their sites more effectively, thereby enhancing accessibility and user experience. High rates of broken links hurt web credibility. Institutions of Eminence (IoEs) should strengthen internal linking, increase external engagement, and maintain high-quality websites to enhance web visibility and impact.

## CONCLUSION

The webometric analysis of Institutions of Eminence (IOE) websites reveals considerable variation in website quality, visibility, and maintenance practices. The findings reveal substantial differences among the Institutions of Eminence (IoEs) in their web presence, connectivity structures, and maintenance procedures. Website size, by itself, does not guarantee increased visibility. Institutions demonstrating robust external connectivity and well-balanced internal link structures generally achieve a greater web effect. OP Jindal Global Institution of Eminence, Manipal Academy of Higher Education (IOE), demonstrates effective website maintenance with minimal broken links. At the same time, Banaras Hindu University (IOE) distinguishes itself through strong external and in-link performance.

**ABSTRACT**

In this research, we provide the **intuitionistic fuzzy cube difference graph (IFCDG)** and explore its structural characteristics inside basic graph types such as path graph($P_n$), cycle graph($C_n$), and star graph($S_{1,n}$). Our goal is to enhance the theoretical knowledge of these graphs and highlight their significance in the larger context of graph theory. We hope this exploration proves both insightful and thought-provoking for researchers and enthusiasts alike.

**Keywords:** IFCDL, IFCDG.
**2020 AMS Classification:**05C78, 05C72

## INTRODUCTION

The development of *intuitionistic fuzzy sets* by Atanassov [7, 8] and further elaborated with Shannon [9, 10], led to the emergence of *intuitionistic fuzzy graphs*, enabling even finer representation of vagueness through the dual notion of membership (MS) and non-membership (NMS). In this context, Karunambigai et al. [12, 13] examined fundamental properties of intuitionistic fuzzy graphs (IFGs), while Nivethana and Parvathi [17] studied arc analysis and its applications. Significant advancements were made by Akram and collaborators,Akram and Davvaz [2], Akram and Dudek [3],and Akram and Alshehri [1],who explored a lot of graph structures.Further contributions by Sahoo and

Pal [15, res16, 17, 18, and 19] include the study of intuitionistic fuzzy competition graphs, tolerance graphs, various graph products, and intuitionistic fuzzy labeling (IFL). Building upon these developments, the present work introduces the novel concept of *intuitionistic fuzzy cube difference labeling graphs (IFCDGs)*. We demonstrate that this labeling scheme naturally integrates with and enhances the structural representation of classical graph families such as paths, cycles, and stars. This contribution not only deepens the theoretical framework but also opens promising directions for further research and applications within the broader scope of intuitionistic fuzzy graph theory.

**Preliminaries**

**Definition 2.1**The process of giving each graph's vertices and edges a unique identity is known as **graph labeling**.
**Definition 2.2**When a function $f$ is injected from $V(G)$ to the set of all integers$0,1,\dots,p-1$, such that the induced function $f^*$ from $E(G)$ to $N$, which is given by$f^*(uv)$, equals the absolute value of the difference between the cube of the function $f(u)^3$ and $f(v)^3$ for each $uv \in E(G)$, then the graph is said to have a **cube difference labeling** (CDL). The term **cube difference graph** (CDG) refers to a graph that allows CDL.

**Definition 2.3 [19]**An **IFG** is defined as$G = (V_X^{'}, \sigma_\alpha^{'}, \mu_\beta^{'})$ where $\sigma_\alpha^{'} = (\sigma_{\alpha_1}^{'}, \sigma_{\alpha_2}^{'}), \mu_\beta^{'} = (\mu_{\beta_1}^{'}, \mu_{\beta_2}^{'})$, and
(i)$V_X^{'} = \{v_0^{'}, v_1^{'}, \dots, v_n^{'}\}$The degrees of MS and NMS of the node$v_i^{'} \in V_X^{'}$ are denoted by $\sigma_{\alpha_1}^{'}: V_X^{'} \to [0,1]$and$\sigma_{\alpha_2}^{'}: V_X^{'} \to [0,1]$ respectively, with $0 \le \sigma_{\alpha_1}^{'}(v_i^{'}) + \sigma_{\alpha_2}^{'}(v_i^{'}) \le 1$for every $v_i^{'} \in V_X^{'}(i = 1,2,\dots,n)$.
(ii) $\mu_{\beta_1}^{'}: V_X^{'} \times V_X^{'} \to [0,1]$ and $\mu_{\beta_2}^{'}: V_X^{'} \times V_X^{'} \to [0,1]$, where $\mu_{\beta_1}^{'}(v_i^{'}, v_j^{'})$ and $\mu_{\beta_2}^{'}(v_i^{'}, v_j^{'})$ indicate the degree of MS and NMS value of the edge $(v_i^{'}, v_j^{'})$ respectively, so that $\mu_{\beta_1}^{'}(v_i^{'}, v_j^{'}) \le \min\{\sigma_{\alpha_1}^{'}(v_i^{'}), \sigma_{\alpha_1}^{'}(v_j^{'})\}$and$\mu_{\beta_2}^{'}(v_i^{'}, v_j^{'}) \le \max\{\sigma_{\alpha_2}^{'}(v_i^{'}), \sigma_{\alpha_2}^{'}(v_j^{'})\}\}, 0 \le \mu_{\beta_1}^{'}(v_i^{'}, v_j^{'}) + \mu_{\beta_2}^{'}(v_i^{'}, v_j^{'}) \le 1$for each edge$(v_i^{'}, v_j^{'})$.

**Definition 2.4 [19]**If$\sigma_{\alpha_1}: V_X \to [0,1], \sigma_{\alpha_2}: V_X \to [0,1]$,and$\mu_{\alpha_1}: V_X \times V_X \to [0,1], \mu_{\alpha_2}: V_X \times V_X \to [0,1]$,then an IFG $G = (V_X, \sigma_\alpha, \mu_\alpha)$is considered an **intuitionistic fuzzy labeling graph (IFLG)**if it is bijective. In the sense that the vertices and edges have different MS and NMS values, and$\mu_{\alpha_1}(v_i, v_j) < \min\{\sigma_{\alpha_1}(v_i), \sigma_{\alpha_1}(v_j)\}, \mu_{\alpha_1}(v_i, v_j) < \max\{\sigma_{\alpha_2}(v_i), \sigma_{\alpha_2}(v_j)\}, 0 \le \mu_{\alpha_1}(v_i, v_j) + \mu_{\alpha_2}(v_i, v_j) \le 1$ for each edge$(v_i, v_j)$.

**Definition 2.3** A walk in a graph is a finite, non-null subspace with words that alternately represent vertices and edges, $W = v_0 e_1 v_1 e_2 \dots e_k v_k$.$W$ is a $(v_0, v_k)$ walk, as we say. When a walk $W$ has distinct vertices, it is called a **path**. The term "**cycle**" refers to a closed trail with the same starting and ending points.

**Definition 2.4** The complete bipartite graph $K_{1,n}$ is known as a star $S_n$, which is a tree with one internal node and n leaves.
**3. Intuitionistic Fuzzy Cube Difference Graph**
**Definition 3.1**An IFG $G = (V, \sigma_\alpha, \mu_\alpha)$ is said to be **Intuitionistic Fuzzy Cube Difference Labeling Graph (IFCDLG)** if it is an Intuitionistic Fuzzy Labeling Graph (IFLG) and satisfies the following conditions,$\mu_{\alpha_1}(u_s, v_t) = |\sigma_{\alpha_1}(u_s)^3 - \sigma_{\alpha_1}(v_t)^3|, \mu_{\alpha_2}(u_s, v_t) = |\sigma_{\alpha_2}(u_s)^3 - \sigma_{\alpha_2}(v_t)^3|, 0 \le \mu_{\alpha_1}(u_s, v_t) + \mu_{\alpha_2}(u_s, v_t) \le 1$ for each$(u_s, v_t) \in E$ are all distinct. The term IFCDLG refers to a graph that is an **IFCDL**.

**Example:**
**Figure 1**

**Theorem 3.2**Path $P_n$ is an IFCDG for all $n \ge 1$.
**Proof:**
Let $P_n$ be any path with length $n \ge 1$, and$v_1, v_2, \dots, v_n$ and $v_1v_2, v_2v_3, \dots, v_{n-1}v_n$are nodes and edges of$P_n$.
Choose the MS value $\omega_1 \to (0,1]$ such that

$\omega_1 = 10^{-1}$ for $n \leq 9$,$\omega_1 = 10^{-3}$for $10 \leq n \leq 99$, $\omega_1 = 10^{-5}$for $100 \leq n \leq 999$ and so on.
Choose the NMS value $\omega_2 \rightarrow (0,1]$ such that
$\omega_2 = 10^{-2}$ for $n \leq 99$,$\omega_2 = 10^{-4}$for $100 \leq n \leq 999$, $\omega_2 = 10^{-6}$for $1000 \leq n \leq 9999$ and so on.
The following are the labels given to nodes and connections, MS values:

$\sigma_{\alpha_1}(v_i) = i * \omega_1,$ $i = 1,2,\dots,n$
$\mu_{\alpha_1}(v_1v_2) = 7 * \omega_1^3,$
$\mu_{\alpha_1}(v_iv_{i+1}) = (6\omega_1^3 * i) + \mu(v_{i-1}v_i),\ i = 2,3,\dots,n-1$
The NMS values of nodes and connections have been given the following labels:

$\sigma_{\alpha_2}(v_i) = i * \omega_2,$ $i = 1,2,\dots,n$
$\mu_{\alpha_2}(v_1v_2) = 7 * \omega_2^3,$
$\mu_{\alpha_2}(v_iv_{i+1}) = (6\omega_2^3 * i) + \mu(v_{i-1}v_i),\ i = 2,3,\dots,n-1$
Each node and connection has a different MS and NMS value.

This labeling obeys the conditions ofIFCDL.
Therefore, every path $P_n$ is an IFCDG.
**Example:**
**Figure 2: IFCDG of $P_9$**

**Theorem 3.2** Everycycle$C_n$, $(n \geq 3)$ is an IFCDG.
**Proof:**
Let $\{v_1, v_2, \dots, v_n\}$ be the set of vertices and $\{v_1v_2, v_2v_3, .., v_{n-1}v_n, v_nv_1\}$ be the set of edges.
Choose the MS value$\omega_1 \rightarrow (0,1]$ such that
$\omega_1 = 10^{-2}$ for $n \leq 99$,$\omega_1 = 10^{-4}$for $100 \leq n \leq 999$, $\omega_1 = 10^{-6}$for $1000 \leq n \leq 9999$ and so on.
Choose the NMS value $\omega_2 \rightarrow (0,1]$ such that
$\omega_2 = 10^{-3}$ for $n \leq 999$,$\omega_2 = 10^{-5}$for $1000 \leq n \leq 9999$, $\omega_2 = 10^{-7}$for $10000 \leq n \leq 999999$ and so on.
The following labels have been given to the nodes and connections MS values:

$\sigma_{\alpha_1}(v_i) = i * \omega_1,$ $i = 1,2,\dots,n$
$\mu_{\alpha_1}(v_1v_2) = 7 * \omega_1^3,$
$\mu_{\alpha_1}(v_iv_{i+1}) = (6\omega_1^3 * i) + \mu(v_{i-1}v_i),\ i = 2,3,\dots,n-1$
$\mu_{\alpha_1}(v_nv_1) = (n^3 - 1) * \omega_1^3,$
Nodes and connections NMS values are labeled as follows:

$\sigma_{\alpha_2}(v_i) = i * \omega_2,$ $i = 1,2,\dots,n$
$\mu_{\alpha_2}(v_1v_2) = 7 * \omega_2^3,$
$\mu_{\alpha_2}(v_iv_{i+1}) = (6\omega_2^3 * i) + \mu(v_{i-1}v_i),\ i = 2,3,\dots,n-1$
$\mu_{\alpha_2}(v_nv_1) = (n^3 - 1) * \omega_2^3.$
Each node and connection has a different MS and NMS value.

This labeling obey the conditions ofIFCDL.
Thus every cycle graph is an IFCDG.
**Example:**
**Figure 3: IFCDG of $C_4$**

**Theorem 3.3**Every star graph $S_{1,n}$ is anIFCDG.

**Proof:**

Let $\{v_1, v_2, \ldots, v_{n+1}\}$ be the set of vertices and $\{v_1v_2, v_1v_3, .., v_1v_{n+1}\}$ be the set of edges.

Choose the MS value $\omega_1 \rightarrow (0,1]$ such that

$\omega_1 = 10^{-2}$ for $n \leq 99$,$\omega_1 = 10^{-4}$for $100 \leq n \leq 999$, $\omega_1 = 10^{-6}$for $1000 \leq n \leq 9999$ and so on.

Choose the NMS value $\omega_2 \rightarrow (0,1]$ such that

$\omega_2 = 10^{-3}$ for $n \leq 999$,$\omega_2 = 10^{-5}$for $1000 \leq n \leq 9999$, $\omega_2 = 10^{-7}$for $10000 \leq n \leq 999999$ and so on.

The following labels have been given to the nodes and connections MS values:

$\sigma_{\alpha_1}(v_i) = i * \omega_1, \qquad 1 \leq i \leq n$

$\mu_{\alpha_1}(v_1v_i) = (i^3 - 1) * \omega_1^3, \qquad 2 \leq i \leq n$

The NMS values of nodes and connections have been given the following labels:

$\sigma_{\alpha_2}(v_i) = i * \omega_2, \qquad 1 \leq i \leq n$

$\mu_{\alpha_2}(v_1v_i) = (i^3 - 1) * \omega_2^3, \qquad 2 \leq i \leq n$

Each node and connection has a different MS and NMS value.

This labeling obey the conditions of IFCDL.

Thus every star graph is an IFCDG.

**Example:**

**Figure 4: IFCDG of $S_{1,5}$**

## CONCLUSION

We introduced IFCDGs and studied their properties in path, cycle, and star graphs. This work extends fuzzy graph theory and highlights the potential of intuitionistic fuzzy models in representing uncertainty. We hope it encourages further exploration in this area.

**ABSTRACT**

This article addresses how AI-augmented teaming is reshaping e-collaboration with new types of accountable, dynamic partnerships between humans and AI systems. Using randomized trials, field experiments, and meta-analyses from a large body of work across a range of problem domains such as customer support, software engineering, healthcare, and education, it shows that AI can substantially augment human productivity, quality, and learning among less-experienced workers. But the benefits are limited by an increasingly "jagged frontier" of model capability: performance improvements are contingent on task fit, oversight, and governance. Counterintuitively, unrestructured AI will decrease decision accuracy and humancapability to grow skills without proper guardrails. This article identifies the key elements of teamwork that are derived from task decomposition, calibrated trust, transparent interfaces, and learning-preserving designs, and links these to governance frameworks like NIST AI RMF, EU AI Act, Iso/IEC 42001, etc. Drawing on empirical research and design practice, it claims that sustainable human-AI collaboration necessitates a realignment of capabilities with accountability, shifting from tool use to principled, resilient teaming in the post-digital workplace.

**Keywords:** Teaming, Digital Workplace, AI, education,

## INTRODUCTION

Across industries and institutions, AI-augmented teaming is shifting e-collaboration from simple tool use to tightly coupled human–machine partnerships that change how teams learn, decide, and produce. In this chapter, we define

AI-augmented teaming, benchmark its measurable effects on productivity, quality, and learning, and synthesize governance and design guidance needed to realize durable, equitable gains at scale. We ground the analysis in recent randomized and field experiments in knowledge work, software engineering, healthcare delivery, and education; systematic reviews of human–AI synergy; and emerging governance frameworks (NIST AI RMF 1.0, EU AI Act, ISO/IEC 42001), balancing performance results with risks around bias, transparency, and trust. AI-augmented teaming is already boosting throughput and quality on well-scoped tasks, especially for less-experienced workers, but it can degrade decision accuracy outside the technology's "jagged" capability frontier and can harm learning when guardrails are weak. Effective practice therefore hinges on targeted task design, calibrated trust, robust evaluation, and governance-by-design to align human expertise with model strengths in accountable ways. This is not simply about faster outputs; it is about building teams that are resilient to error, inclusive of diverse skills, and deliberately governed for safety and equity in the post-digital workplace.

**Defining AI-Augmented Teaming and Its Relevance**

Human–AI teaming (HAIT) is best understood as a human-centered, socio-technical form of collaboration in which humans and AI systems function as interdependent teammates with distinct roles, complementary capabilities, and shared goals. This teaming emphasizes calibrated trust, shared mental models, and adaptive role reallocation as context evolves, with explicit attention to human wellbeing and productivity. Scoping reviews synthesize this definition across disciplines, highlighting eleven dimensions: interdependence, shared goals, AI autonomy, dynamic adaptation, complementary strengths, calibrated trust, explainability, shared situational awareness, team communication, human-centered design, and socio-technical integration. These elements distinguish teaming from mere tool use and anchor designs for sustainable performance gains. In practice, HAIT leverages human creativity, context, and ethics with AI's speed, scale, and pattern detection to handle complexity under uncertainty, provided that oversight, transparency, and task fit are well managed(Abramoff et al., 2023).

**The Post-Digital Workplace**

The post-digital workplace is characterized by pervasive cloud collaboration, integrated data flows, and ubiquitous model access (including generative AI). This environment increases coordination bandwidth but also raises stakes for governance and sociotechnical fit. Evidence shows that generative assistants can raise throughput in support roles by roughly 15% on average while disproportionately helping less-experienced workers, compressing time-to-competence and smoothing experience curves(Noy & Zhang, 2023). Yet the same technology can degrade decision accuracy when applied to tasks beyond current capability frontiers, or undermine skill acquisition in education settings if designs encourage answer-taking rather than guided discovery. These dualities underscore that "AI-augmented" must mean "well-matched and well-governed," not "always faster." Organizational frameworks like NIST AI RMF, the EU AI Act, and ISO/IEC 42001 now provide a backbone to align performance, safety, and accountability across the AI lifecycle(National Institute of Standards and Technology, 2023). AI-Augmented Teaming is revolutionizing e-collaboration and human–AI synergy by lifting throughput and quality on tasks inside the technology's capability frontier, with especially large gains for novices and mid-skill professionals. However, achieving durable, fair, and safe gains requires careful task decomposition, calibrated trust and transparency, and governance practices that map, measure, and manage AI risks across contexts.

**Theoretical Foundations**

**From HCI and CSCW to Human–AI Teaming**

The HCI community has long articulated design guidance for interactive AI, consolidating 18 guidelines spanning initial interaction, ongoing use, handling errors, and system evolution, emphasizing proactive transparency, appropriate control, and graceful failure behavior. These guidelines inform team-aware interfaces that set expectations, expose uncertainty, and support user correction during routine collaboration, foundational for calibrated trust in team settings. In CSCW, the focus on coordination, common ground, and artifacts aligns with shared mental models and communication loops that mixed teams need to avoid miscalibration and drift. Together, HCI and CSCW provide the interactional and organizational substrate for HAIT, while contemporary teaming research reframes AI from tool to teammate with defined roles and interdependence (Kluge et al., 2023)

**AI in Teamwork and Collaboration: Evidence and Limits**

Recent field and lab studies demonstrate substantial productivity gains on creative and content-heavy knowledge tasks, with heterogeneous effects by worker skill and task type. In customer support, access to a GPT-based assistant increased issues resolved per hour by roughly 15% on average across 5,172 agents and 3 million chats, with the largest improvements among less experienced workers; newer agents with two months' tenure plus AI matched the productivity of >6-month untreated agents. Speed gains for top performers came with slight declines in conversation quality, whereas novices improved both speed and quality, suggesting a convergence effect. Escalations fell and customer politeness rose, illustrating not only faster output but better interactional dynamics in certain contexts. This pattern reinforces that HAIT can raise team-level outcomes when workflows fit model strengths and when oversight retains human judgment in edge cases (Brynjolfsson, Li, & Raymond, 2023). Conversely, a systematic review and meta-analysis of 106 experiments (370 effect sizes) found human–AI teams on average underperform relative to the best individual (human or AI), with particularly negative synergy on decision tasks and when AI outperforms humans on its own. The authors argue that synergy demands explicit subtask delegation to the agent best suited for each component, robust evaluation metrics (time, cost, error impact), and standardized commensurability criteria across studies to meaningfully compare results(Vaccaro et al., 2024). This reinforces the idea that "just combine human and AI" is insufficient; the team process must be redesigned to leverage complementarity rather than aggregate judgments in ways that compound errors or overrule the stronger partner.

**AI-Augmented Teaming: Key Concepts and Components**

**Key Concepts**

AI-augmented collaboration refers to workflows in which AI systems contribute intermediate artifacts, suggestions, or decisions that humans integrate, critique, and adapt toward shared goals. Human–AI synergy is achieved when the combined system outperforms its strongest component on relevant metrics (e.g., quality under cost constraints), a condition that is not guaranteed and varies by task mode (creation vs. decision) and decomposability. Intelligent team assistants span copilots, recommenders, and autonomous modules capable of local decisions, interfacing through natural language, structured templates, or domain-specific UIs; their efficacy depends on transparency, uncertainty displays, and controls for feedback and correction. AI-driven decision-making covers advisory through autonomous configurations, requiring clarity on human-in-the-loop roles, escalation protocols, and auditability of rationales and outcomes to sustain trust and accountability in team contexts (Vössing et al., 2022).

**Core Components**

Algorithms and Models: Foundation models adapted via fine-tuning, retrieval augmentation, and tool use can deliver rapid ideation, summarization, classification, and code generation. However, capability is "jagged": seemingly similar tasks can fall inside or outside the current frontier, so pipelines must explicitly route subtasks to human or AI based on expected performance. Field experiments with consultants show >40% quality gains and ~25% faster completion for tasks inside the frontier, but a 19-point drop in correctness outside it, illustrating the stakes of capability mapping in team workflows (Dell'Acqua et al., 2023). Data Analytics and Visualization: Effective teaming requires analytics that surface uncertainty, coverage, and residual risk, not just point predictions, enabling calibrated reliance. In operations settings (e.g., digital twins), combining simulation, visualization, and AI copilots has accelerated design and shop-floor productivity, with reported 30% productivity gains and 50% faster time-to-market for certain workflows, though such figures should be contextualized as vendor-reported and task-specific (NVIDIA, 2025). Human–AI Interface Design: Interaction design must make capabilities and limits legible, offer granular control, and handle errors gracefully. Proactive transparency, uncertainty displays, and quick "escalate-to-human" paths reduce over-trust and prompt effective oversight. These principles build directly on established HCI guidance for human–AI interaction and are codified in governance frameworks that require role clarity and oversight patterns for different autonomy levels (Chen, 2022).

**Applications and Case Studies**

**Knowledge Work and Customer Support**

In a staggered rollout covering 5,172 customer-support agents, a GPT-based assistant increased issues resolved per hour by about 15% on average across 3 million chats. Heterogeneity was pronounced: less-experienced agents saw roughly 30% throughput gains and quicker movement down the experience curve, while the most experienced agents gained small speed boosts with slight quality declines. Resolution rates and NPS did not materially change, but escalations fell and customers were more polite, suggesting that AI support can simultaneously improve throughput and interaction quality when paired with human judgment and escalation protocols. This is a canonical example of AI-augmented teaming boosting e-collaboration efficiency without harming customer experience (Noy & Zhang, 2023).

**Professional Writing and Consulting**

A preregistered experiment of 453 college-educated professionals performing mid-level writing tasks found a 40% reduction in time and an 18% increase in output quality using ChatGPT, with larger gains for weaker writers(Noy & Zhang, 2023). This not only raised average productivity but narrowed performance dispersion—an equity-relevant effect in team composition and development. Complementing this, a field experiment with 758 consultants at a global firm found that for ideation-heavy tasks within AI's frontier, AI users completed 12.2% more tasks, 25.1% faster, and produced >40% higher quality; for a task deliberately outside the frontier, AI users were 19 percentage points less likely to produce correct solutions (Dell'Acqua et al., 2023). These studies together quantify the opportunity and the boundary conditions: map tasks to frontier, design guardrails, and train teams to "delegate and decide" rather than "defer and accept".

**Software Engineering**

A controlled experiment with GitHub Copilot showed developers completed a standard programming task 55.8% faster than controls, indicating substantial speed gains for well-specified tasks with immediate feedback and verifiable tests. While speed is evident, team-level benefits hinge on code review, testing, and maintainability policies—i.e., collaborative processes that absorb AI outputs into shared quality standards and knowledge repositories(Peng et al., 2023). This case underscores how team scaffolding (code review, tests, documentation) translates individual speedups into sustainable team productivity.

**Healthcare Delivery**

In a preregistered, double-masked, cluster-randomized trial in retina clinics, autonomous AI for diabetic eye exams increased specialist productivity by about 39.5% (0.45 more completed encounters/hour), with significant gains in a high-demand, unscheduled environment. The trial's design—masking, cluster randomization by clinic day, and prospective registration—strengthens causal inference and shows that carefully integrated autonomous modules can expand specialist capacity without compromising clinical control. This is a clear instantiation of human–AI teaming: AI performs standardized screening, freeing specialists for higher-complexity care, inside a governance structure that preserves accountability and escalation(Abràmoff et al., 2023).

**Education**

Evidence in education is nuanced. A crossover randomized study in an introductory physics course found that a custom AI tutor produced significantly higher and faster learning gains than active in-class learning, with effect sizes up to ~0.73–1.3 SD by quantile regression after controls(Kestin et al., 2025). By contrast, a large high school field experiment found that unfettered GPT-4 access improved practice performance but harmed subsequent assessments without AI, indicating reduced skill acquisition; importantly, guardrails that enforced teacher-designed hints instead of direct answers mitigated these negative effects. For team-based learning and co-creation, the implication is to design AI roles as scaffolds—not crutches—so human skills compound over time while leveraging AI's capacity for feedback, explanation, and formative (Liu et al., 2024).

**Manufacturing and Industrial Collaboration**

Industrial copilots and Omniverse-powered digital twins are enabling faster design-to-production loops and augmented shop-floor teaming. Reported results from Siemens and NVIDIA include a 30% increase in shop-floor productivity with copilot assistants and a 50% reduction in time-to-market for marketing materials, alongside massive GPU-accelerated simulations equivalent to >10,000 CPU cores—illustrating how visualization, simulation, and AI assistance co-evolve collaboration artifacts. While vendor-reported outcomes require independent validation, they point to a teaming model in which AI agents, digital twins, and human operators coordinate across design, test, and execution, with transparency and override at the human level (NVIDIA, 2025).

**Calculated Statistics: Cross-Study Synthesis**

To contextualize effects across domains, we synthesize consistent metrics:

Throughput increases (team-relevant): Customer support +15.2% (resolutions/hour); specialist clinic +39.5% (encounters/hour); industrial shop-floor +30% (reported). Simple average = 28.2% (range 15.2%–39.5% for peer-reviewed; vendor report 30%). Interpretation: On throughput-measured workflows inside the frontier and with escalation paths, 15%–40% gains are credible and replicable across support and clinical screening; industrial reports suggest similar magnitude but should be independently verified(Noy & Zhang, 2023; Abràmoff et al., 2023; NVIDIA Corporation, 2024). Speed gains on knowledge tasks: Software task +55.8% completion speed; consulting tasks +25.1% faster inside frontier; writing tasks −40% time (equivalent to ~66.7% speed-up if converting time to throughput). Unweighted average of directly reported speed gains (55.8% and 25.1%) = 40.5%; including the implied throughput from the 40% time reduction yields 49.2%. Interpretation: For well-specified, feedback-rich tasks (coding, structured ideation), 25%–55% speed gains are typical, with higher uplifts when evaluation is immediate and failures are cheap.(Peng et al., 2023).

Quality improvements: Writing +18% quality; consulting >+40% quality inside frontier. Simple midpoint ≈ +29%. Interpretation: On creation tasks within frontier, quality uplift accompanies speed gains; outside frontier, quality and correctness can decline materially, underscoring the need for task mapping and human oversight (Noy & Zhang, 2023; Dell'Acqua et al., 2023). Equity/heterogeneity: Novices benefit more. Customer support novices gained ~30% throughput vs. small speed-only gains with slight quality declines for experts; writing study narrowed productivity inequality; consulting study showed both below- and above-average performers gained, but with steeper gains below average.

Interpretation: AI-augmented teaming can compress skill disparities, accelerating onboarding and elevating floor performance—if guardrails protect decision quality (Dell'Acqua et al., 2023).

Method notes: Wereport simple averages and ranges across peer-reviewed or preregistered studies with comparable metrics,and avoid pooled meta-estimates given heterogeneity of designs and outcomes. The Nature Human Behaviour meta-analysis provides the most rigorous cross-study aggregation and cautions that unstructured combinations often underperform the best single agent, especially on decision tasks—hence the emphasis here on task decomposition and calibrated teaming (Vaccaro et al., 2024).

**Challenges and Future Directions**

**Data Quality and Bias**

Bias can arise from data sampling, labeling, and deployment contexts; in teaming, biased outputs can be amplified by over-trust and miscalibration. The NIST AI RMF defines seven socio-technical characteristics of trustworthy AI: Valid/reliable, safe, secure/resilient, accountable/transparent, explainable/interpretable, privacy-enhanced, and fair with harmful bias managed, framing multi-stakeholder criteria for risk treatment. Team designs should expose uncertainty, allow contestation, and ensure data lineage and audit logs to detect and correct drift and disparate impacts over time(National Institute of Standards and Technology, 2023).

**Human–AI Trust and Transparency**

Meta-analytic evidence indicates that naïve combinations underperform without process redesign; transparency alone (e.g., confidence displays) may not fix miscalibration. Teams need workflows that allocate subtasks to the better partner, plus interfaces that clarify limits and provide reasons or exemplars when appropriate (Vaccaro et al., 2024). Clear escalation protocols and role definitions—human-in-the-loop, AI-assisted, autonomous with human oversight—are essential to avoid both abdication and micromanagement, aligning with NIST guidance on human roles in decision-making configurations (National Institute of Standards and Technology, 2023).

**Job Displacement and Workforce Development**

Short-run patterns suggest uplift for less-experienced workers in many tasks (compression toward the mean), but long-run impacts depend on reskilling and role evolution. Education evidence warns that unguided answer-giving harms learning, while structured AI tutors can accelerate it; applied to the workplace, teams should embed AI as guided scaffolds that accelerate mastery (e.g., code review suggestions with rationales, writing assistants that explain revisions) rather than replace learning loops. Organizations should invest in AI collaboration literacyencompassing skills inprompting, critique, verification, and escalationto ensure durable capability building (Kestin, G., et al. 2025).

**Governance and Regulation**

NIST AI Risk Management Framework (AI RMF 1.0) NIST7: Provides four core functions - GOVERN, MAP, MEASURE, MANAGEto embed risk management culture, frame system context, assess/monitor risks, and allocate treatment resources. It also clarifies human–AI interaction configurations and accountability structures to operationalize trustworthy AI in teams(National Institute of Standards and Technology, 2023).

EU AI Act (Regulation (EU) 2024/1689) EU AI Act8: In force since August 1, 2024, with full applicability by August 2026, the Act classifies systems by risk (prohibited, high-risk, limited, minimal),imposing obligations on high-risk systems: risk management, data governance, technical documentation, logging, transparency, human oversight, robustness, and post-market monitoring—directly relevant to AI modules embedded in team workflows (European Union, 2024). ISO/IEC 42001:2023 (AI Management Systems) ISO/IEC 420019: Specifies requirements for establishing, implementing, maintaining, and continually improving an AI Management System (AIMS) via PDCA cycles across organizations of any size, aligning policy, roles, training, risk assessment/treatment, monitoring, and continual improvement—operational scaffolding for sustained, auditable human–AI teaming (ISO/IEC, 2023).

**Future Research and Practice**

Task Decomposition and Routing: Systematically map work into subtasks and assign to humans or AI based on measured comparative advantage; study routing policies that adapt as model capabilities and human expertise evolve, and quantify team-level synergy under budgeted cost-of-error metrics (Vaccaro et al., 2024). Learning-Preserving Designs: Codify guardrails that force explanation, scaffolded hints, and reflective prompts to preserve human learning, preventing dependency while leveraging AI's formative feedback strengths; measure long-horizon skill acquisition and error-checking gains in teams.(Kestin, G., et al. 2025). Equity and Inclusion: Quantify how AI shifts performance distributions and career progression, especially for underrepresented groups; design mentorship-like AI supports with transparency and accountability to avoid stereotyping or differential calibration(Noy & Zhang, 2023). Robust Metrics and Reporting: Implement multi-dimensional evaluation (time, quality, cost, error criticality) and open reporting repositories for reproducibility and commensurability across team studies, in line with meta-analytic recommendations (Vaccaro et al., 2024).

## CONCLUSION

AI-augmented teaming is not a monolith; it is a design space. The most reliable gains occur on creation and content-heavy tasks that are inside the current frontier and can be decomposed with rapid feedback, where studies show 25%–55% speed improvements and ~18%–40% quality gains. Throughput gains of ~15%–40% materialize in structured support and clinical screening contexts, with especially large benefits for newer team members. However,

when tasks step outside the frontier, decision accuracy can fall sharply, and when AI is introduced without learning-preserving guardrails, human skill acquisition can be compromised. The path forward is a principled one: map tasks to capability, decompose and route subtasks, make uncertainty legible, codify escalation and oversight, and embed governance via NIST AI RMF, EU AI Act, and ISO/IEC 42001. In doing so, organizations can turn point gains into durable team capabilities—boosting efficiency and innovation while maintaining safety, fairness, and trust in the post-digital workplace.

## ABSTRACT

*Ditrichum palaniensis* is described here as a new species of moss from the Palani Hills in the Southern Western Ghats. The unique features of this species are the presence of leaves that are not folded inwards along the costa, margin recurved at middle, costa being percurrent to slightly ending below apex, perichaetial leaves being different from the vegetative leaves and peristome teeth being fimbriate-papillose, very narrow and high, 0.34 to 0.36 mm. A detailed description, a photographic plate and a map showing the location of the holotype are provided.

**Keywords:** Palani Hills, *Ditrichum pusillum*, mixed plantations, moss, road-side cut

## INTRODUCTION

*Ditrichum* Hampe is a genus of moss with 56 species world-wide. They are mostly distributed in the tropical and temperate regions of the World (Gangulee, 1971; Brinda and Atwood, 2023). In India, so far 12 species and 2 infra-specific taxa have been reported (Lal, 2005; Dandotiya and al., 2011). Of these, 3 species and one infra-specific taxon occur in the Western Ghats (Daniels, 2010). The present study on the bryoflora of the Palani Hills, initiated a couple of years ago, led to the discovery of a *Ditrichum* species which after a critical study was found to be a novelty. This discovery adds one more species to this genus. Hence, a description, a photographic plate and a location map are provided.

## MATERIALS AND METHODS

Investigations were carried out during and after the monsoon rains. Samples collected were studied under an Olympus SZ51 binocular stereomicroscope and photographs of relevant taxonomic features were taken using an Olympus BX43 compound research microscope. Identification was made based on monographs and recent publications as well as consulting overseas experts. Specimens were preserved following traditional methods and deposited at the herbarium of Scott Christian College (SCCN).

**Diagnosis**

*Ditrichum palaniensis* is closely related to *D. pusillum* (Hedw.) Hampe, but differs from the latter in possessing leaves that are not folded inwards along the costa, margin recurved at middle, costa being percurrent to slightly ending below apex, perichaetial leaves being different from the vegetative leaves and peristome teeth being fimbriate-papillose, very narrow and high, 0.34 to 0.36 mm when compared to that of *D. pusillum* which has a peristome teeth which is broader and c. 0.14 mm high. These features distinguish the former from all the known species of *Ditrichum* and hence, it is described here as new.

**Etymology**

Named after Palani Hills from where the specimen was collected.

**Taxonomic Treatment**

***Ditrichum palaniensis*** A.E.D. Daniels, D.T.T. Daniels and C.P. Ben, sp. nov. (Fig. 1)

**Holotype:** India, Western Ghats, Tamil Nadu, Dindigul District, Palani Hills, on the way to Pillar Rock, c. 2200 m, terricolous, on road-side cuts, in mixed plantations, 10°12'43.72"N and 77°27'54.01"E, 6 November, 2023, *A.E.D. Daniels* and *D.T.T. Daniels 224* (holotype: CAL; isotype: SCCN; paratype: SCCN)

Plants dioicous?, 3–7 mm tall, in loose mats, pale green. Stems simple or branched, 0.18–0.2 × 0.14–0.16 mm in cross section, with a central strand, but always disintegrated, brownish; cortex 1–3-layered; cells 5–10 × 4–10 µm, thick-walled; medullary cells 15–25 × 10–20 µm, thin-walled. Leaves erectopatent, flexuose when dry, 1.4–2.0 × 0.4–0.6 mm, triangular at base, entire, inrolled at middle, long-acuminate, faintly denticulate at apex; apical cells 10–30 × 8–12 µm, quadrate to rectangular; median cells 18–30 × 7–14 µm, rectangular, thick-walled; basal cells 30–50 × 12–25 µm, elongate-rectangular to subrectangular, thick-walled; costa percurrent to ending a little below apex. Sporophytes apical. Perichaetial leaves c. 2.7 × 0.27 mm, linear-oblong, entire, long-acuminate at apex. Setae 8–10 mm high, erect, slightly bent above middle. Capsules erect, cylindric, 2.3–2.5 × 0.35–0.45 mm. Operculum conic, 0.8–1.2 × 0.35–0.45 mm, not rostrate. Peristome teeth 1-rowed, 0.4–0.5 × 0.016–0.018 mm, dicranate, long and slender, highly fimbriate-papillose, yellowish-brown above, yellowish-brown to reddish-brown towards base. Annulus differentiated, 2-rowed; cells 25–40 × 15–20 µm. Spores 8–9 µm, globose, papillose, pale brown.

*Habitat*: Terricolous, on road-side cuts in mixed plantations, c. 2200 m.

**Distribution:** India: Western Ghats of Tamil Nadu (Dindigul).

**Specimens examined:** India, Western Ghats, Tamil Nadu, Dindigul District, Palani Hills, on the way to Pillar Rock, c. 2200 m, terricolous, on road-side cuts, in mixed plantations, 10°12'43.72"N and 77°27'54.01"E, 6 November, 2023, *A.E.D. Daniels* and *D.T.T. Daniels 224, 225* (SCCN). (Fig. 2)

**Ecological notes:** *Ditrichum palaniensis* was found growing as a terricolous form (on soil) in a mixed plantation at an elevation of c. 2200 m.

## DISCUSSION

Palani Hills happens to be one of the most explored areas in the Western Ghats for plants since the arrival of the Colonial Europeans in the late 18th and early 19th centuries. Robert Wight was the first to initiate explorations in September 1836 when he collected approximately 1500 species in 15 days. Subsequently, several others namely A.G. Bourne (1897–1898), P.F. Fyson (since 1904) and the Shenbaganur team explored the Palani Hills for angiosperms and pteridophytes. However, it was Eugène Armand-dit Georges Foreau who organized a team in 1908 for collecting nonflowering plants, especially mosses. The moss collections were named by Jules Cardot (1860 - 1934) and Robert André Leopold Potier de la Varde (1878–1961) of the Paris Museum, and Hugh Neville Dixon (1861–1944) of the Natural History Museum, London (Matthew, 1999). As many as 95 species and 15 varieties of this collection were described as new to science (Potier de la Varde 1922, 1923, 1924, 1925) and Dixon and Potier de la Varde (1927, 1930). These findings were synthesized by Foreau (1930, 1931, 1961, 1964). Subsequently, several Indian botanists started making explorations which were all sporadic. However, Alam and Srivastava (2009) published a checklist on the liverwort diversity of Palani Hills where they enumerated 75 species with 16 as new records for the region and, Alam and al. (2011) published a checklist of mosses of Palani Hills comprising 54 species of mosses with 12 as new to Palani Hills. Daniels (2010) published a comprehensive list of bryophytes of Tamil Nadu where he enumerated 360 species from Palani Hills. Like any other Hill Station on the Western Ghats, Palani Hills have also suffered severe deforestation due to introduction of exotic species for commercial and esthetic purposes by the Colonial Europeans which led to loss of habitats. On the other hand, laying of roads, construction of dams, bridges and buildings were other reasons for habitat destruction which are continuing unabated even today. Almost all sholas are today 'sholas' of concrete structures. Nevertheless, the relicts of the native vegetation are still potential habitats that harbour these elusive plants and so, the remaining native forests of Palani Hills which are in a highly fragmented condition need to be conserved for the sake of these elusive and delicate primitive plants. The occurrence of *Ditrichum palaniensis* in a mixed plantation of exotic species indicates the adaptability of the species as a result of 'struggle for existence'.

## ACKNOWLEDGEMENTS

The permission to explore the study area and the assistance provided in the field by the Tamil Nadu State Forest Department are gratefully acknowledged. The authors also thank the Principal, Scott Christian College, for facilities.

## ABSTRACT

The objective of the study was to develop the herbal gel utilizing *Leucas aspera* extract and to evaluate its efficacy in treating fungal infections. Ethanol was used to dry, grind and extract the plant *Leucas aspera* by using soxhlet apparatus. To create a smooth herbal gel the extract was combined with a gel base (carbopol) the gels colour consistency, spreadability, pH and texture were all evaluated. The agar diffusion method was used to assess its antifungal activity and see whether it could half the growth of fungi. The prepared gel had a homogeneous smooth appearance. It distributed readily on the skin and had a pH that was suitable for skin. The gel was thoroughly mixed with the extract the gel demonstrated an anti-fungal activity. This study presents a straight forward herbal gel derived from *Leucas aspera.* Since this plant is rarely used in gel form to treat fungal infections, the formulation is novel and beneficial. The *Leucas aspera* gel is simple to use, safe and effective. It can be used as a natural substitute for Pharmaceutical antifungal dosage form.

**Keywords:** *Leucas aspera*, anti-fungal activity, herbal formulation, pharmacological activity, phytochemical screening.

## INTRODUCTION

Fungal infections are some of the most prevalent and enduring dermatological conditions, affecting millions of people globally. In tropical countries like India, superficial fungal infections have become considerably more common due to variables including high humidity, perspiration, poor air circulation, and warm temperatures that accelerate fungal development. The potential pharmacological action of a plant can be predicted by identifying its phytoconstituents[1]. Common fungal agents such aspergillosis, candidiasis, and dermatophytosis (tinea infections) not only cause discomfort but, if managed, can lead to recurrent and chronic infections. Therefore, the development of herbal-based antifungal formulations that offer enhanced safety, biocompatibility, and affordability is becoming more and more popular. According to phytochemical research, *Leucas aspera* strong anti-fungal properties are attributed to a variety of bioactive substances, including flavonoids, terpenoids, tannins, phenolic compounds, and essential oils. *Leucas aspera* is a good natural candidate for topical antifungal medication because research indicates that extracts of the plant have inhibitory action against fungus like *Candida albicans, Aspergillus niger, and Trichophyton rubrum.* The current project aims to develop the herbal anti-fungal gel of *Leucas aspera* using a polymeric gelling agent such as Carbopol 934 and evaluate the gel for various physicochemical and biological characteristics[2]. Drug release is prolonged by carbopol. After extracting the entire plant or leaves and creating a gel with ideal concentrations, properties such as appearance, pH, viscosity, extrudability, spreadability, drug content, stability and *in-vitro* anti-fungal efficacy against certain fungal strains are evaluated. The formulation of Leucas aspera gel has the potential to significantly advance the field of herbal pharmaceutical development by offering an effective natural remedy for fungal skin diseases with fewer adverse effects and more patient acceptability. This study further supports the global trend of incorporating traditional medicinal plants into modern pharmaceutical compositions.

## METHODOLOGY

**Collection and Authentication**

*Leucas aspera* was collected from the side of cultivated land of ethappattu village at melmalaiyanur in villupuram district of Tamilnadu and the plant was authentified by respected Dr.Ayappan.M, Msc,M.Phil.,Ph.D., Assistant professor, Government arts college, Tiruvannamalai.

**Preparation of extract**

The fresh leaves were collected the leaf was shadow dried for upto 7days. The dried leaves are powdered mechanically. Powdered leaves were extracted using ethanol at $50^0$ C on a Soxhlet extractor for 6hrs. The extract was filtered and concentrated under reduced pressure in hot air oven at 40-45°C the resulting crude extract was stored under 4°C. Phytochemical study was carried out on the ethanol extract of *Leucas aspera.* Plant Extraction by Soxhlet Apparatus (Fig 1).

**Phytochemical Screening**

The protocol for phytochemical screening and prospection, investigating the presence of alkaloids, flavonoids, terpenoids, tannins, carbohydrates, phenols, and cardiac glycosides. The qualitative analysis was based on precipitation reactions and the formation of colour. Generally, alkaloids are valued for their therapeutic effect like antifungal, anticancer, antibacterial, antiasthma properties.

**Alkaloids**

**Test for Alkaloids (Table 1).**

**Flavanoids**

**Test for flavonoids (Table 2).**

**Terpenoids**
Test for Terpenoids (Table 3).

**Tannins**
Test for Tanins (Table 4).

**Carbohydrates**
Test for Carbohydrate (Table 5).

**Cardiac Glycosides**
Test for Glycosides (Table 6).

**Phenol**
Test for Phenol (Table 7).
Formulation of Gel (Table 8).

**Preparation of Gel**
A weighed amount of carbopol dispersed in 50ml of distilled water with gentle stirring to avoid clumping. After 1hour, stir the carbopol dispersion continuously for 30mins to obtain a homogenous mixture. In 5ml of distilled water, 0.2g of methyl paraben and 5ml of propylene glycol dissolved by heating on water bath. After cooling, 5ml of herbal extract and 3ml of glycerine was mixed. Then the above mixture is mixed properly to the carbopol dispersion with continuous stirring. Triethanolamine added drop wise to the formulation to adjust the $p^H$(4.5 to 7) and to obtain the desired consistency. Finally, 1ml of rose oil was added to the formulation, then store the prepared gel in air tight container.

Preparation of Gel (fig: 2).
Five Formulations (Fig: 3)

**Evaluation of Gel**
**Colour**
One gram of the gel was taken and put on a clean glass slide in order to see its color. The gel was then observed visually for its colour against a white background under natural day light. After that, the gel's color was noted.

**Odour**
0.5 g of the gel was taken in a clean container, and under typical room conditions, the air above the sample was softly breathed to determine the gel's odor. The smell that was detected was classified as either unpleasant, odorless, pleasant or distinctive.

**Spreadability**
1.0gm of sample of each formulation was pressed between two slides (of 20x20cm) and left for about 5 minutes where no more spreading was expected. Diameter of spreaded circles were measures and taken as comparative values for spreadability.

**pH**
pH of the gel formulation was determined using a calibrated pH meter. The electrode was immersed directly in to the gel, and the reading was allowed to stabilize and pH value was recorded.

**Homogeneity**
Homogeneity of the prepared gel were evaluated by visual perception.

**Extrudability**
A closed collapsible tube containing about 20g of gel was pressed firmly at the crimped end and a clamp was applied to prevent any roll back. The cap was removed and the gel was extruded. The amount of extruded gel was collected and weighed. The percentage of the extruded gel was observed.

**Viscosity**
Viscosity of the different gel formulation was determined at $25^0$C using rotational brook field viscometer of with spindle CPE-41.

**Anti-fungal activity**
The antifungal activity was tested by well diffusion method. The potato dextrose agar plates were inoculated with each fungal culture (10 days old) by point inoculation. The filter paper wells (5 mm in diameter) impregnated with 100µg concentrations of the synthesized silver nanoparticles were placed on test organism-seeded plates. Fluconazole (10µg well 1) used as positive control. The activity was determined after 72 hrs of incubation at 28°C. The diameters of the inhibition zones were measured in mm.

***In-vitro* Drug release**
*In vitro* drug study using egg membrane involves isolating the inner membrane was washing and hydrating it in phosphate buffer (pH 6.8 to 7.4). The membrane is placed between donor and receptor compartments of a franz diffusion cell with receptor containing at $37^o$C and stirr continuously with the rpm 100 to 300 rpm using a magnetic stir beat uniform drug distribution. The test formulation is placed in the donor compartment, and samples are withdrawn from the receptor at regular intervals (6 hrs in 30 mins) and analyzed by using spectro photo meter at 273 nm. Phosphate Buffer used as a blank.

## RESULTS AND DISCUSSION

**Colour (Table 9)**
Formulation 3(f3) and formulation 5(f5) has dark olive green while formulation f1 as yellowish green,
Formulation2 (f2) as olive brown and formulation4 (f4) as greenish brown

**Odour (Table 10)**
Fomulation 1(1), formulation 3(3), formulation (4) has pleasant odour while fomulation 2(2) and formulation5 (5) has slightly pleasant.

**Spreadability (Table 11)**
Formulation1(1), formulation 2(2) has 4.7cm range while formulation 4(4) has 4.1cm, formulation 5(5) has 4.4cm and formulation 3(3) has 5.1cm.

**pH (Table 12)**
The formulation5(5) has 6.4 is closets to the skin pH while formulation 1(1) has 5.9, formulation 3(3) has6 and formulation 2(2), formulation 4(4) has 6.1.

**Homogenicity (Table 13)**
**Extrudability (Table 14)**

**Viscosity(Table 15)**
**Anti-fungalactivity(Table 16)**
***In-Vitro* drug release study(Table 17)**
***In-Vitro* drug release (Fig 4)**

## CONCLUSION

The current study has focused on developing and evaluating *Leucas aspera* herbal gel for the treatment of fungal infections. The physical and pharmacological properties of several formulations were produced and examined. The produced formulations (F4) demonstrated a favorable physical appearance, smooth texture, acceptable color, distinctive smell, and high homogeneity without phase separation. The gel can be used topically without causing irritation because its pH was confirmed to be within the acceptable skin range. The revised formulation's adequate viscosity made it easy to apply and had good its spreadability. The antifungal activity tests showed that the formulation considerably suppressed fungal strains, indicating the presence of potent antifungal components in *Leucas aspera.* Effective diffusion of active substances from the gel base was demonstrated by the *in-vitro* drug release investigation, which showed a good and regulated drug release pattern. The enhanced batch outperformed the other formulations in terms of in-vitro drug release profile, antifungal activity, and physical stability. Therefore, the formulated (F4) *Leucas aspera* gel seems to be a safe, effective, and promising herbal topical therapy for the treatment of fungal infections..

## ABSTRACT

Agricultural productivity is increasingly affected by climate variability, irregular weather patterns, and the rising frequency of pest outbreaks. Existing crop yield prediction systems primarily focus on point estimation and lack the capability to generate adaptive agronomic advisories under uncertain environmental conditions. This paper presents ACAS-FLY, an adaptive crop advisory system that integrates fuzzy-driven scenario modeling with LSTM-based yield forecasting to support climate-aware agricultural decision making. The proposed framework combines stochastic scenario generation using bootstrapped sampling and Bayesian modeling to capture rainfall variation, temperature deviation, and pest outbreak probability. An ensemble of deep learning models including stacked LSTM, bidirectional LSTM, and CNN-LSTM architectures is employed to enhance yield prediction robustness across diverse regions, while uncertainty estimation is incorporated through Monte Carlo dropout. Predicted yield trends and environmental risk indicators are further processed by a fuzzy logic-based advisory engine to produce interpretable and actionable agronomic recommendations. The system is evaluated using multi-source datasets comprising historical rainfall records, global weather observations, pest imagery, and crop recommendation data. Experimental results demonstrate that ACAS-FLY consistently outperforms existing deep learning and automated machine learning approaches in terms of accuracy, sensitivity, specificity,

and F-score. The findings confirm the effectiveness of integrating scenario modeling, ensemble learning, and fuzzy reasoning for adaptive crop advisory under climate uncertainty.

**Keywords:** Adaptive advisory systems, Bayesian scenario modeling, Crop yield forecasting, Ensemble LSTM, Fuzzy logic, Monte Carlo dropout, Pest risk prediction, Stochastic climate simulation, Time series prediction, Uncertainty quantification

## INTRODUCTION

The rapid growth of the global population continues to place immense pressure on the agricultural sector to ensure food security. Simultaneously, climate change has introduced significant variability into weather systems, resulting in erratic rainfall patterns, rising temperatures, and increased frequency of extreme weather events. These changes are disrupting traditional farming cycles and increasing the unpredictability of crop yields across regions [1]. For developing economies, where agriculture remains a primary livelihood, the combined effect of population growth and climate instability threatens both economic sustainability and food availability. Modern agriculture faces a multitude of challenges driven by this environmental uncertainty [2]. In addition to climate-induced disruptions, farmers must also contend with soil degradation, pest and disease outbreaks, limited access to timely information, and fluctuating input costs [3]. Conventional advisory mechanisms, often static and generalized, fail to adapt to local, real-time conditions [4]. The absence of dynamic, region-specific, and data-driven recommendations leads to sub-optimal decisions in crop selection, irrigation planning, and pest management, particularly for small and marginal farmers. In recent years, machine learning (ML) techniques have shown strong potential in modeling agricultural parameters and predicting crop yields [5]. Among these, deep learning models such as Long Short-Term Memory (LSTM) networks have demonstrated effectiveness in capturing temporal dependencies within multivariate time series data related to weather, soil, and historical crop performance [6]. However, many existing approaches emphasize yield prediction alone, without extending insights into actionable guidance. Moreover, they often lack mechanisms to address uncertainty in future environmental conditions, limiting their real-world usability [7]. A predictive system intended for deployment in uncertain agricultural environments requires an additional reasoning layer that can transform numerical forecasts into actionable and interpretable guidance. The effectiveness of such systems increases significantly when predictive outputs are combined with contextual domain knowledge, including anticipated rainfall intensity, pest infestation likelihood, and region-specific cultivation practices [8]. In this context, an advisory engine becomes a necessary component rather than an optional extension. Fuzzy logic is particularly well suited for this role, as it enables the representation of expert knowledge and accommodates the inherent ambiguity and precision vagueness present in agricultural decision scenarios. Consequently, an integrated architectural framework is required that not only performs reliable yield forecasting under dynamic conditions but also delivers adaptive, human-understandable agronomic advisories that support informed decision-making at the field level.

**Existing Methods**

The following existing studies have been reviewed to understand current methodologies, applications, and limitations in the domain of crop yield prediction and advisory systems. The paper titled "Crop yield prediction using effective deep learning and dimensionality reduction approaches for Indian regional crops" [9] provides insights into regional crop modeling using modern deep learning frameworks. The work "Developing automated machine learning approach for fast and robust crop yield prediction using a fusion of remote sensing, soil, and weather dataset" [10] highlights the role of automated learning systems in integrating multimodal agricultural data. The study "From data to harvest: Leveraging ensemble machine learning for enhanced crop yield predictions across Canada amidst climate change" [11] explores the use of ensemble methods in handling climate-related variability. Additionally, the paper "Incorporating meteorological data and pesticide information to forecast crop yields using machine learning" [12] examines the impact of external input factors such as weather and pesticide use on yield

forecasting. These studies have been used to examine the current landscape and identify gaps that motivate the design of the proposed ACAS-FLY framework.

**Crop yield prediction using effective deep learning and dimensionality reduction approaches for Indian regional crops (CYPEDL)**

Leelavathi Kandasamy Subramaniam *et al*. in 2024 proposed a deep learning-based model titled Crop yield prediction using effective deep learning and dimensionality reduction approaches for Indian regional crops. The work is designed to improve crop yield prediction accuracy by leveraging deep learning and dimensionality reduction techniques specifically adapted for regional agricultural datasets from South India. The purpose of the study is to address the challenges of high-dimensional input data and optimize the learning structure for better forecasting of crop productivity under diverse climatic and soil conditions. The methodology involves three primary stages comprising data preprocessing, dimensionality reduction, and classification. Agricultural data are cleaned and normalized to remove noise and scale the features. A squared exponential kernel-based principal component analysis is applied to reduce dimensionality and handle non-linear relationships in the data. A deep convolutional neural network is used for prediction, with its weights and biases optimized using an enhanced whale optimization algorithm. This optimization process incorporates chaotic map initialization and adaptive search mechanisms to improve network performance. The architecture includes convolutional layers, pooling layers, activation layers, and a fully connected output stage. The proposed CYPEDL model demonstrates notable improvements in yield prediction accuracy and robustness. It effectively addresses the issues of overfitting and computational inefficiency commonly observed in traditional machine learning models. However, the model's reliance on tailored optimization strategies and deep architectures may limit its portability across different regions or datasets without significant reconfiguration.

**Developing automated machine learning approach for fast and robust crop yield prediction using a fusion of remote sensing, soil, and weather dataset (AMLACYP)**

Ahmed M S Kheir *et al*. in 2024 developed a fully automated machine learning approach aimed at predicting crop yield by integrating diverse environmental datasets including remote sensing indices, soil properties, weather variables, and topography. The core objective of the study was to create a robust and scalable yield prediction framework specifically for wheat production across Egypt, addressing the limitations of traditional modeling approaches and enabling rapid, low-cost predictions even under climate uncertainty. The methodology leverages H2O AutoML to automate the end-to-end machine learning workflow. Data from over 2500 wheat fields were collected and preprocessed, including variables such as NDVI, EVI, GCVI, soil texture, bulk density, temperature, rainfall, elevation, and slope. These were used to train 20 base models along with two stacked ensemble learners. The AutoML system integrated satellite-based vegetative indices with weather reanalysis and gridded soil data to train models using random forest, gradient boosting machines, deep neural networks, and generalized linear models. The model training and validation were executed within the H2O AutoML platform using random splits and hyperparameter search techniques, enabling selection of the most accurate ensemble predictor. The AMLACYP framework demonstrates its utility in handling heterogeneous and large-scale agricultural datasets with minimal manual intervention. It achieves spatial yield forecasting using only remote sensing inputs, making it suitable for regions with limited field data. Moreover, the trained models were extended to simulate yield under future climate change scenarios using downscaled GCM outputs. However, the system's performance could be impacted by variations in land fragmentation, sensor noise, and farmer-level management heterogeneity. The authors note that further generalization across crops and geographies would require model adaptation or transfer learning strategies.

**From data to harvest: Leveraging ensemble machine learning for enhanced crop yield predictions across Canada amidst climate change (EMLECYP)**

Navid Mahdizadeh Gharakhanlou *et al*. in 2024 presented a nationwide-scale study titled “From data to harvest: Leveraging ensemble machine learning for enhanced crop yield predictions across Canada amidst climate change”. The primary objective of this work was to assess the effectiveness of ensemble machine learning models in predicting crop yields—specifically for canola and soybeans—by integrating climate variables, vegetation indices, soil traits, and

honeybee census data. The research focused on building a climate-resilient yield prediction system that supports decision-making at the regional scale through geospatial forecasting under various climate scenarios. The methodology involved training and evaluating five ensemble models, including Adaptive Boosting, Gradient Boosting Machine, XGBoost, LightGBM, and Random Forest. The input data included spatially interpolated climate parameters, MODIS vegetation indices (NDVI and EVI), detailed soil composition, and honeybee colony statistics at the census subdivision level. Variables with multicollinearity were excluded using variance inflation factor analysis, and model training was performed using a 70:30 data split with 10-fold cross-validation and hyperparameter tuning. Once trained, models were tested for generalization on climate projections for the year 2026 under three Representative Concentration Pathway scenarios. Crop yield maps were generated for each model, and feature importance was assessed using XGBoost's gain-based analysis. The EMLECYP framework demonstrated that ensemble models—especially those based on boosting—performed better in capturing spatial and climatic variations in crop yield across Canada. Honeybee colony presence emerged as the most influential factor, followed by soil properties and precipitation. The model provided high-resolution yield forecasts and climate impact assessments at the Census Consolidated Subdivision level, making it useful for policymakers and agronomists. However, the system was constrained by data availability, especially in soil profiles and honeybee census frequency, and may require adaptation for other crops, geographies, or shorter-term predictions.

**Incorporating meteorological data and pesticide information to forecast crop yields using machine learning (MDPIML)**

Hoque *et al*. in 2024 proposed a machine learning-based framework titled Incorporating meteorological data and pesticide information to forecast crop yields using machine learning. The aim of this work was to develop a yield prediction system that integrates weather conditions, pesticide usage, and crop data to model agricultural productivity in India. This study recognizes the critical impact of environmental and chemical variables on food security and proposes a data-driven solution to improve resilience under climate change conditions. The proposed system is built upon a pipeline that includes data extraction, transformation, cleaning, feature engineering, and model training using three machine learning algorithms. Specifically, the study uses multivariate logistic regression, k-nearest neighbors, and gradient boosting regressors to forecast yields of six key crops—rice, wheat, potatoes, soybeans, sweet potatoes, and sorghum. The dataset was sourced from publicly available repositories and includes annual rainfall, average temperature, pesticide application rates, and historical yield data. Data preprocessing steps include duplicate and null value elimination, outlier detection via interquartile range filtering, and standardization using column transformers. Model optimization was performed using k-fold cross-validation and GridSearchCV to fine-tune hyperparameters for each model. The MDPIML system effectively demonstrates the ability of machine learning to generalize across multiple crops and regions with a unified predictive structure. It highlights the importance of including pesticide and meteorological variables for better accuracy and insights. However, the study also notes constraints such as the absence of detailed agronomic features like soil moisture and solar radiation, which may limit its precision. The framework lays the groundwork for future integration with IoT-based environmental sensing systems to enhance decision-making in agricultural forecasting. A comparative summary of the reviewed methods is presented in Table 1, highlighting the authors, titles, methodologies, advantages, and limitations of each approach.

**Problem Statement:** Accurate crop yield prediction is challenged by uncertain climate conditions, pest outbreaks, and region-specific variability. Existing models often focus solely on prediction without providing actionable insights, limiting their use in real-world decision-making. There is a pressing need for an integrated system that not only forecasts yield under dynamic conditions but also generates adaptive, interpretable advisories to support farmers in making timely and informed agronomic decisions.

## Research Gap

While recent advances in machine learning have improved crop yield prediction using remote sensing and weather data, most existing models operate as static predictors with limited adaptability to real-time environmental fluctuations. They rarely address predictive uncertainty or translate outputs into farmer-friendly recommendations. Additionally, current systems often lack integration between scenario simulation, temporal forecasting, and decision reasoning, making them inadequate for dynamic, region-specific advisory generation. This highlights the gap for a unified framework that combines stochastic scenario modeling, deep learning-based yield forecasting, and fuzzy logic-driven advisory to enable adaptive, interpretable agricultural support.

## Research Objectives

- To develop a risk-aware scenario generation module that simulates multiple future environmental conditions using stochastic modeling of climate variables and pest outbreak probabilities.
- To design an ensemble-based LSTM forecasting engine that improves crop yield prediction accuracy and robustness across regions while incorporating uncertainty estimation.
- To implement a fuzzy logic-based advisory system that translates predicted yield and environmental scenarios into adaptive, human-interpretable agronomic recommendations.
- To evaluate the proposed ACAS-FLY framework using multi-source agricultural datasets and assess its performance using classification metrics such as accuracy, sensitivity, specificity, and F-score.
- To compare the effectiveness of ACAS-FLY with existing machine learning-based yield prediction models in terms of prediction accuracy and advisory relevance under uncertain conditions.

## BACKGROUND

Designing an adaptive crop advisory system requires a multidisciplinary foundation that spans agricultural science, climate modeling, and machine learning. To support the development of the proposed ACAS-FLY framework, this section outlines key background concepts relevant to its design. First, the fundamentals of crop yield prediction are discussed, highlighting the critical factors that influence agricultural output and the need for data-driven approaches. Next, the role of climate variability and the importance of scenario modeling in capturing future uncertainties are examined. Finally, the structure and applicability of recurrent neural networks, particularly Long Short-Term Memory (LSTM) networks, are introduced as essential tools for time-series yield forecasting.

**Crop Yield prediction fundamentals**

Effective crop yield prediction needs a clear understanding about how various biophysical and agronomic parameters interact over time. Yield is not solely influenced by isolated variables but by their cumulative impact across the growing season [13]. For instance, a rainfall anomaly during the germination phase may affect yield differently than the same anomaly during flowering. These phase-sensitive dependencies demand predictive systems that can capture both short-term fluctuations and long-term growth patterns. Most recent approaches increasingly depend on integrating multi-source datasets to capture spatial and temporal variability. Remote sensing data, such as vegetation indices from satellite imagery, can reveal crop health trends over large areas, while ground-based measurements like soil nutrient profiles and pesticide applications provide localized insights [14]. Combining such diverse sources enables a more holistic view of yield formation mechanisms. In addition, yield prediction must count for inherent uncertainties in future conditions. Static models trained on historical data alone often fail when applied to new environmental scenarios [15]. Hence, prediction systems should not only learn from patterns in past data but also be adaptable to changing conditions and capable of expressing confidence in their outputs. This sets the stage for the use of time-series models and uncertainty-aware learning techniques, discussed in the subsequent sections.

**Climate Variability and Scenario Modelling**

Climate variability is a significant driver of uncertainty in agricultural systems, affecting the timing, quantity, and quality of crop yields. Irregular rainfall patterns, temperature extremes, delayed monsoons, and unseasonal heatwaves can disrupt crop phenology and lead to substantial yield losses [16]. These effects are further amplified by the increasing unpredictability of climate behavior due to global warming, making static forecasting approaches insufficient for long-term planning and real-time advisory. To address this, scenario modeling has emerged as a technique for generating multiple plausible representations of future conditions. Rather than relying on a single forecast, scenario-based models simulate a range of environmental possibilities such as varying rainfall intensities, temperature deviations, or pest outbreak likelihoods [17]. These simulations help quantify risk and allow agricultural systems to prepare for best-case, worst-case, and most-likely outcomes. Techniques such as Monte Carlo simulation, Bayesian inference, and bootstrapped time series sampling are commonly employed to create stochastic environmental scenarios. These methods introduce variability into input parameters and generate synthetic datasets that reflect potential future conditions. In the context of crop yield prediction, scenario modeling supports risk-aware forecasting and enhances decision-making by allowing the advisory system to evaluate outcomes under diverse environmental pathways.

**Recurrent Neural Networks and LSTM**

Recurrent Neural Networks (RNNs) are a class of artificial neural networks designed for processing sequential data, where each output depends not only on the current input but also on the previous context. This makes RNNs particularly effective for time-series modeling tasks such as crop growth monitoring, weather forecasting, and seasonal yield analysis. By maintaining a hidden state that evolves over time, RNNs are capable of capturing temporal patterns within multivariate agricultural data. Despite their usefulness, traditional RNNs face challenges in learning long-term dependencies due to vanishing or exploding gradients during backpropagation. To address this issue, Long Short-Term Memory (LSTM) networks introduce a gated cell architecture with input, output, and forget gates that control the flow of information across time steps. This mechanism enables LSTM models to retain important signals over longer sequences without degradation in learning performance. LSTM networks have been widely adopted in agricultural forecasting due to their ability to learn complex temporal relationships from weather variables, crop phenology data, and historical yield records. Advanced variants such as stacked LSTM, bidirectional LSTM, and CNN-LSTM combinations further improve prediction by allowing deeper sequence representation and spatial feature integration [18]. These characteristics make LSTM an essential component in the forecasting engine of the ACAS-FLY system.

## PROPOSED METHOD

The ACAS-FLY framework is structured into three integrated modules that collectively support adaptive crop advisory generation. These modules are: the Risk-Aware Scenario Generator (RASG), the LSTM Ensemble Forecasting Engine (LEFE), and the Fuzzy Logic-based Advisory Engine (FLAE). Each module addresses a specific stage in the prediction-to-advisory pipeline and is detailed in the following subsections.

**Risk-Aware Scenario Generator (RASG)**

The Risk-Aware Scenario Generator (RASG) forms the first stage of the ACAS-FLY framework and is designed to simulate diverse future environmental conditions by introducing probabilistic variations into critical agricultural parameters. This approach allows the system to generate multiple plausible realizations of climate and pest-related inputs, enabling downstream modules to account for uncertainties in forecasting and decision-making. Let Daily Rainfall $R_t$, Average Temperature $T_t$, Pest Outbreak Probability $P_t$, Humidity $H_t$, and Crop-Pest susceptibility index $C_t$ be the environment variables of typical scenario generation. These variables are treated as stochastic processes with known or estimated probability distributions derived from historical observations. The Daily Rainfall $R_t$ is modeled as in Equation 1.

$$R_t \sim \Gamma(\alpha, \beta) \quad \text{Equation (1)}$$

where $\alpha$ and $\beta$ represent the shape and scale parameters of the Gamma distribution, estimated from historical data. Temperature $T_t$ is modeled using normal distribution as in equation 2.

$T_t \sim \aleph(\mu T, \sigma_T^2)$ Equation (2)

Similarly, Pest Outbreak is modeled using time-dependent Bernoulli process as in the following equation.

$P_t \sim Berunoulli(p_t)$ with $p_t = f(T_t, H_t, C_t)$ Equation (3)

Using these equations, RASG module generates $N$ stochastic scenario sequences $\{S_1, S_2, \ldots S_N\}$ in which each $S_i$ is a time series vector of sampled environmental variables as in equation 4.

$S_i = \left\{\left(R_t^{(i)}, T_t^{(i)}, P_t^{(i)}\right) | t = 1,2, \ldots \tau\right\}$ Equation (4)

These sequences are generated through two primary stochastic approaches. The first is bootstrapped time series sampling, which involves non-parametric resampling from historical environmental datasets. This method is used to preserve or ignore temporal ordering based on the design objective and supports diversity in generated inputs. The second approach is Bayesian resampling, in which samples are drawn from posterior predictive distributions to incorporate parameter uncertainty. Variational inference is employed to approximate these distributions based on prior knowledge and observed historical data.

The validation process of the scenario is performed based on domain constrains as in following equation.

$Validity(S_i) = \{1\ if R_t^{(i)} \in [R_{min}, R_{max}], T_t^{(i)} \in [T_{min}, T_{max}]\ 0\ otherwise$

Equation (5)

The output of RASG is a scenario ensemble $S = \{S_1, S_2, \ldots S_N\}$ where each $S_i$ represents a different possible trajectory of environmental variables over the growing season. This ensemble is used by the forecasting engine to generate yield distributions and inform risk-sensitive advisory generation. RASG module flowchart is provided in Figure 1. RASG Flow diagram (Figure 1).

**LSTM Ensemble Forecasting Engine (LEFE)**

The LSTM Ensemble Forecasting Engine (LEFE) is responsible for generating yield predictions under the environmental scenarios produced by the RASG module. It is designed to capture complex temporal dependencies and nonlinear interactions in agricultural time-series data, including rainfall trends, temperature cycles, and pest progression across different growth phases. LEFE improves forecasting accuracy and generalization by employing an ensemble of LSTM variants, each specialized in learning different feature hierarchies and temporal characteristics. Each input scenario $S_i = \left\{\left(R_t^{(i)}, T_t^{(i)}, P_t^{(i)}\right)\right\}_{t=1}^{\tau}$ are normalized into a feature matrix X as in equation 6.

$X \in R^{e^{(d)} + log\,(\tau)}$ Equation (6)

where $d$ represents the number of input features per time step, such as rainfall, temperature, and pest index, and $\tau$ denotes the number of time steps, in specific weeks in a growing season,

In LEFE module, the standard LSTM model is improved to be context specific by adding scenario-conditioned variables as one of the novelty contributions of this research work. To incorporate context-awareness into the forecasting process, two additional elements are introduced into the standard LSTM cell. The first is a scenario embedding vectors, which encodes the environmental scenario index generated by the RASG module. This vector captures the broader agro-climatic context, such as low rainfall conditions, high pest probability, or temperature anomalies, and remains fixed for a given scenario sequence. The second element is a yield-relevance vector $\phi_t$, which is computed dynamically at each time step based on agro-contextual variables including rainfall deviation $\Delta R_t$, pest severity $P_t$, and crop stress indicators $\delta_t$. By integrating $s$ and $\phi_t$ into the LSTM gating mechanisms listed below from Equation 7 to 12, the model becomes scenario-aware and sensitive to the varying importance of environmental features over time, improving its capacity to forecast yield under uncertain and evolving field conditions.

$f_t = \sigma(W_f \cdot [h_{t-1}, x_t, s, \phi_t] + b_f)$ Equation (7)

$i_t = \sigma(W_i \cdot [h_{t-1}, x_t, s, \phi_t] + b_i)$ Equation (8)

$\tilde{C}_t = tanh(W_C \cdot [h_{t-1}, x_t, s, \phi_t] + b_C)$ Equation (9)

$C_t = f_t \odot C_{t-1} + i_t \odot \tilde{C}_t$ Equation (10)

$o_t = \sigma(W_o \cdot [h_{t-1}, x_t, s, \phi_t] + b_o)$ Equation (11)

$h_t = o_t \odot tanh\,(C_t)$ Equation (12)

The rainfall deviation $\Delta R_t$ is computed by equation 13.

$\Delta R_t = \{\frac{R_t^2 - \underline{R}^2}{R_t + \underline{R}}\ if\ R_t \neq \underline{R}\ 0\ otherwise$ Equation (13)

Let $z_t$ become the intermediate input feature vector that records key agro-environmental indicators at timestamp $t$. $z_t$ is computed using the following equation.

$z_t = [\Delta R_t, P_t, \delta_t]$ Equation (14)

Here, the yield-relevance vector $\phi_t$ is calculated using equation 15.

$\phi_t = tanh\ tanh\left(2 \times \left(W_\phi \cdot z_t + \left(\frac{b_\phi - W_\phi \cdot z_t}{2}\right)\right)\right)$ Equation (15)

A key innovation in the proposed forecasting engine is the integration of both static and dynamic environmental context directly into the LSTM cell. The model introduces a scenario representation that allows internal memory updates to be conditioned on the specific environmental profile being evaluated, such as low rainfall or high pest pressure. In addition, a dynamic relevance vector is computed at each time step to modulate the influence of input signals like rainfall deviation or crop stress indicators based on their agronomic importance. This dual-context integration enables the forecasting process to adapt more effectively across different crop stages and regional conditions, enhancing both predictive accuracy and interpretability under uncertain environmental scenarios. While the proposed LSTM cell incorporates scenario and yield-relevance conditioning to enhance prediction quality, agricultural forecasting is inherently noisy and non-stationary due to spatial and temporal variability. A single model, no matter how carefully designed, may struggle to generalize across diverse cropping zones, phenological stages, or extreme weather scenarios. LEFE integrates the predictive outputs of three complementary LSTM-based architectures to achieve robust yield estimation. A stacked LSTM is employed to capture deep temporal patterns over long sequential windows, enabling the model to learn complex seasonal and growth-stage dynamics. A bidirectional LSTM is incorporated to account for both forward and backward temporal dependencies, thereby improving sensitivity to past trends as well as future context within the sequence. In addition, a CNN–LSTM architecture applies one-dimensional convolution layers to extract localized spatial or short-range temporal features prior to sequential modeling. The individual predictions generated by these three variants are denoted as $\hat{Y}_1, \hat{Y}_2$, and $\hat{Y}_3$, and the final yield prediction is computed by aggregating these outputs through a weighted averaging mechanism. The final prediction $\hat{Y}$ is achieved as follows.

$\hat{Y} = \sum_{i=1}^{n_p} w_j \hat{y}_j$ Equation (16)

where Weights $w_j$ are empirically tuned based on validation performance, and $n_p$ is the total number of prediction models in the ensemble, which is 3 in this case.

Prediction uncertainty is addressed by incorporating Monte Carlo dropout within the ensemble, in which dropout layers remain active during the inference phase to produce multiple stochastic output $\{\hat{Y}_1, \hat{Y}_2, \ldots \hat{Y}_{n_t}\}$. These repeated forward passes make it possible to approximate uncertainty in the predictions model. The resulting set of outputs is then used to compute the predictive mean and standard deviation, providing both an expected yield estimate and a quantitative measure of prediction variability. Let $n_t$ be then number of timestamps taken as the sample, equations 17 and 18 are used to calculate the predictive mean and standard deviation.

$\mu_{\hat{y}} = \frac{1}{n_p} \sum_{i=1}^{n_t} \hat{y}_i$ Equation (17)

$\sigma_{\hat{y}} = \sqrt{\frac{1}{n_p} \sum_{i=1}^{n_t} \left(\hat{y}_i - \mu_{\hat{y}}\right)^2}$ Equation (18)

This process generates a point estimate of the predicted yield along with a confidence interval that quantifies forecast uncertainty. The ability to represent prediction spread enhances transparency and supports risk-aware interpretation.

This uncertainty modeling is a key innovation in the proposed system, enabling the advisory engine to deliver recommendations that account for prediction confidence rather than relying solely on deterministic outputs.

**Fuzzy Logic-based Advisory Engine (FLAE)**

The Fuzzy Logic-based Advisory Engine (FLAE) provides a rule-based reasoning layer that translates quantitative forecasts and environmental indicators into qualitative agronomic advisories. It bridges the gap between data-driven prediction and farmer-level decision-making by modeling expert knowledge under uncertainty. FLAE is particularly effective in handling imprecise, overlapping, or linguistically defined input conditions that are common in agricultural environments. The inputs to the FLAE are obtained by consolidating the outputs of preceding modules along with key environmental indicators. These inputs include the mean yield predicted by the LSTM ensemble in LEFE, denoted as $\mu_{\hat{y}}$, which represents the expected production level, and the standard deviation of the predicted yield, denoted as $\sigma_{\hat{y}}$, which captures forecast uncertainty. Rainfall at the current time step, represented as $R_t$, is incorporated from the selected RASG scenario to reflect moisture availability, while the pest probability at the same time step, denoted as $P_t$, represents the likelihood of biotic stress conditions derived from the same scenario. In addition, a temperature-derived crop stress index, denoted as $\text{Stress}_t$, is included and computed using deviation-based thresholds to indicate the severity of thermal stress experienced by the crop. Collectively, these variables form a comprehensive and context-aware input set for adaptive advisory generation within FLAE.

**The first fuzzy input variable rainfall $R_t$ is** derived from the "Rainfall in India" dataset which is available on Kaggle repository. The observed values range from approximately 0 mm to 700 mm per month, which translates to about 0–175 mm per week during the peak monsoon season. For the purpose of fuzzy rule generation, rainfall is categorized into three linguistic sets: Low Rainfall (0–40 mm), Moderate Rainfall (30–100 mm), and High Rainfall (90–175 mm). Triangular or trapezoidal membership functions are used to allow smooth overlap between these categories.

**The second input is the pest probability $P_t$,** extracted from pest classifier outputs applied to the "Plant Disease Dataset" on Kaggle. The classifier produces a probability score between 0 and 1 for each time step. These values are fuzzified into three sets: Low Pest Risk (0.0–0.3), Medium Pest Risk (0.2–0.6), and High Pest Risk (0.5–1.0). These ranges account for overlap and uncertainty in classification confidence levels.

**The third input is the temperature-based stress score $\delta_t$,** computed from the "Global Weather" dataset. The raw temperature values range from 5°C to 45°C. The stress score is defined as the absolute deviation from an optimal crop-specific temperature, such as 25°C for rice. This is calculated as $\delta_t = |T_t - T_{opt}|$, based on the degree of deviation, the stress is classified into No Stress (0–3°C deviation), Moderate Stress (2–7°C deviation), and Severe Stress (greater than 6°C deviation), with overlapping membership functions to capture transitions.

**The fourth input is the predicted mean yield $\mu_{\hat{y}}$,** which is computed from the LSTM ensemble forecasting engine (LEFE) based on nutrient-soil-climate mappings found in the "Crop Recommendation Dataset." As the forecast output is normalized, its values are mapped into three fuzzy sets: Low Yield (0.0–0.4), Moderate Yield (0.3–0.7), and High Yield (0.6–1.0). This classification helps identify yield performance bands for advisory generation.

**The fifth input is the yield uncertainty $\sigma_{\hat{y}}$,** which measures the standard deviation of the ensemble yield predictions. The values typically range from 0.0, indicating high confidence, to approximately 0.3 for highly uncertain forecasts. The uncertainty is fuzzified into Low Uncertainty (0.0–0.1), Medium Uncertainty (0.08–0.2), and High Uncertainty (0.15–0.3). These ranges help capture the model's confidence in its prediction and enable the advisory engine to adjust recommendations accordingly. The fetched feature value ranges are enumerated in table 2. Features and their numerical ranges Table 2. The advisory decisions within FLAE are derived from a fuzzy rule base composed of IF–THEN statements that encode expert agronomic reasoning under uncertainty. Each rule combines fuzzified input variables to infer a context-appropriate action. For instance, if the predicted mean yield $\mu_{\hat{y}}$ is classified as Low Yield and the rainfall $R_t$ is Low Rainfall, then the system recommends a Drought-Resistant Variety. Similarly, if $\mu_{\hat{y}}$ is

Moderate Yield and the pest probability $P_t$ is High Pest Risk, the advisory suggests a Bio-Pesticide Schedule. In cases where the yield uncertainty $\sigma_{\hat{y}}$ is High and the temperature-induced stress score $\delta_t$ is Severe, a Risk Reassessment Advisory is triggered. Conversely, if $\mu_{\hat{y}}$ is High Yield and $\sigma_{\hat{y}}$ is Low Uncertainty, the system concludes that No Immediate Action is required. The truth value $\tau_i$ of each rule $i$ is calculated using the minimum membership degree among the involved input terms, ensuring that the inference reflects the most limiting condition in the rule antecedents as in flowing equation.

$$\tau_i = min\left(\mu_{L_1}(\mu_{\hat{y}}), \mu_{L_2}(\sigma_{\hat{y}}), \mu_{L_3}(R_t), \mu_{L_4}(P_t), \mu_{L_5}(\delta_t)\right) \quad \text{Equation (19)}$$

where $\mu_{L_1}(x)$ refers the membership value of input parameter $x$ in the corresponding fuzzy set $L_i$

The outputs of all activated fuzzy rules are combined through an aggregation process to form a composite fuzzy set that represents the overall advisory outcome. Each rule contributes to this aggregated set in proportion to its firing strength, ensuring that all relevant conditions influence the final decision. The aggregated fuzzy output is then converted into a single crisp advisory value $A^*$ using the standard centroid defuzzification method (given as equation 20), which computes the center of gravity of the combined membership function. This approach provides a balanced and interpretable decision by accounting for the relative influence of all contributing rules.

$$A^* = \frac{\int a \cdot \mu_A(a) da}{\int \mu_A(a) da} \quad \text{Equation (20)}$$

where $\mu_A(a)$ is the aggregated membership function for the advisory output variable.

The defuzzified output $A^*$ is mapped to a predefined set of advisory labels that represent specific agronomic actions. These may include recommendations such as Drought-Resistant Variety Selection, Initiation of Pest Control Schedule, Irrigation Adjustment, No Immediate Action, or Risk Alert for Field Review. Each label corresponds to a fuzzy output region and reflects expert knowledge embedded in the rule base. These recommendations are generated in real time for each environmental scenario and predicted yield context, enabling adaptive, location-aware, and expert-informed decision support for farmers and agricultural planners. The ACAS-FLY framework integrates its three core modules namely RASG, LEFE, and FLAE into a unified and adaptive decision support system. The process begins with RASG, which generates diverse environmental scenarios by modeling variations in rainfall, temperature, and pest probability. These scenarios serve as input to LEFE, which forecasts crop yield along with associated uncertainty using an ensemble of deep learning models. The outputs from LEFE, including the predicted mean yield and standard deviation, along with environmental indicators from RASG such as rainfall, pest probability, and stress scores, are passed to FLAE. FLAE applies fuzzy inference to these inputs to produce interpretable, scenario-specific agronomic advisories. This modular integration enables the system to deliver context-aware recommendations that are both data-driven and expert-informed.

**Experimental Setup**

The ACAS-FLY framework was implemented in a Windows 11 environment using Visual Studio IDE [19] with C++ 23.0 [20] and Advanced C 24.0 [21] runtime libraries. All modules were developed using Microsoft Foundation Classes (MFC) [22], and integrated through a Common Gateway Interface (CGI) [23] layer to support backend execution and browser-based interaction. This allowed scenario parameters to be submitted via local or remote interfaces, with advisory results returned in real time. The system was executed on a development machine configured with a 12th Generation Intel Core i7 processor, 32 GB DDR4 RAM, and a 1 TB NVMe M.2 SSD. High-volume simulations and scenario evaluations were also deployed on an i2k2 dedicated server. The datasets used include: Rainfall in India (Kaggle) [24] for generating weekly rainfall sequences in RASG, Global Daily Weather (Kaggle) [25] for deriving temperature-based stress scores, Plant Disease Dataset (Kaggle) [26] for estimating pest probability inputs using a CNN classifier, and the Crop Recommendation Dataset (Kaggle) for soil-climate-yield associations [27] used in LEFE output validation and FLAE advisory mapping.

## RESULTS AND DISCUSSIONS

ACAS-FLY was evaluated using five key performance parameters: Accuracy, Precision, Sensitivity, Specificity, and F-Score. tWeekly crop cycle inputs were used to generate rainfall, temperature stress, and pest sequences, which were

then used for yield prediction. Metric-wise comparisons were recorded over multiple runs to ensure stability and consistency. The results confirm that the proposed system delivers high accuracy with balanced Precision, Sensitivity, and Specificity, while maintaining a strong F-Score across diverse simulation conditions.

**Accuracy**

Accuracy reflects the overall correctness of the yield prediction model by measuring the proportion of true results, both positive and negative, among the total predictions made. In the context of ACAS-FLY, accuracy indicates how well the LEFE module forecasts the appropriate yield class under varying environmental scenarios. Higher accuracy confirms the model's ability to generalize effectively across different regions and input variations. The measured Accuracy values at 10 different timestamps for the discussed methods are provided in Table 3. Accuracy (Table 3). Across multiple test runs, the proposed ACAS-FLY method achieved an average accuracy of 99.062%, which is the highest among all compared models. CYPEDL and EMLECYP also demonstrated consistently strong accuracy, averaging 98.277% and 97.732% respectively, reflecting their effective learning strategies. AMLACYP and MDPIML maintained reasonable accuracy at 96.661% and 95.849%, highlighting their robustness across input types. The improved accuracy of ACAS-FLY can be attributed to the combination of scenario-aware sequence modeling in LEFE and the integration of diversified environmental conditions generated by RASG. This layered structure enhances the model's ability to generalize under uncertainty while maintaining precision in yield classification. Without discrediting the reliability of existing approaches, ACAS-FLY offers a notable improvement in prediction consistency and correctness across varied conditions. A comparison graph for measured accuracy values is provided in Figure 2. Accuracy (Figure 2).

**Precision**

Precision measures the proportion of correctly predicted positive outcomes to the total predicted positives. In the context of yield forecasting, it reflects how accurately the model identifies relevant yield classes without including incorrect predictions. Higher precision indicates that the model produces fewer false positives, which is important when issuing specific agronomic recommendations. The proposed ACAS-FLY model achieved the highest average precision of 99.035%, outperforming all baseline methods. CYPEDL and EMLECYP followed with 98.492% and 98.077% respectively, reflecting well-structured learning strategies and stable performance. AMLACYP recorded a moderate precision of 97.329%, while MDPIML maintained 96.305%, indicating reasonable predictive capability with a slight tendency toward false positives under certain conditions. Measured precision values of the compared method during evaluation with 10 timestamps are enumerated in Table 4. Precision (Table 4). The superior precision of ACAS-FLY demonstrates its effectiveness in minimizing incorrect yield predictions. This performance gain can be attributed to the contextual embedding and yield-relevance modulation within the LEFE module, which filters less-relevant features more effectively. While all methods maintained acceptable levels, ACAS-FLY consistently delivered more focused and reliable positive predictions. The precision comparison graph is provided in Figure 3. Precision (Figure 3).

**Sensitivity**

Sensitivity, also known as recall, measures the proportion of actual positive cases that are correctly identified by the model. In the context of yield prediction, it reflects the ability of the system to correctly capture all high-yield or risk-prone cases without missing them. A high sensitivity score ensures that the model responds effectively to critical agricultural conditions that demand intervention. Measured sensitivity scores are logged in table 5, and the comparison graph is given in Figure 4. Sensitivity (Table 5). Sensitivity (Figure 4). The proposed ACAS-FLY model achieved an average sensitivity of 99.090%, the highest among all evaluated methods. This indicates the model's strong ability to correctly identify all relevant yield conditions, especially under uncertain or shifting environmental scenarios. CYPEDL followed closely with 98.072%, while EMLECYP maintained a stable average of 97.407%, showcasing dependable recall performance. AMLACYP and MDPIML recorded 96.047% and 95.434% respectively, reflecting moderate sensitivity in detecting true positive predictions. ACAS-FLY's high sensitivity highlights the advantage of integrating scenario-aware modeling within the LEFE module, which helps capture subtle yield-related patterns often overlooked by conventional architectures. While other methods perform consistently, the proposed

approach stands out in its ability to minimize false negatives, ensuring critical yield conditions are not missed during advisory generation.

**Specificity**

Specificity measures the proportion of actual negative cases that are correctly identified by the model. In the context of yield forecasting, it reflects how well the model avoids false alarms by correctly identifying non-critical or low-risk conditions. A higher specificity score ensures that unnecessary interventions are minimized, contributing to more efficient and targeted agricultural recommendations. Measured specificity scores of the compared methods are enumerated in Table 6. Specificity (Table 6). The proposed ACAS-FLY method achieved an average specificity of 99.036%, the highest among all compared models. CYPEDL and EMLECYP followed with averages of 98.486% and 98.064%, indicating consistent accuracy in identifying non-critical yield conditions. AMLACYP recorded 97.294%, while MDPIML maintained 96.272%, showing moderate effectiveness in reducing false alarms. ACAS-FLY's strong specificity confirms its ability to avoid unnecessary alerts by correctly identifying stable or non-actionable scenarios. This precision is enabled by the integration of environmental scenario modeling in RASG and uncertainty-aware yield forecasting in LEFE. Without compromising sensitivity, the model maintains high discrimination power, ensuring that field recommendations are only issued when truly required. The Specificity score comparison graph is provided in Figure 5. Specificity (Figure 5).

**F-Score**

F-Score is the harmonic mean of Precision and Sensitivity, offering a balanced measure of the model's classification performance. It is particularly useful when dealing with imbalanced outcomes, as it considers both false positives and false negatives. In yield forecasting, a high F-Score indicates that the model not only detects critical yield classes effectively but also avoids incorrect alarms. The proposed ACAS-FLY model recorded the highest average F-Score of 99.062%, reflecting its balanced performance in both detecting true yield cases and avoiding false positives. CYPEDL and EMLECYP followed with 98.281% and 97.740% respectively, showing consistent classification strength. AMLACYP and MDPIML achieved 96.684% and 95.868%, maintaining reasonable harmonic precision–recall trade-offs. ACAS-FLY's superior F-Score confirms its ability to combine high sensitivity and precision without sacrificing one for the other. This balance results from the integration of environmental scenario awareness in RASG and adaptive sequence learning in LEFE. The improvement is particularly valuable in agricultural contexts, where missing a critical condition or over-alerting both lead to suboptimal decisions. Observed F-Score values during the evaluation are provided in Table 7 and the comparison graph is provided in Figure 6. F-Score (Table 7). F-Score (Figure 6).

**Additional Findings**

**Crop Disease Class Frequency Distribution (Figure 7).**

The bar chart illustrates the distribution of image samples across four crop health categories in the Plant Disease dataset. The dataset includes a higher proportion of healthy crop images, followed by cases of blight, rust, and mildew. This imbalance highlights the importance of precision-focused classification during pest probability estimation, as used in the FLAE module of ACAS-FLY. The trained CNN model accounts for this class distribution while generating pest risk scores used in downstream advisory decisions.

**Nitrogen Level vs. Predicted Mean Yield**

The scatter plot numbered as Figure 8 presents the relationship between nitrogen content (N) and predicted mean yield values as estimated by the LEFE module. Data points are derived from the Crop Recommendation dataset and aligned to normalized yield outputs. The distribution suggests a non-linear correlation, with moderate nitrogen levels frequently associated with higher predicted yields. This behavior is consistent with agronomic expectations, where both nitrogen deficiency and excess can negatively impact crop productivity. The mapping reinforces the relevance of soil nutrient features in model training and the utility of LEFE's context-aware learning for yield prediction. Nitrogen Level vs. Predicted Mean Yield (Figure 8).

## CONCLUSION

ACAS-FLY presents an adaptive crop advisory framework that integrates scenario modeling, sequence-based yield forecasting, and fuzzy logic–driven decision-making. The proposed architecture introduces three key innovations: (i) the use of a Risk-Aware Scenario Generator (RASG) to simulate stochastic rainfall, pest risk, and stress profiles; (ii) an enhanced LSTM ensemble with context-aware gating using scenario and relevance vectors for yield forecasting; and (iii) a fuzzy rule-based advisory engine (FLAE) that maps predictions and environmental factors into interpretable agronomic recommendations. Extensive evaluation across benchmark datasets demonstrated that ACAS-FLY outperforms existing models in terms of Accuracy, Precision, Sensitivity, Specificity, and F-Score. The results confirm the system's ability to adapt to environmental uncertainty and deliver targeted, high-confidence crop guidance. Its modular design allows seamless integration into region-specific advisory systems while ensuring interpretability and scalability. Future work may focus on real-time deployment with sensor integration, active feedback loops from farmers, and the extension of the fuzzy rule base using reinforcement learning. Expanding the model to support multi-crop advisory across geospatial zones is also planned to enhance its practical applicability at scale.

### CONFLICT OF INTEREST

The authors declare that there is no conflict of interest regarding the publication of this research work.

### CODE AVAILABILITY

The ACAS-FLY framework has been implemented using C++23 with Microsoft Foundation Classes (MFC) in the Visual Studio environment. The source code and execution modules are available online and can be shared upon reasonable request for academic and non-commercial use.

### DATA AVAILABILITY

All datasets used in this study are publicly accessible. Rainfall, weather, crop disease, and crop recommendation datasets were obtained from Kaggle and can be accessed via the following links:

**Table 1: A comparative summary of the reviewed methods is presented in Table 1, highlighting the authors, titles, methodologies, advantages, and limitations of each approach.**

| Author | Title | Methodology | Advantages | Limitations |
|---|---|---|---|---|
| Subramaniam *et al.* | Crop yield prediction using effective deep learning and dimensionality reduction approaches for Indian regional crops (CYPEDL) | WTDCNN with EWOA optimization and SEKPCA for feature reduction | High prediction accuracy, customized for Indian regions | High training complexity, limited geographic generalization |
| Ahmed M S Kheir *et al.* | Developing automated machine learning approach for fast and robust crop yield prediction using a fusion of remote sensing, soil, and weather dataset (AMLACYP) | H2O AutoML with fused satellite, soil, and climate data | Fully automated model, scalable to large datasets | Sensitive to regional data quality, limited model transparency |
| Mahdizadeh Gharakhanlou *et al.* | From data to harvest: Leveraging ensemble machine learning for enhanced crop yield predictions across Canada amidst climate change (EMLECYP) | Ensemble ML with climate, soil, NDVI, and honeybee census integration | Climate scenario support, high spatial resolution maps | Relies on specific pollinator data, soil profile gaps in some regions |
| Hoque *et al.* | Incorporating meteorological data and pesticide information to forecast crop yields using machine learning (MDPIML) | Logistic regression, k-NN, and gradient boosting with weather and pesticide usage | Multi-crop support, incorporates chemical usage | Missing features like soil moisture and solar radiation |

**Table 2: Features and their numerical ranges**

| Input Variable | Dataset Source | Observed / Computed Range | Fuzzy Sets |
|---|---|---|---|
| Rainfall (Rt) | Rainfall in India – Kaggle | 0–175 mm/week | Low (0–40), Moderate (30–100), High (90–175) |
| Pest Probability (Pt) | Plant Disease Dataset – Kaggle | 0.0–1.0 | Low (0.0–0.3), Medium (0.2–0.6), High (0.5–1.0) |
| Stress Score ( $_t$) | Global Weather – Kaggle | \|Tt – Topt\|, Topt = 25°C | No Stress (0–3°C), Moderate (2–7°C), Severe (>6°C) |
| Predicted Mean Yield ($\mu\hat{Y}$) | Crop Recommendation Dataset – Kaggle | 0.0–1.0 (normalized) | Low (0.0–0.4), Moderate (0.3–0.7), High (0.6–1.0) |
| Yield Uncertainty ($\sigma\hat{Y}$) | Derived from LEFE ensemble | 0.0–0.3 | Low (0.0–0.1), Medium (0.08–0.2), High (0.15–0.3) |

## ABSTRACT

India's tribal population, constituting approximately 8.6% of the country's total, faces significant health disparities and barriers to accessing healthcare services. This study examines the systemic challenges hindering healthcare access and explores the effectiveness of government initiatives aimed at addressing these issues. The research aims to understand the nature of healthcare gaps in tribal areas, with particular attention to infrastructure, cultural barriers, and healthcare delivery systems. Efforts to improve tribal health include initiatives under the National Health Mission, which focuses on enhancing healthcare infrastructure in rural and urban areas. Additionally, the Tribal Sub-Plan allocates specific funds for tribal development, including health benefits. Programs introduced by the Ministry of Tribal Affairs, such as mobile medical units and tribal research institutes, aim to address specific health-related challenges. However, in many cases, these efforts fall short due to geographical isolation, poor infrastructure, limited transportation, and cultural or linguistic differences that restrict access to healthcare delivery. The study explores how malnutrition, maternal and child health issues, and the neglect of traditional healing practices exacerbate health inequities. Findings highlight the need for collaboration between mainstream healthcare providers and tribal communities to develop inclusive and culturally sensitive healthcare interventions. The analysis emphasizes the importance of integrating traditional methods with modern medicine to improve healthcare performance and acceptance among tribal populations. The study also highlights the critical role of community leaders and local healthcare workers in delivering targeted treatments for conditions like sickle cell anaemia and malnutrition. Efforts should focus on providing health literacy education and developing effective communication strategies. By fostering collaboration

across education, health, and social welfare programs, the research underscores the necessity of addressing the social determinants of tribal health. This integrated approach is vital for improving health outcomes and achieving equitable healthcare access for tribal populations.

## INTRODUCTION

Tribals communities officially recognized as schedule tribe in India consider them as a one of the most marginalised and distinct group of communities. In Indian constitution its mentioned that 366(25) provided that are socially economically disadvantage group of societies often characterized by physical location, lack of cultural practices and away from mainstream society.The term "tribal" refers to a wide range of indigenous communities with diverse traditions, languages and livelihoods. These communities live predominantly in forested, hilly, and isolated places, relying on natural resources for survival. In India Tribal is a second largest in the world according to 2011 census. In India around 8.6 percent over all population, total around 10.4 crores to separate into different part into 750 ethnic group. Tribal communities face barriers compare to non-tribal communities in various socio, economic, education and in health aspect in the society. Basically, away from mainstream of societies. Therefore, their requirement regarding health required unique need due to their distinct living environments. Health disparities among tribal population is a major issue in India this difference due to structural disadvantages such as geographical isolation, poverty, and cultural marginalisation. indigenous group has greater number of hungers, maternity and newborn mortality and communicable diseases than the mainstream society. These population attain the disease such as sickle cell anaemia, directly impact these communities. Nevertheless, government focus on these issues accessing health care remain restricted due to poor infarstrure, cultural and language barriers and unable to attain the services.

**Healthcare Challenges in Tribal Communities**

Tribal communities face many challenges in accessing health care services. Geographic allocation is a main factor contributing to limit their accessibility. The remote location builds in a manner where people are unbale reach health care centres and poor infrastructure and limits transportation. Natural barriers such as landslides, floods during monsoon as well as various whether pattern futhur posed a challenge on them. Interiors placed people mostly do forest dwellers, hunters and food gathering job. Roads are main point to connect the people to spread information, raw material, people and goods and services. Its main pillar for economic development of tribal people. Since from British Era, indigenous people most used natural resources only psychologically and administratively isolated they are neglected and untouched communities. Another problem is infrastructure deficit, where Health care infrastructure such as well-developed medical service centres and successful transportation system, are essential for ensuring adequate access to medical service. However, lack of infrastructure facilities are major challenges in many rural remote and disadvantage areas. Primary health care centres (PHCs) in India lack key medical equipment, such as diagnostic tools and functional laboratories, restricting their capacity to deliver quality care. Similarly, there is report from NITI Aayog (2021) highlight that lack of specialized care services cause inconsistency in healthcare results between rural and urban place. Cultural barrier is another challenge language difference main threat to reach the health provision centres for tribal people. High prevalence of malnutrition, maternal and child health problems, and neglected diseases like sickle cell anaemia remain critical concerns. Moreover, already existing services due to poor maintenance lack the infrastructure services such as electricity, clean water, toilet condition and compromising service delivery.

**Global Perspectives**

In global arena many challenges continues and WHO identified that low income and middle countries face considerable challenges because of inadequate healthcare infrasture and transportation.To effectively tackle these gaps, the organization encourages targeted investments in road relations and healthcare facility standards. Ouma et al. (2019) and other studies in Sub-Saharan Africa emphasize the relevance of community-based solutions, such as mobile health clinics, in alleviating the consequences of infrastructural shortfalls.This all-major challengeis rectified by technological intervention, where it offers potential remedies. Word bank (2020) underscore that use of drones for medical supply in village remote areas in a cost-effective way to tackle transportation challenges. As well as UNICEF (2021) emphasized that necessity of solar powered facilities in these remote regions.by developing multifaceted approach that along investments in physical infrastructure with creative remedies like health units and drone tech through addressing the issues necessities offering insight unique dimension of their experience. By understanding the intricacies of tribal initiatives for population in India. The importance of this research lies not only in highlighting the challenges faced by tribal people in India but also contributing development of evidence-based strategies and policies to rectify these issues.

By combining data driven insight with real-life narratives, this research aim is to provide holistic understanding of Health Initiatives for Tribal Populations in India their Current Programs, Challenges, and Future Directions and many initiatives from NGO, private sectors, are essential to bridges these gaps and ensure access of health care equally for all .example…In 21st century despite change, achieve significant justice the ultimate goal is to contribute meaningful recommendation for policies and intervention the priorities the right in global stage. Health issuesor High prevalence of malnutrition, maternal and child health problems, and neglected diseases like sickle cell anaemia remain critical concerns.

**Government Initiatives and Efforts**

There are various government initiatives aim to better healthcare access and outcomes for tribal communities:
National Health Mission (NHM) was launched by govt of India since 2013, is a flagship programme objective to have health care deliver system in rural and tribal region areas. To become comprehensive healthcare development this programme, align with national rural health programme and national urban health programme. This intervention reduces the burden of inequities in healthcare by accessing infrastructure ensuring healthcare services further it strengthensub,primary,and community health care services centres. it's impacted to increase PHC and CHC in tribal belt and this intervention also impacted to launch Janani Suraksha Yojana (JSY) and Janani Shishu Suraksha Karyakram (JSSK) helps to improve institutional deliveries.Moreover,establishment of Accredited Social Health Activists (ASHAs), Reproductive, maternal, newborn, child and adolescent health(RMNCH+A),Mobile Medical Units (MMUs) and telemedicine service providing to rural area or tribal regions to improve their healthcare condition.Other major initives government brought for tribals are Tribal sub plan where it allocates funds for tribals to develop their health care service.Sub plan funds also allocate to nutrition programmes for maternal, child health which is affecting byepidemic like malaria, tuberculosis, Sickel cell anaemia which are most prevailsin tribal regions. These funds due to poor planning, unaccountability unable to spent properly, logistical barriers createlack of establishment of programmes and further cultural barrier is another problem to adopt modern method of health care use. In order to rectify these challenges required community participation and training need to provide to the local workers to tackle this obstacle. Further Ministry of tribal Affairs programs introduced mobile medical unites without the person there by access the technology throughrectify their medical needs by government to attain health services and also conduct tribal health research centres were based on evidence can assimilate the specific health care medicine and targeted intervention is possible by healthcare challenges faced by tribal people. Despite these efforts, many programs struggle to meet their goals due to systemic inefficiencies and continues barriers.

**Statement of problem**

Health Initiatives for Tribal Populations in India their challenges remain and required necessary steps to give equal opportunities to tribal population. Despite national efforts and legal framework aimed at protecting tribal population health and wealth and the study aim is to comprehensive approach required to examine tribal population their

health intervention in Indian society to improve their deteriorated condition by focusing need based approach in Indian society.

**Significance of study:** The studyseeks to uncover the multifaceted dimension of tribal health problems and their barriers while intervention and understanding unique socio-cultural economic factor. By underscoring their lived experience, the research aims to inform national strategies to overcome the challenges against health and illness problems and promote various health programmes to uphold the right in the Indian society with the help of constitution. Thereby giving contribution to a more democracy world.

**Objective:**

The study investigates health intervention. The aims to analysis the nature of healthcare gaps in tribal areas, with particular attention to infrastructure, cultural barriers, and healthcare delivery systems and the study explore how malnutrition, maternal and child health issues, and the neglect of traditional healing practices exacerbate health inequities and examine the effort to better tribal health includes such as National Health Mission in order to focus on developing healthcare infrastructure in rural and urban areas. Further the tribal sub plans a lot funds for tribal health development programme. Explore the opportunities for collaboration to prevent their education, health, and social welfare programs to strengthen the intervention of health of tribal population for future directions.

## METHODOLOGY

The study adopted descriptive and analytical qualitative approach to explore Health Initiatives for Tribal Populations in India: Current Programs, Challenges, and Future Directions. It includes comprehensive methodology. A literature review established context, and identity gap, legal analysis for evaluating framework and suggesting reforms, case studies. This approach aims to inform evidence-based policies and healthcare interventions for addressing the challenges faced by tribal population in India in the health context. This included secondary data utilised included books, articles and reports from national and international websites.

## FINDINGS AND DISCUSSION

**Barriers to Healthcare**

Indigenousgroups are often located in hilly and difficult terrain therefore, accessing health facilities is a challenge to them due to lack of transportations and many more issues. Adequately witnessed of PHC and CHC further problem for them to approach health centres despite the development. Poor construction and lack of funds posed a serious challenge to remain with same standard of living life. As traditional believeris not comfortable to adopt modern medicine therefore it makes them gradual healer of their own use of traditional medicine such as herbs and medicinal plants and affecting their health. Language barrier become serious communication problem to create a misunderstanding and reduce quality care and further barrier to deliver them to access health services. Lackof antenatal care, low institutional delivery rates, and poor postnatal care major health barrier to pave the way for maternal and neonatal mortality rate in tribal regions.Consequently, genetic disorder such as sickle cell anaemiamore frequently appeared in tribal population and managing in difficult in that geographic location because it required a modern method of screening and to facilitates the diagnostic but it's not possible in that restricted time.

**Gaps in Government Interventions**:

Lack of integration of conventional healing approachesoften plays under tribal region become rarelyvisible to incorporate in the system.The lack of engaged community involvement in the creation and execution of healthcare actions has led to in low service utilization.Programs like as Village Health and Sanitation Committees (VHSCs) are either neglected or poorly delivered, failing to engage tribal groups in decision-making.The shortage of culturally applicable medical models further divides tribal groups off modern healthcare systems.

**Discussion and Policy Implications:**
Providing good infrastructure facilities can help overcome these challenges, reduce barriers, and transform the area into a more accessible and resource-abundant place. Improving ambulance services in these constrained locations increases the chances of reducing mortality rates and managing critical emergency situations effectively and Giving training to tribal communities in their own languages, while understanding their cultural sensitivities, helps reduce communication gaps and incorporates modern methods into their healthcare system.

**Integrated health interventions:**
Strengthening the scope of nutritional programs such as Integrated Child Development Services (ICDS) and mid-day meals is critical in combating malnutrition.Newborn and maternal health issues can be handled with specific mother and child health initiatives that involve the community.

**Community Empowerment**:
Traditional healers address community health needs, particularly in regions with high prevalence of diseases like malaria and jaundice.Therefore, required own ownership to effectively execute the policy with the help of government. Further promoting health campaign can enhance the uptake of services centres.

**Focus on Genetic Disorders**
The best way to address individuals affected by health conditions in a timely manner is to implement screening programs that help them understand the challenges caused by the lack of modern healthcare interventions, while also creating public awareness.

**Recommendations**
The study underscores the need for collaboration between mainstream healthcare providers, tribal community leaders, and local healthcare workers to develop inclusive and effective healthcare strategies. Key findings include:
1}According to studies, traditional healing procedures frequently have great cultural and spiritual importance for tribal groups, which fosters trust and commitment to treatments. For example, combining traditional herbal medicines with allopathic medicine has showed potential in treating common ailments while preserving cultural identities.
2}Health literacy programs are critical for bridging the gap between healthcare systems and native communities. According to studies, tribal populations frequently encounter challenges such as poor literacy rates, linguistic disparities, and misunderstanding regarding diseases and treatments.
3}Understanding bigger factors of health among aboriginal populations requires collaboration across multiple industries. The merging of education, health, and community development serves as essential for addressing issues such as starvation, hunger, and lack of facilities which greatly impact medical conditions
Therefore by healthcare needs of tribal communities requires an integrated, culturally sensitive approach. Efforts should focus on enhancing healthcare accessibility, equipping facilities with adequate resources, and empowering community leaders to act as bridges between tribal traditions and modern medical systems. Through collaboration and targeted strategies, it is possible to reduce health disparities and improve the overall well-being of India's tribal populations.

## CONCLUSION

As far discussed, healthcare in tribal areas including physical isolation, cultural, language difference required a persistence delivery of quality health service system. Solving malnutrition, maternal and infant health matters andspecifically of genetic disorders required need based intervention. Government programmes such as NHM,TSP, and mobile based health care need to integrate further with various schemes and polices to the development of tribal people and foster community engagement while adopting cultural sensitive approaches to overcome barriers and A comprehensive involvement and health care method is necessary to encourage health outcomes for tribal population

in developing countries like India and the same coin has two sides as initiativesprogrammesinitiated by international forum still required focused specific intervention through get back the next stage of healthy environment style of life.

## ABSTRACT

The present work is aimed at assessing the physico-chemical properties of Tannery effluent in Dindigul District. The effluent was brownish colored with a disagreeable odor, the parameters such as pH, Electrical Conductivity (EC), Total Dissolved Solids (TDS), Total hardness, Chlorides etc., and also calculating the WQI for the following parameters like Turbidity, TDS, pH, Alkalinity, Ammonia, Calcium, Chromium, Fluoride, Hardness, Iron, Magnesium, Nitrate, Potassium, Sodium, Sulphate. The high value of WQI has been found to be mainly from the higher value of TDS, hardness, chloride, sodium, chromium in the tannery effluent. Although in Dindigul tannery effluent , all the physicochemical parameters were higher then the permissible limit, and Water quality index showed this effluent is incompatible for drinking agriculture or any other purpose.

**Keywords** - Tannery effluent Physical, parameters, Chemical parameters, Water quality index.

## INTRODUCTION

The tannery industry forms the foundation of the leather sector, but it generates colored wastewater due to various processes such as bleaching, mercerizing, dyeing, printing, and packing, which involve substantial amounts of synthetic chemicals. This effluent, often discharged into sewage systems or neighboring land, poses significant environmental problems (Murali*et al.,* 2013). Although the leather industry is one of India's oldest and most significant sectors, contributing substantially to foreign exchange earnings, it suffers from severe environmental pollution. This pollution undermines some of the societal benefits associated with the industry. Leather production, along with the creation of leather goods, boards, and fur, results in numerous by-products, including solid waste and high volumes of wastewater containing various pollutants and toxic chemicals. The tannery sector plays a crucial role in the economies of many countries. However, depending on the specific processes used, it generates substantial quantities of wastewater containing ammonium, sulfates, surfactants, acids, dyes, emulsified oils, and organic substances, including both natural and synthetic tannins (Reddy and De Busk, 2007). Leather processing involves significant amounts of chemicals such as sodium chloride, chromium, sulfate, calcium salts, sodium sulfide, acids, alkalis, fats, liquors, and organic dyes. A significant environmental challenge facing the tanning industry is the disposal of chromium-contaminated sludge, which is a by-product of wastewater treatment.

In India, tannery industries are concentrated in specific regions: Vaniamvadi, Ambur, Trichy, and Dindigul focus primarily on processing goat or sheep skins, while tanneries in Ranipet, Pernampet, Erode, and Pallavaram handle skin hides. The industrial effluent from these tanneries contains various chemicals, including dispersants, and is characterized by high salinity, significant organic loading, and specific pollutants like chromium (Saritha*et al.,* 2013). Major issues include wastewater contaminated with heavy metals, toxic chemicals, chlorides, lime, high dissolved and suspended salts, and other pollutants. Tanneries generate wastewater in the range of 30-35 liters per kilogram of processed skin or hide. This wastewater typically has variable pH and high concentrations of suspended solids, biological oxygen demand (BOD), chemical oxygen demand (COD), tannins, and chromium. The expansion of industrialization has reached even small towns and villages, bringing with it severe pollution problems (Babich*et al.,* 1982). Leather processing presents a significant environmental challenge due to the nature and volume of chemicals used, as well as the large amounts of waste generated and discharged. Tannery effluent is widely recognized as a serious environmental threat globally. Water is commonly used by industries for waste disposal (Thamizhiniyan*et al.,* 2009).To address this issue, several methods such as reverse osmosis, ion exchange, membrane filtration, and electro-dialysis are employed to remove heavy metals from wastewater. However, these techniques are expensive and produce concentrated waste that requires additional treatment for proper disposal. Biological removal processes may offer a more viable alternative for wastewater treatment (Lovely and Coates, 1997; Rittmann*et al.,* 2004).

The discharge of industrial effluents leads to chemical changes in the soil due to the continuous release of polluted water. High levels of pollution can severely damage root systems, reducing plant yield significantly by maturity. Key indicators of yield loss include delayed germination and premature leaf senescence. Coir pith has emerged as an effective means to reduce phenolic compounds entering water resources. It serves as a bio-adsorbent due to its ability to enhance water infiltration and improve nutrient availability for crops. Water pollution remains a critical and escalating issue. Despite existing regulations, toxic chemical pollution in aquatic environments persists, with domestic and industrial effluents being major contributors to this contamination (Claxton *et al.,* 1998; White and Rasmussen, 1998). The Water Quality Index (WQI) is a highly effective tool for conveying water quality information to both the public and policymakers (Mishra and Patel, 2001). It is defined as a rating that reflects the combined influence of various water quality parameters (Ramakrishnaiah*et al.,* 2009). This method provides a composite score that assesses the overall quality of water based on individual parameters (Al-Mohammed and Mustasher, 2013). In this study, the water quality of the Dindigul tannery effluent was evaluated using the weighted arithmetic index, a method that calculates the WQI to determine the suitability of the water.

## MATERIALS AND METHODS
## PHYSICO-CHEMICAL ANALYSIS OF EFFLUENT

Industrial effluent was collected in polyethylene containers from an outlet of the industry in Dindigul, Tamil Nadu, India, and transported to the laboratory for further analysis. The physico-chemical parameters of the effluent—including pH, Electrical Conductivity (EC), Biochemical Oxygen Demand (BOD), Chemical Oxygen Demand (COD), Total Dissolved Solids (TDS), Total Suspended Solids (TSS), Total Hardness, Chloride, Sodium, Calcium, and heavy metals—were measured using the standard methods outlined by APHA (2012).

**Water Quality Index**

To compute the Water Quality Index (WQI), the following steps were taken:

1. **Parameter Weight Assignment**: Parameters were assigned weights based on their significance in water quality assessment. Chloride and fluoride were given the maximum weight of 5 due to their crucial impact on water quality (Srinivasamoorthy et al., 2008). Turbidity, calcium, potassium, sodium, magnesium, and chromium were assigned the minimum weight of 2, reflecting their lesser role in the assessment.
2. **Intermediate Weight Assignment**: Parameters such as pH, Total Dissolved Solids (TDS), alkalinity, iron, nitrate, and sulfate were assigned a weight of 4, indicating their moderate importance in evaluating water quality.
3. **Variable Weight Assignment**: Total hardness and ammonia were assigned a weight of 3, based on their relevance to determining water quality. In next step, the relative weight (Wi) is computed from the following equation:

$$Wi = wi / \sum_{i=1}^{n} wi$$

In calculating the Water Quality Index (WQI), the following steps are applied:

1. **Weight Assignment**: Each parameter is assigned a weight based on its importance. The relative weight (Wi) for each parameter is computed, where wiw_iwi is the weight assigned to the parameter and nnn is the total number of parameters. The calculated relative weight (Wi) values for each parameter are detailed in Table 1.
2. **Quality Rating Scale**: For each parameter, a quality rating scale (qi) is determined by dividing its concentration in the water sample by the corresponding standard value, as specified by BIS (2012). This ratio is then multiplied by 100 to obtain the quality rating scale for each parameter.

$$qi = (Ci / Si) \times 100$$

where, qi is the quality rating, Ci is the concentration of each chemical parameter in each water sample in mg/L, and Si is the Indian drinking water standard for each chemical parameter in mg/L according to the guidelines of the (BIS, 2012) . For computing the WQI, the SI is first determined for each chemical parameter, which is then used to determine the WQI as per the following equation (Tiwari and Mishra)

$$SIi = Wi * qi$$
$$WQI = \sum SIi$$

SIi is the subindex of ith parameter; qi is the rating based on concentration of ith parameter and n is the number of parameters. The computed WQI values are classified into five types, “excellent water” to “water, unsuitable for drinking”.

## RESULTS AND DISCUSSION

**Physical parameters of effluent from tannery industry**

The water quality parameters analyzed in the tannery effluent included appearance, odor, turbidity, electrical conductivity, and total dissolved solids. The tannery effluent sample exhibited a brownish color and an unpleasant odor. The odor in water can be attributed to chemical substances such as hydrogen sulfide, free chlorine, ammonia, phenols, alcohols, esters, and hydrocarbons, as well as biological agents like algae, fungi, and other microorganisms (Sharma, 2000). The turbidity of the tannery effluent was measured at 680 NTU. Turbidity in effluent is primarily caused by colloidal and suspended impurities, which reduce light penetration and subsequently hinder photosynthesis (Aisien *et al.*, 2010). This increased turbidity often leads to higher turbulence and mixing in the water, resulting in a greater concentration of suspended particulate matter. Typically, turbidity levels rise following heavy rainfall, as rainwater picks up small particles of dirt from the ground before reaching the water source. Additionally, high turbidity in surface water can be associated with decaying organic matter, clay, microorganisms such as bacteria, and small amounts of mineral salts (Frada, 2001).

The electrical conductivity of the tannery effluent was found to be very high (Table 2). Electrical conductivity measures the water's ability to conduct an electric current, which is directly related to the concentration of dissolved minerals. However, it does not specify which particular elements are present. A high electrical conductivity value often indicates the presence of contaminants such as sodium, potassium, chloride, or sulfate (Nazir*et al.*, 2015). The total dissolved solids (TDS) in the tannery effluent were high (Table 2). TDS in water can originate from a variety of sources, including natural processes, sewage, urban and agricultural runoff, municipal waste, and the chemical weathering of rocks (Hussain, 1989). Water with extremely low TDS concentrations can also be undesirable due to its flat taste and lack of mineral content (WHO, 1994). TDS levels indicate the salinity of water, and a high TDS content can impact water density, affect the osmoregulation of freshwater organisms, and reduce the solubility of gases. This can also affect the water's suitability for drinking, irrigation, and industrial uses. Based on TDS concentration, water can be classified as either desirable or permissible for drinking (Wilcox, 1955).

**Chemical examination of effluent from tannery industry**

The hydrogen ion concentration of the tannery effluent was alkaline, with a pH of 7.9. pH is a crucial factor in determining the corrosive nature of water; a lower pH indicates higher corrosivity. pH is positively correlated with electrical conductivity and total alkalinity (Gupta *etal*., 2009). Elevated pH levels can reduce photosynthetic activity and affect the assimilation of carbon dioxide and bicarbonates, contributing to the higher pH observed. Various factors can influence water pH. The high alkalinity in the tannery effluent, as indicated by its high pH (Table 2), suggests that the equilibrium between carbon dioxide and carbonate-bicarbonate is significantly affected by changes in physico-chemical conditions (Karanth, 1987).

The total hardness of the tannery effluent in Dindigul was recorded at 2600 mg/L (Table 2). Hardness refers to the concentration of multivalent metallic cations in water. It varies by location, with groundwater typically being harder than surface water. The hardness of water reflects the geological formations it has interacted with (Garg *et al.*, 2007). The effluent showed a high calcium concentration of 560 mg/L. Calcium contributes significantly to water hardness. Its presence in high concentrations suggests that the removal processes were insufficient, leading to precipitation in the lake water as ionic strength increased (Jayaprakash*et al.*, 2005). Calcium interacts with various cations, including carbonates, bicarbonates, and fluorides. Elevated levels of $Ca^{2+}$ are directly related to increased water hardness, which can render the water unsuitable for both domestic and agricultural use (Pirzada*et al.*, 2013). The tannery effluent contained a high chloride concentration of 4500 mg/L. Chloride is introduced into tannery effluents primarily as sodium chloride due to the substantial use of common salt in hide and skin preservation or the pickling process. Chlorides are highly soluble and stable, making them resistant to removal during effluent treatment, and they persist as environmental pollutants. Elevated chloride levels can inhibit the growth of plants, bacteria, and fish in surface waters, potentially causing damage to cellular structures. When used for irrigation, high chloride concentrations can

lead to increased surface salinity through evaporation, resulting in reduced crop yields. Additionally, chlorides can be leached from the soil by rain, reentering the ecosystem and potentially contaminating groundwater (Bosnic*et al.,* 2000). The fluoride content in the effluent samples was 0.4 mg/L, which is within permissible limits. However, the sulfate content was measured at 400 mg/L. Sulfates in tannery effluents typically arise from the use of sulfuric acid or products containing high levels of sodium sulfate (Bosnic*et al.,* 2000). Various factors, including calcium, magnesium, carbonates, bicarbonates, sulfates, chlorides, nitrates, and organic matter, collectively contribute to water hardness (Salim *et al.,* 2013).

The magnesium content in the tannery effluent was notably high at 250 mg/L. Ammonium was present at 10 mg/L, while nitrate concentration, measured using the electrode method, was 38 mg/L. Nitrate esters can migrate over long distances and pose environmental risks (Rifler and Medina, 2006). Additionally, the nitrite level was recorded at 0.5 mg/L, which is considered elevated. The Biological Oxygen Demand (BOD) is a critical parameter for assessing the impact of wastewater on receiving water bodies. In the present study, the tannery effluent exhibited a high BOD level of 500 mg/L, indicating a substantial presence of organic matter. Previous studies have also reported elevated BOD levels in tannery effluents, ranging from 600 to 1622 mg/L (Noorjahan, 2014; Kulkarni, 1992). High BOD levels reflect the increased microbial oxygen demand, which can lead to a depletion of Dissolved Oxygen (DO) in the water. This reduction in DO may result in hypoxic conditions, adversely affecting aquatic life (Jerin, 2011).

The Chemical Oxygen Demand (COD) test is an effective method for estimating organic matter and determining the total oxygen demand exerted by organic compounds in a sample. The current study found high COD levels in the tannery effluent, measuring 1450 mg/L. This elevated COD is likely due to the presence of organic compounds that are not readily degraded by bacterial action (Nagarajan and Ramachandramoorthy, 2002). Furthermore, tannery wastewater is often contaminated with elevated levels of metals such as iron, nickel, chromium, zinc, cadmium, manganese, and copper. These metals can contaminate agricultural soil, posing significant health risks to consumers through the crops and vegetables grown in these soils (Mohanta*et al.,* 2010).

## CONCLUSION

The present investigation aimed to assess the physicochemical properties and Water Quality Index (WQI) of tannery effluent in the Dindigul District. The study found that the physical and chemical parameters of the effluent either met or exceeded permissible limits. The resulting water quality index indicated that the effluent is unsuitable for drinking, agricultural, or any other uses. The presence of harmful pollutants in the effluent poses significant environmental risks, potentially impacting plant, animal, and human health.To address these challenges, bioremediation has been proposed as a promising solution. This approach utilizes natural biological processes to degrade or neutralize contaminants in the tannery effluent. Ongoing research is focused on exploring greener bioremediation methods to effectively manage and mitigate the environmental impact of these pollutants.

## ACKNOWLEDGEMENTS

## ABSTRACT

Neurological illnesses have a substantial impact on cognitive performance and are linked to one of the highest rates of morbidity, disability, and death worldwide. Cerebrovascular, neurodegenerative, autoimmune, and spinal cord illnesses are the most frequent neurological disorders, followed by intracranial tumors and craniocerebral trauma. Due to the disadvantages and potential side effects of established therapies, herbal components have been examined as a viable option for treating neurological diseases. Alzheimer's disease is the most prevalent neurodegenerative illness that worsens over time in humans. It is distinguished by gradual cognitive deficits, the most visible of which is memory loss, as well as senile plaques and neurofibrillary tangles. Various therapeutic therapies, including synthetic and natural techniques, are used to combat AD in light of the disease's pathogenesis. Common herbal compounds used to treat neurological illnesses such as Alzheimer's, Parkinson's, and multiple sclerosis have been demonstrated to enhance both symptoms and cognitive performance. These are *Ginkgo biloba, Bacopamonnieri, Withania somnifera, Passiflorain carnata, Rhodiola rosea,* and *Curcuma longa*. To reduce oxidative damage to the nervous system, researchers have studied the Nrf2 pathway and natural compounds that positively control it. This researchwere carried out both in vivo, mostly utilizing mouse models, and in vitro, employing stress-induced neurons and microglia. Controlling numerous Nrf2 upstream activators, quercetin, curcumin, anthocyanins, tea polyphenols, and other phenolic compounds that have not gotten enough attention can also have an effect on Nrf2. Terpenoids, which include carotenoids (astaxanthin, lycopene), diterpenes (ginkgolides), triterpenes (ginsenosides), and monoterpenes (aucubin, catapol), are another class of phytochemical substances that activate this pathway. With this review, we hope to bring up to date our understanding of how the Nrf2 pathway is activated by secondary metabolites of health importance.

**Keywords:** Neurological, NRF2 Pathway, Extract, Oxidative Stress.

# INTRODUCTION

Neurological problems rank among the highest in the world in terms of morbidity, disability, and mortality. They also seriously impair cognitive functioning. The most common neurological illnesses include cerebrovascular, neurodegenerative, autoimmune, spinal cord, intracranial tumour, and craniocerebral trauma. Because of the limits and potential side effects of conventional medicines, herbal remedies have been investigated as a viable therapeutic alternative for neurological illnesses. Alzheimer's disease is the most common neurological disease that progresses with time in humans. It is distinguished by senile plaques and neurofibrillary tangles, as well as progressive cognitive abnormalities, the most evident of which is memory loss. A range of medicinal interventions, encompassing both synthetic and natural methods, are being employed to address AD in view of the in light of the disease's pathogenesis (1).According to statistics from national, regional, and worldwide sources, the global burden of all noncommunicable neurological illnesses, the total number of disabled adjusted life years, and the number of persons who have died from noncommunicable neurological diseases has grown considerably. The majority of patients with neurological disorders are only clinically detected when nerve damage is exceedingly severe, so they miss out on the greatest potential treatment period, even with the recent fast development of numerous surgical, pharmacologic, and interventional techniques. Patients still have a dismal outlook overall, and the majority of medications have potential negative side effects (2,3).

**Pathogenesis and progression of neurological disorders:**

Numerous studies have already revealed the well-established significance of nitric oxide, a naturally occurring chemical, in the central nervous system's function. It is also a key molecule that is involved in several important and beneficial metabolic processes. Numerous neurological illnesses have been associated to deregulation of its metabolism, including increased nitric oxide synthesis, which has been proposed as a cause or aggravating factor. There is mounting evidence that this molecule may have a role in prevalent neurodegenerative diseases such amyotrophic lateral sclerosis, Parkinson's disease, and Alzheimer's disease. Nitric oxide is a naturally occurring molecule that has been demonstrated in various studies to have an important role in the function of the central nervous system. It is also a critical molecule engaged in a variety of key and beneficial metabolic processes. Dysregulation of its metabolism, specifically the increased synthesis of nitric oxide, has been linked to a number of neurological disorders and has been considered as a trigger or aggravator. An increasing body of research suggests that this molecule could be involved in prevalent neurodegenerative diseases like Alzheimer's, Parkinson's, and amyotrophic lateral sclerosis (4).

A growing body of studies demonstrates that decreased energy metabolism leads to brain aging. Specifically, neurons' glucose metabolism gradually decreases, resulting in a growing shortage in adenosine triphosphate (ATP) generation and, as a result, glucose absorption is restricted. Rising nicotinamide adenine dinucleotide (NAD) shortages in the mitochondrial salvage pathway, as well as subsequent Krebs cycle impairments, initiate this vicious cycle of energy metabolism at the cellular level. Furthermore, a low NAD level inhibits the function of NAD-dependent enzymes, increasing genetic errors and initiating the degeneration and death processes of neurons. Neurons in the brain have the highest energy metabolism, and this pattern of events is typical of various brain areasv (5). The primary source of ATP produced by the high brain metabolic activity is oxidative phosphorylation. But mitochondria also perform other crucial roles in the brain. The endoplasmic reticulum and mitochondria collaborate to regulate neurotransmission by buffering calcium in presynaptic terminals and modulating somato-dendritic calcium levels. Calcium concentrations in the cytosol vary due to constant signaling. Furthermore, mitochondria regulate both the cell cycle and cell death. Maintenance of mitochondrial fitness is essential for carrying out these various functions, and this requires effective quality control mechanisms, which are accomplished through mitochondrial biogenesis, fission (the division of a single organelle into two or more daughter organelles, which is necessary for providing dividing or growing cells with an adequate number of mitochondria), fusion (the process by

which mitochondria share essential components), and mitophagy. Furthermore, for mitochondria to supply energy throughout an axon, they must be trafficked along them (6).

**Pharmacological Treatment associated side effects:**

The fundamental ideas of treatment strategies for neurological illnesses are the same as those for non-comorbid patients, with the difference that medication interactions require special care. A variety of therapy approaches are offered, including electroconvulsive therapy, somatic therapies, cognitive-behavioral therapy, and pharmaceutical medications. While some of the suggested techniques focus on treating depression and anxiety at the same time, others are more disorder-specific. Medications having anxiolytic qualities, like benzodiazepines, are typically started for a brief duration to alleviate anxiety; However, due to their negative influence on cognitive problems in AD and balance concerns in PD, they should be used as a last option. Since the 1950s, antidepressants have been widely used to treat depression and anxiety with positive effects. Some disadvantages of oral antidepressant medication include probable drug interactions, a limited tolerance for adverse effects, and low effectiveness. Tricyclic antidepressants and MAO inhibitors, two first-generation antidepressants that improve the extracellular usefulness of monoamines, have been phased out in recent decades, with the exception of a few conditions. Despite certain limitations, new generation antidepressants are frequently suggested for the treatment of anxiety and depression. list withdrawal syndrome, gastrointestinal problems, and sexual dysfunction as some of the adverse effects. By raising the level of serotonin in the synaptic cleft, these medications function as selective serotonin reuptake inhibitors (SSRIs). At different dosages, SSRI medications are also useful in treating anxiety. When used for neurological conditions and anxiety disorders, the adverse effect profile is typically worse. While there are several biological therapy options available for both disorders, psychological therapies are also effectively employed in both (7). As depicted in figure 1 pharmacological treatment of neurological disorders may have number of side effect.

**Herbals in treatment of Neurological disorders:**

Antioxidant qualities of phytochemicals are linked to longer lifespans and improved human health. They also lessen the toxicity of diseases including cancer, heart disease, and Neurological Disorders. Even though multiple studies have proved their benefits in the treatment of neurological disorders, further research is needed to employ natural chemicals such as curcumin, resveratrol, quercetin, and epigalloca techingallate. The nuclear factor erythroid 2-related factor 2 (Nrf2) pathway has received increased interest in recent years, with a focus on both fundamental science and clinical applications. Organic chemicals are given special attention since they have the potential to change the pathway's function and so ameliorate oxidative stress. The purpose of this study is to transmit the current understanding of the impact that various natural compounds can have on the Nrf2/ARE (antioxidant response element) pathway, as well as to evaluate the feasibility of targeting this pathway for the treatment of noncommunicable illnesses. The review covered both in vivo and in vitro research on how natural substances interact with the Nrf2 pathway and how they can lessen oxidative stress and neuronal damage (8).

**Phytoconstituents treatment as modulator of NrF2:**

It has recently been demonstrated that curcumin somewhat protects against radioactivity. We looked into curcumin's ability to prevent brain damage brought on by 12C6 + radiation in vivo. Our findings show that curcumin consistently reduces brain superoxide dismutase (SOD) activity levels, improves spatial strategy and memory loss induced by 4Gy heavy ion radiation, and increases cerebral malonaldehyde. Curcumin-pretreated mice showed consistent up-regulation of the nuclear erythroid 2-related factor 2 (Nrf2) protein, as well as three known Nrf2 downstream genes: heme oxygenase-1 (HO-1), γ-glutamyl cysteine synthetase (γ-GCS), and NAD(P)H quinine oxidoreductase 1 (NQO1).Our research supported curcumin's antagonistic actions to prevent radiation-induced brain damage in vivo and revealed that curcumin's strong Nrf2 activation potential might be valuable for the protective effects of curcumin against radiation (9). Curcumin is a natural polyphenol with anti-inflammatory, anti-cancer, antibacterial, and antioxidant effects. It has been demonstrated that this material influences Nrf2 signaling, a stress-induced pathway that lowers levels of electrophilic compounds and reactive oxygen species. Curcumin's effects on Nrf2 have been investigated in a range of contexts, including cancer, ischemia-reperfusion injury, diabetes mellitus, neurological system disorders, renal illnesses, pulmonary diseases, and cardiovascular disease. In this review, we

focus on curcumin's Nrf2-mediated therapeutic benefits in various disorders.According to the results examined in this publication, curcumin may be able to activate Nrf2 and function as a therapeutic agent to shield cells from a variety of pathological diseases (10). Tyrosine hydroxylase enzyme levels were raised and the development of synucleinopathy was suppressed after treatment with GBS, which also avoided loss of striatal dopaminergic loss and greatly reduced motor behavioral and neuromuscular impairments. Following intraperitoneal rotenone treatment, oxidoinflammatory/nitroinflammatory stress, significant cholinergic transmission inhibition, and damage to the ileal epithelium and striatal neurons were detected. Furthermore, the pretreatment + concurrent (Pre-CONC) and concurrent (CONC) GBS treatment pattern reversed the significant hyperplasia of cryptal cells in ileal epithelial tissues, the loss of striatal pyramidal neurons with a marked decrease in the length and width of the dendritic spines, and the increased striatal executioner caspase-3 and decreased nuclear factor erythroid-2-related factor 2 (Nrf2).Overall, we demonstrated the possible dual impact of GBS in averting both dopaminergic neural-related impairments and gut wall abnormalities linked with PD (11).

Renowned for their antioxidant properties, Camellia sinensis and *Withania somnifera* have been studied in this work for their protective effects against neuronal damage caused by haloperidol, reserpine, and tacrine. The results demonstrated that the 1:1 combination (HECS:HEWS) significantly enhanced antioxidant status and behavioral activities impacted by vacuous chewing movement, tacrine-induced vacuous chewing movement, and haloperidol-induced catalepsy in a dose-dependent manner. One combination has antioxidant properties and guards against neuronal damage, which becomes more apparent at doses of 30 mg/kg against the effects of tacrine on vacuous chewing, reserpine on hypolocomotion, and haloperidol on catalepsy (12). Bacopamonnieri, Centellaasiatica, Cannabis sativa, Gastrodiaelata, *Ginkgo biloba*, Panax ginseng, and *Withania somnifera* were identified as the most promising plants for Huntington's disease therapy; several of these plants are known to be CNS-active drugs. Curcumin, epigallocatechin-gallate, ginsenosides, kaempferol, naringin, resveratrol, and S-allylcysteine were anti-Huntington's disease compounds; some of these are well-known neuroprotectants. To assess the medicinal effectiveness of the previously identified as well as the novel herbal extracts and chemicals in models of Huntington's disease, more investigation is still required (13).

The goal of this research is to see how standardized extracts of the memory-enhancing herb Bacopamonnieri and the antioxidant melatonin alter the nuclear factor erythroid 2 related factor 2 (Nrf2) pathway in rats with oxalic acid-induced memory impairment. Rats were given intracerebroventricular (ICV) administration of OKA (200 ng) to cause memory impairment. Melatonin (20 mg/kg) and Bacopamonnieri (BM-40 and 80 mg/kg) were administered one hour before the OKA injection and continued daily until day 13. On days 13–15, the Morris water maze test was employed to assess memory. Rats were killed to detect oxidative stress, neuroinflammation, and apoptosis, as well as to explore the molecular expressions of Nrf2, HO1, and GCLC in the cerebral cortex and hippocampus. Significant memory loss was brought on by OKA and oxidative stress (14).

A useful plant in traditional Chinese medicine is ginseng. Its many health advantages, as demonstrated by contemporary research, include restoring blood pressure, feeding and strengthening the body, soothing the mind, enhancing cognitive function, and tonifying vital energy. One of ginseng's main active ingredients is Rg1. It strengthens immunity, increases synaptic plasticity, preserves hippocampus neurons, and improves cognitive function. It also has anti-aging and anti-fatigue qualities, and it has a lot of promise for controlling and preventing neurodegenerative disorders (NDDs). Inhibiting neuroinflammation and oxidative stress, Rg1 treatment was shown in this study to improve chronic LPS-induced cognitive impairments and neuronal ferroptosis in mice. The underlying processes might have something to do with Nrf2 signaling activation and AIM2 inflammasome inhibition. These results offer important new information on treating chronic neuroinflammation and related NDDs (15). Rosemary (*Rosmarinus officinalis* L.), a member of the Lamiaceae family, is noted for its wide range of therapeutic applications due to its distinctive secondary metabolites, Carnosol, Carnosic acid, and rosmarinic acid. In the era of pharmaceuticals and procedures, although we are progressing and achieving, we are getting diverted by numerous ailments, resulting in a growing number of fatalities among young people. One example is a neurological condition, which is defined by alterations in the nerve system, brain, or spinal cord. The majority of young and elderly

individuals worldwide suffer from neurological problems, namely stroke, epilepsy, dementia, Alzheimer's disease (AD), Parkinson's disease (PD), and migraine. Natural goods are promoted globally to reduce the aforementioned loss and emphasize the urgent need for alternate medicinal regimens. This chapter explains how R. officinalis L. and its bioactive metabolites protect against several forms of neurological diseases. AChE, neuroinflammation, β-secretase (BACE-1), mitochondrial redox state, neuronal cell death, and amyloid-beta (A-β) aggregation are some of the mechanisms. Because of its multiple uses and its potent bioactive secondary metabolites, R. officinalis is a great alternative medicine source for treating a variety of neurological illnesses (16).

An inflammatory reaction causes a secondary damage known as intracerebralhemorrhage (ICH). In this work, we discovered that oxidative stress and NLRP3 play a role in ICH damage, and we investigated if silymarin may protect against it. We discovered that 24 hours after ICH damage, oxidative stress indicators (ROS and lipid peroxides) increased as compared to the sham group. Silymarin (200 mg/kg) therapy 30 minutes after ICH damage reduced an increase in oxidative stress markers while increasing antioxidant status. After ICH damage, there was a considerable rise in nuclear levels of NF-κB-p65 and pro-inflammatory cytokines. ICH damage significantly increased NLRP3 inflammasome activation and downstream targets, including as caspase-1 and IL-1β production.Silymarin treatment suppressed NF-κB-p65 levels and inflammasome-mediated caspase-1/IL-1β expressions, leading to decreased inflammation. Additionally, silymarin therapy elevated Nrf-2/HO-1 after ICH damage, which enhanced overall cytoprotection. All of these results demonstrate that silymarin functions as a neuroprotective agent by inhibiting the activation of inflammation and increasing Nrf-2/HO-1 signaling during ICH damage (17).

Chronic cerebral hypoperfusion (CCH), a neurocognitive health concern, is linked to a variety of vascular disorders and other comorbidities. The primary purpose of this study is to determine how glycyrrhizic acid (GA) can restore cognitive health when it is compromised by chronic cerebral hypoperfusion. By reestablishing the enzymatic and non-enzymatic antioxidant activity of mitochondrial complex I and IV, the antioxidant propensity of GA lowered the generation of reactive oxygen species.. When compared to GA, the Li group's antioxidant defense was noticeably lower. In comparison to Li treatment, GA treatment resulted in a significant repair of pyramidal neurons, myelin, and dendritic spine density due to the robust antioxidant defense. When compared to lesion rats, the cognitive deficits in the GA-treated rats were remarkably improved. Finally, GA inhibited the release of cytochrome C, impeding the advancement of following apoptotic processes. The findings of Sathyamoorthyet al., 2020 paper demonstrate conclusively that GA increases endogenous antioxidants and prevents apoptosis by reducing cytochrome-c release, potentially providing neuroprotection in rats induced by CCH. Additionally, it was discovered that GA is significantly superior to Li because it modulates the GSK3β/Nrf2 pathway, which in turn lessens the negative effects of CCH (18).

As shown by Basil et al., 2021 a diterpene found in Salvia miltiorrhiza Bunge (Danshen) that has been proven in numerous experimental models to increase cytoprotection. Chlorpyrifos (CPF), an agricultural pesticide, causes bioenergetic failure, redox impairment, inflammation, and apoptosis in animal tissues. We investigated whether T-I could protect the human dopaminergic SH-SY5Y cells from the effects of CPF exposure. Pretreatment with T-I at 2.5 μM for 2 hours reduced lipid peroxidation, protein carbonylation, and nitration in the mitochondrial membranes of CPF-treated cells. T-I also reduced the formation of radical superoxide ($O_2^{-\bullet}$) by CPF-affected cells' mitochondria. T-I also reduced the generation of hydrogen peroxide ($H_2O_2$) and nitric oxide ($NO^{\bullet}$) in cells exposed to CPF. After pretreatment with T-I, the CPF-induced reduction in the activity of complexes I-III, II-III, and V was abolished. T-I prevented CPF-treated cells from decreasing their mitochondrial membrane potential ($\Delta\Psi m$) and generated less ATP. T-I inhibited inflammation in CPF-treated cells by reducing IL-1β, TNF-α, and NF-κB activity. T-I mediated protection against inflammation and mitochondria was inhibited by heme oxygenase-1 (HO-1) inhibition or silencing of nuclear factor erythroid 2-related factor 2 (Nrf2) (19).

Centellaasiatica is a medicinal plant that has long been recognized to have neuroprotective and cognitive-enhancing effects. Prior study has indicated that providing a water extract of Centellaasiatica (CAW) for two weeks promotes cognitive performance and initiates the endogenous antioxidant response pathway, while preserving the amount of

Aβ plaque. This study aims to assess the effectiveness of long-term CAW treatment in the 5xFAD mice model of Aβ accumulation. After three months of ingesting 2 g/L of CAW in their drinking water, four-month-old 5xFAD mice were cognitively assessed and their levels of Aβ plaque, antioxidant capacity, and synaptic gene expression were investigated. CAW and the targeted inhibitor ML385 were delivered to neurons isolated from 5xFAD rats to confirm the function of the antioxidant regulating transcription factor NRF2 in CAW's effect on synaptic plasticity..Results: After three months of CAW treatment, 5xFAD mice showed improvements in executive function, contextual and spatial memory. Compared to untreated 5xFAD rats, this improvement was accompanied by a decrease in the burden of Aβ plaque and an increase in the expression of antioxidant genes.. ML385 treatment reduced the effects of CAW on dendritic arborization and synaptic gene expression in isolated neurons. Conclusion: These findings imply that extended exposure to CAW may be protective against Alzheimer's disease and that NRF2 activation is probably involved in these benefits. Furthermore, our results imply that focusing on NRF2 directly can be a useful therapeutic approach for enhancing synaptic plasticity and cognitive performance in Alzheimer's patients (20). The result by Mundkar et al., 2022 showsMoringaoleifera, often known as the horseradish tree, drumstick, or sahajna, is a traditional Indian plant belonging to the Moringaceae family. Moringa'sphytoconstituents, including β-carotene, quercetin, kaempferol, ascorbic acid, flavonoids, phenolic acid, rhamnose, glycosylates, glucomoringin, and isothiocyanates, are responsible for its anti-inflammatory, anti-apoptotic, and antioxidant properties. It is widely used as animal and human feed in developing countries. These components have been demonstrated to have neuroprotective advantages in a number of neurodegenerative illnesses, including Parkinson's disease, Alzheimer's disease, Huntington's disease, and amyotrophic lateral sclerosis. They also support mitochondrial functioning, neurogenesis, and antioxidant enzyme levels in the brain with activating NrF2 pathway (21).

Cerebral ischemia-reperfusion (CIR) is a common feature of ischemic stroke and a primary cause of disability and mortality among stroke sufferers worldwide. The lignin polyphenol phyllanthin is well-known for its numerous biological properties, however there is no evidence that it can protect against CIR. We studied phyllanthin'sneuroprotective efficacy against CIR, as well as the involvement of NF-κB and AMPK/Nrf2. Experimental mice were divided into five groups: controls (sham-operated); CIR-induced via middle cerebral artery occlusion (MCAO); and CIR-induced with phyllanthin administered at 2.5, 5, and 10 mg/kg, respectively. We looked into inflammatory indicators, different signaling genes, and neurological processes. In vitro experiment findings showed that phyllanthin assertively improved cellular functions through abrogation of the Nrf2 pathway (22). To examine ginger root ethanol extract (GRE)'s protective efficacy against apoptotic and 6-hydroxydopamine (6-OHDA)-induced oxidative stress, as well as the mechanism behind this action. A Parkinson's disease (PD) model was created using 6-OHDA in rat adrenal pheochromocytoma (PC12) cells. GRE therapy increased the viability of 6-OHDA-induced damage in PC12 cells. The GRE effectively prevented 6-OHDA-induced apoptosis by decreasing the expression of Bax and cleaved caspase 3 while increasing the expression of B-cell lymphoma 2 (Bcl-2). GRE also decreased reactive oxygen species (ROS), avoided oxidative stress produced by 6-OHDA, and improved the activity of antioxidant enzymes such catalase, glutathione (GSH), superoxide dismutase (SOD), 8-oxoguanine glycosylase1 (OGG1), and NAD(P)H quinone oxidoreductase1 (NQO1). Additionally, GRE down-regulating nuclear factor and up-regulating nuclear erythroid 2-related factor kappa-light-chain-enhancer of activated B cells (NF-κB) translocation, together with the mitogen-activated protein kinase (MAPK) phosphorylation (23).

Ionizing radiation (IR) exposure occurs frequently in nuclear detonation or reactor disaster occurrences as well as therapeutic treatment. It is damaging because IR sets off cellular processes that lead to oxidative stress and macromolecule destruction. Although it was previously believed that the central nervous system (CNS) was radiation-resistant, emerging study suggests that even low doses of IR can harm the brain. Overexposure to radiation can cause increased blood-brain barrier (BBB) permeability, neuronal loss, reduced neurogenesis, impaired synaptic plasticity, and cognitive impairment. The potential benefits of dietary supplements and phytochemicals for radiation-induced damage and mental health have recently garnered a lot of attention. Notably, phytochemicals like vitamin E, corilagin, curcumin, resveratrol, and ursolic acid, as well as Amaranthuspaniculatus, Grewiaasiatica, and Lyciumbarbarum, have shown promise in reducing radiation-induced brain damage (24).

The West is more affected by neurodegenerative disorders (NDs) as a result of longer life expectancies. One of the things that starts and quickens neurodegeneration is oxidative damage that accumulates in nervous cells. Cells, on the other hand, have systems for defending themselves against oxidative stress (OS) and reactive oxygen species. On the gene expression level, the transcription factor Nrf2 (nuclear factor erythroid 2-related factor 2) regulates several of these endogenous antioxidant mechanisms. When prooxidants are present, Nrf2 migrates to the nucleus and triggers the transcription of genes with an antioxidant response element (ARE). Recent research has focused on the Nrf2 pathway and the natural substances that positively modulate it to reduce oxidative damage to the nervous system, both in vitro and in vivo, with neurons and microglia exposed to stress stimuli, as well as in vivo studies employing primarily mouse models. regulate numerous Nrf2 upstream activators, quercetin, curcumin, anthocyanins, tea polyphenols, and other phenolic compounds that have not received as much attention as they deserve can also affect Nrf2. Terpenoids, which include carotenoids (astaxanthin, lycopene), diterpenes (ginkgolides), triterpenes (ginsenosides), and monoterpenes (aucubin, catapol), are another class of phytochemical substances that activate this pathway. With an eye on treating non-diagnosed neurological disorders (NDs), this study seeks to provide current information on the impact of secondary metabolites of health interest on Nrf2 pathway activation (8).

Scientist Brankiewicz et a., 2023 shows that Following 24 hours of cell stimulation with HpExs and hyperforin salt, major oxidative stress-related parameters such as cell survival, apoptosis, ROS generation, and NRF2 and HO-1 expression were investigated. The extracts' polyphenol content, radical scavenging activity, and hyperforin concentration were all determined. We observed that the oxygen concentration, stage of melanoma progression, and extract composition all influence the cytotoxic, pro-apoptotic, and antioxidant effects. H. perforatum extracts exhibited more efficacy than hyperforin salt. For the first time, our research demonstrated that H. perforatum extracts' anticancer efficacy varies depending on the oxygen saturation level. Crucially, the composition of extracts from different sources including in vitro cultures and their distinct qualities could have a role in the choice of plants for medicinal use (25). Neurological illnesses cause functional or sensory loss of neural cells. Oxidative stress has a significant role in neurodegeneration, in addition to hereditary or environmental variables. In recent years, there has been a renewed interest in understanding more about the benefits of extra virgin olive oil (EOs), particularly in the context of treating neuropathologies. The chemical and biological effects of EOs have enabled important therapeutic possibilities for the treatment of a wide range of neurological diseases. Essential oils (EO) extracted from numerous species of medicinal plants have showed positive benefits in neurological disorders such as anxiety, dementia, oxidative stress, cerebral ischemia, and oxidative toxicity. As a result, EOs show promise as substitute drugs for the treatment of neurological conditions (26).

Sleeping difficulties result in inadequate recovery after a restful night's sleep, which leads to daily weariness, mental disorientation, and hypersensitivity. Certain medications, such benzodiazepines and antihistaminic medicines, aid in promoting sleep and treating insomnia. However, tolerance and reliance make the continued treatment inappropriate. Consequently, scientists look for novel medications with fewer side effects. Natural products have long been a valuable resource for the development of novel therapies for the treatment of conditions including cancer, diabetes, heart disease, sleeplessness, and issues with the liver and kidneys. Numerous studies have supported the legitimacy and applicability of using these herbs to treat insomnia. Notably, we investigated the potential of many Persian herbs, including lettuce, Capparisspinose, Viola tricolor, Artemisia annua, Salvia reuterana, and Passifloraincarnata, to cure insomnia in this work through both in vivo and clinical trials. Studies have shown that n-butanol fractions containing non-polar compounds, in particular, have hypnotic effects on benzodiazepine receptors (27). The current study intended to examine and investigate the mechanisms behind the anti-aging activities of Scutellariabaicalensis Georgi (LSBG) leaves. SD rats were fed LSBG intragastrically(0.4 g/kg or 0.8 g/kg) and D-galactose subcutaneously (0.3 g/kg) for seven weeks. Every rat was subjected to behavioral tests to assess their cognitive abilities. The results demonstrated that LSBG corrected memory deficits. The possible processes were then examined using metabolomics of the brain and hippocampus. Aging rats revealed alterations in 21 metabolites in the cortex and 22 metabolites in the hippocampus. Furthermore, the data revealed that the LSBG may regulate the levels of key metabolites as well as the activity of enzymes involved in glutamate metabolism and its downstream metabolism (glutathione metabolism). In addition, proteins implicated in the Nrf2 signaling pathway

were examined using western blot. Furthermore, the LSBG had a considerable impact on the expression of Nrf2, GCLC, HO-1, and NQO-1 proteins in the cortex and hippocampus. Above all, the Nrf2 signaling pathway and glutamate metabolism were regulated by the LSBG's anti-aging actions (28).

New therapeutic techniques are necessary for the effective treatment of glioblastomamultiforme (GBM), an aggressive primary brain tumor. In this study, we investigated PBI-05204's underlying processes and potential for targeting GBM stem cells (GSCs). PBI-05204 therapy delayed the carcinogenesis of GBM9 xenografts and significantly reduced the number and size of tumor spheres formed by patient-derived GSCs (TS543, GBM9, and GSC28). Furthermore, GBM9 and GSC28 GSCs treated with PBI-05204 revealed a substantial decrease in the expression of NANOG and CD44, two key progenitor stem cell markers. In both GSC types, this therapy also decreased the expression of GRP78. Reduced spheroid size and CD44 were also seen in GBM9 and GSC28 GSCs that had GRP78 expression knocked down using GRP78 siRNA transfection. When PBI-05204 is combined with GRP78 siRNA, the number of spheroid cells is reduced much more than when GRP78 siRNA is administered alone. PBI-05204 treatment enhanced pRIP1K and pRIP3K expression, as well as RIPK1/RIPK3 binding in GBM9 and GSC28 cells, which was comparable to the results obtained in GRP78-silenced GSCs, showing that PBI-05204 triggered necroptosis. Furthermore, the principal active cardiac glycoside component of PBI-05204, oleandrin, has been shown to inhibit GSC self-renewal. These results demonstrate PBI-05204's potential as a viable option for the creation of innovative treatments that concentrate on GBM stem cells (29).

Because of its anti-inflammatory and neuroprotective properties, hemp seed (Cannabis sativa L.) and nigella sativa (black seed) have been utilized to treat a variety of chronic disorders. In an effort to advance research toward a preventative and curative strategy for this debilitating illness, we address a novel therapeutic approach to treating multiple sclerosis. An electronic search of published literature regarding the effects of hemp seed and Nigella sativa was used to conduct the article review. The preventative benefits of nigella sativa ingestion by MS patients can be therapeutic since it reduces the production of TGF β1 in rats, enhances remyelination, and suppresses inflammation. It is thought that using hemp seed as a medicinal plant to treat multiple sclerosis will boost AMPK, block the release of pro-inflammatory mediators in rat models, reduce NF-κB, and enhance the and NrF2 pathway (30,31). The goal of this study was to look into the possible advantages of a new piperine derivative (HJ22) for ibotenic acid (IBO)-induced neurological problems in rats, as well as the underlying processes. Our group produced HJ22, which displayed a high affinity for Keap-1 and the ability to activate the Keap1-Nrf2-ARE signaling pathway in vitro. It is noteworthy to note that HJ22 significantly decreased the cognitive impairment produced by IBO in the Morris water maze, Y-maze, and passive avoidance tests. Furthermore, HJ22 significantly decreased cholinergic dysfunction and neuronal morphological changes by inhibiting IBO-induced apoptosis. HJ22 was shown to have a significant influence on the interaction between Keap1 and Nrf2. This was followed by an increase in nuclear Nrf2 expression, which in turn prevented oxidative stress and the activation of the Nod-like receptor protein 3 (NLRP3) inflammasome that is mediated by Thioredoxin-interacting protein (TXNIP) (32).

Berberis vulgaris, often known as barberry or B. vulgaris, has been used in traditional medicine for a variety of applications. Berberine is one of the most common alkaloids found in B. vulgaris and other plants. Both B. vulgaris and berberine have been shown in several animal models and clinical investigations to have anti-inflammatory, antioxidant, and immunomodulatory activities. The goal of this research is to present an overview of the available evidence on the roles and processes of berberine and B. vulgaris in the regulation of immunological responses, oxidative stress, and inflammation. Vulgaris and berberine have been proven to have favorable effects in a variety of inflammatory, oxidative, and immune-related conditions, including diabetes, obesity, cardiovascular disease, neurodegenerative illnesses, autoimmune diseases, allergic diseases, and infections. To clarify the ideal dosages, safety profiles, and possible interactions between B. vulgaris and berberine with other medications or organic substances, additional research is necessary (33). This study investigated the effects of Melissa officinalis extract (MOE) on oxidative stress, inflammation, and neurotransmitters in the hippocampus of rats treated with pilocarpine (PILO). The findings suggested that Nrf2/HO-1 signaling was involved. Following an intraperitoneal injection of PILO, rats were treated with MOE for two weeks. MOE suppressed glial fibrillary acidic protein, lowered lipid

peroxidation, Cox-2, PGE2, and BDNF, and prevented neuronal death in PILO-treated rats' hippocampus areas. Furthermore, MOE elevated the levels of GSH and antioxidant enzymes, HO-1 mRNA and Nrf2 nuclear translocation, and hippocampus GSH in epileptic rats. In the hippocampal regions of epileptic rats administered MOE, glutamate and acetylcholine were reduced, whereas Na+/K+-ATPase activity and GABA were elevated (34).

## CONCLUSION

Neurological problems are among the highest in the world in terms of morbidity, disability, and death. They also seriously impair cognitive performance. The most common neurological disorders include cerebrovascular, neurodegenerative, autoimmune, spinal cord, intracranial tumour, and craniocerebral trauma. Due to the limits and potential side effects of conventional medicines, herbal remedies have been investigated as a viable treatment option for neurological illnesses. Alzheimer's disease is the most common neurodegenerative disorder that progresses over time in humans. It is characterized by senile plaques and neurofibrillary tangles, as well as progressive cognitive abnormalities, the most visible of which is memory loss. Given the etiology of AD, a variety of medical therapies, including both synthetic and natural techniques, are being used to treat the illness.Common herbal compounds used to treat neurological illnesses such as Alzheimer's, Parkinson's, and multiple sclerosis have been demonstrated to enhance both symptoms and cognitive performance. Quercetin, curcumin, anthocyanins, tea polyphenols, and other phenolic substances that have received insufficient attention can all alter Nrf2 via controlling a number of Nrf2 upstream activators. Terpenoids are another class of phytochemical substances that activate this pathway. They include carotenoids (astaxanthin, lycopene), diterpenes (ginkgolides), triterpenes (ginsenosides), and monoterpenes (aucubin, catapol). We want to update our knowledge of how important secondary metabolites for health activate the Nrf2 pathway with this review.

**Table 1: Herbals used in treatment of various neurological disorders with modulating NrF2 pathway**

| Sr. No | Plant Used | Name of Neurological Disorder | Mechanism of Action | Reference |
|---|---|---|---|---|
| 1 | ***Curcuma longa*** | Cerebral Injury | Enhancing Nrf2 may help to mitigate radiation-induced brain damage. | 9-10 |
| 2 | ***Ginkgo biloba*** | Parkinson's Disease | Ginkgolides and bilobalide enhance Nrf2 pathway, inhibit dopaminergic neuron loss, and reduce oxidative stress. | 11 |
| 3 | ***Camellia sinensis*** | Multiple Sclerosis | Epigallocatechingallate (EGCG) in green tea activates Nrf2, decreases inflammation, and protects myelin. | 12 |
| 4 | ***Withania somnifera*** | Huntington's Disease | Withaferin A upregulates Nrf2, reduces oxidative stress, and inhibits apoptosis. | 13 |
| 5 | ***Bacopa monnieri*** | Memory loss | Bacopamonnieri modulates neurotransmitters, enhances Nrf2 pathway, and reduces oxidative damage. | 14 |
| 6 | ***Panax ginseng*** | Neuroinflammation | Ginsenosides activate Nrf2, reduce infarct size, and protect against ischemia-reperfusion injury. | 15 |
| 7 | ***Rosmarinus officinalis*** | Treatment for neurological illnesses involves addressing amyloid-beta (A-β) | Rosmarinic acid activates Nrf2, reduces neuroinflammation, and protects motor neurons. | 16 |

| | | | | |
|---|---|---|---|---|
| | | accumulation, neuronal cell death, acetylcholinesterase (AChE), neuroinflammation, β-secretase (BACE-1) activity, and mitochondrial redox state. | | |
| 8 | ***Silybum marianum*** | Ischemic Stroke | Silibinin activates Nrf2, scavenges free radicals, and reduces oxidative stress. | 17 |
| 9 | ***Glycyrrhiz aglabra*** | Alzheimer's Disease | Glycyrrhizin activates Nrf2, reduces amyloid-beta toxicity, and attenuates neuroinflammation. | 18 |
| 10 | ***Salvia miltiorrhiza*** | Parkinson's Disease | Tanshinones activate Nrf2, protect dopaminergic neurons, and reduce oxidative damage. | 19 |
| 11 | ***Centella asiatica*** | Cognitive Decline | Asiatic acid activates Nrf2, enhances antioxidant defense, and improves memory function. | 20 |
| 12 | ***Moringa oleifera*** | Neurodegenerative Disorders | Isothiocyanates activate Nrf2, reduce oxidative stress, and provide neuroprotection. | 21 |
| 13 | ***Phyllanthus emblica*** | Alzheimer's Disease | Emblicanin A and B activate Nrf2, reduce oxidative damage, and improve cognitive function. | 22 |
| 14 | ***Zingiber officinale*** | Parkinson's Disease | Gingerol activates Nrf2, reduces neuroinflammation, and protects dopaminergic neurons. | 23 |
| 15 | ***Amaranthusp aniculatus, Grewia asiatica, Lyciumb arbarum, as well as phytochemicals including vitamin E, corilagin, curcumin, resveratrol, and ursolic acid*** | Anxiety and Depression | Eugenol activates Nrf2, reduces oxidative stress, and improves neurotransmitter balance. | 24 |
| 16 | ***Curcuma aromatica*** | Epilepsy | Curcumin activates Nrf2, reduces oxidative damage, and improves neuroprotection. | 8 |
| 17 | ***Hypericumperforatum*** | Cancer | Hypericin and hyperforin activate Nrf2, reduce oxidative stress, and modulate neurotransmitters. | 25 |
| 18 | ***Lavandulaangustifolia*** | Dementia induced by scopolamine In vivo/ inhalation | Linalool activates Nrf2, reduces oxidative stress, and provides SOD, Catalase increses | 26 |
| 19 | ***Passiflora incarnata*** | Insomnia | Antioxidant | 27 |
| 20 | ***Scutellariab aicalensis*** | Alzheimer's Disease | Baicalin activates Nrf2, reduces oxidative stress, and provides neuroprotection. | 28 |
| 21 | ***Nerium oleander*** | Glioblastoma | Oleandrin activates Nrf2, induces apoptosis in glioblastoma cells, and | 29 |

| | | | | |
|---|---|---|---|---|
| | | | provides neuroprotection. | |
| 22 | ***Cannabis sativa*** | Multiple Sclerosis | Cannabidiol activates Nrf2, reduces neuroinflammation, and protects against neurodegeneration. | 30,31 |
| 23 | ***Piper nigrum*** | Cognitive Decline | Piperine activates Nrf2, enhances memory function, and provides neuroprotection. | 32 |
| 24 | ***Berberis vulgaris*** | Neurodegenerative Disorders | Berberine activates Nrf2, reduces oxidative stress, and provides neuroprotection. | 33 |
| 25 | ***Melissa officinalis*** | Anxiety and Cognitive Decline | Rosmarinic acid activates Nrf2, reduces oxidative stress, and improves cognitive function. | 34 |

## ABSTRACT

Premature fusion of the cranial sutures, or craniosynostosis, necessitates precise imaging for prompt diagnosis, differentiation from deformational plagiocephaly, and suitable surgical planning. Although computed tomography (CT) is still the gold standard because it provides superior spatial resolution and 3D reconstruction, radiation exposure in newborns poses safety risks. Although it is more expensive, less accessible, and frequently requires sedation, magnetic resonance imaging (MRI), especially with more recent methods like black-bone and ultrashort echo time (UTE) sequences, offers a radiation-free substitute. Although its diagnostic accuracy varies with age and is operator-dependent, ultrasound is a quick, safe, and affordable bedside tool that is particularly helpful in infants. The most successful strategy is an integrated, multimodal one in which CT directs surgical planning and MRI and ultrasound are useful auxiliary modalities. Future developments, such as artificial intelligence-enhanced ultrasound, novel MRI sequences, and ultra-low-dose CT protocols, have the potential to improve diagnostic accuracy while lowering risks, enabling safer and more efficient treatment of craniosynostosis.

**Keywords:** Cranial sutures, Craniosynostosis, Computed tomography, Magnetic resonance imaging, Ultrasonography.

# INTRODUCTION

Skull lesions are usually asymptomatic and found accidentally during imaging that is done for other reasons. They can also be discovered while examining local symptoms or during staging tests for other diseases. In some cases, patients may show up with a noticeable lump or other symptoms. The patient's history and age are important factors in helping with the radiological diagnosis(1).Craniosynostosis (CSO) is a rare birth defect. It occurs when the cranial sutures fuse too early. This leads to abnormal skull growth and, in severe cases, cognitive issues because of restricted brain development. The most common subtype is sagittal craniosynostosis. This type happens when the sagittal suture ossifies early, resulting in an elongated head shape called scaphocephaly(2).The normal and abnormal sonographic appearances of cranial sutures have been described. However, ultrasound has not been widely used as a screening tool. In 2005, we introduced ultrasound as the main method for diagnosing craniosynostosis (CS). During the first year, we focused on educating paediatric neurologists and community paediatricians to help them understand this method. We presented the advantages and limitations of the approach at medical conferences, showing comparative images of normal sutures and craniosynostosis(3).Positional plagiocephaly is a change in skull shape that happens without the early fusion of cranial sutures. It results from external forces, either before or after birth, that distort the skull. Importantly, it occurs without any underlying structural problems. In contrast, craniosynostosis is a medical issue marked by the early closure of one or more cranial sutures in the skull, sometimes along with early closing of cranial fontanelles. Cranial sutures are fibrous joints that connect the skull bones, allowing the skull to grow outward as the brain develops. Fontanels are soft spots where the skull bones haven't fused yet. They provide necessary flexibility during birth and the first year of life, helping the skull adjust to the rapid growth of the brain(4).Craniosynostosis is a serious and relatively common condition that affects about 1 in 2,100 children. It occurs when cranial sutures fuse too early during childhood. The early closure of different major cranial sutures results in distinct head shapes, depending on which suture is involved. For instance, the premature fusion of the lambdoid suture leads to posterior plagiocephaly. In contrast, fusion of the sagittal suture causes scaphocephaly, which results in an elongated and narrow head shape. Coronal suture synostosis can cause anterior plagiocephaly or brachycephaly. Meanwhile, metopic synostosis often results in trigonocephaly, a triangular forehead deformity(5).

**Anatomy and Clinical Relevance of Cranial Sutures**

Cranial sutures are a type of fixed joint where neighboring bones are tightly joined by fibrous tissue. In the adult human skull, the cranial vault has 15 sutures. These include three unpaired sutures: the coronal, sagittal, and lambdoid sutures. There are also several paired sutures, such as the squamous, spheno-frontal, spheno-squamous, spheno-parietal, parieto-mastoid, and occipito-mastoid sutures(6). Cranial sutures are not straight lines; they twist and interlock. This structure strengthens the connections between adjacent bones and improves the protection of the brain inside. In newborns, these bones are not tightly fused; they remain separated by wide fibrous areas at the suture sites. This setup allows for movement and overlapping of bones during birth, which helps with passage through the birth canal. It also permits rapid brain growth, especially in the first year of life. At places where more than two bones meet, the gaps are larger and are called fontanelles. These fontanelles differ in size, with the anterior fontanelle being the largest(7).The skull serves several important roles that help each species succeed in its specific environment. It aids in capturing prey, eating, and breathing, while also safeguarding the brain and sensory organs needed for perception, such as vision and hearing. In vertebrates, neighboring cranial and facial bones connect through fibrous joints known as cranial sutures (Opperman, 2000). As joints, sutures consist of the fibrous connective tissue in between and the bone fronts that form new bone. These components stay linked and coordinated through the fibres, enabling growth and expansion(8).

**Imaging Modalities in Cranial Suture Evaluation**

**Computed Tomography**

The treatment of craniosynostosis is complex and usually requires surgery. This typically occurs between 3 and 12 months of age. Computed tomography (CT) imaging is a common method for checking the early fusion of cranial

sutures. However, rising public concern has brought attention to the risks of radiation exposure from CT scans. These risks include the possible development of leukemia and malignant tumors. This issue is especially important for craniosynostosis patients, as they receive radiation at a younger age and more often than typical children. Additionally, children are more susceptible than adults to the harmful effects of ionizing radiation. This is due to their greater organ sensitivity and longer life expectancy, which provides more time for radiation-related health problems to arise.(9)Traumatic brain injury (TBI) is a leading cause of disability and death worldwide. The most common causes of TBI are falls, vehicle accidents, work-related injuries, and physical assaults. TBI can result in serious and life-threatening complications, such as skull fractures, intracranial and orbital injuries, cerebrospinal fluid (CSF) leakage, cranial nerve palsy, and vascular injuries (brain hematomas). These conditions often require hospitalization and major surgery. The global annual incidence of TBI is estimated at 69 million cases, or 939 cases per 100,000 people. However, this figure may be uncertain and likely underestimates the true prevalence. In the U.S., statistics from 2019 to 2021 showed 223,135 hospitalizations and 69,473 fatalities related to TBI. This means that each day, 611 people are injured and 190 people die from TBI(10).

**Magnetic Resonance Imaging**

Craniometric traits within a population can be compared to genetic markers. Correctly identifying cranial sutures is crucial for finding important craniometric landmarks, like the bregma and lambda. These landmarks are used to take cranial vault measurements. Typically, researchers use caliper gauges, compasses, polemus, or more precise tools like the Microscribe to gather these measurements. In this study, we aimed to assess the effectiveness of standard MRI in locating cranial anthropometric landmarks and measuring cranial vault dimensions.(11)Magnetic Resonance (MR) imaging is a non-ionizing technique that offers better contrast resolution and shows higher sensitivity and specificity for parenchymal lesions compared to Computed Tomography (CT). Advanced MR techniques like diffusion-weighted imaging (DWI) and susceptibility-weighted imaging (SWI) provide extra diagnostic information and match well with clinical findings. Non-bleeding shear injuries and small microbleeds are usually detected more sensitively on MR imaging than on CT. However, the role of MR imaging in the initial diagnostic process for pediatric head trauma is still limited. This limitation may be partly due to longer acquisition times, the need for sedation, and the relatively low sensitivity of MR imaging for skull fractures. Recently, black bone MR imaging has been introduced as a new method for assessing structural bone abnormalities like craniosynostosis(12).

**Ultrasound**

Sutures define the edges between curved cranial bones. It can be difficult to see these sutures with a two-dimensional (2D) ultrasound. The diagnosis of craniosynostosis mainly relies on spotting related abnormalities or recognizing unusual cranial shapes. This approach does not directly show the early closure of sutures or fontanelles. Isolated craniosynostosis is, however, diagnosed less often before birth(13).During normal development, skull formation starts with the formation of ossification centers in the membranous anlage that surrounds the brain. From these centers, the calvarial bones grow through gradual ossification at their edges, and cranial sutures appear at the points where neighboring bones come together. While open, cranial sutures are the main areas for calvarial growth. Normally, the metopic suture fuses completely by about one year of age, while the sagittal suture stays open throughout childhood and usually closes between 22 and 24 years. If any cranial suture fuses too early, a condition called craniosynostosis occurs. This leads to an unusual head shape and may raise the risk of increased intracranial pressure. The early fusion process can begin as soon as 15 weeks of gestation in trigonocephaly and around 18 weeks in scaphocephaly(14).

**Radiation Concerns and Safety Considerations**

In 2006, about 380 million radiologic procedures were performed in the United States. This included 67 million computed tomography (CT) scans and 18 million nuclear medicine procedures. Notably, U.S. patients made up roughly half of all nuclear medicine procedures worldwide, even though they accounted for only 4.6% of the global population. This rise in imaging use has led to a sixfold increase in annual per capita radiation exposure. It grew from 0.5 mSv to 3.0 mSv between 1980 and 2006. In contrast, the natural background radiation dose has stayed fairly steady over the past 30 years at 2.4 mSv per year. To measure biological damage from radiation, the terms “sievert”

(Sv) and "rem" are now preferred. These terms adjust for absorbed radiation based on a tissue weighting factor. This is a shift from the older units "gray" (Gy) and "rad."(15)

**Role in Diagnosis of Craniosynostosis**

Craniosynostosis, also called cranial synostosis, craniostenosis, or simply synostosis, is a birth defect where one or more cranial sutures fuse too early. This early closure disrupts normal skull growth and often leads to unique skull shapes, facial asymmetry, and, in some cases, problems with brain development. The condition can show up as simple synostosis, where only one suture fuses, or as complex synostosis, which affects multiple sutures. It may occur as a primary issue, either in a standalone form or as part of a syndromic condition. It can also appear as a secondary issue due to underlying problems like metabolic, intracranial, teratogenic, or blood-related conditions(16).

**Future direction:**

Ultra-low-dose CT protocols

In one institution's study of pediatric craniosynostosis, routine brain CT was replaced with a low-dose protocol that used 100 kV, 10 mA, and iterative reconstruction. This allowed for high diagnostic confidence for suture evaluation while achieving effective doses of 0.06–0.22 mSv (up to 67-fold reduction)(17).

**Comparison of Direct CT and Black-Bone MRI**

BB-MRI and 3D-CT were compared in the preoperative assessment of craniosynostosis, demonstrating the usefulness of MRI in surgical planning procedures(18).

As an alternative to CT, black-bone MRI may effectively reveal patent and prematurely fused cranial sutures, which matches clinical findings and CT. Suture gaps look hyperintense, allowing for 3D reconstructions(19).

**AI-assisted ultrasound developments**

Future AI-assisted cranial suture ultrasound applications appear promising as AI-assisted ultrasound scanning demonstrates advancements in standard-plane detection, scanning guiding, and automated acquisition support(20).

## CONCLUSION

Early diagnosis and treatment of craniosynostosis depend heavily on the assessment of cranial sutures. Every imaging modality, including CT, MRI, and ultrasound, has advantages and disadvantages of its own. Though ionizing radiation concerns require careful use, especially in infants, CT is still the gold standard for accurate visualization and three-dimensional reconstruction of cranial sutures. MRI offers a non-ionizing substitute with increasing potential to replace CT in certain situations, particularly with newer techniques like Black-Bone, UTE, and ZTE sequences. However, problems with accessibility, expense, and the requirement for sedation still exist. For infants, especially those under a year old, ultrasound provides a first-line, safe, affordable, and easily accessible tool; however, its diagnostic accuracy is limited in older children and greatly depends on operator skill.

## ABSTRACT

Cervical spondylosis is osteoarthritis in the cervical spine's.it is a slowly progressive degenerative disorder that present a major therapeutic challenge in modern medicine because of its complex pathophysiology and wide range of clinical manifestation. Although treatment such as NSAIDs, physiotherapy and surgical intervention are commonly employed, they often provide only temporary relief and are associated with potential safety issue. Viddha-AgniKarma is an innovative Ayurvedic technique that integrates Viddhakarma(therapeutic needle piercing) with Agnikarma(heat cauterization) to reduce the pain through focused thermal stimulation.This method provides an alternative strategy for pain control, especially in chronic musculoskeletal disorder, by producing localized therapeutic effect without depending on medicinal drugs. This single patient case study describes a 30-years-old male diagnosed with cervical spondylosis who was treated with Viddha-Agnikarma therapy. His clinical features, such as pain, stiffness and limited neck movement, were evaluated using standardized and validated assessment tools. The main aim of the study was to assess the therapeutics effectiveness of Viddhakarma in the management of cervical spondylosis, with special emphasis on pain reduction, improvement in cervical range of motion, and enhancement of functional ability. The outcome showed marked improvement in pain level, reduction in stiffness and better cervical mobility, along with a significant decrease in pain intensity and functional impairment. These results indicate that Viddhakarma is serves as a safe, economical, and minimally invasive alternative to conventional pain management methods. This case study underscores the promising role of Viddhakarma in the treatment of cervical spondylosis and supports the need for further large-scale studies to confirm its efficacy and safety.

## INTRODUCTION

Cervical spondylosis is a degenerative condition of the cervical spine found almost universally in person over 50 years of age.it is a major therapeuticchallenge in modern medicine because of its complex pathophysiology and wide range of clinical manifestations. This aliment impacts the cervical spine's vertebrae, intervertebral discs, ligament, leading to periphery osteophyte formation [1] causing persistent neck pain, stiffness, nerve root irritation, abnormal sensation and neurological impairment. The incidence of cervical spondylosis rises with advancing age, affecting nearly 85% of people over the age of 60.[2] In Ayurveda, Cervical spondylosis is associated with Greeva Stambha or Manya Stambha resulting from accumulated Vata and Kapha affecting the cervicalvertebrae and discsand it's marked by pain, rigidity, and limited movement resulting from an aggravated Vata Dosha in the neck region. The concept of Vata Dosha, responsible for movement, communication and nerve function, is fundamental to understanding the disease's development from an Ayurvedic viewpoint.[3] Contemporary studies have identified multiple factor that increase the risk of cervical spondylosis, including a sedentary lifestyle, Neck injury, age, Occupation, genetic factors, and chronic conditions like diabetes and hypertension.[4]

Diagnosis is commonly confirmed through imaging method such as X-ray, CT scans, and MRI, which reveal typical features like bone spurs, osteophyte formation, discs degeneration. Treatment of cervical spondylosis usually involves a comprehensive strategy that includes medication, physical rehabilitation and sometimes surgery. Nevertheless, these standard treatments often offer only temporary relief and may carry notable side effects. Conversely, Ayurvedic treatment such as Snehan(oleation), Swedana(sudation), Nasya(nasal therapy), Basti(medicated enemas), Agnikarma(thermal cauterization) and Viddhakarma (piercing needle) have very effective in managing cervical spondylosis which is aggravation of Vata Dosha.[5]. Agnikarma is considered one of the most effective para-surgical procedures described for Vata-dominant painful musculoskeletal disorders.Among its various forms, Viddha-Agnikarma involves controlled therapeutic puncturing followed by application of heat at specific point, aiming to relieve pain, improve mobility and correct local Vata imbalance.it has very low recurrence rate and sustained therapeutic effect.[6]. This case study is designed to evaluate the therapeutic effect of Viddha-Agnikarma in a patient suffering from cervical spondylosis, with special emphasis on reduction of pain, improvement in functional ability, and enhancement of patient-reported quality of life. By assessing the effectiveness of Viddha-Agnikarma in the management of cervical spondylosis, the study intends to add valuable evidence to the expanding research on Ayurvedic treatment modalities for musculoskeletal conditions.

## MATERIALS AND METHODS

This was a forward-looking pilot interventional study carried out at shalya department of Quadra institute of ayurveda & hospital, Roorkee with the objective of assessing the clinical effectiveness of Viddha-Agnikarma in the management of cervical spondylosis.

A. Patient Selection
   A compressive screening procedure was undertaken to identify a patient presenting with the classical clinical feature of GreevaStambha (cervical spondylosis). Strict inclusion and exclusion criteria were followed to ensure that only a patient with a confirmed diagnosis of cervical spondylosis was selected for the study.
B. Inclusion: The study enrolled patient between 24 and 60 years of age, regardless of gender, who exhibited classical signs and symptoms of GreevaStambha for minimum duration of two months. Patient was selected if their pain had not responded adequately to conventional therapies, including Non-steroidal, Anti-inflammatory Drugs(NSAIDs), physiotherapy, or other non-surgical pain management approaches.
C. Exclusion criteria: Patient suffering from Rheumatoid arthritis(RA) or other musculoskeletal disorder, those with uncontrolled diabetes mellitus(DM) or hypertension(HTN), individuals having systemic diseases or anatomical abnormalities, and women who are pregnant or lactating were considered under Exclusion category.

**Case Report**

A 32-year-old Male patient reported with complaints of continuous neck pain and stiffness that radiated to both upper limbs, associated with tingling sensation and limitation of neck movement. He was an office employee whose work involved long hours of computer use.

**History of Present Illness**

The patient developed symptoms two months before consultation, initially experiencing occasional neck discomfort that gradually worsened into persistent, dull aching pain. He also had episode of sharp pain radiating to the shoulder and upper limbs, along with morning stiffness lasting more than 30 min. The increasing restriction in cervical mobility and difficulty in carrying out routine activities, such as turning his head while driving, led him to seek medical care. There was no prior history of trauma, fracture, or surgical procedure. The patient had no known chronic illness such as diabetes, hypertension, or autoimmune disorder. Additionally, there was no history of previous spinal disorder or inflammatory arthritis.

**Lifestyle and Habitual Pattern**

The patient follows a mixed diet with irregular meal timing and leads a predominantly sedentary lifestyle with minimal physical activity. Due to long hours of desk work and poor ergonomic posture, there is added strain on the musculoskeletal system. Sleep is often disturbed as a result of pain and discomfort. There is no history of addiction, and the patient does not use tobacco or consume alcohol.

**Clinical Examination**

**General examination**

The patient was fully conscious, alert, and well oriented.

Vital parameter was within normal limits, with a blood pressure of 130/90 mmHg.

Pulse rate of 76 beats per minute and body temperature of 98.6°F. There were noclinical indication of systemic disease or infection.

**Local examination**

- On inspection, the spinal curvature was within normal limits, with no observable deformity, swelling, injury, or surgical scars.
- On palpation,a mild increase in local temperature was noted along with tenderness in the cervical region.
- Assessment of cervical movement revealed that active range of motion were painful during flexion, extension, and lateral rotation.

**Test**

1. **Spurling test positive -** with cervical compression eliciting an increase in neck pain accompanied by radicular radiation into the upper extremity.
2. **Ihermitte's sign-**As flexion of the cervical spine produced an electric shock-like sensation radiating into the upper limbs.

**Dashvidha Pariksha**

**Parameter Assessment**

1. **Dosha -** Vata & Kapha Dosha.
2. **Dusya -** AsthiDhatu, Majja Dhatu &Snayu.
3. **Prakriti -** Vatta-Kapha Prakriti.
4. **Sara –** Madhyama,Asthi&Majja Sara.
5. **Samhanan -** Madhyama Samhana.
6. **Pramana–**Height; 5'3", weight – 52, BMI: 24(within normal range).
7. **Satmya-** Madhyama.
8. **Satva -** Madhyama Satva.
9. **Ahara shakti -** Reduce appetite at times, heaviness after meal.

**10. Vyayama shakti -** Heena Vyayam Shakti.

**2.Asthvidha Pariksha**
**1. Nadi Pariksha -** Vata Pradhan + Kapha Anubandh
**2.Mutra Pariksha -** Normalquantity but pale or slightly concentrated.
**3.Mala Pariksha –**Constipation or incomplete evacuation
**4.Jihva Pariksha –**White/Slightly thick coating
**5.Shabda Pariksha –**Low energy voice sometimes heaviness or fatigue while speaking
**6. Sparsha Pariksha –**Neck region: Cold to touch+ Stiffness.
**7. Drik Pariksha(Eye) –**Dry eyes, Eye Strain, Mild redness sometimes.
**8.Akruti Pariksha (Body,structure & Posture) –**Forward head posture, rounded shoulder & stiff neck movement.

**Radiological Findings**
The x-ray of the cervical spine(fig no. 1) shows a straightening of the normal cervical curvature, indicating a loss of cervical lordosis. There is evidence of bony outgrowths (osteophyte) present at the C4 to C6 vertebral level, along with a reduction in the intervertebral disc space. These radiological findings are consistent with degenerative change in the cervical spine and are suggestive of cervical spondylosis.

**Assessment criteria**

**Plan of Work:**
A seven-days treatment protocol was formulated, whereinViddha-Agnikarma therapy was administrated on alternate days, namely on the 1st, 3rd, and 5th days. No specific dietary restriction or therapeutic dietary interventions were advised during the course of treatment.

**Study Procedure**
**Purva Karma (Pre procedure preparation)**
After Detailed examination of the patient and confirmation of diagnosis procedure with benefits, and possible complications was explained to the patient and informed consent was taken.
Identified and marked the most tender points(maximum pain point) over the cervical and paracervical regions.
The patient is made to sit in a comfortable position with proper support to the neck.
Necessary instrument such as Agnikarma Shalaka(Rajat Shalaka), needle(for viddha), candle,cotton, antiseptic, and soothing agents like Ghritawere ready.

**Pradhan Karma(main procedure)**
The Agnikarma Shalaka is heated until it becomes red hot.
First, Viddha Karma is performed: a sterile needle is gently pricked at the selected tender points to create a micro-opening. [Fig. No.2 (a)]
Immediately after this, AgniKarma is done by touching the heated Shalaka over the same points or just adjacent to the needle puncture site for a fraction of second. [Fig.No. 2 (b)]
Multiple dots(Bindu type AgniKarma) are applied in a systematic manner, maintaining adequate distance between each point.[7]
Care is taken to avoid excessive depth or prolonged contact to prevent deep burns.
The patient's tolerance and comfort are continuously monitored during the procedure.

**Paschat Karma(Post procedure)**
Applied Ghrit over the treated area to soothe the skin and promote healin.[8]
Keep the area clean and dry: advise the patient not to scratch or disturb the sites. Light banding can be done if necessary. The patient is advised to avoid cold exposure, excessive neck movement, heavy work, and improper

posture for few days. Pathya-Apathya(dietary and lifestyle advice) is given, including warm, easily digestible food and avoidance of cold, oily, and heavy lentils.

**Follow-up and course of treatment**

Three sittings of the same procedure were given on alternate days. Along with Viddha-Agnikarma, supportive therapies such as mild neck exercise, proper ergonomics were advised.

**Therapeutic Effect**

Viddha- Agnikarma works by relieving pain, relieving stiffness, improving local circulation, pacifying Vata-Kapha dosha, and removing Srotorodha (obstruction), thus providing effective relief in cervical spondylosis.

## RESULT

The procedure provides significant relief in pain and stiffness and improves functional mobility of the neck, sustained results and not observed adverse effect. The therapeutic efficacy of Viddha-Agnikarmais attributed to its Usna,Tiksna, and Suksma Guna, which pacify vitiated Vata, promote Srotoshodhana, and facilitate VataAnulomana in the Greeva region. Classical references from Charak and Sushrut Samhita support the use of Agnikarma in pain-dominant Vata-Kapha disorder, particularly those involving Snayu, Sandhi, and Asthi. The patient reported improvement in sleep quality and was able to resume occupational duties without functional limitation. No adverse effects or complications were observed during or after the procedure. Thus, Vidhha-Agnikarmacan be considered as a cost-effective, minimally invasive, and clinically beneficial modality for the management of GreevaStambha.

## DISCUSSION

Cervical pain, comparable to Geerva Shoola or Greeva Stambha in Ayurveda, is a primarily a Vata Pradhan Vyadhi, often associate with Kapha due to degenerative and structural changes. It is characterized by Shula, Stambha, and Greeva Gati Avarodha, caused by the localization of vitiated Vata in Snayu, Sandhi, Asthi, and Majja Dhatu of the cervical region. Acharya Charak identifies 'Vata' as the principle cause of pain.[9] Acharya Sushrut has emphasized Agnikarma as an effective treatment for chronic pain-dominant Vata-Kapha disorder, particularly involving Snayu, Sandhi, and Asthi, and states that diseases treated with Agnikarma do not recur.[10]. Viddha-Agnikarma, a modified form of Agnikarma, enables precise and controlled thermal stimulation through needle puncture, faciliating deeper action on Snayu Gata and Sandhi Gata Vata in the Greeva region with minimal tissue injury. The Usna, Tikta, and Sukshma of Agni counteract the Shita and Usna Guna of Vata, thereby reducing pain and stiffness. The procedure enhance local blood flow, clears Srotorodha, and stimulates Dhatvagni, promoting functional restoration of affected tissue. Form a modern prespective, the thermal stimulus can modulate nociceptive pathway, reduce inflammatory mediators, and activate pain inhibitory mechanisms. Thus, Viddha-Agnikarma produces rapid analgesic and functional improvement, making it effective modality in the management of cervical spondylosis.

## CONCLUSION

The present case study demonstrates that Viddha-Agnikarma is an effective Ayurvedic intervention in the management of cervical spondylosis. Significant improvement was observed in pain intensity, stiffness, and cervical mobility, as evidenced by objective clinical assessment. The findings suggest that Vidda-Agnikarma can be considered a safe minimally invasive and clinically beneficial therapeutic modality for cervical spondylosis. However, further studies with a large sample size are required to establish the efficacy of this intervention.

**ABSTRACT**

Plastic waste production has produced dire environmental and disposal challenges as a result of the rapid growth in waste production. Meanwhile, the traditional bituminous pavements are generally subject to premature failures because of the heavy traffic loads and variations of temperatures. The purpose of this experimental research is to establish the possibility of using waste plastic as a partial substitute of VG-40 grade bitumen in flexible pavements. The replacement of the bitumen by waste plastic was done at 2.5% and 5%, 7.5% and 10% weight. The tests carried out in the laboratory on modified bitumen samples included: penetration, softening point, ductility, flash and fire point as well as stripping value test. Such aggregate tests as impact value, crushing value, and abrasion value were also conducted. The findings reveal that the plastic modified bitumen enhances the strength, temperature resistant and durability hence it is appropriate in sustainable road construction.

**Keywords:** Waste plastic, VG-40 bitumen, flexible pavement, penetration test, sustainable roads

## INTRODUCTION

One of the most significant parts of infrastructure development is road transportation because it is associated with the economic and social development of a state. Flexible pavements are popular in India because of their low-cost at the beginning stage, ease in construction, and flexibility to change in terms of traffic loads and climatic conditions (Barmade et al., 2022). Flexible pavements are composed of layered systems where bitumen is the major binding agent, which presents flexibility and load distribution. Nevertheless, as the amount of traffic, loads on the axle, and extreme variations in the temperature rise exponentially, the traditional flexible pavements tend to fail prematurely

including rutting, cracking, stripping, and formation of potholes. Such failures lead to a high cost of maintenance and short life of pavement(Chavan, 2013).

Bitumen is a viscoelastic substance, the nature of which is very temperature-sensitive. When heated, bitumen becomes soft and easily deformed whereas when cooled it becomes brittle and liable to crack(Hirekhan, 2023). Traditional bitumen does not usually satisfy the performance criteria of new roads with heavy traffic, in particular in the areas with hot climatic conditions. In order to counter these shortcomings, a number of techniques of modification have been embraced such as polymers, rubber, and chemical additives to enhance the mechanical and longevity characteristics of bituminous binders(Mannar et al., 2021). Meanwhile, plastic waste management has already become one of the significant environmental issues. Plastics find wide applications in packaging, household and industrial applications owing to its strength and low cost. Plastic materials on the other hand are not biodegradable and may take a number of several hundreds of years to disappear in the environment(Wang et al., 2022). The poor management of plastic waste, in the forms of open dumping and burning, causes pollution of soil and water, drainage system blockage, and emission of harmful gases, which are dangerous to the environment and human health. Hence the proper use of waste plastic has become an issue of concern on sustainable development(Ameur et al., 2025).

The construction of waste plastic into flexible pavements has received considerable attention as a new and environmentally friendly alternative(Hasan, 2020). The use of waste plastic in bitumen offers a two-fold benefit of enhancing the performance of pavements and also solving the plastic waste disposal problem. Polyethylene and polypropylene are thermoplastic in nature and can be softened through heating and then a combination can be made with bitumen or a coating around the aggregates to produce a better bond and resistance to moisture damage(Mashaan, 2022). Normally, plastic-modified bitumen has a higher softening point and low penetration values, which implies that it is more resistant to deformation at high temperatures. VG-40 grade of bitumen is usually applied in heavy-duty pavements that experience high number of traffic and high temperatures. It is suitable on the highway and industrial roads because of its increased viscosity and stiffness(Chavan, 2021). VG-40 bitumen can be further enhanced with the addition of waste plastic to strengthen it, increase durability and stability at temperature. But too much plastic may cause the stiffness to be excessive to an acceptable degree, and result in brittle. It is therefore important to come up with the optimal rate of plastic replacement.

The proposed study is based on an experimental research to examine the possibility of waste plastic as a partial substitute of VG-40 bitumen in flexible pavements. The incorporation of waste plastic is done at a replacement level of 2.5%, 5%, 7.5% and 10% weight of bitumen. Penetration, softening point, ductility, flash and fire point and stripping value are some of the laboratory tests that are used to test the workability of plastic-modified bitumen. The outcomes of the present research should be used to justify sustainable road construction activities and proper management of the plastic waste.

The overall aim of this experimental research is to determine the practicability and efficiency of waste plastic as a partial substitute of bitumen in the construction of flexible pavements. The objectives of the study are the following particular ones:

1. To research the influence of waste plastic addition to the physical and mechanical properties of VG-40 grade bitumen.
2. To investigate the change of penetration, softening point, ductility, flash point and fire point of bitumen with various content of waste plastic.
3. To test the strip value parameter of the plastic-modified bitumen using the stripping value test.
4. To determine the appropriateness of the aggregates to be used in the study by undertaking aggregate impact value, aggregate crushing value and abrasion tests.
5. To establish the comparison of performance between the conventional and plastic-modified bitumen on replacement levels of 2.5, 5, 7.5 and 10.

6. To establish the best proportion of waste plastic, which would give better strength, durability, and temperature resistance without negatively influencing flexibility.
7. To encourage sustainable and environmentally friendly pavement construction through the use of waste plastic as an alternative material in road construction.

**Materials Used**

The components of this experimental study are the bitumen, waste plastic and aggregates. To make all materials reliable and consistent in the results, all materials were chosen and tested according to the relevant Indian Standard (IS) specifications.

**Bitumen**

In this study, VG-40 grade bitumen was taken as the binding material. VG-40 is a paving grade bitumen with a high viscosity value that is recommended to be used in pavements that experience high temperatures, highways, expressways, and heavy traffic roads. It has higher deformation and rutting resistance in comparison to lower grades of bitumen. VG-40 is more rigid and viscous hence fitting in the tropical climatic environments where the pavement temperatures are very high. Before and after the modification with waste plastic, the basic properties of the bitumen were tested on penetration, softening point, ductility, and flash and fire point.Aggregates of nominal sizes 4.75 mm and 2.36 mm were used throughout the experimental investigation.

**Waste Plastic**

In this study, waste plastic was made up of discarded plastic carry bags, milk covers, packaging material and plastic wrappers, which were found in the local areas. These plastic wastes are either thermoplastics like low-density polyethylene (LDPE) and high-density polyethylene (HDPE) that soften on heating and can easily be mixed with bitumen. Plastic waste collected was properly washed to get rid of dust and impurity, dried and shredded into small pieces of about 24 mm. The plastic materials were shredded and used as a partial substitute of weight of bitumen in the proportions of 2.5%, 5%, 7.5% and 10%.

**Aggregates**

The current experimental study used crushed stone aggregates. Aggregates constitute the large part of the flexible pavements and contribute greatly in terms of load distribution, strength and the overall performance of the pavement. The aggregates of the local quarry were gathered in a local quarry source, washed and dried with air and then utilized. To prepare bituminous mixtures, aggregates of 4.75 mm and 2.36 mm sizes were picked and they are normally used in bituminous wearing courses. These aggregate volumes guarantee even coating of bitumen and make it possible to interact with waste plastic efficiently in the course of mixing. Correct grading of aggregates will help in enhancing stability, durability and bonding properties of the bituminous mix.

In order to determine the appropriateness of aggregates in the construction of pavements, standard laboratory tests were carried out in compliance with the relevant Indian Standard specification. To measure toughness, Aggregate Impact Value Test was conducted, load-bearing capacity was measured under the Aggregate Crushing Value Test, and wear and abrasion resistance was checked by Los Angeles Abrasion Test. The outcome of these tests proved that the aggregates utilized in this study were appropriate in being used in flexible pavement applications.

**Water**

Stripping value tests and other laboratory tests were done using clean potable water that was void of impurities. Water quality is also significant when it comes to consideration of moisture susceptibility of bituminous mixes.

## METHODOLOGY

The approach taken to this experimental study aims at assessing the influence of the use of waste plastic as a partial replacement of VG-40 grade bitumen to the flex pavements. The experimental program was conducted in a systematic way which entailed the collection of materials, preparation of plastic-modified bitumen and lab testing of both bitumen and aggregates.

**Collection and Preparation of Materials**

VG-40 grade bitumen was procured from an authorized supplier and stored under recommended conditions. Waste plastic materials such as carry bags, milk covers, and packaging plastics were collected from local sources. These plastics were cleaned thoroughly to remove dust, dirt, and other impurities, and then air-dried. The cleaned plastic waste was shredded into small pieces of size approximately 2–4 mm to ensure uniform mixing with bitumen. Crushed stone aggregates were collected and prepared as per standard specifications for laboratory testing.

**Preparation of Plastic-Modified Bitumen**

This study embraced the use of the wet process in the preparation of plastic-modified bitumen. VG-40 bitumen was heated in a temperature range of 160-170 o C until it reach a liquid state. The waste plastic was shredded before gradually being added to the hot bitumen and this was done with constant stirring to ensure equal blending. Bitumen was partially replaced by plastic in content of 2.5%, 5%, 7.5%, and 10% or one-tenth of the weight of bitumen. It was mixed until a uniform and uniform plastic-modified bitumen was formed.

**Testing of Aggregates**

Aggregates were also subjected to tests to verify their appropriateness to be used in construction of pavements before bitumen tests were carried out. The tests conducted below were conducted as per Indian Standard (IS) specifications:

- For measuring the toughness of aggregates, there is the Aggregate Impact Value Test.
- Aggregate Crushing Value Test to test load bearing power.
- Abrasion Test to evaluate the resistance to the wear and tear.

These tests were able to guarantee that the aggregates employed in the study were strong and durable enough.

**Testing of Conventional and Plastic-Modified Bitumen**

Conventional VG-40 and plastic-modified bitumen were subject to laboratory tests to determine how the physical and performance property of the material changed with the addition of the plastic.

**Penetration Test**

The penetration test was conducted to find out the hardness and consistency of bitumen. The experiment was run at 25$^{o}$C, applying a load of 100g upon the standard needle in 5 seconds.

**Softening Point Test**

To test the softening point of bitumen we used the ring and ball apparatus to find the temperature of bitumen when it softens. The test is used in evaluating the sensitivity of temperature of the binder.

**Ductility Test**

The ductility test was done to determine the elongation ability of bitumen before breaking. To measure the flexibility characteristics, the test was done at 27$^{o}$C.

**Flash and Fire Point Test**

Standard equipment was used to run flash and fire point tests and identify the temperatures of the bitumen vapors to ignite temporarily and continue to burn respectively. These analyses show that bitumen is safe and the temperature is not fluctuating during the process of construction.

**Stripping Value Test**

A stripping value test was done to determine the moisture susceptibility of the bitumen by determining the extent of the bitumen coating left on the aggregates after being immersed in water.

**Analysis of Results**

All laboratory tests were performed and their results analyzed. The plastic-modified bitumen performance at varying replacement levels was compared to the conventional VG-40 bitumen. It is on this comparative analysis that the best percentage of waste plastic was discovered to give a better strength, temperature resistance and durability.

**Experimental Results and Discussion**

The chapter shows the findings of the lab experiments that were done with conventional VG-40 bitumen and plastic-modified bitumen at 2.5%, 5%, 7.5% and 10% replacement. The influence of the use of waste plastics on the physical qualities of bitumen and the appropriateness of aggregates is elaborated.

**Results of Tests on Aggregates**

The cumulative value of 18.6% represents high toughness and ability to withstand impact loads that are not predictable. The crushing value of 21.4% provides evidence on the sufficient load bearing capacity and the abrasion value of 23.8% provides evidence on the adequate resistance to wear and tear. All the values are within the acceptable range, which proves that the aggregates employed to construct flexible pavements are the right ones.

**Results of Tests on Bitumen**

**Penetration Test Results**

Penetration value continues to fall as the percentage of plastic content rises. This decrease means that it has become hard and stiffening the bitumen. Reduced values of the penetration imply higher resistance to deformation during high traffic loads. Nonetheless, too high penetration at 10% plastic content signals that it was more rigid and this can influence flexibility.

**Softening Point Test Results**

There is an increment in the softening point with the increase in plastic content, which suggests that it is less likely to be exposed to high temperatures. The improvement minimizes chances of rutting during hot climatic conditions. This rise goes up to 7.5% of plastic content, which demonstrates enhanced temperature stability of the binder.

**Ductility Test Results**

The higher the plastic content, the lower the ductility values and this means that the capacity of the elongation reduces. Though the decrease in ductility signifies the increase in stiffness, the level of ductility to 7.5% replacement is within acceptable levels of pavement use. Ductility decreases considerably at 10% plastic content and this can lead to brittle behaviour with repeated loading.

**Flash and Fire Point Test Results**

The addition of flash and fire points with plastic implies that it is safer when handling and mixing. Increase in the ignition temperatures minimized the chances of fire hazards and improved thermal stability of the binder in construction.

**Stripping Value Test Results**

With increase in plastic content, the stripping value is lower, which means that there is better adhesion of bitumen and aggregates. Plastic coating makes it water resistant and less prone to damage by moisture. This characteristic is desired most in areas that receive excessive precipitation.

**Overall Performance Evaluation**

Based on the results of the experiment, it is clear that waste plastic enhances mechanical and durability of VG-40 bitumen. A higher softening point and flash point improve temperature resistance and a lower penetration and stripping value increases strength and moisture resistance. Nonetheless, high plastic contents result in decreasing ductility and high stiffness.According to the relative weight of strength, flexibility and durability, the percentage of waste plastic replacement is found to be 7.5% that can be used in flexible pavement work.

## CONCLUSION

- The plastic waste can be successfully utilized as the alternative to the VG-40 grade bitumen partially in the construction of flexible pavement.
- Aggregate impact value, crushing value, and abrasion value has met the requirements of Indian Standard, and it proved that the aggregates utilized in the study were appropriate.
- The deeper the content of the plastic, the lower the values of penetration, as a result, the stiffer and the higher the resistance to deformation at the heavy traffic loads.
- The values of softening points were also greatly enhanced when waste plastic was added that contributes the high-temperature performance of the bitumen and decreases the possibility of rutting.
- The values of ductility were minimized as the amount of plastic content rose and this indicates more stiffness but at least 7.5 percent of plastic substitution was tolerated.
- Plastic modification also resulted in higher flash and fire point temperature, which is a sign of enhanced safety and thermal stability during heating and construction processes.
- The loss of value was lessening significantly with plastic content and it showed improved adhesion between bitumen and aggregates and high resistance to moisture.
- Out of all the levels of replacement that were carried out, 7.5 percent waste plastic weight of bitumen was defined to be the most appropriate level of material since it offered a good mix of strength, flexibility, temperature resistance and durability.
- Waste plastics when used in the bituminous pavements help in the construction process that is sustainable through environmental pollution reduction and effective management of plastics waste.
- Bitumen that has been modified with plastic is a cost effective and ecological alternative to building durable flexible pavement particularly in high traffic areas and high temperatures.

Although the present study depicts the use of waste plastic in the manufacture of bitumen to its benefit, further research can also be carried out to ensure that it is more applied. The behaviour of plastic-modified pavements under the real traffic and environmental conditions is also to be researched in the long run to see the performance of these pavements. The fatigue behavior, aging properties and rutting performance can be studied in future research using advanced methods of testing. It is also possible to study the influence of different types of plastic waste and combinations. In addition, environmental impact assessment and cost-benefit analysis can be conducted in order to support the application of the large-scale one. The studies will help in establishing of uniform sets of guidelines on the extensive use of plastic-modified bitumen in the construction of flexible pavements.

## ABSTRACT

Multiply-Accumulate (MAC) blocks are essential elements in digital signal processing (DSP) platforms, yet they dominate power draw in high-throughput scenarios. This paper introduces a configurable approximate MAC design that combines a truncated multiplier with a carry-cut approximate adder to deliver energy-efficient operation. The architecture permits adjustment of truncation and approximation degrees, offering a tunable compromise between precision and power reduction. Benchmarks on FIR filters show that the proposed approximate MAC can cut energy consumption by as much as 15.4%, with a Mean Absolute Error (MAE) of 25.89, a Mean Relative Error of 9.9%, and a Signal-to-Noise Ratio (SNR) of –8.75 dB under aggressive approximation. Error analysis and simulations indicate that modest approximation levels markedly lower power while preserving acceptable signal quality. These findings confirm the suitability of approximate MAC units for low-power DSP, edge computing, and neural-network accelerators, presenting a viable approach for energy-limited digital systems.

**Keywords:** Approximate Computing, MAC (Multiply-Accumulate) Architecture, Low-Power Digital Signal Processing, Reduced-Precision Multiplier, Carry-Cutting Adder

# INTRODUCTION

Digital signal processing (DSP) serves as a fundamental pillar of contemporary electronics, supporting tasks like image and video handling, audio filtering, communications, and neural-network inference. The Multiply-Accumulate (MAC) operation, which carries out a multiplication and then adds the result, lies at the heart of the majority of DSP algorithms. MAC blocks are widely employed in digital filters, convolutional neural networks, and matrix calculations. Nevertheless, conventional MAC units demand heavy computation, draw considerable dynamic power, and take up a large silicon footprint, especially in high-speed, high-throughput designs. With the rise of energy-restricted devices—like Internet-of-Things (IoT) sensors, smartphones, and edge AI accelerators—cutting the power and energy use of MAC units has turned into a vital design issue. Traditional methods concentrate on refining exact computation via voltage scaling, low-power circuit design, and clock gating, yet these strategies often have limited capacity for further energy savings. An emerging approach is approximate computing, which exploits the error tolerance built into many DSP applications. In approximate computing, some computational errors are accepted in return for lower power, area, and latency. In particular, approximate MAC designs create controlled inaccuracies by employing methods like truncated multipliers that discard the least-significant bits (LSBs) of operands, and carry-cut adders that restrict carry propagation during addition. These changes decrease switching activity and critical-path delay, thus reducing energy use.

This study introduces a configurable approximate MAC architecture for DSP applications, offering a balance between power efficiency and computational precision. The design enables adjustable truncation and adder approximation levels, making it appropriate for a broad spectrum of error-tolerant uses. The architecture is assessed with FIR filter benchmarks, and performance indicators such as Mean Absolute Error (MAE), Mean Relative Error (MRE), Signal-to-Noise Ratio (SNR), and projected energy savings are examined. Results show that approximate MAC units can deliver significant energy reduction while preserving acceptable accuracy, positioning them as a practical solution for low-power, high-throughput digital systems.

**Problem Description**

Multiply-Accumulate (MAC) units serve as essential components in digital signal processing (DSP) systems, executing millions of operations each second in tasks like FIR/IIR filtering, convolutional neural networks, and image/video processing. However, conventional precise MAC units consume a lot of power because of the intricate multiplication and full-width addition processes, particularly in high-throughput and resource-limited settings.

In edge devices, IoT sensors, and mobile apps, the substantial power draw of traditional MAC blocks curtails performance efficiency and shortens battery lifespan. At the same time, numerous signal-processing tasks naturally tolerate minor computational inaccuracies, indicating that modest approximations can be employed without markedly degrading output quality.

The task is to develop a MAC architecture that can:

1. Decrease energy usage and dynamic power in digital signal processing circuits.
2. Ensure computational precision stays within acceptable bounds for signal processing tasks.
3. Provide adjustable approximation settings to manage the compromise between energy efficiency and output fidelity.
4. Facilitate straightforward incorporation into digital hardware platforms like ASICs, FPGAs, or edge accelerators.

Current MAC implementations either concentrate exclusively on precise calculation (causing high power consumption) or employ static approximation schemes that lack adjustable energy-accuracy balances. A flexible, power-saving MAC structure is required, one that leverages approximation methods such as truncated multipliers and carry-cut adders while measuring their effect on precision and energy use.

**Investigation Gap**

Multiply-Accumulate (MAC) blocks are the core of digital signal processing (DSP) and AI accelerator designs, yet their substantial power draw and silicon expense pose major obstacles. Although numerous investigations have examined approximate computing methods to cut energy use and chip area, a thorough literature survey uncovers a number of shortcomings:

1. Limited Configurability: Several current approximate MAC implementations employ constant truncation or preset adder approximation degrees, offering minimal adaptability for various uses. This restricts the capacity to adjust the energy-accuracy balance according to particular signal-processing needs.
2. Lack of Quantitative Energy-Accuracy Analysis: Although approximation methods lower switching activity and footprint, only a handful of investigations report concrete figures like Mean Absolute Error (MAE), Mean Relative Error (MRE), Signal-to-Noise Ratio (SNR), or projected energy reductions for actual DSP tasks. The majority of research stays theoretical or limited to simulations, failing to link hardware-level approximation with signal-processing outcomes.
3. Application-Specific Evaluation: Current designs frequently aim at universal applications and fail to assess approximate MAC units within real-world DSP scenarios like FIR/IIR filtering, convolution, or neural-network inference. Consequently, the effect of approximation on actual signal fidelity is still insufficiently investigated.
4. Trade-off Optimization: Research on interactive or systematic examination of the energy-accuracy trade-off is scarce. Designers find it difficult to pinpoint the best mix of truncation and adder approximation for a particular application.

**Goals of the Research**

The main goal of this work is to create and assess a configurable approximate Multiply-Accumulate (MAC) architecture that enables energy-efficient digital signal processing (DSP) while preserving acceptable computational precision. This research seeks to overcome the shortcomings of current MAC designs and deliver a practical approach for low-power, high-throughput digital systems.

The particular objectives are:

- Develop a configurable approximate MAC architecture:
  - Design a MAC block that utilizes a truncated multiplier together with a carry-cut adder.
  - Enable variable truncation and adder approximation settings to balance the energy-accuracy trade-off.
- Assess Accuracy Metrics:
  - Measure the effect of approximation with Mean Absolute Error (MAE), Mean Relative Error (MRE), and Signal-to-Noise Ratio (SNR).
  - Examine how varying truncation and approximation levels influence output fidelity.
- Estimate Energy and Power Savings:
  - Create a digital energy estimation model for the approximate MAC unit.
  - Calculate the proportion of energy reduction obtained relative to an exact MAC design.
- Emulate DSP Applications:
  - Use the approximate MAC unit for FIR filter benchmarks and other signal processing workloads
  - Evaluate the practical effect of approximation on real DSP signals
- Examine Energy-Accuracy Trade-Off:
  - Create interactive graphs of error versus truncation levels.
  - Determine the best configuration settings that boost energy efficiency while keeping accuracy within acceptable limits.
- Offer a Structure for Deploying Digital Systems:
  - Make sure the design is hardware-compatible, appropriate for deployment on ASICs, FPGAs, or edge accelerators.
  - Enable incorporation into low-power digital platforms.

## LITERATURE REVIEW

Rising demand for energy-efficient, high-speed digital systems has spurred considerable investigation into approximate computing, especially regarding Multiply-Accumulate (MAC) modules, which account for the bulk of computational power consumption in digital signal processing (DSP) and neural-network accelerators.

Traditional MAC Architectures

Conventional MAC blocks use exact multipliers and full-width adders to obtain accurate computation. Configurations such as array multipliers, Booth multipliers, and Wallace-tree multipliers provide high throughput and precision, yet they increase silicon area, power usage, and latency. Research [1][2] shows that in DSP-intensive tasks, MAC units may draw over 50 % of the total power, emphasizing the requirement for optimization.

Inexact Multipliers

Approximate multipliers seek to lower power consumption by discarding certain partial products or truncating LSBs. Methods include:

- Truncated Multipliers: Discard the low-order bits of the inputs to ease the calculation of partial products. Reported reductions in power consumption and silicon area reach as much as 30-40% [3].
- Segmented/Logarithmic Multipliers: Convert inputs to the logarithmic domain to make multiplication easier; appropriate for error-tolerant tasks such as image processing [4].

Although these methods lower energy use, they frequently cause measurable computational errors, requiring a careful trade-off analysis.

Imprecise Adders

Carry propagation in adders plays a major role in causing delay and switching activity in MAC units. Approximate adder designs include:

- Carry-Cut Adders: Omit carries in the lower bits to shorten the critical path delay [5].
- Speculative Adders: Employ anticipated carry values to accelerate computation, accepting slight inaccuracies.

Studies indicate that integrating approximate adders with truncated multipliers can significantly lower power consumption while preserving acceptable accuracy for DSP applications.

Multiply-Accumulate operations for DSP and Neural Networks

Lately, research has concentrated on approximate MAC architectures for signal processing and AI accelerators:

- Edge AI: Approximate MAC units have been employed in convolutional neural networks on edge devices, delivering up to 20% energy reduction while incurring less than a 5% drop in accuracy [6].
- DSP Filters: Using approximate multipliers in FIR and IIR filters can lower power usage while having no noticeable effect on the output signals [7].

Nevertheless, most research concentrates on either cutting energy use or preserving accuracy, yet it does not offer a configurable framework for systematically examining the energy-accuracy trade-off.

Detected Shortcomings

A review of the literature reveals the following gaps:

1. Restricted Flexibility: Current approximate MAC implementations typically employ predetermined truncation and adder approximation settings.
2. Insufficient Quantitative Analysis: Numerous studies fail to present metrics such as MAE, MRE, SNR, or energy savings for real-world DSP workloads.

3. Application-Specific Evaluation: Only a limited number of studies assess approximate MACs using actual DSP signals, like FIR/IIR filters or convolution operations.
4. Trade-Off Optimization: Systematic analysis of the energy-accuracy trade-off is missing, preventing designers from choosing optimal approximation parameters.

**Proposed System**

The intended solution seeks to create a configurable approximate Multiply-Accumulate (MAC) architecture for DSP applications that optimizes energy consumption while maintaining computational precision. It incorporates truncated multipliers and carry-cut approximate adders, offering an adjustable platform to assess energy-accuracy compromises in real-world DSP tasks.

System Summary

The system is composed of the following components:

- Input Registers (A and B):
  - Keeps the inputs for the MAC calculation.
  - Takes integer or fixed-point inputs for DSP calculations.
- Shortened Multiplier:
  - Executes multiplication by disregarding the least significant bits (LSBs) to lower switching activity and dynamic power
  - The truncation level can be adjusted to balance energy consumption and accuracy.
- Carry-Cut Approximate Summation Unit:
  - Adds the product to the accumulator while restricting carry propagation in the low-order bits
  - The degree of approximation can be adjusted to lower power usage even more.
- Accumulator / Output Register:
  - Stores the cumulative total of MAC operations.
  - Enables step-by-step accumulation in FIR filtering and convolution tasks.
- Error and Energy Assessment Component (Optional):
  - Calculates accuracy indicators such as Mean Absolute Error (MAE), Mean Relative Error (MRE), and Signal-to-Noise Ratio (SNR).
  - Calculates power reductions with a streamlined CMOS energy model that relies on truncation and varying adder approximation levels.
- Bulk Signal Processing (DSP Workload):
  - Utilizes the approximate MAC unit on a series of input signals (e.g., FIR filters) to assess real-world performance.
  - Offers interactive visualizations for error analysis and energy-accuracy trade-offs.

System Process / Functionality

The outlined system works in the following way:

- Input Collection:
  - Load the input operands AAA and BBB, or a batch signal sequence.
  - Set the truncation bits of the multiplier and the approximation bits of the adder.
- MAC Calculation:
  - Compute the product of inputs using a truncated multiplier.
  - Accumulate the result with a carry-cut approximate adder.
- Result Repository:
  - Save the MAC result in the accumulator.
  - Execute repeatedly in order for batch processing or FIR filter tasks.
- Precision Assessment
  - Contrast the approximate outcomes with the exact MAC calculation.
  - Calculate MAE, MRE, and SNR for analysis.

- Energy Assessment:
  - Estimate dynamic energy use by decreasing switching activity.
  - Determine the percentage of energy savings in comparison with the exact MAC design.
- Visual representation:
  - Create plots of error versus truncation bits, compare signal outputs, and generate energy versus accuracy graphs for analysis.

Benefits of the Suggested System

- Configurable Approximation: Users may modify truncation and adder approximation settings to satisfy application-specific energy-accuracy requirements.
- Energy Efficiency: Decreases switching activity in multipliers and adders, resulting in reduced dynamic power consumption.
- Hardware-Friendly: The architecture is suitable for deployment on ASICs, FPGAs, or edge accelerators.
- Practical Evaluation: Handles batch DSP workloads such as FIR filters to assess real-world impact.
- Interactive Analysis: Offers visual representation of error metrics and energy savings to aid optimal design choice.

System Architecture Illustration

The architecture may be outlined as:

**Input Registers → Reduced-Precision Multiplier → Carry-Cut Approximate Adder → Accumulator → Output Register**

Optional modules for Error and Energy Estimation may be attached to the output for simulation and analysis.

## METHODOLOGY

The methodology describes the sequential procedure for creating, deploying, and assessing the suggested approximate MAC architecture. It includes the design of the MAC unit, simulation of digital signal processing workloads, accuracy evaluation, and energy estimation.

System Architecture and Execution

- Creation of Approximate MAC Unit:
  - Truncated Multiplier: Achieved by disregarding a tunable count of the least-significant bits (LSBs) in operands AAA and BBB, which lessens switching activity and lowers computational complexity.
  - Carry-Cut Approximate Adder: Restricts the carry flow to the higher-order bits and omits the lower-order bits according to a tunable approximation setting, thereby lowering both critical-path latency and dynamic power consumption.
  - Accumulator: Gathers multiplication outcomes in order, enabling batch processing for DSP tasks like FIR filtering.
- Adjustable Settings:
  - Truncation Bits (Multiplier): Count of LSBs omitted in the multiplication stage.
  - Adder Approximation Bits: Count of the least-significant bits where carry propagation is omitted.
  - These settings enable adjustment of the energy-accuracy balance.

Preparing the Input Signal

- One MAC Input:
  - Allow integer or fixed-point numbers as operands AAA and BBB.
- Batch Signal Handling:
  - Create or import sequences of input signals (e.g., FIR filter inputs).
  - Create filter coefficients for convolution or FIR/IIR processing.

MAC Operational Workflow

1. Multiply the operands by means of the truncated multiplier.
2. Add the product to the accumulator using the carry-cut approximate adder.
3. Iterate over each input sample in order while in batch processing mode.

**Movement:**
**Input A, B → Reduced Multiplier → Carry-Trim Adder → Register → Output**
Evaluation of Accuracy

For every setting of truncation and approximation bits:

1. Exact Output: Generate the MAC result employing full-precision multiplication and addition.
2. Approximate Output: Generate MAC result using a truncated multiplier and a carry-cut adder
3. Metrics Computation:
    - Mean Absolute Error (MAE): Calculates the mean absolute difference from the true output.
    - Mean Relative Error (MRE): Evaluates the relative discrepancy between the estimated and true output.
    - Signal-to-Noise Ratio (SNR): Measures the proportion of signal power to noise generated by approximation.

Power Assessment

1. Represent dynamic energy consumption as directly proportional to switching activity and the complexity of the critical path.
2. By truncating and approximating the adder, switching activity diminishes, resulting in reduced energy consumption.
3. Calculate the percentage of energy saved compared to the exact MAC implementation.

Comparison of Error and Energy

1. Adjust the truncation bits and adder approximation bits across a range of values.
2. Run batch signal simulations and calculate the associated MAE, MRE, SNR, and energy savings.
3. Create interactive graphs to visualize:
    - Mistake vs Truncation Bits
    - Power Conservation versus Precision
    - Estimated vs Precise Signal Output

Deployment Environment

- Simulations and assessments are carried out with Python and Streamlit via an interactive interface.
- The approach provides chip-level understanding for ASIC or FPGA deployment, such as:
    - Energy savings estimate
    - Analysis of error propagation
    - Investigation of adaptable MAC architecture

## RESULTS AND DISCUSSIONS

The suggested approximate MAC design was tested using FIR filter tasks and separate MAC operations to gauge precision, power reduction, and their trade-off. Multiple settings of truncation bits and adder approximation bits were examined to deliver a thorough analysis.

Data Input and Setup

- Input Signal: Arbitrary sequence of seven integers (0–9)
- Filter Coefficients: Random integer series of length 3 (-3 to 3)
- MAC setup:
    - Bits for Truncation (Multiplier): 0–8
    - Estimated Adder Bits: 0–8

Accuracy Measures

The approximate MAC was compared with an exact MAC design. Main metrics for a typical configuration (truncation bits = 2, adder approx bits = 2) are listed below:

**Conversation:**

- The MAE and MRE show that an aggressive approximation causes significant differences in the results.
- The negative SNR indicates that, with this setup, the approximation-induced noise surpasses the signal strength for some samples, implying that a moderate level of approximation is required in sensitive DSP tasks.
- Lowering the number of truncation or adder-approximation bits enhances SNR and decreases MAE, though it slightly raises energy use.

**Deliberation:**

- Energy savings result from lower switching activity in truncated multipliers and carry-cut adders.
- The amount saved can be adjusted, growing as truncation and approximation levels rise.
- This validates the compromise between power efficiency and computational precision that is intrinsic to approximate computing.

Analysis of Error and Truncation Bits

A dynamic chart was created to display Mean Absolute Error against Truncation Bits:

- Error grows exponentially as the count of truncation bits rises.
- Applying low truncation (0–2 bits) yields an acceptable MAE.
- Extensive truncation (over 4 bits) causes a substantial drop in accuracy.

**Conversation:**

- Designers may choose truncation degrees that optimize energy savings while maintaining errors within acceptable bounds.
- This chart offers a visual understanding for selecting the optimal energy-accuracy balance.

Output Signal Comparison

- Comparison of the exact and estimated outputs for FIR filtering indicates:
    - Approximate output mirrors the overall pattern of the exact signal.
    - Small variations in the sample values arise from approximation.
    - Significant errors occur only at high truncation or adder approximation levels.

**Deliberation:**

- For error-tolerant DSP tasks such as image processing or neural network inference, an approximate MAC result is acceptable.
- In applications requiring high precision, truncation and adder approximation must remain minimal to ensure SNR stays above 0 dB.

Power-Precision Balance

- The research verifies a clear trade-off:
    - Increased truncation/approximation → greater energy savings → larger errors

- Reduced truncation/approximation → decreased energy savings → smaller errors
- With the suggested interactive framework, designers are able to choose configurations that optimize energy efficiency while keeping MAE and SNR within acceptable limits.

Main Findings

1. Approximate MAC units are capable of delivering 15–25% lower energy consumption on typical DSP workloads.
2. MAE and MRE grow as truncation and approximation bits increase, illustrating the energy-accuracy trade-off.
3. SNR is a valuable measure for assessing signal fidelity when approximations are applied.
4. Interactive analysis (charts and batch simulation) enables straightforward choice of optimal MAC setups for energy-limited applications.
5. Approximate MACs are well-suited for edge devices, IoT sensors, and low-power neural network accelerators.

## CONCLUSION

This study presents a configurable approximate Multiply-Accumulate (MAC) architecture for energy-efficient digital signal processing (DSP), integrating truncated multipliers and carry-cut approximate adders to reduce dynamic power and switching activity. The proposed system allows adjustable truncation and adder approximation levels, providing a flexible framework for exploring the trade-off between energy efficiency and computational accuracy. Experimental evaluation using FIR filter workloads shows that the approximate MAC can attain up to 15.4% energy reduction while preserving acceptable computational accuracy, with reported metrics of MAE = 25.89, MRE = 9.90%, and SNR = -8.75 dB for a representative configuration. Analysis of error propagation, signal output comparisons, and interactive error-vs-truncation plots underscores the importance of selecting moderate approximation levels to balance energy savings and signal fidelity. The findings verify that approximate MAC units are appropriate for low-power, energy-limited digital systems—including IoT devices, edge AI accelerators, and mobile DSP platforms—where minor computational errors are acceptable.

Subsequent research could concentrate on:

- Deploying the suggested architecture onto FPGA or ASIC platforms for genuine hardware validation.
- Creating flexible approximation methods that automatically modify truncation and adder parameters according to the properties of the input signal.
- Applying the approach to neural network accelerators, image/video processing pipelines, and other high-throughput DSP applications to further improve energy efficiency while maintaining performance.

## ABSTRACT

A simple, Accurate, precise method was developed for the simultaneous estimation of the Foslevodopa and Foscarbidopa in ointment dosage form. Chromatogram was run through Kromosil C18 250 x 4.6 mm, 5µm. Mobile phase containing Buffer 0.1% Formic acid: Acetonitrile taken in the ratio 60:10 was pumped through column at a flow rate of 0.8 ml/min. Buffer used in this method was 0.1% formic acid buffer. Temperature was maintained at 25°C. Optimized wavelength selected was 260 nm. Retention time of Foslevodopa and Foscarbidopa were found to be 2.138 min and 2.687. %RSD of the Foscarbidopa and Foslevodopa were and found to be 0.5 and 0.9 respectively. %Recovery was obtained as 100.76% and 99.67% for Foscarbidopa and Foslevodopa respectively. LOD, LOQ values obtained from regression equations of Foscarbidopa and Foslevodopa were 0.01, 0.02 and 0.02, 0.04 respectively. Regression equation of Foslevodopa is y = 544690x + 3371.1, and y = 31839x + 149.5 of Foscarbidopa. Retention times

were decreased and that run time was decreased, so the method developed was simple and economical that can be adopted in regular quality control test in industries.

**Keywords:** Foslevodopa, Foscarbidopa, RP-HPLC

## INTRODUCTION

The pharmaceutical sector produces a variety of medications with distinctive applications. Sometimes the combination of two or more active medications leads to a fixed-dose combination (FDC) or combination dosage to improve therapy. These combination medications enhance medication compliance and offer superior therapy. With increased therapeutic activity, these medications pose problems in the development of analytical methodologies and validation parameters. Upon investing a lot more time on research, analytical procedures are produced by researchers, professors etc., around the globe. These methods are used to ascertain the identity, safety, potency, and other characteristics of a medicine. Foscarbidopa is an L-tyrosine derivative that is carbidopa in which the hydroxy group at position 4' is replaced by a phosphonooxy group. It is a water-soluble prodrug of carbidopa which is used for the treatment of Parkinson's disease. Foslevodopa is an L-tyrosine derivative that is L-dopa in which the hydroxy group at position 4' is replaced by a phosphonooxy group. It is a water-soluble prodrug of levodopa which is used for the treatment of Parkinson's disease. According to the literature study, different techniques such as HPLC were used to determine Foscarbidopa and Foslevodopa, either alone or in combination with other medications. Only few analytical methods described for its quantification comprises LC-MS and HPLC. We have discovered that a straightforward, economical, precise, and trustworthy approach is required. The objective of this research is to develop a routine analysis that is simple to use, precise, accurate, and cost-effective for the concurrent estimate of Foscarbidopa and Foslevodopa in bulk and combination dosage forms. With its capacity to identify active ingredients and contaminants in the sample, RP-HPLC outperforms other techniques for routine analysis and improved assessment of a chemical entity or medicine.

## MATERIALS AND METHODS

**Materials**

Foslevodopa and Foscarbidopa pure drugs (API), Combination Foslevodopa and Foscarbidopa Injections (synthetic mixture), Distilled water, Acetonitrile, Phosphate buffer, Methanol, Potassium dehydrogenate ortho phosphate buffer, Ortho-phosphoric acid. All the above chemicals and solvents are from Rankem

**Instruments:**

Electronics Balance manufactured by Denver, $p^H$ meter and Ultrasonicator by BVK enterprises, India, WATERS HPLC 2695 SYSTEM equipped with quaternary pumps, Photo Diode Array detector and Auto sampler integrated with Empower 3 Software, UV-VIS spectrophotometer PG Instruments T60 with special bandwidth of 2 mm and 10mm and matched quartz cells integrated with UV win 6 Software.

**Methods:**

**Diluent:** Based up on the solubility of the drugs, diluent was selected, Acetonitrile and Water taken in the ratio of 50:50

**Preparation of Standard stock solutions:** Accurately weighed 10mg of Foslevodopa, 1mg of Foscarbidopa and transferred to 100ml and 100ml individual volumetric flasks and 3/4 th of diluents was added to this flask and sonicated for 10 minutes. Flask was made up with diluents and labeled as Standard stock solution. (100µg/ml of Foslevodopa and 100µg/ml Foscarbidopa)

**Preparation of Standard working solutions (100% solution):** 5ml from Foslevodopa stock solution and 1ml from foscarbidopa stock solution was pipetted out and taken into a 100ml volumetric flask and made up with diluent. (5µg/ml of Foslevodopa and 1µg/ml of Foscarbidopa)

**Preparation of Sample stock solutions:** Transferred 10 ml of the sample solution into a 500ml volumetric flask and diluted to the volume with diluent and mixed well.

**Preparation of Sample working solutions (100% solution):** 0.25ml of sample stock solution of Foslevodopa and 1ml of sample stock solution of foscarbidopa was transferred to 250ml volumetric flask and made up with diluent. (5µg/ml of Foslevodopa and 1µg/ml of Foscarbidopa)

**Preparation of buffer:**

0.1% Formic acid Buffer: 1ml of formic acid was diluted to 1000ml with HPLC grade water.

## RESULTS AND DISCUSSION

**Optimized Chromatographic conditions:**

A Kromosil C18 (4.6 x 150mm, 5µm) column was used for the chromatographic analysis. For separation, a mobile phase consisting of Formic acid and Acetonitrile (60:40v/v) was used, with a flow rate of 0.8 ml/min. The eluents were detected at 260 nm with an injection volume of 10µL. The HPLC system was operated at room temperature, which was 25◦C with a run time of 5min and Water and Acetonitrile in the ratio 50:50 v/v was used as diluent.

**System suitability:**

The system suitability parameters were determined by preparing standard solutions of Foslevodopa (5ppm) and Foscarbidopa (1ppm) and the solutions were injected six times and the parameters like peak tailing, resolution and USP plate count were determined. The % RSD for the area of six standard injections results should not be more than 2%.

**Specificity:**

Checking of the interference in the optimized method. We should not find interfering peaks in blank and placebo at retention times of these drugs in this method. So this method was said to be specific.

**Precision**

**Preparation of Sample stock solutions:** Transferred 10 ml of the sample solution into a 500ml volumetric flask and diluted to the volume with diluent and mixed well.

**Preparation of Sample working solutions (100% solution):** 0.25ml of sample stock solution of Foslevodopa and 1ml of sample stock solution of foscarbidopa was transferred to 250ml volumetric flask and made up with diluent. (5µg/ml of Foslevodopa and 1µg/ml of Foscarbidopa)

The precision was determined by preparing sample solutions of Foslevodopa (5ppm) and Foscarbidopa (1ppm) and the solutions were injected six times and the % RSD for the area of six sample injections results should not be more than 2%.

**Linearity:**

**25% Standard solution:** 1.25ml from Foslevodopa standard solution and 0.25ml from Foscarbidopa standard stock solutions was pipetted out and made up to 100ml. (1.25µg/ml of Foslevodopa and 0.25µg/ml of Foscarbidopa)

**50% Standard solution:** 2.5ml from Foslevodopa standard solution and 0.5ml from Foscarbidopa standard stock solutions was pipetted out and made up to 100ml. (2.5µg/ml of Foslevodopa and 0.5µg/ml of Foscarbidopa)

**75% Standard solution:** 3.75ml from Foslevodopa standard solution and 0.75ml from Foscarbidopa standard stock solutions was pipetted out and made up to 100ml. (3.75µg/ml of Foslevodopa and 0.75µg/ml of Foscarbidopa)

**100% Standard solution:** 5ml from Foslevodopa standard solution and 1ml from Foscarbidopa standard stock solutions was pipetted out and made up to 100ml. (5µg/ml of Foslevodopa and 1µg/ml of Foscarbidopa)

**125% Standard solution:** 6.25ml from Foslevodopa standard solution and 1.25ml from Foscarbidopa standard stock solutions was pipetted out and made up to 100ml. (6.25µg/ml of Foslevodopa and 1.25µg/ml of Foscarbidopa)
**150% Standard solution:** 7.5ml from Foslevodopa standard solution and 1.5ml from Foscarbidopa standard stock solutions was pipetted out and made up to 100ml. (7.5µg/ml of Foslevodopa and 1.5µg/ml of Foscarbidopa)

**Accuracy:**
**Preparation of Sample working solutions (100% solution):** 0.25ml of sample stock solution of Foslevodopa and 1ml of sample stock solution of foscarbidopa was transferred to 250ml volumetric flask and made up with diluent. (5µg/ml of Foslevodopa and 1µg/ml of Foscarbidopa)
**Preparation of Standard working solutions (100% solution):** 5ml from Foslevodopa stock solution and 1ml from foscarbidopa stock solution was pipetted out and taken into a 100ml volumetric flask and made up with diluent. (5µg/ml of Foslevodopa and 1µg/ml of Foscarbidopa)
**Preparation of 50% Spiked Solution:** 0.12ml from Foslevodopa sample solution and 0.5ml from Foscarbidopa sample stock solution was pipetted out and made up to 250ml to that 12 ml from Foslevodopa standard stock solution and 2ml from foscarbidopa standard stock solution was pipetted out, and made up to the mark with diluent.

**Preparation of 100% Spiked Solution:** 0.25ml from Foslevodopa sample solution and 1ml from Foscarbidopa sample stock solution was pipetted out and made up to 250ml to that 12 ml from Foslevodopa standard stock solution and 2ml from foscarbidopa standard stock solution was pipetted out, and made up to the mark with diluent.
**Preparation of 150% Spiked Solution:** 0.12ml from Foslevodopa sample solution and
0.4ml from Foscarbidopa sample and stock solutions was pipetted out and made up to 250ml to that 12 ml from Foslevodopa standard stock solution and 2ml from foscarbidopa standard stock solution was pipetted out, and made up to the mark with diluent.

**Robustness:**
Robustness conditions like Flow minus (0.7ml/min), Flow plus (0.9ml/min), mobile phase minus, mobile phase plus, temperature minus (20°C) and temperature plus (30°C) was maintained and samples were injected in triplicate manner. System suitability parameters were not much affected and all the parameters were passed. %RSD was within the limit.LOD sample Preparation: 0.25ml each from two standard stock solutions was pipetted out and transferred to two separate 100ml volumetric flasks and made up with diluents. From the above solutions 0.1ml each of Foslevodopa, Foscarbidopa, solutions respectively were transferred to 100ml volumetric flasks and made up with the same diluents.

**Sensitivity:**
Sample preparation: 0.25ml each from two standard stock solutions was pipetted out and transferred to two separate 100ml volumetric flask and made up with diluent. From the above solutions 0.3ml each of Foslevodopa and Foscarbidopa, solutions respectively were transferred to 100ml volumetric flasks and made up with the same diluent.

**Degradation studies**:
**Oxidation:**
To 1 ml of stock solution of Foslevodopa and Foscarbidopa, 1 ml of 20% hydrogen peroxide (H2O2) was added separately. The solutions were kept for 30 min at 60°c. For HPLC study, the resultant solution was diluted to obtain 5µg/ml&1µg/ml solution and 10 µl were injected into the system and the chromatograms were recorded to assess the stability of sample.

**Acid Degradation Studies:**
To 1 ml of stock s solution Foslevodopa and Foscarbidopa, 1 ml of 2N Hydrochloric acid was added and refluxed for 30mins at 60ºc. The resultant solution was diluted to obtain 5µg/ml&1µg/ml solution and 10 µl solutions were injected into the system and the chromatograms were recorded to assess the stability of sample.

**Alkali Degradation Studies:**
To 1 ml of stock solution Foslevodopa and Foscarbidopa, 1 ml of 2N sodium hydroxide was added and refluxed for 30mins at 60ºc. The resultant solution was diluted to obtain 5µg/ml&1µg/ml solution and 10 µl were injected into the system and the chromatograms were recorded to assess the stability of sample.

**Dry Heat Degradation Studies:**
The standard drug solution was placed in oven at 105°C for 1 h to study dry heat degradation. For HPLC study, the resultant solution was diluted to 5µg/ml&1µg/ml solution and10µl were injected into the system and the chromatograms were recorded to assess the stability of the sample.

**Photo Stability studies:**
The photochemical stability of the drug was also studied by exposing the 4000µg/ml & 10 µg/ml Foscarbidopaµg/ml solution to UV Light by keeping the beaker in UV Chamber for 1days or 200 Watt hours/$m^2$ in photo stability chamber. For HPLC study, the resultant solution was diluted to obtain 400µg/ml& 1µg/ml solutions and 10 µl were injected into the system and the chromatograms were recorded to assess the stability of sample.

**Neutral Degradation Studies:**
Stress testing under neutral conditions was studied by refluxing the drug in water for 1h r s at a temperature of 60º. For HPLC study, the resultant solution was diluted to 400µg/ml& 1µg/ml solution and 10 µl were injected into the system and the chromatograms were recorded to assess the stability of the sample.

## CONCLUSION

This simultaneous estimation of the Foscarbidopa and Foslevodopa in ointment dosage form had produced good results like retention time and theoretical plate count and resolution. Retention times were decreased and that run time was decreased. All the validation parameters met the acceptable criteria, so the method developed was simple and economical that can be adopted in regular quality control test in industries.

**ABSTRACT**

This study examines the tribological behavior of EN8 medium-carbon steel before and after surface modification with an electroless nickel–boron (Ni–B) coating under dry sliding conditions. The Ni–B coating was deposited using an alkaline autocatalytic bath containing nickel chloride as the metal source and sodium borohydride as the reducing agent. Tribological performance was evaluated using a pin-on-disc tribometer at applied loads of 20–40 N and sliding speeds of 60 and 80 rpm. Wear rate, mass loss, and coefficient of friction were systematically analyzed to assess the influence of coating on surface durability.The results indicate that wear rate increased with increasing normal load for both coated and uncoated specimens, reflecting higher contact stresses and intensified material removal at elevated loads. However, the Ni–B coated EN8 specimens consistently demonstrated lower wear rate and reduced mass loss compared to the uncoated substrate under identical testing conditions. At lower loads, higher sliding speed resulted in greater wear, whereas at 40 N the wear rate became less sensitive to speed variation, suggesting the possible stabilization of the sliding interface at higher contact pressures. The enhanced tribological performance of the coated specimens is attributed to the improved surface hardness and load-bearing capability of the Ni–B layer. Overall, the findings confirm that electroless Ni–B coating is an effective approach for improving the wear resistance of EN8 steel components subjected to dry sliding conditions.

**Keywords:** Electroless Ni–B coating; EN8 steel; Tribological performance; Wear rate; Surface engineering; Dry sliding

## INTRODUCTION

Tribological deterioration remains a persistent challenge in mechanical systems where components operate under repeated sliding or rolling contact. Friction-induced material loss not only shortens service life but also contributes significantly to energy dissipation and maintenance costs in industrial machinery and automotive assemblies [1]. In

many practical situations, surface damage precedes bulk structural failure, emphasizing the importance of modifying surface characteristics rather than altering core material composition [2]. Medium-carbon steels such as EN8 are extensively employed in shafts, gears, spindles, and load-bearing elements due to their favorable balance of strength, machinability, and cost-effectiveness [3]. Despite these advantages, EN8 steel exhibits limited surface hardness and moderate resistance to adhesive and abrasive wear under dry sliding conditions [4]. When subjected to repeated contact stresses, localized plastic deformation, micro-cutting, and oxidative wear mechanisms accelerate material removal, ultimately restricting its application in severe tribological environments. Consequently, improving the surface integrity of EN8 steel without compromising its bulk toughness has become a practical engineering priority. Surface engineering techniques offer viable solutions for enhancing wear resistance while preserving core mechanical properties. Among these techniques, electroless nickel-based coatings have attracted sustained attention because of their ability to deposit uniformly on complex geometries without the requirement of external electrical current [5]. The autocatalytic nature of electroless deposition ensures consistent thickness and compositional homogeneity, making it particularly suitable for precision components [6].

In this class of coatings, electroless nickel–boron (Ni–B) systems have emerged as promising candidates for tribological applications. The incorporation of boron into the nickel matrix leads to the formation of a metastable structure that can transform into hard intermetallic phases such as $Ni_3B$ during thermal exposure, thereby enhancing hardness and load-bearing capacity [7,8]. Even in the as-deposited state, Ni–B coatings typically exhibit higher hardness compared to conventional Ni–P systems, which contributes to improved resistance against surface deformation and material removal during sliding [9]. However, hardness alone does not dictate tribological performance. Increasing evidence suggests that coating morphology plays a decisive role in governing frictional behavior and wear mechanisms [10]. Features such as nodular structure, grain refinement, porosity distribution, and surface roughness influence the real contact area between interacting surfaces. These morphological characteristics directly affect stress concentration at asperities, crack initiation sites, debris formation, and ultimately the wear mode transition from mild to severe regimes [11,12]. The morphology of electroless Ni–B coatings is strongly dependent on bath composition, reducing agent concentration, stabilizer content, pH, and deposition temperature [13]. Subtle variations in these parameters can produce significant changes in surface topography and microstructure, which in turn alter friction coefficient evolution and wear rate under sliding conditions [14]. While several studies have addressed the mechanical and corrosion performance of Ni–B coatings, systematic investigations correlating coating morphology with tribological response particularly on EN8 steel substrates remain limited [15].A comprehensive understanding of the morphology–tribology relationship is therefore essential for rational optimization of electroless Ni–B coatings in practical applications.

In this context, the present study aims to investigate the influence of coating morphology on the tribological performance of electroless nickel–boron deposits on EN8 steel. By correlating microstructural characteristics with friction behavior and wear mechanisms under controlled dry sliding conditions, this work seeks to establish a clear structure–property relationship that can guide the design of durable surface-engineered components for demanding mechanical environments.

## MATERIALS

**Substrate Material**

Commercial EN8 medium-carbon steel was used as the substrate material in this investigation. EN8 is an unalloyed structural steel containing 0.35–0.45 wt.% carbon and is widely employed in power transmission components such as shafts, axles, fasteners, and connecting rods due to its favorable strength–machinability balance. The nominal chemical composition of the EN8 steel is presented in Table 1. The material exhibits a tensile strength in the range of 500–800 MPa depending on heat treatment condition. Despite its adequate bulk mechanical strength, EN8 steel demonstrates limited surface hardness and moderate resistance to adhesive and abrasive wear, making it suitable for surface modification studies.

**Electroless Nickel–Boron Plating Bath**

An alkaline electroless nickel–boron (Ni–B) bath was prepared using analytical-grade chemicals and deionized water. The bath composition was designed to ensure stable autocatalytic deposition and controlled boron incorporation into the nickel matrix. Nickel chloride ($NiCl_2 \cdot 6H_2O$) was employed as the source of $Ni^{2+}$ ions. Sodium borohydride ($NaBH_4$) was used as the reducing agent owing to its strong reducing potential and effectiveness in promoting boron co-deposition. Ethylenediamine (EDA) served as the complexing agent to regulate free nickel ion concentration and prevent premature precipitation. Lead nitrate ($Pb(NO_3)_2$) was introduced in trace quantities as a stabilizer to suppress bath decomposition and maintain deposition control. Sodium hydroxide (NaOH) was used to maintain the required alkaline pH of the solution.

**Rationale for Material Selection**

The selection of EN8 steel was motivated by its widespread industrial usage and its susceptibility to surface degradation under sliding contact. The Ni–B coating system was chosen due to its high intrinsic hardness, potential for intermetallic phase formation, and demonstrated suitability for tribological enhancement. The combination enables systematic evaluation of morphology-dependent tribological behavior without interference from alloying complexities.

## METHODOLOGY

Electroless Nickel–Boron Coating

Medium-carbon EN8 steel was used as the substrate material for electroless nickel–boron (Ni–B) coating deposition. Cylindrical specimens were machined to dimensions compatible with the pin-on-disc tribometer holder to ensure stable contact during sliding wear experiments.

**Surface Preparation**

Prior to coating, the substrates were mechanically polished using successive grades of emery papers, followed by degreasing in acetone and rinsing with distilled water. The specimens were then ultrasonically cleaned and dried. To initiate autocatalytic deposition, the cleaned substrates were activated by immersion in a palladium chloride ($PdCl_2$) solution maintained at 55 °C for 30 s. This activation step promotes nucleation and ensures uniform coating initiation.

**Bath Preparation**

The Ni–B electroless bath was prepared using a two-solution approach to prevent premature decomposition of sodium borohydride. Beaker A (Metal ion solution): Nickel chloride ($NiCl_2$), ethylenediamine (EDA), sodium hydroxide (NaOH), and lead nitrate ($Pb(NO_3)_2$) were dissolved in 100 mL of deionized water. The solution was heated to 90 °C under continuous magnetic stirring at 470 rpm. Beaker B (Reducing agent solution): Sodium hydroxide and sodium borohydride ($NaBH_4$) were dissolved separately in 100 mL of deionized water and heated to 90 °C with stirring at 470 rpm.

**Deposition Process**

After preparing both solutions, Beaker B was slowly added to Beaker A under continuous stirring to form the final plating bath. The bath temperature was maintained at 90 °C, and the pH was adjusted to approximately 12.5 using sodium hydroxide, as borohydride-based systems require highly alkaline conditions for stable operation.Activated EN8 substrates were immersed in the plating bath for 60 minutes. The temperature was continuously monitored using a digital temperature sensor integrated with the hot plate stirrer to ensure thermal stability. After deposition, the coated samples were rinsed thoroughly with distilled water and air-dried.

**Friction and Sliding Wear Test**

Tribological behavior of the coated specimens was evaluated using a pin-on-disc tribometer (DUCOM, India) under dry sliding conditions (no lubricant). The coated cylindrical specimens served as the pin material, while the counterface disc was hardened steel.The wear volume, wear rate, and coefficient of friction (COF) were recorded using the integrated data acquisition system. The test parameters are presented in Table 4.

## RESULT AND DISCUSSION

**COF and Wear-rate of EN8 Steel with Ni-B coating**

The data table 5 contains all of the results of the co-efficient of friction and wear of Ni-B coating under various loading conditions and rpm.

An increase in applied load can promote adhesive wear mechanisms accompanied by surface smoothening due to enhanced plastic deformation at the contact interface. Under higher normal loads, asperities tend to deform and flatten, which may reduce localized stress concentrations and consequently decrease the effective wear rate of the Ni–B coatings. Furthermore, elevated load conditions can generate significant frictional heating at the sliding interface. This localized temperature rise facilitates the formation of a compact tribo-oxide layer, which acts as a protective barrier between the contacting surfaces. The development of such a tribo-oxide film can reduce direct metal-to-metal interaction, thereby contributing to a reduction in wear rate with increasing load.

In the coefficient of friction (COF) analysis, the blue curve represents the variation of COF at a sliding speed of 60 rpm, whereas the red curve corresponds to the COF measured at 80 rpm.

**Mass-loss of Ni-B coating**

Weight loss is estimated using the initial and end weights measured by a weight machine. The weight loss of the Ni-B coating at 60 and 80 rpm is given in table 6.

The weight loss of the Ni–B coated specimens increased progressively with the application of normal loads of 20 N, 30 N, and 40 N at sliding speeds of both 60 rpm and 80 rpm. This trend indicates that higher applied loads intensify material removal due to increased contact stresses at the sliding interface. A comparative analysis of sliding speed reveals that the specimens tested at 80 rpm exhibited relatively higher weight loss compared to those tested at 60 rpm, suggesting that increased sliding velocity enhances frictional interaction and accelerates wear. In the graphical representation, the red curve corresponds to the weight loss recorded at 80 rpm, whereas the blue curve represents the weight loss measured at 60 rpm.

**Wear rate of Ni-B coating**

The wear rate of Ni-B coating at various loads such as 20 N, 30 N, 40 N at 60rpm and 80rpm is shown in table 7. The wear rate of the Ni–B coated specimens increased progressively with increasing applied load at both sliding speeds. At 60 rpm, the wear rate increased from $3.31 \times 10^{-6}$ $mm^3/N{\cdot}m$ at 20 N to $9.94 \times 10^{-6}$ $mm^3/N{\cdot}m$ at 40 N. A similar increasing trend was observed at 80 rpm, where the wear rate increased from $7.46 \times 10^{-6}$ $mm^3/N{\cdot}m$ to $9.94 \times 10^{-6}$ $mm^3/N{\cdot}m$ over the same load range. At lower loads (20 N and 30 N), the wear rate at 80 rpm was significantly higher than at 60 rpm, indicating that increased sliding speed contributes to enhanced frictional energy input and material removal. However, at 40 N, the wear rate values converged for both sliding speeds, suggesting a transition in wear mechanism or the formation of a stable tribo-layer at higher load conditions.

## CONCLUSION

The present investigation systematically evaluated the tribological performance of EN8 steel with and without electroless Ni–B coating under varying load and sliding speed conditions. Based on the experimental findings, the following conclusions can be drawn:

1. The coefficient of friction (COF) generally increased with increasing applied load, although slight variations were observed at certain load levels due to changes in contact conditions and possible tribo-layer formation.
2. Wear and wear rate increased progressively with increasing normal load (20–40 N) for both uncoated and coated specimens, indicating higher contact stresses and intensified material removal at elevated loads.
3. The Ni–B coated EN8 specimens exhibited significantly lower wear rate compared to uncoated EN8 steel under identical testing conditions.
4. Mass loss measurements confirmed that Ni–B coating effectively reduces material degradation during sliding.
5. The improved tribological performance of the coated specimens can be attributed to the higher surface hardness and enhanced load-bearing capacity of the electroless Ni–B layer.
6. Electroless Ni–B coating is therefore an effective surface modification technique for improving the wear resistance of EN8 steel components operating under dry sliding conditions.

**ABSTRACT**

[7] A dominating set ( D ) of a graph ( (S(G) = (V, E) ) is called a **Co-even dominating set** if for every vertex ( v \in V - D ), the degree of ( v ) is an even number. The **Co-even domination number** of (S(G) ), denoted by ( $\gamma_{coe}$ [S(G)] ), is the minimum cardinality (size) among all Co-even dominating sets of ( S(G) ). "In this paper, we studied the co-even domination number of certain split graphs, namely $(S(P_n))$, $(S(H_n))$, $(S(C_n))$, $(S(P_n^+))$, $(S(P_n oNK_1))$

**Keywords**: Domination, Co-even domination number, Co - even domination set.
**Subject classification:** AMS 05C69, 05C70

## INTRODUCTION

A graph G is a finite non –empty set of objects called vertices together with a set of unordered pair of distinct vertices of G which are called edges. Each pair $e = \{u, v\}$ of vertices in E is called an edge or a line of G in which e is said to join u and v. We write $e = uv$ and say that u and v are adjacent vertices (sometimes denoted as u adjv);vertex u and the edge e are incident with each other, as are v and e. If two distinct edges $e_1$ and $e_2$ are incident with a common vertex, then they are called adjacent edges.

[6]The maximum degree of a vertex in G is denoted by $\Delta(G)$ and the minimum degree of a vertex in G is denoted by $\delta(G)$. "In this paper, we studied the co-even domination number of certain split graphs, namely $(S(P_n))$, $(S(H_n))$, $(S(C_n))$, $(S(P_n^+))$, $(S(P_n oNK_1))$

## PRELIMINARIES

**Definition [7]**

A dominating set ( D ) of a graph ( (S(G) = (V, E) ) is called a **Co-even dominating set** if for every vertex ( v \in V - D ), the degree of ( v ) is an even number. The **Co-even domination number** of (S(G) ), denoted by ( $\gamma_{coe}$ [S(G)] ), is the minimum cardinality (size) among all Co-even dominating sets of ( S(G) ).

**3. $\gamma_{coe} - of\ Splitted$ Graphs Results**

**Theorem 3.1** $\gamma_{coe}[S(P_n)] = n \quad if\ 2 \le n \le 5$

**Proof.** Let S($P_n$) be path splitted graph of $P_n$ . Let V [S($P_n$)] = {$f_i$ , $g_i$: $1 \le i \le n$ }, Let $E[S(P_n)]$ = {($f_i f_{i+1}$) ∪ ($g_i f_{i+1}$) ∪ ($f_i g_{i+1}$) ; 1≤ i ≤ n-1}. In $S(P_n)$ graph, If we take all the $g_i$ vertices, these vertices act as a co- even dominating set. As follows vertex $g_i$ is adjacent to $f_{i-1}$& $f_{i+1}$, by defn., $g_i$ are vertices satisfy the co – even dominating set condition.

Hence, $\gamma_{coe}[S(P_n)] = n$.

Given [ $\gamma_{coe}[S(P_3)]$ = {$g_1$ , $g_2$,$g_3$ } = 3]

**Theorem 3.2** $\gamma_{coe}[S(P_n)] = \left\lceil \frac{n}{2} \right\rceil + 2 \quad if\ n \equiv 1(mod\ 2)\ and\ n \ge 7\ \&\ n\ is\ odd$

**Proof.** Let S($P_n$) be path splitted graph of $P_n$ . Let V [S($P_n$)] = {$f_i$ , $g_i$: $1 \le i \le n$ }, Let $E[S(P_n)]$ = {($f_i f_{i+1}$) ∪ ($g_i f_{i+1}$) ∪ ($f_i g_{i+1}$) ; 1≤ i ≤ n-1}. In $S(P_n)$ graph, we can first select the vertices with odd degree . As $g_1 and\ g_n$ are odd degree vertices. If $n \equiv 0\ (mod\ 4)$ Then the remaining vertices from $f_i$ is adjacent to $f_{i-1}$ , $g_{i-1}$ $and\ g_{i+1}$ where as $f_{i+1}$ is adjacent to $f_{i+2}$ , $g_i$ $and\ g_{i+2}$ . by defn $g_1, g_n, f_i$and $f_{i+1}$ are vertices satisfy the co – even dominating set condition.

If $n \equiv 1\ (mod\ 4)$, $n \ge 7$ the remaining one vertices from $f_i$ ; $(i = n)$ (since $f_n$ vertex is already select , it is enough to select $g_n$ vertex), vertex $f_n$ is adjacent to $f_{i-1}$ , $g_{i-1}$ by defn $f_n$ is vertex satisfy the co – even dominating set condition.

Hence, $\gamma_{coe}[S(P_n)] = \left\lceil \frac{n}{2} \right\rceil + 2$

For example $\gamma_{coe}[S(P_7)]$ = {$g_1$,$g_7$ , $f_2$ , $f_3$,$f_6$ , $f_7$} = 6 .

**Theorem 3.3** $\gamma_{coe}[S(P_n)] = \frac{n+4}{2} \quad if\ n \equiv 0(mod\ 2)\ and\ n \ge 6\ \&\ n\ is\ even$

**Proof.** Let S($P_n$) be path splitted graph of $P_n$ . Let V [S($P_n$)] = {$f_i$ , $g_i$: $1 \le i \le n$ }, Let $E[S(P_n)]$ = {($f_i f_{i+1}$) ∪ ($g_i f_{i+1}$) ∪ ($f_i g_{i+1}$) ; 1≤ i ≤ n-1}. In $S(P_n)$ graph, we can first select the vertices with odd degree . As $g_1 and\ g_n$ are odd degree vertices. If $n \equiv 0\ (mod\ 4)$ Then the remaining vertices for each of four vertices $f_i$ , $g_i$ from $f_i$ is adjacent to $f_{i-1}$ , $g_{i-1}$ $and\ g_{i+1}$ where as $f_{i+1}$ is adjacent to $f_{i+2}$ , $g_i$ $and\ g_{i+2}$ . by defn $g_1, g_n, f_i$and $f_{i+1}$ are vertices satisfy the co – even dominating set condition.

If $n \equiv 2\ (mod\ 4)$, the remaining two vertices of $f_i$ , $g_i$ $(n - 1 \le i \le n)$ (since $f_n$ vertex is already select , it is enough to select $g_n$ vertex), vertex $f_n$ is adjacent to $f_{i-1}$ , $g_{i-1}$ by defn $f_n$ is vertex satisfy the co – even dominating set condition.

Hence, $\gamma_{coe}[S(P_n)] = \frac{n+4}{2}$

For example $\gamma_{coe}[S(P_8)]$ = {$g_1$ , $g_8$ , $f_2$ , $f_3$,$f_6$ , $f_7$,} = 6.

**Theorem 3.4** $\gamma_{coe}[S(H_n)] = n + 6 \quad if\ n \equiv 0(mod\ 2)\ and\ n \ge 6\ \&\ n\ is\ even$

**Proof.** Let V [S($H_n$)] = {$f_i$ , $g_i$,$f_i'$ , $g_i'$ : 1≤ i ≤$n$ },

Let E[S($H_n$)] = {($f_i f_{i+1}$) ∪ ($g_i f_{i+1}$) ∪ ($f_i g_{i+1}$) ∪ ($f_{\frac{n}{2}} f'_{\frac{n+1}{2}}$) ∪ ($f_{\frac{n}{2}} g'_{\frac{n+1}{2}}$) ∪ ($g_{\frac{n}{2}} f'_{\frac{n+1}{2}}$)∪($f_i' f'_{i+1}$)∪ ($g_i' f'_{i+1}$) ∪ ($f_i' g'_{i+1}$); 1≤ i ≤ n-1}.

In S($H_n$) graph, we can first select the vertices with odd degree. As $g_1, g_n$are odd degree vertices. Then the remaining vertices if $n \equiv 0\ (mod\ 4)$ for each of four vertices $f_i$ , $g_i$.

Vertex $f_i$ is adjacent to $f_{i-1}$,$g_{i-1}$,$g_{i+1}$. where as $f_{i+1}$ is adjacent to $f_{i+2}$,$g_i$,$g_{i+2}$. If the remaining $n \equiv 2(mod4)$ two vertices of $f_i$ , $g_i(n - 1 \le i \le n)$. (since $g_n$ vertex is already selected, it is enough to select $f_n$ vertex). Vertex $f_n$ is adjacent to $f_{n-1}$,$g_{n+1}$.

we can first select the vertices with odd degree. As $g_1', g_n'$are odd degree vertices. Then the remaining vertices if $n \equiv 0\ (mod\ 4)$ for each of four vertices $f_i', g_i'$.

Vertex $f_i'$is adjacent to $f_{i-1}', g_{i-1}', g_{i+1}'$. where as $f_{i+1}'$is adjacent to $f_{i+1}', g_i', g_{i+2}'$. If the remaining $n \equiv 2(mod 4)$ two vertices of $f_i', g_i' (n-1 \leq i \leq n)$. (since $g_n'$ vertex is already selected, it is enough to select $f_n'$vertex). Vertex $f_n'$ is adjacent to $f_{n-1}', g_{n-1}'$.

By definition, $g_1, g_n, g_1', g_n', f_i, f_{i+1}, f_n, f_i', f_{i+1}'$ and $f_n'$ are vertices satisfy the co-even dominating set condition.

Hence $\gamma_{coe}[S(H_n)] = n + 6$

For example $\gamma_{coe}[S(H_8)] = \{g_1, g_4, g_8, f_2, f_3, f_6, f_7, g_1', g_5', g_8', f_2', f_3', f_6', f_7'\} = 14$.

**Theorem 3.5.** $\gamma_{coe}[S(H_n)] = n + 5$ *if* $n \equiv 1(mod\ 2)$ *and* $n \geq 5$ & $n$ *is odd* and $n \not\equiv 21(mod\ 20)$

**Proof.** Let V [S($H_n$)] = $\{f_i, g_i, f_i', g_i' : 1 \leq i \leq n\}$,

Let E[S($H_n$)] = $\{(f_i f_{i+1}) \cup (g_i f_{i+1}) \cup (f_i g_{i+1}) \cup (f_{\frac{n}{2}} f_{\frac{n+1}{2}}') \cup (f_{\frac{n}{2}} g_{\frac{n+1}{2}}') \cup (g_{\frac{n}{2}} f_{\frac{n+1}{2}}') \cup (f_i' f_{i+1}') \cup (g_i' f_{i+1}') \cup (f_i' g_{i+1}'); 1 \leq i \leq n-1\}$.

We can first select the vertices with odd degree. As $g_1, g_n$ and $g_{\frac{n+1}{2}}$ are odd degree vertices. Therefore, all the above mentioned vertices will form a co- even dominating set.

If $n \equiv 7(mod\ 4)$ when this $g_{\frac{n+1}{2}}$ vertex is a co-even dominating set, this $H_n$ graph can be divided into equal two parts. The first part contains $f_i$, ( $1 \leq i \leq \frac{n-1}{2}$ ) vertices. Then the first half and the second half can be divided into 3, 5, and 7 ( $f_i$ & $g_i$ ) vertices.

In $_{11}$ graph the first half consists of $_{,}$ ( $1 \leq \ \leq \frac{-1}{2}$ ) vertices and the second half consist of $_{,}$ ( $\frac{+3}{2} \leq \ \leq$ ).

Therefore in this first part $_{+1}, _{+2}, _{+3}$ are vertices and in the second half $_{-3}, _{-2}, _{-1}$ are vertices can be taken as co-even dominating set. If there are 3 (or) 7 vertices in the first half and the second half, then for every four ( ) vertices it is enough to take the two vertices in the middle.

If $n \equiv 5(mod\ 4)$ when this $g_{\frac{n+1}{2}}$ vertex is a co-even dominating set comes, this $H_n$ graph can be divided into equal two sections. The first section contains $f_{i,}$ ( $1 \leq i \leq \frac{n-1}{2}$ ) vertices. "The first half and the second half each contain vertices labeled ( *fi* ) *and* ( *g*i ), with indices ( i = 2, 4, 6, 8 )."

In this $H_{13}$ graph, the first half consists of 6 vertices, in which $f_1$is adjacent to $g_2$, $f_2$.we have already selected $g_1$ is odd degree (co- even dominating set). Therefore, the remaining vertices are $f_3, f_4, f_5, f_6$ form these four ( $f_i, 3 \leq i \leq 6$) vertices, the middle two vertices should be taken. Similarly, the second half consists of 6 vertices, in which $f_{13}$ is adjacent to $g_{12}, f_{12}$. We have already selected $f_{13}$ odd degree (Co-even dominating set). Therefore, the remaining vertices are $f_i$ ($8 \leq i \leq 11$). From these four $f_i$ ($8 \leq i \leq 11$) vertices, the middle two vertices can be taken.

Suppose in the $H_9$ graph, the first half has four $f_i$ ($1 \leq i \leq 4$). from these four vertices, we can take the middle two vertices. Similarly the second half has four $f_i$ ($6 \leq i \leq 8$)vertices. Form these four vertices, we can take the middle two vertices.

Just as the $f, g$ vertices work, the same as process applies to $f', g'$.

Hence $\gamma_{coe}[S(H_n)] = n + 5$

For example $\gamma_{coe}[S(H_{11})] = \{g_1, g_5, g_{11}, f_2, f_3, f_6, f_9, f_{10}, g_1', g_5', g_{11}', f_2', f_3', f_6', f_9', f_{10}'\} = 16$.

**Theorem 3.6.** $\gamma_{coe}[S(H_n)] = 2n$ *if* $2 \leq n \leq 4$

**Proof.** Let V [S($H_n$)] = $\{f_i, g_i, f_i', g_i' : 1 \leq i \leq n\}$,

If n is odd, Let E[S($H_n$)] = $\{(f_i f_{i+1}) \cup (g_i f_{i+1}) \cup (f_i g_{i+1}) \cup (f_{\frac{n}{2}} f_{\frac{n+1}{2}}') \cup (f_{\frac{n}{2}} g_{\frac{n+1}{2}}') \cup (g_{\frac{n}{2}} f_{\frac{n+1}{2}}') \cup (f_i' f_{i+1}') \cup (g_i' f_{i+1}') \cup (f_i' g_{i+1}'); 1 \leq i \leq n-1\}$.

If n is even, Let E[S($H_n$)] = $\{(f_i f_{i+1}) \cup (g_i f_{i+1}) \cup (f_i g_{i+1}) \cup (f_{\frac{n}{2}} f_{\frac{n+1}{2}}') \cup (f_{\frac{n}{2}} g_{\frac{n+1}{2}}') \cup (g_{\frac{n}{2}} f_{\frac{n+1}{2}}') \cup (f_i' f_{i+1}') \cup (g_i' f_{i+1}') \cup (f_i' g_{i+1}'); 1 \leq i \leq n-1\}$.

If we take all the $g_i$ *and* $g_i'$ vertices, these vertices act as a co-even dominating set. By definition, $g_i$ *and* $g_i'$ are co-even dominating set

Hence $\gamma_{coe}[S(H_n)] = 2n$

For example $\gamma_{coe}[S(H_3)] = \{g_1, g_2, g_3, g_1', g_2', g_3'\} = 6$.

**Theorem 3.7.** $\gamma_{coe}[S(H_n)] = n + 7 \quad if\ n \equiv 21\ (mod\ 20)$

**Proof.** Let V $[S(H_n)] = \{f_i, g_i, f_i', g_i' : 1 \leq i \leq n\}$,

Let E$[S(H_n)] = \{(f_i f_{i+1}) \cup (g_i f_{i+1}) \cup (f_i g_{i+1}) \cup (f_{\frac{n}{2}} f'_{\frac{n+1}{2}}) \cup (f_{\frac{n}{2}} g'_{\frac{n+1}{2}}) \cup (g_{\frac{n}{2}} f'_{\frac{n+1}{2}}) \cup (f_i' f'_{i+1}) \cup (g_i' f'_{i+1}) \cup (f_i' g'_{i+1});\ 1 \leq i \leq n-1\}$.

We can first select the vertices with odd degree. As $g_1, g_n$ and $g_{\frac{n+1}{2}}$ are odd degree vertices. Therefore, all the above mentioned vertices will form a co- even dominating set.

For each four $f_i\ (1 \leq i \leq n-1)$ vertices, vertex $f_{i+1}$ is adjacent to $f_{i+2}, f_i, g_{i+2}$ where as vertex $f_{i+2}$is adjacent to $f_{i+3}, f_{i+1}, g_{i+3}, g_{i+1}$. If only one vertex comes last, that vertex can be taken from the co-even dominating set.

Just as the $f, g$ vertices work, the same as process applies to $f', g'$. By definition, $g_1, g_n, g_{\frac{n+1}{2}}, f_{i+1}, f_{i+2}, g_1', g_n', g'_{\frac{n+1}{2}}, f'_{i+1}$ *and* $f'_{i+2}$ are co-even dominating set.

Hence $\gamma_{coe}[S(H_n)] = n + 7$

For example: $\gamma_{coe}[S(H_{21})] = \{g_1, g_{11}, g_{21}, f_2, f_3, f_6, f_7, f_{10}, f_{11}, f_{14}$
$, f_{15}, f_{18}, f_{19}, f_{20}, g_1', g_{11}', g_{21}', f_2', f_3', f_6', f_7', f_{10}', f_{11}', f_{14}', f_{15}', f_{18}', f_{19}', f_{20}'\} = 28$.

**Theorem 3.8** $\gamma_{coe}[S(P_n^+)] = 2n$

**Proof.** Let $S(P_n^+)$ be splitted graph of $P_n^+$. Let V$[S(P_n^+)] = \{f_i, g_i, f_i', g_i' : 1 \leq i \leq n\}$,

Let E$[S(P_n^+)] = \{ [ (f_i f_{i+1}) ;\ 1 \leq i \leq n-1] \cup [ (f_i f_i') \cup (f_i g_i') ;\ 1 \leq i \leq n] \cup [ (g_i f_{i-1}) \cup (g_i f_i') \cup (g_i f_{i+1}) ;\ 2 \leq i \leq n-1] \cup (g_1 f_1') \cup (g_1 f_2) \cup (g_n f_n') \cup (g_n f_{n-1}) \}$

In $S(P_n^+)$ graph, If we take all the $g_i$ & $g_i'$ vertices, these vertices act as a co-even dominating set. As fellows vertex $g_{i+1}$ is adjacent to $f_i, f_{i+2}, f'_{i+1}\ (1 \leq i \leq n)$ where as $g_i$ adjacent to $f_i'(1 \leq i \leq n)$.

Moreover $g_i'$ adjacent to $f_i(1 \leq i \leq n)$. by definition, $g_i$ *and* $g_i'$ satisfy co – even dominating set.

Hence $\gamma_{coe}[S(P_n^+)] = 2n$.

For example: $\gamma_{coe}[S(P_5^+)] = \{g_1, g_2, g_3, g_4, g_5, g_1', g_2', g_3', g_4', g_5'\} = 10$.

**Theorem 3.9.** $\gamma_{coe}[S(P_n o NK_1)] = n\ (1 + N)$.

**Proof.** Let $S(P_n o NK_1)$ be splitted graph of $P_n \circ NK_1$.

Let V$[S(P_n o NK_1))] = \{f_i, g_i, f_{ij}, g_{ij};\ 1 \leq i \leq n,\ 1 \leq j \leq m\}$,

Let E$[S(P_n o NK_1))] = \{ [ (f_i f_{i+1}) ;\ 1 \leq i \leq n-1] \cup [ (f_i f_{ij}) \cup (g_i f_{ij}) \cup (f_i g_{ij}) ;\ 1 \leq i \leq n, 1 \leq j \leq N ] \cup [ (g_i f_{i-1}) \cup (g_i f_{i+1}) ;\ 2 \leq i \leq n-1] \cup [ (g_1 f_2) \cup (g_n f_{n-1}) ] \}$

In $S(P_n o NK_1)$ *graph*, we can first select the vertices with odd degree. As $g_{ij}(1 \leq i \leq n, 1 \leq j \leq N)$ are odd degree and moreover $g_1$ *and* $g_n$ are odd degree. Therefore all the above mentioned will form a co –even dominating set.

Then the minimum co- even dominating set must be selected from the remaining vertices. If $g_i(1 \leq i \leq n)$ vertices are selected from the remaining vertices, the minimum co-even dominating set is obtained. Vertex $g_{i+1}$ is adjacent to $f_i, f_{i+1}, f_{ij}(1 \leq i \leq n, 1 \leq j \leq N)$, By definition, , $g_i, g_{ij}$ all vertices satisfy co – even dominating set.

Hence $\gamma_{coe}[S(P_n o NK_1)] = n\ (1 + N)$

For example: $\gamma_{coe}[S(P_4 o 2K_1)] = \{g_{11}, g_{12}, g_{21}, g_{22}, g_{31}, g_{32}, g_{41}, g_{42}, g_1, g_2, g_3, g_4\} = 12$.

## ABSTRACT

Anti-cyclic citrullinated peptide (anti-CCP) antibodies highly specific markers of autoimmune activity primarily studied in rheumatoid arthritis have recently been implicated in other autoimmune conditions including thyroid disorders. In a case-control study of 70 patients with subclinical hypothyroidism (TSH > 5 mIU/L, normal FT4) and 70 age and sex-matched euthyroid controls, anti-CCP antibodies were measured by ELISA alongside inflammatory markers such as C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR). Anti-CCP positivity was significantly higher in subclinical hypothyroidism cases (22.5%) compared to controls (5%, $p < 0.01$) and anti-CCP positive patients exhibited elevated CRP (5.8 ± 1.9 mg/L vs. 3.2 ± 1.1 mg/L) and ESR (26 ± 8 mm/hr vs. 14 ± 6 mm/hr, $p < 0.01$) compared to anti-CCP negative cases. Regression analysis confirmed anti-CCP positivity as an independent predictor of systemic inflammatory burden. These findings suggest that anti-CCP antibodies may serve as a novel

biomarker linking thyroid autoimmunity with systemic inflammation in subclinical hypothyroidism warranting further longitudinal studies.

**Keywords:** Autoimmune hypothyroidism, Hashimoto's thyroiditis, Anti TPO antibodies, Anti TG antibodies, Anti CCP antibodies, Rheumatoid arthritis, Citrullination, Autoimmune overlap syndromes, Systemic inflammation, Biomarkers.

## INTRODUCTION

Subclinical hypothyroidism (SCH) is defined biochemically by elevated thyroid-stimulating hormone (TSH) with normal free thyroxine (FT4) levels. It is frequently associated with autoimmune thyroiditis, particularly Hashimoto's thyroiditis, which remains the most common cause of hypothyroidism worldwide (1,2). Hashimoto's thyroiditis is characterized by lymphocytic infiltration, progressive follicular destruction and the presence of thyroid autoantibodies most notably anti-thyroid peroxidase (anti-TPO) antibodies(3,4). While anti-TPO antibodies are well-established markers of thyroid autoimmunity other autoantibodies may contribute to systemic immune dysregulation. Anti-cyclic citrullinated peptide (anti-CCP) antibodies, highly specific for rheumatoid arthritis (RA) are known to predict disease severity and erosive progression(5,6). Interestingly anti-CCP positivity has also been reported in non-rheumatic autoimmune conditions including systemic lupus erythematosus, Sjögren's syndrome and autoimmune thyroid disease(7–9). Their presence may reflect shared mechanisms of autoimmunity such as citrullination-driven neoantigen formation and chronic inflammatory activation(10,11).

Systemic inflammation in SCH has been documented through elevated C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) even in the absence of overt hypothyroidism(12–14). CRP is a sensitive marker of acute-phase response(15) while ESR reflects chronic inflammatory activity(16). Both markers have been widely used in autoimmune and endocrine disorders to assess inflammatory burden. The clinical significance of these findings is considerable. SCH has been linked to cardiovascular risk, metabolic syndrome and polyautoimmunity(17–19). Rotondi and Chiovato emphasized that thyroid autoimmunity should be considered within the broader context of systemic inflammation(20) while Ruggeri et al. highlighted that systemic inflammatory activity in autoimmune thyroid disease may influence disease progression and therapeutic outcomes(21). Tang et al. further demonstrated that CRP and TSH together may act as risk factors in thyroiditis(22).

Moreover, studies have shown that anti-TPO antibody positivity correlates with inflammatory markers in SCH(23) and environmental and genetic factors play a role in autoimmune thyroid disease susceptibility(24). Cytokine-mediated immune responses also contribute to thyroid autoimmunity(25). Importantly, cardiovascular risk has been linked to both RA and thyroid autoimmunity, suggesting overlapping inflammatory pathways (26). Autoantibodies in autoimmune diseases, including thyroiditis may therefore serve as predictors of systemic involvement(27–29). The potential association between anti-CCP antibodies and inflammatory markers in SCH remains underexplored. Identifying such a relationship could provide insights into the systemic nature of thyroid autoimmunity and its overlap with other autoimmune pathways.

## MATERIAL AND METHODS

This case–control study was conducted on a total of 140 individuals, comprising 70 patients diagnosed with subclinical hypothyroidism (SCH) and 70 age and sex-matched healthy controls. Participants were recruited from the outpatient clinics of the Department of Endocrinology.

**The inclusion criteria for the SCH group were:**

a) Age between 18 and 50 years.
b) Newly diagnosed cases of subclinical hypothyroidism, defined as elevated serum thyroid-stimulating hormone (TSH) levels with normal free triiodothyronine (FT3) and free thyroxine (FT4) concentrations.
c) No prior history of thyroid hormone replacement therapy or immunosuppressive treatment.

**Exclusion criteria included:**

a) Overt hypothyroidism or hyperthyroidism.
b) Pregnancy or lactation.
c) Presence of autoimmune diseases other than thyroid autoimmunity.
d) Chronic inflammatory disorders, recent infections, or any systemic illness known to influence thyroid function or inflammatory markers.
e) Use of medications that could interfere with thyroid function or immune response.

**Healthy controls:-** were selected from the same demographic population, matched for age and sex and confirmed to have normal thyroid function tests and no history of autoimmune or chronic inflammatory disease.

Ethical Considerations

The study protocol was reviewed and approved by the Institutional Ethics Committee (Ref. No. SMC/UECM/2024/914). Written informed consent was obtained from all participants prior to enrollment.

Sample Collection and Processing

Venous blood samples (5 mL) were collected from each participant under strict aseptic precautions using sterile vacutainers. Samples were allowed to clot at room temperature and subsequently centrifuged at 3000 revolutions per minute (rpm) for 10 minutes. The separated serum was aliquoted into sterile cryovials and stored at –20 °C until further biochemical and immunological analysis.

Laboratory Investigations

Statistical Analysis

Correlation analysis performed using Pearson's correlation coefficient to assess relationships between:

- Anti-CCP and TSH
- Anti-CCP and hsCRP
- Anti-CCP and ESR

Statistical significance was defined as $p < 0.05$.

## RESULTS

In the case group (n = 70). The mean serum triiodothyronine (T3) level was 1.61 ± 0.60 ng/mL, with a median of 1.5 ng/mL. Thyroxine (T4) levels averaged 102.80 ± 23.20 nmol/L (median: 98.5 nmol/L), while thyroid-stimulating hormone (TSH) levels were elevated, with a mean of 8.58 ± 1.48 μIU/mL and a median of 8.6 μIU/mL, suggesting a trend toward hypothyroid function. Anti-cyclic citrullinated peptide (Anti-CCP) antibodies averaged 17.77 ± 7.59 U/mL (median: 16.4 U/mL), indicating active autoimmune involvement.

High-sensitivity C-reactive protein (hsCRP) levels averaged 14.22 ± 3.50 mg/L (median: 14.4 mg/L), and erythrocyte sedimentation rate (ESR) was 28.28 ± 5.53 mm/hr (median: 30 mm/hr), reflecting a heightened systemic inflammatory state.

All parameters showed statistically significant deviations from reference norms, with P values < 0.0001, indicating strong evidence of altered thyroid function, autoimmune activity, and inflammation in the case group.

In the case group (n = 70), thyroid-stimulating hormone (TSH) levels were elevated, with a mean of 8.58 ± 1.48 μIU/mL and a median of 8.6 μIU/mL. Anti-cyclic citrullinated peptide (Anti-CCP) antibody levels also showed elevation, with a mean of 17.77 ± 7.59 U/mL and a median of 16.4 U/mL. Pearson correlation analysis revealed a statistically significant moderate negative association between TSH and Anti-CCP levels (R = –0.279, P = 0.020).

In the case group (n = 70), anti-cyclic citrullinated peptide (Anti-CCP) antibody levels averaged 17.77 ± 7.59 U/mL with a median of 16.4 U/mL, while high-sensitivity C-reactive protein (hsCRP) levels showed a mean of 14.22 ± 3.50 mg/L and a median of 14.4 mg/L, indicating elevated autoimmune and inflammatory activity, respectively. Pearson correlation analysis revealed a weak positive association between Anti-CCP and hsCRP levels (R = 0.178), which did not reach statistical significance (P = 0.144).

In the case group (n = 70), anti-cyclic citrullinated peptide (Anti-CCP) antibody levels had a mean of 17.77 ± 7.59 U/mL and a median of 16.4 U/mL, while erythrocyte sedimentation rate (ESR) values were elevated, with a mean of 28.28 ± 5.53 mm/hr and a median of 30 mm/hr, indicating ongoing systemic inflammation. Pearson correlation analysis revealed a very weak negative association between Anti-CCP and ESR levels (R = –0.020), which was not statistically significant (P = 0.867).

## DISCUSSION

Our study demonstrates that anti-cyclic citrullinated peptide (anti-CCP) antibody positivity is significantly more prevalent in patients with subclinical hypothyroidism (SCH) compared to euthyroid controls and is associated with elevated systemic inflammatory markers. These findings expand the understanding of thyroid autoimmunity by suggesting that anti-CCP antibodies, traditionally considered highly specific for rheumatoid arthritis (RA) may also play a role in non-rheumatic autoimmune conditions such as autoimmune thyroid disease (30, 8). The elevated anti-CCP levels observed in SCH patients support the hypothesis that citrullination-driven neoantigen formation contributes to immune dysregulation across multiple autoimmune disorders (31, 11). Systemic inflammation in SCH has been well documented, with increased C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) even in the absence of overt hypothyroidism (13, 14). In this study, anti-CCP positive patients exhibited significantly higher CRP and ESR values compared to anti-CCP negative cases, reinforcing the concept that thyroid autoimmunity is not confined to the thyroid gland but reflects a systemic inflammatory state (32, 33). These findings align with previous reports linking SCH to cardiovascular morbidity and metabolic syndrome (17, 2).

Correlation analysis revealed a moderate negative association between TSH and anti-CCP levels suggesting that higher autoimmune activity may coexist with relatively lower TSH elevations. This observation highlights the complex interplay between thyroid function and systemic immune activation, and may indicate that anti-CCP positivity identifies a subset of SCH patients with distinct immunological profiles. Interestingly anti-CCP showed only weak non-significant correlations with CRP and ESR implying that while anti-CCP positivity marks heightened inflammatory burden it may not directly scale with the magnitude of CRP or ESR elevation. Similar dissociations have been reported in autoimmune thyroiditis, where autoantibody positivity does not always parallel inflammatory marker levels (9, 22). The clinical implications of these findings are considerable. SCH has been increasingly recognized as a condition with systemic consequences, including cardiovascular risk and polyautoimmunity (2, 26). Identifying anti-CCP positivity in SCH patients may help stratify risk, guiding closer monitoring and potentially earlier intervention. Moreover, the overlap between RA-associated biomarkers and thyroid autoimmunity underscores shared inflammatory pathways, raising the possibility of common therapeutic strategies. This is consistent with the broader literature emphasizing that autoantibodies in autoimmune diseases may serve as predictors of systemic involvement (33, 34). Nevertheless, this study has limitations. Its cross-sectional design

precludes causal inference, and longitudinal studies are needed to determine whether anti-CCP positivity predicts progression to overt hypothyroidism or the development of comorbid autoimmune conditions. The sample size, although adequate for initial associations may limit generalizability. Furthermore, cytokine profiling and endothelial function assessment could provide deeper mechanistic insights into the link between anti-CCP antibodies and systemic inflammation in thyroid autoimmunity[2]. Future research should explore whether anti-CCP positivity in SCH patients predicts cardiovascular outcomes or polyautoimmunity, thereby refining risk stratification and management strategies.

## CONCLUSION

Our study highlights that anti-cyclic citrullinated peptide (anti-CCP) antibody positivity is significantly more common in patients with subclinical hypothyroidism (SCH) compared to euthyroid controls and is associated with elevated systemic inflammatory markers such as C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR). These findings suggest that anti-CCP antibodies, traditionally considered specific for rheumatoid arthritis, may also serve as a novel biomarker in thyroid autoimmunity, reflecting broader systemic immune activation. The moderate negative correlation between TSH and anti-CCP levels indicates a complex interplay between thyroid function and autoimmune activity, while the weak associations with CRP and ESR highlight that anti-CCP positivity may identify a distinct subset of patients with heightened inflammatory burden. Clinically, this underscores the importance of considering SCH not merely as a biochemical abnormality but as a condition with systemic consequences, including cardiovascular risk and polyautoimmunity. Although limited by its cross-sectional design, the study provides a foundation for future longitudinal research to explore whether anti-CCP positivity predicts progression to overt hypothyroidism, cardiovascular outcomes, or comorbid autoimmune diseases. Integrating anti-CCP testing into the evaluation of SCH may enhance risk stratification and guide more personalized management strategies.

**Limitations and Future Directions**

This study has several limitations that should be acknowledged. First, the cross-sectional design restricts the ability to establish causality between anti-CCP antibody positivity and systemic inflammation in subclinical hypothyroidism (SCH). Longitudinal studies are required to determine whether anti-CCP positivity predicts progression to overt hypothyroidism, cardiovascular complications, or the development of other autoimmune conditions. Second, the sample size, although adequate for initial associations, may limit the generalizability of the findings to broader populations, particularly older individuals or those with comorbidities. Third, the study focused primarily on conventional inflammatory markers such as C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR), without incorporating cytokine profiling or advanced immunological assays, which could provide deeper mechanistic insights into the pathways linking anti-CCP antibodies with thyroid autoimmunity. Fourth, environmental and genetic factors known to influence autoimmune thyroid disease susceptibility were not assessed, which may have contributed to variability in immune responses. Finally, cardiovascular outcomes were not directly evaluated, despite the established link between systemic inflammation, thyroid autoimmunity, and cardiovascular risk.

Future research should aim to address these limitations by conducting large-scale, multicenter longitudinal studies to evaluate the prognostic value of anti-CCP antibodies in SCH. Incorporating cytokine panels, endothelial function markers, and genetic susceptibility analyses would help clarify the immunopathogenic mechanisms underlying the observed associations. Additionally, exploring the role of anti-CCP positivity in predicting cardiovascular outcomes and polyautoimmunity could refine risk stratification and guide personalized management strategies. Integrating anti-CCP testing into routine evaluation of SCH, alongside traditional thyroid autoantibodies, may ultimately enhance clinical decision-making and improve patient outcomes.

## ACKNOWLEDGEMENT

The authors sincerely acknowledge the support and guidance received from the Departments of Biochemistry, Endocrinology, and Immunology at CSSH Hospital, Subharti Medical College, Meerut, Uttar Pradesh, India, where this study was conducted. We extend our gratitude to the faculty and technical staff for their assistance in laboratory investigations and data collection. We are deeply thankful to the Institutional Ethics Committee for reviewing and approving the study protocol, ensuring that the research was conducted in accordance with ethical standards. Our heartfelt appreciation goes to all the participants who volunteered for this study and provided valuable samples and clinical information. Without their cooperation, this research would not have been possible. Finally, we acknowledge the contributions of colleagues and peers who provided constructive feedback during the preparation of the manuscript.

**Conflict of interest:-** No Conflict of interest to disclose.
**Funding:-** Nil.

## ABSTRACT

Resource management should begin at micro spatial units as mankind has gradually evolved observing, learning and using nature and its resources to satisfy their requirements at micro spatial scale i.e. immediate surroundings. Deterioration, destruction, degradation of natural ecological units at micro spatio-temporal scale is cause of decline in global biodiversity and ecosystem obliterations at large. The Kalyani Reserve Forest (KRB), regarded among the richest biodiversity zones in India is impacted in terms of human introduced land cover dynamics which leads to forest fragmentation and shrinking of total forest area .The chief reason for forest fragmentation in this region is due to shifting agriculture. It is observed and estimated from a two decade (2000-2020) change detection analysis of forest cover using vegetation indices like NDVI,AVI, BSI and finally Forest Canopy Density (FCD) that a reduction of 12.44 .% of total forest cover has taken place with the rate of shrinking forest area estimated at 0.62km²/year estimated for twenty years .The chief effort should be to restore ecological balance by restoring soil fertility through sustainable methods. This paper attempts to analyze, quantify and discuss the change in land cover and subsequent deterioration due to forest canopy fragmentation which begin at microspatial scales chiefly due to clearing forest floor for shifting agriculture. The estimation and assessment of shrinking forest canopy will help to understand the deterioration to floral and faunal habitats which on a macro scale contribute to depleting forest areas .It will alternatively help to suggest appropriate means of livelihoods for the indigenous people residing here in the natural environment that will safeguard their traditions.

**Key Words:** landcover change, degradation, jhum cultivation, forest ecosystems,landuse

# INTRODUCTION

Forest fragmentation reduces forest space and resources.It endangers ecosystems contributing to global degradation and reduction of forest cover limiting the scope for carbon sequestration. This poses a major challenge for natural ecosystems conservation efforts and controlling air pollution.Land cover change is a dynamic process which can be explained as a break or interruption over land inhabited by generally similar natural vegetation or pedological character as a result of a particular temperature and moisture conditions. For any assimilation or estimation of forest canopy cover degradation,quantitative methods using vegetation indices as NDVI,AVI and BSI change detection is one of the most essential parameter which can be assessed quantitatively to indicate scales of degradation in Forest Canopy Cover(FCD). This helps in formulation of conservation/ restoration strategies to safeguard habitats. Land cover change is the initiation of change in natural floral coverage over surface either by physical causes or by actions of anthropogeny for economic, demographic orpolitical(wars/conflict zones) reasons.Land use is the use or management of land which is characterized by natural entities like forest, water body,grassland, wetland, desert terrain and utilize it for anthropogenic purposes giving economic benefits.

**Objectives:**

This study attempts to assess in the study area:

i) the areal extent of change in FCD
ii) to classify the pattern of forest fragmentation of KRB.

**Study area:**

The Kalyani River Basin(KRB) with a total catchment area of 1254 sq.km is located between 26° 13' 47" N 26° 40' 38" N longitudes and 93° 12' 28" E - 93° 12' 48" E latitudes. A part of the Kalyani Reserve Forest to the east of the Mikir Hills in Assam isa part of the KarbiAnglong district (Diphu subdivision)of Assam, India.The"the general elevation ranges from 100 m (Kamargaon) mouth,to1281 m (InglangIkpi)"(Mukherjee 2012).There are a large number of non-tribalsand tribals who live together in this hill region. The tribalethnic groups are Dimasas, Garos, Karbis, Tiwas, Hmars, Nagas, Kukis, Bodos, Rengma,Man(Tai speaking) Fig.1. The climate of the region is characterized withcold winters and humid summers as prevalent in tropical regions .The cold months are from October to February .Summers are from March to June .The temperature ranges from 6° to 11° in winter 22° to 31 °Celsius in summer. The monsoons are experienced betweenJuly to September with the average rainfall about 210 cms .Thenatural vegetation of the region was extensively classified and documentedby Champion and Seth in 1968. Following their classification the study area is covered by dense tropical evergreen forest alternated by moist deciduous varieties with moist bamboo brakes (*Dendrocalamus hamiltonii, Bambusa pallida,* and *Melocanna bambusoides* are commonly found in the area. The study region is characterized by moist deciduous forest species such as Tetrameles nudiflora, *Duabanga sonneratioides, Lagerstroemia parviflora, Careya arborea, Kydia calycina, Gmelina arborea, Albizia procera, Terminalia myriocarpa, various Bamboo species, Terminalia tomentosa, Shorea robusta,* and *Dillenia pentagyna* (Roy et al., 1991).The pedology of the region consists of new alluvial soil derived from the weathering of gneissic terrain. The soils are generally well developed. Due to heavy rainfall, significant leaching occurs, resulting in acidic soils. In general, the soils are very deep, except on hilltops (Roy et al., 1991).

# MATERIALS AND METHODS

Topographical sheets(SoI) 83F/3, 83F/6 , 83F/7, 83F/8, 83 F/10 , 83F/11, 83F/14 and 83F/15 of scale1:50,000 ,satellite data, secondary data on agriculture,climate, demography,and published researches on the present status of shifting cultivation(2000 –2021)were gone through.An attempt has been made to reconstruct the land cover alteration due tofragmentation in the forested regions of KRB that reveal disruption/perforation of forest cover within the study area. New satellite data sets reveal at high resolution how human activities are gradually and irreversibly,transforming forest space over a temporal span.The forest canopy cover alterations through satellite

imageries are clearly and easily noticed due to sharp contrast in tone and texture between dense vegetation cover in forests and anthropogenic land cover types/afforested areas having interrupted canopy and comparatively more exposed bare soil.*"The present study was carried out with an attempt to analyze the change in LULC and forest fragmentation using satellite data"*(Shimrah et al.,2021)

**Data sets**

NDVI analysis for preparationof LULC map is from satellite imageries of LANDSAT 5,7 & 8 and resolution -30 meters (Table 1).The satellite imagery are from Landsat 4-5 (TM), 7 (ETM+) & 8 (OLI) March 2000 - February 2020.They were observed to assess the status of forest cover in the study area. Usually satellite images captured during winter have a clear spectral reflectance and are not obstructed by cloud cover.*Image preprocessing attempts to minimize these effects to the extent desired for a particular application* (Young et al, 2017).*The images that are used in this study were atmospherically corrected and converted to Top of Atmosphere (TOA) radiance using the following formula –*

$L\lambda = MLQcal + AL$

*where,*

*Lλ= TOA spectral radiance (Watts/( m2× srad×μm)).*

*ML= Band-specific multiplicative rescaling factor from the metadata.*

*AL= Band-specific additive rescaling factor from the metadata.*

*Qcal= Quantized and calibrated standard product pixel values (DN)*.(Figure 2) (Awad2019,Patra etal2022)

The maps in this study have been done using Arc GIS 10.5 software.*"Accurate and periodic mapping of the shifting cultivation areas is vital for assessing their spatio-temporal dynamics for effective management of land use, and more so for the jhum-dominated landscape"*(Das et al, 2021,Patra etal2022). The analysis was done for satellite data at five years interval for the temporal window 2000-2020 evaluate the change in spatial patternsof shifting cultivation areas as "*significant relative differences in surface reflectance values of vegetation, and used to derive shifting cultivation patches*."(Das et,al 2021,Patra et al 2022)where estimated .Vegetation Indices (VI) have been prepared to analyze forest cover. *Most two-band VIs make use of reflectances in red and NIR bands"*(Chen 2018).The analysis of Land Use/ Land Cover (LULC) was carried out using NDVI datasets for the years 2000, 2005 , 2010, 2015 and of 2020 .The pattern and extent of spatial shrinkage over a temporal scale was identified for forest and non forest covers.The spatio-temporal assessment of forest pattern using multi temporal satellite data over a span of two decades (2000-2020), 3 vegetation indices (Table 2 and LFT (v.0.2) developed by CLEAR (Univ.of Connecticut)within the KRB to assess forest canopy density status and identify the patternof fragmentation of forest canopy cover. The region is a part of the KarbiAnglong plateau and covered by dense evergreen and moist deciduous forest specie similar to lower Himalayan mountain regions.Physiographically it is a plateau and exhibits a granitic rock surface character. Usually forests on "*Mountainous areas contain some of the best-preserved natural habitats, but they are threatened by changes in land use and climate* "(Thuiller et al 2005).Dry bare soil has higher reflectance in shortwave IR and humid bare soil has low reflectance due to presence of soil moisture. "*Bare soil index is an indication of how much land is disturbed /cultivated or used by anthropogeny.It also indirectly reflects that how much forest canopy cover is there in a specific time span*" (Rikimaru and Miyatake 1997,Bera 2020).The bare soil spatial units within the forest are cleared areas or those left fallow after cropping .*"Over the years, Northeast India has experienced major changes in LULC and forest fragmentation.There are limited information and data regarding the change in LULC patterns and causes of forest fragmentation"*(Shimrah et al.,2021)

## RESULTS

The study was attempted to assess land cover change dynamics due to natural (forest fires, floods, earthquakes etc.) as well as anthropogenic causes (agriculture, infrastructure development extraction of tree stands for economic reasons etc.), specifically like shifting agriculture because it leads to habitat and forest fragmentation. According to McGarigal et al. 2005 – "habitat fragmentation is a process of landscape change and not just a patch level process only". This type of land use practice is generally prevalent amongst human communities that cultivate on a subsistence basis on hill slopes and requiring minimal soil moisture. "Shifting cultivation tends to persist when population density is low and when options for agricultural development or alternative livelihoods are limited"

(Mertz 2002,2009, Heinimann et al 2013,2017).Therefore such agricultural practice endangers flora and fauna of the region and is a silent threat to ecology, stripping the forest zone of natural vegetative cover and accelerating forest environment moisture depleteon, soil moisture loss and soil organic content deteoraration. The detrimental practice generates patches of land that become open systems ,develop interrupted food chains and ecosystems in spatio-temporal effect. The edge /overlap region between dense forest cover and cleared areal units are affected by heat which impacts biological life within the adjacent areal extension of forest. They also bear major duress and distress due to population ingress in its peripheral vicinity for collection of firewood, extricating bamboo for sale, medicinal plants, hunting of animals, food supplements and any other forms of supplemental gratification for living .The LULC change analysis using NDVI with ground truth verification on field have been carried out to corroborate the analysis

## DISCUSSIONS

It is observed that with an increase in water bodies, built up area ,barren land, shrub and grassland proliferation, sparse vegetation in abandoned shifting agriculture patches within the forest there has been a gradual shrinking in dense vegetation area along the banks of lower course of the Kalyani river as observed in NDVI for 2000 to 2005(Fig.2) With the immediate consequence of forest loss and increase in size of anthropogenic land cover ( example, agricultural fields and urban areas,transport corridors etc.),the remnant forests edges are most impacted.The edge is a zone of temperature buffer zone with exposed terrains and forested land having noticeable land surface temperature contrasts.To clearly understand the dynamics of forest canopy density and its fragmentation, simply NDVI alone does not address all changes. Those areas characterised by shifting agriculture have highpresence of aerosols due to burning of slashed foliage , fallow land have exposed soil cover reclaimed by shrubs and coarse grasses for areas.This is further validated by using vegetation estimation indices to carry out this study.

**Advanced Vegetation Index (AVI )**

Advanced Vegetation Index (AVI) is used in vegetation studies to assess forest variations over a temporal frame. It is almost similar to NDVI, and uses the red and near-infrared spectral bands. Like NDVI, AVI can be used for vegetation studies to detect forest cover variations over time . The canopy displays a distinct yellow orange tone due to drying of leaves during winter for 2000. This is a suitable index as some of the slopes in the study area are covered by tea and rubber plantations and the canopy pattern helps to identify natural and cultural entities. The AVI for the areal coverage in the medium class is 381.60 km² for 2000 and 414.33 km² 2020.(Table 3)Fig.5&6.

**Bare soil index (BSI)**

It is an indication of how much land is disturbed /cultivated or used by anthropogeny. It also indirectly reflects that how much forest canopy cover is there in a specific time span" (Rikimaru and Miyatake 1997, Bera 2020) Dry bare soil has higher reflectance in shortwave IR and humid bare soil has low reflectance due to presence of soil moisture. It is observed (Table 5) that the threshold values of BSI for the study area in the low range(0.089-0.060) occupies maximum area of 485.56 sq.km i.e 38.72% of the total basin area in 2000 and remains nearly the same in 2020 , indicating dense vegetation cover for a larger part of the basin .While in the very high threshold range ( 0.016-0.158 ) covers only 63.69 sq.km in 2000 and a slight increase in threshold values (0.026 -0.376)covers 81.01 sq.km in 2020 within the basin area. The Landsat 8 OLI data ( path 136 row 042 resolution 30 metres) of 2020 shows bare patches which are distinguishingly different from the dense forested areas . In the eastern part it is observed there are cleared land for sedentary agriculture and ground validation showing seasons of fallow during summer , transport corridors (NH35) and built up patches. These built up areas can be classified into primary bare land with incidences of slope failure (seen as broad teardrop shapes and along slope edges ).Anthropogenic intrusion along the Kalyaniriver , in patches within the basin are observed in square or rectangular polygons for shifting cultivation. They are usually near villages to facilitate easy access and the middle to lower courses of tributaries for being characterized by gentle slopes . Requirement for water is minimal as cultivation is chiefly rain dependent. The other

type can be classified as secondary bare land with fallow and built up area. Bare soil plays a significant role in any ecosystem by accelerating top soil loss through wind or water.Table 4. Fig.7&8

**Forest Canopy Density(FCD)for KRB-Assam**

Forest Canopy Density (FCD) refers to the proportion of an area in the field/ground that is covered by the crown of trees and is expressed in percentage of the total area."*Forest Canopy Density (FCD) is a biophysical analysis model that can be used to analyze a forest canopy density changes*" (Himayah et al 2016).The identified forest cover estimation was obtained as per Forest Canopy Density. (Fig.9&10)Shifting cultivation is identified to have two categories i.e freshly cleared and the other being fallow or abandoned."*Abandoned shifting cultivation with heavy growth of shrubs on hills is classed separately. Whereas current shifting cultivation, non-forest, barren hills and woodland less than 10 percent tree crown density*" (Roy et al 1991) are classed separately.

**The extent of Forest Fragmentation for two decades in KRB : ( 2000 – 2020 )**

The Very Dense Forest (VDF) area occupies 903. 01 km² i.e 72 % in the western part and south western part, Moderately Dense Forest (MDF) occupies 266.19 km² i.e 21.23 in the central and north central and southern part,Open Forest (OF) 76.90 km² i.e 6.15 % in the eastern part and Non-Forest (NF) 7.90 km² i.e 0.63%, of the north eastern part of the KRB area ( Fig.11) These classes were derived from the Forest Canopy Density model. According to the forest classification map five classes have been designated with Very High and High class being considered under VDF. VDF class dominates primarily and cultural features are found on the far eastern side of the study area. However there has been a decrease of 132.17 km² i.e 10.54 %, which is nevertheless nominal- an indicator of slow depletion of forested area. The rate is estimated to be at 6.61km²/year. TheKalyani river flowing west to north east through the basin splits it into two halves and the banks experience the Edge Effect whereby the immediate banks offer scope for human habitation and livelihoods through farming and extraction of bamboo .

Haddad et. al (2015) and Sexton (2013)analyzed the world's first high-resolution map of global tree cover to measure the magnitude of forest fragmentation."*This analysis revealed that nearly 20% of the world's remaining forest is within 100 m of an edge—in close proximity to agricultural,urban,orother modified environments where impacts on forest ecosystems are most severe"* (Laurance et al 2002) In the present millennium, use of geographical knowledge together with geospatial analysis is essential not only to estimate and combat climate change and landscape transformation but understand the interrelation,estimate the impact and find solutions for development of proper land use patterns.

**Core** – The VDF zone can suitably be designated as the core area of the forest covering an area of 903.01 sq.km which are seen as pixels suitably away from the non forest,open forest and barren land (orange and yellow) pixels.This class comprising Very high and High classes together has reduced by 132.17 sq.km i.e 6.61 sq km/year. (0.53% per year of the total forest area).

**Perforated** – They comprise of openings in the canopy just initiated by forest clearing for shifting agriculture or clearing pure bamboo stands. (Photo plate 7).They are observed as orange colouredpixels,usually in clusters and found more on the left bank slopes along the lower middle course of the Kalyani river. The moderate forest zone has seen an increase of 86.33 sq.km ( 4.32 sq.km /year) ie 0.34% per year.This is the only class which is increasing in areal expanse in the study area.

**Patch** – They are isolated points not far from the non forestzone and display edge effect. Open land with none of the original species of natural vegetation is found on ground validation. They cover a total area of 183 sq.km in KRB. They have maximum spectral reflectance during pre monsoonseason due to dry soil while exposed rock masses have the same reflectance in all seasons. A rural settlement is usually found nearby and these patches are used as a playground by locals which gradually gives way to built up structures like places of worship or a plywood factory.

The patch matrix in the study area is observed to be having two separate and distinct shapes as discussed briefly below-

i)**Polygonal matrix**–Euclidian shape (circle/square) found on the gentle slopes of not more than 20°-25°slope incline which is classified under moderate slope. They maybe in isolation or in aggregation.This is further found as in:

a)**Isolation**–where each patch is spatially segregated from each unit.The rural settlement units are BuraSignar, BuraTisso, Patargaon, Rongdang to name a few.

b)**Aggregation**–where the patches are clustered with their borders integrated.The patches have been used and abandoned not at the same time,so a thin border can be made out usually between each patch cleared and abandoned.A collection of patches near rural settlement units of DiliTerang , NW of Rensing,aroundSilonijan where noticed on ground validation.

ii)**Linear matrix**–longitudinal and convulated at places along the river can also be called patch corridors,from source to mouth(near the rural settlements of ofBaliramEngti ,NE of Rensing)

**Edge**–Found along the fringe of densely vegetated arealunits,perforations, patches and along the patch corridors on both banks of the river.They are about 50 metres in width and adjacent to the open forest region.They are the zones of maximum transgress by locals and avoided by animals .

**Implication of the study -**

It is analyzedfor KRB that"*the accuracy of shifting cultivation has been found to be very low (60%) due to its overlap of signature with degraded forest"* (Roy et al.,1991).The fragmentation analysis using Landscape Fragmentation Tool (LFT v2.0) showed the core area shrinking at very gradual rates and an increase in perforated,edge and patch areas by 5.93 %,3.64 % and 0.66 %, respectively.

The occupation of larger area under high forest canopy density,the forest area is an ideal carbon sink,absorbing pollution from local fires of slash and burn methods (jhum),household fires ,agriculture stubble burning and transport.Itassists climate regulation augmenting the regions contribution to global carbon cycle as well as the nutrient cycle of this particular ecosystem of flora and fauna at vertical and horizontal levels.At present the AQI(obtained from open source datasets ) of the study area, ranges between 70 - 80 on the fringe zone which points to moderate quality of air.The efforts should be to bring down the level between 0-50 of AQI signifying good air quality. The region is a part of world biodiversity hotspot zone in North East India. The change detection analysis results reveal that the negative impact of forest clearing is minimal in 2020 but can escalate as was the case in 2005."*Forest fragmentation is associated with the deterioration of the ecosystem's integrity, has negative impacts on biodiversity, degradation of forest, and spatial pattern of the landscape, and become a global conservative issue".*(Ahanthem et al.,2021)

"*More than 70% of the world's forests are within 1 km of a forest edge.Thus, most forests are well within the range where human activities, alteredmicroclimate, andnon forest species may influence and degrade forest ecosystems*"(Broadbent et al 2008, Haddad 2015).Forest fragmentation in the study area can be attributed to chiefly two conditions as analyzed from satellite images and ground truth verification reveals-

a.Due to nature of gneissic terrain, minimally weathered,metamorphic rocky outcrops which do not support natural vegetation cover due to the dynamics of landscape changeon the higher slopes.

b.Due to anthropogenic factors like sedentary cultivation, shifting cultivation,felling of trees and bamboo for plywood and paper mills respectively,gradual proliferation of cultural features like tea plantation areas, roads, bridges, settlementsetc.'*which initiate landscape changes with regard to disturbances and succession processes*' as McGarigal et al.,2005points out. In forests which are adjoining to human settlements like the study area,harvesting of forest products (eg. wood or bamboo) together with uneven nature of terrain and natural causes like flooding can be considered as severe perturbations. The river basin is prone to rapid erosion with regard to its geologic character and geomorphic processes in operation. The channel is susceptible to flash floods due to washing down of exposed soil from fallow fields situated on higher ground. Shifting agriculture (Jhum ) accelerates the rate of soil erosion thereby reducing the water carrying capacity of the drainage channel.This poses a severe hazard during and post monsoons periods. The fringe of settlements adjoining to forested regions are most compromised."*In 2010,KarbiAnglong district had 31.3 Mha of natural forest,extending over 11% of its land area.In 2020,it lost 132kha of natural forest, equivalent to 67.3Mt of $CO_2$ of emissions".*(4&5)

"Air temperatures at the edge of a forest remnant, for example, can be significantly higher than those found in either the interior of the remnant or the surrounding agricultural land "(Geiger 1965, Kapos 1989).The impact of forest fragmentation in KRB results in significant disruption of forest ecosystems and change in energy fluxes within it .The exposure of soil to direct rays of the sun leads to decline in soil moisture and reduction in its organic content. The loss of soil moisture reduces the scope for leaf mulch severely. Reduction of trees simultaneously reduces moisture within forest air and escalates the edge effect on patches where trees have been removed. The exposed soil with negligent moisture has redundant quality for tree cover re-generation. The KRB region slopes towards the Kalyani river and loose soil is washed down and deposited in the channel after heavy rains, reducing the water carrying capacity of the river and spillage on banks. The land cover character is altered with more exposed bare land.This results in increased heat absorption by the terrain, leading to hotter summers and less cooler winters. Anthropogenic intrusion along the Kalyaniriver,in patches within the basin are observed in square or rectangular polygons for shifting cultivation.They are usually near villages to facilitate easy access and the middle to lower courses of tributaries for being characterized by gentle slopes.Secondary bare land with fallow and built up area plays a significant role in degrading any ecosystem by accelerating top soil loss through wind or water. The shifting agriculture driven destruction of habitat in ecosystems takes place horizontally (i.e on ground ) and vertically (tree perch /branches ) simultaneously reduces the capacity of carbon sequestration in study area. The causes and probable solutions can be understood as below-

a. Deforestation leading to destruction of ecosystems and breaking of links in the nutrient cycles.Retreat of birds,animals and reptiles to core area compromises capacity to naturally generate food for those already there because of those newly arrived. This can be balanced by intensive afforestation of cleared areas.

b. shortening the period of shifting agriculture cycle the fallow period from 25 to 30 years before to now of 4 to 5 years there is rapid decrease in land productivity and meager to poor replenishment of forest cover with destruction of original tree species and forest cover to clear space for cropland. This can be addressed through Community Forest Development projects by local people to supplement income and regenerate forest cover and canopy density.

c.rotational felling and clearing of forest land for bamboo and plantations of both tea and rubber.This can be addressed by improving exposed soil quality after a season of cultivation through introducing of composting techniques (vermicomposting,leaf compost)

**Suggestions**

*Shifting agriculture produces organic* yields and is hence preferred by indigenous people for its high nutritional value.*Requirement of water for irrigation is minimal as cultivation is chiefly rain dependent*. The chief requirement is to introduce methods which will enhance soil quality in a sustainable process for land cover regeneration and prevent soil erosion.According to Bos et al (2020),*one of the reasons in support of Jhumming is that jhum rice is considered to be tastier among the Karbi, and they regard it to have higher health benefits than rice and vegetables intercropped and grown on sedentary subsistence farms which use chemical fertilizers.* Wangpan and Tangjang (2015)pointed out similar findings for the Arunachal Pradesh region of India, wherejhumming plays an important role*'nurturing rare germ plasms of different indigenous plant species, which are preferred for taste and nutritional benefits by these people'*. Wangpan and Tanjang (2015) further point out that '*dietary diversity has been found to be higher under a jhum regime in comparison to other cash cropping systems'*. Growing and healthy forests sequester and store the highest amount of carbon and in tropical countries like India it is essential that they are prevented from being degraded. On a global scale carbon sequestration is the natural and inexpensive way to offset impact of global warming and slow down climate change.

## CONCLUSION

Fragmentation of forest space degrades forests canopy cover and resulting in separate units /parcels of land which already had an established and functional ecosystem operating over a long temporal span, interconnected to adjoining natural units.It has been observed that nature always replenishes herself,but there is limit to this capacity of regeneration and replenishment. When extraction and exploitation of natural resources transcends the capacity to regenerate, replenish and restore,it results in gradual elimination of domestic flora and fauna and interruption in

ecosystem dynamics that propels the web of life in any micro region.The retreat of organisms further into core forest due to loss of existing habitats and forage space at the outer edges,renders limited access to biotic resources in their own habitats, reduces capacity for carbon sequestration and poses a risk to biodiversity.Land cover change initiates food web interruptions for flora and fauna resulting in degradation of natural systems in that particular areal unit and affecting global ecosystems collectively. The degraded patches left fallow with exposed soil and coarse vegetation need to be reclaimed under dense vegetation class by suitable methods of conservation and regeneration and improvement to soil quality.This will facilitate spatial patterns of human settlement in co-existence with their immediate ecosystem for improved human - environmental sustainability as envisaged by the United Nations SDGs-11 Sustainable Cities and Communities for Agenda 2030.

## ABSTRACT

To systematically evaluate and compare the diagnostic accuracy of Diffusion-Weighted Imaging (DWI) versus T2-Weighted Imaging (T2WI) in detecting acute stroke, stratified by age groups, to inform best practices in emergency radiology. A comprehensive search of PubMed, ScienceDirect, and Scopus databases was conducted for studies published between 1990 and 2024. Studies that directly compared DWI and T2WI in the diagnosis of acute ischemic stroke were included. Data extraction and quality assessment were conducted independently by two reviewers using PRISMA guidelines and the QUADAS-2 tool. A random-effects meta-analysis was performed to calculate pooled sensitivity, specificity, and diagnostic odds ratios (DOR) across different age cohorts. A total of 28 studies with over 5,600 patients were included. DWI showed significantly higher sensitivity (mean 92%) compared to T2WI (mean 75%) in hyperacute stroke, particularly within the first 6 hours of symptom onset. Age-stratified analysis revealed that the diagnostic superiority of DWI over T2WI was most prominent in patients over 60 years of age. DWI also demonstrated better performance in identifying small cortical infarcts and lacunar strokes. However, DWI-negative strokes were more common in younger patients and in transient ischemic attacks. DWI outperforms T2WI in the early detection of acute ischemic stroke, particularly in older adults and hyperacute presentations. Emergency radiology protocols should prioritize DWI, though limitations in younger populations and early transient presentations warrant complementary imaging strategies.

**Keywords:** Diffusion-weighted imaging, T2-weighted imaging, acute stroke, diagnostic accuracy, emergency radiology, age stratification.

## INTRODUCTION

Acute ischemic stroke (AIS) is a tough global health concern, placing it among the leading causes of long-term disability and mortality. The WHO estimates that nearly 15 million people suffer strokes annually, and approximately 85% of these constitute ischemic strokes. Prompt diagnosis allows timely intervention therapies for AIS, such as intravenous thrombolysis and endovascular thrombectomy, as they are time-sensitive in nature, with the best treatment outcome achieved within a restricted period of 4.5 to 6 hours after symptom onset [1]. The diagnostic imaging world for AIS has seen DWI rise to prominence as a first-line modality able to detect cytotoxic edema, one of the very earliest changes in ischemia, within minutes after onset [2,3]. It is due to the fact that water molecules are free to move in ischemic tissue, which contrasts with the changes in signal on DWI that appear quite early before any visible abnormalities are seen on conventional sequences. On the other hand, T2-weighted imaging (T2WI), once considered the imaging study of choice for most stroke diagnoses, is now said to be less useful during the hyperacute phase because it demonstrates abnormalities following vasogenic edema and tissue necrosis [4,5].

Seminal studies by Moseley et al. and Warach et al. in the early 1990s demonstrated that DWI could detect ischemic lesions as early as 30 minutes after arterial occlusion, well before changes become evident on T2WI or CT [2,6]. This revolutionized the stroke imaging paradigm, particularly in tertiary and academic centers where MRI is readily available. Still, many institutions—especially in resource-limited or rural settings—continue to rely heavily on T2WI and CT due to the lack of immediate MRI access [7]. Despite the established role of DWI in stroke imaging, emerging literature has pointed out scenarios where DWI may not detect all ischemic strokes. DWI-negative stroke—an occurrence where clinical signs suggest ischemia but the DWI appears normal—has been reported in approximately 6% to 20% of cases, particularly in transient ischemic attacks (TIAs), small cortical infarcts, or posterior circulation strokes [8-10]. Edlow et al. conducted a meta-analysis revealing that false negatives in DWI were more frequent in younger populations and in cases with rapid clinical resolution [9]. Conversely, T2WI, though delayed in its signal evolution, may sometimes detect hemorrhagic or late-stage infarcts not initially visible on DWI, underscoring the complementary role of multimodal imaging [11].

The age-related variation in clinical appearance of a stroke and in its radiological visibility further nourishes this very much complicated diagnostic scene. The cerebral atrophy brought in by age, accompanied by vascular comorbidities, and variation in cerebral perfusion, has a bearing on the visibility of ischemic lesions on both DWI and T2WI [12]. According to Luijten et al., in the elderly, diffusion restriction is more apparent, either because of more severe hypoperfusion or because the lesion is contrasted by prior white matter disease [13]. DWI, in the meantime, may not be able to detect small or subtly ischemic changes in younger patients in the early stages [14]. Several comparative studies have aimed to assess the diagnostic accuracy of DWI versus T2WI across different clinical settings. Fiebach et al. [3] reported a sensitivity of DWI of 88% against 50% for T2WI in hyperacute stroke patients imaged within 6 hours of onset of symptoms. In the same way, Singh et al. [15], in a prospective study, showed a correct diagnosis of ischemic stroke with DWI in 96.6% of cases, compared to T2WI in 73.3%, again demonstrating the superior diagnostic yield of DWI in those crucial early hours.

These results are further supported by recent meta-analyses and systematic reviews. Zhang et al. [16] reported in their network meta-analysis that, among MRI techniques, DWI had the highest pooled sensitivity and specificity, while T2WI had higher variability depending on imaging time and lesion location. Another study by Ahmad et al. [17] concluded that while DWI retained high diagnostic performance for both anterior and posterior circulation strokes, T2WI failed to adequately detect posterior fossa infarcts due to beam-hardening artifacts and motion susceptibility. T2WI remains relevant for the detection of concurrent problems like hemorrhagic transformation, tumors, or old infarcts, which might hold therapeutic implications [18]. Luijten et al. [13] revealed that T2*GRE and SWI sequences, usually combined with T2WI, greatly increase the ability to find hemorrhagic components after reperfusion therapy, suggesting that DWI is not enough for complete diagnostics.

With these developments, there is a renewed focus on stratifying diagnostic performance according to patient characteristics such as age, time from symptom onset, stroke subtype, or imaging protocols. The comparative performance of DWI and T2WI resting on age groups is yet somehow an unresearched but definitely clinical concern. Elderly patients often present with atypical presentations and comorbidities that hamper diagnosis. According to Karis [19], there operates the fear that delayed diagnoses could be eliminated if clinicians have accurate and prompt imaging customized according to patient age and stroke subtype in the ER setting. Furthermore, with personalized medicine bringing with it growing emphasis, understanding age-specific diagnostic imaging performance might strengthen triage algorithms, resource allocation, or clinical decision-making in acute stroke care [20]. Given the literature available and the heterogeneity of study designs, a systematic review and meta-analysis on the diagnostic accuracy of DWI and T2WI, with a focus on age strata, can provide valuable evidence to help amend emergency radiology protocols and thereby improve patient outcomes.

The purpose behind this review was to bridge that very gap by synthesizing the existing evidence regarding the comparative diagnostic accuracy of DWI and T2WI for acute ischemic stroke and to consider whether diagnostic performance changes with patient age. It also sets out to draw consequences applicable to emergency radiological practice, especially where timely and accurate imaging guides time-critical intervention.

# METHODS

Search Strategy and Selection Criteria

An extensive search of the literature was conducted systematically through the three main electronic databases: PubMed, Scopus, and ScienceDirect. Identification of studies was attempted that compared DWI and T2WI in the diagnosis of acute ischemic stroke. Different permutations and combinations of the following keywords were set: "diffusion-weighted imaging," "T2-weighted imaging," "acute stroke," "ischemic stroke," "MRI," and "diagnostic accuracy." Boolean operators such as AND or OR were used for the effective combination of terms. The search was limited to papers published in English within the time frame of January 1990 to June 2024. Also, the search strategy was applied to review the reference lists of relevant review articles and included studies for the purpose of capturing any additional eligible publications not indexed in the main search.

Eligibility Criteria

Studies were included based on predefined inclusion and exclusion criteria. The **inclusion criteria** were: (1) studies that performed direct comparisons between DWI and T2WI in diagnosing suspected acute ischemic stroke; (2) availability of patient-level data or extractable summary statistics, such as sensitivity and specificity, allowing for meta-analytic synthesis; and (3) studies that provided data stratified by relevant variables such as age group (<40, 40–60, >60 years) or time from symptom onset to imaging where available. The **exclusion criteria** were: (1) studies based on animal models or in vitro imaging techniques; (2) case reports, reviews, editorials, and conference abstracts without full data; (3) studies not providing direct imaging comparisons between DWI and T2WI; and (4) studies lacking sufficient methodological details or quantitative results for analysis.

Studies were included upon consideration of pre-specified criteria for inclusion and exclusion. Inclusion criteria were the following: (1) Studies that performed direct comparisons between DWI and T2WI for diagnosing suspected acute ischemic stroke; (2) Provided patient-level or summary data from which sensitivity, specificity, or derived statistics could be extracted for meta-analytic synthesis; (3) Provided data stratified by pertinent covariates, e.g., age groups (<40, 40–60, >60 years) or, if available, time from symptom onset to imaging. Studies were excluded if they were: (1) animal model studies or in vitro imaging techniques; (2) case reports, reviews, editorials, or conference abstracts with no full data; (3) studies not doing direct imaging comparisons between DWI and T2WI; and (4) studies without sufficient details for methods and quantitative results that could be analyzed.

Data Extraction and Quality Assessment

Data extraction was performed independently by two trained reviewers to minimize bias and errors. Disagreements in data selection or interpretation were resolved through discussion and consensus, and if needed, a third reviewer was consulted. Extracted variables included: study year, geographic region, sample size, imaging modality, time from stroke onset to scan, patient age group, stroke subtype (e.g., lacunar vs. cortical), and diagnostic performance metrics such as sensitivity, specificity, positive predictive value, and negative predictive value for both DWI and T2WI. Quality assessment of included studies was conducted using the QUADAS-2 (Quality Assessment of Diagnostic Accuracy Studies) tool. This framework assesses risk of bias across four domains: patient selection, index test, reference standard, and flow/timing. Each study was rated for risk of bias and applicability concerns, and results were tabulated for transparency.

Statistical Analysis

Statistical synthesis was conducted using a DerSimonian–Laird random-effects model, appropriate for accounting for inter-study variability. Pooled estimates of sensitivity and specificity for DWI and T2WI were calculated with 95% confidence intervals. Heterogeneity among studies was quantified using the $I^2$ statistic, where values above 50% indicated moderate to substantial heterogeneity. Meta-regression and subgroup analyses were performed to explore potential sources of heterogeneity, particularly age stratification (<40, 40–60, >60 years) and symptom-to-scan time intervals (<3 hours, 3–6 hours, >6 hours). All statistical analyses were conducted using Review Manager (RevMan) and STATA software.

## RESULTS

**Study Characteristics**

Twenty-eight studies encompassing a total of 5,632 patients met the inclusion criteria. The sample sizes across individual studies ranged from 38 to 412 participants. Most studies included patients who presented within 12 hours of symptom onset, which aligns with clinical emphasis on early stroke detection. All included studies utilized magnetic resonance imaging (MRI) scanners with diffusion-weighted imaging (DWI) protocols incorporating b-values of at least 1000 s/mm². While minor protocol variations existed (e.g., slice thickness, repetition time), the diagnostic performance was considered comparable across studies. T2-weighted imaging (T2WI) protocols were more variable and often depended on scanner availability and institutional practices. Among the included studies, 60% were conducted in tertiary care or academic hospitals, and 40% were from regional or community-based stroke centers, enhancing generalizability. Imaging acquisition was most performed using 1.5 Tesla MRI systems, although 6 studies used 3.0 Tesla scanners.

**Pooled Diagnostic Accuracy**

The pooled sensitivity of DWI for detecting acute ischemic stroke was 92.3% (95% CI: 89.6–94.5%), and its pooled specificity was 89.2% (95% CI: 85.7–91.8%). In contrast, T2WI demonstrated a significantly lower pooled sensitivity of 74.6% (95% CI: 68.5–80.2%) and specificity of 82.7% (95% CI: 78.1–87.2%). The difference in diagnostic accuracy between DWI and T2WI was statistically significant ($p < 0.001$), suggesting that DWI provides a superior modality for early stroke identification. The figure below visualizes the sensitivity estimates for Diffusion-Weighted Imaging (DWI) in detecting acute ischemic stroke across individual studies included in the meta-analysis. Each study is represented by its sensitivity value, and the pooled sensitivity of 92.3% is indicated as a vertical reference line.

**Subgroup Analyses by Age**

"Age-stratified analyses revealed substantial variation in the diagnostic yield of both DWI and T2WI. In patients aged <40 years", DWI demonstrated a sensitivity of 87.4% and T2WI 70.2%. Among patients aged 40–60 years, DWI achieved a sensitivity of 91.8%, compared to 76.5% for T2WI. The most pronounced disparity was observed in patients aged >60 years, where DWI showed a sensitivity of 94.1% versus 73.3% for T2WI. Specificities followed a

similar trend, although the absolute difference was less pronounced. These age-based findings suggest an increasing advantage of DWI with advancing age, potentially due to greater tissue contrast and clearer demarcation of ischemic regions in older brains. The heterogeneity ($I^2$) for sensitivity estimates across studies was 38% for DWI and 54% for T2WI, indicating moderate variability. Specificity estimates showed lower heterogeneity, with $I^2$ values of 31% for DWI and 42% for T2WI. Subgroup analysis confirmed that age significantly moderated diagnostic yield ($p < 0.01$), underscoring the need for age-adapted imaging strategies in acute stroke evaluation.

The following ROC curves visually compare the diagnostic performance of Diffusion-Weighted Imaging (DWI) and T2-Weighted Imaging (T2WI) in detecting acute stroke among different age groups (<40 years, 40–60 years, and >60 years). These curves use pooled sensitivity and specificity data and illustrate that:

- DWI exhibits consistently higher area under the curve (AUC) values than T2WI for all age groups, indicating superior diagnostic accuracy.
- The distinction is most pronounced in patients over 60 years, where the DWI curve is the steepest, reflecting notably higher sensitivity and specificity in this demographic.
- These findings support prioritizing DWI, especially for elderly patients in emergency radiology protocols.

**Interpretation**: The table quantitatively reinforces the ROC curve findings, highlighting the consistent superiority of DWI over T2WI in all age groups, with the gap widening in older populations.

## DISCUSSION

This meta-analysis stands as a firm confirmation of the superiority of diffusion-weighted imaging (DWI) over T2-weighted imaging (T2WI) in the earliest diagnosis of acute ischemic stroke. These results corroborate the early landmark studies that first documented DWI's sensitivity toward ischemic changes occurring within minutes of symptom onset, owing to its capacity to detect cytotoxic edema earlier than any other structural imaging modalities [1,2]. Our pooled analysis, encompassing 28 studies and more than 5,600 patients, demonstrates that DWI is always superior to T2WI both in sensitivity (92.3% vs. 74.6%) and specificity (89.2% vs. 82.7%), and that the difference is statistically significant ($p < 0.001$). The diagnostic advantage of DWI is particularly relevant during hyperacute stroke, when the narrow therapeutic windows allow interventions like intravenous thrombolysis and mechanical thrombomy for treatment [3,4]. The early ischemia detection by DWI affords clinicians a time-sensitive decision-making option with much higher confidence. In contrast, T2WI, while beneficial in identifying cerebral edema, intracerebral hemorrhage, and mass effects, demonstrates a lag in the visualization of early ischemic changes, leading to reduced sensitivity and potential diagnostic delays [5].

Our age-stratified analysis reveals a nuanced pattern in DWI performance. Notably, DWI sensitivity increases progressively with age—87.4% in patients <40 years, 91.8% in those aged 40–60, and 94.1% in patients >60 years. T2WI shows lower and more inconsistent sensitivity across all age groups. These results suggest that aging-related neuroanatomical and vascular changes may amplify ischemic signal contrast on DWI. Brain atrophy, commonly observed in older adults, can enhance gray-white matter differentiation and lesion conspicuity on diffusion sequences [6,7]. Additionally, the fragility of the microvascular system in older populations may result in more extensive or homogenous ischemic changes, further improving DWI's diagnostic clarity. Conversely, DWI appears more prone to false negatives in younger populations, particularly in cases of transient ischemic attack (TIA) or small lacunar infarcts [8,9]. Several mechanisms may account for these limitations. In younger patients, better collateral circulation and neuroplasticity may lead to rapid tissue recovery and perfusion restoration, reducing the likelihood of detectable diffusion restriction. Furthermore, smaller infarct volumes—especially in posterior circulation strokes—often escape detection in early DWI scans, despite clinical symptoms [10,11].

DWI-negative ischemic strokes have been a subject of increasing concern in recent literature. Meta-analytic data suggest that up to 6–15% of clinically confirmed strokes may yield negative DWI findings in the hyperacute phase

[12]. While some of these may represent TIAs or imaging artifacts, others may reflect true ischemic events that fall below the spatial or temporal resolution threshold of current DWI protocols [13,14]. These findings underscore the importance of clinical judgment and multimodal imaging approaches, especially in patients with high National Institutes of Health Stroke Scale (NIHSS) scores but negative diffusion imaging. Our results are consistent with those of previous systematic reviews comparing advanced MRI techniques for acute stroke diagnosis. Several studies have demonstrated that DWI, either alone or as part of multiparametric MRI, has superior sensitivity and specificity compared to conventional imaging modalities, including non-contrast CT and T2-weighted MRI [15–17]. Importantly, the findings of our meta-analysis align with recent recommendations from stroke imaging guidelines, which advocate the use of DWI as the preferred modality for early ischemic stroke detection when MRI is available [18].

One important consideration in interpreting these results is the heterogeneity across imaging protocols. Although all included studies used b-values ≥1000 s/mm², parameters such as slice thickness, acquisition time, and magnetic field strength varied. Some studies employed 3T MRI scanners, while others relied on 1.5T systems. However, the diagnostic benefit of DWI was consistently observed across this technical variability, suggesting robustness of the technique. Moreover, the $I^2$ statistics for heterogeneity were moderate for both sensitivity and specificity, indicating that the pooled estimates are reliable despite minor protocol differences. The superior performance of DWI may also be attributed to its biophysical underpinnings. DWI detects the restriction of water molecule motion, which is one of the earliest manifestations of neuronal injury due to energy failure and ion pump dysfunction [1]. In contrast, T2WI relies on changes in tissue water content and architecture that occur later in the ischemic cascade. Thus, the time-sensitive advantage of DWI is rooted in its ability to image the fundamental molecular disturbances that precede visible structural changes [19].

It is also notable that several studies have emphasized DWI's potential role in stroke subtype classification. For example, DWI signal patterns differ in cardioembolic, large artery atherosclerotic, and small vessel occlusive strokes, which may inform secondary prevention strategies [20]. T2WI offers limited ability in this regard, as it lacks specificity in differentiating infarct subtypes during the hyperacute window. Despite the advantages of DWI, its limitations must be acknowledged. As discussed earlier, false negatives in posterior circulation strokes and TIAs present diagnostic challenges. In addition, susceptibility artifacts near bone or air-tissue interfaces can degrade image quality, particularly at the skull base [21]. DWI sequences are also more sensitive to patient motion, which can be problematic in emergency settings or in patients with altered mental status.

In clinical practice, integrating DWI with other MRI sequences such as FLAIR, T2*, and perfusion imaging may improve diagnostic yield and provide critical information regarding infarct age and penumbra viability [22,23]. Recent studies suggest that the "DWI-FLAIR mismatch" can identify patients eligible for thrombolysis beyond the conventional 4.5-hour window [24]. Similarly, DWI combined with perfusion-weighted imaging has been used to estimate infarct core and mismatch, guiding mechanical thrombectomy decisions [25]. The implications of our findings are substantial for stroke triage algorithms and imaging resource allocation. While CT remains the most accessible imaging modality in emergency settings, especially in low-resource environments, the growing availability of rapid MRI protocols suggests a shift toward broader adoption of DWI in stroke pathways. The evidence presented here strongly supports the integration of DWI into acute stroke diagnostic algorithms where feasible.

There are several strengths to our meta-analysis. We conducted a comprehensive literature search, included a large and diverse patient population, and applied rigorous inclusion criteria focused on studies that directly compared DWI and T2WI. Quality assessment using the QUADAS-2 tool revealed low risk of bias in most domains, and subgroup analyses helped clarify the influence of age on diagnostic performance. Nevertheless, certain limitations must be considered. Publication bias cannot be entirely excluded, as studies with non-significant or negative findings may be underrepresented. Furthermore, although we conducted subgroup analyses by age and time-to-scan intervals, other confounders—such as comorbidities, stroke location, and scanner type—could not be fully accounted for. Future studies should aim to explore these factors using individual patient-level data.

In conclusion, this meta-analysis affirms that DWI is significantly more accurate than T2WI for early diagnosis of acute ischemic stroke, particularly in older patients and during the hyperacute window. While T2WI retains value in hemorrhage detection and anatomical localization, its reduced sensitivity limits its utility as a standalone tool for ischemic stroke diagnosis. Given the high diagnostic yield and time-critical nature of stroke interventions, DWI should be prioritized in imaging protocols where available. Clinicians must also remain vigilant for DWI-negative strokes, especially in younger populations, and use a combination of imaging modalities and clinical acumen to guide diagnosis and treatment.

# CONCLUSION

This meta-analysis confirms that diffusion-weighted imaging (DWI) provides significantly superior diagnostic accuracy compared to T2-weighted imaging (T2WI) in detecting acute ischemic stroke across all age groups. The pooled sensitivity and specificity values clearly demonstrate the enhanced capacity of DWI in identifying ischemic lesions, particularly during the hyperacute phase. While T2WI remains a valuable modality, its lower sensitivity—especially among younger and older patients—underscores its limitations in early stroke detection when immediate clinical decision-making is critical. The stratified subgroup analysis reveals that the diagnostic advantage of DWI increases with patient age. In individuals aged over 60 years, DWI achieved its highest sensitivity (94.1%), while T2WI was least effective (73.3%) in this group. These findings suggest that age significantly moderates imaging efficacy, likely due to differences in brain water content, comorbidities, and lesion presentation that affect T2 signal characteristics. Consequently, DWI should be regarded as the preferred first-line imaging tool, particularly for elderly patients who are at higher risk for severe outcomes following ischemic stroke.

Despite the strong performance of DWI, some limitations must be acknowledged. False negatives can still occur, particularly in cases with small infarcts or very early presentation. Therefore, reliance solely on DWI could lead to underdiagnosis in a subset of patients. This reinforces the importance of integrating imaging findings with clinical judgment and supplementary modalities such as perfusion imaging or MR angiography when indicated. In conclusion, the evidence strongly supports the prioritization of DWI in emergency radiologic protocols for suspected acute ischemic stroke. It enhances diagnostic certainty, enables earlier therapeutic intervention such as thrombolysis or thrombectomy, and contributes to improved patient outcomes. Future studies should explore optimized imaging algorithms combining DWI with other modalities to address current limitations and further refine stroke diagnosis strategies.

## ABSTRACT

Keratoconus (KC) is a progressive corneal thinning disorder, correlated in Ayurveda with *Vataja Timira* (~Distortion of vision due to *vatadosa*) due to *Vata* vitiation in the *Krishna Mandala* (~Cornea and Iris). Modern management involving corneal collagen cross-linking (CXL), is often invasive and does not guarantee corneal thickening. This report details the 20-month management of a 28-year-old male diagnosed with progressive bilateral KC (OD: Severe, Kmax 61.4D; OS: Moderate, Kmax 52.1D), who opted for Ayurvedic treatment over CXL. The treatment protocol, administered over three inpatient phases, centered on *Shodhana* (~purification) using *ChakṣusyaVasti* (~Medicated Enema) and *Anu TailaNasya* (~Medication through nasal route), followed by intensive *Bṛmhaṇa* (~nourishing) *Kriyakalpas* (~ocular therapeutic procedures) like *Netra Tarpana* (~soothing collyrium) with *Dashamoola Jeevanthyadi Ghritha* and *Piṇḍa Sveda* (~poultice therapy) with *Shashtikashali*, augmented systemically with collagen-supportive nutraceuticals. Functionally, the patient experienced significant clinical improvement: visual acuity improved from 6/18 to 6/9 (OD) and 6/6 (OS), and the debilitating symptom of diplopia was eliminated. The required spherical correction in the right eye reduced dramatically from +3.00D to 0D. Anatomically, the treatment successfully halted the expected progressive thinning, evidenced by an overall increase in central corneal thickness (Pachymetry) by approximately +8µm in both eyes. The

maximum keratometry (K max) remained stable, showing minimal change (OD: +0.5D; OS: +0.2D). This case supports that the integrated Ayurvedic regimen, focusing on localized ocular nourishment and systemic detoxification, is a viable, non-invasive option for achieving both anatomical stability and significant functional visual improvement in patients with progressive Keratoconus.

**Keywords:** Keratoconus, *Nasya, Tarpana, Timira, Kriyakalpa, Shashtika Shaali Pinda Sweda*

## INTRODUCTION

Keratoconus (KC) is a progressive disorder characterized by central or paracentral corneal stromal thinning, accompanied by apical protrusion and irregular astigmatism. The prevalence is reported as 0.1% to 0.2%, with men being slightly more affected than women. Presentation commonly occurs during the teens or twenties, often initially affecting one eye. Approximately 50% of normal fellow eyes will progress to KC within 16 years. KC can be graded by the highest axis of corneal power on keratometry as mild (<48D), moderate (48–54D), or severe (>54D). Most patients do not have a family history, with only about 10% of offspring developing KC. Risk factors include allergy, asthma, eczema, and persistent eye rubbing from any cause. Systemic associations include Down, Ehlers-Danlos, and Marfan syndromes, and Osteogenesis imperfecta. Ocular associations include vernal keratoconjunctivitis, blue sclera, aniridia, Retinitis Pigmentosa, and Leber congenital amaurosis. Modern management involves avoidance of eye rubbing and spectacle correction. Corneal collagen cross-linking (CXL) with riboflavin may slow the progression of the disease but will not reverse the damage caused to the cornea. Modern management requires invasive therapy and cannot guarantee corneal thickening.(1)

According to *Acharya Sushrutha*, *Krishna mandala* (~cornea and iris) is originated *from Vayu mahabhootha*(~air element), and *Vatadosha* is responsible for its regular functions.(2) Any abnormality in *Vatadosha* leads to a disturbance in the normal functions of *Krishna mandala*. In Ayurveda, there is no direct reference for KC, but based on symptoms, it can be correlated to *VatajaTimira*(~Distortion of vision due to Vatadosa). Symptoms like *Vyavidhadarshana* (~the straight line of object appears to be curved), *Avila darshana* (~blurred or hazy vision), and *Chandra deepadyaanekatwam* (~luminous objects appearing multiple) are observed in keratoconus.(3) Ayurveda treatments not only manage symptoms but also aim to strengthen the cornea to prevent further progression, working at a cellular level to heal and restore ocular function naturally, thereby offering a non invasive,sustainable and physiology restorative alternative to conventional modern interventions.

**CASE REPORT**

**Patient Information**

The patient is a 28-year-old male from Jharkhand, employed as an engineer, who presented with gradual loss of vision over the past three years, accompanied by diplopia (doubling of objects) and glare. He had previously been diagnosed with bilateral keratoconus via corneal topography and was advised to undergo collagen cross-linking (C3R) but was apprehensive about the procedure. Informed consent for both treatment and publication of this case report was obtained. His medical history was unremarkable, with no known history of diabetes mellitus or hypertension. Family history revealed that his father is hypermyopic, with no other significant conditions reported. The patient follows a vegetarian diet, has sound sleep, and maintains a sedentary lifestyle, with no history of substance abuse. He avoids rubbing his eyes as a self-care measure. The main medical problem is progressive bilateral keratoconus, and he had not received any previous medication specifically for this condition prior to presentation

**Clinical Findings**

On general examination, blood pressure measured was 120/86 mmHg and pulse rate was an average of 86/min. No other systemic involvement was found. On ocular examination, distant visual acuity was 6/18 in both eye with

doubling and no improvement in pinhole. Best corrected visual acuity was 6/12+2 in right eye and 6/9+2 in left eye. In slit lamp examination, corneal ectasia was observed and on retinoscopy, scissoring reflex was present in both eye. Other examinations were normal.

**AshtavidhaPariksha(~Eight-Fold Examination):-**The *Naadi* (~Pulse) was *Vata* predominant. Both *Mootra* (~Micturition) and *Mala* (~Defecation) were *Prakritha* (~normal). The *Jihwa* (~Tongue) was *Aliptha* (~uncoated), and the *Shabda* (~Voice) was *Prakritha* (~normal). The *Sparsha* (~Touch) was *Anushnasheeta* (~normal). The *Drik* (~Vision) was *Vikrutha* (~abnormal), while the *Aakrithi* (~Body Structure) was *Prakritha* (~normal).

**DashavidhaPariksha (~Ten-Fold Examination):**The *Prakriti* (~Constitution) was *Vata Pitta*, and the *Vikriti* (~Pathology) indicated *Vatapradhanatridosha*. The *Sara* (~Quality of tissue), *Samhanana* (~Structural integrity), *Satwa* (~Mental status), and *Satmya* (~Adaptability) were all *Madhyama* (~Moderate). The *Pramana* (~Measurement) recorded a height of 168 cm and a weight of 62 kg. The *Ahara Shakthi* (~Digestive capacity) showed *Abhyavaran Shakthi* and *Jarana Shakthi* as *Madhyama* (~Moderate). The *Vyayama Shakthi* (~Exercise tolerance) was *Madhyama* (~Moderate), and the *Vaya* (~Stage of life) corresponded to *Youvana* (~Young age).

**Relevant Ocular Clinical Findings (Baseline): Table 1**
**Figure 1**-CT findings on 26-08-22 of OD
**Figure 2**- CT findings on 26-08-22 of OS

***SrotoPariksha* (~Channel Examination):**
*Srotas* involved: *Vataja* (due to *Vatapradhanavikriti*in *Krishna Mandala, Rasa* and *Rakta* (due to *Timira* pathology).

**Timeline: Table 2**
**Therapeutic Interventions: Table 3**
**Changes in intervention (with rationale)**
In Phase 2, the tablet RuxoNewten (containing eggshell membrane, *Punarnava*, undenatured type II collagen, and vitamin C) was introduced into the systemic regimen. The rationale was to enhance collagen synthesis and support corneal cross-linking and remodeling, thereby promoting greater biomechanical stability. This approach aligns with the Ayurvedic therapeutic objective of *Bṛṃhaṇa*(~Nourishing therapy) and *Dhatu Poṣaṇa*(~Nourishment of tissues of body)—strengthening and nourishing the corneal tissues.

**Diagnostic Assessment:**
The primary diagnostic evidence (corneal topography) was obtained outside the treating facility in Jharkhand, indicating a limitation in access to continuous advanced ophthalmic monitoring. Despite these constraints, the patient chose to pursue an alternative Ayurvedic approach rather than the advised corneal collagen cross-linking (CXL), overcoming both financial and cultural barriers to care.The patient's gradual decline in vision, along with diplopia and glare, and the presence of corneal ectasia with a scissoring reflex, confirmed the modern diagnosis of keratoconus. From an Ayurvedic perspective, the progressive corneal thinning (*Kṣaya*), visual distortion (*Vikṛtadṛk*), and symptoms such as *Vyaviddhadarshana* reflect predominant *Vatadoṣa* vitiation affecting the *KṛṣṇaMaṇḍala* , thereby correlating with *VatajaTimira*.Keratoconus is an inherently progressive disease. The baseline maximum keratometry (*Kmax*) values of 61.4 D (OD) and 52.1 D (OS) denote severe keratoconus in the right eye and moderate involvement in the left eye, indicating an unfavourable natural prognosis for maintaining functional vision without therapeutic intervention.

**Follow up and Outcome:**
Patient was treated on IPD basis for three distinct periods over 16 months (Jan '23, Nov '23, May '24).Functional Gains: Clinically significant improvement in DVA (OD: 6/18→6/9; OS: 6/18→6/6), BCVA (OS: 6/9+2→6/6), and a favorable reduction in required spherical correction (OD: +3.00D→0D). The patient-reported symptom of diplopia was eliminated, which is a major quality-of-life improvement.Anatomical Stabilization: The total change in

maximum corneal curvature (Kmax) was minimal over 20 months (OD: +0.5D; OS: +0.2D), indicating relative stability against the expected rapid progression.Corneal Thickening: Crucially, the central corneal thickness (Pachymetry) showed an overall increase of ~8µm in both eyes (OD: 467→475µm; OS: 479→487µm). This is a positive finding, counteracting the primary mechanism of progressive corneal thinning.Intervention Adherence and Tolerability: The patient underwent three inpatient courses of treatment over 16 months, indicating good adherence to the intensive therapies. All systemic and local interventions were well-tolerated, with no adverse or unanticipated events reported. Tolerability was assessed via daily patient interviews and observation during the IPD stay.

**Figure 6**- CT findings on 06-05-24 of OS

## DISCUSSION

This case report shows the successful application of an integrated Ayurvedic protocol in managing progressive Keratoconus (KC), a degenerative disorder characterized by corneal thinning and visual impairment. The management protocol was guided by the Ayurvedic correlation of KC symptoms to *VatajaTimira*, necessitating *VataShamana* and *Brumhana* therapies directed at the *Krishna Mandala*.

**Case Management Rationale:** The protocol centered on *Shodhana* using *Vasti* and *Nasya*, followed by intensive *Kriyakalpas* aimed at *Brumhana* and *Chakshushya* (ocular health).

**Shodhana:***Vasti* (enema), particularly *ChakshushyaVasti* with ingredients like *Erandamoola* (rich in antioxidants), is fundamental for removing vitiated *Doshas* (*Vata*), which is crucial in degenerative eye diseases like KC. It is proposed that rectal drainage into systemic circulation allows for enhanced absorption of lipophilic drugs, nourishing the ocular tissues.(6)*DhanwantharamTaila* is a *madhuroushadha siddha taila* which has properties of *Vatashamana, Balya* and *Brimhana*.Studies show that fibroblasts from keratoconus cornea produce more prostaglandin than those from normal corneas.(7)The molecules of *DhanwantharamTaila* is said to render the inactivation of Cox 1 and Cox 2 enzymes, thus stopping the synthesis of prostaglandins which are said to be produced more by cornea having keratoconus.(8)
*Anu TailaNasya* directly acts on ocular tissues, aiming to strengthen the corneal epithelium and delay KC progression.(9)

**Kriyakalpa (Local Therapies):***Netra Seka/Kashaya Dhara* with *Triphala,Raktacandanam*, *Chandanam*, *Laksha*, *Daruharidra*, *Draksha*, *Lodhra*, *Yashtimadhu*, *Gairika*, provides a high concentration of antioxidants, Vitamin C, and minerals, which are essential co-factors for collagen synthesis, thus strengthening the cornea.Symplocosracemosa (*Lodhra*) is proven to be effective in wound healing where in the remodeling phase, tissue tensile strength is increased due to intermolecular cross-linking of collagen via vitamin-C dependant hydroxylation which is the same pathology required in KC treatment.(10)

*Netra Tarpana* with *DashamoolaJeevanthyadiGhritha* encourages corneal healing and improves vision. Various studies show the role of Tarpana in improving visual acuity and reducing other subjective symptoms. (11) The amphipathic nature of *Ghritha* allows deep penetration into the corneal layers. The drugs are rich in Vitamin A-like compounds, preventing epithelial damage and providing targeted nutritional supply to halt degeneration. *Netra PindaSwedana* with *ShashtikaShali* is *Balya* (~strengthening) and *VataShamana*. The gentle mechanical effect provides pressure that may aid in reshaping and strengthening corneal collagen fibers.(12)

*Netra Abhyanga* with *Ksheerabala 101* is *VataShamana* and promotes nerve regeneration and provides strength to muslces due to its *balya*and*brimhana*property and also exerts a gentle mechanical pressure, potentially aiding in flattening the corneal curvature.Bohra, Mohita& Kk, Sharma.(13)

**Systemic Augmentation (Collagen Support):** The introduction of *Tab RuxoNewten* (containing Egg Shell Membrane (ESM), undenatured Type 2 Collagen, and Vitamin C) in Phase 2 was a targeted addition. ESM contains glycosaminoglycans and collagen which are vital in supporting corneal strength and integrity.(14) This, along with Vitamin D3/Magnesium supplementation, aimed to provide the necessary nutritional factors for enhancing corneal cross-linking and remodeling, aligning with the Ayurvedic principle of *Brumhana*.(15)

The positive finding of increased central corneal thickness (~8 μm) and minimal *Kmax* progression is a crucial indicator of successful biomechanical stabilization, a primary goal of modern treatments like CXL.(16) This outcome supports the hypothesis that the combination of Ayurvedic*Shodhana* and *Brumhana* therapies, potentially augmented by collagen-synthesis supporting nutraceuticals, can promote the integrity of the corneal epithelium and enhance collagen synthesis and remodeling, confirming the results of other investigations into the structural benefits of Ayurvedic ocular therapies.(15) The improvement in visual acuity, despite minimal *Kmax* change, strongly suggests that the treatment successfully induced a regularization of the corneal optical surface.

## CONCLUSION

This case report illustrates the favourable outcome of an integrated Ayurvedic management approach in a patient with progressive keratoconus followed for a period of 20 months. The treatment effectively arrested further corneal thinning, demonstrated an increase in central corneal thickness of approximately +8 μm in both eyes, and maintained anatomical stability with minimal changes in maximum keratometry (OD: +0.5 D, OS: +0.2 D). Clinically, the patient experienced significant improvement in visual performance, with Best Corrected Visual Acuity improving by at least one line in both eyes (OS reaching 6/6) and a marked reduction in spherical correction (OD sphere from +3.00 D to 0 D). These findings suggest that localized and systemic therapies may have contributed to enhanced corneal regularity and biomechanical strength. Overall, this case demonstrates the potential role of a structured Ayurvedic protocol as a non-invasive therapeutic option for stabilizing keratoconus progression and improving visual function. Further clinical studies are warranted to validate these observations in a larger cohort.

**Informed Written Consent-** The patient provided informed written consent for publication of this case report. The consent document is available and can be reviewed for verification by the editor of the journal.
**Author Contribution-** Each author has made an equal contribution to the overall care of the patient, including treatment, documentation, and the preparation and development of the manuscript for publication.

**ABSTRACT**

This research evaluates the structural performance and dynamic behavior of an Electric Overhead Traveling (EOT) crane girder using Finite Element Analysis (FEA) and empirical validation. The girder is the primary load-bearing component and is prone to failure under cyclic industrial loading. Using Response Surface Methodology (RSM) for design optimization, a reduced plate thickness of 7.4 mm was identified as the optimal configuration. This modification resulted in a 9.5% reduction in total weight (156 kg) while maintaining structural safety within a Factor of Safety (FOS) of 1.5. Validation results demonstrated high correlation between FEA and experimental data, with stress and deflection variances restricted to less than 3% and 5% respectively.

**Keywords:** EOT Crane, Girder Optimization, Finite Element Analysis (FEA), Response Surface Methodology, Experimental Validation.

## INTRODUCTION

EOT cranes are indispensable for heavy-load transportation in modern industrial environments. The bridge girder, spanning two rails, serves as the critical structural element. Conventional manual calculations, while fundamental, often fail to account for localized stress concentrations and complex dynamic behaviors under variable loading

cycles. This study bridges the gap between theoretical estimation and real-world performance by integrating manual calculations with FEA simulations and actual site measurements. The objective is to determine the minimum web and flange thicknesses required to sustain operational loads while maximizing material efficiency.

## METHODOLOGY

### Technical Specifications and Experimental Setup

The study analyzed a 10-ton capacity girder using Mild Steel (IS 2062 A / FE 410W) with a yield stress of 255 MPa and ultimate tensile stress of 410 MPa. Strain gauges were deployed at critical mid-span points to monitor real-time stress during a load test of 11.2 tons.

### Analytical Framework

Manual calculations were performed based on IS:807-2006 standards. The analysis considered:

- **Vertical Bending Moments:** Calculated with and without impact factors (IF) for both drive and trailing side girders.
- **Horizontal Moments:** Derived from acceleration/deceleration forces and wind loads for outdoor scenarios.
- **Allowable Stresses:** Defined based on material properties and a safety factor.

### Crab/Trolley (CT) Wheel Load Calculations

The analysis determines wheel loads under various operational conditions to understand the forces exerted on the girder rails.

- With Impact: Calculated using an Impact Factor (IF), the maximum load ($T_1$) on the drive side is 9.90T.
- **Without Impact:** The steady-state load ($T_{11}$) is **8.30T**.
- Acceleration/Deceleration Forces: A horizontal force factor of 0.045 is derived based on the Long Travel (L.T.) speed, resulting in an acceleration load ($T_{1ACC}$) of 0.49T.

### Bending Moment Analysis

Bending moments are calculated for both the drive and trailing side girders to identify the critical stress points.

- **Live Load (With Impact):** The maximum vertical bending moment (BMVD) for both girders is **32.74 T-M**.
- **Uniformly Distributed Load (UDL):** The dead weight of the girder, platforms, and electrical contributes **11.34 T-M** for the drive side and **9.74 T-M** for the trailing side.
- **Total Vertical Bending Moment:** Summing all vertical forces results in a total of **45.80 T-M** for the drive side and **44.05 T-M** for the trailing side.

### Stress and Section Verification

The paper uses these moments to verify the structural integrity of the selected girder section.

- **Allowable Stresses:** Based on Mild Steel (IS 2062 A), the allowable bending tensile stress is calculated at **1603.77 kg/cm²** using a factor of safety and duty factor.
- **Section Proportions:** The girder geometry is checked against standard limits. For example, the Span to Girder Depth ratio is **20.10**, which is within the acceptable limit of 25.
- **Deflection Limits:** The allowable total deflection is set at **44.44 mm** (Span/360), which the current section satisfies.

### FEA and Optimization Strategy

A 3D model was developed and meshed in ANSYS to determine Von Mises stress and deflection.

- **RSM Optimization:** Response Surface Methodology was utilized to evaluate plate thickness as a design variable. **Convergence:** Mesh size was optimized to ensure computational accuracy without sacrificing detail at high-stress zones.

## RESULTS AND DISCUSSION

**Comparative Validation**

The initial experimental site measurement recorded a deflection of 17 mm under 11.2T loading. FEA simulations closely matched these findings:

- **Stress Correlation:** The variance between experimental and simulated stress was <3%.
- **Deflection Accuracy:** Observed variance remained <5%, confirming the reliability of the finite element model.

**Optimization Results**

The parametric study focused on reducing plate thickness to achieve material savings without compromising the allowable deflection limit (SPAN/900).

- **Optimal Configuration:** A thickness of 7.4 mm was found to satisfy all safety requirements.
- **Weight Efficiency:** This optimization successfully removed 156 kg of surplus material, equivalent to a 9.5% reduction in girder weight.
- **Dynamic Stability:** Vibration analysis confirmed that the first mode frequency remained above the resonance threshold, ensuring operational endurance.

## CONCLUSION

This research demonstrates that integrating FEA with Response Surface Methodology allows for significant material optimization in heavy industrial equipment. The study successfully validated that a 7.4 mm plate thickness maintains the required structural integrity for a 10-ton EOT crane while reducing weight by 9.5%. The high correlation between manual, simulated, and experimental results provides a robust framework for manufacturers to design safer and more cost-effective crane structures.

## ABSTRACT

The human population depends on surface water for agricultural irrigation and a continuous drinking water supply. India uses about 690 billion cubic meters (BCM) of surface water annually. Tamil Nadu has a total surface water potential of 36 km, or 24864 M cum. The state has 17 large river basins, 61 reservoirs, and roughly 41,948 tanks. Surface flows make up roughly half of the 46540 million cubic meters (MCM) of water potential that exists each year. The present study attempted to identify the various culturable bacteria in Cauvery River (Station 1) and Coleroon River (Station 2), Tanjavur District, Tamil Nadu, India, and conformed to Molecular characterization. A total of 20 bacteria from 13 genera were identified; five species belonged to the genus *Bacillus,* and two each to the genera *Salmonella* and *Klebsiella*. There was just one species in each of the other genera. In both stations, the majority of the bacteria grow throughout the summer, while the pre-monsoon and post-monsoon bacterial populations are modest and the bacterial population is low during the monsoon season. The bacterial isolates are then confirmed using 16s rRNA Analysis, and the subcultured colonies are recognised using morphological and biochemical methods. The 20 isolates (MS1 to MS20) were identified by BLASTn results, and taxonomy designations were given based on the NCBI database's nearest neighbour. Twenty isolates, PV668924 to PV668943. The

phylogenetic connection of the 20 isolates, with an ideal branch length total of 1.227. Both trees are depicted as legends in the illustration and are drawn to scale.

**Keywords :** Cauvery River, Coleroon River, Bacteria, 16s rRNA and Phylogenetic analysis.

## INTRODUCTION

The human population depends on surface water for agricultural irrigation and a continuous drinking water supply. India uses about 690 billion cubic meters (BCM) of surface water annually. This surface water contributes to 1121 BCM of exploitable water resources, together with roughly 431 BCM of groundwater. Forty-three percent of the Ganga, Brahmaputra, and Meghna river systems are part of the catchment area of India's major river systems. The Indus, Sabarmati, Mahi, Narmada, Tapi, Brahmani, Mahanadi, Godavari, Krishna, Pennar, and Cauvery are other noteworthy river systems. With a catchment area of 1.9 million hectares, Subernarekha is the largest of these medium river systems [1,2]. Tamil Nadu has a total surface water potential of 36 km, or 24864 M cum. The state has 17 large river basins, 61 reservoirs, and roughly 41,948 tanks. Surface flows make up roughly half of the 46540 million cubic meters (MCM) of water potential that exists each year. Since irrigation is the biggest user, the majority of the surface water has already been tapped. Through major, medium, and small schemes, surface water is used to irrigate 24 lakh hectares. Approximately 90% of surface water is used for irrigation.

In terms of agriculture and replenishing its water supplies, monsoon precipitation has been India's lifeblood. An average of 4000 BCM of precipitation and snowfall falls on India each year, with 3000 BCM falling during the monsoon season (June to September). Precipitation varies greatly across the nation, ranging from less than 100 mm in Rajasthan to more than 2500 mm in Assam [3]. Tamil Nadu has seventeen river basins. The only significant basin is the Cauvery. There are three minor river basins and thirteen medium river basins. The State generates 692.78 TMC (19,619 MCM) of surface water annually with a reliability of 75 percent. The State receives a significant amount of its annual flow from its bordering States, around 261.70 TMC (7411 MCM). The catchment area of the Cauvery River Basin is 81155 km2, with an average water resource potential of 21.36 BCM. Resources of usable water: 19 BCM. In addition to providing recreational opportunities, surface water has been contributing significantly to global development by fostering economic expansion and improving the health of people and animals (aquatic and terrestrial), whose existence depends on a healthy habitat ecosystem. According to studies, the ecosystem's activities may be disrupted if its microbial diversity declines [4].

One of the main environmental concerns in the aquatic ecosystem is pollution, which alters the nutrient cycle and water quality indicators [5]. According to estimates, the annual cost of the limited freshwater ecosystem services caused by poor water quality to the world economy is more than $1.7 trillion [6]. According to Judd *et al.* [7], Singh *et al.* [8], and Bailey *et al.* [9], bacteria are a significant contributor to climate change that is influenced by feedback responses. Climate change may intensify minor bacterial processes that impact the stability of ecosystems [10]. Over time, alterations in the ecosystem's physico-chemical components change the structure and composition of bacterial communities and lead to the development of biogeographical patterns [11,12,13]. It is possible to think of these biogeographical patterns as a gauge of past environmental shifts. The response of bacteria to future climatic changes is yet unknown, despite the growing number of microbiome studies [14]. Hence, the present study attempted to identify the various culturable bacteria in Cauvery River (Station 1) and Coleroon River (Station 2), Tanjavur District, Tamil Nadu, India, and conformed to Molecular characterization

## MATERIALS AND METHODS

Water samples for microbiological testing were gathered, aseptically transferred into sterile 500 ml sampling bottles, and analysed in the lab within one to two hours of collection. The American Public Health Association [15] guidelines were followed for analysing all water samples for the presence of pathogenic Salmonella, faecal Streptococci, and total and faecal coliform bacteria using the most probable number (MPN) method. After 48 hours of incubation at 28°C, nutrient agar plates were used to measure the total viable count (TVC) of all heterotrophic bacteria. After that, 0.1 ml of the homogenate was plated onto nutrient agar and incubated for 24 to 48 hours at 37°C. Fresh solid media of modified faecal coliform (M-FC) agar were injected in duplicate and incubated at 37°C for 24 hours in order to qualitatively identify different bacteria from water samples. Following the development of different coloured colonies of different bacteria on the plates, the bacterial colonies were identified using the methods [16,17,18. 19,20]. Colonies were moved to NA plates for the purification process, and subcultures were carried out repeatedly until the strains were conglomeration-free. Every isolated strain was kept in permanent storage at 4°C in NA stab cultures and at -20°C in 80% glycerol stock.

**Biochemical characterization**

Each purified strain was subjected to a total of fourteen biochemical tests, including those for determining Gramme Character, Methyl Red (MR), Gelatinase, Triple Sugar Iron (TSI), starch degradation, Voges-Proskauer (VP), indole production, citrate, oxidase, motility tests, etc., in accordance with Bergey's Manual of Systematic Bacteriology [21].

**Molecular Characterization**

A bacterial genomic DNA isolation kit (GCC Biotech, India) was used to separate the genomic DNA from the cultivated bacterial strains. To determine purity, genomic DNA was electrophoresed on a 0.8% agarose gel and quantified spectrophotometrically at 260 nm. A Gradient Thermal Cycler (Biorad Laboratories, USA) was used to amplify the 16S rRNA gene in the samples. In combination with 2X PCR MasterMix (Thermo Fisher Scientific, India), universal primers 27f (5'- AGAGTTTGATCMTGGCTCAG-3') and 1492r (5'-GGTTACCTTGTTACGACTT-3') covering the V1-V9 hypervariable region of 16S rDNA were employed for PCR amplification. After 30 cycles of PCR amplification, the amplicons (around 1.4 kbp) were examined using Ethidium Bromide dye on a 1.5% agarose gel. The Agarose Gel purification kit (NEB, USA) was used to purify the amplicons, and PAR Life Sciences and Research Pvt. Ltd. (Tiruchirappalli) performed the sequencing.

**In–silico analysis**

BLASTn (NCBI database) was used to examine the sequences in-silico; the hits were noted in order to identify the nearest neighbour with the greatest Max score. For MEGA 12's subsequent studies, the aligned sequences were acquired in the FASTA format. The CLUSTALW technique was utilised for alignment analysis, and the resulting data were taken into consideration for Neighbor-Joining phylogenetic analyses. The Maximum Likelihood Composite approach was used to determine the evolutionary distance, and base substitution per site was used to get the branch lengths. The consensus tree representing the evolutionary history of the taxa under analysis was constructed using bootstrap testing with 1000 replicates. The phylogenetic tree was constructed using each isolate's nearest neighbours from the BLASTn hits. All strains' partial 16S rDNA sequences were added to the GENBANK database.

## RESULTS

**Isolation of bacteria**

The different bacteria that were found in two different stations, the Cauvery River (Station 1) and the Coleroon River (Station 2), are listed in Table 1. A total of 20 bacteria from 13 genera were identified, as the table makes clear. Of these, five species belonged to the genus *Bacillus*, and two each to the genus *Salmonella* and *Klebsiella*. There was just one species in each of the other genera. In both stations, the majority of the bacteria grow throughout the summer,

while the pre-monsoon and post-monsoon bacterial populations are modest and the bacterial population is low during the monsoon season.

**Biochemical Characterization**

All of the isolates' biochemical traits are compiled. Eleven of the isolates were Gram-positive bacteria, while the remaining ones were Gram-negative. In both aerobic and anaerobic settings, the isolates' levels of fermentation potential varied, according to the analysis of sugar fermentation using TSI assays. Five of the investigated strains generate $H_2S$ in TSI medium (Table 2).

**Analysis of Bacteria by 16S rRNA**

Only reproducing cells that can form visually distinct colonies can be subcultured using classic culturable procedures. The bacterial isolates are then confirmed using 16s rRNA Analysis, and the subcultured colonies are recognised using morphological and biochemical methods.

**Molecular Characterization and Phylogenetic analysis**

The 20 isolates (MS1 to MS20) were identified by BLASTn results, and taxonomy designations were given based on the NCBI database's nearest neighbour. The bacterial strains' BLASTn analysis is shown in Table 3. Twenty isolates, PV668924 to PV668943, have accession numbers (Table 4). Figure 1 displays the phylogenetic connection of the 20 isolates, with an ideal branch length total of 1.227. Both trees are depicted as legends in the illustration and are drawn to scale.

**Evolutionary relationships of 20 isolates and 20 of their nearest neighbour taxa**

The Neighbor-Joining approach was used to infer the evolutionary history (Saitou and Nei, 1987). The ideal tree is displayed with a branch length sum of 1.227. The branches are accompanied by the proportion of duplicate trees where the related species clustered together in the bootstrap test (1,000 repetitions) [22]. With branch lengths in the same units as the evolutionary distances used to estimate the phylogenetic tree, the tree is depicted to scale. The evolutionary distances are expressed in terms of the number of base substitutions per site and were calculated using the Kimura 2-parameter technique [23]. Forty nucleotide sequences were included in the analysis process. Each sequencing pair's ambiguous places were all removed using the pairwise deletion option, yielding a final data set with 1,575 positions. MEGA12 was used to perform evolutionary analyses using up to seven parallel computer threads [24].

**Evolutionary analysis by the Maximum Likelihood method**

The tree with the highest log likelihood (-9,899.79) is displayed. The phylogeny was inferred using the Maximum Likelihood method and Kimura's [23] two-parameter model of nucleotide substitutions. Besides the branches, the percentage of duplicate trees where the related taxa clustered together (1,000 repetitions) is displayed [22]. The tree with the higher log-likelihood between a Maximum Parsimony (MP) tree and a Neighbor-Joining (NJ) tree (Saitou and Nei 1987) was chosen as the starting tree for the heuristic search. A matrix of pairwise distances calculated with the Kimura [23] 2-parameter model was used to create the NJ tree. Out of ten MP tree searches with randomly generated starting trees, the MP tree had the least length. Forty nucleotide sequences were included in the analysis process. All positions with less than 95% site coverage were removed using the partial deletion option, yielding a final data set of 1,339 positions. MEGA12 was used to perform evolutionary analyses using up to seven parallel computer threads [24].

**Pairwise Distance**

The number of base substitutions between sequences is displayed for each location. Above the diagonal are the standard error estimates or estimates. The Kimura 2-parameter model [23] was used for the analyses. Twenty nucleotide sequences were included in the analytical process (Table 5). Each sequencing pair's ambiguous places

were all removed using the pairwise deletion option, yielding a final data set with 1,575 positions. In MEGA12, evolutionary analyses were performed [24].

## DISCUSSION

Communities have benefited from surface water in numerous ways. *Salmonella, E. coli,* and *Vibrio cholerae* were detected during the evaluation of the two water bodies (the Cauvery River and the Coleroon River) in the current study. Because of their widespread distribution in nature, microorganisms can be utilised as an indication to determine whether water quality is suitable [25]. This investigation identifies a number of pathogens in the water of the Coleroon and Cauvery rivers. The findings showed that the Cauvery River's water had a low microbiological quality in accordance with drinking water quality standards. Both the effluent sample and the river water were found to contain coliforms [26]. The number of bacteria logically indicates the extent of human influence on the water. Faecal coliform is a sign of biological wastes from domestic animals or point and non-point human sources when it is present [27]. The rainy season was shown to have increased faecal coliform levels. Similar incidents caused by human waste have been documented from the Ganges River [28] and the Mandovi and Zuari estuaries [29]

A potent method for identifying and categorising bacteria is 16S rRNA sequencing; in this study, the 16S rRNA sequencing method is utilised to reconstitute the identified bacterial isolates. It is important to limit the potential of barcoding for species discovery using the currently suggested approaches. Since degrees of overlap between intra- and interspecific differences are anticipated to be high in most major clades, especially within varied but poorly described groupings, the use of thresholds for species delineation is unpromising and strongly discouraged. According to our results, using thresholds to screen for very divergent novel taxa can be successful, but it will miss at least one-fifth of the unique but less divergent forms of life. More sophisticated approaches that take into account sibling group characteristics, intraspecific variability knowledge, and population genetics concepts will be needed. When taxa have not undergone extensive taxonomic scrutiny and species recognition is restricted to a small number of conventional character sets that have not been validated by further research and instruments, DNA barcoding is far less successful. Due to flawed taxonomy, which contributes to a high mistake rate for barcode-based identification, many species in these little-known groups—which comprise the majority of life on Earth—will appear to be genetically non-monophyletic. Therefore, large taxonomically well-explored comparison datasets are required to produce an appropriate environment for identification using barcoding. The standards and protocols needed to create these databases and support their growth will be developed primarily by the barcoding effort.

## ABSTRACT

Indigenous practices in India historically embodied principles that align closely with circular economy business models. These traditional practices focus on minimising waste, reusing and repurposing resources, and maintaining harmony with natural systems—thereby acting as natural enablers for circular economy approaches. This research analyses the impact of traditional Indian practices on the development of circular economy (CE) business models using empirical methods. CE is based on many technological innovations, but often neglects to recognise indigenous knowledge, particularly in India. For a long time, Indigenous peoples across the globe, especially in India, have been practising sustainable living rooted in holistic community governance and circular resource use. The customs are generally unofficial and non-commercial but are deeply spiritual, favouring nature more like a companion than a commodity. A mixed-methods research design was employed to explore the alignment of indigenous practices in India with circular economy principles. Quantitative surveys of rural practitioners, artisans, and small-scale entrepreneurs provided data on the economic and environmental impacts of their traditional methods. Qualitative interviews with policymakers, community leaders, and NGO members offered deeper insights into cultural and operational frameworks. Field observations documented local practices like organic farming and handloom weaving, and combining all approaches enabled robust data triangulation, clarifying both enablers and barriers to formalising circular economy models. From the analysis, the study claims that Indigenous production and consumption paradigms are centred on CE principles, drawing from over 120 participants in surveys, interviews, and participatory observations. The findings illustrate the importance as well as the complexities of adapting Indigenous wisdom within contemporary CE frameworks and providing pathways for sustainable, inclusive business innovation. The research paper underscores several important implications for policy, business, and community

development in India. Indigenous practices offer a culturally rooted foundation for advancing circular economy models, presenting opportunities for inclusive, sustainable growth.

**Keywords:** Indigenous practices, Circular Economy, Business models.

## INTRODUCTION

**Indigenous Practices in India.**

Indigenous practices in India are deeply rooted in ecological wisdom and community resilience, reflecting an age-old commitment to sustainability and resource stewardship. Traditional agricultural systems like zero-budget natural farming, agroforestry, and mixed cropping enhance biodiversity, maintain soil health, and help local communities adapt to climate change and weather extremes. Water conservation techniques, such as rainwater harvesting and the use of step wells or tankas, demonstrate a nuanced understanding of local ecosystems and ensure resource availability even in drought conditions. Many tribal and rural communities practice circular habits, including zero-waste food systems and the reuse or recycling of materials, informed by cultural and spiritual values that prioritise harmony with nature. Sacred groves, community-led conservation, and folk festivals all reinforce these principles while protecting biodiversity. Construction methods, too, embody sustainable strategies, favouring local materials like mud, timber, and lime, and encouraging the reuse of waste. Together, these indigenous practices offer valuable models for modern sustainability and circular economy initiatives in India. In addition to agricultural and water conservation systems, many indigenous groups in India have pioneered sustainable forest management and the ethical harvesting of non-timber forest products. For example, communities in the Nilgiri Biosphere Reserve practice-controlled collection of honey, amla, and soap nuts, ensuring regeneration and ecosystem stability by following traditional rituals and limiting overexploitation of resources. These approaches not only conserve biodiversity but also sustain livelihoods in rural and forest-dependent areas. Indian urban and peri-urban neighbourhoods exhibit a unique form of circularity through the informal waste economy (1). Women's self-help groups, waste pickers, and local artisans participate in decentralised waste collection, segregation, and upcycling—transforming what would be landfill-bound waste into compost, biofuel, or value-added goods. Initiatives like converting temple floral waste into incense or compost, and community-scale biogas plants processing market waste, create green jobs and enhance livelihoods for marginalised communities. Cultural acceptance of repair, reuse, and frugality remains ingrained in Indian society. Practices such as extended use and repair of household items, clothes, and vehicles exemplify everyday circular behaviours. Indigenous and modern circular practices increasingly intersect, opening vast opportunities for transition to a formalised circular economy that builds on traditional strengths while leveraging new technological and entrepreneurial innovations (2).

**Indigenous Practices in India as Enablers of Circular Economy Business Models**

Circular economy business models are designed to keep products, materials, and resources in use for as long as possible by maximising reuse, repair, remanufacturing, and recycling. Examples include product-as-a-service, where companies retain ownership of goods and lease them to customers; sharing models that enable greater utility from shared assets; and closed-loop systems that transform waste into new raw materials. These approaches not only minimise waste and environmental impact but also generate value and resilience by creating innovative business opportunities centred on sustainability. Waste, biodiversity loss, and resource scarcity are growing ecological issues in the 21st-century world. Additionally, countries are shifting towards the circular economy (CE) for sustainable growth and development. The CE focuses on reuse, recycling, reduction, and rejuvenation, unlike the "take-make-dispose" linear model, which is wasteful and unsustainable. Instead of fostering economic growth, CE aims to achieve resilient as well as restorative economies (3). CE is based on many technological innovations, but often neglects to recognise indigenous knowledge, particularly in India. For a long time, Indigenous peoples across the globe, especially in India, have been practising sustainable living rooted in holistic community governance and circular resource use. The customs are generally unofficial and non-commercial but are deeply spiritual, favouring

nature more like a companion than a commodity. India is home to over 700 tribal groups and many traditional rural communities. This unique environment allows Indigenous customs to thrive, even with the pressures of modernisation. In Indigenous cultures, circularity is a lived reality.

This is evident in practices such as organic farming, seed preservation, traditional water management systems, and sustainable forest use. These practices provide clear examples of using resources efficiently, reducing waste, adapting to climate change, and promoting social inclusion. All these elements are vital for a circular economy. Tribal farmers in Odisha grow millets using methods that preserve agrobiodiversity, improve the soil, and require few outside resources. Bamboo craft communities in Nagaland create new products from waste materials and rely on rapidly growing renewable resources. Johads and kunds are two types of rainwater harvesting systems in Rajasthan. They demonstrate closed-loop water cycles that support entire ecosystems. These methods are low-carbon, decentralised, and based on cooperation and self-reliance. Therefore, they are highly relevant to circular economy transition plans that prioritise social justice and sustainability. Indigenous knowledge takes a holistic approach to systems thinking, which is vital for advancing circular economy (CE) models. For generations, Indigenous communities have managed resources with a focus on sustainability rather than short-term profits. They rely on wisdom passed down through generations, community agreement, and observation of natural cycles to guide their decisions. These characteristics align well with CE frameworks, which aim to reuse materials, eliminate waste, and restore natural ecosystems [3]. Recognising Indigenous practices as active supporters of the circular economy is both a matter of justice and a necessity for protecting our environment. It involves acknowledging and raising knowledge systems that have sustained people and the environment for generations [2]. It also requires creating inclusive spaces where traditional and modern systems can coexist, share knowledge, and collaborate to find solutions that fit their cultures and contexts. In conclusion, there is an important opportunity to link Indigenous knowledge with modern circular economy practices as the world faces the urgent need for sustainable development. We can learn from those who have mastered living within ecological limits instead of creating new solutions. India can lead this integration due to its rich collection of Indigenous knowledge and traditions. By doing this, we will not only promote the goals of the circular economy but also preserve and honour the cultural heritage that holds the keys to a sustainable future.

## LITERATURE REVIEW

(Times of India, 2025a) Community-based waste management schemes in India show how circularity is enabled by social structures held by Indigenous peoples. Case studies from the Himalayas show local waste banks, school-based segregation drives and community-based recycling cooperatives that create microeconomic systems. (Abbasi, 2024) demonstrates that rural circular systems are built on Indigenous agroecological practices — including mixed cropping, livestock integration and organic nutrient recycling. Through empirical research, these models' lower reliance on chemical inputs, improve soil fertility and produce co-products such as compost and bio-based materials. (CEEW, 2024) Policy studies highlight that the CE transition in India should include Indigenous practices and community knowledge systems. Reports from the Council on Energy, Environment and Water. (UN-PAGE, 2023) Community models emphasise the significance of social capital, trust and collective decision making to facilitate financially viable, small-scale circular businesses. Patel (2020) The Circular Economy (CE) business models promote waste reduction, increased product life and regeneration of natural systems. explores the rotational food production and forest regeneration and communal seed banks among tribal communities in India. The practices are circular, and sustainable. The principles of regenerative use and intergenerational fairness are essential to circular economy frameworks and are reflected in these. In India, the informal economy sometimes is the quiet engine behind circularity. Bocken et al. (2014), propose a sustainable business model type framework consisting of resource conservation, reuse and closed-loop systems. The principles closely align with Indigenous practices, such as community composting, seed preservation and local craft economies, in India. These models provide a rational framework for integrating traditional systems into contemporary business operations. Circular model sustainability assessment is one of the key indicators of its viability. Arora and Romijn (2012) also reinforce this notion by indicating that if it is built upon community invention rather than corporate control, the BoP economy can bring

about productive circular solutions. Indigenous Indian innovations — mud-refrigerators (mitticool) and clusters of natural dye textiles — reinforce this perspective by extracting value from fewer resources and waste. By its nature, there is a philosophical base behind the circularity of Indian indigenous practices. Singh et al. (2009) summarize comparative evaluation of the various sustainability evaluating approaches. Their models are important for the assessment of indigenous business practices such as handloom weaving, organic farming. While standard metrics may not always adequately capture these practices, they make a meaningful contribution to environmental and social sustainability. Mishra (2010) revisits the approach of rural development by Gandhi as a means to self-reliance, minimalism, and resource-based living. Khadi spinning, vermicomposting and decentralised biogas units are examples of activities which reflect the principles and philosophy of circular economy, but which do so all informed by India's socio-cultural situation. Chikarmane and Narayan (2005) likewise demonstrate how a waste-picking community in Pune operates as a decentralised way of dealing with waste. These workers in turn have developed successful business models by organising on a grassroot level that emphasize reuse and recycling and use fewer resources. Banerjee (2003) takes to task sustainable development discourse at that point for relegating local concerns to the periphery of its deliberations with a focus on technical solutions. This criticism is significant for circular economy researchers as it serves as a warning as to the dangers in excluding from official CE frameworks the existence of indigenous practices. Elkington's (1997) concept of the triple bottom line – people, planet, and profit – offers an effective way to measure success. Indian indigenous practices are frequently abundant in social and ecological resources and benefits, even when they are valued at little economic cost. Appreciating these behaviors through more comprehensive valuation approaches can bridge grassroots sustainability with formal business innovation. Narain and Agarwal (1989) highlight the need for decentralisation and local participation in environmental management. Their idea of "green villages" predated the current language of circular economy, but its intentions are the same. These are value-add to closed nutrient chains, to low-carbon infrastructure, and to community ownership — all of which may indeed have more distinctiveness in a conventional Indian rural model. Although indigenous systems have immense potential, mainstream business models either ignore or undervalue their advantages.

## METHODOLOGY

**Objectives of the study**

1. To find Indigenous practices that work under the principles of the circular economy.
2. To measure their influence on the sustainability of business and development of communities.
3. To investigate barriers and support for the implementation of these practices throughout the country.

**Statement of the Problem**

India possesses a deep historical background of indigenous sustainability-related practices, which are geared towards resource conservation and local community living. Many of them, such as traditional agriculture, water saving practices, handicrafts and informal recycling systems, are natural allies for the circular economy. This economy is centred on reuse, regeneration and cutting waste. Despite the potential of these local practices to contribute to sustainable development and circular business models, however, they are mostly neglected, under-researched, and excluded from official economic policies. This means there is a mismatch between traditional models of sustainability rooted in community and official/mainstream circular economy strategies. Thus, it is important to identify and examine whether certain indigenous practices of India are congruent with circular economy concepts. And for inclusion in official business models, we need to evaluate their environmental and economic sustainability and acknowledge the challenges of doing so.

**Research Design**

Using a mixed-methods research design, we aimed to understand the alignment of indigenous practices in India in line with the concepts of circular economy itself. Sustainably surveyed rural practitioners, artisans, and small-scale entrepreneurs produced quantitative data in their traditional ways but were also rewarded through economic and

environmental results. To achieve a more qualitative understanding, we interviewed policy members, community leaders, and NGO stakeholders engaged in sustainability and rural development. This allowed extensive insight into ethnographic, historic, and operational frameworks. This methodology allowed observations of specific regions—organic farming, handloom weaving, rainwater harvesting, and informal waste management—through direct exercises. Collecting all of these approaches also provided a better opportunity for triangulation of data, not only in the description of what facilitates or hinders the adoption of formalised circular economy frameworks but in this way, further qualitative insights on the role of knowledge production.

**Scope of study**

The objectives of the study are to find how three ecologically and culturally different Indian states, Rajasthan, Odisha and Nagaland, show how Indian ecological practice in different environmental settings embodies the principles of being circular. The sites were intentionally selected to convey different types of aboriginal knowledge systems in resources, management systems and local communities' ways of livelihood that are characterized by sustainable use and tight-loop use of nature in nature.

**Data Collection**

A variety of data collection techniques were used in this study to generate a broader and wider diversity of insights. Surveys were completed with 90 respondents, 30 from Rajasthan, 30 from Odisha and 30 from Nagaland. These respondents were mainly farmers, artisans, and indigenous entrepreneurs engaged in traditional practices. 30 in-depth interviews with key informants (NGO workers, village elders and local community leaders) were conducted to complement the quantitative data. They offered the practical insights and knowledge from their field experience on indigenous practices related to sustainability. Focus Group Discussions (FGDs, three in different study sites) were conducted for group discussion, facilitating community dynamics and communication. Participatory immersion as field observation allowed the researcher to capture immediate practices, tools, and processes. This gave the data some rich firsthand perspective about how circular principles are integrated into daily living.

**Data Analysis**

This analysis applied both quantitative and qualitative techniques. The quantitative data for our surveys were analysed with SPSS software using descriptive statistics. This enabled us to discern patterns and trends across the three study regions. The qualitative results were analysed by conducting thematic analysis in NVivo using responses to interviews and focus group discussions. We used this approach to organise, code and interpret key themes related to sustainability, resource use, and traditional practices. This mixed-methods approach provided a complete understanding of how indigenous practices connect with the principles of a circular economy

## RESULTS AND FINDINGS

**Analysis**

Objective One sought to systematically analyse patterns of indigenous practices in Rajasthan, Odisha and Nagaland based on circular economy principles. Using the combined research approach employed in this study, our analysis is informed by structured surveys (90 participants), the use of 30 interviews, 9 Focus Group Discussions and field observations, and in this way a triangulated perspective is provided regarding the ways traditional Indian practices contribute to the realisation of resource circularity.

**Patterns from the Quantitative Survey Analysis (SPSS)**

In a descriptive analysis from 90 survey respondents, we found the consistent adoption of practices aligned naturally with the principles of circular economy (CE):

• 82% of farmers and artisans indicated use of renewable materials sourced locally, like bamboo, millets and cow dung.

• 76% said they depend on closed loop agricultural or craft systems, such as seed preservation, composting and natural fertilisers.
• 68% stated being involved in reusing or upcycling methods, especially in bamboo craft clusters and dairy-based families.
• 71% referred to waste-to-resource conversions, primarily cow-dung composting and biomass.

**Qualitative Thematic Analysis (NVivo)**
Thematic coding of interviews and FGDs revealed recurring themes supporting the profound circularity of indigenous systems:

a. Resource Regeneration and Localised Ecosystems
Communities across every region focused on practices like:
• Construction of Johad in Rajasthan that helps rebuild water tables and can reuse water cyclically.
• Traditional millet farming in Odisha, with biodiversity conservation practices with minimal external inputs.
• In Nagaland sustainable bamboo harvesting, where cutting has been done in rotation cycles, allowing regrowth.

b. Knowledge Systems Facilitating Closed Loops
Interview participants consistently associated traditional knowledge with cyclical thinking:
• Seed networks managed by the community avoid dependence on commercial inputs.
• Ritual-based forest rules govern extraction, limiting overuse.
• Traditional composting and organic inputs reduce external waste.
These constitute decentralised, closed-loop systems, a foundational CE principle.

c. Cultural Norms of Repair, Reuse, and Frugality
Some of the behaviours that FGDs indicated were culturally ingrained would include:
• Multi-generational repair of tools, household goods, and clothing.
• Utilisation of crop waste (straw, husk, dung).
• Sharing tools, water resources, and seeds in a community environment.
These norms align with CE strategies for reuse, sharing and life cycle extension of products.
**Table 2** summarises the main indigenous practices in relation to core CE principles. These principles include resource regeneration, localisation, renewable inputs, and waste minimisation.

Objective Two was evaluated regarding the way indigenous practices impact economic sustainability and livelihood security, community development, and long-term ecological resilience. Applying a mixed-methods approach — quantitative surveys, interviews, FGDs, and field observations — this analysis shows the direct and indirect contributions of traditional systems to sustainable business models.

**Contribution to Business Models shown under Graph 1**
• Income Generation: Seventy-two percent of respondents reported earning extra income from traditional methods such as millet farming, bamboo crafting, or cow dung composting in the study's survey, alongside their main jobs.
• Low Capital Use: One of the study's findings was that input costs for indigenous practices were significantly lower—38% less on average—compared to modern commercial alternatives.
• Sustainable Livelihoods: The practices studied showed a strong link to long-term sustainability, with 87 percent of participants indicating their methods support resource renewal and environmental health.
• Entrepreneurial Models: Indigenous practices have increasingly become the basis for community-based business models, particularly through cooperatives and microenterprises.

Objective Three focused on identifying the major constraints that limit the adoption or scaling of indigenous practices within formal circular economy (CE) business models, as well as the enabling factors that facilitate their growth. Using evidence from surveys, interviews, FGDs, and field observations, this analysis presents a detailed

understanding of both the challenges and the support mechanisms currently shaping these traditional systems. Responses from 90 survey participants revealed several structural and systemic constraints that hinder the wider adoption of indigenous practices:

**Challenges Identified**

Table 2 reveals the critical challenges that block the incorporation of indigenous practices into the formal circular economy business models as identified by the study. Access to market was the most common issue to be confronted by respondents, with 61 per cent arguing that traditional products (such as handcrafted crafts or millet-based goods) cannot access the market if the infrastructure is very poor or if there is no branding opportunity. Non-formal acknowledgement was mentioned by 54% with most of these practices being excluded from the official initiatives for sustainability or economic benefits. Moreover, 43% of the participants were worried about lost knowledge, particularly due to youth migration and reduced interest in traditional skills. Finally, 38% attributed inadequate policy support to the idea of government schemes rarely prioritizing or protecting indigenous systems, making it tough for communities to grow or maintain their practices amid modernisations. These problems emphasise the need for institutional aid, capacity-building and inclusive market strategies.

## DISCUSSION

The results of this study prove that indigenous practices in India align with circular economy (CE) principles. They provide resource-efficient, regenerative, and community-driven models. These practices are rooted in local contexts, unlike high-tech or industrial CE interventions. They utilise locally available materials, traditional knowledge, and communal labour. Whether they are Johad water harvesting in Rajasthan, bamboo crafts in Nagaland, or millet farming in Odisha, these systems are built on the pillars of waste reduction, reuse, biodiversity, and renewable inputs. Their link with cultural and ecological systems provides long-term sustainability. They are environmentally friendly, socially acceptable, and economically feasible solutions for rural populations. But these practices face notable hurdles to expansion. Problems like lack of market access, limited recognition from institutions, and the erosion of traditional knowledge due to youth migration and modernisation prevent their scale. This highlights the requirement for gender-sensitive circular economy strategies that recognise and capitalise on women's contributions. Policies should be designed to incorporate women-led indigenous practices into formal CE frameworks to enhance social and environmental benefits. Sustainable development should be culturally grounded and sensitive to gender issues.

**Policy and Business Recommendations**

- Policy Recognition: Indigenous practices should be formally acknowledged and included in national circular economy frameworks and sustainability policies.
- Incentivise Traditional Knowledge: Governments and institutions should provide subsidies, tax benefits, and procurement support for eco-friendly products produced using traditional methods.
- Community Business Models: Policymakers should encourage cooperative and self-help group models that promote community ownership of circular enterprises.
- Education and Youth Engagement: Indigenous practices need to be documented, digitised, and integrated into school curricula to counter the loss of knowledge.
- Eco-Certification and Branding: Creating eco-certification systems for products that utilise indigenous circular practices can build consumer trust and access to niche markets.

## CONCLUSION

In India Indigenous practices offer a blueprint for circular economy business models that make sense. Rooted in local knowledge, cultural heritage, and ecological understanding, these practices have provided communities continuity through generations. This analysis confirms that these models are not just feasible but are in practice on a small scale,

generating tangible benefits for example through employment provision, conservation of resources, and development of a community. Connection to the key circular economy principles like (re)generation, reuse and decentralisation highlight the importance of taking a local, culturally sensitive mindset towards sustainability. To harness their potential, they need to be bound up with the CE formalization as a method: traditional practices need to be brought into dialogue with formal CE constructs. To carry out this process, we need policy backing, institutional acknowledgement and business strategies that recognise and empower indigenous systems. Through the integration of these bottom-up models with wider sustainability strategies, India can build a resilient, inclusive, and environmentally responsible future for its economy. Acknowledging women and youth as maintainers of these traditions will advance social impact and maintain cultural identity amidst the changing world.

**Table 1: Shows Data Collection Methodology**

| Method | Description | Sample Size / Frequency | Study Locations | Target Participants | Purpose / Key Insights |
|---|---|---|---|---|---|
| Structured Surveys | Quantitative questionnaires for quantifying data on Indigenous knowledge and engagement in circular economy. | 90 respondents (30 each from Rajasthan, Odisha, and Nagaland) | Rajasthan, Odisha, Nagaland | Farmers, artisans, local entrepreneurs | To gather standardised data on current traditional and sustainable practices supporting circular economy models. |
| In-depth Interviews | Semi-structured qualitative interviews exploring individual experiences and perceptions of sustainability. | 30 interviews | Across three study sites | NGO workers, village elders, community leaders | To gain detailed insights into Indigenous knowledge, cultural values, and their connection to circular practices. |
| Focus Group Discussions (FGDs) | Group discussions facilitate collective reflection and shared experiences related to Indigenous practices. | 9 FGDs (3 per site) | Rajasthan, Odisha, Nagaland | Mixed community participants (6–8 per group) | To understand community-level dynamics, shared values, and variations in practices. |
| Field Observations / Participatory Immersion | To document contemporary Indigenous activities in real time in community activities through direct observation and engagement. | Continuous observation throughout fieldwork | All three sites | Local households, artisans, farmers | To offer an insight into practical applications of circular principles and traditional techniques. |

## ABSTRACT

Polyphenol rich medicinal plants are increasingly investigated for their potential role in managing oxidative stress associated metabolic and inflammatory disorders. The present study evaluated the phytochemical composition and in-vitro antioxidant, anti-diabetic, and anti-inflammatory activities of aqueous extracts of *Camellia sinensis*, *Solanum trilobatum*, and *Trachyspermum ammi*, both individually and in combination. Total flavonoid and phenolic contents were determined using standard colorimetric methods, revealing that *C. sinensis* possessed the highest flavonoid (5.74 mg/mL) and phenolic (13.248 mg/mL) concentrations among the tested extracts. In the DPPH radical scavenging assay, *C. sinensis* demonstrated superior antioxidant activity with an $IC_{50}$ value of 8.47 µg/mL, followed by *T. ammi* (10.18 µg/mL) and *S. trilobatum* (16.94 µg/mL), with statistically significant differences ($p < 0.05$). Combination studies indicated enhanced antioxidant efficacy, with the ternary mixture exhibiting an $IC_{50}$ of 10.09 µg/mL. Evaluation of anti-diabetic potential through $\alpha$-amylase inhibition showed that *S. trilobatum* exhibited comparatively higher individual enzyme inhibitory activity, while selected binary combinations demonstrated synergistic interactions; however, the ternary combination showed antagonistic behaviour. In the anti-inflammatory protein denaturation assay, *C. sinensis* produced the highest individual inhibition (44.59 ± 7.65% at 50 µg), whereas the triple combination displayed pronounced synergism (60.80 ± 1.91%), exceeding its predicted cumulative value. Overall, the findings

suggest that polyphenol-rich extracts, particularly *C. sinensis*, contribute significantly to antioxidant, anti-diabetic, and anti-inflammatory effects, and that carefully optimized combinations may enhance therapeutic potential for managing oxidative stress and metabolic inflammation.

**Keywords:** *Camellia sinensis*, DPPH assay, anti-diabetic, anti-inflammatory, flavonoids, phenols.

## INTRODUCTION

Medicinal plants have underpinned traditional healthcare systems for centuries and remain central to modern biomedical exploration. Growing scientific interest in plant-derived bioactive compounds stems from their structural diversity and broad pharmacological spectrum. Leaves, seeds, fruits, roots, and bark contain abundant phytochemicals including polyphenols, flavonoids, alkaloids, and terpenoids recognized for antioxidant, anti-inflammatory, antimicrobial, and anti-diabetic properties. Consequently, plant extracts are increasingly investigated as candidates for functional foods, nutraceuticals, and disease-targeted formulations. Among globally consumed botanical beverages, *Camellia sinensis* (green tea) is distinguished by its dense polyphenolic composition. Its principal catechins, epigallocatechin-3-gallate (EGCG), epigallocatechin (EGC), epicatechin (EC), and epicatechin-3-gallate (ECG)account for much of its bioactivity (Khan and Mukhtar, 2007; Graham, 1992). EGCG, the predominant catechin, exhibits antioxidant activity exceeding that of conventional antioxidants such as vitamins C and E (Cao *et al*., 2002). These compounds neutralize reactive oxygen species (ROS) through hydrogen atom (H•) donation and single-electron transfer ($e^-$), while also modulating cytoprotective pathways including Nrf2/ARE signaling (Shahidi and Ambigaipalan, 2015; Zhang *et al*., 2022). Oxidative stress defined as ROS production > endogenous antioxidant capacity contributes to lipid, protein, and DNA damage and underlies chronic disorders such as diabetes, cardiovascular disease, neurodegeneration, and cancer (Halliwell and Gutteridge, 1989). Inflammation, closely linked to oxidative imbalance, involves cytokine release, prostaglandin synthesis, and NF-κB activation. While acute inflammation is protective, persistent low-grade inflammation promotes metabolic syndrome and related pathologies (Bagad and Joseph, 2013). *In vitro* protein denaturation assays are widely employed to assess anti-inflammatory potential (Prakash *et al*., 2011), and green tea catechins have demonstrated suppression of pro-inflammatory mediators (Khan and Mukhtar, 2007; Zhang *et al*., 2022). Diabetes mellitus, characterized by dysregulated glucose homeostasis, further exemplifies the oxidative inflammatory nexus. Inhibition of carbohydrate-hydrolyzing enzymes such as α-amylase and α-glucosidase reduces postprandial hyperglycemia (Kamiyama *et al*., 2010). Catechins have shown protective effects on pancreatic β-cells and improvements in insulin sensitivity (Anderson *et al*., 2002; Ye *et al*., 2010, Berenbaum, 1989; Wagner and Ulrich-Merzenich, 2009). *Trachyspermum ammi*, rich in thymol, and *Solanum trilobatum*, containing flavonoids and steroidal alkaloids, possess complementary bioactivities. Accordingly, this study comparatively evaluates the individual and combined *in vitro* bioactivities of *C. sinensis*, *T. ammi*, and *S. trilobatum*, assessing antioxidant capacity, enzyme inhibition, and anti-inflammatory potential to determine additive, synergistic, or antagonistic interactions.

## MATERIALS AND METHODS

## MATERIALS

All chemicals used were of analytical grade. The reagents included 2,2-Diphenyl-1-picrylhydrazyl (DPPH) for Sigma Aldrich, ascorbic acid, quercetin dehydrate, sodium bicarbonate, aluminium chloride, potassium acetate, Folin–Ciocalteu reagent, methanol, bovine serum albumin, catechol, and α-amylase (HiMedia). All reagents were used without further purification.

**Sample Collection**

Leaves of *Camellia sinensis* were procured from a local hypermarket in Munnar, Kerala, during December 2022 and Fresh leaves of *Solanum trilobatum* L. were collected from Tirunelveli district, Tamil Nadu, in December 2022. The leaves were thoroughly rinsed to remove debris and contaminants, then air-dried for three hours prior to further processing. *Trachyspermum ammi* (ajwain) seeds were purchased from a local hypermarket in Bangalore, Karnataka, in January 2023. Seeds were cleaned under running tap water, sterilized with distilled water, and air-dried for two days.

**Extraction and Preparation**

25 g of air-dried leaves of *C. sinensis*, *S. trilobatum*, and ajwain seeds were weighed individually and soaked in 100 ml of distilled water for one hour, followed by homogenization respectively. The homogenised mixtures were boiled for 20 minutes. The extracts were filtered through muslin cloth, and the filtrates were centrifuged at 8000 rpm for 15 minutes at 20°C. Supernatants was collected in sterile, airtight containers respectively and stored at 4°C until further analysis. For comparative experiments, 3 g of shade-dried *S. trilobatum* leaves and air-dried ajwain seeds were processed similarly: soaked in 100 ml distilled water, homogenized, boiled for 20 minutes, filtered, centrifuged at 8000 rpm for 15 minutes at 20°C, and the supernatant was stored at 4°C.

**Phytochemical analysis**

**Determination of Total Flavonoid Content**

Total flavonoid content (TFC) was quantified using a modified aluminium chloride colorimetric assay (Chang *et al*., 2020). Quercetin (100 µg/ml) was used to prepare standards (20–100 µg). Aliquots of sample extracts (0.01–0.1 ml; 5–25 µg) were adjusted to 2 ml with methanol. Blank tubes contained 2 ml methanol. To each tube, 0.1 ml 10% $AlCl_3$ and 0.1 ml 1M potassium acetate were added, followed by 2.8 ml distilled water. The mixtures were incubated at room temperature for 30–60 seconds, and absorbance was measured at 415 nm. Flavonoid content was expressed as mg quercetin equivalents per g of tissue.

**Determination of Total Phenolic Content**

Total phenolic content (TPC) was determined using the Folin-Ciocalteu method (Singleton and Rossi, 1965) with catechol as a standard. Catechol solutions (1 mg/ml) were prepared at concentrations of 0.2–1 mg. Sample extracts (0.004–0.01 ml; 5–25 µg) were diluted to 3 ml with distilled water. A blank of 3 ml distilled water was prepared. To each tube, 0.5 ml Folin–Ciocalteu reagent was added and incubated for 3 minutes at room temperature, followed by addition of 2 ml 20% sodium carbonate solution. Samples were shaken and incubated at room temperature for 20 minutes. Absorbance was measured at 650 nm using a colorimeter. Phenolic content was expressed as µg catechol equivalents per mg of extract.

**Antioxidant Activity: DPPH Radical-Scavenging Activity Assay**

Antioxidant activity was assessed by DPPH radical scavenging assay with modifications (Braca *et al*., 2002). Ascorbic acid (0.1 mg/ml) served as the standard. Aliquots of ascorbic acid (100–500 µl) and sample extracts (5–25 µg) were prepared and adjusted to 1 ml with methanol. Blanks contained methanol alone, while controls contained methanol and DPPH. Then DPPH solution was added to each tube, and samples were incubated in the dark for 5 minutes. Absorbance was measured at 517 nm. Radical scavenging activity was calculated as:

$$\text{DPPH scavenging effect (\%)} = \frac{\text{Abs control} - \text{Abs test}}{\text{Abs control}} \times 100$$

where Abs control and Abs test represent the absorbance of control and sample, respectively.

**Anti-diabetic Activity: α-amylase inhibition assay**

α-Amylase inhibitory activity was evaluated using a modified method (McCue and Shetty, 2004). The enzyme (0.5%) was pre-incubated with phosphate buffer (pH 7), Acarbose (2 mg/ml), or sample extracts (5–25 µg) for 10 minutes at

room temperature. Subsequently, 1 ml of 1% starch solution was added, and the mixture was incubated for 20 minutes. The reaction was terminated by adding 1 ml dinitrosalicylic acid reagent and heating for 5 minutes. After cooling and dilution, absorbance was measured at 545 nm. Percentage inhibition was calculated as:

$$\%\text{Inhibition} = \frac{A_{540\text{Control}} - A_{540\text{Sample}}}{A_{540\text{Control}}} \times 100$$

where $A_{540\text{Control}}$and $A_{540\text{Sample}}$ are absorbances of control and test samples, respectively.

**Determination of Anti-inflammatory activity: Protein Denaturation Assay**

Anti-inflammatory activity was evaluated using the protein denaturation assay as described by Gambhire *et al*. (2009) with minor modifications (Gunathilake *et al*., 2018). Briefly, different concentrations of the sample extracts (10 - 50 µg/mL) and aspirin (5 mg/mL) were mixed with 0.2 mL of 1% (w/v) bovine serum albumin (BSA). The final volume was adjusted to 5 mL with phosphate-buffered saline (PBS, pH 6.4).The mixtures were incubated at 37 °C for 20 min, followed by heating at 70 °C for 5 min. After cooling, absorbance was measured at 660 nm using a UV–Visible spectrophotometer. A reaction mixture containing PBS instead of the test sample served as the control (100% denaturation).

Percentage inhibition of protein denaturation was calculated as:

$$\%\ \text{Inhibition} = \frac{A_{control} - A_{test}}{A_{control}} \times 100$$

where $A_{control}$is the absorbance of the control and $A_{test}$is the absorbance of the sample.

## RESULT AND DISCUSSION

**Phytochemical analysis: A. Total Flavonoid Content**

Flavonoids represent an important subclass of polyphenolic secondary metabolites widely distributed in plants. These compounds, which structurally contain a 15-carbon backbone arranged in a C6–C3–C6 configuration, include flavones, flavanols, flavanones, isoflavones, and chalcones. Owing to their hydroxylated structure, flavonoids are generally water soluble and contribute significantly to the antioxidant defence system of plants and humans. Beyond their free radical scavenging potential, flavonoids are known to modulate intracellular signalling pathways, regulate enzyme activity, and influence gene expression associated with inflammation and metabolic disorders (Panche *et al*., 2016; Chen *et al*., 2020). Total flavonoid content (TFC), determined by the aluminium chloride method using quercetin as standard, was expressed as mg QE/g extract. *Camellia sinensis* showed the highest TFC (5.74 mg/ml), followed by *Solanum trilobatum* (3.43 mg/ml) and *Trachyspermum ammi* (1.12 mg/ml) (Table 1). This ranking (5.74 > 3.43 > 1.12) aligns with reports of catechin-rich green tea (Khan *et al*., 2007; Cao *et al*., 2002). Flavonoids act via radical scavenging, metal chelation, and Nrf2/ARE modulation (Chen *et al*., 2020; Zhang *et al*., 2022), supporting anti-inflammatory and metabolic benefits (Panche *et al*., 2016; Salehi *et al*., 2021).

**Total Phenolic Content**

The total phenolic content (TPC) of the aqueous extracts was quantified using the Folin–Ciocalteu colorimetric method following the procedure of Singleton and Rossi (1965), with catechol as the calibration standard. The calibration curve demonstrated good linearity (y = 0.030x + 0.013; $R^2$ = 0.984), confirming the reliability of the assay. TPC was expressed as catechol equivalents (CE) per gram of extract. *Camellia sinensis* exhibited the highest total phenolic content (13.248 mg/ml), substantially greater than *Solanum trilobatum* (3.873 mg/ml) and *Trachyspermum ammi* (3.166 mg/ml) (Table 1). This elevated level aligns with previous reports describing green tea as a rich source of catechins and polyphenols (Khan *et al*., 2007). Phenolics act via hydrogen atom (H•) donation and single-electron

transfer ($e^-$), neutralizing reactive species (Shahidi and Ambigaipalan, 2015). The ranking (13.248 > 3.873 > 3.166 mg/ml) supports their antioxidant and redox-modulatory roles (Zhang *et al*., 2022; Cory *et al*., 2018).

***In-vitro* Antioxidant property: DPPH radical scavenging activity of *Camellia sinensis*, *Solanum trilobatum*, and *Trachyspermum ammi* Extracts and Their Combinations**

The DPPH free radical scavenging assay revealed concentration-dependent antioxidant activity, comparable to the standard ascorbic acid. Among individual extracts, *Camellia sinensis* (green tea leaf extract, GTLE) exhibited the highest radical scavenging efficiency, reaching 90.88 ± 0.7% inhibition at 25 µg/mL, closely matching ascorbic acid (93.94 ± 0.07%). *Trachyspermum ammi* (AJSE) showed moderate activity (82.33 ± 1.7%), while *Solanum trilobatum* leaf extract (STLE) had the lowest scavenging potential (52.07 ± 5.6%) at the same concentration (Table 2, Figure 1). The $IC_{50}$ values further emphasized the potency of these extracts: GTLE (8.47 µg/mL) < AJSE (10.18 µg/mL) < STLE (16.94 µg/mL), indicating that green tea polyphenols exerted effective radical neutralization even at lower concentrations (Table 2). One-way ANOVA confirmed that these differences were statistically significant ($p < 0.05$) across all concentrations, with post-hoc analysis revealing that GTLE significantly outperformed the other extracts. These results are consistent with prior studies reporting high catechin and polyphenol content in green tea, which stabilizes free radicals through hydrogen donation (Cao *et al*., 2002; Khan *et al*., 2007; Temneanu *et al*., 2011). The moderate activity of AJSE can be attributed to phenolic compounds like thymol, while the lower activity of STLE likely reflects its comparatively smaller flavonoid content. The antioxidant potential of combined extracts was also assessed using equal proportion mixtures of GTLE, STLE, and AJSE. Three combinations were tested: GTLE + STLE, GTLE + AJSE, and GTLE + STLE + AJSE. At 25 µg/mL, GTLE + STLE achieved 84.91 ± 1.6% scavenging, GTLE + AJSE showed 87.86 ± 0.9%, and the ternary combination exhibited 83.75 ± 6.4% activity. These results indicate a synergistic interaction between extracts, particularly involving GTLE + AJSE, enhancing radical scavenging beyond what would be expected from individual components alone (Table 3, Figure 2). $IC_{50}$ analysis of the combinations supported these observations. The ternary combination of GTLE + STLE + AJSE showed the lowest $IC_{50}$ (10.09 µg/mL) among combinations, suggesting enhanced potency due to synergistic effects of polyphenols, flavonoids, tocopherols, and organic acids present in multiple extracts(Table 4, Figure 3). The results demonstrate that combining plant extracts enhances antioxidant capacity through complementary mechanisms such as hydrogen atom transfer (HAT), single electron transfer (SET), and radical stabilization. This cooperative behavior explains the superior scavenging activity of binary (GTLE + AJSE) (Suh *et al*., 2011; Kumar *et al*., 2020; Wang *et al*., 2021). GTLE showed the strongest individual effect, yet combinations provided amplified protection, supporting multi-component nutraceutical development against oxidative stress–related disorders (Chen *et al*., 2020; Li *et al*., 2022).

***In-vitro* Anti-diabetic property: α-amylase inhibition assay of *Camellia sinensis*, *Solanum trilobatum* and *Trachyspermum ammi* extracts.**

The $\alpha$-amylase inhibitory activity of *Camellia sinensis* (GTLE), *Solanum trilobatum* (STLE), and *Trachyspermum ammi* (AJSE) was evaluated to assess their potential anti-diabetic properties. As expected, the inhibition of $\alpha$-amylase increased with concentration for all individual extracts, demonstrating a dose-dependent effect. At 25 µg, STLE exhibited the highest inhibition (66.68 ± 11.6%), followed by GTLE (59.15 ± 3.6%) and AJSE (59.03 ± 0.76%), while the standard inhibitor, Acarbose (2 mg/mL), showed 67.61 ± 1.54% inhibition. This suggests that STLE possesses strong anti-diabetic potential, likely due to its higher content of bioactive phytochemicals capable of modulating enzymatic activity, consistent with previous reports highlighting the $\alpha$-amylase inhibitory role of Solanum species (McCue and Shetty, 2004; Patel *et al*., 2022) (Table 5, Figure 4). To further explore potential synergistic or antagonistic interactions, extracts were tested in equal 1:1 combination. The GTLE + STLE combination showed the highest $\alpha$-amylase inhibition at 25 µg (63.78 ± 2.14%), exceeding its calculated theoretical cumulative value of 62.91%, indicative of a synergistic interaction. Similarly, the GTLE + AJSE combination demonstrated synergy, with practical inhibition (61.73 ± 6.07%) higher than the mathematical cumulative value (59.09%). Conversely, the ternary combination of GTLE + STLE + AJSE showed antagonistic effects, as the observed inhibition (53.55 ± 9.54%) was lower than the predicted cumulative value (61.62%) Table 6 and 7, Figure 5 and 6). The present findings demonstrate that extract combinations can produce variable outcomes depending on phytochemical composition and the relative concentrations of active constituents. Synergy may occur when polyphenols, flavonoids, and related bioactives act

through complementary pathways to enhance $\alpha$-amylase inhibition, whereas antagonism may arise from competitive binding or chemical incompatibility that reduces overall effectiveness (Sharma and Bhat, 2009; Kwon *et al*., 2020). The improved inhibitory response observed with the GTLE + STLE combination suggests that catechins from GTLE and flavonoid–alkaloid fractions from STLE may collectively broaden the inhibitory spectrum of $\alpha$-amylase. These results reinforce the concept that multi-herb formulations can deliver greater therapeutic value than single extracts (Patel *et al*., 2022; Li *et al*., 2023). Such interactions are particularly relevant for functional food development targeting postprandial hyperglycemia, where enhanced enzyme inhibition may improve glycemic regulation. Further molecular investigations are necessary to elucidate the precise mechanisms underlying both synergistic and antagonistic effects.

***In vitro* Anti-Inflammatory activity: Protein denaturation inhibition assay of *Camellia sinensis, Solanum trilobatum* and *Trachyspermum ammi* extracts**

The anti-inflammatory potential of aqueous extracts from *Camellia sinensis*, *Solanum trilobatum*, and *Trachyspermum ammi* was evaluated using the bovine serum albumin (BSA) denaturation method, based on Gambhire *et al*. (2009) with slight modifications (Gunathilake *et al*., 2018). Inhibition of heat-induced protein denaturation reflects the extract's capacity to counter inflammation-related structural damage. The extracts demonstrated concentration-dependent inhibition of protein denaturation. Among the individual extracts, *C. sinensis* exhibited the strongest activity, reaching 44.59 ± 7.65% inhibition at 50 µg. This was followed by *T. ammi* (40.53 ± 3.82%) and *S. trilobatum* (39.19 ± 3.80%) at the same concentration (Table 8, Figure 7a and 7b). The comparatively higher efficacy of *C. sinensis* may be attributed to its abundance of polyphenolic compounds, particularly catechins, which are widely recognized for their anti-inflammatory and protein-stabilizing properties. Green tea bioactives have been reported to modulate inflammatory mediators and reduce oxidative stress, thereby limiting inflammatory damage (Yang *et al*., 2022; Khan *et al*., 2023). Considering the moderate yet encouraging anti-inflammatory effects of the individual extracts, combination studies were performed in equal ratios (1:1) to evaluate possible interaction effects. The combined formulations exhibited greater inhibition than the single extracts. At 50 µg, the ternary mixture (GTLE + STLE + AJSE) produced the highest inhibition (60.80 ± 1.91%), followed by GTLE + AJSE (54.72 ± 2.86%) and GTLE + STLE (48.64 ± 3.83%) (Table 9; Figure 8). To determine whether these enhancements were additive or synergistic, observed (practical) inhibition values were compared with theoretical cumulative values calculated by summing individual effects. In each case, the measured inhibition exceeded the predicted additive value. Most notably, the triple combination showed 60.80 ± 1.91% inhibition compared to a theoretical 41.43%, confirming strong synergism. Similar patterns were evident for the binary combinations (Table 10; Figure 9), indicating cooperative phytochemical interactions. Synergistic activity in polyherbal formulations may result from the complementary actions of catechins in *C. sinensis*, thymol-rich compounds in *T. ammi*, and flavonoid–alkaloid constituents in *S. trilobatum*. Together, these bioactives can modulate inflammatory pathways and oxidative stress more effectively than individual extracts, producing enhanced therapeutic outcomes (Williamson, 2022; Zhang *et al*., 2023).

## CONCLUSION

The present study systematically examined the phytochemical composition and *in vitro* biological activities of aqueous extracts of *Camellia sinensis*, *Solanum trilobatum*, and *Trachyspermum ammi*, evaluated both individually and in combination. The results clearly indicate that phenolic and flavonoid richness plays a decisive role in determining antioxidant, anti-inflammatory, and anti-diabetic efficacy. *C. sinensis* demonstrated the highest phenolic content and exhibited strong radical scavenging and anti-inflammatory activity, emphasizing the functional significance of catechin-rich polyphenols. *S. trilobatum* showed notable $\alpha$-amylase inhibitory potential, suggesting relevance in glycemic control. Importantly, polyherbal formulations particularly the ternary combination displayed synergistic enhancement in antioxidant and anti-inflammatory assays, although antagonistic interaction was observed in enzyme inhibition. These findings reinforce the value of rationally designed phytochemical combinations and support their potential application in functional foods, nutraceuticals, and plant-based therapeutic development. Further mechanistic and *in vivo* investigations are necessary to validate clinical applicability.

## ACKNOWLEDGMENT

The authors sincerely thank Mount Carmel College (Autonomous), Bengaluru, for providing essential laboratory facilities, infrastructure, and institutional support that made this research possible. They also extend heartfelt gratitude to the faculty and departmental staff for their guidance, encouragement, and continuous support throughout the successful completion of the study.

**Table 1: Quantitative analysis of total phenols and flavonoids of *C.sinensis*, *S.trilobatum* , and *T. ammi***

| Sample | Total Phenols (mg CE/g DW) | Total Flavonoids (mg QE/g DW) |
|---|---|---|
| *Camellia sinensis* | 13.248 ± 0.45 | 5.74 ± 0.04 |
| *Solanum trilobatum* | 3.873 ± 0.11 | 3.43 ± 0.03 |
| *Trachyspermum ammi* | 3.166 ± 0.05 | 1.12 ± 0.02 |

One-way ANOVA revealed a statistically significant difference in total phenolic content among the three plant extracts ($F(2,6) = 1313.4$, $p < 0.0001$).

**Table 2:DPPH Radical Scavenging Activity of *C.sinensis*, *S.trilobatum* , and *T. ammi***

| Concentration (µg/ml) | Ascorbic acid (% Scavenging ± SD) | *C.sinensis* (% Scavenging ± SD) | *S.trilobatum* (% Scavenging ± SD) | *T. ammi* (% Scavenging ± SD) |
|---|---|---|---|---|
| 5 | 26.83 ± 2.5 | 69.33 ± 3.6 | 17.64 ± 2.4 | 23.45 ± 2.0 |
| 10 | 43.32 ± 1.8 | 80.81 ± 3.4 | 29.17 ± 5.5 | 50.47 ± 17.3 |
| 15 | 67.92 ± 2.5 | 86.47 ± 0.8 | 39.40 ± 1.1 | 78.52 ± 2.4 |
| 20 | 84.70 ± 1.7 | 90.17 ± 1.3 | 46.12 ± 4.2 | 80.34 ± 2.3 |
| 25 | 93.94 ± 0.07 | 90.88 ± 0.7 | 52.07 ± 5.6 | 82.33 ± 1.7 |
| **$IC_{50}$ (µg/ml)** | 7.1 | 8.47 | 16.94 | 10.18 |

Statistical analysis: One-way ANOVA showed significant differences ($p < 0.05$) between extracts at all tested concentrations.

**Table 3: DPPH Radical Scavenging Activity of Combinations and $IC_{50}$ Values**

| Concentration (µg) | *C.sinensis* + *S.trilobatum* (% Scavenging) | *C.sinensis* + *T. ammi* (% Scavenging) | *C.sinensis* + *S.trilobatum* + *T. ammi* (% Scavenging) |
|---|---|---|---|
| 5 | 46.12 ± 3.3 | 47.63 ± 11.5 | 48.02 ± 8.9 |
| 10 | 60.61 ± 7.1 | 69.05 ± 20.5 | 64.06 ± 8.8 |
| 15 | 69.10 ± 10.6 | 74.03 ± 17.1 | 73.40 ± 1.15 |
| 20 | 79.56 ± 4.5 | 81.98 ± 4.8 | 80.39 ± 7.6 |
| 25 | 84.91 ± 1.6 | 87.86 ± 0.9 | 83.75 ± 6.4 |
| Estimated $IC_{50}$ (µg/mL) | ~6.2 | ~6.5 | ~5.8 |

One-way ANOVA revealed significant differences ($p < 0.05$) between the different combinations of plant extracts at all tested concentrations.

**Table 4: Combinatorial effect of sample on DPPH Radical Scavenging Activity and type of interaction**

| Sample (25 µg) | Mathematical cumulative value (%) | Practical value (mean ± SD) (%) | Type of interaction |
|---|---|---|---|
| GTLE + STLE | 71.47 | 84.91 ± 1.6 | Synergism |
| GTLE + AJSE | 86.60 | 87.86 ± 0.9 | Synergism |
| GTLE + STLE + AJSE | 75.09 | 83.745 ± 6.4 | Synergism |

**Table 5: α-Amylase Inhibitory Activity of *C. sinensis, S. trilobatum* and *T. ammi* with $IC_{50}$ Values**

| Concentration (µg) | *C. sinensis* (GTLE) % Inhibition (Mean ± SD) | *S. trilobatum* (STLE) % Inhibition (Mean ± SD) | *T. ammi* (AJSE) % Inhibition (Mean ± SD) |
|---|---|---|---|
| 5 | 13.34 ± 8.2 | 26.19 ± 5.07 | 28.78 ± 4.64 |
| 10 | 30.58 ± 13.9 | 32.23 ± 5.56 | 36.01 ± 0.23 |
| 15 | 40.58 ± 14.82 | 42.15 ± 3.57 | 43.89 ± 1.96 |
| 20 | 51.36 ± 8.59 | 57.92 ± 9.87 | 52.05 ± 1.61 |
| 25 | 59.15 ± 3.6 | 66.68 ± 11.62 | 59.03 ± 0.76 |
| **$IC_{50}$ (µg/mL)** | 20 | 18 | 21 |

One-way ANOVA indicated significant differences among the three extracts at all concentrations ($p < 0.05$). Values represent mean ± SD of triplicate independent experiments ($n = 3$).

**Table 6: α-Amylase Inhibitory Activity of combination of *C. sinensis, S. trilobatum* and *T. ammi* with $IC_{50}$ Values**

| Concentration (µg) | *C. sinensis* + *S. trilobatum* (% Inhibition ± SD) | *C. sinensis* + *T. ammi* (% Inhibition ± SD) | *C. sinensis* + *S. trilobatum* + *T. ammi* (% Inhibition ± SD) |
|---|---|---|---|
| 5 | 29.62 ± 8.73 | 33.61 ± 8.49 | 27.37 ± 14.64 |
| 10 | 39.75 ± 5.02 | 40.73 ± 6.44 | 38.47 ± 12.28 |
| 15 | 48.71 ± 5.79 | 50.75 ± 5.59 | 42.49 ± 11.95 |
| 20 | 55.34 ± 4.46 | 54.65 ± 8.08 | 48.63 ± 8.59 |
| 25 | 63.78 ± 2.14 | 61.73 ± 6.07 | 53.55 ± 9.54 |
| **Estimated $IC_{50}$ (µg)** | 16–17 | 15 | 22 |

$IC_{50}$ values are estimated from dose-response curves. Values are expressed as mean ± SD from triplicate experiments ($n = 3$).

**Table 7: Comparative α-Amylase Inhibitory Activity and type of interaction of *C. sinensis*, *S. trilobatum* and *T. ammi* with $IC_{50}$ Values**

| Sample | Practical % Inhibition (25 µg) | Mathematical Cumulative % | $IC_{50}$ (µg/mL) | Interaction |
|---|---|---|---|---|
| GTLE (*C.sinensis*) | 59.15 ± 3.6 | 59.15 | 20 | – |
| STLE (*S.trilobatum* ) | 66.68 ± 11.62 | 66.68 | 18 | – |
| AJSE (*T. ammi* ) | 59.03 ± 0.76 | 59.03 | 21 | – |
| GTLE + STLE | 63.78 ± 2.14 | 62.91 | 6.2 | Synergism |
| GTLE + AJSE | 61.73 ± 6.07 | 59.09 | 6.5 | Synergism |
| GTLE + STLE + AJSE | 53.55 ± 9.54 | 61.62 | 5.8 | Antagonism |

GTLE + STLE and GTLE + AJSE combinations showed synergistic inhibition, with practical values exceeding the mathematical cumulative predictions. The ternary combination (GTLE + STLE + AJSE) showed antagonistic interaction, as the practical inhibition was lower than the cumulative value. $IC_{50}$ values indicate that combinations achieve effective α-amylase inhibition at lower concentrations than individual extracts.

**Table 8: Effect of *C. sinensis*, *S. trilobatum*, and *T. ammi* extracts on inhibition of protein denaturation.**

| Concentration (µg/mL) | Standard (Aspirin) | *C. sinensis* | *S. trilobatum* | *T. ammi* |
|---|---|---|---|---|
| 10 | 27.69 ± 0.95 | 27.02 ± 5.73 | 12.83 ± 2.86 | 24.31 ± 3.83 |
| 20 | 35.81 ± 0.96 | 33.10 ± 4.78 | 19.59 ± 0.96 | 29.05 ± 2.87 |
| 30 | 40.53 ± 1.91 | 38.51 ± 6.68 | 27.02 ± 3.81 | 31.76 ± 0.95 |
| 40 | 49.32 ± 2.87 | 41.88 ± 7.64 | 33.78 ± 3.82 | 37.16 ± 2.86 |
| 50 | 56.08 ± 1.88 | 44.59 ± 7.65 | 39.19 ± 3.82 | 40.54 ± 3.82 |

Statistical analysis was performed using one-way analysis of variance (ANOVA) to determine significant differences among groups at different concentrations. Differences were considered statistically significant at $p < 0.05$.

**Table 9: Effect of combined *C. sinensis*, *S. trilobatum*, and *T. ammi* extracts on inhibition of protein denaturation.**

| Concentration (µg/mL) | *C. sinensis* + *S. trilobatum* | *C. sinensis* + *T. ammi* | *C. sinensis* + *S. trilobatum* + *T. ammi* |
|---|---|---|---|
| 10 | 27.70 ± 0.23 | 36.48 ± 0.87 | 36.48 ± 0.93 |
| 20 | 37.83 ± 1.50 | 42.57 ± 1.02 | 41.22 ± 1.05 |
| 30 | 43.92 ± 2.03 | 46.62 ± 0.68 | 50.00 ± 1.67 |
| 40 | 46.62 ± 1.05 | 52.03 ± 1.54 | 55.40 ± 0.96 |
| 50 | 48.65 ± 0.75 | 54.73 ± 2.01 | 60.81 ± 2.06 |

Data were analyzed using one-way analysis of variance (ANOVA) to compare the inhibitory effects among treatment groups at each concentration level. Statistical significance was considered at $p < 0.05$.

**Table 10: Cumulative effect and interaction type of combined *C. sinensis*, *S. trilobatum*, and *T. ammi* extracts**

| Sample | Mathematical Cumulative Value (%) | Practical Value (%) (Mean ± SD, n = 3) | Type of Interaction |
|---|---|---|---|
| GTLE + STLE | 41.88 | 48.64 ± 3.83 | Synergism |
| GTLE + AJSE | 42.56 | 54.72 ± 2.86 | Synergism |
| GTLE + STLE + AJSE | 41.43 | 60.80 ± 1.91 | Synergism |

Data are expressed as mean ± SD (n = 3). statistically significant at $p < 0.05$.
