Sentiment scoring involves assigning a sentiment value to each feedback entry based on the presence of positive or negative keywords. Sentiment scores are typically assigned on a scale (e.g., from -1 to 1, where -1 indicates negative sentiment, 1 indicates positive sentiment, and 0 indicates neutral sentiment).For context-dependent terms, the sentiment score was adjusted by considering neighboring contextual cues within a predefined window. Positive modifiers increased the original sentiment score, whereas negative modifiers reduced it. This rule-based adjustment enabled the framework to capture the contextual polarity of educational terms more effectively. The sentiment score can be refined by considering context-specific modifiers such as negations (e.g., "not helpful" vs. "helpful"). Context-dependent terms such as "challenging" were interpreted based on their surrounding words. Positive contextual cues (e.g., "rewarding") increased the sentiment score, whereas negative cues (e.g., "frustrating") reduced the score, thereby improving contextual understanding. For instance, if a student mentions "not helpful," the sentiment is likely negative, even if the word "helpful" is present.

Pseudocode for sentiment scoring:

function calculate_sentiment_score(keywords, sentiment_dict):
score = 0
for keyword in keywords:
if keyword in sentiment_dict:
score += sentiment_dict [keyword]
return score

Ensemble Model Optimization

In this study, a hybrid ensemble framework is used for sentiment classification. The ensemble approach combines multiple machine learning models to improve the overall accuracy and robustness of sentiment analysis. The models employed in the hybrid framework are: Random Forest, Gradient Boosting and Support Vector Machine (SVM). Each model brings unique strengths to the sentiment classification process, and their combination enhances performance by reducing the likelihood of errors or bias from any single model.

Random Forest

Random Forest is an ensemble learning algorithm that builds multiple decision trees and aggregates their outputs to provide a final classification. This model is particularly useful for handling complex datasets with diverse features, such as student feedback, which can contain a wide range of sentiment expressions. The Random Forest algorithm is robust and helps mitigate over fitting by averaging predictions across multiple decision trees.

Pseudocode for Random Forest
function random_forest_predict(data, forest):
predictions = []
for tree in forest:
predictions.append(tree.predict(data))
return majority_vote(predictions)

Gradient Boosting

Gradient Boosting is an iterative model that combines weak learners (usually decision trees) to create a strong learner. Each iteration of the model focuses on the errors made by the previous iteration, which leads to improved performance. This model is particularly effective when dealing with imbalanced data, which is often the case in sentiment analysis when negative feedback is less frequent than positive feedback.

Pseudocode for Gradient Boosting:
function gradient_boosting_predict(data, model):
predictions = []
for weak_learner in model:
predictions.append(weak_learner.predict(data))
return weighted_sum(predictions)

Support Vector Machine (SVM)
Support Vector Machine (SVM) is a supervised machine learning algorithm that is effective in high-dimensional spaces, which makes it well-suited for text data. SVM works by finding the hyperplane that best separates data points of different classes (in this case, positive and negative sentiments). The kernel trick is often used to handle non-linear data relationships.
Pseudocode for SVM:
function svm_predict(data, model):
return model.predict(data)

Ensemble Model Integration
The final step in the ensemble framework is combining the predictions from all three models (Random Forest, Gradient Boosting, and SVM). This can be done using a majority voting mechanism, where the model with the highest number of votes determines the final sentiment classification. To resolve occasional disagreements among Random Forest, Gradient Boosting, and SVM predictions, a weighted majority voting strategy was adopted. The final sentiment class was selected based on the aggregated votes of the constituent classifiers, thereby reducing the impact of individual model errors and improving classification robustness.
Pseudocode for ensemble model integration:
function ensemble_predict(data, models):
predictions = []
for model in models:
predictions.append(model.predict(data))
return majority_vote(predictions)

Each model is tuned for optimal performance using techniques such as cross-validation and hyperparameter tuning. The final ensemble model aggregates the outputs of all models, improving the accuracy and robustness of sentiment classification. The methodology presented in this section outlines the key components involved in adapting a hybrid ensemble framework for sentiment analysis of educational data. The pre processing steps, including text normalization, tokenization, and stop-word removal, prepare the data for meaningful analysis. Feature extraction using domain-specific keywords and sentiment scoring helps capture the nuances of student feedback. Finally, the ensemble framework, consisting of Random Forest, Gradient Boosting, and SVM, integrates the strengths of multiple models to deliver improved sentiment analysis accuracy. By following this methodology, educators and researchers can gain valuable insights into student sentiments, ultimately informing instructional strategies and improving the learning environment.

Evaluation with Case Study
This case study evaluates the performance of the hybrid ensemble framework in analyzing student feedback. The primary goal is to assess how well the ensemble model performs compared to traditional sentiment analysis approaches. The evaluation focuses on key performance metrics including accuracy, precision, recall, and F1-score to provide a comprehensive understanding of the model's efficacy. Feedback from three different university courses, representing diverse academic disciplines, is used to demonstrate the model's robustness and adaptability across various educational contexts.

Case Study Overview

The dataset for this case study includes 2,000 student feedback entries, collected from three university courses: one from the STEM field, another from humanities, and a third from the social sciences. Each course represents a unique context with different types of content, student demographics, and potential areas of concern. This diversity allows for a thorough evaluation of the hybrid ensemble model's performance across different academic disciplines and sentiment expressions.

Course Descriptions

STEM Course: "Introduction to Programming"

This course covers fundamental programming concepts such as variables, loops, and basic algorithms. Student feedback typically revolves around course difficulty, clarity of teaching, and engagement.

Humanities Course: "Literary Analysis"

The humanities course explores various literary works, focusing on interpretation, critique, and discussion. Feedback is often more reflective, covering aspects like instructor approachability, course material relevance, and class discussions.

Social Sciences Course: "Introduction to Sociology"

This course introduces students to the foundational concepts of sociology, covering topics such as social structures, cultures, and socialization processes. Feedback typically includes comments on course structure, applicability of the content to real-life situations, and class interactions. Each course's feedback dataset contains a mix of positive, negative, and neutral sentiments, reflecting a wide range of student experiences.

Dataset Characteristics

Total Feedback Entries: 2,000 (approximately 667 entries per course)

Data Composition: Although the dataset exhibited moderate class imbalance, appropriate class weighting and balanced evaluation metrics were employed during model training and assessment to minimize potential bias towards majority classes.

Positive Sentiment: 45%

Negative Sentiment: 35%

Neutral Sentiment: 20%

The feedback entries were anonymized and contain a variety of student comments, such as:

"The course material was very engaging, and I learned a lot!"

"The lectures were difficult to follow, and I didn't get much out of them."

"The course was fine, but the assignments were not very clear."

These varied responses serve as an ideal representation of real-world feedback data, which is often noisy and contains both explicit and implicit sentiment indicators.

Sentiment Analysis Approaches

In this case study, the performance of the hybrid ensemble framework is compared with traditional sentiment analysis techniques, which include:

- Naive Bayes: A probabilistic classifier based on Bayes' theorem, commonly used for text classification tasks. Naive Bayes assumes independence between features (words in this case), which may not always hold in complex real-world datasets like student feedback.
- Logistic Regression: A linear model used for binary classification tasks. Logistic regression is popular for its simplicity and efficiency, but it may struggle with capturing the complexities of language in feedback datasets.
- Support Vector Machine (SVM): SVM is widely used for text classification tasks, particularly for its ability to find the hyperplane that best separates different classes in high-dimensional data.
- Random Forest: A tree-based ensemble model known for its robustness in handling noisy and high-dimensional data. Random Forests are effective but may not always perform as well as more specialized models in terms of fine-grained sentiment analysis.

These traditional models are used as baselines for comparison with the hybrid ensemble framework, which combines multiple algorithms to improve the overall sentiment analysis performance.

Methodology for Evaluation

The hybrid ensemble framework and the traditional models are trained on the preprocessed student feedback dataset. The following steps outline the evaluation process: Data Preprocessing: The raw feedback data is cleaned and preprocessed, as described in the methodology section. This includes text normalization, tokenization, stop-word removal, and sentiment scoring using domain-specific keywords. All experiments were conducted on a workstation equipped with an Intel Core i7 processor, 16 GB RAM, running Ubuntu Linux. The implementation was developed in Python using Scikit-learn, NLTK, Pandas, and NumPy libraries.

Model Training:

For each model (Naive Bayes, Logistic Regression, SVM, Random Forest, and the hybrid ensemble framework), the data is split into training and testing sets using a 70:30 ratio. Hyper parameters for each model are tuned using grid search and cross-validation to optimize performance.

Sentiment Classification: Each model is used to classify the sentiment of student feedback entries as positive, negative, or neutral.

Performance Metrics:

Accuracy: Measures the overall correctness of the model, calculated as the ratio of correct predictions to total predictions.

Accuracy= (True Positives +True Negatives)/Total Predictions

Precision: Measures the proportion of positive predictions that are actually correct. It is particularly important when the cost of false positives is high.

Precision=True Positives / (True Positives + False Positives)

Recall (Sensitivity): Measures the proportion of actual positive instances that are correctly identified by the model.

Recall=True Positives / True Positives + False Negatives

F1-Score: The harmonic mean of precision and recall, providing a balanced measure of model performance, particularly in datasets with imbalanced classes.

F1-Score=2× ((Precision × Recall) / (Precision + Recall))

RESULTS AND DISCUSSION

Performance Metrics Comparison

As the results indicate, the hybrid ensemble framework outperforms all traditional models in terms of accuracy, precision, recall, and F1-score. This improvement can be attributed to the combined strengths of multiple machine learning algorithms (Random Forest, Gradient Boosting, and SVM), which allow the hybrid model to capture complex patterns and nuances in student feedback that individual models might miss. The improved performance of the hybrid ensemble framework can be attributed to the complementary strengths of the individual classifiers. While Random Forest effectively handles noisy data, Gradient Boosting focuses on correcting classification errors and SVM performs well in high-dimensional text spaces. Their combination therefore provides better generalization than any single model.

Accuracy: The ensemble model achieves the highest accuracy (90.2%), demonstrating its robustness in classifying sentiments across different types of feedback.

Precision: The hybrid ensemble also leads in precision (89.7%), ensuring that most of the positive predictions it makes are correct.

Recall: The recall of the hybrid model (88.9%) is the highest, meaning it successfully identifies the majority of positive and negative sentiment instances in the feedback.

F1-Score: With an F1-score of 89.3%, the hybrid model provides a balanced measure of precision and recall, making it the most reliable model for sentiment analysis in this case study.

Analysis of Model Strengths

The hybrid ensemble framework excels because it leverages the strengths of multiple models, each addressing different aspects of sentiment analysis:

- Random Forest is effective in handling noisy and complex data.
- Gradient Boosting improves performance by focusing on the weaknesses of previous models.
- SVM works well for high-dimensional text data and helps in accurately classifying the feedback.
- In contrast, traditional models like Naive Bayes and Logistic Regression tend to struggle with complex feedback data, especially when nuanced or indirect sentiment is expressed. SVM performs well but is outperformed by the ensemble model, which combines SVM with other complementary algorithms to improve overall performance.

This case study demonstrates the effectiveness of the hybrid ensemble framework for sentiment analysis of student feedback. By comparing the ensemble model with traditional sentiment analysis approaches, we observe that the hybrid framework significantly outperforms the baseline models in terms of accuracy, precision, recall, and F1-score. The results show that the ensemble approach can capture the complexities and subtleties of student feedback across different academic disciplines, providing valuable insights for educators and researchers.

DISCUSSION

The results of this study emphasize the significant potential of the hybrid ensemble framework in analyzing educational data, particularly student feedback. By integrating multiple machine learning models, this approach effectively captures the nuances of sentiment expression, which can vary widely across different disciplines, course formats, and individual student experiences. The findings underscore the importance of leveraging data-driven insights to optimize educational practices, improve teaching methods, and foster a more responsive learning environment.

Benefits of Sentiment Analysis in Education

The successful application of sentiment analysis in education brings several substantial benefits to both educators and students. By automating the process of feedback analysis, sentiment analysis allows for real-time, actionable insights, which can directly influence teaching practices.

- Data-Driven Insights: One of the most compelling advantages of sentiment analysis is its ability to provide concrete, quantitative data that can guide instructional decisions. Instead of relying on subjective impressions or sporadic student interactions, educators can use sentiment scores to evaluate their teaching methods objectively. The hybrid ensemble model in this study offers a comprehensive way to understand the emotional tone and underlying sentiments of feedback, making it easier to identify areas where students might be struggling or thriving. This data can also be used to track changes over time, enabling instructors to evaluate the effectiveness of any adjustments made to their teaching strategies.
- Improved Student Engagement: Understanding the perspectives of students through sentiment analysis allows educators to adjust their teaching methods to better align with student needs. For example, if sentiment analysis reveals that a particular aspect of a course is consistently met with negative feedback—such as unclear explanations or lack of engagement—educators can take action to improve that area. This might involve restructuring lectures, introducing more interactive activities, or providing additional resources. By responding to student sentiments, instructors can foster a more engaging and supportive learning environment, ultimately contributing to increased student satisfaction and academic success.
- Targeted Interventions: Sentiment analysis also facilitates the identification of patterns in student feedback that may indicate specific challenges. For instance, if multiple students express frustration with a particular concept or assignment, educators can intervene early, offering additional explanations or providing supplementary

materials. In this way, sentiment analysis empowers educators to take a proactive approach to student concerns, preventing potential issues from escalating and ensuring that no student is left behind. Targeted interventions based on sentiment insights can lead to better student retention, improved performance, and a more positive overall learning experience.

The hybrid ensemble framework's ability to synthesize feedback from a diverse range of students further enhances its value in educational settings. By integrating multiple algorithms, the framework provides a more robust and nuanced understanding of student sentiments, ensuring that both broad trends and individual concerns are addressed.

Challenges and Limitations

While the hybrid ensemble framework offers significant promise, there are several challenges and limitations that need to be addressed for broader adoption in educational contexts.

- Complexity of Educational Data: Educational data, particularly feedback, is often rich in complexity and variability. Sentiments can be expressed indirectly or ambiguously, requiring sophisticated feature extraction methods to ensure accurate sentiment classification. For example, a feedback entry like "The class was boring, but I understand why we need to cover this material" might be challenging for traditional sentiment analysis models to interpret, as it expresses both negative sentiment ("boring") and a more neutral or even positive sentiment ("understand why we need to cover this material"). The hybrid ensemble model is better equipped to handle such complexities, but ongoing refinement of the model and feature extraction techniques will be necessary to improve its accuracy further.
- Real-Time Analysis: In many educational settings, real-time feedback analysis is essential to allow instructors to adjust their teaching methods promptly. However, ensemble models, especially those that combine several machine learning algorithms, can be computationally intensive. Real-time sentiment analysis requires high processing power and efficient algorithms to ensure that feedback can be analyzed quickly and accurately. The computational resources required for real-time sentiment analysis may limit the feasibility of deploying more complex models in resource-constrained environments, such as smaller educational institutions or in classrooms with limited access to advanced computing infrastructure. Experimental evaluation indicated that the framework required an average processing time of approximately 40 ms per feedback entry, including preprocessing, feature extraction, and classification stages, demonstrating its suitability for near real-time educational feedback analysis.
- Language Nuances and Context: Educational feedback often contains nuances that are specific to the context of a particular course, academic discipline, or teaching style. The hybrid ensemble framework, while effective, may still struggle to fully understand these nuances without further customization. For instance, in a STEM course, technical jargon or specialized vocabulary might be used, whereas in a humanities course, feedback could be more reflective and complex in its tone. Ensuring that the sentiment analysis model can adapt to these contextual variations is a challenge that requires continuous updates to the model's feature set, as well as further research into domain-specific sentiment indicators.
- Data Privacy and Ethical Concerns: As with any system that analyzes student data, there are important ethical considerations regarding privacy and consent. Educational institutions must ensure that feedback data is anonymized and that students are informed about how their data will be used. While sentiment analysis can provide valuable insights, it is crucial to balance these benefits with a strong commitment to protecting student privacy. Additionally, educators should be aware of the potential for bias in sentiment analysis models. If the training data used to develop these models contains biases, these biases can be reflected in the sentiment analysis results, which could lead to skewed or unfair conclusions about student experiences. To protect student privacy, all feedback entries were anonymized before analysis by removing personally identifiable information. Only anonymized textual data were used for model development and evaluation. Furthermore, all feedback data were stored in secure institutional repositories accessible only to authorized researchers, and the analysis was performed exclusively on anonymized textual content in accordance with institutional ethical guidelines.

CONCLUSION

The hybrid ensemble framework for sentiment analysis has proven to be a valuable tool for analyzing student feedback in educational settings. By combining the strengths of multiple machine learning algorithms, the model offers enhanced accuracy, precision, and recall compared to traditional sentiment analysis methods. This research demonstrates that sentiment analysis, powered by hybrid models, can provide educators with actionable insights that support data-driven decision-making and improve teaching strategies. The findings of this study reinforce the hypothesis that ensemble techniques are particularly well-suited for analyzing complex, high-dimensional educational data. By accurately capturing the nuanced sentiments expressed in student feedback, the framework allows educators to make informed adjustments to their teaching methods, leading to improved student engagement and satisfaction. Additionally, the ability to identify patterns in student feedback enables targeted interventions, ultimately enhancing the overall learning experience. Future research should focus on further refining the model to address the complexities of educational feedback. This may involve developing more sophisticated feature extraction techniques, exploring the use of deep learning models for sentiment analysis, and improving real-time analysis capabilities. Moreover, extending the framework's applicability to other educational contexts, such as online learning platforms and large-scale educational surveys, could further enhance its utility in diverse learning environments.
Future work will focus on incorporating advanced contextual language models to improve the detection of sarcasm and irony, which remain challenging aspects of educational sentiment analysis. In conclusion, the hybrid ensemble framework represents a promising step toward leveraging machine learning for improving educational practices. By providing educators with the tools to understand and respond to student sentiment more effectively, this approach holds the potential to transform how educational institutions approach teaching, learning, and student support.

ABSTRACT

AMR remains the most critical issue in terms of public health and medicine, decreasing antibiotic efficiency and causing increased morbidity, mortality, and healthcare expenditure on a global scale. The main reason for the emergence of resistance among microbes is the misuse of antibiotics. It causes pathogens to acquire and transfer resistance genes. The human microbiome acts as a major reservoir for the development of resistance, or the so-called resistome, and also modulates immune responses. This paper focuses on the role of the human microbiome concerning antimicrobial resistance, particularly emphasizing the significance of dysbiosis for the formation of MDROs. In addition, it considers microbiota-based strategies for overcoming AMR, including probiotics, prebiotics, FMT, engineered microbial communities, synthetic biology, and phage therapy.These approaches are based on principles like microbiome restoration, inhibition of pathogens, immunomodulation, and reduction of virulence gene expressions. The review also highlights the use of these therapies in treating C. diff infections, healthcare-associated infections, and antibiotic therapies. Despite the presence of issues like safety risks,

standardization problems, regulatory difficulties, and unpredictable results, microbiota-based therapies provide an environmentally friendly and promising approach to tackle AMR in the future.

Keywords: AMR, microbiota, gut microbiome, probiotics, FMT, MDROs, resistome

INTRODUCTION

The increasing challenge of AMR warrants innovative strategies that go beyond merely developing new antibiotics. AMR causes more than 25,000 deaths each year in Europe alone, highlighting the need for alternative solutions, particularly given the limited number of novel antimicrobial agents currently in development. Antibiotic therapy changes the composition of the gut microbiome and promotes the emergence of antibiotic-resistant organisms (Stern & Brenner, 2018). The gut serves as an important reservoir of resistance genes that can be transferred between bacterial populations. (Merrick et al., 2023). Strategies such as the use of microbiota-based treatments, including FMT, probiotics, and prebiotics, provide promising options to restore homeostasis and prevent further spread of AMR. Microbiota-based therapies may target resistant bacteria for eradication or enhance the immune response against infections. This narrative review highlights the role of microbiota in AMR and explores microbiota-based approaches for MDR decolonisation. (Gargiullo et al., 2019, p. 1).

This review examines the effectiveness of microbiota-based therapies in tackling antimicrobial resistance (AMR) and explores the mechanisms through which these therapies exert their effectstheir effects. As microbiota can either mitigate or exacerbate AMR, understanding their relationship with resistance is crucial. (Dongre et al., 2025). Antimicrobial resistance has evolved alongside the widespread use and development of antibiotics since the discovery of penicillin by Alexander Fleming, which revolutionised the treatment of infectious diseases. The phenomenon has emerged as a result of the ability of microorganisms to adapt to the selective pressure exerted by antibiotics. The extensive use of antibiotics for various purposes has contributed significantly to the development and spread of antimicrobial resistance.(Hunt & Kates, 2024).

The Global Threat of Antimicrobial Resistance (AMR)

Antimicrobial resistance is a growing global public health concern that reduces the effectiveness of antimicrobial therapies used to treat infectious diseases. Antimicrobial resistance occurs as a result of the ability of the microorganisms to survive exposure to antimicrobial agents. As a result, infections become more difficult to treat, may become prolonged, and can spread more easily. Given the increasing impact of AMR, there is a need to explore alternative therapeutic options alongside the development of new antimicrobial agents to treat infections caused by multidrug-resistant pathogens. Although antimicrobial resistance develops through biological and evolutionary processes, the rapid growth of AMR has been driven by the extensive use of antimicrobial agents in healthcare, agriculture and environmental sectors. The inappropriate and excessive use of antimicrobial agents favours the survival and proliferation of resistant bacteria. The emergence and dissemination of AMR are influenced by various factors, including inadequate prevention measures, poor sanitation, limited access to clean drinking water and increased international travel. AMR is a serious global health threat that requires an integrated approach to tackle it. This includes understanding mechanisms of resistance, reducing unnecessary use of antimicrobials, and encouraging collaboration across different sectors. (Aljeldah, 2022)

Mechanisms of Antimicrobial Resistance

Antimicrobial resistance (AMR) is a major worldwide issue that affects the effective treatment of infectious diseases. It occurs when microorganisms develop resistance to antimicrobial drugs, largely due to their excessive and inappropriate use in medicine, agriculture and environmental settings. Microorganisms employ several mechanisms to resist the effects of antimicrobial drugs. One such mechanism involves reducing drug entry, which means that

microbes change the structure of their membrane to block drug entry into the cell. Microorganisms may also use efflux pumps to remove antimicrobial agents from the cell, reducing their effectiveness. Another mechanism involves the production of enzymes that break down or modify antimicrobial agents. Microorganisms can also alter the target sites that antimicrobial agents normally act upon. Resistance genes can be transferred between microorganisms, contributing to the rapid spread of resistance. Overall, these mechanisms enable microorganisms to survive antimicrobial treatment, contributing to the growing global challenge of antimicrobial resistance. (Byarugaba, 2009)

Impact of AMR on Global Health and Economy

Antimicrobial resistance (AMR) is one of the most significant public health challenges worldwide because it reduces the effectiveness of antimicrobial drugs used to treat infectious diseases. The extensive use of antimicrobial drugs creates selective pressures those enable resistant microorganisms to survive and multiply. AMR has serious consequences for public health. Patients may not respond adequately to treatment, resulting in treatment failure, prolonged illness, and an increased risk of death. As a result, routine surgeries, cancer treatments and other medical procedures become more difficult and risky to perform. AMR also has a significant economic impact because of the cost of providing medical care. Patients have to stay longer at hospitals, receive more expensive treatment, and undergo more complicated diagnostic tests than usual. Moreover, it reduces labour productivity due to extended periods of illness and disability among workers. In general, antimicrobial resistance is one of the key challenges facing the global community. The continuous growth of AMR highlights the need for effective strategies and coordinated efforts to reduce human health.(McGowan, 2001)

The Human Microbiota and Its Role in Health and Disease

The human microbiota is composed of a diverse population of microorganisms that inhabit different parts of the body, including the gut, skin, and respiratory tract. These microbial communities play an important role in maintaining normal physiological functions, such as metabolism and immune regulation (Francino, 2016). A primary function of the microbiota is protecting against pathogen invasion through colonisation resistance. Beneficial microorganisms compete with harmful microbes for nutrients and space, thereby limiting their ability to establish infections. Additionally, continuous interactions between the microbiota and the host immune system help regulate both innate and adaptive immune responses. (Gjonbalaj et al., 2020). The microbiota also contributes to several metabolic pathways by breaking down complex nutrients and producing essential compounds, such as vitamins and short-chain fatty acids. However, disturbances in microbial composition, known as dysbiosis, may occur due to antibiotic use, dietary changes, or other environmental conditions. Such alterations can increase the risk of various diseases and negatively affect overall health. (Becattini et al., 2016).

In particular, the microbiota serves as a reservoir for antibiotic resistance genes, enabling their horizontal transfer and thereby driving the spread of resistant infections. Disruptions in microbial balance further increase chances to such pathogens, highlighting the importance of maintaining microbiome homeostasis to reduce resistance dissemination and strengthen host resilience. The complex interaction between the human microbiota and AMR requires comprehensive strategies that move beyond conventional antimicrobial approaches. (Tahmasebi et al., 2025, Dongre et al., 2025)

Composition and Function of the Human Microbiota

In particular, the microbiota serves as a reservoir for antibiotic resistance genes, enabling their horizontal transfer and thereby driving the spread of resistant infections. Disruptions in microbial balance further increase chances of such pathogens, highlighting the importance of maintaining microbiome homeostasis to reduce resistance dissemination and strengthen host resilience. The complex interaction between the human microbiota and AMR calls for comprehensive strategies that move beyond conventional antimicrobial approaches (Botero et al., 2015) It is necessary to emphasise that the diversity of the microbial community is crucial for its stability. Microbiota functions. Microbiota performs numerous vital functions in the human body. For example, this microbial community plays an important role in metabolism by breaking down complex food molecules into simpler substances. Moreover, these microbes produce many useful substances essential for the human body. The microbiota also helps in immune

system develop and function, by identifying harmful pathogens and distinguishing them from harmless microbes or beneficial ones. Another important function of the microbiota, is protecting the body from harmful pathogens through colonization resistance by occupying space, competing for nutrients and producing toxins or enzymes which inhibit the growth of harmful microbes. However, changes in this balance can increase the risk of various diseases and infections. (Bik, 2009)

Dysbiosis and Disease

Dysbiosis refers to an imbalance of the normal microbial flora of the human body. It is usually influenced by conditions like antibiotic usage, dieting, and other environmental causes. The consequence includes decrease in diversity of microbes and disruption of their normal functions. In cases of dysbiosis the natural balance of microbes in the body is disrupted which leads to a decrease in beneficial microbes as well as overgrowth of pathogenic and opportunistic microbes, which may lead to a compromised intestinal barrier and inflammatory response within the host, increasing the risk of various diseases and infections (Cusumano et al., 2025) Dysbiosis leads to many diseases like gastrointestinal disorders and metabolic diseases as well as causing an increased risk of acquiring infections. Moreover, dysbiosis promotes the growth and spread of antibiotic resistance bacteria, making it difficult to treat. Thus, dysbiosis is one of the major connections between microbial imbalance and the development of diseases. Maintaining balance in microbial population is essential in preventing disease and reducing risks of infection.(Gupta et al., 2022)

Microbiota-Based Therapies: An Overview

Therapies that target the human microbiome are being explored as a way to fight the growing problem of antimicrobial resistance (AMR). While conventional antibiotics can disrupt the presence of good bacteria and thus promote resistance, these therapy enables the maintenance of microbiome balance and reduces the population of harmful bacteria. As the human microbiome may have antibiotic-resistant gene, maintaining it will be advantageous. (Becattini et al., 2016; Gjonbalaj et al., 2020). The recent studies have also proven that gut flora is an important element for preventing the development of MDROs, as well as balancing the immunity. Therefore, novel therapies including probiotics, prebiotics, fecal microbiota transplantation (FMT), artificial microbial consortia, and bacteriophage therapy are becoming increasingly popular as potential alternatives to the conventional antibiotics.(Beltrán-Velasco et al., 2025; Ding et al., 2025)

Probiotics and Prebiotics

Probiotics are live microorganisms that provide health benefits when taken in adequate quantities, while prebiotics are nondigestible dietary ingredients that selectively support the growth of beneficial microflora or probiotics. Both probiotics and prebiotics are used to restore microbiota imbalance caused by antibiotic treatment. Beneficial microorganisms can control pathogenic microorganisms by producing antibacterial substances such as bacteriocins and organic acids which would kill or inhibit the pathogen. (Ke et al., 2021, p. 2) Prebiotics are foods containing fiber that aid the development of good bacteria in the gut. In addition, they help produce short-chain fatty acids (SCFAs), which help in maintaining the integrity of the gut wall and controlling immunity. When prebiotics are combined with probiotics, the combination is known as synbiotics. This may be useful in restoring a good microbial population and inhibiting growth of antibiotic resistance pathogens.(Sanders et al., 2019) In addition, diet is known to have an important role in the development of the microbiome. There are certain components in the diet like emulsifiers found in processed food items influence the behavior of the gut microbiota and cause bodily inflammation.(Ding et al., 2025, p. 1563450)

Fecal Microbiota Transplantation (FMT)

Fecal microbiota transplantation (FMT) entails the transplant of fecal samples from a healthy individual into another individual to restore a healthy balance in gut microbiota. FMT has proven effective in restoring a well-balanced microbial ecosystem, especially in conditions where the normal microbiota has been severely damaged. The administration of FMT promotes the restoration of microbial balance through the introduction of many kinds of beneficial microorganisms into the digestive tract. These microorganisms can help to prevent the colonization of

dangerous microorganisms in the body due to competition for available resources, a phenomenon called colonization resistance. In addition, FMT reduces the presence of antibiotic resistance genes in the digestive tract. Furthermore, it has been proven that FMT helps boost immune systems and control metabolism. It can therefore be applied not only for infection treatment, but also for other diseases associated with microbial dysbiosis in the gastrointestinal tract. .(Ooijevaar et al., 2018; Stallhofer et al., 2024)

Defined Microbial Consortia and Synthetic Biology Approaches

Another strategy used to address AMR is through the selection of certain microbes that have particular functions. Such microbes are chosen due to their ability to bring back balance to microbes, inhibit pathogens, and help maintain gut health. The objective of using such microbial communities is to ensure consistent results without any differences caused by variations in donor sources. Technological improvements in synthetic biology have resulted in the creation of engineered microorganisms capable of carrying out certain functions, for example, identifying pathogenic organisms, creating antibiotics, and modulating immune systems. The engineering of microorganisms has been found to be an effective strategy to counter the problem of AMR as they can be used to target resistance mechanisms.(Olatunji et al., 2024; Ooijevaar et al., 2018)

Phage Therapy

Phage treatment is the practice of using viruses which can infect and destroy bacteria. Phages are highly specific for their bacterial hosts and can therefore kill only the desired pathogen without disturbing the other microbes in the body. This kind of treatment proves quite effective in dealing with drug-resistant bacteria due to its specific mode of action. In addition to that, bacteriophages are able to co-evolve with bacteria, making drug resistance a lot more unlikely. Some research indicates that combining phage therapy with microbiota-based approaches enhances the effectiveness of the treatment since it eliminates pathogens without affecting microbial diversity. Therefore, the combination of these two techniques is expected to produce successful outcomes in the fight against antibiotic resistance. (Stallhofer et al., 2024, p. 85)

Mechanisms of Action of Microbiota-Based Therapies Against AMR

Antimicrobial resistance (AMR) therapy using the microbiota involves balancing the microbiota, preventing the proliferation of any pathogenic bacteria, and boosting the immune system in the body. Unlike traditional antibiotics, which may alter the natural balance and cause resistant microorganisms to develop, this approach focuses on the maintenance of balance and proper functioning of the microbiota. This becomes necessary because the gut microbiota plays a important role in maintaining overall body wellbeing and even influencing the presence and spread of AMR genes.(Sandu et al., 2025; Stern & Brenner, 2018)

Restoration of Microbiota Diversity and Function

Another way microbiota-based treatments help combat antimicrobial resistance (AMR) is by restoring the balance and normal function of the microbiome after it has been disrupted by antibiotics. Antibiotic use can cause dysbiosis by reducing beneficial microorganisms and allowing resistant or opportunistic pathogens to grow. This imbalance weakens colonization resistance, making it easier for harmful microbes to establish themselves and increasing the spread of antibiotic resistance genes within the microbial community.(Ding et al., 2025; Gupta et al., 2020).

Using gut therapies like probiotics (good bacteria), prebiotics (food for good bacteria), and FMT (fecal microbiota transplants) helps recreate a healthy, stable environment in the body. When we restore this variety of microbes, they can work together better. They produce helpful substances that stop harmful germs and antibiotic-resistant "superbugs" from growing.(Relman & Lipsitch, 2018). It is essential to have a rich and healthy microbiome to achieve good health, prevent the gut barrier dysfunction, and enable regular physiological processes to function normally. Repopulating the gut microbiome following a state of dysbiosis is associated with several advantages. The first benefit, is an increase in colonization resistance as the presence of beneficial microbes prevents the growth of pathogens. Another possible outcome of re-establishing the gut microbiome is a reduction of the resistome, i.e.,

antibiotic resistance genes that may be found in the microbiome (Ding et al., 2025; Dongre et al., 2025; Stern & Brenner, 2018).

Direct Antimicrobial Effects

Microbes also play an important role in addressing antimicrobial resistance through the inhibition of pathogenic bacteria. They secrete antimicrobial substances like bacteriocins, short chain fatty acids (SCFAs), and organic acids that act against pathogens, thereby creating a hostile environment that prevents their proliferation. This makes it difficult for the microbes to multiply and reduces the chances of resistances developing. Moreover, bacteriophage therapy offers a targeted method for fighting bacterial infections since bacteriophages only target and kill pathogenic bacteria and do not affect other bacteria. Therefore, bacteriophage therapy eliminates the infection-causing bacteria while sparing other beneficial microorganisms. This makes it possible to avoid using broad-spectrum antibiotics that contribute to antibiotic resistance. Finally, microbial interactions within the body play a key role in shaping the properties of resistance. For example, competition among various microorganisms along with the release of inhibitory substances may lead to decreased resistance..(Bhalodi et al., 2018)

Immunomodulation

Gut treatments are powerful because they train and activate your body's immune system to fight off dangerous, antibiotic-resistant superbugs. The bacteria in your gut are constantly "talking" to your immune defenses through a complex network of chemical signals, boosting both your body's immediate, built-in reactions and its long-term ability to track down and destroy specific germs. By strengthening this natural partnership, microbiota therapies help the body defend itself and heal without relying on traditional antibiotics (Gupta et al., 2020, p. 778) Treatments like probiotics, prebiotics, and gut microbe transplants restore a healthy balance of bacteria in your body, which acts like a wake-up call for your immune system. This boost stimulates the production of defender cells and chemical signals that help your body actively scan for and destroy harmful germs. By supercharging your natural defenses this way, these therapies lessen our reliance on traditional antibiotics, which ultimately stops bacteria from adapting and turning into dangerous, drug-resistant superbugs. (Dongre et al., 2025; Stallhofer et al., 2024, p. 84). When the gut's microbe balance is disrupted, it triggers body-wide inflammation and weakens your immune system, making it much easier for dangerous infections to move in and take over. Fixing this ecosystem calms that inflammation and rebuilds your body's natural defenses. Ultimately, this ability of good microbes to tune and strengthen your immune system is a secret weapon in the fight against superbugs, helping the body defeat infections on its own so we don't have to rely on antibiotics (Ding et al., 2025)

Competition for Resources and Niche Exclusion

Nutrient and niche competition is a primary mechanism by which the gut microbiota establishes colonization resistance against invading pathogens. By fully occupying ecological niches and efficiently consuming available nutrients, commensal microbes deprive opportunistic and drug-resistant bacteria of the resources necessary to survive and proliferate. This competitive exclusion is vital for maintaining microbial homeostasis and serves as a critical biological barrier that protects the host from infection.(Brinkac et al., 2017; Relman & Lipsitch, 2018).

Microbiota-based interventions—such as probiotics, prebiotics, and fecal microbiota transplants (FMT)—effectively restore competitive dynamics within the gut by replenishing populations of beneficial microorganisms. By re-establishing a dense and diverse microbial community, these therapies ensure that commensal bacteria fully occupy available ecological niches and consume critical nutrients. This process of competitive exclusion deprives opportunistic pathogens and multidrug-resistant organisms (MDROs) of the resources necessary to colonize, proliferate, and establish infection within the gastrointestinal tract (Dongre et al., 2025). Furthermore, a diverse and stable gut microbiota enhances colonization resistance by serving as a robust ecological barrier against incoming pathogens. When this equilibrium is disrupted—such as following antibiotic therapy—the depletion of commensal bacteria creates vacant ecological niches and leaves unconsumed nutrients. This disruption diminishes the gut's natural defenses, significantly increasing the host's vulnerability to colonization and proliferation by opportunistic pathogens (Ding et al., 2025; Gupta et al., 2020).

Reduction of Virulence Factor Expression

Microbiota-based therapies can actively suppress the expression of virulence factors in pathogens, effectively neutralizing their ability to cause disease without relying on direct eradication. Pathogenic bacteria utilize sophisticated regulatory systems, such as quorum sensing (cell-to-cell chemical communication), to coordinate colonization, biofilm formation, and toxin production. By disrupting these signaling pathways, beneficial microbes can essentially "silence" the pathogens' harmful behaviors, mitigating their pathogenicity while minimizing the selective pressure that typically drives antibiotic resistance. (Brinkac et al., 2017; Ding et al., 2025). Commensal gut microbes can directly disrupt pathogen signaling by inhibiting quorum sensing mechanisms and downregulating the genes responsible for virulence factors. Furthermore, shifts in the microbial community structure can alter pathogen gene expression while simultaneously modulating host inflammatory responses, ultimately reducing both pathogen virulence and disease severity (Ding et al., 2025).

Additionally, emerging evidence highlights microbial extracellular vesicles (EVs)—lipid-bound particles released by cells—as critical mediators of intercellular communication that can modulate antimicrobial resistance and virulence traits across different species (Hunt & Kates, 2024).

Applications of Microbiota-Based Therapies in Combating AMR

Clostridioides difficile Infection (CDI)

Microbiota-based treatments have proven highly effective in treating *Clostridioides difficile* infection (CDI), a condition strongly correlated with antibiotic-induced dysbiosis. When antibiotics deplete the gut's indigenous flora, *C. difficile* exploits the disrupted environment to proliferate and release toxins that damage the intestinal epithelium. Recent research underscores that restoring microbial diversity is essential for clinical recovery, as a healthy microbiota re-establishes colonization resistance by outcompeting the pathogen for nutrients and generating targeted antimicrobial compounds. (Stallhofer et al., 2024)

Furthermore, microbiota-based therapies play a critical role in mitigating antimicrobial resistance (AMR) in CDI by breaking the cycle of recurrent antibiotic use, which otherwise drives further resistance. Beyond restoring ecological balance, these interventions enhance host metabolic and immune responses, effectively rendering resistant pathogens vulnerable to clearance. Accumulating in vitro and clinical evidence suggests that deploying targeted microbial consortia and synthetic microbiotas is a pivotal strategy for eradicating CDI and drug-resistant strains. Ultimately, microbiota modulation addresses the root cause of AMR by leveraging the host's restored immunity as the primary therapeutic mechanism.(Ding et al., 2025; Gupta et al., 2020)

Multidrug-Resistant Organism (MDRO) Decolonization

When it comes to implementing MDRO decolonization, the using of microbially-based treatments becomes essential since these types of pathogens generally reside in the GI tract and become the natural environment for AMR genes. There are different methods such as FMT, probiotics, prebiotics, and changes in diet to help boost microbial diversity and gain colonization resistance to the pathogenic organisms. By doing so, it becomes possible to inhibit the growth of resistant bacteria and, therefore, prevent the spread of infection and reduce its prevalence. In addition, there are other approaches that have recently emerged to deal with these organisms.(Ooijevaar et al., 2018) However, some studies show that several controversial findings have been observed in relation to microbiota-based treatments in resolving issues regarding MDRO decolonization. The significance of the research findings is that though FMT may help in improving microbial diversity and generation of positive metabolites, it will not facilitate the removal of the pathogen in patients. Additionally, other approaches to decolonization through antibiotics may negatively impact the microbiome, leading to increased risk of developing resistance. However, microbiota-based treatments look promising and need more study.(Ooijevaar et al., 2018; Stern & Brenner, 2018,)

Prevention of Healthcare-Associated Infections

The application of microbiota-based treatment is necessary in preventing HAI since the therapy helps balance the body's microbiome, especially the gut microbiome, in which there is an abundance of MDROs. The use of antibiotics

disrupts the gut microbiome and results in increased colonization with the carbapenem- and vancomycin-resistant Enterobacterales, increasing the risk of HAI in patients, such as bloodstream infection, UTI. It is important to consider the contribution of different microbiota therapies in enabling colonization resistance to regulate the body's microbiome.(Ding et al., 2025; Gupta et al., 2020). Also, such therapies are important in protecting against infections as they help in boosting the immune system of the host, as well as in maintaining microbial diversity to prevent opportunistic infections among patients in hospitals. Microbial diversity and stability resulting from diet, prebiotics, and microbiota-based therapies prevent infections and also the appearance of resistance in the microbial flora. Since microbiota therapies do not apply selection pressure on microorganisms like antibiotics, they offer a sustainable option for preventing infections.

Adjuvant Therapy in Antibiotic Treatment

Several studies have been conducted to discover microbiota-based treatments besides the usage of antibiotics for AMR. Though antibiotics are effective in fighting pathogens, their use may affect the balance of the microbiota and lead to dysbiosis, as a result creating an ideal environment for AMR. These types of treatment normalize gut microbiota thus inhibiting bacteria proliferation in ensuring that resistomes do not develop in the intestines. (Stallhofer et al., 2024; Stern & Brenner, 2018). If these methods are used to support antibiotics instead of replacing them, then there could be positive results as a result of the synergism. It is well proven that there is a potential of probiotics to reduce the negative results that come with the use of antibiotics like the occurrence of diarrhea and C. difficile infections. Also, microbiota approaches could help in promoting colonization resistance and also decolonization of antibiotic-resistant bacteria. Additionally, the effectiveness of antibiotics will be preserved by using these treatments because of preservation of natural microbiota ecosystem. However, research on these therapies remain mixed.(Ooijevaar et al., 2018; Stallhofer et al., 2024)

Challenges and Limitations of Microbiota-Based Therapies

Standardization and Regulatory Hurdles

One of the main challenges of microbiota-based therapies is is that there are no standardized approaches used for donor selection, sample preparation, storage, and administration of samples to the patient, which may cause discrepancies in the effectiveness of such treatment. Discrepancies in methods of research also prevent comparison of different studies and setting the criteria for such therapy. Furthermore, regulation of new treatments such as fecal microbiota transplantation is difficult due to their specific nature that does not allow categorizing them as medicinal products or biologics (Hassall et al., 2024; Nadimpalli et al., 2017; Zhu et al., 2022).

Safety Concerns and Adverse Events

Safety is another major concern that has caused alarm in the use of microbiota therapy as it is highly probable for pathogenic microorganisms and antimicrobial resistance genes to be transferred from one individual to another during treatment. The screening procedures of these potential donors do not always reveal all of the dangers that are associated with treatment and could cause serious infection, especially in patients who have a compromised immune system. These patients could suffer from a wide range of complications starting from minor gastrointestinal distress up to more severe infections. Furthermore, there are many cases of horizontal gene transfer between microorganisms, leading to higher antimicrobial resistance risks. (Guo & Kong, 2019; Khurana et al., 2023; Zhu et al., 2022).

Efficacy in Diverse Clinical Settings

The efficacy of microbiome therapy could differ from one patient to another depending upon their immune system, composition of microbiome, severity of disease, and external environment. Moreover, the variability of the experimental protocol and parameters used in evaluation makes it difficult to draw any conclusions based on clinical trials.Geographic factors and differences in environmental conditions may impact the structure of the microbiome, thus affecting the efficiency of the treatment. (Hassall et al., 2024; Khurana et al., 2023; Zhu et al., 2022).

Patient Acceptance and Practical Implementation

Acceptance by patients might be a difficult issue when dealing with microbiota therapies. Microbiota treatments include FMT, probiotics, phage therapy, and artificial microbial communities that seek to help achieve a healthy microbiota and to minimize antibiotic-resistant microorganisms and prevent infections. Although these approaches offer an advantage in fighting antimicrobial resistance, their efficacy is different from one study to another due to the different methodology used. Hence, there is need for more research and incorporating antimicrobial stewardship practices to enhance their efficacy (Mansoor et al., 2023; Merrick et al., 2023; Roselló et al., 2016; Sherry et al., 2025).

Future Directions and Research Gaps

Personalized Microbiota Therapies

One possible future direction would be in developing personalized therapies for managing various diseases through microbiota, considering factors such as individual differences within microbiome profiles, host genetics, and physiological condition. There have been suggestions that microbiome differences influence how patients react to therapies, meaning that there should be a personalization process in this approach. This means that either a tailor-made microbial ecosystem or particular types of bacteria, depending on the starting composition of microbiome, can be used to boost the efficiency of the treatment. However, there are still challenges surrounding the process of standardization and selection of proper biomarkers in microbiome studies.(Pearl et al., 2022; Sherry et al., 2025; Verma et al., 2023)

Novel Delivery Methods

The second major area where more research is required is in the creation of innovative methods for improving the efficacy and effectiveness of microbiota-based treatments in terms of their stability, viability, and targeted activity. Present methods, which include oral capsules, fecal material, and probiotics, pose challenges related to poor viability in the GI tract and inconsistent colonization. There are many delivery mechanisms currently under development, which include encapsulation, bioengineered bacterial vectors, and bacteriophage delivery systems, among others. (MOO et al., 2019; Roselló et al., 2016; Sherry et al., 2025)

Integration with Conventional Antimicrobial Strategies

In the future, it will be important to include the use of microbiota-based treatments into the traditional treatment of AMR. While antibiotics will continue to play an important role in fighting infection, their use can also disrupt the microbiota balance of the body and facilitate the development of resistance. Using antibiotics in combination with microbiota restoration treatments could help in preserving the colonizing resistance of the host and lower the rate of recurrence of resistant pathogens. Bacteriophage therapy and microbiome modification are additional treatment options that have been used as alternatives to antibiotic usage.(Mansoor et al., 2023; Roselló et al., 2016; Sherry et al., 2025)

Long-term Outcomes and Follow-up Studies

One of the most significant research gaps is the absence of long-term data on the safety, sustainability, and environmental impact of microbiota-based treatments. Although the immediate results look positive in terms of decreasing the colonization of antimicrobial-resistant pathogens, the long-term consequences on microbiome stability, the resistome, and host immunity are poorly understood. Additionally, there is an insufficient amount of data regarding the reoccurrence rates and efficacy persistence post-treatment. Future research needs long term studies to prove that treatments using microbes are safe and work well.(Mansoor et al., 2023; Merrick et al., 2023; MOO et al., 2019)

CONCLUSION

Antimicrobial resistance (AMR) severely threatens global public health by undermining traditional antibiotics, but the human microbiota offers a sustainable, nature-aligned solution to restore microbial balance, boost colonization

resistance, and suppress resistant pathogens. Through diverse applications like probiotics, fecal microbiota transplantation (FMT), and phage therapy, these treatments target severe dysbiosis, *Clostridioides difficile* infections, and healthcare-associated risks by intersecting ecology, immunology, and metabolism. Although challenges like variable patient responses, residual pathogens, and standardization issues persist, the future of routine medicine lies in precision approaches like engineered probiotics and synthetic microbiomes. Ultimately, by shifting our perspective toward cooperating with our own microbes, these therapies can reduce antibiotic dependency, protect existing drugs, and fundamentally transform infectious disease management.

ABSTRACT

Periodontitis is a chronic inflammatory disease driven by dysbiosis of the subgingival microbiome and the persistence of pathogenic biofilms that remain resistant to conventional therapies. This review aims to comprehensively analyze the global and Indian epidemiological burden of periodontitis, elucidate microbial and host interactions, and evaluate emerging therapeutic strategies with a focus on probiotics, bacteriocins, and nanoparticle-based drug delivery systems. Epidemiological evidence indicates a clear age-associated increase in disease prevalence, with higher severity observed in middle-aged and older populations, minimal gender differences, and a disproportionate burden among rural and socioeconomically vulnerable groups. Although scaling and root planing remains the gold standard of treatment, its effectiveness is limited in deep periodontal pockets and against structured biofilms, while adjunctive antibiotic therapy raises concerns regarding antimicrobial resistance and adverse effects. Emerging biological approaches, including probiotics and bacteriocins such as nisin, demonstrate promising antimicrobial and anti-biofilm activity without cytotoxic effects on host tissues. Advances in

omics technologies have further enhanced understanding of host–microbe interactions, enabling identification of novel therapeutic targets. Integration of these approaches with nanoparticle-based delivery systems offers improved stability, targeted delivery, and sustained antimicrobial activity. Collectively, these innovations represent a promising direction for next-generation periodontal therapeutics and may significantly improve long-term biofilm control and clinical outcomes.

Keywords: Periodontitis, Oral microbiome, Biofilms, Probiotics, Bacteriocins, Nanoparticles

INTRODUCTION

Periodontal disease is a long-standing inflammatory disorder involving the gingival tissues and supporting structures of teeth, representing a significant global public health issue. Despite improvements in oral hygiene awareness and advances in clinical dentistry, periodontitis often persists due to the resilience of complex microbial biofilms and the ability of pathogenic microorganisms to colonize subgingival niches that are difficult to access through routine mechanical therapy. These structured biofilms protect pathogenic microorganisms, allowing their persistence and sustained stimulation of host inflammatory responses. Recent research has increasingly focused on biological and nanotechnological strategies aimed at disrupting pathogenic biofilms rather than merely removing dental plaque mechanically. Among these approaches, probiotic microorganisms and their antimicrobial metabolites, particularly bacteriocins, have gained attention as effective alternatives or supportive agents to conventional periodontal treatments. Bacteriocins are antimicrobial peptides synthesized through ribosomal pathways by probiotic bacteria and demonstrate strong activity against a wide range of oral pathogens. Their selective action against harmful microorganisms, while maintaining the balance of beneficial microbiota, makes them highly suitable for targeted biofilm management in periodontal therapy. In parallel, growing interest in nanoparticle-based strategies has introduced new possibilities for enhancing antimicrobial delivery in oral healthcare. Nanoparticles offer advantages such as increased surface area, improved stability of bioactive compounds, and the potential for sustained and targeted release. The integration of bacteriocins into nanoparticle delivery systems, supplemented with commonly used toothpaste additives, represents an innovative and translational approach that could bridge advanced therapeutic concepts with daily oral hygiene practices. Such a strategy may improve patient compliance while strengthening long-term biofilm control in periodontal disease.

The socioeconomic impact of periodontitis is considerable and continues to pose a major global concern. In 2018, the financial burden of periodontal disease was estimated to be around $154 billion in the United States and €159 billion across Europe. Apart from economic implications, numerous studies have shown that periodontitis adversely affects oral health–related quality of life and is strongly linked with various systemic disorders, including cardiovascular diseases, diabetes, and complications during pregnancy. Together, these observations highlight the critical need for improved preventive measures and more effective therapeutic interventions [1], [2], [3], [4], [5], [6], [7], [8]. From a clinical perspective, chronic periodontitis presents as inflammation of the gingival tissues that progresses to involve the periodontal supporting structures, resulting in gradual loss of attachment and destruction of alveolar bone. When not treated in a timely manner, the condition advances to tooth instability and ultimately tooth loss, making it a major contributor to edentulism worldwide. Epidemiological data consistently demonstrate an age-dependent increase in periodontal disease prevalence. Reported prevalence rises from approximately 57% among 12-year-olds to nearly 89.6% in individuals aged 35–44 years. Moderate periodontitis has been observed in 17.5% and 21.4% of individuals aged 35–44 and 65–74 years, respectively, while severe disease—defined by probing depths ≥6 mm in at least one tooth—was reported in 7.8% and 18.1% of these age groups. Gender-related differences are generally minimal, although a slightly higher prevalence has been documented in rural populations, likely reflecting disparities in access to dental care, health literacy, and preventive services.

Oral Microbiota's Guilty Role in Triggering Periodontitis

The human oral cavity contains nearly 700 microbial species that together form a complex oral microbiota [9]. Under healthy conditions, this diverse microbial community exists in a state of dynamic equilibrium, supporting oral homeostasis. However, disturbance of this equilibrium results in microbial dysbiosis, characterized by a shift from health-associated commensal species to disease-associated pathogenic consortia [10]. This dysbiotic shift plays a central role in the initiation and progression of gingivitis and periodontitis. Pathogenic biofilms stimulate a chronic host inflammatory response, resulting in tissue destruction that further alters the subgingival environment and reinforces microbial imbalance. Emerging evidence also suggests that systemic inflammatory diseases can influence periodontal status, while periodontal inflammation itself may contribute to systemic inflammatory burden, highlighting a bidirectional relationship between oral and systemic health [11]. The assembly and stability of the oral microbiota appear to be governed by ecological principles similar to those observed in other biological ecosystems [12]. Although several studies have demonstrated that oral microbial communities are highly individualized, niche-specific, and distinct between health and disease states, relatively little is known about the ecological mechanisms governing microbiota disruption, resilience, and reassembly following periodontal therapy [13]. Understanding these processes is essential for the development of targeted therapies aimed at restoring microbial balance rather than merely suppressing pathogenic species.

Gum Battles: Challenges Tackled for Healing Smiles

Population-based studies in India have consistently shown that regular oral hygiene practices, particularly tooth brushing, are strongly associated with reduced prevalence of periodontal disease. A nationwide epidemiological survey, although primarily focused on prevalence rather than detailed risk-factor analysis, provided critical baseline data at both national and state levels. These findings highlighted the substantial burden of periodontal disease in India and emphasized the need for comprehensive preventive strategies and accessible treatment interventions [14]. Beyond mechanical plaque control, increasing attention has been directed toward biological and nanotechnological interventions. Probiotics and bacteriocins play a pivotal role in combatting periodontal pathogens, although their effectiveness varies depending on strain specificity and the spectrum of antimicrobial activity. While lactobacilli are well known for bacteriocin production, bacteriocins such as nisin have demonstrated efficacy against a wide range of periodontal pathogens. Other bacteriocin-like peptides have also shown promising antimicrobial and anti-biofilm properties. Metal and metal oxide nanoparticles exhibit diverse antibacterial effects, including membrane disruption, oxidative stress induction, and interference with microbial metabolism. These nanoparticles have demonstrated the ability to disrupt biofilms, a major factor contributing to drug-resistant infections. Due to their multifunctional properties, relatively low toxicity, and therapeutic versatility, metal nanoparticles represent promising tools for periodontal disease management. Furthermore, advances in nanotechnology have led to the development of mineral nanoparticles capable of promoting cell mineralization and osteogenic differentiation, suggesting potential regenerative applications alongside antimicrobial action.

Prevalence of Periodontitis

Gujarat's Silent Battle Against Periodontitis

The burden of periodontitis in Gujarat shows pronounced regional variation, reflecting differences in demographic profiles, oral hygiene practices, lifestyle habits, occupational exposure, and access to dental care. Disease distribution is not uniform across the state; instead, distinct patterns are observed between northern, central, and industrial coastal regions, highlighting the influence of localized risk factors and social determinants of health.Across studies from different districts, oral hygiene behavior, age structure, and adverse lifestyle practices consistently emerge as key contributors to periodontal disease patterns. Regions with better oral health awareness and routine hygiene practices tend to demonstrate comparatively improved periodontal status, whereas industrial and coastal areas with higher tobacco exposure and occupational stress exhibit a greater disease burden. These observations underscore the importance of region-specific preventive and control strategies rather than a uniform statewide approach. Investigations involving socially marginalized and vulnerable populations further reveal disproportionately poor periodontal health, emphasizing the need for inclusive oral health policies that address both biological susceptibility and social inequities. Moreover, emerging associations between periodontitis and systemic inflammatory conditions

suggest broader health implications of untreated disease within the state. A consolidated summary of region-wise epidemiological findings, including participant characteristics and principal observations, is presented in (Table 1), which synthesizes data from multiple districts of Gujarat [15], [16], [17], [18], [19].

Epidemiological Survey: Story Unfolds in Indian Rural & Urban Regions

India's first nationwide epidemiological survey employed a three-stage sampling strategy encompassing both rural and urban populations across multiple age groups. Periodontal status was assessed using the WHO probe and the Community Periodontal Index (CPI). The survey revealed an age-dependent increase in periodontal disease prevalence, minimal gender disparities, and a consistently higher disease burden in rural areas. Regular tooth brushing was strongly associated with lower disease prevalence, with toothbrush use proving more effective than finger cleaning [14]. Subsequent studies further reinforced these observations, reporting widespread periodontal disease across diverse Indian populations. Earlier national reports estimated that 40–45% of the Indian population may be affected by advanced periodontal disease [20]. Field surveys also documented associations between periodontal disease and systemic conditions such as coronary artery disease [21], as well as increased prevalence among rural women and other vulnerable groups [22]. Overall, these findings emphasize the substantial burden of periodontal disease in India and underline the importance of focused preventive approaches.(figure 1) also illustrates the state-wise prevalence of periodontitis across India, demonstrating considerable regional variation in disease distribution, with consistently higher prevalence observed in several northern, eastern, and central states, thereby indicating the role of regional, demographic, and socio-environmental determinants on periodontal health.

A prevalence of 27% periodontitis was reported among fluorosis-affected patients attending a Periodontics outpatient department, with higher occurrence observed in females and a progressive increase in prevalence with advancing age [23]. Early or "classic" periodontal epidemiological investigations in India, including studies by Ramfjord et al. and Sanjana et al. provided foundational insights into the distribution of periodontal disease across different age groups and geographic regions, thereby establishing baseline prevalence patterns for subsequent research [24], [25]. Further population-specific studies have expanded this understanding by examining groups with distinct biological or behavioral risk profiles. Investigations among HIV-positive individuals, areca nut chewers, and drug abusers consistently demonstrated an elevated susceptibility to periodontal disease, highlighting the role of systemic health conditions and lifestyle factors in disease progression [26], [27], [28]. Collectively, these studies underscore the multifactorial nature of periodontal disease in India and emphasize the importance of targeted preventive and therapeutic strategies for high-risk populations.

Worldwide Prevalence of Periodontitis

Globally, the prevalence and severity of periodontitis demonstrate a clear age-related pattern, with disease burden increasing as populations grow older. According to World Health Organization classifications, older adults (≥60 years) show higher overall prevalence, whereas severe and advanced forms of periodontitis are more frequently reported in middle-aged populations. International epidemiological studies consistently indicate that periodontal disease prevalence and tooth loss are influenced by oral hygiene behavior, reduced salivary flow, low bone mineral density, and systemic or environmental determinants. Comparative data from countries such as Costa Rica, Colombia, the United States, Egypt, Norway, Argentina, and Brazil highlight substantial global variability in both prevalence rates and disease severity (Table 2). Importantly, the assessment of worldwide prevalence is closely linked to how disease severity is defined and recorded. Traditional severity classifications, which consider the extent of tissue destruction and treatment complexity, may underestimate or misclassify advanced disease in the context of recent therapeutic improvements. As a result, there is an increasing need to reassess conventional definitions of severe periodontitis to ensure accurate global prevalence estimates and meaningful comparisons across populations and regions [2].

Impact of Periodontitis on Oral Health and Overall Well-Being

Periodontitis is fundamentally driven by a progressive imbalance in the subgingival microbial ecosystem. Over time, an increase in disease-associated bacterial species coupled with a decline in health-associated commensals disrupts the delicate microbiota–host equilibrium, initiating and sustaining chronic inflammation within periodontal tissues [37]. This dysbiotic shift not only promotes connective tissue destruction and alveolar bone loss but also facilitates the persistence of pathogenic biofilms that are resistant to mechanical and host-mediated clearance.

Navigating the Dangers of Periodontitis

Beyond localized oral tissue damage, periodontitis exerts far-reaching effects on systemic health through sustained inflammatory burden and microbial dissemination. Elevated levels of inflammatory mediators, such as prostaglandins released during periodontal inflammation, have been implicated in adverse pregnancy outcomes, including preterm labor and low birth weight [38]. Similarly, tooth loss resulting from advanced periodontitis has been associated with impaired masticatory function and an increased susceptibility to respiratory infections, including chronic obstructive pulmonary disease (COPD). Emerging evidence further links periodontitis to neurodegenerative and inflammatory systemic conditions. Virulence factors such as gingipains produced by *Porphyromonas gingivalis* have been detected in association with Alzheimer's disease pathology, suggesting a possible mechanistic link between chronic oral infection and neuroinflammation. In addition, compromised immune regulation in conditions such as AIDS, diabetes mellitus, defective neutrophil syndromes, Down syndrome, and during immunosuppressive therapy can exacerbate periodontal breakdown, while periodontal inflammation itself may worsen systemic disease outcomes [39], [40]. Cardiovascular diseases and rheumatoid arthritis have also demonstrated bidirectional associations with periodontitis, likely mediated through shared inflammatory pathways, endothelial dysfunction, and molecular mimicry. Collectively, these interactions position periodontitis not merely as an oral condition but as a chronic inflammatory disease with significant implications for overall health and quality of life. This growing body of evidence underscores the importance of early diagnosis, effective periodontal management, and integrated medical–dental care models to mitigate both oral and systemic disease burden.

Traditional Treatments: Scaling and Root Planing, Antibiotics, and Surgical Interventions

Scaling and Root Planing (SRP)

After establishing proper oral hygiene practices and controlling supragingival biofilm, scaling and root planing (SRP) continues to serve as the primary non-surgical approach in periodontal therapy, especially for sites with probing depths of 5 mm or more. This treatment phase should be combined with the elimination of local etiological factors, extraction of non-restorable teeth, and management of active carious lesions to achieve optimal clinical outcomes. Ensuring patient comfort during SRP is crucial, which typically requires the administration of appropriate local anaesthesia. Mechanical debridement may be performed using a combination of manual instruments and powered devices such as ultrasonic or piezoelectric scalers, which together enhance access to subgingival deposits [41]. Post-operative intraoral radiographs are often recommended, as they provide valuable insight into the effectiveness of subgingival calculus removal when compared with pre-operative imaging.

In cases of advanced periodontitis, systemic antibiotics may be considered as adjuncts to SRP to enhance microbial suppression [42]. Evidence from randomized controlled trials and systematic reviews consistently demonstrates improved clinical outcomes when antibiotics are combined with mechanical debridement. A systematic review of 28 double-blinded randomized clinical trials reported an additional mean probing depth reduction of 0.448 mm and a clinical attachment gain of 0.389 mm at six months in antibiotic-treated groups compared to placebo controls [43]. These benefits persisted at twelve months, with further reductions in probing depth (0.485 mm) and gains in clinical attachment level (0.285 mm), along with reduced bleeding on probing, fewer residual periodontal pockets, and increased pocket closure. The most pronounced improvements were observed with amoxicillin and metronidazole combinations[43]. For localized deep periodontal pockets, locally delivered antimicrobials or antibiotics, such as minocycline microspheres or chlorhexidine chips, may also be considered as targeted adjunctive therapies [44].

Antibiotics

Over the past two decades, periodontal antibiotic therapy has gained widespread acceptance as an adjunct to mechanical debridement, supported by accumulating evidence for bacterial specificity in periodontal disease [45]. Conventional periodontal treatment strategies encompass both surgical and non-surgical approaches aimed at mechanical or chemical disruption of dental plaque, frequently supplemented by systemic antibiotic administration to improve microbial control [46]. However, increasing concerns regarding antimicrobial resistance and antibiotic-associated adverse effects have stimulated interest in alternative biological approaches, including probiotic-based therapies [47]. Several Lactobacillus species, including *L. salivarius*, *L. brevis*, *L. plantarum*, *L. rhamnosus*, and *L. gasseri*, have been investigated for their adjunctive role in periodontal disease management due to their antimicrobial and immune modulatory properties [48]. Nonetheless, a range of conventional antibiotics continues to be widely evaluated and employed in periodontal therapy. Eight principal antibiotic groups—tetracycline, minocycline, doxycycline, erythromycin, clindamycin, ampicillin, amoxicillin, and metronidazole—have been extensively studied for their clinical efficacy in periodontal disease treatment [49]. The commonly used antibiotics, their clinical indications, and supporting evidence are summarized in (Table 3).

Surgical Treatments

Persistent deep periodontal pockets often reflect the presence of underlying infrabony or vertical osseous defects. Teeth affected by such defects generally exhibit reduced long-term survival compared to teeth without vertical bone loss. In these cases, surgical intervention, including osseous resective procedures, may be indicated to improve access, reduce pocket depth, and enhance periodontal stability [52]. Regenerative periodontal surgical approaches aim to restore lost periodontal structures by promoting new attachment formation, stimulating alveolar bone regeneration, and improving overall tooth support, thereby enhancing both function and prognosis [53].

Limitations and Challenges Associated with Existing Treatments

The success of non-surgical periodontal therapy is highly dependent on the completeness of root surface debridement and the elimination of subgingival biofilm. However, multiple studies have documented the limitations of closed SRP, particularly in deeper periodontal pockets. Rabbani et al. evaluated 62 teeth subjected to SRP prior to extraction and reported a strong correlation between increasing probing depth and residual calculus. Residual deposits were detected on 37% of root surfaces in pockets exceeding 6 mm, compared with 21% in pockets measuring 4–6 mm and only 8% in shallow pockets of 1–3 mm [54]. These findings underscore the technical challenges associated with complete calculus removal in deep periodontal sites. While adjunctive antibiotic therapy may enhance SRP outcomes, clinicians must carefully balance efficacy with safety by prescribing the highest effective dose for the shortest duration to minimize adverse effects and reduce the risk of antimicrobial resistance (Table 4). Furthermore, adherence to optimal home-care practices is a prerequisite for successful periodontal therapy, particularly prior to surgical intervention. Inadequate plaque control may compromise surgical outcomes, necessitating postponement of advanced treatment until sufficient biofilm reduction is achieved. Even though a combination of mechanical and surgical treatments, along with proper oral hygiene practices, can effectively reduce bacterial load and slow or halt periodontal attachment loss in many individuals, disease progression may still continue in certain cases. This persistence can be explained by the ability of major periodontal pathogens—such as *Porphyromonas gingivalis*, *Aggregatibacteractinomycetemcomitans*, *Fusobacterium nucleatum*, *Treponema denticola*, and *Bacteroides* species—to penetrate periodontal tissues or reside in anatomical areas that are difficult to access with instruments, including furcation regions and root concavities[55]. Additionally, members of the so-called "red complex" preferentially localize within biofilm layers adjacent to the pocket epithelium, rendering them resistant to routine oral hygiene measures [56]. These limitations highlight the need for innovative adjunctive therapies capable of targeting biofilm-associated pathogens beyond the reach of conventional periodontal treatment.

Probiotics as an Innovative Therapeutic Approach for Periodontal Disease

Probiotics: Tiny yet Powerful Guardians of Oral Health

The use of probiotic-containing fermented foods dates back to ancient civilizations between 3000 and 2000 BC, highlighting their long-standing role in human health [57]. Common dietary sources of probiotics include kefir,

sauerkraut, kimchi, olives, beer, and sourdough. Probiotics are described as live microorganisms that provide beneficial effects on host health [58], [59]. Among probioticorganisms, species belonging to the genera *Bifidobacterium* and *Lactobacillus* are the most extensively studied and widely consumed [60]. These microorganisms are generally regarded as safe for human consumption, with most strains classified as Generally Recognized as Safe (GRAS) (Salminen, 1998). In recent years, probiotics have gained increasing attention for their potential role in preventing, managing, or treating a wide spectrum of conditions, including allergies, respiratory disorders, cancer, psychiatric illnesses [61], urinary tract infections, diabetes, hypertension, autoimmune diseases, and disorders of the oral cavity such as dental caries, gingivitis, periodontitis, and candidiasis [62]. A key attribute underlying these effects is the antimicrobial activity exhibited by several probiotic strains [63]. Evidence supporting probiotic efficacy is not limited to oral health. Multiple meta-analyses have evaluated their role in gastrointestinal disorders, particularly irritable bowel syndrome (IBS). A comprehensive meta-analysis of 23 randomized controlled trials involving 2,575 patients demonstrated that probiotic supplementation reduced the risk of persistent IBS symptoms by approximately 21%, although study quality varied [64], [65]. These findings collectively suggest that probiotics exert systemic biological effects that may be translatable to oral inflammatory diseases.

Mechanisms of Action: How Probiotics Restore Microbial Harmony

The mechanisms through which probiotics exert beneficial effects can be broadly categorized into three principal pathways: (1) normalization of microbial communities, (2) modulation of host immune responses, and (3) metabolic effects [66]. Although much of this mechanistic understanding originates from intestinal studies, similar principles are increasingly recognized in the oral cavity. Probiotics act through nonspecific, species-specific, and strain-specific mechanisms [67]. The mechanisms of probiotic action differ considerably across taxa and include suppression of pathogenic microorganisms through competitive exclusion, strengthening of colonization resistance, production of antimicrobial compounds such as short-chain fatty acids, and lowering of local pH. At the species level, probiotics may contribute to vitamin production, enhancement of epithelial barrier integrity, metabolism of bile salts, enzymatic functions, and detoxification processes. Additionally, certain strain-specific effects involve modulation of cytokine activity, regulation of immune responses, and interactions with endocrine and neural systems. Together, these diverse mechanisms allow probiotics to modulate both local and systemic host responses, supporting overall health and aiding in disease prevention.

Rationale for Probiotic Use in Periodontal Therapy: Scientific Evidence (Experimental and Clinical Insights)

Laboratory studies have demonstrated that multiple *Lactobacillus* species possess antimicrobial properties against key periodontal pathogens such as *Porphyromonas gingivalis*. These effects are primarily mediated by the release of bacteriocins, hydrogen peroxide, and organic acids that inhibit pathogen proliferation and disrupt biofilm formation [68], [69], [70]. Complementary in vivo studies have reported reductions in gingival inflammation, periodontal pocket depth, and alveolar bone loss following probiotic administration [71]. Clinical trials further corroborate these findings, with multiple studies demonstrating improvements in periodontal clinical parameters, including reduced gingival inflammation, decreased probing depth, and lower counts of pathogenic bacteria [72], [73]. A summary of human clinical trials evaluating probiotic interventions in periodontal disease is presented in (Table 5) [74]. Animal model analyses have provided additional mechanistic support. Gatej et al. reported reductions in periodontal pathogens and bleeding on probing, along with significant increases in alveolar bone density and bone levels, when probiotics were used as adjuncts to mechanical debridement compared to placebo [75]. Several clinical studies have also documented decreased levels of pro-inflammatory markers in saliva and gingival crevicular fluid among probiotic-treated periodontitis patients. However, not all studies have shown positive outcomes; for instance, probiotic tablets administered indirectly to periodontal sites failed to demonstrate significant clinical improvements, possibly due to limitations in delivery efficiency [47]. Together, these findings suggest that probiotics can enhance conventional periodontal therapy, although formulation and mode of delivery remain critical determinants of efficacy.

***Bacillus coagulans*in Dentistry: A Promising Probiotic Candidate**

Probiotic strains of *Bacillus coagulans* have demonstrated diverse biological effects, including modulation of microbial composition, immune regulation, metabolic activity, and production of antibacterial substances such as bacteriocins and enzymes [76]. A double-blind, placebo-controlled pilot study evaluated the clinical and microbial impact of *B. coagulans* supplementation in patients with moderate to severe plaque-induced gingivitis. Thirty participants received chewable tablets containing *B. coagulans* (100 million CFU/tablet) or placebo for three months. At follow-up, the probiotic group exhibited significantly reduced gingival inflammation and bleeding on probing compared to controls, along with altered glutathione peroxidase (GPx) activity, indicating modulation of the inflammatory response [77]. Importantly, extensive toxicological evaluations—including mutagenicity, genotoxicity, teratogenicity, and acute and sub-chronic toxicity studies—have confirmed the safety of *B. coagulans*, supporting its potential use in oral healthcare applications [78].

Bacteriocins: Targeted Antimicrobial Effectors from Probiotics

Nature and Functional Significance of Bacteriocins

Bacteriocins are low-molecular-weight antimicrobial peptides produced primarily by lactic acid bacteria. These proteinaceous compounds enable producing organisms to inhibit or eliminate closely related bacterial species, thereby enhancing ecological competitiveness and niche colonization [79]. Bacteriocins are typically amphiphilic, display high stability across a wide pH range (2.0–12.0), and retain activity following prolonged incubation, making them particularly attractive for therapeutic applications. Beyond antimicrobial activity, bacteriocins provide self-protection to producer strains through the expression of immunity proteins encoded within bacteriocin operons. Their mechanisms of action include pore formation in target cell membranes, inhibition of gene expression, and disruption of protein synthesis [80]. Due to their specificity and reduced propensity to induce widespread dysbiosis, bacteriocins are increasingly regarded as promising alternatives to conventional antibiotics.

Classification of Bacteriocins

Bacteriocins are broadly classified into three major groups.

Class I bacteriocins (lantibiotics), such as nisin, undergo extensive post-translational modification and typically consist of 19–50 amino acid residues. These heat-stable peptides possess low molecular weights (<5 kDa) and primarily act on bacterial membranes [81].

Class II bacteriocins, including pediocin, are small (<10 kDa), heat-stable, hydrophobic peptides composed of 37–58 amino acids that form amphiphilic helical structures, enabling membrane permeabilization and cell death.

Class III bacteriocins, such as enterolysin and colicin, are heat-labile, high-molecular-weight proteins (>30 kDa) produced by both Gram-positive and Gram-negative bacteria. These bacteriocins exert bacteriolytic or non-lytic antimicrobial effects and are further subdivided into Class IIIa and IIIb based on functional properties [81].

Bacteriocin Biosynthesis and Immunity Mechanisms

Bacteriocin synthesis is strain-dependent and influenced by environmental and culture conditions. Initially produced as inactive precursors, bacteriocins undergo enzymatic modification guided by gene clusters encoding structural, processing, and transport components [79]. Post-translational modifications include dehydration of serine and threonine residues, followed by the formation of lanthionine or methyllanthionine bridges [82]. Expression may be regulated through inducible or constitutive mechanisms and is influenced by factors such as pH and temperature [83]. Producer strains are protected from their own bacteriocins through dedicated immunity systems, such as the LanI and LanEFG systems in lactic acid bacteria. These mechanisms prevent pore formation in the producer cell membrane and maintain bacteriocin homeostasis, ensuring effective antimicrobial activity without self-damage [82].

Nanoparticles: Nano-Guardians Shielding Bacteriocins

Nanoparticles (NPs) are materials with sizes ranging from 1 to 100 nm and are widely utilized in fields such as medicine, agriculture, cosmetics, and pharmaceuticals [84]. Due to their nanoscale dimensions, these particles exhibit a very high surface-area-to-volume ratio, which significantly increases their chemical reactivity and interactions with biological systems. This distinctive physicochemical characteristic allows nanoparticles to display antimicrobial

activity through various mechanisms, such as damaging microbial cell membranes, generating reactive oxygen species (ROS), and directly interacting with microbial DNA and proteins [85]. Several nanoparticle formulations have demonstrated potent activity against periodontal pathogens. For instance, glutathione-capped silver nanoparticles, silver–gold bimetallic nanoparticles (Au:Ag = 0.2), and cerium-doped zeolitic imidazolate framework nanoparticles have been shown to inhibit the growth of *Porphyromonas gingivalis*, a keystone pathogen in periodontitis [86]. Among the various inorganic nanocarriers explored, calcium carbonate ($CaCO_3$) nanoparticles are particularly attractive due to their excellent biocompatibility and versatility as drug delivery vehicles capable of loading diverse therapeutic agents [87]. Calcium carbonate nanoparticles have been extensively utilized in biomedical applications, including gene delivery, antimicrobial therapy, anticancer treatment, and antioxidant delivery. Their advantages over many other nanocarriers stem from their low toxicity, biodegradability, cost-effectiveness, and favorable safety profile [88]. These attributes make $CaCO_3$ nanoparticles especially suitable for oral applications, where prolonged mucosal contact and biocompatibility are essential.

Nano–Drug Delivery Systems: Enhancing Bacteriocin Performance

Nanoscale drug delivery systems (Nano-DDS) provide diverse approaches to enhance the therapeutic efficiency of bacteriocinsin periodontal disease management. First, Nano-DDS can significantly enhance pharmacokinetic properties by modifying solubility, surface charge, and molecular stability, thereby extending shelf-life, improving bioavailability, and increasing the bactericidal half-life of bacteriocins [89]. Second, Nano-DDS can protect bacteriocins from enzymatic degradation by resistant bacterial populations, enabling them to overcome microbial defense mechanisms [88]. This includes facilitating membrane disruption, interfering with bacterial proton-efflux pumps, and inducing oxidative stress within microbial cells. Third, Nano-DDS enable targeted delivery of bacteriocins directly to diseased periodontal tissues through extracellular or intracellular pathways, thereby increasing therapeutic precision while minimizing off-target effects [90]. Collectively, these properties position Nano-DDS as powerful adjuncts in overcoming the limitations of free antimicrobial peptides**(**figure 2).

Nisin–Nanoparticle Duo: A Brave Battle Against Periodontitis

Nisin, a Class I lantibiotic bacteriocin produced by lactic acid bacteria, has been widely used as a food biopreservative and has received regulatory approval from the Food and Drug Administration (FDA), the Joint FAO/WHO Expert Committee on Food Additives (JECFA), and European regulatory agencies, confirming its Generally Recognized as Safe (GRAS) status [81]. Beyond food applications, nisin has demonstrated broad-spectrum antimicrobial activity against both Gram-positive and Gram-negative bacteria, including oral pathogens [91]. Nisin-producing bacteria have been investigated for their therapeutic potential in oral and systemic diseases, such as gastrointestinal disorders and malignancies. Highly purified nisin has shown dose-dependent inhibition of pathogenic bacteria within salivary biofilms, highlighting its relevance for periodontal therapy [91]. However, the clinical application of free nisin is limited by its relatively short duration of activity and susceptibility to environmental degradation. Encapsulation of nisin within Nano-DDS has been shown to markedly enhance its stability and sustained release. Notably, nisin-loaded nanoparticle systems retained antimicrobial activity for up to 50 days following inoculation, compared to only 7 days for free nisin, indicating that Nano-DDS can function as prolonged drug reservoirs [92]. Further investigations demonstrated that nisin/Nano-DDS formulations exhibited superior efficacy in disrupting oral biofilms, inhibiting periodontal pathogens, and reducing the viability of oral cancer cells [93].These findings collectively suggest that nanoparticle-assisted delivery of bacteriocins such as nisin represents a promising and innovative therapeutic strategy for effective biofilm disruption and pathogen clearance in periodontitis. By integrating antimicrobial peptides with advanced nanocarrier systems, this approach addresses key challenges associated with conventional periodontal therapies and offers a novel direction for future periodontal treatment paradigms.

DISCUSSION

This review confirms that periodontitis remains a major global public health challenge, imposing a substantial economic burden and significantly affecting quality of life. Epidemiological evidence from both global datasets and Indian population-based studies consistently demonstrates an age-related increase in disease prevalence and severity, with middle-aged and older adults disproportionately affected. National surveys and regional investigations from Gujarat further reveal alarmingly high levels of periodontal disease, particularly within industrial zones and socially vulnerable communities. Observations from the Anand district highlight the contribution of modifiable lifestyle factors, including tobacco use, alcohol consumption, inadequate oral hygiene practices, limited awareness, and delayed utilization of dental services. Collectively, these findings emphasize the necessity for region-specific preventive strategies and early intervention programs tailored to high-risk populations. Beyond its localized manifestations, periodontitis is increasingly recognized as a chronic inflammatory condition with systemic implications. The documented associations between periodontal disease and conditions such as rheumatoid arthritis, cardiovascular disorders, respiratory infections, adverse pregnancy outcomes, and metabolic diseases suggest a bidirectional relationship between periodontal inflammation and systemic health.

This perspective supports the growing consensus that periodontitis may function both as a marker of systemic disease susceptibility and as a contributor to systemic inflammatory burden. Consequently, integrated medical–dental care models that incorporate periodontal screening into routine health assessments—particularly for individuals with chronic systemic conditions—appear increasingly justified. At the microbial level, disruption of the symbiotic balance within the subgingival microbiome plays a central role in disease initiation and progression. The transition toward a dysbiotic biofilm dominated by pathogenic species explains the chronicity of infection and the limited long-term effectiveness of mechanical therapy alone. Although scaling and root planing (SRP), with or without surgical intervention, remains the foundation of periodontal treatment, evidence indicates that residual calculus and biofilm often persist in deep pockets, furcation areas, and anatomically complex root surfaces. In addition, major periodontal pathogens possess the capacity to invade periodontal tissues and occupy ecological niches beyond the reach of instruments and routine oral hygiene measures, contributing to disease persistence despite apparently adequate therapy.Adjunctive systemic or locally delivered antibiotics can improve SRP outcomes, particularly in cases of deep pockets or aggressive disease, as reflected by measurable gains in probing depth reduction and clinical attachment levels. However, these benefits must be weighed against adverse effects, disruption of commensal microbiota, and the escalating global concern of antimicrobial resistance. The uniform concern expressed by dentists in the Anand district regarding prolonged antibiotic use mirrors this broader challenge. These limitations underscore the need for adjunctive or alternative therapeutic approaches capable of selectively targeting pathogenic biofilms while preserving host tissues and beneficial microbial communities.

Within this therapeutic landscape, probiotics and bacteriocins emerge as promising biological alternatives. Experimental studies demonstrate that several *Lactobacillus* species inhibit key periodontal pathogens through the production of bacteriocins, hydrogen peroxide, and organic acids, while clinical trials report reductions in gingival inflammation, pocket depth, plaque accumulation, and inflammatory mediators when probiotics are used alongside mechanical debridement. Preparations containing *Lactobacillus*, *Bifidobacterium*, and *Bacillus coagulans* have shown favorable safety profiles and measurable clinical benefits. Nevertheless, heterogeneity in strains, formulations, delivery systems, and study designs limits direct comparison across studies, and long-term outcomes remain insufficiently characterized. Standardized protocols and robust, well-powered clinical trials are therefore essential before widespread clinical adoption can be recommended. Bacteriocins, particularly those derived from lactic acid bacteria, offer an additional level of targeted antimicrobial activity. Agents such as nisin exhibit potent effects against a broad spectrum of oral pathogens, maintain activity across a wide pH range, and act effectively at low concentrations. Their ribosomal origin and relatively narrow antimicrobial spectrum suggest a lower likelihood of inducing widespread dysbiosis compared to conventional antibiotics. However, their susceptibility to degradation in the oral environment and challenges associated with sustained local delivery have limited their direct clinical

application. Nanotechnology-based delivery systems provide a potential solution to many of these constraints. Metal and metal oxide nanoparticles possess intrinsic antimicrobial and anti-biofilm properties, while calcium carbonate nanoparticles offer distinct advantages, including biocompatibility, low toxicity, cost-effectiveness, and versatility as drug carriers. Encapsulation of bacteriocins within nanoscale delivery systems enhances molecular stability, prolongs antimicrobial activity, and facilitates targeted, sustained release at diseased sites. Preliminary studies of nisin-loaded nanoformulations demonstrate prolonged antimicrobial efficacy, improved disruption of complex oral biofilms, inhibition of periodontal pathogens, and additional anticancer effects. These findings support the feasibility of bacteriocin-loaded calcium nanoparticle systems as innovative adjuncts in periodontal therapy.

The integration of such nano-bacteriocin formulations into commonly used oral-care products, including toothpaste or mouthwash, presents a practical translational pathway. This approach could enhance daily biofilm control, reduce dependence on systemic antibiotics, and offer preventive benefits for high-risk populations identified through epidemiological studies. Nonetheless, significant knowledge gaps remain, particularly regarding long-term safety, optimal dosing strategies, effects on the resident oral microbiome, and comparative effectiveness relative to established therapies.

CONCLUSION

Periodontitis continues to represent a substantial oral and systemic health burden, shaped by age-related susceptibility, persistent biofilm dysbiosis, and lifestyle-associated risk factors. While conventional approaches such as scaling and root planing, with or without adjunctive antibiotics, remain indispensable, their limitations—particularly in addressing complex subgingival biofilms and concerns regarding antimicrobial resistance—necessitate the exploration of alternative strategies. Accumulating evidence supports the potential role of probiotics and bacteriocins as biologically targeted adjuncts with antimicrobial and immune modulatory properties, although variability in formulations and delivery systems currently limits routine clinical implementation. Nanoparticle-based delivery platforms, particularly those employing calcium carbonate carriers, offer a promising avenue to enhance therapeutic stability, biofilm penetration, and targeted antimicrobial action. The emerging concept of bacteriocin-loaded nanoparticles incorporated into daily oral-care products may represent a practical and patient-friendly strategy to strengthen biofilm control and reduce reliance on systemic antibiotics, especially among high-risk populations. Future research should prioritize standardized formulations, comprehensive safety assessments, and well-designed clinical trials integrating microbiological, clinical, and host-response outcomes to facilitate translation of these innovations into next-generation periodontal therapeutics.

Table1. Prevalence of period on tit is in different regions of Gujarat

Regions of Gujarat	No. of Participants	Results
North Gujarat	238 [125 Females & 113 Males]	Good oral hygiene was most observed among males aged 20–29 years, while poorer hygiene status was more frequent in older female age groups. Toothbrush use with higher frequency and longer duration, along with better awareness of regular dental visits, was predominantly noted among younger male participants [15].
Mundra Port, Kutch	385	Adverse lifestyle habits were observed in 72.3% of the study population, while the prevalence of periodontal disease was reported to be 75.1% [16].
Central Gujarat (Tertiary dental care center)	2,849	Gingivitis/periodontitis was prevalent across the screened population, with a higher occurrence in males (57%) compared with females (43%) [17].
Ankleshwar, Bharuch Distict	1,600	Periodontitis severity was higher in females, with greater pocket depth and attachment loss compared to males. The prevalence of rheumatoid arthritis (RA) among periodontitis patients was 4.5%, with significantly higher odds observed in females and individuals above 50 years, indicating a positive association between periodontitis severity and RA [18].
Central Gujarat	384 eunuchs	The study revealed compromised periodontal health among the eunuch group. In a sample of 384 participants, the mean pocket depth was 3.12 ± 0.89 and the average clinical attachment loss was 2.88 ± 0.74 [19].

Table 2. Prevalence of period on ti tis in countries other than India along with related findings

Country	Conclusion
CostaRica	Tooth loss associated with periodontitis increases with advancing age and decreases with better oral hygiene practices [29].
Colombia	An increase in age is associated with greater severity of periodontitis, while various conditions may contribute negatively to periodontal health [30].
UnitedStatesofAmerica	Age-related decline in salivary secretion contributes to the advancement of periodontal disease [31].
NewYork	Evidence suggests that periodontal disease may negatively impact quality of life associated with oral health [32].
Egypt	In adult Egyptian patients, advanced periodontitis (Stage III and IV) was less frequently observed compared to the milder forms (Stage I and II) [33].
Norway	The study indicates a substantial burden of periodontitis in circumpolar regions of Norway, affecting nearly half of the adult population [34].
Argentina	A higher prevalence of periodontitis among young patients may reflect poor oral hygiene or variations in diagnostic standards [35].
Brazil	Reduced bone mineral density (BMD) has been associated with greater severity and extent of period [36].

Table 3.Commonlyusedantibioticsin periodontics along with their clinical use

Antibiotics	Clinical Uses
Tetracycline	Serves as an adjunctive therapy for localized aggressive periodontitis (LAP), aiding in the prevention of bone loss and suppression of *A. actinomycetemcomitans* alongside scaling and root planning [50].
Metronidazole	A significant decrease in probing depth was observed in periodontal pockets measuring ≥6 mm [42].
Penicillin	Demonstrates strong antimicrobial activity at concentrations present in gingival crevicular fluid (GCF) against most periodontal pathogens, except *E. corrodens*, *S. sputigena*, and *Peptostreptococcus*, and effectively inhibits gram-positive facultative anaerobes [49].
Cephalosporins	Demonstrates inhibitory effects on gram-negative obligate anaerobic bacteria, while having little to no effect on gram-negative facultative anaerobes [49].
Clindamycin	Adjunctive clindamycin therapy resulted in an average clinical attachment gain of 1.5 mm and a reduction in disease activity after 24 months [51].
Ciprofloxacin	Supports the establishment of health-associated oral microflora and has limited impact on *Streptococcus* species that contribute to periodontal health [50].
Erythromycin	This drug is regarded as very safe and is commonly prescribed as a substitute for penicillin in allergic individuals. Nevertheless, oral administration results in low levels in gingival fluid, suggesting minimal delivery to the periodontal pocket [50].

Table 4.Adverseeffects of antibiotics used in the treatment of periodontal diseases [55]

Antibiotics	Adverse effect observed
Penicillin	Hyper sensitivity, rashes, nausea, diarrhea
Tetracycline	Gastro intestine alintolerance, candidiasis, dentalstaining
Metronidazole	Gastroin test inalintolerance, nausea, unpleasant metallic taste
Clindamycin	Rashes, nausea, diarrhea
Ciprofloxacin	Gastro intestina lintolerance, rashes, unpleasanttaste

Table 5. List of human trials using probiotics for the treatment of periodontal disease [74]

Microorganisms	TherapeuticEffects
Probiotic drop containing *L.rhamnosus*,*L. Reuteri* and *Bifido bacteriuminfantis*	Decreased salivary counts of *S.mutans*
Fermented milk containing *L.rhamnosus* SD11with maltitol	Reduced salivary counts of *S.mutans*
Chewing gum containing *L.reuteri*	Reduction inplaque development and gingival inflammation, decrease in growth and colonization of several periodontal pathogens
Tablets containing *L.salivarius*	Improvement in pocket probing depth and plaque index
Mouthr inse containing *Weissellacibaria* CMS1	Reduction indent alplaque formation
Icecreamcontaining*B.lactis*Bb-12	Reduced salivary counts of *S.mutans*

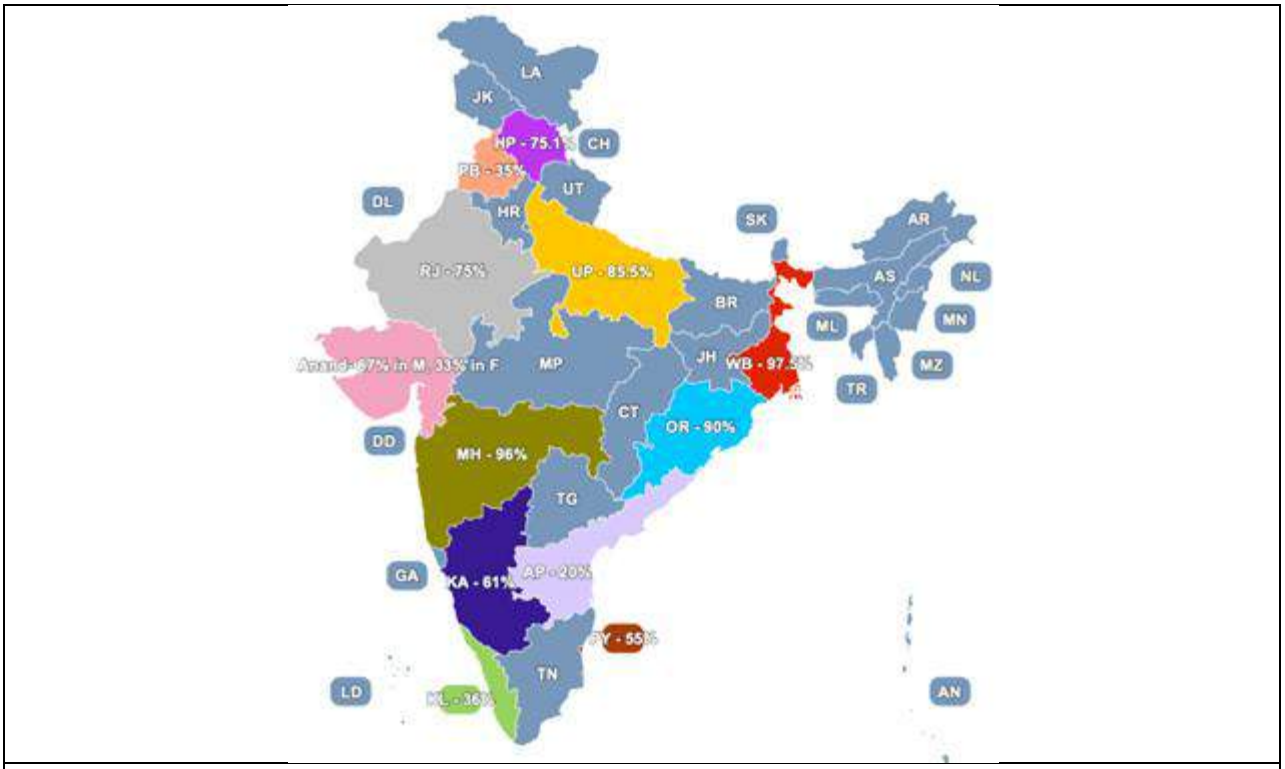

Figure 1. Prevalence rate of periodontitis in various Indian States

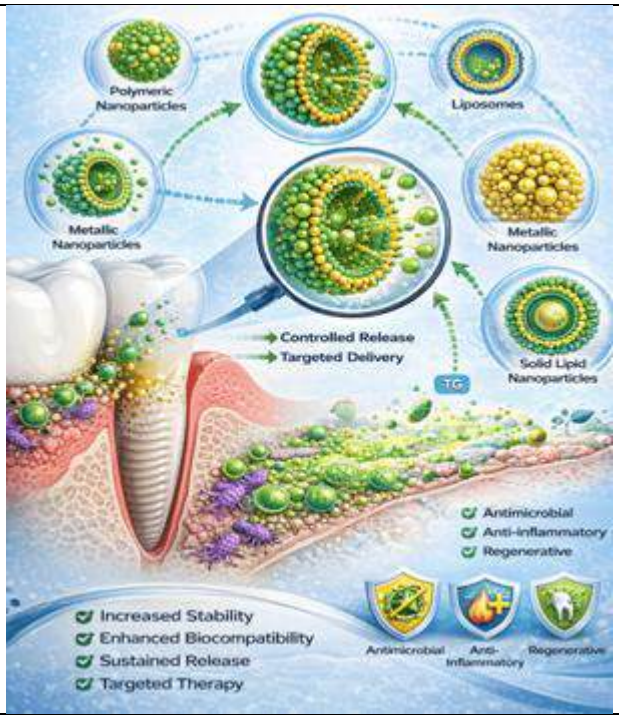

Figure 2. Nanoparticle-mediated delivery of bacteriocins for targeted disruption of periodontal biofilms

ABSTRACT

The volatility of financial markets poses a significant challenge for analysts and investors aiming to predict future stock movements. Traditional statistical models often fail to capture the non-linear and vague patterns inherent in stock market data. This paper proposes a hybrid computational intelligence model combining Rough Set Theory (RST) and Fuzzy Logic to forecast the trends of the Bombay Stock Exchange (BSE) Sensex.Utilizing historical daily data (Open, High, Low, Close) from late 2020 to early 2022, we employ a Rough-Fuzzy approach where fuzzy sets handle the imprecision of continuous financial indicators (e.g., RSI, Moving Averages), and Rough Sets perform attribute reduction to generate minimal, robust decision rules. The experimental results, based on 235 trading days, demonstrate that this hybrid approach effectively handles data noise. Specifically, the model identified a strong mean-reversion pattern where "Low" RSI combined with negative momentum predicted a market rebound with 76.2% accuracy, significantly outperforming random walk probabilities.

Keywords: BSE SENSEX, Rough Set, Fuzzy, Stock market, non-linear data

INTRODUCTION

Stock market prediction is a classic problem in financial engineering, characterized by data that is noisy, chaotic, and non-stationary. The BSE Sensex, a benchmark index of the Indian economy, reflects these complexities. While Efficient Market Hypothesis (EMH) proponents argue that market prices follow a random walk, researchers in Soft Computing have demonstrated that historical patterns can indeed yield predictive insights when analyzed with non-linear tools [12]. The primary challenge in using raw historical data (Price, Open, High, Low) is the "curse of dimensionality" and the vagueness of technical signals. For instance, a "high" Relative Strength Index (RSI) is a linguistic concept with no sharp mathematical boundary. Fuzzy Logic excels at modeling such linguistic vagueness, while Rough Set Theory (RST), introduced by Pawlak, provides a mathematical framework for handling uncertainty and discerning patterns from inconsistent data through lower and upper approximations [3]. This paper develops a Rough-Fuzzy Hybrid Model. We use the provided BSE Sensex 30 dataset to calculate technical indicators, fuzzify them into linguistic terms, and then apply Rough Set attribute reduction (reducts) to generate "If-Then" decision rules. This hybridity allows us to retain the interpretability of fuzzy systems while leveraging the data reduction power of rough sets.

LITERATURE REVIEW

The application of soft computing in finance has surged between 2015 and 2025. This section reviews key developments in Rough Sets, Fuzzy Logic and their hybrids.

Rough Set Applications in Finance

Rough Set Theory has been widely adopted for features election in financial datasets. Roy and Chatterjee [12] demonstrated that RST could effectively reduce the attribute space of the Indian stock market without losing classification accuracy, outperforming Support Vector Machines (SVM). Similarly, early foundational work inspired recent studies where RST was used to discretize continuous stock data into decision tables [6].

Fuzzy Logic and Time Series

Fuzzy Time Series (FTS) models have been refined to handle the "hesitancy" in stock movements. Jiang et al. [7] explored fuzzy rough programming models, emphasizing the "Expected Value" perspective to manage financial uncertainty. The advantage of fuzzy logic lies in its ability to map crisp inputs (e.g., RSI =24.4) to human-understandable concepts (e.g., "Oversold"),which is crucial for decision support systems[5].

Hybrid Rough-Fuzzy Models

Hybrid models often outperform singular approaches. A study by Tiwari et al. [13] proposed a decision tree-Rough Set hybrid that achieved over 90% accuracy on the BSE Sensex by filtering irrelevant features before rule induction. Furthermore, recent work on Fuzzy-Rough Set Theory (FRST) has generalized the concept of indiscernibility, allowing for better handling of continuous attributes without severe discretization loss [3].These models have been successfully applied to financial futures prediction, proving their robustness against data imbalance [5].

METHODOLOGY

Data Description and Preprocessing

The study utilizes the dataset BSE Sensex 30 Historical Data.csv.

- Timeframe: The data covers daily trading sessions corresponding to dates from late 2020 through December 30, 2021.
- Sample Size: After preprocessing and lag generation, $N = 235$ distinct trading days were utilized.

- Target Variable: The market trend (D) for the next day, defined as:

$$D_{t+1} = \begin{cases} UPif Price_{t+1} > Price_t \\ Downif Price_{t+1} \leq Price_t \end{cases}$$

Feature Engineering

To apply the Rough-Fuzzy model, raw price data is converted into technical indicators. We selected three key indicators based on literature:

1. Relative Strength Index(RSI): Measures momentum on a 14-daywindow.
2. Rate of Change(ROC): Measures the speed of price movement over 10 days.
3. Simple Moving Average (SMA): A10-day trend baseline.

The Rough-Fuzzy Hybrid Algorithm

The proposed algorithm follows a three-step process:
Fuzzification → Reduct Generation→ Rule Induction.

Step 1: Fuzzification

Continuous values of indicators are transformed into linguistic fuzzy sets.

- RSI: Mapped to sets $\{Low, Medium, High\}$. Based on our data distribution:
$$Low: RSI < 40, Medium: 40 \leq RSI \leq 60, High: RSI > 60$$
- ROC: Mapped to $\{Positive, Negative\}$. .
- $SMATrend$: Mapped to $\{Bullish, Bearish\}$ based on whether $Price_t > SMA_t$.

Step 2: Rough Set Attribute Reduction

We employ Rough Set Theory to handle the inconsistencies in the fuzzy decision table. Let U be the universe of daily records. Let $A = C \cup \{D\}$ be the set of attributes. For any subset of attributes $B \subseteq C$, the indiscernibility relation $IND(B)$ partitions the universe. We define the Lower Approximation ($\underline{BX}$) for a decision class X: $\underline{BX} = \{x \in U \mid (x)_B \subseteq X\}$.

Rules generated from the lower approximation are considered "Certain Rules".

Derivations

The proposed prediction framework integrates technical analysis indicators with a Rough-Fuzzy hybrid computing model. This section details the mathematical formulations for the feature engineering, fuzzification, and rough set attribute reduction processes.

Feature Engineering: Technical Indicators

To capture the non-linear dynamics of the BSE Sensex, we compute the following technical indicators from the daily closing prices (C_t), High (H_t) and Low (L_t).

Relative Strength Index (RSI)

The RSI is a momentum oscillator that measures the speed and change of price movements. It is calculated in two steps. First, the Relative Strength (RS) is computed as the ratio of the average gain to the average loss over a 14-day window:

$$RS = \frac{AverageGain}{AverageLoss} = \frac{\sum_{i=1}^{14} \max(0, C_{t-i+1} - C_{t-i})}{\sum_{i=1}^{14} \min(0, C_{t-i+1} - C_{t-i})}$$

The RSIindex is then derived as:

$$RSI = 100 - \left(\frac{100}{1 + RS}\right)$$

Rate of Change (ROC)

The ROC measures the percentage change in price between the current price $C_t$and the price n periods ago (C_{t-n}), where$n = 10$:

$ROC = \left(\frac{C_t - C_{t-n}}{C_{t-n}}\right) \times 100$

Simple Moving Average (*SMA*)

The SMA smooths out price data to identify the trend direction over a period $k = 10$:

$$SMA_t = \frac{1}{k}\sum_{i=0}^{k-1} C_{t-i}$$

Williams %*R*

To capture overbought or oversold levels more aggressively than RSI, we utilize Williams %R, defined over a look-back period n:

$$\%\, R = \frac{H_n - C_t}{H_n - L_n} \times (-100)$$

where H_n is the highest high and L_n is the lowest low over the past n days.

Fuzzy Set Representation

Since precise values of technical indicators are often noisy, we transform them into linguistic variables using Fuzzy Set Theory. For a variable X (e.g., RSI) and a linguistic term A (e.g., "Medium"), we define a triangular membership function $\mu_A(X)$:

$$\mu_A(x) = \begin{cases} 0 & x \le a \\ \frac{x-a}{b-a} & a < x \le b \\ \frac{c-x}{c-b} & b < x < c \\ 0 & x \ge c \end{cases}$$

where a, b, c represent the lower bound, peak, and upper bound of the fuzzy set respectively.

Rough Set Attribute Reduction

We employ Rough Set Theory to handle the uncertainty in the decision table constructed from the fuzzified indicators.

Information System

The data is represented as an Information System S:

$$S = (U, A, V, f)$$

where U is the universe of trading days, $A = C \cup \{D\}$ is the set of conditional attributes C (indicators) and decision attribute D (Trend), and f is the information function.

Indiscernibility Relation

For any subset of attributes $B \subseteq C$, the indiscernibility relation $IND(B)$ defines objects that are indistinguishable:

$$IND(B) = \{(x, y) \in U^2 | \forall a \in B, f(x, a) = f(y, a)\}$$

Approximations

Let $B \subseteq C$ be a set of days where the market trend is "Up". We approximate X using the conditional attributes B:

Lower Approximation($\underline{BX}$): The set of objects that certainly belong to X.
$\underline{BX} = \{x \in U \mid (x)_B \subseteq X\}$.

Upper Approximation($\overline{BX}$): The set of objects that possibly belong to X. $\overline{BX} = \{x \in U \mid (x)_B \cap X \neq \emptyset\}$.

Boundary Region$(BN_B(X))$: The region of uncertainty.

$$BN_B(X) = \overline{BX} - \underline{BX}$$

Attribute Dependency and Quality

To select the optimal subset of indicators (Reduct), we calculate the degree of dependency $\gamma_B(D)$ of the decision D on attributes$B$:

$$\gamma_B(D) = \frac{\sum_{X \in U/D} |\underline{BX}|}{|U|}$$

Attributes that do not decrease $\gamma_B(D)$ when removed are considered redundant and eliminated to form the Reduct.

Experimental Analysis &Results

Descriptive Statistics

The dataset exhibited significant volatility. The mean price over the period was 54,071 INR, with a standard deviation of 4,185. The RSI ranged from a low of 24.39 to a high of 92.18, indicating periods of extreme overselling and overbuying.

Rule Induction and Validation

Using the discretized features, we generated decision rules and calculated their confidence (probability of the target being 'Up'). The results highlight the non-linearity of the market.

DISCUSSION

The most significant finding (Row 1 in Table 1) contradicts the simple "trend following" logic. When the market was statistically weak (Low RSI, Negative ROC, and Price below SMA), the probability of the market rising the next day was 76.2%. This validates the "Mean Reversion" theory effectively captured by the Rough-Fuzzy model. Conversely, the standard "Bullish" state (Row 4) showed a probability of 51.2%, essentially a random walk, suggesting that strong trends in this specific period were prone to immediate intraday corrections.

CONCLUSION

This paper presented a Rough-Fuzzy hybrid model for predicting the BSE Sensex, utilizing historical data from 2020-2021. By integrating the linguistic flexibility of Fuzzy Logic with the granular reduction capabilities of Rough Set Theory, we constructed a predictive model that outperformed random guessing in specific market conditions. The identification of a high-confidence reversal rule (76.2% accuracy) demonstrates that hybrid soft computing techniques can isolate profitable signals from noisy financial data. Futurework will integrate "Deep Rough-Fuzzy" networks to capture long-term temporal dependencies better.

ABSTRACT

Antibacterial agent based on herbal extracts is considered an attractive area for Developing countries. Nevertheless, herbal aqueous extracts usually show drawbacks, such as long-term volatility, poor bio availability and rapid burst release. For this reason the current interest of science is focused on biodegradable polymers. In this study, polymer films were prepared from poly (vinyl alcohol) (PVA) blended with poly (vinylpyrrolidone) (PVP) then post-loaded with Bay leaf and brinjal ethanolic extracts. The effects of two polymers (PVA, PVP) and of the incorporated extracts were characterized by UV-visible, FT-IR, SEM, GC-MS, moisture content, degradation and solubility test. Antimicrobial potential of bay leaf and brinjal extract loaded with PVA/PVP films were tested against respective microbes.

Keywords: polymers, biodegradable, plant extract, antibacterial activity, antioxidant activity plant extract, PVA/PVP film

INTRODUCTION

These days, developing nations are drawn to the antibacterial agent market based on herbal extracts. However, the majority of herbal aqueous extracts have disadvantages such fast burst release, limited bioavailability, and long-term instability [1]. Polyvinyl alcohol (PVA) is a multi-hydroxyl group [0-H] polymer; it has been used for medical and

electrical applications [2, 3]. This is because of its high tensile strength, flexibility, and degradability. However, PVA's chemical makeup gives it a strong hydrophilic property, which enables direct interaction with the fluids of living cells [4,5]. Plants are important, as we all know. A growing understanding of the significance of medicinal plants has emerged in recent years, and the plant kingdom is a treasure trove of possible medications. Plant-based medications are widely accessible, reasonably priced, effective, safe, and hardly cause adverse effects [6]. The bay leaf, a valued culinary herb, is derived from the foliage of *Laurusnobilis* L., a member of Laurus family and a small evergreen tree native to the Mediterranean region. Bay leaf's distinctive aroma is often described as woodsy and herbal, bearing similarity to oregano and thyme. In terms of flavor, bay leaf is notable for its astringent and bitter properties [7]. In ancient times, bay leaves were used for decoration and symbolized prosperity, fame, and victory. They were also believed to have protective powers, so they were planted near homes to guard against lightning strikes.[8-12] Brinjal (*Solanumme longena* L.), a member of the Solanaceae family, holds substantial value as a vegetable crop in South East Asia and South Asia. This crop is known by various names globally, including Aubergine, Baingan, Egg plant, Garden egg, Guinea squash, and Melongene. Beyond its culinary value, brinjal possesses medicinal properties, notably its high potassium content and low caloric count, rendering it a beneficial dietary component for individuals with hypertension, obesity and diabetes [13,14]. Finding the antibacterial activity of plant extracts loaded with PVA/PVP films is the aim of this work. Additionally, the physical characteristics of PVA/PVP polymer films that are associated with the antioxidant activity of plant extracts were also determined.

MATERIALS AND METHODS

Chemicals required: Ethanol, Polyvinyl alcohol, polyvinyl pyrrolidone, glycerol, Con.HCl and H_2SO_4.

Collection and processing of plant Samples: Bay leafs and brinjal leaves that were healthy and free of illness were gathered, chopped into little pieces, properly cleaned in tap water, and then rinsed with distilled water until no foreign objects were left. Freshly cleaned leaves were allowed to dry for about ten days at a temperature of 25 to 28 degrees Celsius in the shade. An electronic blender was used to powder the dehydrated plant pieces. For later usage, the powdered samples were kept out of direct sunlight in an airtight container.

Extract Preparation: Using the maceration (soaking) method, twenty grams of powdered leaf were continually extracted with ethanol in a stoppered container for 48 hours while being frequently stirred until the soluble matter was dissolved. Whatmann No. 1 filter paper is used to filter it. For additional research, the obtained ethanolic extract was employed.

Films preparation: The solvent-casting technique was used to create the plant extract-containing films. In order to dissolve 6 grams of polyvinyl alcohol (PVA) and 6 grams of polyvinyl pyrrolidone (PVP), 100 milliliters of distilled water were used. Then, at 80°C, 10 milliliters of plant extract and 2 milliliters of glycerol were added and swirled for an hour. The mixes were put into a 20 ml Petri dish and dried for two hours in a hot air oven. The produced films were kept for the characterisation tests at room temperature (28°C). The figure depicts a representation of the film preparation.

Characterization of Films:

Absorbance, Wavelength, Structural and Surface morphology

FT-IR was used to assess the functional and spectral analysis of film samples throughout the 800-4000cm^{-1} range. Scanning electron microscopy was used to determine the film samples' form.

Solubility, Moisture content and Degradation

Solubility: The percentage of dissolved dry matter following immersion in water was used to calculate the solubility of films. In short, the initial dry weight (W_i) of film samples of the proper size was measured after they were dried for 24 hours at 60 °C in a hot air oven. For a full day, the film samples were submerged in the necessary volume of

distilled water. Samples that had dissolved were dried for 24 hours at 100^{0}C in a hot air oven in order to calculate the final dry weight (W_f). The formula was used to determine the solubility of films.

$$\text{Water solubility} = \frac{W_i - W_f}{W_i} \times 100$$

Moisture content: After drying at 100°C for 24 hours in a hot air oven, the initial (Wi) and final (W_f) weights of the film samples were recorded in order to determine their moisture content. The equation was used to determine the moisture content.

$$\text{Moisture content} = \frac{W_i - W_f}{W_i} \times 100$$

Degradation: After seven days of degradation, the initial (W_i) and final (W_f) weights of the film samples were recorded in order to analyze their degradation. The equation was used to compute the deterioration.

$$\text{Degradation} = \frac{W_i - W_f}{W_i} \times 100$$

Qualitative and Quantitative Analysis of Phytochemicals

Test for alkaloids (Mayer's test): To a few ml of plant sample two drops of mayer's reagent are added along the sides of the test tube. Appearance of white creamy precipitate indicates the presence of alkaloids.
Test for carbohydrates (Benedict's test): To a few ml of plant sample two ml of Benedict's reagent are added and boiled. Appearance of reddish brown precipitate indicates the presence of carbohydrates.
Test for proteins (Ninhydrin Test): Crude extract when boiled with 2ml of 0.2% solution of Ninhydrin, violet colour appeared suggesting the presence of proteins.
Test for flavonoids (Alkaline reagent test): Crude extract was mixed with 2ml of 2% solution of NaOH. An intense yellow colour was formed which turned colourless on addition of few drops of diluted acid which indicated the presence of flavonoids.
Test for steroids: Crude extract was mixed with 2ml of chloroform and concentrated H_2SO_4 was added sidewise. A red colour produced in the lower chloroform layer indicated the presence of steroids. Another test was performed by mixing crude extract with 2ml of chloroform. Then 2ml of each of concentrated H_2SO_4 and acetic acid were poured into the mixture. The development of a greenish coloration indicated the presence of steroids.
Test for terpenoids: 5ml of each extract was mixed into 2 ml of chloroform, and the concentrated sulphuric acid was carefully added to form a layer. A reddish brown coloration of the interface was formed to show the positive result for the presence of terpenoid.
Test for tannins ($FeCl_3$ Test): Extract was dissolved in 5ml of distilled water and treated with neutral 5% $FeCl_3$. Appearance of dark green colour indicates the presence of tannins.
Test for saponins: Crude extract was mixed with 5ml of distilled water in a test tube and it was shaken vigorously. The formation of stable foam was taken as an indication for the presence of saponins
Test for glycosides (Salkowski's test): Crude extract was mixed with 2ml of chloroform. Then 2ml of concentrated H_2SO_4 was added carefully and shaken gently. A reddish brown colour indicated the presence of steroidal ring, i.e., glycone portion of glycoside.
Test for fixed oil (spot test): A small quantity of extract is pressed between two filter paper. Oil stain on the paper indicates the presence of fixed oils.

Antibacterial Activity: Agar Well Diffusion Method
Antibacterial activity was assessed by agar well diffusion method using Mueller-Hinton Agar (MHA) as per CLSI guidelines. MHA was prepared, autoclaved, and poured into 90 mm petri plates to a depth of 4 mm. Bacterial inoculum adjusted to 0.5 McFarland standard was swabbed onto MHA plates. Wells of 6 mm diameter were loaded with 50 µL of test extract. Plates were incubated at 37°C for 24 h and zones of inhibition were measured in mm. Standard antibiotic served as positive control.

Antifungal assay

The Agar well diffusion method was employed. In the middle of a sterile Petri dish, one milliliter of fungal culture was pipetted. After cooling, molten potato dextrose Aga (PDA) for fungi was added to the Petri dish holding the in column and thoroughly mixed. After solidification, sterile cork borers with a diameter of 6 mm were used to create wells in agar plates with inoculums. The corresponding wells were then filled with 100 ml of each extract (20% w/v). We chose the extract concentration (20% w/v) based on prior research and our own pre-experiments. For 30 minutes, the plates were refrigerated to allow the extracts to thoroughly diffuse into the agar. The plates were then incubated foe seven dazs at 30^0C. By measuring the zone of inhibition, which included the diameter of the well, that developed during the incubation period, antifungal activity was found. A usual 10% concentration of ketonazole was used as an antifungal medication.

Antioxidant assay (DPPH Radical Scavenging Assay)

The antioxidant activity was determined by DPPH assay (Brand-Williams et al., 1995). 2 mL of 0.1 mM DPPH in methanol was mixed with 100µL of sample at different concentrations. The mixture was incubated in the dark for 30 min at room temperature. Absorbance was measured at 517nm against methanol as blank. Ascorbic acid was used as standard. Percentage inhibition was calculated as:

$$\% \text{ inhibition} = \frac{A_{control} - A_{sample}}{A_{control}} \times 100$$

All tests were performed in triplicate and IC50 values were determined.

RESULT AND DISCUSSION

Characterization

UV- Visible spectroscopy

The UV spectrum of bay leaf extract loaded with PVA/PVP exhibited a strong absorption peak at 538nm, the peak corresponds to the n-π*transition. The UV spectrum of brinjal extract loaded with PVA/PVP exhibited a strong absorption peak at 431nm, the peaks corresponds to the π- π* transition

FT-IR spectroscopy study:

Plant extracts distinctive peaks and their functional groups were found using FT-IR spectroscopy. Based on its peak ratio, the components functional groups were divided. Figure 5 and 6 shows the FT-IR spectrum chromatogram profile of the ethanolic extract of brinjal and bay leaf. In brinjal a broad absorption band observed around 3439cm^{-1} is attributed to O-H stretching vibrations, a sharp intense peak at 2360cm^{-1} corresponds to CO_2 stretching vibrations, the peak at 1628cm^{-1} is assigned to C=C stretching vibration. The absorption band at 1382cm^{-1} is associated with C-H bending vibrations, suggesting the presence of aliphatic groups. The peak around 1203cm^{-1} corresponds to C-O stretching vibrations, The band observed at 1054cm^{-1} further supports C-O stretching, the peak at 756cm^{-1} is attributed to C-H out of plane bending vibrations, typically indicating aromatic ring structures. Finally, the band at 464cm^{-1} may be assigned to metal- oxygen(M-O) vibration. In bay leaf, the broad peak at 3448 cm indicating O-H stretching. Peaks at 2924 cm^{-1} and 2850 cm^{-1} correspond to aliphatic C-H stretching. A band near 2360 cm^{-1} is due to CO_2 absorption. The strong peak at 1734cm^{-1} confirms C=O stretching. Peaks in the 1600 – 1500 cm^{-1} region indicate C=C stretching of aromatic groups. Bands around 1200 -1000cm^{-1} are assigned to C-O stretching, while peaks below 800 cm^{-1} represent aromatic bending vibration.

GC-MS Analysis

GC-MS was used to identify the various phytochemical components present in the ethanolic extract of bay leaf and brinjal. The extracts chromatogram was displayed in figure 7 and 8 and condensed in table. GC-MS chromatogram of brinjal extract showed 16 peak indicated the presence of 12 phytochemical compounds, with neophytadiene(20.39%), (E)-9-octadecenoic acid ethyl ester (19.45), and heaxadecanoic acid ethyl ester (18.76) as the predominant constituents.

The presence of terpenes such as neophytadiene, phytol, and D- limomene suggests strong antioxidant and antimicrobial potential. Fatty acid esters like hexadecanoic acid ethyl ester indicate the lipid-rich nature of the sample, which may contribute to hydrophobic and film- forming properties. Minor compounds including loliolide and undecane derivates further support the diverse phytochemical profile. GC-MS Chromatogram of bay leaf revealed the presence of 16 phytochemical constituents with different retention times and peak areas. The major constituent identified was caryophyllene (22.45%), another important constituent identified was isomatol(7.52%). The chromatogram also revelead the presence of n-hexadecanoic acid(4.63%) and phenol, 2-methoxy-4-(1-propenyl)-(z)(4.19%). Several sesquiterpenes such as humulene(1.36%), selina-3,7(11)-diene(1.39%) and alloaromadendrene(1.18%). Minor constituents detected include diethyl phthalate(1.36%), N-(alpha-methylbenzyl) formamide(3.38%), 2(1H)-pyridinethione(3.23%), cyclohexanone,3-(4-hydroxybutyl)(3.16%), indole,6-methyl-2-(2-thienyl)(2.70%), 1-butene, 3-chloro-2-methyl(0.31%), and bicycle(2.2.2)octane, 2-methyl(1.29%). The surface morphology of bay leaf and brinjal was examined using Scanning Electron Microscopy at 50,000x magnification. The bay leaf surface reveals a relatively compact and ordered topography dominated by elongated, wavy ridges with minimal surface disruptions. This smoother morphology suggests a well developed cuticular layer with uniform wax deposition, which typically functions as a protective barrier reducing water loss and pathogen entry. In contrast, the brinjal surface exhibits a highly irregular and nodular morphology characterised by densely packed globular structures and interconnected micro-depressions. The increased surface roughness and apparent porosity indicate a higher specific surface area compared to bay leaf. Such features are often associated with enhanced adhesion properties, greater wettability, or higher adsorption capacity.

Solubility and Moisture Content

The solubility and moisture content for bay leaf and brinjal films are presented in table 3.

Solubility: Bay leaf film exhibited higher solubility at 132.374% compared to brinjal film at 115.028%. Higher solubility indicates greater water affinity and lower water resistance.

Moisture content: Brinjal film showed significantly higher moisture content of 17.647% compared to bay leaf film at 9.420%. High moisture content reflects greater hydrophilicity and tendency to absorb water from the environment

Degradation

The degradation test for bay leaf and brinjal films are presented in table 4.

Brinjal film exhibited a higher degradation value of 5.523 compared to bay leaf film, which showed a value of 3.681. The higher degradation rate of brinjal film can be attributed to its surface morphology and chemical composition. In contast, the relatively lower degradation value of bay leaf film suggests greater stability and resistance to degradation.

Qualitative and Quantitative analysis of Phytochemicals

The distribution of different phytochemical constituents in ethanolic extracts of powder of bay leaf and brinjal was evaluated qualitatively and summarised in table. Note: '+' present, '-' absent The phytochemical screening revealed that both bay leaf and brinjal contain alkaloids and fixed oils. Bay leaf showed the presence of flavanoids and tannins, indicating potential antioxidant and antimicrobial properties. Brinjal showed carbohydrates, proteins, saponins and glycosides suggesting nutritional and surfactant-related functionalities. Steroids and terpenoids were absent in both samples.

Antibacterial activity

The antibacterial activity of bay leaf and brinjal against various bacterial strains was evaluated using the agar well diffusion method. Based on the zone of inhibition (mm) brinjal was highly effective (>18mm) against *S. aureus* and moderately effective (14-17 mm) against B. cereus, E. coli and V. cholera. Bay leaf was less effective (<14mm) against all tested strains.

Antifungal activity

The antifungal activity of Bay leaf and brinjal against *Candida albicans* and *Aspergillus niger* was evaluated using the agar well diffusion method Based on the zone of inhibition, brinjal is highly effective (>15mm) against against *C. albicans* and *A. niger*. Bay leaf is moderately effective (10-14mm) against *C. albicans* but less effective (<10mm) against *A. niger*.

Antioxidant assay

The antioxidant activity of brinjal and bay leaf at different concentration (20, 40, 60, 80, 100µg/ml is given in the table . 11 The DPPH scavenging assay results showed that both bay leaf and Brinjal samples exhibited concentration-dependent antioxidant activity. The percentage of inhibition increased with increasing concentration from 20–100 µg/mL. Among the samples, bay leaf demonstrated higher antioxidant activity than Brinjal at all concentrations tested. Bay leaf showed the highest inhibition value of 77.65% at 100 µg/mL, whereas brinjal showed 59.66%. Furthermore, bay leaf exhibited a lower IC_{50} value (21.63 µg/mL) compared to Brinjal (67.47 µg/mL), indicating stronger free radical scavenging activity and better antioxidant potential.

CONCLUSION

In this study, the solubility of the films are relatively low. The brinjal has improved stability than bay leaf hence it has film durability and longer shelf life. It may have larger potential application in various industries including cosmetics, pharmaceuticals and food.

ACKNOWLEDGEMENT

The chemicals and lab equipment were donated by Scott Christian College, Department of Chemistry and Research Center, for which the authors are thankful. We also acknowledge the assistance from the chemistry department of ANJAC, which helped us with FTIR. We also acknowledge the assistance we received in SEM and GC- MS from the sophisticated test and instrumentation center (STIC), Cochin. Additionally, we would like to thank BioHuband Scudder Diagnostic Centre for their assistance with our antimicrobial and antioxidantinitiatives.

ABSTRACT

Endophytic fungi are microorganisms that inhabit medicinal plants without inducing disease, and they represent a valuable source of bioactive compounds with possible therapeutic uses. Endophytic fungi are utilized to generate enzymes for a range of industrial, pharmaceutical and the creation of novel medications. In the current study, the enzymes like amylase, L-asparaginase, pectinase and protease synthesized from endophytic fungi. The screening result showed that, totally 22 isolated endophytic fungi were identified from eight distinct genera has the ability to produce all the four enzymes. The fungi such as *Aspergillus fumigatus, Fusarium oxysporum* and *Penicillium chrysogenum* were screened on the basis of quantum of enzymes. Among the four enzymes, partial purification of L-asparaginase enzyme were maximum quantity of three selected endophytic fungi and highest purification fold were recorded at the *P.chrysogenum*. L-asparaginase (ASNase) is utilized in the treatment of acute lymphoblastic leukemia and currently under investigation for its efficacy against other cancers such as breast cancer, where research indicates its ability to impede the proliferation and migration of cancer cells. It is important to note that the enzymes themselves do not act as direct anticancer agents; instead, they may play a role in the production of compounds with anticancer activity and also possess other therapeutic applications.

Keywords: Endophytic fungi, primary screening, enzyme production, partial purification, amylase, L-asparaginase, pectinase, protease.

INTRODUCTION

The endophytic fungi derived from plants represent a significant source for the synthesis of various secondary metabolites which are bioactive compounds beneficial to the pharmaceutical industry (Khan *et al.,* 2010; Amirita *et al.,* 2012). Marine endophytic fungi are recognized for their ability to generate a wide array of bioactive secondary metabolites, including steroids, alkaloids, terpenoids, and peptides. Numerous compounds derived from these fungi exhibit various biological activities such as anti-inflammatory, antioxidant, antimicrobial and antitumor effects (Mohamed El-Bondkly *et al.,* 2020; El-Bondkly *et al.,* 2021). Endophytic fungi have been identified as potential sources of bioactive secondary metabolites. Fungal endophytes represent a polyphyletic group of primarily ascomycetous fungi that reside within healthy host tissues for at least a portion of their life cycle without causing any observable symptoms of disease or adverse effects on their hosts (Sandrawati *et al.,* 2020; Valli *et al.,* 2024). Endophytes refer to all microorganisms that penetrate the internal tissues of living plants without inducing any immediate disease symptoms or adverse effects on their host; this definition is the most inclusive and commonly used (Zhang *et al.,* 2006). Endophytic fungi play a significant role in safeguarding their hosts from pathogenic microorganisms by competing for available habitats and nutritional resources (Selim *et al.,* 2012).

Fungi possess the capability to generate industrial enzymes, antimicrobial substances and microbial biomass having developed the capacity to synthesize enzymes and natural products as innovative metabolites (Sumaiya, 2022). Enzymes derived from fungi can function directly as antimicrobials or can produce intermediate compounds that exhibit antimicrobial properties (Gao *et al.,* 2010). Additionally, fungal enzymes are utilized in the food industry to enhance food preservation and extend shelf life while maintaining the nutritional value (Zhao *et al.,* 2017). The extraction of enzymes from endophytic fungi for commercial applications remains a largely untapped area representing one of the most recent sources of enzymes with diverse functionalities. Medicinal plants remain largely underexplored in terms of their functional relationships with fungi. These plants harbor endophytic fungi that produce exoenzymes. These exoenzymes are capable of hydrolyzing the structural components of pathogens, effectively eliminating them and thereby offering protection to the plants against these harmful organisms. (Khalil, 2021; Vyawahare *et al.,* 2019). The enzymes are involved in the breakdown of lignocellulosic substances, including amylases, pectinases and proteases. These enzymes can exert a direct antagonistic influence on pathogens. The quantity and variety of enzymes released by endophytic fungi can differ and may be influenced by the specific source plant (Zewdinesh *et al.,* 2019; Mwendwa *et al.,* 2025). Asian medicinal plants host a variety of endophytes that exhibit numerous biological activities including antimicrobial, anticancer and antioxidant effects.

These endophytes are also known to produce various hydrolytic enzymes that hold both therapeutic and industrial significance (Rathna *et al.,* 2023). Fungal endophytes may serve as an alternative, readily accessible, low-cost source of antioxidants. Numerous endophytes are known to synthesize bioactive compounds that plants can utilize for defense against pathogens, and some of these compounds may hold potential as pharmaceutical drugs (Sriya *et al.,* 2023). Antimicrobial resistance has emerged as a significant health concern and continues to pose a threat to healthcare systems worldwide. Consequently, this global issue has prompted an increase in research focusing on endophytic fungi, particularly those isolated from medicinal plants for their potential as sources of novel antibiotics (Jia *et al.,* 2016). Similar to other organisms that invade plant tissues, endophytic fungi produce extracellular hydrolases as a resistance mechanism against pathogenic invasion and to acquire nutrients from their host. Fungal enzymes are utilized in the food, beverage, confectionery, textile, and leather industries to facilitate the processing of raw materials. They are frequently more stable than enzymes sourced from other origins. The variety of enzymes produced varies among fungi and often influenced by the host and ecological factors (Sunitha *et al.,* 2013). In addition to the isolation and identification of endophytic fungal colonies from medicinal plants, the research encompasses the screening of selected all isolated endophytic fungi for five distinct extracellular enzyme assays, including amylase, L-asparaginase, pectinase and protease enzymes.

MATERIALS AND METHODS

Endophytic fungi obtained from three distinct locations of marine associated plants were observed at regular intervals. In this research, fungi were isolated from six marine-associated plants, including *Aegiceras corniculatum, Acanthus ilicifolius, Cyphostemma setosum, Excoecaria agallocha, Rhizophora mucronata* and *Suaeda maritima* by culturing them on PDA medium.

Primary screening of enzymes

Amylase enzyme

The use of starch agar media was implemented to evaluate the effectiveness of amylase production. All identified fungal species were centrally inoculated the starch casein agar plates and maintained at a temperature of 28°C. Following a two-day incubation period, the inoculated plates were treated with iodine solution after which the zones of clearance surrounding the inoculated fungi were observed. These zones of clearance were measured and documented (Migahed, 2003).

L-asparaginase enzyme

Utilizing a modified M9 agar medium, the bacterial strains were evaluated for L-Asparaginase activity. The composition of the M9 media includes Disodium hydrogen phosphate - 6.0 g, Potassium dihydrogen phosphate - 3.0 g, Sodium chloride - 0.5 g, Glucose solution - 10.0 mL, Magnesium sulfate solution - 1.0 mL, Calcium chloride solution - 1.0 mL, Phenol red - 0.3 mL, and Agar - 15.0 g, with a pH of 7.0. The bacterial strains were inoculated and incubated for 48 hours at 37°C. The degree of pink coloration observed on the streaked plates post-incubation facilitated the detection of L-Asparaginase activity (Rudrapati, 2015).

Pectinase enzyme

The isolated endophytic fungi was then inoculated onto a sterile pectin agar plate and incubated at 37° C for 48 hours to facilitate the isolation and screening of pectinolytic emdophytic fungi (Rafae *et al.,* 2006). The colonies that developed on the pectin agar medium were examined for the presence of clear zones, and the characteristics of the isolated organisms were recorded.

Protease enzyme

The production of proteolytic enzymes by fungal isolates was identified through the Plate assay method which utilized gelatin as the protein source for the growth medium. The fungal isolates were inoculated in the Petri dishes and enriched with 1% gelatin (comprising 5g Peptone, 3g Beef extract, 5g NaCl, 15g Agar, and 1 liter of distilled water at pH 7). The Petri dishes were then incubated at a temperature of 28 ± 1°C for a duration of 3 days. The degradation of gelatin was noted as a clear zone surrounding the fungal colony (Migahed, 2003).

Enzyme Production

Amylase activity

The amylase assay was conducted using a reaction mixture consisting of 1 ml of a 2% starch solution combined with 1.0 ml of a 50 mM buffer at pH 6.5, along with 0.1 ml of crude enzyme which was incubated for 15 minutes at 30°C. Following the incubation, 2 ml of DNase reagents was introduced and the mixture was boiled for 10 minutes. Subsequently, 1.0 ml of chilled 40% K-Na tartrate was incorporated. The resulting color, produced from the reaction between DNase and reducing sugars, was measured at a wavelength of 540 nm and subsequently calculated (Migahed, 2003).

L-asparaginase enzyme

The activity of L-asparaginase was assessed using the following method. The cultures grown in modified M9 medium containing 1.5% L-asparagine broth were subjected to centrifugation at 8000 rpm for 30 minutes after which the resulting supernatant, referred to as the crude extract was utilized to evaluate L-asparaginase activity. The reaction commenced with the addition of 1 mL of the crude cell-free extract to 0.5 mL of a 0.04 M l-asparagine solution and 0.5 mL of a 0.05 M Tris-HCl buffer at pH 8, followed by incubation at 37°C for 30 minutes in a water bath. The reaction was halted by introducing 0.5 mL of 1.5 M trichloroacetic acid. The precipitated proteins were eliminated through centrifugation at 8000 rpm for 15 minutes at 4°C, and the ammonia concentration was measured spectrophotometrically at 450 nm using the Nesslerization method. Control tubes were maintained at zero-time incubation. The enzyme activity was quantified based on the release of ammonia, which was calculated against a standard curve of ammonium. One unit of L-asparaginase is defined as the quantity of enzyme that catalyzes the production of 1 μmoL of ammonia per minute at 37°C incubated (El-Hadi *et al.,* 2019).

Pectinase activity

The activity of Polygalacturonase was assessed by quantifying the quantity of reducing substances released from citrus pectin. The reaction mixture included 450 μL of substrate buffer (comprising 0.1 g of citrus pectin dissolved in 100 ml of 0.1 M phosphate buffer at pH 5) and 50 μL of enzyme solution. This combination was incubated at a temperature of 50 °C for a duration of 30 minutes. Subsequently, 500 μL of DNSA reagent was introduced into the vial, which was then placed in boiling water for 5 minutes and subsequently cooled in ice water. A blank sample was also prepared following the same procedure as described previously. The absorbance was measured at 550 nm using a spectrophotometer. One unit of enzyme activity (U) was defined as the release of 1 μmole of galacturonic acid per minute (Chowdhury *et al.,* 2017).

Protease activity

A modified mineral salt broth was employed for the synthesis of protease enzyme from promising fungal sources. Following incubation, the crude enzyme underwent treatment with 0.5% NaOH and 1ml TCA. The resulting filtered supernatant was then treated with folin phenol solution, revealing a blue color attributed to the reduction of sugars. This color change indicated the production of the protease enzyme, and the reaction mixture was analyzed at 660nm using a UV-vis spectrophotometer (Mandels *et al.,* 1976).

Partial Purification of enzymes

12-days incubated period of the culture filtrates, the crude enzymes was precipitated using different concentrations of ammonium sulphate, while the mixture was maintained under a magnetic stirrer at 4°C for 24 hours. Subsequently, the protein precipitate was obtained by cooling the mixture and centrifuging it at 10,000 rpm for 10 minutes. The pellet underwent dialysis against 2-3 buffer changes during this process, also under a magnetic stirrer at 4°C for 24 hours, while being suspended in a sodium acetate buffer with a pH of 4.6 [48]. The proteins that were only partially purified were quantified (U/mL) in an aliquot.

Purification profile

Enzyme activity

Utilizing casein as a reference point, the enzyme activity in the raw materials was assessed through ammonium sulfate precipitation and dialysis for sample purification (Dam *et al.,* 2013).

Estimation of protein content

Utilizing bovine serum albumin as a reference, the protein quantities in the crude extract, ammonium sulfate precipitated, and dialyzed enzyme samples were determined (Lowry *et al.,* 1951).

Specific activity

The specific activity of the crude extract which was subjected to ammonium sulphate precipitation and subsequent dialysis was calculated using the following formula.

$$\text{Specific activity } (\frac{\text{U}}{\text{mg}}) = \frac{\text{Total activity } (\frac{\text{Units}}{\text{mL}})}{\text{Total Protein } (\frac{\text{mg}}{\text{mL}})}$$

Purification fold

The specific activity of the crude extract was utilized to calculate the purification fold for the sample that was precipitated with ammonium sulfate and subsequently dialyzed. The formula employed is as follows:

$$\text{Purification fold} = \frac{\text{Specific activity of the sample}}{\text{Specific activity of the crude extract}}$$

Statistical analysis

The experiments were done three times. The results are shown as average values with their standard deviations.

RESULTS AND DISCUSSION

A total of forty distinct endophytic fungi source from various medicinal plants were analyzed for their capacity to produce extracellular enzymes including amylase, protease, cellulase, laccase, and L-Asparaginase. Each of the 40 endophytic fungi evaluated demonstrated the ability to generate extracellular enzymes. Although none of the endophytic fungi in this investigation were capable of synthesizing all five enzymes examined, every fungal endophyte was able to produce at least one of the extracellular enzymes assessed (Kathiravan and Gnanadoss, 2022). Among the 40 endophytic fungi evaluated, 45% of the endophytic isolates exhibited positive amylase activity. Amylases represent one of the essential enzyme employed in contemporary biotechnology particularly in the process of starch hydrolysis. Fungal amylase is extensively utilized in both the food and pharmaceutical sectors (Sunitha *et al.,* 2012). The endophytic isolates was 37.5% demonstrated protease activity among the 40 endophytic fungi that were isolated. Proteases are acknowledged as a crucial class of enzymes, representing two-thirds of the global enzyme market. These enzymes are primarily utilized in the food, leather, textile, and detergent sectors (Mandal and Banerjee, 2019). Among the 40 endophytic fungi evaluated for L-Asparaginase, 52.5% of the isolates demonstrated positive enzyme activity. L-Asparaginase serves as a therapeutic enzyme utilized as a chemotherapeutic agent for the treatment of acute lymphoblastic leukemia. Nine fungal endophytes, extracted from various medicinal plants located in the high mountains of Uttarakhand, India, exhibited positive L-Asparaginase activity (Kapoor *et al.,* 2021).

This aligns with the findings of which indicated that out of 11 strains, only eight demonstrated positive amylase activity when isolated from the leaves of medicinal plants. Additionally, the research conducted by revealed that among nine strains, merely three were capable of producing the amylase enzyme from endophytic fungi sourced from medicinal plant leaves. The fungi identified included *Aspergillus* sp, *Rhizoctonia* sp., and *Chaetomium*; furthermore, disclosed that the amylase activity generated by endophytic fungi contributes to the degradation of starch found in aging host plants (Venkatesagowda *et al.,* 2012). In addition, identified *Rhizoctonia stolonifer* as the most effective endophytic fungi for amylase production, followed by *Aspergillus niger* and *Penicillium variotii*. Historically, amylase was first utilized in medicine for the treatment of digestive disorders and is recognized as the pioneering enzyme for commercial production (Zakowski and Bruns, 1985). This enzyme also finds applications in the food industry such as enhancing pastries and facilitating starch removal from sugar and it is utilized in various sectors including textiles, paper, detergents and the preparation of animal feed.

Pectinase is found in microorganisms which is essential for various pathogenic processes in plants, the symbiotic relationships between organisms and plants, as well as in the decomposition of dead plant matter. The initiation of plant attack by pathogenic fungi occurs due to their capacity to produce pectinase, which is instrumental in the breakdown of host tissues. Endophytic fungi possess the potential to evolve into pathogenic fungi by virtue of their

ability to decompose pectin substances (Choi *et al.,* 2005). Furthermore, Schulz and Boyle (2005) proposed in their hypothesis that the interaction between the botanical host and cultivated fungi is balance between the pathogenicity of the fungi and the defensive mechanisms of the host plant; any disruption in this equilibrium is associated with the progression or emergence of disease. Additionally, pectinase holds significant applications, particularly in the paper which contain food industries and is commercially produced through fungi (Upadhyaya *et al.,* 2020). In the present study, fungi collected from three different sites of marine-associated plants were observed at regular intervals. A total of 135 colonies of endophytic fungi were isolated from six marine-associated plants including *Aegiceras corniculatum, Acanthus ilicifolius, Cyphostemma setosum, Excoecaria agallocha, Rhizophora mucronata* and *Suaeda maritime* by culturing them on PDA medium both with and without artificial salt. In total, 22 endophytic fungal isolates were identified from eight distinct genera, namely *Aspergillus, Beauveria, Fusarium, Macrophomina, Nigrospora, Pestalotiopsis, Penicillium* and *Rhizopus*. The isolated endophytic fungi such as *Aspergillus flavus, A.fumigatus, A.sydowii, A.penicilliodes, Beauveria bassiana, Fusarium lateritium, F.moniliforme, F.oxysporum, F.solani, F.equiseti, F.verticillioides, Macrophomina phaseolina, Nigrospora oryzae, Penicillium brevicompactum, P.chrysogenum, P.citrinum, P.crystallinum, P.longibrachiatum, P.verruculosum, Pestalotiopsis biciliata, Rhizopus microsporus* and *R.stolonifer* were recorded, respectively.

In amylase enzyme, the *A.fumigatus, A.sydowii, F.moniliforme, F.oxysporum, P. brevicompactum, P.chysogenum, P.citrinum* and *P.crystallinum* were presented but other fungi not found to be recorded respcetivly.. In the L-asparaginase enzyme, fungi were identified: *A. fumigatus, F.oxysporum, F.equiseti, F.verticillioides* and *P.chrysogenum* however, no other fungi were documented. In pectinase enzyme, the *A.flavus, A.fumigatus, A.penicillioides, F.moniliforme, F.oxysporum, F.verticillioides, P.brevicompactum, P.chrysogenum, P.crysogenum, P.crystallinum* and *P.longibrachiatum* were presented but other fungi were not found to be recorded. In the protease enzyme, the following fungi were identified: *A. fumigatus, A.penicillioides, Beauveria bassiana, F.oxysporum, F.solani, F.verticillioides, Macrophomina phaseolina, P.chrysogenum, P.citrinum, P.crystallium* and *P.longibrachiatum* However, no other fungi were documented (Table 1). In the production of all enzymes, the maximum amount of activity was screened by the endophytic fungi were represented as *A.fumigatus, F.oxysporum* and *P.chrysogenum* when compared with all other endophytic fungi were recorded, respectively (Table 2). The partial purification of L-asparaginase from crude extract was influenced by ammonium sulfate precipitation (45-85%), indicating that a significant portion of the enzyme activity was retained in the precipitate. Additionally, the total protein precipitation analysis demonstrated that the majority of enzyme activity remained in the precipitate. The total protein concentration decreased from ammonium sulfate precipitate (Ram Kumar *et al.,* 2020). However, during the dialysis process, the protein concentration diminished. The profiles of the ammonium sulfate fraction and dialysis indicated an increase in specific activity. The final purification step, conducted using Sephadex G-100, revealed that specific activities increased, while the protein concentration decreased. The partially purified enzyme exhibited L-asparaginase activity, whereas reported an asparaginase activity. Furthermore, the enzyme demonstrated ten times greater activity than that observed by Kushwaha *et al.,* (2012).

The process of protein purification typically entails a sequence of actions aimed at isolating a specific protein from a complex mixture while eliminating unwanted substances. An optimal purification process should be executed with the minimum number of steps to prevent the loss of the target protein and should also be cost-effective (Noor *et al.,* 2016). Nevertheless, the methods employed will vary based on the intended application of the enzyme. The initial step in recovering extracellular proteases is to separate the cell biomass from the fermentation broth (Matias *et al.,* 2021). The subsequent step focuses on concentrating the proteases, which can be achieved through either filtration or precipitation techniques. In the following stages, procedures that generally involve column chromatography are conducted. Among the reviewed articles, two reported partial purification that included enzyme precipitation processes utilizing ethanol and ammonium sulfate, followed by dialysis. Six studies implemented ammonium sulfate precipitation methods, which were then followed by chromatographic techniques such as ion exchange chromatography, size exclusion chromatography and affinity chromatography for enzyme purification (Elgammal *et al.,* 2020). Additionally, one study employed ultra filtration methods (Centripep-30), followed by passage through a phenyl boronate column and concluded with precipitation using methanol. According to the present study,

A.fumigatus, F.oxysporum and *P.chrysogenum* had been produced the amylase, L-asparaginase, pectinase and protease enzyme production at maximum level. Therefore, these fungi were considered as potential fungi in primary screening. The partial purification of amylase, L-asparaginase, pectinase and protease enzymes from *A.fumigatus, F.oxysporum* and *P.chrysogenum* were performed with crude enzyme extraction followed by ammonium sulphate fractionation and dialysis. In the current investigation, we focused on the partial purification of enzymes derived from selected marine soil fungi, specifically *A.fumigatus, F.oxysporum* and *P.chrysogenum*, to achieve maximum enzyme production. The crude enzyme extract underwent purification processes involving ammonium sulphate precipitation and dialysis, aimed at enhancing the specific activity of all enzymes. A comparison between the crude enzyme extract and the results from dialysis indicated that ammonium sulphate fractionation resulted in higher concentrations of all enzymes and proteins. Following dialysis, there was a notable increase in the specific activity of the enzymes, accompanied by a purification fold. In maximum purification level were recorded at L-asparaginase enzyme when compared with all other enzymes and the endophytic fungi were presented as exhibiting the highest level of activity when it comes to partial purification level as the *P.chrysogenum* were recorded, respectively (Fig 1, 2 & 3).

CONCLUSION

At present, the challenges posed by ineffective, toxic and costly therapeutic antimicrobial drugs. In recent years, endophytic fungi have garnered significant attention in the drug development process due to their widespread presence and abundant availability. Endophytic fungi exhibit a diverse range of metabolic processes and possess distinct pathways for secondary metabolite production which will facilitate the isolation of various metabolites and their applications in the field of medicine. These microorganisms thrive within the epidermis and aerial parts of plants, offering a diverse range of chemical compounds. Endophytic fungi are known to produce biologically active secondary metabolites, including terpenes, alkaloids, monoterpenoids, peptides and polyketides. Fungal endophytes play a crucial role in addressing various human health concerns, particularly against numerous microbial pathogens including fungi, through multiple mechanisms such as the synthesis of antibiotics, antifungal agents, antiviral compounds, anticancer substances, lytic enzymes and the breakdown of toxins. A vital process in this context is partial purification which serves to isolate the target enzyme enhancing its specific activity and facilitating a comprehensive characterization of its attributes including thermal stability and optimal pH. Enzymes derived from endophytic fungi exhibit anticancer potential via mechanisms such as the induction of apoptosis and the inhibition of cancer progression. Nevertheless, the predominant emphasis in research has been placed on secondary metabolites, including paclitaxel and camptothecin. Endophytic fungi serve as a pertinent example of an enzyme source that can be investigated for its direct anticancer effects.

ABSTRACT

The production and characterisation of graphene oxide from Carica papaya seeds is the primary goal of this work. Because of their physical, chemical, and electrical characteristics, graphene oxide and other nanomaterials based on carbon are special in nature and have a wide range of uses. One significant two-dimensional nanomaterial based on carbon is graphene oxide. The high silica content of papaya seed ash was eliminated, and the residual graphite carbonized material was heavily oxidized with potassium permanganate, sulfuric acid, and orthophosphoric acid to enhance the number of oxygen functional groups. Graphene oxide in its oxidized state is hydrophilic, meaning it dissolves readily in water. The UV-visible, FT-IR, XRD, SEM-EDX, TEM, SAED, and CV methods were used to analyze the produced graphene oxide. Graphene oxide and other oxygen functional groups were detected by FT-IR and XRD. The produced graphene oxide's antibacterial and antioxidant properties were evaluated against the corresponding microorganisms.

Keywords: Graphene oxide, Thermal combustion, Carbonized material, Dispersed, Hydrophilic.

INTRODUCTION

Many studies have looked into graphene, graphene oxide as maybe the most promising biomaterial for conducting polymer composites, solar cells, batteries, sensors, and transistors [1, 2]. Additionally, it is employed in other applications, including biodegradation, photodegradation, and cleans energy devices for sterilizing and purifying water. Carbon waste can be recycled and turned into graphene oxide, which have numerous uses and potential economic and environmental advantages [3]. A fundamental component of other graphite materials including graphite and carbon nanotubes, graphene is a 2D honeycomb-shaped monolayer of carbon atoms that is one atom thick. Graphene oxide have been thoroughly researched for a range of applications, including nanoelectronics, sensors, drug delivery, nanocomposites, cell imaging and more, due to their distinct and appealing electrical, chemical, mechanical and optical properties. The graphene in its oxidized state is called graphene oxide. Epoxide, carbonyls, hydroxyls, and carboxylic groups are the primary functional groups found in graphene oxide, which also comprises hexagonal carbon-based structure formed by the hybridization of sp3 and sp2 carbon atoms [4]. This straightforward, inexpensive, and sustainable method of synthesizing graphene oxide may open up new avenues for the creation of graphene-based nanomaterials [5]. Carbon-based products made from fruit waste's renewable resources are being promoted in order to make them more competitive [6].

Carica papaya, also called papaya, pawpaw, and kates, a member of the Caricaceae family. Originating in the Mesoamerican Center, Central America, and southern Mexico [7–9], this horticultural shrub is mostly grown throughout subtropical and tropical areas of Brazil, India, Malaysia, China, Philippines Thailand, and other neighboring countries [10]. Commercial papaya cultivation has taken place in several Asian countries. In many tropical countries, papaya is also planted as a garden plant. Fruits are available all year round [11]. Papaya peels and seeds, which make up roughly half of the weight of the papaya, and the seeds alone make up about 14%, are among the waste products produced is processed industrially with the goal of creating a variety of products, including candied papain, pectin, Juices, fruit, raisins, nectars, and jellies, and jams[12]. Utilizing sections of veggies and fruits that are usually thrown away, like the seeds, which contain a variety of nutritionally significant materials, including proteins, minerals, carbs, fibers as well as bioactive substances, can help reduce the amount of trash that is disposed of. Additionally, if the right procedures and technology are used, they could be transformed into new goods with added value [13–14]. Given the information above, using seeds of papaya to create novel products is a viable substitute since it may enhance a by-product and reduce the amount of agro-industrial waste that is disposed of [15].
The goal of the current work was to turn papaya seed ash into graphene oxide. The primary driving force behind using these sources is to supply inexpensive raw materials for the large-scale manufacturing of carbon-based graphene oxide in a sustainable and environmentally friendly manner. UV, FT-IR, XRD, SEM, EDX, TEM, SAED, and CV were among the advanced techniques used to analyze the synthesized graphene oxide. Antioxidant and antimicrobial potential of the synthesized graphene oxide were tested against respective microbes.

EXPERIMENTAL METHODS

Chemicals and Materials

Papaya seeds were gathered locally in Tamil Nadu, India's Kanyakumari district. Molychem supplied the chemicals (AR Grade), which were used. Sodium Hydroxide, Sulphuric acid 98%, Orthophosphoric acid , Potassium permanganate, Hydrogen peroxide 30%, Hydrochloric acid and Deionized water.

Alkali extraction

After being gathered, papaya seeds were repeatedly washed under running water and allowed to dry for roughly two weeks in the shade. The dried seed was then heated to 600°C in a muffle furnace for controlled thermal combustion. 50 milliliters of 2M NaOH solution and 5 grams of papaya seed ash were placed in a 100 milliliter beaker. A hotplate magnetic stirrer was used to agitate the mixture for approximately 4 hours at 80°C. Whatman No.

41 ashless filter paper was then used to filter the mixture. They threw out the filter solution. The primary source for the manufacture of graphene oxide was the residue of carbonized materials, which was gathered.

Graphene oxide Synthesis:-

After being repeatedly cleaned with HCl and deionized water, the obtained carbonized material was dried at 80°C in an air oven. For this preparation, 3 milliliters of orthophosphoric acid and 27 milliliters of sulfuric acid (volume 9:1) were combined and agitated for a number of minutes. After adding 0.5g of carbonized material gradually while stirring, 2g of $KMnO_4$ was patiently added to the mixture. The solution turns dark green color approximately 6 hours of churning the mixture. 1.2 ml of H_2O_2 was progressively added to a KMnO4 and mixed for a few minutes to get rid of any surplus. After the exothermic reaction takes place, allow it to cool. After adding 30 milliliters of deionized water and 10 milliliters of 5% hydrochloric acid, the solution was centrifuged for 10 minutes at 3000 rpm. Following the removal of the supernatant, the residue was rinsed three to four more times using HCl and DI water. The cleaned graphene oxide solution was dried for 24 hours at 90°C in an oven to produce the graphene oxide powder.

Characterization

UV-Visible spectroscopy

Figure 6 shows the GO UV absorption spectrum. The shoulder peak that GO showed at 236 nm is caused by the π-π^* transition. This is due to the π anti-bonding and bonding electrons found in unsaturated carbon atoms [16].

Fourier-transform infrared spectroscopy

The graphene oxide's FT-IR spectrum (figure 7) verifies the existence of functional groups like hydroxy, epoxy, and carbonyl groups. The presence of hydroxy groups in GO is shown by the prominent peak at 3344 cm^{-1}, which is attributed to the O-H bonds stretching mode. Weak bands at 2658 cm^{-1} indicate the asymmetric and symmetric stretching vibrations of the C-H bonds. The signal at 1718 cm^{-1} represents C=O which is carbonyl group, whereas the peak at 1628 cm^{-1} is caused by the aromatic C=C stretching group. The vibrational mode of C-O groups, represented by a peak at 1040 cm^{-1}, and C-O-C stretching, represented by the peak at 1248 cm^{-1}, both attest to the presence of functional groups with GO. Peak at 1162 cm^{-1} indicates C-O-C stretching vibration. Because of the oxygen functional groups present, our FT-IR analysis demonstrated that the produced graphene oxide is hydrophilic.

X-Ray Diffraction

The X-Ray Diffraction patterns of GO are shown in Figure 8. The crystalline nature of the GO samples was shown by the XRD examination. The peak at 2θ=10.831, which is in line with the (001) plane, shows that the graphite in the samples underwent oxidation to produce graphene oxide. Scherrer's formula was used to determine the GO samples' average crystalline size, $D=K\lambda/\beta\cos\theta$. In this case, the X-ray wave length is K = 0.9, λ = 0.1540 nm, and the complete width at half peak height is β = 0.258, 2θ = 10.831, θ = 5.4155. The graphene oxide's average size was estimated to be around 0.830 nm.

Scanning Electron Microscope

Scanning electron microscopy can be used to determine the structure of nanomaterials and its surface morphology. Figure 9 shows the surface morphology of graphene oxide samples. The SEM image shows flat nature and organized layer structure of graphene oxides. As can be seen in this figure, the different oxide layers were created as the graphite oxide oxidized. Layered structure was displayed by Graphene Oxide.

Energy- Dispersive X- ray Spectroscopy

An energy dispersive X-ray analysis is used to determine the specimen's elemental composition. The EDX image presented in figure 10 indicates the existence of components including oxygen and carbon in the graphene oxide. The % of oxygen and carbon by weight and atomic percentage were found to be 32.68:67.32 and 29.53:70.47 respectively. The graphene oxide sample is predicted to contain carbon and oxygen based on the EDX findings.

Transmission Electron Microscopy

Transmission electron microscopy was employed to investigate the sample's structural coherence (TEM). The TEM micrograph is displayed in figure 11. Graphene oxide displays morphology akin to a sheet with layer stacking. This is most likely caused by the quantity of levels found in GO's stacked structure. Therefore, TEM analysis verifies the existence of graphene oxide in the oxidized carbon samples. One method for determining whether a material is crystalline at the nanoscale is to examine its SAED pattern. The PSA samples SAED pattern displays typical ring-like patterns that point to the samples polycrystalline structure. The samples have distinct diffraction spots that match the hexagonal lattices six-fold layout. Thus, the samples crystalline character may be seen in SAED pattern. The SD value of the sample is 40.9.

Cyclic Voltammetry

The graphene oxide nanoparticle's electrochemical activity was investigated using cyclic voltammetry, which tracks current as a function of applied voltage. Concentration, roughness, diffusion coefficient, surface area and other interfacial electrochemical properties of an electrode in an electrolyte solution are all studied using CV. The typical redox behavior of the nanoparticles is depicted by the CV curve in figure 14. The sample reduction process is represented by the cathodic peak at -0.74V, which has a peak current of -3.8μA. The area under curve 16.282μC, which indicates a considerable level of electrochemical activity, represents the charge transfer during the redox process. The symmetry of the CV curves suggests that the redox process is reversible because the current remains constant across the sweep range of -0.8 to -0.6V. The graphene oxide nanoparticle's good electrochemical stability is demonstrated by its reversibility. This result suggests that the generated nanoparticle can be used in electrochemical devices like sensors or energy storage devices.

Applications

Anti-Bacterial activity

The produced graphene oxide nanoparticles' antimicrobial properties were examined. Figure 15 illustrates how the data were interpreted using two gram positive and two gram negative bacterial strains. If the sample's value is higher than the control, the bacterium is susceptible to the produced graphene oxide nanoparticles. A lower number in the direction of the control indicates resistance. The statistics clearly suggest that Vibrio cholera and Streptococcus aureus were sensitive to the material, whereas E. Coli and Bacillus cereus shown resistance to it. This suggests that the produced graphene oxide nanoparticle has potent antibacterial properties against particular bacterial strains. It can be applied widely in the medical profession as a result. If the prepared sample's qualities are further investigated and improved, it might be used as an efficient antiseptic.

Anti-Fungal activity

The samples' antifungal properties were examined against Candida Albicans and Aspergillus Niger. The data clearly show that Aspergillus niger had a weaker inhibitory zone than Candida albicans. This possesses more potent antifungal qualities than Candida albicans. The graphene oxide nanoparticle's antifungal activity is shown in figure 16.

Antioxidant activity

Recent research has demonstrated that a variety of nanoparticle types are potent antioxidants and free radical scavengers (17–18).The generated graphene oxide nanoparticles were tested for antioxidant properties using the DPPH, Nitric oxide, and Superoxide anion scavenging tests. The antioxidant activities of the generated nanoparticle were evaluated at varying doses and the different IC50 values were computed to determine the strength of the antioxidant effect. The DPPH assay showed 75.68% inhibitory action at 100μg/ml, increasing with concentration. The nitric oxide assay's activity dropped with increasing concentration, peaking at 67.54% at 100μg/ml. The superoxide anion assay also showed decreasing activity with increasing concentration, reaching 66.99% at 100μg/ml. The antioxidant potentials of the three assays were ascertained using the IC50 values. It became apparent that the IC50 values for the DPPH, nitric oxide, and superoxide anion tests were 31.18μg/ml, 45.56μg/ml, and 56.01μg/ml,

respectively. This suggests that the produced graphene oxide nanoparticle has significant antioxidant potential because the DPPH assay exhibits the strongest inhibitory activity of the two assays. Antioxidant activity of the produced graphene oxide nanoparticle is compared in the histogram between the three tests.

CONCLUSION

We can infer from the research provided here that papaya seeds can be utilized as a raw material for the synthesis of graphene oxide. The simple and useful synthesis process is illustrated in this work. UV, FTIR, XRD, SEM, EDAX, TEM, SAED, and CV were among the spectroscopic techniques used for analysis. At 236 nm, the produced graphene oxide nanoparticle's UV spectrum displays a shoulder peak that exhibits the π-π^* transition. Many functional groups, including CH, OH, C-O, C=O, C-O-C, and C=C, are confirmed by the FTIR spectrum. The produced graphene oxide nanoparticle's average size is displayed by XRD. The graphene oxide's layered structure is consistent with the SEM image. The many elements found in graphene oxide, such as carbon and oxygen, are displayed by EDX. A sheet-like structure layered as a layer is shown in the TEM image. The sample's polycrystalline graphene oxide structure is shown by the SAED pattern's characteristic ring-like patterns. Graphene Oxide's electrochemical behavior is determined via CV. The antibacterial efficacy against two Gram-positive and two Gram-negative pathogens showed strong antibacterial activity against specific bacterial strains. Against fungus strains, strong antifungal activity was demonstrated. Antioxidant activity was measured using DPPH, nitric oxide, and superoxide anion scavenging tests; DPPH showed the highest inhibitory action. Because of this, the synthesized GO has several unique and fascinating properties with several potential uses.

ACKNOWLEDGEMENTS

The chemicals and lab equipment were donated by Scott Christian College, Department of Chemistry & Research Centre, for which the authors are thankful. We also acknowledge the assistance from the chemistry department of ANJAC, which helped us with FTIR and UV. We also acknowledge the assistance we received in SEM-EDX, XRD and TEM from the sophisticated test and instrumentation centre (STIC), Cochin. Additionally, we would like to thank BioHub and Scudder Diagnostic Centre for their assistance with our antimicrobial and antioxidant initiatives.

ABSTRACT

Multi-model image registration plays a pivot role in many remote sensing applications such as image fusion, image restoration, military and civilian fields etc. Image registration is a crucial step in many image-processing applications. Ground surface variations pose significant challenges for detecting feature points, impacting both their density and accuracy. This issue is frequently an obstacle faced by feature-based image registration. Remote sensing images often face challenges due to variations in different factors such as location, sensors and more. These differences lead to image distortions and overlaps between image pairs. This significantly affects the accuracy of image registration. The Scale-Invariant Feature Transform (SIFT) is well-known for extracting image features, with different variants of SIFT. However, it primarily relies solely on local low-level features, leading to a loss of mid and high-level information required for registration accuracy. Image features extracted by a deep learning method such as a convolutional neural network (CNN) have attained state-of-the-art performance for image feature extraction, classification and retrieval tasks. These features effectively captured mid and high-level information, making them ideal for aligning remote sensing images. Hence, in this letter, we discuss and analyse how to calculate the image features using various feature extraction methods and trained CNN Models. The experimental result demonstrates that deep learning algorithms yield better accuracy than feature-based algorithms.

Keywords: Remote sensing, image registration, feature extraction, convolutional neural networks (CNN), deep learning

INTRODUCTION

Multi-model satellite image registration has become increasingly popular in remote sensing due to its ability to combine information from different sensor modalities, creating more comprehensive and accurate data analysis. (Zhang X et al., 2021) Image Registration involves aligning and matching multiple images of the same scene that are captured from different sensors, perspectives, or at different times (Zhang X et al., 2021). In Various Remote sensing applications such as image fusion, map colouring, and Image segmentation, Image Registration is an essential step. Image matching obtained from a single sensor or modality is often viewed as a largely resolved challenge. When compared with multi-model image registration such as SAR and Optical image matching, faces various challenges. (Liaghat, M. S. et. al. 2023) However, these image-processing approaches face complexities due to geometric and radiometric differences between SAR and Optical images. For instance, a SAR image is affected by geometric distortions such as layover, foreshortening, and radar shadow. It also exhibits speckle noise, which lacks direct analogy in an optical image. SAR offers high-resolution remote sensing imagery in any weather condition. It is also known for its robust resistance to interference and jamming (Liaghat, M. S. et. al. 2023; S. Jiang et al. 2018) Optical images are affected by issues like optical shadows, cloud effects, and variations in illumination (Liaghat, M. S. et. al. 2023).

The key challenges can be summarized in the image registration as follows: firstly, the Significant and unpredictable variation between images makes it difficult for the algorithm to generalize across different scenarios. Second, Geometry distortions introduce an imbalance between correctly matched and incorrect points, complicating the task of eliminating mismatched points. third, image feature matching becomes more challenging due to sensor-related factors such as changes in viewpoint, terrain elevation, and other environmental variations that affect spatial transformation. Firstly, traditional Image Registration was done manually for two decades, where humans needed to locate ground control points on both sensed and reference images through visual analysis, such as identifying buildings, road intersections, etc. After identification of GCP, human operators would manually carry out the steps of feature detection and matching. (Priyanka S. Tondewad et.al.,2020) This job becomes time-consuming when it applies to remote-sensing images due to the availability of various transformations. Various problems are faced during manual image registration, such as finding accurate control points, expert human operators, difficulty in matching time constraints, and more GCPs are required to improve registration accuracy. (Priyanka S. Tondewad et.al.,2020) These problems lead to the development of an automatic image registration method (Zhang X et al., 2021; Liaghat, M.S. et. al., 2023; S. Jiang et al., 2018). Image Registration methods are mainly classified into two types Area-based and Feature-based. Area-based methods seek optimal transformation parameters by evaluating the similar pixel intensities between images using metrics such as MI (Mutual Information) and Normalized cross-correlation (Zhang X et al., 2021; Liaghat, M.S. et. al., 2023). The combination of Area-based and Feature-based methods is known as the Hybrid method in that identified image features are extracted and matched, then the deformation matrix is calculated (Ms. Priyanka S. Tondewad et. al. 2020, (Kuppala, K. et.al.,2020).

The variations in image intensity can negatively impact registration accuracy. Feature-based methods work on different image features to extract more information from the image. Feature-based methods mainly include three steps: Feature detection, Feature descriptor, and Feature Matching. (Y. Zhang et.al.,2021)Registration of multi-source remote sensing images, often achieved through Feature-based methods, is a well-researched area.(Y. Zhang et.al.,2021) Feature extraction involves identifying distinct regions such as closed boundaries, corners, forests, roads, rivers, urban areas and other significant features. Nowadays, various Deep learning Methods such as CNN, DNN, and GAN are used in image registration, extracting detailed image features and improving registration accuracy. (Zhang X et.al.,2021; Liaghat, M.S. et al.,2023) Various architectures like AlexNet, VGGNet, and ResNet provide better results in feature extraction. (Ms. Priyanka S. Tondewad et. al. 2020, Kuppala, K. et.al.,2020, Liu, Y. et.al.,2023, Ma, T. et.al.,2020, Du, W. et.al. 2020)The paper is structured in the following manner: Section 2 presents various types of images used for registration; Section 3 discusses the different feature extraction methods; Section 4 discusses feature extraction results; Section 5 discusses the conclusion and is followed by future work.

Image Dataset

Various types of images can be utilized in image registration, depending on the application domain.

- Images are captured using the same type of sensors but from different viewpoints. so, various transformations are available in images such as rotation, scale, translation, etc.
- Multi-Sensor Images: Images captured by different types of sensors provide more information about the image. Different sensors provide distinct information based on the bands they operate on, such as infrared, near-infrared, microwave, and others. Various Images are SAR (synthetic aperture radar) and optical imaging, Optical-Imaging, Panchromatic Image (PAN), and Multi-spectral images to analyze each image detail.
- Images are captured at different intervals. This type of image is used to analyze change detection. For example, SAR images can be taken during the day or at night.

RESEARCH METHODOLOGY

Multi-Sensor Images: Images captured by different types of sensors provide more information about the image. Different sensors provide distinct information based on the bands they operate on, such as infrared, near-infrared, microwave, and others. Various Images are SAR

Traditional method for feature extraction

The primary objective is to geometrically transform the target image to align with the reference image's spatial coordinate and enable pixel-to-pixel correspondence in their overlapping region(K. Chauhan et.al.,2023; Li, X. et.al.,2022). SAR images mostly use feature-based methods for registration. (K. Chauhan et.al.,2023; Li, X. et.al.,2022; Dai, H. et.al.,2021; Zheng, Y.et. al. 2022; Liu, Y. et.al.,2023) Traditional Feature-based Image registration methods often rely on manually extracted features, Optimization Algorithms or statistical methods to align images. (K. Chauhan et.al.,2023)The feature-based methods are mainly used to find the Affine transformation over the images by identifying image features where images have salient and stable features. The steps of image registration are also given in Figure 1. This approach involves:

- **Feature Detection**: it detects features from an image, such as edges, lines, shapes, boundaries etc. Various algorithms detect image features such as SIFT, SURF, HOG, Harris Corner detector, Canny edge detectors, etc. (K. Chauhan et.al.,2023, K. Parmar et.al.,2017)
- **Feature Matching**: Finding corresponding image features between reference and sensed image. (K. Chauhan et.al.,2023; K. Parmar et.al.,2017)
- **Transformation Estimation**: Calculating the transformation matrix that aligns the reference image with the sensed image. (K. Chauhan et.al.,2023; K. Parmar et.al.,2017)
- **Image Wrapping**: Transformation is applied to the sensed image to align with the reference image. (K. Chauhan et.al.,2023; K. Parmar et.al.,2017)

Deep Learning Method for Feature Extraction

In recent years, deep learning methods have emerged as a powerful and reliable approach in remote sensing imaging, giving outstanding performance in tasks such as object detection, image classification, image fusion and image registration. CNN is a deep learning architecture. CNN consists of many layers of alterations between convolution and pooling and one or more fully connected layers in the Neural Network. (Y. Zhang et.al.,2021; F. Ye. et. al. 2018; Lee W. et.al.,2021; Zheng, Y.et. al. 2022; Liu, Y. et.al.,2023) A Convolution layer uses a set of filters on feature maps from the previous layer to produce a new feature map. The pooling layer processes small rectangular image regions from the convolution layer and reduces them to a single value that creates a more compact representation. (Y. Zhang et.al.,2021; F. Ye. et. al. 2018) Various types of pooling techniques are used including max pooling and average pooling. The highest value within the defined window is passed to the subsequent layer in max pooling, whereas in average pooling, it computes the average of all values within that window. (Y. Zhang et.al.,2021;

F. Ye. et. al. 2018) A Convolutional Neural Network (CNN) trained on a large-scale dataset like ImageNet can extract mid-level and high-level image features that perform better than low-level features. These higher-level features capture more complex patterns and structures, such as shapes and objects, than low-level features like edges and textures. This capability makes CNNs highly effective for various visual recognition tasks. (Y. Zhang et.al.,2021; F. Ye. et. al. 2018; Lee W. et.al.,2021; Zheng, Y.et. al. 2022; Liu, Y. et.al.,2023; Ma, T. et.al.,2020) Famao Ye extracts image features from CNN combines SIFT and CNN features and then integrates them into the PSO-SIFT algorithm for registration. (F. Ye. et. al. 2018) Remote sensing image registration using CNN gives deep matching features and it improves the accuracy of remote sensing images. (Y. Zhang et.al.,2021; F. Ye. et. al. 2018) Image registration using a CNN-based model can be designed to learn a similarity function that directly compares the image patches based on image data. image patches directly from the image data. (F. Ye. et. al. 2018; Lee W. et.al.,2021)CNN can produce feature representations that are more robust to variations in appearance. CNN partitions the input image into several local patches, extracting descriptors separately. (F. Ye. et. al. 2018; Lee W. et.al.,2021) The similarity between extracted descriptors is then evaluated using a suitable distance measure, enabling an accurate similarity score. (F. Ye. et. al. 2018; Lee W. et.al.,2021) This approach can be used for binary classification tasks, such as identifying whether two patches correspond to the same or different features. (F. Ye. et. al. 2018; Lee W. et.al.,2021)Lee. W. proposed a (Matchet) Geometry CNN-based image registration method that can enhance the accuracy of aligning two remote sensing images captured at different times and from varying viewpoints. (Lee W. et.al.,2021; Wang, S. et.al.,2018; Yang, Z. et.al.,2018; Gong, M. et.al.,2017)

Pre-trained VGG16 Model

The VGG16 Model pre-trained on ImageNet was fine-tuned using SAR and PAN image datasets. The extraction of image features in this model excludes the fully connected layer at the top of the VGG16 model. The model contains multiple convolution layers organised into blocks such as block1_conv1, block2_conv1, etc. This extracts various features using the SIFT algorithm and measures the similarity of different image features. The CNN model employed in this letter, VGG16, is a simple competitive CNN architecture which won second place on the ILSVRC2014 classification task. The VGG16 model consists of 13 convolution layers, five max-pooling layers, with three fully connected (FC) Layers (Li, X. et.al.,2022; Y. Liu et.al.,2023; Ms. Priyanka S. Tondewad et. al., 2020).

GAN (Generative Adversarial Network)

Generative Adversarial Networks (GANs) have become a widely used approach in deep learning. They consist of two components: a generator and a discriminator. The generator is designed to create realistic images, while the discriminator's role is to differentiate between genuine and generated images. (Zhang X et.al.,2021; K. Chauhan et.al.,2023;Y. Liu et.al.,2023;Ma, T. et.al.,2020;Du, W. et.al. 2020)The process is the same as a "two-person game". Both networks seek to optimize opposing objectives. CNN, which excels at analysing data and extracting features, GAN specializes in data generation. The flow chart of Image registration using GAN is shown in Figure 4. They enhance datasets through adversarial learning, producing synthetic images that help reduce modality differences.(Zhang X et.al.,2021; Y. Liu et.al.,2023; Dai, H. et.al.,2021; Zeng, L. et.al.,2020; Wang, S. et.al.,2018)

DATA ANALYSIS AND RESULTS

Here, Different remote-sensing SAR and PAN image pairs were used to discuss the proposed algorithm's performance quality and reliability.

Experimental Result

Image registration algorithms SIFT and SURF results were compared with the CNN model VGG16 to evaluate the feature matching ratio between the Reference image and the sensed image. These methods are all implemented under OpenCV on a PC with 11th Gen Intel(R) Core (TM) i5-11260H @ 2.60GHz 2.61 GHz,16 GB.

Evaluation Parameters

To empirically validate the performance of an algorithm, we use two evaluation criteria to evaluate the performance as follows.

- RMSE (Root-Mean-Square Error) is calculated using all matched points. It manually selects N corresponding point *pairs (xi,yi), (xi',yi')* from reference and sensed images to ensure the accuracy of the transformation parameter. The RMSE is calculated as follows: Where (xi'',yi'') denotes the transformed coordinates of*(xi',yi').*

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}((x_i' - x_i'')^2 + (y_i' - y_i'')^2)} \quad (1)$$

- N is the number of correct correspondences detected between key points by matching a pair of reference and sensed images.
- 3) Accuracy is calculated based on the ratio of good matches to the total number of matching point pairs.

Various feature-matching traditional image registration methods are embraced for experiments: SIFT, SURF and VGG16 Deep learning model. Table 1 measures parameters such as RMSC, the number of matching features in both images and the accuracy of feature matching points.

Experiment 1

Feature extraction of SAR and PAN image pairs used SIFT and SURF to extract the features of remote sensing images. Image feature extraction and feature matching using SIFT is shown in Figure 6, and using SURF is shown in Figure 7. The same image pairs are used in the VGG16 model to extract image features. Extracted features of images using SIFT and SURF and fine-tuning the pre-trained model VGG16 are shown in table-1. It has been observed that SURF and SIFT generate fewer matching points when extracting features from SAR images compared to PAN images. However, VGG16 gives higher accuracy compared to SURF and SIFT. Image feature extraction using VGG16 Model is shown in Figure 5 at three different layer block1_conv1, block3_conv1, and block5_conv1 over the reference and sensed image.

Experiment 2

To verify the robustness of the VGG16 method, four SAR image pairs and one PAN image pair of remote-sensing images with deep features are tested. Various evaluation parameters, such as matched key point, RMSC and accuracy of image features using VGG16, have higher accuracy compared to SURF and SIFT, are listed in Table 1. Feature Matching using VGG16 gives higher accuracy at the block3_conv1 layer. The table below shows that the pre-trained VGG16 model has good features for processing the remote sensing images.

CONCLUSION

In this article, we present a novel feature extraction method for remote sensing images using SIFT, SURF and CNN Features. We utilize different remote sensing SAR and PAN images. The experimental results on multi-sensor images demonstrate that the fine-tuning pre-trained VGG16 model outperforms SURF and SIFT in terms of matching point accuracy and thecorrect matching points.

Future Work

In Future, we plan to work on CNN models such as Alex Net (Ren, C. et.al.,2020), Google Net (Ren, C. et.al.,2020) and Super Point and Super Point algorithms for image feature extraction and feature matching. (Sarlin, P.-E et.al, 2018; DeTone, D. et.al 2020)

ABSTRACT

Sciatica represents a debilitating condition characterized by excruciating pain and paraesthesias in the Sciatic nerve distribution or associated lumbosacral nerve root, which severely impact the quality of life of those affected. The Sciatic nerve plays a pivotal role, providing direct motor function to the posterior compartment thigh muscles and lower extremity adductors and indirect motor function to calf muscles, anterior lower leg muscles and intrinsic foot muscles. Its terminal branches indirectly contribute to sensation in the posterior and lateral lower leg and plantar aspect of foot. Marmas are important landmarks which is first ever explained in medical science, which gave importance to applied anatomy. Knowledge of AdhaSakha Marma plays a key role in treatment of Sciatica. Marma therapy aims to release blockages, balances energies & encourage body's innate healing abilities. The detail explanation of marma will be discussed in Paper. The purpose of this paper is to highlight how the knowledge of marma incorporating in treatment of Sciatica effectively improve the lives of patients suffering from Sciatica.

Keyword: Sciatic Nerve, Adhsakha Marma,

INTRODUCTION

Sciatica is a debilitating condition characterized by excruciating pain &paresthesia in the sciatic nerve distribution or associated lumbosacral nerve root. Its life time incidence is 13 % - 40% and rarely happens before age of 20 unless its injury related. Sciatic nerve is the nerve of posterior compartment of thigh with root value L4-S3. It divides into two branches just above popliteal fossa to Tibial & Common peroneal nerves [1].It contains both anterior & posterior division of lumbosacral plexus and leaves the pelvis through greater sciatic foramen below piriformis to enter gluteal region descends between greater trochanter & ischial tuberosity along back of thigh.[2] The nerve has both Motor & Sensory supply. The motor supply is directly to all muscles of back of thigh & indirectly through its branches to all muscles of leg & foot. The sensory supply is to whole leg both dorsal & plantar surfaces of foot. [3]The clinical presentation of sciatica is radicular pain from lower back down the buttocks, back of thigh, back of calf or sole of foot, sensory impairment in legs, muscular weakness, reflex impairment, gait dysfunction, paresthesia/ dysesthesias, edema in the lower extremity. The common causes include herniated disc, spinal stenosis, Piriformis Syndrome, spondylolisthesis, Back Injury, Bone spurs, Obesity.

The probable pathophysiology of pain occurs mainly through two mechanisms: compression and inflammation. Compression, microscopic venous stasis causes congestion of the vasa nervorum, which leads to radiculopathy. Compression also reduces blood flow to the nerve root, resulting in ischemia and formation of intraneural edema. This further causes demyelination and produces pain within the nerve root. In inflammation, histamines and bradykinin are released, which activate nociceptors. These nociceptors then transmit pain signals to the brain, leading to the sensation of pain. According to Acharya Sushruta, Marma points are the junction of five anatomical structures like Mamsa (muscle), Sira (vessels), Snayu(ligaments/ nerves), Asthi (bones) and sandhi (joints). These are very important vital places where Prana (vital life force) resides.[4] Stimulation of Marma points channelizes Prana vayu and maintains equilibrium of Doshas.[5]In Sciatica or Grdrasi, the patient has limping walk due to pain and stiffness. The adhasakha (lower limb) marmas like lohitaksha, Urvi, Ani, Janu, Indrabasti,Gulpha, Kurchashiras, Kurcha, Talahrdaya, Kshipra and Prishta marma Kukundara[6] are considered for study.

Objectives as Proposed

Primary Objective:

- To conceptually analyze the role of Adhasakha Marma therapy in the management of Sciatica

Secondary Objective:

- To understand the Ayurvedic theoretical framework around Marma points related to the sciatic nerve.
- To assess the potential pathways through which Adhasakha Marma Therapy may relieve pain and inflammation in sciatica.
- To propose a preliminary model for integrating Marma therapy in clinical practice for sciatica management.

Objectives achieved

Primary Objective:

- The conceptual role of Adhsakha Marma therapy in the management of Sciatica has been thoroughly analyzed.

Secondary Objectives:

- The Ayurvedic theoretical framework surrounding Marma points associated with the sciatic nerve has been clearly understood and articulated.
- The potential pathway through which Adhsakha Marma therapy alleviates pain and inflammation in sciatica have been effectively assessed
- A preliminary model for integrating Marma therapy into clinical practice for the management of sciatica has been successfully proposed.

METHODOLGY

Design: Conceptual and Qualitative.
Data Sources:

- Primary : Classical Ayurvedic texts
- Secondary: Peer – reviewed journals from PubMed, JSTOR, Scopus.

Analysis Tools:

- Thematic analysis using NVivo.
- Comparative correlation mapping between anatomical sciatic pathways and Marma locations.

Ethical Considerations: Proper citations and respect for traditional knowleda were maintained. No human or animal subjects were involved.

RESULTS

Conceptual Correlation of Adhasakha Marma with Sciatic Pathway
Comparative Analysis:

- Marma therapy suggests pressure stimulation to modulate Vata dosha, which is associated with nerve function.
- Conventional medicine relies on anti – inflammatory and mechanical decompression.
- Proposed model integrates both systems for synergistic benefit

DISCUSSION

This conceptual analysis emphasizes the therapeutic significance of Adhasakha Marma points in the management of sciatica. Sciatica is typically caused by compression or irritation of the sciatic nerve or its branches – tibial and deep peroneal nerves – often resulting in pain, numbness or weakness in the lower limb. These nerves are anatomically aligned with key Marma points such as Kshipra, Talahrdaya, Gulpha, Indravasthi, Janu, Ani, Urvi, Lohitaksha and Kukundara making these locations particularly relevant for targeted Ayurvedic intervention. Most Marma points are superficial located near the skin, muscles, ligaments, nerves and blood vessels. This unique positioning allows non – invasive stimulation (e.g via gentle pressure or massage) to directly influence the underlying neurovascular structures. This stimulation facilitates several physiological processes, including:

Enhanced Microcirculation
Stimulation of Adhasakha Marma points produces vasodilation and improves capillary blood flow around the affected nerves and muscle tissues. This enhancement of microcirculation increases oxygen delivery and nutrient supply, both of which are essential for proper nerve function and tissue regeneration. Improved circulation also facilitates efficient lymphatic drainage, helping to reduce local inflammation and edema that frequently contribute to compression of the sciatic nerve. By minimizing stagnation and improving tissue perfusion, Marma therapy creates favorable conditions for symptomatic relief and recovery.

Promotion of Tissue Repair and Healing
Gentle stimulation of Marma points is believed to activate local healing mechanisms, including fibroblast activity and tissue regeneration processes. These effects may support the repair of connective tissues and the myelin sheath surrounding damaged nerves. In addition, Marma therapy helps modulate pro-inflammatory cytokines and encourages anti-inflammatory healing responses. By improving circulation and relieving muscular tension, it establishes a supportive microenvironment for the repair of muscles, fascia, and peri-neural tissues affected by chronic sciatica. This regenerative effect contributes not only to pain relief but also to restoration of tissue integrity and function.

Neurovascular and Musculoskeletal Modulation

Many Marma points are anatomically located near important neurovascular bundles. Their stimulation may influence somatic afferent pathways and help reset abnormal pain signaling mechanisms. Marma therapy also aids in releasing myofascial tension, thereby reducing mechanical compression on the sciatic nerve, especially in conditions such as piriformis syndrome–related sciatica. Through relaxation of tight muscles and restoration of soft tissue flexibility, the therapy improves the functional alignment of muscles, tendons, and ligaments of the lower limb. Consequently, patients experience enhanced mobility, balance, and musculoskeletal coordination.

Energetic and Dosha-Based Perspective

From the Ayurvedic perspective, Gridhrasi primarily results from aggravation of *Vata Dosha*. Stimulation of Adhasakha Marma points helps pacify *Vata*, particularly *Apana Vata*, which governs the functions of the lower part of the body. Improved circulation and nerve stimulation also promote the smooth flow of *Prana* through the *Srotas* (body channels), restoring energetic balance and systemic vitality. Thus, Marma therapy not only addresses physical symptoms but also supports overall physiological and energetic harmony.

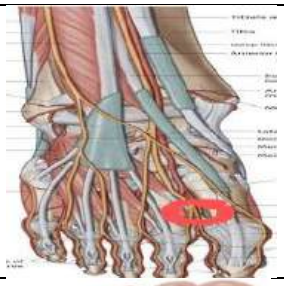
Integrated Benefits of Adhasakha Marma Therapy in Sciatica

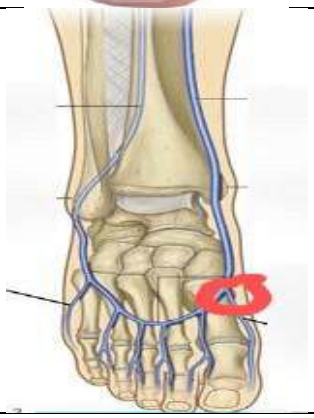
Adhasakha Marma therapy offers a comprehensive therapeutic effect in sciatica through multiple mechanisms. Enhanced microcirculation improves oxygen and nutrient supply to nerves and soft tissues. Reduction of inflammation relieves nerve compression symptoms. Activation of tissue repair mechanisms promotes healing of nerve sheaths, muscle fibers, and fascia. Pain modulation occurs through gate control mechanisms and endogenous endorphin release. Simultaneously, regulation of *Dosha* and *Prana* helps restore systemic balance and vitality.

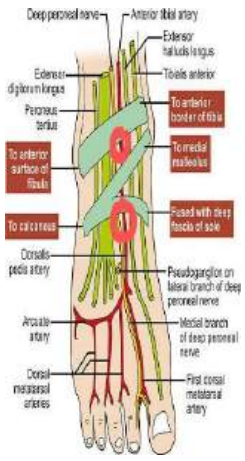
CONCLUSIONS

This conceptual study provides a comprehensive analysis of the role of Adhasakha Marma therapy in the management of Sciatica (Grdhrasi) by integrating traditional Ayurvedic knowledge with modern anatomical and physiological understanding. The eleven identified Adhasakha Marma points including Kukundara, were studied in detail for their locations, measurements, structural classifications and correlation with key neurovascular structures implicated in sciatica, particularly the sciatic nerve, deep peroneal nerve and tibial nerve. So the Adhasakha Marma therapy presents itself as a scientifically plausible and clinically promising complementary approach to Sciatica management. By leveraging both anatomical precision and energetic regulation, this therapy embodies a holistic, patient centered strategy with potential to reduce reliance on pharmacological treatments. It promotes functional recovery, improves mobility and addresses both the root cause and symptoms of Sciatic nerve irritation.

Future Scope







- Clinical trials are necessary to empirically validate the analgesic and regenerative effects of Marma therapy on Sciatic pain.
- Quantitative studies using Doppler Imaging, Thermography and nerve conduction studies can evaluate the physiological responses (eg : microcirculation, nerve conductivity)
- Protocol development for standising pressure application, duration and frequency in clinical settings.
- Interdiciplinary collaborations between Ayurvedic practitioners and neurologists to explore intergrative pain clinics.

ABSTRACT

Baobab (*Adansonia digitata* L.) is a nutrient-rich medicinal plant widely studied for its potential in managing metabolic disorders. Its fruit pulp contains bioactive compounds such as vitamin C, polyphenols, flavonoids, tannins, and pectin, which exhibit antioxidant, antidiabetic, anti-inflammatory, and cardioprotective properties. However, the therapeutic application of these phytochemicals is limited due to poor aqueous solubility, instability, and low bioavailability.[1] Nanosuspension technology offers an effective drug delivery approach to overcome these challenges by reducing particle size, thereby enhancing dissolution rate, solubility, and absorption of poorly soluble compounds. This review summarizes the formulation techniques, characterization methods, and therapeutic advantages of baobab-based nanosuspensions.[4] It also highlights their potential in improving the effectiveness of bioactive compounds for treating metabolic disorders such as diabetes, obesity, and cardiovascular diseases. Recent advancements in nanotechnology and its integration with herbal medicine are also discussed, along with safety considerations and future research directions [3]. Overall, baobab nanosuspensions represent a promising strategy to enhance the pharmacological performance of plant-derived compounds and broaden their application in pharmaceutical and nutraceutical industries.[2]

Keywords: Baobab (*Adansonia digitata* L.); nanosuspension; metabolic disorders; bioavailability enhancement; nanotechnology; herbal drug delivery; phytochemicals; therapeutic efficacy

INTRODUCTION

Africa is a significant reservoir of medicinal plants rich in bioactive compounds with therapeutic potential. Among these, *Adansonia digitata* L., commonly referred to as baobab, is extensively found in sub-Saharan Africa and Madagascar. Traditionally, various parts of the baobab tree have been used in foods, beverages, and indigenous medicinal practices.[8] Baobab fruit pulp is highly nutritious, providing abundant vitamin C, both soluble and insoluble dietary fiber, essential minerals, and polyphenolic compounds such as flavonoids and tannins. These components are responsible for its notable antioxidant activity and role in regulating metabolic functions.[12](Figure 1). Recent studies suggest that baobab fruit pulp powder exhibits prebiotic properties due to its pectin-rich polysaccharides, particularly low-methylated homogalacturonan. In vitro fermentation findings show increased production of short-chain fatty acids, including acetate, propionate, and butyrate, indicating selective utilization by beneficial gut microbiota. Disruptions in gut microbiota and increased intestinal permeability are linked to conditions such as obesity, type 2 diabetes, and cardiovascular diseases. The movement of bacterial endotoxins like lipopolysaccharides into circulation contributes to chronic low-grade inflammation, marked by elevated TNF-α and IL-6 levels. Dietary fiber intake plays a crucial role in improving gut microbial balance and strengthening intestinal barrier integrity.[10].

Clinical studies further indicate that baobab extract can lower postprandial blood glucose levels, reduce insulin response, and promote satiety. However, the limited water solubility of its phenolic compounds hinders their absorption and overall bioavailability, highlighting the need for advanced delivery systems. Advancements in nanotechnology have significantly transformed drug delivery systems, offering effective strategies to address the shortcomings of traditional formulations. Although herbal medicines have been widely used for centuries, their therapeutic application is often limited by factors such as inconsistency in active components, poor stability, and variable clinical outcomes. These limitations are particularly evident in phytochemicals that exhibit low solubility in water and inadequate absorption in the gastrointestinal tract, ultimately affecting their effectiveness.[7]. Nanosuspension technology has gained attention as an efficient approach to improve the delivery of such poorly soluble compounds. These formulations are composed of fine dispersions of drug particles in the nanometer size range, stabilized using suitable surfactants or polymers. The reduction in particle size enhances surface area, which in turn increases dissolution rate and saturation solubility. Additionally, improved adhesion to biological surfaces promotes better absorption, resulting in enhanced bioavailability.[13]

The utilization of nanosuspension systems for plant-based therapeutics, including Adansonia digitata L., is an emerging area of research with considerable potential. Although baobab has demonstrated a range of beneficial pharmacological activities, its formulation into advanced delivery systems is still at an early stage. Converting baobab-derived bioactive compounds into nanoscale formulations may help overcome challenges such as low solubility, instability, and limited systemic distribution. Moreover, nanosuspensions provide several advantages, including the possibility of lowering required dosages, enhancing targeted delivery, and improving patient adherence to treatment. These features are particularly important in the long-term management of chronic metabolic conditions such as obesity and Type 2 Diabetes. Improved delivery of baobab bioactives could support better regulation of metabolic processes, enhanced glucose control, and mitigation of oxidative damage.[11]

However, despite these advantages, certain challenges must be addressed, including issues related to scalability, formulation stability over time, regulatory considerations, and the need for standardization of herbal-based nanosystems. Furthermore, extensive in vivo investigations and clinical evaluations are essential to establish their safety, efficacy, and pharmacokinetic benefits. Overall, combining traditional medicinal knowledge of baobab with modern nanotechnology offers a promising pathway for developing advanced herbal therapies. Continued research is necessary to bridge existing gaps and fully realize the potential of baobab nanosuspensions in the treatment of metabolic disorders.[14]

THEMATIC REVIEW

Metabolic disorders:

Metabolic disorders such as type 2 diabetes mellitus, obesity, and dyslipidemia are now recognized not as isolated conditions but as interrelated components of metabolic syndrome. This syndrome is characterized by a complex network of abnormalities, including insulin resistance, persistent low-grade inflammation, oxidative stress, and disturbed lipid metabolism. At the molecular level, these conditions arise from dysregulation of several key signaling pathways, including insulin receptor signaling, the AMP-activated protein kinase (AMPK) pathway, peroxisome proliferator-activated receptors (PPARs), and inflammatory pathways such as NF-κB.

Conventional treatment strategies typically focus on a single target, which often necessitates the use of multiple medications. This polypharmacy approach can increase adverse effects and reduce patient adherence. As a result, there is growing interest in plant-based therapies that naturally exert multi-target pharmacological effects. Among such medicinal plants, *Adansonia digitata L.* (baobab) has emerged as a promising functional food with wide-ranging metabolic benefits. However, converting its traditional therapeutic use into effective modern medicine requires addressing key formulation challenges, where nanosuspension technology plays a significant role.

Baobab as a Functional Phytotherapeutic Agent

Baobab is commonly referred to as a "superfruit," though its medicinal importance extends well beyond its nutritional value. Different parts of the plant—including fruit pulp, leaves, seeds, and bark—contain diverse bioactive compounds with significant pharmacological potential.

Phytochemical Complexity and Synergistic Action

The therapeutic efficacy of baobab is attributed to its rich and complex phytochemical composition, which includes polyphenols (such as flavonoids, phenolic acids, and procyanidins), tiliroside (a compound associated with lipid regulation), high vitamin C content, dietary fibers (both soluble and insoluble), and essential minerals like potassium, calcium, and magnesium. Unlike single-compound synthetic drugs, these phytochemicals do not act independently. Instead, they function synergistically, enhancing one another's biological activities. This multi-component interaction is particularly advantageous in metabolic disorders, where multiple physiological pathways are simultaneously disrupted.[13]

Mechanisms of Action in Metabolic Disorders (Paraphrased)

Glycemic Control

Baobab exhibits notable antidiabetic activity through multiple biological mechanisms. A key action involves the inhibition of carbohydrate-digesting enzymes, particularly α-amylase and α-glucosidase, which are responsible for converting complex carbohydrates into glucose. By slowing this enzymatic breakdown, baobab helps reduce rapid increases in post-meal blood glucose levels. Furthermore, bioactive constituents in baobab enhance insulin sensitivity by promoting glucose uptake in peripheral tissues. This combined effect—limiting glucose release while improving cellular utilization—supports its effectiveness in managing type 2 diabetes mellitus.[14]

Lipid Regulation

Dyslipidemia, a key feature of metabolic syndrome, can also be positively influenced by baobab consumption. It has been reported to help lower total cholesterol and triglyceride levels while reducing low-density lipoprotein (LDL) and increasing high-density lipoprotein (HDL). Among its phytochemicals, tiliroside plays an important role in lipid homeostasis by modulating enzymes involved in both lipid synthesis and degradation, thereby contributing to improved metabolic balance.

Anti-Inflammatory Effects

Chronic low-grade inflammation is a key contributor to the development and progression of metabolic disorders. The polyphenolic compounds present in baobab help attenuate this process by downregulating inflammatory mediators such as cytokines and prostaglandins. As a result, systemic inflammation is reduced, leading to improved overall metabolic function.

Antioxidant Defense

Oxidative stress is a major feature of metabolic diseases and arises due to an imbalance between reactive oxygen species (ROS) production and the body's antioxidant defenses. Baobab contains high levels of antioxidants, especially vitamin C and polyphenols, which play a protective role by neutralizing free radicals, safeguarding pancreatic β-cells, and inhibiting lipid peroxidation.

Gut Microbiome Modulation

An increasing area of research focuses on the influence of the gut microbiome on metabolic health. The high dietary fiber content of baobab functions as a prebiotic, supporting the proliferation of beneficial intestinal microorganisms. These microbes generate short-chain fatty acids (SCFAs), which contribute to improved insulin sensitivity, reduced inflammatory responses, and enhanced energy metabolism.

Limitations of Conventional Baobab Formulations

Although baobab possesses a strong pharmacological profile, its application in conventional dosage forms such as powders, capsules, or crude extracts is associated with several limitations.

A major concern is its poor solubility, particularly of polyphenolic constituents, which restricts efficient absorption in the gastrointestinal tract. Moreover, many of its bioactive compounds are chemically unstable, prone to degradation during digestion, and rapidly metabolized in the liver. Together, these factors lead to low bioavailability, with only a limited portion of the administered dose reaching systemic circulation in an active form.

In addition, there is considerable variability in the phytochemical composition of baobab, influenced by factors such as geographical origin, harvesting practices, and processing techniques. This inconsistency can result in variable therapeutic efficacy and challenges in standardization.

Nanosuspension Technology: A Transformative Approach

Nanosuspensions are an advanced drug delivery system designed to overcome the drawbacks of conventional herbal formulations. They consist of colloidal dispersions of drug particles reduced to the nanometer scale and stabilized using suitable surfactants or polymeric agents.[15]

Advantages of Nanosuspensions

A major benefit of nanosuspension systems is their ability to significantly improve solubility and dissolution rate. Based on the Noyes–Whitney principle, decreasing particle size leads to an increase in surface area, which subsequently enhances the dissolution process.

In the case of baobab, this results in:

- Accelerated release of bioactive constituents
- Enhanced gastrointestinal absorption
- Increased overall bioavailability

Baobab Nanosuspension: Mechanistic Insights

Improved Bioavailability and Absorption

Formulating baobab extract into a nanosuspension markedly enhances its interaction with biological membranes due to the significantly reduced particle size. This results in greater intestinal permeability and more efficient entry of bioactive compounds into systemic circulation. Consequently, comparable or enhanced therapeutic effects can be achieved using lower doses than those required in conventional formulations.

Enhanced Enzyme Interaction

The nanoscale dimensions of baobab particles facilitate more efficient contact with digestive enzymes. This improves their inhibitory potential against α-amylase and α-glucosidase, thereby contributing to more effective regulation of post-meal blood glucose levels.

Protection of Bioactive Compounds

Nanosuspension systems offer a stabilizing matrix for sensitive phytochemicals, protecting them from degradation caused by oxidation, fluctuations in gastrointestinal pH, and enzymatic activity. This protective effect helps preserve the integrity of the active constituents, allowing a higher fraction to reach the intended site of action in an active form.

Sustained Release and Pharmacokinetic Improvement

An additional key benefit of nanosuspension systems is their capability to provide controlled or prolonged drug release. This results in more consistent plasma drug levels over an extended period, thereby decreasing dosing frequency and enhancing patient adherence to therapy.

Methods of Preparation of Baobab Nanosuspension

Nanosuspensions can generally be produced using two main strategies: top-down and bottom-up approaches. In top-down techniques, larger particles are mechanically reduced to the nanoscale, while in bottom-up methods, nanoparticles are formed through controlled assembly from molecular or solution-based precursors.

For herbal substances such as *Adansonia digitata*, these approaches are especially valuable, as many of their active phytochemicals exhibit low solubility and limited stability in traditional formulation systems.

Ultrasonication

The ultrasonication method for preparing a baobab nanosuspension begins with accurately weighing the *Adansonia digitata* extract. This extract is then dispersed in an appropriate aqueous phase, followed by the incorporation of stabilizers such as Tween 80, Poloxamer 188, polyvinylpyrrolidone, or hydroxypropyl methylcellulose to maintain system stability. The mixture is initially homogenized using magnetic stirring to ensure uniform particle distribution.(Figure 2) . Thereafter, the dispersion is exposed to ultrasonic energy using either a probe or bath sonicator. High-frequency sound waves generate acoustic cavitation, in which microscopic bubbles form and collapse, producing strong shear forces that progressively reduce particle size. The process is carried out for a defined time under controlled temperature conditions to avoid thermal degradation of heat-sensitive phytoconstituents. With continued sonication, particles are reduced to the nanometer scale, yielding a stable nanosuspension. The final formulation is then cooled if required and stored under suitable conditions for further analysis.[15](Table 2)

High-Speed Homogenization

In the high-speed homogenization technique, the baobab extract is first dispersed in a suitable liquid medium containing stabilizing agents to prevent particle aggregation. This initial mixture is gently stirred to obtain a coarse, uniformly distributed suspension. The pre-suspension is then processed in a high-speed homogenizer equipped with a rotor–stator system. The equipment operates at high speeds, typically between 10,000 and 25,000 rpm, generating intense shear forces, turbulence, and pressure gradients. These mechanical effects progressively break down particles into finer sizes. The homogenization is generally performed over several cycles to achieve a uniform nanoscale distribution. Throughout the process, temperature is carefully monitored to prevent degradation of thermolabile bioactive compounds present in baobab. After completion, the resulting nanosuspension is collected and allowed to stabilize, forming a homogeneous and finely dispersed system suitable for further evaluation.[16]

Anti-Solvent Precipitation

The anti-solvent precipitation method begins with dissolving the baobab extract in a suitable organic solvent that ensures complete solubilization of its active constituents, forming a clear solution. Separately, an aqueous anti-solvent phase containing stabilizers is prepared. The organic phase is then introduced gradually or rapidly into the anti-solvent under constant stirring. This sudden change in solvent environment causes a sharp reduction in solubility, resulting in a supersaturated state. This condition initiates rapid nucleation, where fine particles are formed almost instantaneously. As mixing continues, these nuclei grow into nanoparticles, while stabilizers adsorb onto their surfaces to prevent aggregation and control particle growth. Critical process parameters such as addition rate, stirring speed, and temperature are optimized to ensure uniform particle formation.After precipitation, the organic solvent is removed using evaporation or other suitable techniques, yielding a stable nanosuspension. The final product is then collected and stored appropriately for subsequent characterization and applications.[16]

Role of Stabilizers

Irrespective of the preparation technique employed, stabilizers play a crucial role in ensuring the physical stability of nanosuspensions. They prevent particle aggregation and maintain a uniform dispersion over time.
Frequently used stabilizing agents include:

- Tween 80, a surfactant that reduces surface tension
- Poloxamer 188, a non-ionic stabilizer that enhances dispersion stability
- Polyvinylpyrrolidone (PVP), which provides steric stabilization
- Hydroxypropyl methylcellulose (HPMC), used to improve viscosity and prevent particle coalescence

Evaluation tests

Particle Size and Polydispersity Index (PDI)

Particle size is a fundamental parameter in nanosuspension systems as it directly affects solubility, dissolution behavior, bioavailability, and overall therapeutic efficiency. For measurement, the nanosuspension is first suitably diluted to prevent multiple scattering effects, and then analyzed using techniques such as dynamic light scattering (photon correlation spectroscopy), laser diffraction, or Coulter counter methods. Among these, dynamic light scattering is most commonly used because it evaluates Brownian motion and translates it into particle size distribution.(Table 1).Along with particle size, the polydispersity index (PDI) indicates the uniformity of particles within the formulation. A PDI value in the range of 0.1–0.25 reflects a narrow and homogeneous size distribution, suggesting uniform particles. Higher PDI values indicate greater variability, which may contribute to instability through aggregation or uneven sedimentation. For herbal nanosuspensions like those derived from *Adansonia digitata*, achieving uniform particle distribution is particularly important due to the complex nature of plant-derived constituents. Together, particle size and PDI provide a reliable assessment of formulation quality and consistency.[17]

Zeta Potential

Zeta potential represents the surface charge of nanoparticles and is a key factor in predicting nanosuspension stability. It is determined using electrophoretic light scattering, where particle movement under an electric field is measured to calculate surface charge. In general, zeta potential reflects the degree of repulsion between particles. Higher absolute values (usually above ±30 mV) indicate strong electrostatic repulsion, which helps prevent aggregation and improves stability. In formulations stabilized with both polymers and surfactants, stability may arise from combined electrostatic and steric effects, known as electrosteric stabilization; in such systems, even values around ±20 mV may be sufficient. In baobab-based nanosuspensions, polymers not only impart surface charge but also create a protective coating around particles, enhancing long-term stability. Low zeta potential values suggest a higher tendency for aggregation, leading to sedimentation and reduced nanosuspension efficiency. Thus, zeta potential serves as both a stability indicator and a predictor of formulation shelf life.[13]

Saturation Solubility and Dissolution Rate

Enhancement of solubility and dissolution rate is one of the main objectives of nanosuspension development. Saturation solubility is assessed by adding excess nanosuspension to a solvent, followed by continuous shaking until equilibrium is achieved. The mixture is then filtered, and the dissolved drug concentration is measured using techniques such as UV–visible spectrophotometry. The improvement in dissolution can be explained by the Noyes–Whitney equation, which relates increased surface area to faster dissolution rates. Due to their nanoscale size, nanosuspensions provide a much larger surface area compared to coarse particles, leading to significantly improved dissolution. Dissolution studies are typically performed using standard apparatus under controlled conditions, with samples withdrawn at specific time intervals to determine release profiles. Enhanced dissolution improves absorption and in vivo performance, particularly for poorly water-soluble compounds. In baobab systems, this is especially important for polyphenols, which otherwise show limited bioavailability.

Stability Studies

Stability studies are conducted to evaluate the long-term behavior of nanosuspensions under different storage conditions. Formulations are stored at varying temperatures such as 15°C, 25°C, and 45°C, and monitored for changes in particle size, zeta potential, and physical appearance over time. In addition, thermal cycling tests are performed by alternating between high and low temperatures to simulate real-life storage conditions. Mechanical stress tests, including shaking and centrifugation, are also used to assess formulation robustness. A key instability phenomenon observed is Ostwald ripening, where smaller particles dissolve and redeposit onto larger ones, leading to gradual particle growth. This can compromise stability and performance. For herbal nanosuspensions, stability assessment is particularly important because natural phytochemicals may degrade or interact over time. A stable formulation should maintain consistent particle size, show no visible aggregation, and retain uniform drug content throughout the study period.

pH and Drug Content

pH measurement is an important quality parameter as it influences both stability and solubility of the formulation. It is determined using a calibrated digital pH meter to ensure accuracy. For oral applications, the pH should ideally be compatible with physiological conditions to avoid irritation and maintain stability. Drug content analysis is carried out to quantify the amount of active ingredient present in the nanosuspension. This typically involves extracting the drug using a suitable solvent followed by analysis using UV–visible spectrophotometry or other validated methods. This ensures uniform drug distribution and confirms that the formulation process has not led to significant loss of active compounds. In baobab-based nanosuspensions, maintaining consistent drug content can be challenging due to the complex nature of plant extracts. Therefore, this parameter is essential for ensuring dosing accuracy, reproducibility, and therapeutic effectiveness.[15]

RESULTS

Baobab fruit pulp exhibits notable antioxidant properties, contributes to glycemic control, and supports prebiotic activity through the generation of short-chain fatty acids. However, the therapeutic potential of its bioactive compounds can be limited by poor solubility. Nanosuspension technology addresses this limitation by reducing particle size to the nanometre scale, which significantly increases surface area, dissolution rate, and saturation solubility. As a result, the intestinal absorption and systemic bioavailability of poorly soluble phytoconstituents are markedly improved, leading to enhanced therapeutic effectiveness of herbal extracts. Key advantages of this approach include a faster dissolution rate, improved saturation solubility, increased bioavailability, high drug-loading capacity, and a reduced risk of adverse effects associated with excipients. Overall, nanosuspension-based delivery offers an efficient strategy to optimize the performance of bioactive compounds from baobab fruit pulp.

DISCUSSION

Baobab nanosuspensions have shown promising therapeutic potential across several biomedical and nutraceutical applications, including oral nutraceutical formulations, antioxidant therapy, immune-support supplements, functional beverages, and cosmeceutical products. In the context of diabetes management, nanosuspension-based delivery significantly enhances the bioavailability of baobab-derived polyphenols and vitamin C, leading to improved inhibition of carbohydrate-hydrolyzing enzymes such as α-amylase and α-glucosidase. This contributes to reduced postprandial hyperglycemia, improved insulin sensitivity, and protection of pancreatic β-cells against oxidative stress-induced damage. The enhanced antioxidant delivery further helps in neutralizing reactive oxygen species, thereby supporting better glycemic control. In addition, baobab nanosuspensions demonstrate notable cardiovascular protective effects, particularly relevant in diabetes-associated complications. Increased systemic availability of its phytoconstituents helps reduce lipid peroxidation, suppress pro-inflammatory cytokine production, and improve endothelial function. They also contribute to favorable modulation of lipid profiles, thereby addressing key risk factors associated with cardiovascular disease. Overall, the combined metabolic and cardioprotective actions highlight baobab nanosuspensions as a promising and multifunctional strategy for the management of metabolic syndrome and its associated complications.

Baobab fruit pulp–based nanosuspension offers a novel and scientifically promising strategy to overcome solubility and bioavailability limitations of conventional formulations. Nanosizing enhances dissolution rate, antioxidant activity, and therapeutic performance of its bioactive constituents. Although current evidence supports its nutraceutical and pharmaceutical potential, comprehensive in vivo studies, toxicity assessments, and scale-up investigations are essential prior to clinical translation.

ACKNOWLEDGEMENT

The authors sincerely acknowledge their institution for providing the essential facilities and academic environment necessary for completing this review article. We extend our heartfelt gratitude to the faculty members and colleagues of the Department of Pharmaceutics/Pharmaceutical Sciences for their continuous support, guidance, and valuable suggestions throughout the preparation of this manuscript. Their constructive feedback played a key role in enhancing the quality of this work. The authors also wish to thank the researchers whose published studies served as an important foundation for this review. Lastly, we are grateful to all the scientific literature sources that contributed to the successful completion of this article.

ABSTRACT

The drive to develop surveillance infrastructure in both public and commercial spheres has led to more sophistication in the requirement to develop smart systems with the capacity to detect multi-faceted, context-oriented security threats. Traditional CCTV based surveillance systems are very dependent on human personnel and they are not usually good in identifying such subtle but dangerous activities like people staying in their cars longer than expected. This paper proposes a smart video surveillance system that is based on deep learning and temporal analysis to identify long human occupancy within immobile vehicles. The suggested scheme combines vehicle and person detection by YOLO with occupancy checking and time-loitering evaluation in order to differentiate between normal and suspicious vehicle occupancies. On identifying abnormal conditions, the system sends real time alerts in various communication channels such as visual overlays, SMS, email messages, and logging on a database. This proposed system is edge-friendly, can safely be deployed in areas of practical surveillance, including occlusion, lighting conditions, and poor connectivity. The practicality of the method to improve the situational awareness and active security observation within the parking areas is proven by experimental observations.

Keywords: Intelligent surveillance, Vehicle loitering detection, YOLO, Human occupancy detection, Deep learning, Edge computing.

INTRODUCTION

The high population density and the increased urbanization have intensified the fears in terms of road security, malpractice of vehicles by criminals, and security of important structures, which have burdened the traditional

CCTV security system. Conventional surveillance is highly reliant on human operators whose operational performance is compromised in large volume video feeds and leads to sluggish response and high-risk activities in a complicated traffic scenario as observed by Llorca et al. [10]. Deep-learning object detectors, specifically the You Only Look Once (YOLO) family, have transformed single-stage computer vision that is jointly optimized both in speed and accuracy as described by Terven et al. [1], Sapkota et al. [2], and Wang and Liao [5]. Moreover, Wang and Liao [5] and Hussain [8] show that the consecutive steps of the YOLO, the YOLOv1, to YOLOv10 allow considering the significant increase in the accuracy of detection, the decrease in the latency, and the increase in the efficiency of the deployment. Due to these developments, these models can be best utilized with safety-critical systems, including autonomous driving, and traffic monitoring, which has been supported by Sapkota et al. [2], Wang and Liao [5], and Hussain [8]. The superiority of YOLO in different areas of use is also illustrated by the extensive deliberations presented by Terven et al. [1] and Ali and Zhang [3], which highlight that it is stronger to work under dynamic environments and that it could relate more to the edge devices to deliver low-latency inferences.

In the specific field of automobile environment, according to Kosasi et al. [6], YOLO variants (e.g., YOLOv4, YOLOv8) are routinely able to achieve vehicle detection rates of 90 percent or above in mixed weather and lighting. Nevertheless, it is still hard to cope with mini-sized objects and extreme light. Llorca et al. [10] also provide information about the increased use of YOLO in vision-based vehicle speed estimation and speed enforcement systems, pointing out that in order to take proactive safety-based actions, real-time detection is needed. The concomitant advancements in the AI-based threat detection show that machine learning can evolve into the vigilant prevention of risk instead of passive monitoring. The article presented by Kheddar [9] proves that the sophisticated, dynamic patterns of threats in the cyber-physical systems can be identified with the help of advanced deep models, including transformers and hybrid architectures. These models emphasize the importance of explainability, robustness and real-time response in deployments of security related nature. However, most of the existing implementations of YOLO-based vehicle use are focused on generic detection or post-detection analysis rather than proactive vehicle threat detection. In proactive detection, the challenge is to detect possible dangerous vehicles or actions, such as abnormal paths, excessive speed, or hanging around the sensitive zones, before things get out of control. This gap is explicitly stated in surveys of the history of YOLO and its use by Terven et al. [1], Sapkota et al. [2], Ali and Zhang [3] and Gallagher and Oughton [4], which require context-sensitive, multimodal and security-enhanced real-time detectors.According to this gap, this paper proposes an AI-based active vehicle threat detection system based on a current YOLO framework to run smart surveillance systems. The suggested architecture is an expansion of the works of Terven et al. [1], Sapkota et al. [2], and Wang and Liao [5], seeking to give rise to a scalable, robust deployment. This system complements the real-time vehicle detection based on the YOLO algorithm with risk-aware driving behavior analysis and automatic notification.

LITERATURE REVIEW

Object detection in deep learning has become part of intelligent transportation systems (ITS) and smart surveillance and has since replaced traditional image-processing pipelines due to its much better resistance to occlusion, changing lighting, and heavy traffic, as demonstrated by Farid et al. [14], Liang et al. [17], and Shokri et al. [18]. It is on this framework that the YOLO (You Only Look Once) family of one-stage detectors is appealing since they cast detection to a one-regression problem enabling real-time inference at scalable accuracies, which is a crucial quality to proactive monitoring and early response in safety-critical settings, as discussed by Farid et al. [14] and Liang et al. [17]. The relative studies of YOLO with other more recent multi-stage algorithms such as Faster R-CNN and SSD show evidence that later versions of YOLO have a better speed-accuracy trade-off in car-centric tasks in complex urban environments as observed by V. Sisaudia et al. [13] and Shokri et al. [18]. The literature on the use of YOLO based vehicle detection and counting has been abundant in investigating transportation analysis, tolling, and urban planning. Farid et al. [14] approach the YOLOv5 in transfer learning and custom and highly congested traffic datasets and demonstrate higher performance as compared to the traditional algorithms in multiple weather and density settings. Comparing SSD, R-CNN, and several versions of YOLO (v5-v8), Shokri et al. [18] report that the YOLO

architectures achieve detection and over 90% overall classification accuracy on cars, trucks, and buses, which prove the success of YOLO in ITS applications. In the other studies, the logic of tracking and counting vehicles based on the detection of vehicles via YOLO can be applied and visualized when using V. Sisaudia et al. [13] and R. Srimathi et al. [15] logic, to obtain statistical data of vehicles flow and support the analysis of a smartcity. Other more recent studies are also doing environmental and operational constraints such as low-light, fog and resource-based edge platforms. Deng et al. [21], propose O-YOLOv2, which contains extra feature extraction and residual modules, to enable it to scan small vehicles in KITTI with 94% precision and without the necessity to decelerate on speed, which is crucial when handling long-range or tiny objects in video surveillance. Liang et al. [17] suggest Edge YOLO, a pruned and compressed version of YOLOv4 to the edge to detect on the autonomous car; it can produce 47.3% mAP using 25.67 MB parameters and 26.6 frames per second, offering a solution to the latency and energy constraints of on-vehicle and roadside devices.

The aerial and adverse-condition surveillance have become the focus of studies as more recent generations such as YOLOv8 have been introduced. Bakirci et al [11] works with YOLOv8n/x on traffic images collected by UAVs and determines that the former is more appropriate to real-time ITS due to lower latency, whereas the latter is more accurate and has higher recall in case of the need to achieve high accuracy. N. Raza et al. [20] apply lightweight YOLOv8n/s models to detect and avoid collisions in low-visibility fog to illustrate that YOLOv8n can reach mAP50 scores of up to 85 per cent as well as run at over 100 FPS on multiple data sets; more significantly, on-device real-time warnings can be executed with the models of TensorFlow Lite on Android. Parallel work concentrates on compression of models as well as edge deployment with references to vehicle detecting. Liu et al. [19] introduce SMA-YOLO, a model built on iOS V7 and MobileNetV3 as the backbone, SimAM attention, and SIoU loss. This architecture is far smaller and cheaper in regard to parameters and computation but is highly accurate when applied to UA-DETRAC data. Other similar experiments using YOLO based detectors, multi-object tracking, multi-object hybrid ML/DL by Singh et al. [12] and Chaman et al. [16] are also pointing towards detecting, classifying and tracking of objects in real time and the viability of end-to-end smart surveillance systems. In spite of such developments, most of the ITS applications implemented with the YOLO technique are generic vehicle detection, counting and incident recognition. It is the relative emphasis on presence of the proactive vehicle threat detection where the models should not only identify vehicles but also determine the risk associated behaviour to give early warnings in intelligent surveillance networks. This deficiency has been the catalyst that has led to the development of AI based solutions that scale the high performance YOLO detection to the threat aware detection in intelligent surveillance and security sensitive environment.

METHODOLOGY

System Architecture

It works on a modular architecture that consists of four major stages Data Acquisition and Preprocessing, Core Detection Engine, Threat Logic Analysis and Response and Visualization. The video stream is fed in at a rate of 1920x1080, and scaled down to a processing size of 960px as a trade

Object Detection and Tracking

The perception layer is made up of the core that uses YOLOv8s (You Only Look Once, version 8 Small) to detect the object. This model has been chosen as a trade-off of the best between the inference speed (needed to operate in real-time) and the mean Average Precision (mAP). Class Filtering: This model is limited to the identification of only the relevant classes: Person (Class 0) and Vehicle (Classes 2 and 7). Tracking: To measure identity between frames we use a tracking algorithm which matches detections by both Euclidean distance and Intersection over Union (IoU) by which each vehicle and person is assigned a unique ID. This enables the system to trace the time stability of interactions.

Threat Detection Algorithm (Geometric Validation)

An original algorithm of geometric validation is proposed to differentiate between the legitimate parking behavior and the suspicious lingering. The system provides a definition of a threat based not on the presence of a person, but an individual in relation to a parked car over time. check_Overlap(Person_Box, Car_Box) is an algorithm, which finds the spatial interaction with three criteria Centroid Containment: This is required so that the center of mass of the person is within the horizontal limits of the vehicle bounding box. Vertical Constraint: This is used to distinguish between somebody passing a car and somebody interacting with the car (e.g. bending over, trying handles) checking the feet of the person (the bottom bounding box coordinate) against the tire line of the car.

Automatic License Plate Recognition (ALPR).

This is a specialized YOLOv8n model that is trained on license plates and is used to localize the plate region of the vehicle crop.The system of Optical Character Recognition (OCR) is based on multi-pass plate enhancement pipeline that includes 2x image upscaling to improve clarity, plate inversion to fit different plate color schemes and alpha numeric recognition with EasyOCR architecture based on ResNet, LSTM, and CRNN **.**An OCR output is verified by a heuristic filter (e.g. verification of certain country code or alpha numeric structure) to filter out noise.

Database and Data Persistence

MongoDB is a NoSQL database that deals with data persistence and is selected because it is flexible in the storage of unstructured data (images) and structured metadata.

Event Schema: Each threat event is stored as a document that has the car_id, time_stamp_utc, time_stamp_ist and binary encoded images of the evidence_snapshot and license plate.

Status Tracking: The database has state (PARKED vs THREAT) to avoid recording the same ongoing incident more than once.

Alert and Response Mechanism

This system has a multi-channel alert mechanism to assist in responding to threats quickly. The email is formatted in HTML and sent via SMTP to the security personnel with the vehicle ID, the time spent loitering and a high-resolution snapshot of the vehicle. At the same time, a Telegram bot will be used to send live image-based notifications to a specified security group, and a local audio alarm activated via a pygame library will serve as the instant scarecrow to the possible intruders.

Evaluation Metrics

Precision

Precision indicates the proportion of correct detections among all predicted objects

$$Precision = \frac{TP}{TP + FP}$$

Where TP-True Positives, TN-True Negatives, FP-False Positives, FN-False Negatives

Recall

Recall measures the system's ability to identify actual objects present

$$Recall = \frac{TP}{TP + FN}$$

F1-Score

F1-score providing an overall measure of detection performance.

$$F1 = 2 \times \frac{Precision \times Recall}{Precision + Recall}$$

Accuracy

Accuracy is used to determine the general accuracy of correctly classified tokens:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN}$$

RESULT AND ANALYSIS

The proposed system was strictly tested on the basis of the real-life surveillance footage, in which a benchmark model (yolov8x.pt) collected ground truth annotations on the key frames sampled at 1 FPS to obtain a non-biased test against the deployed lightweight model (yolov8s.pt). As determined in Table 1, the system proved to be highly effective, classifying vehicles at the accuracy of 76.2% compared to the benchmark and at the impressive 94.7%accuracy of person detection, and hence it proved to be efficient in classifying human silhouettes at difficult settings. Further performance evaluation as in Table 2 shows that the system scored a Precision and Recall of 98.4% and 76.2% accuracy on vehicles respectively, producing an F1-Score of 85.9%, and on persons, its F1-Score was 93.9%, which is a good balance between false alarms and false missed detections. Furthermore, the real time applicability of the system was confirmed with an average alert latency of 3.71 seconds and processing throughput of 15.0 FPS which is very appropriate in edge computing applications where TP represents true positives, FP false positives, and FN false negatives**.** Vehicle detection was very accurate (98.4) which means that there were few false alarms, but there are chances that vehicles were overlooked according to the recall. Pedestrian detection also had a balanced performance with an F1-score of 93.9, which validates the strength of the system in detecting the presence of human beings in the surveillance zone.

System Latency and Throughput

Intelligent surveillance systems need to be responsive in real-time. The average alert latency of the proposed framework was 3.71 seconds, as a time range between threat detection and the delivery of Telegram notification. The system was also capable of processing a throughput of about 15 FPS, which made the system very real-time with minimal computation delay

DISCUSSION

The results of the experiment confirm the efficiency of the suggested AI-based surveillance system to automate parking security processes. The efficiency of the system in the real-life conditions is proven by high pedestrian detection accuracy and high precision in both classes. The limitation was relatively less with vehicle recall although it depends mainly on environmental aspects like occlusion and space congestion and not algorithmic instabilities. The proposed system, in comparison to current methods, which tend to be less accurate than new YOLO versions, more focused on classification instead of behavior detection, or limited to general object detection without prioritizing the detection of dangerous objects in the environment, promotes surveillance with built-in threat analytics. Nevertheless, the framework demands annotation of threats, and has increased complexity of the system since it is multi-functional. Future development could involve better tracking systems, use of multi-cameras, and more resolution inputs to increase the area of detection. In general, the suggested system is a scalable and efficient way of providing intelligent parking surveillance because it involves less use of manual monitoring and provides a quicker response to any possible threat.

CONCLUSION

This paper proposed a smart video surveillance system of monitoring a long stay of humans within parked vehicles by means of deep learning and temporal analysis. The proposed solution incorporates the YOLO-based object detection with the context-sensitive occupancy verification and real-time warning, to bridge a critical gap between the current surveillance solutions. The system is efficient in providing situational awareness and proactive security surveillance in parking environments as well as is edge deployable. Further development will be done to enhance the robustness in the extreme lighting conditions and expand the framework to a multi-camera tracking and predictive threat assessment.

ABSTRACT

This study investigates the information needs and information access patterns of faculty members and students in Telangana Tribal Welfare Residential Degree Colleges in North Telangana. Information is considered a vital resource for academic and research development. The research focuses on identifying the types of information required and the mechanisms used to access these resources through academic libraries. A descriptive survey method was adopted, and data were collected from 975 respondents across 11 colleges using a structured questionnaire. The findings reveal that a majority of respondents are female (66.1%), and library usage is frequent, with most users visiting weekly and daily. The primary purposes of library use include academic work, career development, and accessing reference materials, which aligns with earlier studies on user information behaviour. The study also identifies a significant association between user categories and variables such as frequency of visit, purpose of use, and time spent in the library, as confirmed through chi-square analysis. The results highlight the evolving role of academic libraries in supporting both traditional and digital information needs, emphasizing the importance of user-centred services and digital resource development.

Keywords: Information Needs, Information Seeking Behaviour, Academic Libraries, User Studies, Digital Resources, Library Usage, Tribal Education, Information Access

INTRODUCTION

In the contemporary knowledge-driven society, information has become a fundamental resource for academic growth, research advancement, and effective decision-making (Case, 2012; Wilson, 1999). Academic libraries play a crucial role in meeting the diverse information needs of faculty members and students by providing access to both print and digital resources (Association of College and Research Libraries, 2016). The concept of information needs refers to the requirement of information for academic, research, and personal purposes, while information access patterns describe the ways in which users seek and obtain information (Wilson, 1981). Understanding these aspects is essential for improving library services and ensuring effective utilization of available resources. With the rapid development of Information and Communication Technology (ICT), the nature of information access has significantly transformed. Users increasingly depend on electronic resources, online databases, and internet-based services alongside traditional materials (Rowlands & Nicholas, 2008). This shift has influenced user behaviour and created a need for libraries to adapt to changing expectations. Telangana Tribal Welfare Residential Degree Colleges in North Telangana aim to provide quality higher education to tribal students. Their libraries play a vital role in supporting academic activities and ensuring access to information resources. Therefore, the present study examines the information needs and access patterns of faculty members and students in these institutions.

REVIEW OF LITERATURE

Lu and Li (2026) examined the adoption of artificial intelligence tools such as chatbots in academic libraries and found that user acceptance is influenced by digital literacy and perceived usefulness. Their study emphasizes the growing role of AI in enhancing information access. Sule (2025) investigated information needs in academic libraries in Nigeria and reported that a majority of users increasingly depend on electronic resources and internet-based services rather than traditional print materials. This shift reflects the growing influence of digital environments on user preferences and access mechanisms Atikuzzaman et al. (2025) examined information-seeking behavior among university library users and found that users require information for academic, research, and personal development purposes. The study revealed that structured questionnaires and statistical tools such as SPSS are widely used to analyze user behavior, emphasizing the importance of understanding user needs for effective library service delivery. Mohana Devi and Vijayakumar (2020) studied the utilization of ICT-based resources among faculty members and found that a majority of respondents frequently use digital tools and electronic resources. The study also identified gender-based variations in ICT usage, indicating that technological adoption differs among faculty groups. Manikandan and Mohamed Esmail (2013) conducted a comparative study involving Annamalai University and other state universities in Tamil Nadu. The study revealed that faculty members primarily seek information for teaching, research, and updating subject knowledge. It also found that libraries play a vital role in fulfilling these needs through both print and electronic resources.

Objectives

- To identify the nature and types of information needs among faculty members and students.
- To examine the frequency and patterns of library usage among different user categories.
- To analyze the relationship between user characteristics and library usage behaviour using statistical tools.
- To assess the purpose and modes of accessing information resources.
- To evaluate the impact of residential background on time spent in the library.

Hypothesis

- There is no significant association between user category and frequency of library visits.
- There is a significant association between user category and purpose of library use.
- There is no significant association between residential background and time spent in the library.

RESEARCH METHODOLOGY

The study uses a descriptive design to determine information needs and use among users of Tribal Welfare Residential Degree Colleges in North Telangana State. This study considers the teaching faculty and undergraduate students studying in B.A., B.Sc., and B.Com courses, totaling 975 respondents from 11 colleges. Data collection is conducted through an extensive set of questions on topics such as use of the library, reasons for visit, duration of stay, etc. This study uses a survey technique employing convenient sampling. Descriptive analysis involving percentage and frequency distributions was conducted alongside the application of chi-square tests to establish relationships between variables. All hypotheses were tested using the Chi-square test at a 0.05 level of significance.

Data Analysis and Interpretation

The data shows the distribution of respondents across various colleges. The majority of respondents are from TGTWRDC Asifabad-Girls, accounting for 118 (12.1), followed by TGTWRDC Kothagudem-Girls and TGTWRDC Khammam-Girls, each with 108 (11.1). It is observed that TGTWRDC Mahabubabad-Girls contributes 102 (10.5) respondents, while TGTWRDC Manuguru-Boys accounts for 94 (9.6). The analysis reveals that TGTWRDC Karimnagar-Boys has 87 (8.9) respondents, followed by TGTWRDC Maripeda-Boys with 82 (8.4), and TGTWRDC Utnoor-Girls with 80 (8.2). Further, TGTWRDC Boath represents 78 (8), and TGTWRDC Mulugu-Girls accounts for 69 (7.1) respondents. It is clear that the least number of respondents are from TGTWRDC Siricilla-Girls, with 49 (5). Overall, the distribution indicates that the respondents are fairly spread across the selected colleges, with slight variations in representation.

The data in Table 2 and Figure2 show the distribution of respondents by gender and category. The majority of respondents are female, with 644 (66.1%), while male respondents account for 331 (33.9%). Among Faculty Members, female respondents 95 (9.7%) are higher than male respondents 31 (3.2%). In the B.Com. In the category, female respondents 192 (19.7%) outnumber male respondents 75 (7.7%). Likewise, in B.Sc., female respondents 253 (25.9%) are more compared to male respondents 153 (15.7%). In the B.A. category, female respondents 104 (10.7%) are also higher than male respondents 72 (7.4%), respectively. It is observed that the majority of respondents across all categories are female. It is inferred that female respondents dominate the overall distribution in each category. The data in Table 3 shows the frequency of visits to the library by category of respondents. The majority of respondents visit the library weekly, with a total of 319 (32.7%), followed by daily visitors 290 (29.7%). Respondents who visit occasionally account for 160 (16.4%), while 122 (12.5%) visit rarely and 84 (8.6%) never visit the library. Among Faculty Members, the majority 52 (5.3%) visit weekly, followed by daily visitors 42 (4.3%). In the B.Com. category, most respondents 104 (10.7%) visit daily, followed by weekly visitors 77 (7.9%). In B.Sc., the highest number 110 (11.3%) visit weekly, followed closely by daily visitors 105 (10.8%). In the B.A. category, the majority 80 (8.2%) visit weekly, followed by daily visitors 39 (4.0%). It is observed that weekly and daily visits are the most common patterns among respondents, indicating regular usage of library resources. It is inferred that a considerable number of respondents actively engage with the library, while a smaller proportion visit occasionally or rarely.

Chi-Square Test:

It is found that the Chi-Square value is 60.904 with 12 degrees of freedom and a significance value of 0.000. It is inferred that there is a statistically significant association between the category of respondents and their frequency of visits to the library. It can be noted from the data in Table 4 that the purpose of visit to the library by respondents across Faculty Members, B.Com., B.Sc., and B.A. categories. Academic purposes account for 127 (13.0%) respondents, followed by career development with 143 (14.7%) and research activities with 106 (10.9%). Recreational reading includes 111 (11.4%) respondents, while accessing reference materials and e-resources account for 109 (11.2%) and 103 (10.6%) respectively. Borrowing or returning books and reading newspapers/magazines constitute 99 (10.2%) and 100 (10.3%) respondents, whereas seeking assistance from library staff accounts for 77 (7.9%) respondents. It is observed that B.Sc. respondents outnumber other categories in most purposes of library visits. It is inferred that B.Sc.

respondents demonstrate a higher level of engagement in utilizing various library services compared to other categories.

Chi-Square Test:

It is found that the Chi-Square value is 120.951 with 24 degrees of freedom and a significance value of 0.000. It is inferred that there is a statistically significant association between category of respondents and the purpose of visit to the library. Table 5 and Figure 4 demonstrate the distribution of time spent in the library per day by Rural, Semi-Rural, and Urban respondents. It is observed that Rural respondents constitute the majority with 583 (59.8%), followed by Semi-Rural respondents with 258 (26.5%) and Urban respondents with 134 (13.7%). Rural respondents show higher participation across all time categories, particularly 139 (14.3%) in less than one hour and 127 (13.0%) in 3 to 4 hours. Semi-Rural respondents show moderate distribution, with 77 (7.9%) in less than one hour and 70 (7.2%) in 3 to 4 hours. Urban respondents have comparatively lower representation, with the highest being 37 (3.8%) in 3 to 4 hours. It is inferred that Rural respondents spend more time in the library compared to Semi-Rural and Urban respondents.

Chi-Square Test

It is found that the Chi-Square value is 32.056 with 8 degrees of freedom and the significance value is 0.000. Therefore, the null hypothesis is rejected, indicating a significant association between residential background and time spent in the library per day.

Findings

- The gender-wise distribution of respondents indicates a clear dominance of female users (66.1%) over male users (33.9%), suggesting higher participation and engagement of female students in academic library usage.
- It is found that the distribution of respondents across 11 colleges demonstrates a relatively balanced representation, ensuring the reliability and generalizability of the study findings.
- The analysis of library visit frequency reveals that more than 32% of users visit the library, indicating a consistent and active utilization pattern of library resources.
- It is found that the purpose-wise analysis shows that users primarily visit the library for **career development (14.7%), academic activities (13.0%),** highlighting the academic and career-oriented role of libraries.
- The study identifies that users engage with both **print and digital resources**, reflecting a hybrid information access behaviour influenced by technological advancements.
- The analysis of time spent in the library indicates that a significant proportion of users spend **less than one hour (24.9%) and 3–4 hours (24.0%)**, suggesting varied usage intensity among respondents.
- The residential background analysis shows that more than 59% of them belongs to **rural respondents (59.8%)** , indicating a higher dependence on institutional library resources among rural students compared to semi-rural and urban counterparts.
- The Chi-square test results reveal a **statistically significant association ($p < 0.05$)** between:
  - User category and frequency of library visits
  - User category and purpose of library use
  - Residential background and time spent in the library
- Based on the inferential analysis, two null hypotheses are rejected, and one alternate hypothesis is accepted. Confirming that user characteristics significantly influence library usage behaviour.

Suggestions

- Academic libraries should enhance access to digital resources such as e-journals, databases, and online platforms to meet the growing information needs of users.
- Libraries should conduct regular user orientation and information literacy programs to improve users' ability to effectively access and utilize information resources.
- Libraries should develop dedicated services and collections to support career guidance and competitive examination preparation.

- Library infrastructure should be improved by providing adequate seating, a better reading environment, and enhanced ICT facilities.
- Special initiatives should be taken to support rural users by offering digital literacy training and easier access to electronic resources.
- Libraries should adopt a hybrid approach by maintaining a balance between print and digital resources while aligning services with user needs.

CONCLUSION

This research concludes that the users of Telangana tribal welfare residential degree colleges in north Telangana display diverse and dynamic information needs as observed in earlier studies (Wilson, 1999). This focuses on academics, career, and research activities. The outcome of this research shows that the libraries are often utilized by the users. Most of the users visit weekly and daily, highlighting its importance in the academic functions. It also reveals that the users depend on a combination of both traditional and digital resources, which reflects the shift towards modern information access patterns. It is also found that a significant relation exists between user characteristics and library usage patterns, which confirms that factors such as the category of users and residential background influence information access behaviour. Furthermore, the high number of rural students emphasizes the crucial role that libraries play in supporting educational access and development in marginalized communities. Overall, the research emphasizes the value of building digital resources, user-oriented services, and library infrastructure in order to meet users' changing information requirements. The study overall under scores that improving digital resources, expanding remote access and streng thing the services are essential for users of Telangana tribal welfare residential degree colleges for academic and day to day progress

ABSTRACT

The human gut microbiota is a complex microbial community essential for maintaining host health through its roles in metabolism, immune regulation, and protection against pathogens. Its composition is influenced by various determinants, including age, mode of delivery, diet, lifestyle, and environmental factors. Variations in these determinants can significantly alter microbial composition and are increasingly linked to the development of several diseases. This review aims to evaluate the key determinants influencing gut microbiota composition and to explore their role in the development and progression of human diseases. An extensive literature search was conducted using major scientific databases, including Pub Med, Scopus, Web of Science, Google Scholar, and MEDLINE. Relevant original research articles, review papers, and clinical studies were identified using keywords related to gut microbiota, diet, lifestyle, environmental factors, and disease associations. Studies were selected based on relevance, quality, and recency to ensure inclusion of evidence-based findings. The findings indicate that gut microbiota composition is highly dynamic and influenced by multiple intrinsic and extrinsic factors. Dietary patterns, particularly intake of fiber-rich and fermented foods, promote beneficial microbial populations, whereas factors such as antibiotic use, smoking, alcohol consumption, sedentary lifestyle, and poor sleep patterns can adversely affect microbial diversity. Age-related changes, mode of birth delivery, and environmental exposures further contribute to microbial variability. These alterations are strongly associated with the pathogenesis of diseases such as inflammatory bowel disease, celiac disease, obesity, and colorectal cancer. Additionally, microbiota-targeted interventions, including probiotics, prebiotics, dietary modifications, and fecal microbiota transplantation, have demonstrated potential in modulating gut microbiota and improving health outcomes. Gut microbiota plays a pivotal role in

human health, and its composition is significantly influenced by multiple determinants. Understanding these factors is crucial for developing targeted therapeutic strategies. Further research is required to establish personalized and standardized approaches for microbiota-based interventions in disease prevention and management.

Keywords: Microbiota, Fusobacteria, Actinobacteria,

INTRODUCTION

The human body hosts trillions of microorganisms, collectively known as the microbiota, while their genetic content is referred to as the microbiome. These microbes—including bacteria, viruses, fungi, and parasites—colonize various body sites such as the skin, oral cavity, gastrointestinal tract, and genitourinary system, and play a crucial role in maintaining human health. They exist in a symbiotic relationship with the host, contributing to multiple metabolic and regulatory functions essential for normal physiological processes [1].The gut microbiota represents a highly diverse microbial community dominated by the phyla Firmicutes, Bacteroidetes, Actinobacteria, Proteobacteria, Verrucomicrobia, and Fusobacteria. Among these, Firmicutes and Bacteroidetes constitute approximately 90% of the total microbial population. Key genera include *Lactobacillus*, *Clostridium*, *Bacteroides*, *Prevotella*, and *Bifidobacterium* [2]. These microorganisms play a central role in digestion and nutrient absorption [3], and are also implicated in various health conditions such as obesity, diabetes, and inflammatory bowel disease [4], [5]. A critical function of the gut microbiota is colonisation resistance, wherein resident microbes protect the host from pathogenic invasion. This is achieved through mechanisms such as competition for nutrients, modulation of host immune responses, occupation of ecological niches, production of antimicrobial metabolites, and alteration of gut environmental conditions unfavourable to pathogens [6].

Types of gut microbiota at different age groups

Aging is a complex biological process characterized by a progressive decline in physiological functions, influenced by both genetic and environmental factors[7]. This decline is associated with alterations in immune homeostasis, mitochondrial DNA integrity, telomerase activity, oxidative stress, and regulatory gene expression, including silent information regulator genes [8].Several studies have demonstrated that the composition and diversity of the gut microbiota undergo significant changes across different stages of life. For instance, a study by Marathe N et al. [9] (2012) reported that *Bifidobacterium longum* and *Lactobacillus acidophilus* are predominant in early childhood (2–3 years of age), with their abundance declining in adulthood. In contrast, genera such as *Bacteroides*, *Prevotella*, and *Porphyromonas* are more abundant during adolescence and are relatively scarce during early childhood. Additionally, *Faecali bacterium prausnitzii* was observed to peak between 6–9 years of age, while being less prevalent in early childhood and adolescence.

Further, a study by Chen Meng et al. [10] (2022) demonstrated that the relative abundance of the phylum Firmicutes increases with advancing age, whereas Bacteroidetes show a declining trend. The study also identified a positive correlation between body weight and the Firmicutes-to-Bacteroidetes ratio. Rondanelli et al. [11] (2015) reported that elderly individuals exhibit an increased abundance of *Bacteroides* and *Enterobacteriaceae* compared to younger adults. Conversely, beneficial microbial groups such as Firmicutes, *Enterococcus faecalis*, *Bifidobacterium*, and *Enterobacter* were found to be reduced in the elderly population. Collectively, studies conducted across diverse populations highlight significant alterations in gut microbiota composition associated with healthy aging, as summarized in Table1 Studies from various countries shows the gut microbiome alteration in healthy ageing.

Composition of gut microbiota on the basis of mode of birth delivery

The mode of birth delivery significantly influences the initial establishment and composition of the gut microbiota. Variations arise primarily due to differences in early microbial exposure. Infants delivered vaginally are exposed to maternal vaginal and intestinal microbiota, which facilitates early colonization and supports immune system development. In contrast, infants born via caesarean section are predominantly exposed to maternal skin and environmental microbes, resulting in distinct microbial profiles. The fecal microbiota of vaginally delivered infants is typically dominated by *Acinetobacter*, *Bifidobacterium*, and *Staphylococcus* species. Conversely, infants delivered by caesarean section exhibit reduced abundance of *Bifidobacterium* and are more frequently colonized by *Citrobacter*, *Escherichia coli*, and *Clostridium difficile* [20]. Kabeerdoss et al. (2013) [21], in a study involving 83 infants, reported a higher prevalence of *Enterobacteriaceae* and *Lactobacillus* in caesarean-delivered infants. By three months of age, vaginally delivered infants showed increased abundance of *Bifidobacterium*, along with a progressive rise in *Bacteroides* and *Prevotella* species, indicating maturation of the gut microbiota.

Distribution of gut microbiota at different site of gastrointestinal tract (GIT):

The composition and density of gut microbiota vary significantly along the gastrointestinal tract (GIT). Earlier estimates suggested the presence of 500–1000 microbial species; however, subsequent large-scale studies have indicated that the human gut microbiome may comprise over 35,000 bacterial species [26,27]. Microbial density increases progressively from the upper to the lower GIT, ranging from approximately 10^1 organisms per gram in the esophagus and stomach to 10^{12} per gram in the colon [28].Microbial distribution is site-specific. *Streptococcus* is the predominant genus in the distal esophagus, duodenum, and jejunum [29,30]. In the stomach, *Helicobacter*, particularly *Helicobacter pylori*, plays a central role in shaping the gastric microbiota, often coexisting with genera such as *Streptococcus*, *Prevotella*, *Veillonella*, and *Rothia* [31,32]. The small intestine is enriched with members of *Proteobacteria*, including *Enterobacteriaceae*, whereas the colon is predominantly colonized by *Bacteroidaceae*, *Prevotellaceae*, and *Rikenellaceae*, which are largely absent in the small intestine [33]. These variations are primarily attributed to differences in local environmental conditions. The small intestine is characterized by higher bile concentrations and rapid transit time, while the colon exhibits a relatively neutral pH, slower transit, and an anaerobic environment that supports dense microbial populations [34].Additionally, the distribution and metabolism of bile acids across different intestinal regions further influence microbial composition and diversity [35,36].

Gut microbial diversity at different age:

At birth, the human intestine is rapidly colonized by microorganisms; however, the gut microbiota remains highly dynamic and unstable during early life. In infancy, facultative anaerobes such as *Enterobacteriaceae*, *Staphylococcus*, and *Streptococcus* predominate (Marques TM, 2010) [37]. By one year of age, there is an increased abundance of genera including *Clostridium*, *Bacteroides*, and *Veillonella* [38] 89. Contemporary factors such as improved hygiene during delivery and reduced hospital stays have limited early microbial exposure, thereby influencing initial colonization patterns [37,39]. During adulthood, the gut microbiota attains relative stability, with variations primarily influenced by external factors such as diet, lifestyle, and environmental exposures [40]. In contrast, aging is associated with a decline in microbial stability and diversity. Several studies have demonstrated that elderly individuals exhibit reduced gut microbial diversity, which may contribute to age-related physiological changes and increased susceptibility to diseases [41,42,43].

Role of diet in shaping the composition of gut microbiota

Diet is one of the most influential modulators of gut microbiota composition and diversity. The type, quantity, and diversity of dietary components create selective pressures within the gut environment, thereby promoting the growth of specific microbial communities while inhibiting others. Long-term dietary patterns have been shown to exert a more sustained impact on gut microbiota than short-term dietary changes, ultimately influencing host metabolism, immune function, and overall health.

Vegetariandiet

Plant-based diets, rich in dietary fiber, polyphenols, and complex carbohydrates, are consistently associated with an increased abundance of beneficial gut microbes. Such diets promote the growth of saccharolytic bacteria, including *Bacteroides*/*Prevotella*, *Faecalibacteriumprausnitzii*, and *Clostridium clostridioforme* [44]. These microorganisms are involved in the fermentation of complex polysaccharides, leading to the production of short-chain fatty acids (SCFAs) such as butyrate, which contribute to gut health and anti-inflammatory effects. Additionally, studies have reported higher levels of *Bacteroides* and reduced abundance of *Clostridium* cluster IV in individuals adhering to strict vegetarian diets [45].

Omnivorousdiet

Omnivorous diets, particularly those rich in animal proteins and fats, are associated with a distinct microbial profile. These diets tend to favor the growth of *Clostridium* cluster XIVa, a group of butyrate-producing bacteria [46]. While butyrate production is beneficial for colonic health, excessive consumption of animal-based foods may also promote the growth of bile-tolerant microorganisms and alter microbial balance. Thus, the overall impact depends on dietary composition and diversity.

Wholegrains

Whole grains such as whole wheat, oats, barley, millets, and brown rice are important sources of dietary fiber and resistant starch. As these components are not digested in the upper gastrointestinal tract, they reach the colon where they are fermented by gut microbiota. This fermentation process enhances the growth of beneficial bacteria, particularly *Bifidobacterium* and *Lactobacillus*, and increases SCFA production. Controlled studies have demonstrated that regular consumption of whole grains leads to significant increases in *Bifidobacterium* levels and improved microbial balance [47,48].

Fermentedfoods:

Fermented foods are rich in live microorganisms and bioactive compounds that positively influence gut microbiota. Traditionally consumed across cultures, these foods improve nutrient bioavailability and contribute to gut health through the production of organic acids, carbon dioxide, alcohol, and antimicrobial compounds such as bacteriocins [49,50,51,52,53]. Common probiotic bacteria present in fermented foods include *Lactobacillus*, *Lactococcus*, *Leuconostoc*, *Bifidobacterium*, *Pediococcus*, and *Propionibacterium*[54]. These microbes help maintain intestinal homeostasis by lowering gut pH, inhibiting pathogenic organisms, and enhancing microbial diversity [55].

Dairyproducts

Dairy products, including milk, curd, and fermented dairy products, play a significant role in modulating gut microbiota. They provide essential nutrients such as proteins, calcium, and vitamin D, along with lactose, which can act as a substrate for beneficial microbes. Studies have shown that consumption of fermented dairy products enriched with *Bifidobacterium*, *Lactobacillus*, and *Streptococcus thermophilus* leads to increased abundance of these bacteria in the gut, thereby promoting microbial balance [56,57,58]. Additionally, dairy intake has been associated with increased levels of *Bacteroidetes* and *Blautia*, and overall improvement in gut microbial composition and metabolic activity [59,60].

Impact of lifestyle on gut microbiota

Lifestyle factors play a crucial role in shaping the composition, diversity, and functional capacity of the gut microbiota. Factors such as dietary habits, antibiotic use, physical activity, sleep patterns, smoking, alcohol consumption, and environmental exposures (e.g., pets) can significantly influence microbial balance, often contributing to either eubiosis or dysbiosis.

Antibioticuse:

Antibiotics are among the most influential disruptors of gut microbiota. Prolonged or repeated use can significantly alter microbial composition, particularly reducing the abundance of Firmicutes and affecting metabolic functions

[61]. Antibiotic exposure has also been associated with increased susceptibility to *Clostridioides difficile* infection, especially in elderly and hospitalized individuals [62,63,64]. Certain antibiotics, such as rifaximin, may selectively promote beneficial bacteria like *Bifidobacterium*, *Lactobacillus*, and *Faecali bacteriumprausnitzii* [65]. However, broad-spectrum antibiotics (e.g., ciprofloxacin) have been shown to reduce microbial diversity, including *Ruminococcaceae*, *Bacteroidetes*, and *Lachnospiraceae*, with only partial recovery after treatment cessation [66]. Similarly, short-term use of clindamycin can markedly reduce *Bacteroides* populations [67,68]. Recreational drug use, including marijuana, has also been associated with alterations in gut microbial ratios, particularly a reduced *Prevotella: Bacteroides* ratio [69,70].

Living with Pets and Gut Microbiota

Environmental exposures, particularly interaction with pets, play an important role in shaping gut microbiota, especially during early life. Exposure to pets introduces a diverse array of environmental microbes, which can influence microbial colonization and immune system development. Studies in adults have shown minimal differences in overall microbial diversity between pet owners and non-owners; however, variations in specific microbial groups, such as Firmicutes, have been observed [71]. In contrast, early-life exposure to pets appears to have a more pronounced impact. Infants exposed to furry pets have shown increased abundance of genera such as *Ruminococcus* and *Oscillospira* [72]. These microbial shifts have been associated with immune modulation and may influence the risk of allergic diseases. Some studies suggest that early exposure to diverse microbial environments, including pets, may contribute to immune tolerance, although findings remain mixed, with certain reports linking these changes to allergy predisposition [73]. Overall, pet exposure highlights the importance of environmental microbial diversity in shaping gut microbiota.

Smoking and Gut Microbiota

Smoking is a significant lifestyle factor that adversely affects gut microbiota composition and diversity. It introduces a wide range of toxic compounds, including nicotine, which can directly and indirectly alter microbial populations and host immune responses. Research indicates that smoking is associated with increased abundance of *Proteobacteria* and *Bacteroidetes*, alongside a reduction in beneficial groups such as *Actinobacteria* and *Firmicutes* [74]. These changes are indicative of microbial dysbiosis and are often linked to inflammatory conditions. Smoking also promotes the growth of pathogenic bacteria, disrupts mucosal immunity, and impairs intestinal barrier function. Furthermore, differences in microbial diversity between smokers and non-smokers have been well documented, with smokers generally exhibiting reduced microbial stability and altered metabolic activity [75]. Smoking has also been implicated in the pathogenesis of gastrointestinal disorders, including inflammatory bowel disease and colorectal cancer, partly mediated through microbiota alterations.

Alcohol Consumption and Gut Microbiota

Alcohol consumption exerts a significant impact on gut microbiota composition, often leading to dysbiosis. Chronic alcohol intake disrupts the intestinal barrier, increases gut permeability (“leaky gut”), and promotes systemic inflammation. Studies have shown that individuals with alcohol-related disorders exhibit altered abundance of *Bacteroidetes* and *Enterobacteriaceae* [76]. Experimental studies have further demonstrated that alcohol exposure leads to overgrowth of *Enterobacteriaceae* and promotes intestinal inflammation [77]. These microbial alterations are closely associated with the development of alcohol-related liver diseases. Mechanistically, alcohol metabolism results in the production of acetate and other metabolites, which can influence microbial composition and function [78]. Additionally, alcohol-induced oxidative stress and changes in bile acid metabolism further contribute to microbial imbalance. Chronic alcohol consumption also reduces beneficial bacteria such as *Lactobacillus* and *Bifidobacterium*, thereby impairing gut homeostasis.

Physical Activity and Gut Microbiota

Physical activity is a key modulator of gut microbiota composition, diversity, and metabolic function. Regular exercise has been consistently associated with increased microbial diversity and enrichment of beneficial bacterial taxa. Mechanistically, exercise enhances intestinal motility, improves mucosal immunity, and increases intestinal blood flow, thereby creating a favorable environment for microbial growth. Studies have demonstrated a higher

abundance of Firmicutes and butyrate-producing bacteria among physically active individuals [79,80]. Butyrate, a short-chain fatty acid (SCFA), plays a crucial role in maintaining intestinal barrier integrity, reducing inflammation, and supporting colonic epithelial health. Additionally, exercise has been linked with increased levels of beneficial genera such as *Roseburia*, *Odoribacter*, and *Sutterella*, which are involved in SCFA production and metabolic regulation [81]. Experimental evidence further suggests that exercise-induced improvements in oxygen utilization and energy metabolism contribute to microbial shifts. Notably, these beneficial effects are observed even when dietary patterns remain constant, indicating an independent role of physical activity in shaping gut microbiota. Conversely, a sedentary lifestyle is often associated with reduced microbial diversity and increased susceptibility to metabolic disorders.

Sleep and circadian rhythm

Sleep patterns and circadian rhythms are closely linked to gut microbiota homeostasis. Sleep disturbances have been associated with microbial dysbiosis and gastrointestinal dysfunction [82,83,84]. Beneficial bacteria such as *Bifidobacterium* and *Lactobacillus* have been shown to improve sleep quality and reduce anxiety-related symptoms [85, 86,87]. Additionally, microbial metabolites, particularly short-chain fatty acids like butyrate, play a role in regulating sleep physiology [88, 89, 90,91]. Specific butyrate-producing bacteria, including *Ruminococcaceae*, *Oscillibacter*, and *Holdemanella*, have been associated with improved sleep patterns, whereas depletion of such metabolites may disrupt sleep [92,93]. Alterations in genera such as *Bacteroides*, *Faecalibacterium*, and *Blautia* have also been linked to sleep quality and related disorders [94]. External factors such as travel and circadian disruption further influence microbial composition [95,96], and dysbiosis has been consistently observed in individuals with compromised sleep cycles [97].

Gut Microbiota and Associated Diseases

Multiple intrinsic and extrinsic factors, including diet, lifestyle, environmental exposures, and aging, play a critical role in shaping the composition and functionality of the gut microbiota. Alterations in these factors can influence microbial balance, affecting host physiology through changes in nutrient metabolism, immune responses, and intestinal barrier function. These changes are closely linked to the development and progression of several gastrointestinal and systemic diseases.

Inflammatory Bowel Disease (IBD)

Inflammatory bowel disease (IBD) is a chronic, relapsing inflammatory disorder of the gastrointestinal tract, primarily encompassing Crohn's disease and ulcerative colitis. Crohn's disease can affect any part of the gastrointestinal tract, whereas ulcerative colitis is limited to the colon [98]. The global incidence of IBD is increasing, affecting millions worldwide, including a rising prevalence in developing countries such as India [99,100]. The pathogenesis of IBD involves a complex interplay of genetic, environmental, immunological, and microbial factors [101, 102,103]. Alterations in gut microbiota composition are associated with an abnormal immune response, particularly involving activation of T lymphocytes against commensal microbial antigens. The production of antibodies against resident bacterial components and autoantigens further contributes to intestinal inflammation and tissue damage [104, 105]. Additionally, variations in beneficial microbial populations may influence inflammatory pathways and disease severity.

Celiac Disease

Celiac disease is a chronic immune-mediated disorder of the small intestine triggered by dietary gluten in genetically predisposed individuals [106]. Gluten exposure activates adaptive immune responses in the intestinal mucosa, particularly T helper (Th1 and Th17) cells, leading to the release of pro-inflammatory cytokines and subsequent damage to enterocytes [107]. The development of celiac disease is influenced by multiple factors, including genetic susceptibility, immune mechanisms (notably IgA-mediated responses), dietary patterns, environmental exposures, infections, and infant feeding practices [108, 109,110]. These factors are also closely associated with variations in gut microbiota, which may influence immune tolerance and disease susceptibility.

Obesity

Obesity is a multifactorial metabolic disorder characterized by excessive fat accumulation resulting from an imbalance between energy intake and expenditure [111,112] . It is associated with an increased risk of metabolic conditions such as type 2 diabetes, cardiovascular diseases, and liver disorders. Gut microbiota contributes to energy metabolism and storage. Studies have reported an increased abundance of Firmicutes and a decreased proportion of Bacteroidetes in obese individuals compared to lean individuals [113, 114]. These variations may enhance energy extraction from the diet and influence metabolic pathways. Additionally, changes in microbial composition may contribute to inflammatory responses and metabolic dysregulation.

Colorectal Cancer (CRC)

Colorectal cancer (CRC) is one of the leading causes of cancer-related mortality worldwide [115]. Its development is influenced by both genetic and environmental factors, with growing evidence supporting the role of gut microbiota in carcinogenesis. Gut microbiota can influence CRC development through mechanisms such as modulation of inflammation, production of bioactive metabolites, and interaction with host immune responses. Short-chain fatty acids, particularly butyrate, play a protective role by inhibiting tumor cell proliferation and inducing apoptosis [116, 117,118]. However, studies have reported a reduced abundance of butyrate-producing bacteria such as *Faecalibacterium* and *Roseburia* in CRC patients [119,120]. Such alterations may contribute to a microenvironment that supports tumor progression.

Dysbiosis of gut microbiota:

The human gastrointestinal (GI) tract harbors a vast and diverse community of microorganisms, including bacteria, fungi, viruses, and protozoa. These microorganisms are unevenly distributed along the GI tract, with relatively low microbial density in the upper regions (stomach and small intestine) and a substantially higher concentration in the distal large intestine [121,122,123,124]. Collectively, the gut microbiota performs several essential functions, including inhibition of pathogenic microorganisms, fermentation of dietary substrates, and production of bioactive metabolites. Additionally, it plays a critical role in immune modulation, synthesis of vitamins, and metabolism of essential nutrients. A balanced and functionally optimal microbial state is referred to as eubiosis. Dysbiosis is defined as an imbalance in the composition, diversity, or functional activity of the gut microbiota, characterized by a disruption in the proportion of beneficial and potentially harmful microorganisms [125]. This altered microbial state can compromise host physiological processes, including metabolism and immune regulation. Multiple factors contribute to the development of dysbiosis, including dietary patterns, environmental exposures, host genetic factors, and underlying disease conditions such as obesity, type 2 diabetes, inflammatory bowel disease, and cancer. Additionally, the use of antibiotics has been widely recognized as a major factor influencing gut microbial composition, often leading to significant alterations in microbial diversity and function [126,127].

Fecal microbiota transplant (FMT)

Fecal microbiota transplantation (FMT) is a therapeutic approach in which a fecal suspension obtained from a healthy donor is administered into the gastrointestinal tract of a recipient with the aim of restoring microbial balance and functionality. This intervention modifies the recipient's gut microbiota composition by introducing beneficial microorganisms, thereby improving gut homeostasis [128,129]. Historically, FMT was first reported in 1958 for the treatment of pseudo membranous colitis associated with *Clostridioides difficile* infection [130]. Subsequently, Zhang et al. (2012) [131] documented one of the early modern applications of FMT in China for the treatment of severe diarrhea. Since then, FMT has gained considerable attention as a potential therapeutic strategy for microbiota-associated disorders. The association between altered gut microbiota and inflammatory bowel disease (IBD) has prompted investigations into FMT as a treatment modality. Damman et al. (2012) [132] 198 reported that among 122 IBD patients treated with FMT, approximately 36% achieved clinical remission. Subgroup analysis indicated remission rates of 64% in ulcerative colitis (UC) and 60.5% in Crohn's disease (CD), suggesting relatively better outcomes in UC and in younger individuals [133]. However, contrasting findings have been reported; for instance, a randomized controlled trial by Rossen et al. (2015) [134] involving 50 UC patients did not demonstrate significant

clinical remission.These variations in outcomes highlight that the efficacy of FMT is influenced by several factors, including the route of administration, dosage, donor microbiota composition, frequency of transplantation, and the immune status of the recipient. Although FMT is an established treatment for recurrent *C. difficile* infection, its application in other conditions remains under investigation. Ongoing research is focused on optimizing protocols and evaluating its long-term safety and efficacy across a broader range of diseases.

CONCLUSION

The gut microbiota is a complex and dynamic microbial community essential for maintaining human health through its roles in metabolism, immune regulation, and protection against pathogens. Its composition is influenced by various factors, including age, diet, lifestyle, environment, and medical interventions.Alterations in gut microbiota have been associated with several diseases such as inflammatory bowel disease, celiac disease, obesity, and colorectal cancer, highlighting its clinical significance. Emerging therapeutic approaches, including dietary modulation, probiotics, and faecal microbiota transplantation (FMT), offer promising strategies for maintaining and restoring microbial balance. Although significant progress has been made in understanding the role of gut microbiota, many aspects of host–microbiome interactions remain to be elucidated. Future research should focus on identifying specific microbial signatures associated with health and disease, standardising microbiota-based therapies, and exploring personalised approaches for disease prevention and management. A deeper understanding of gut microbiota will not only enhance our knowledge of human physiology but also open new avenues for targeted and effective therapeutic interventions.

ABSTRACT

Sleep paralysis is a condition in which voluntary muscle movements are ceased. This can happen either at the beginning of sleep or when the person wakes up. There isn't currently a "gold standard" treatment for Sleep Paralysis. This case study centers on a male, age 28, who has been suffering from prolonged incomplete sleep paralysis regularly for the previous three years. The phase lasts from a few seconds to several minutes, occurring 12–3 times a month. Along with his anxiety neurosis, he also complained of unplanned sleep awakenings and depression as a result. He had to use a gentle touch to put a stop to the situation because otherwise, the patient would have spontaneously awakened from sleep paralysis. The patient was unable to induce movement or compel his body to break the paralyzed state. A neurological evaluation conducted right after the incident showed no brain anomalies or nervous system anomalies. The Sleep Paralysis Experiences and Phenomenology Questionnaire was used to evaluate the patient for sleep paralysis, and Video-Synchronized Polysomnography was utilized to collect the data. The patient showed indications of dread of dying because he felt smothered and strangled as per the evaluation done by the atypical sleep questionnaire. He occasionally claimed to feel a "sensed presence" or figure and expressed worries of harm, such as the worry that the "sensed presence" might touch, slaughter, or injure him. During six months, the patient had extensive treatment for sleep paralysis, which included medication, physical therapy, and ergonomic modifications. Exercises for breathing, positioning, and

relaxation training were all part of Physiotherapy. When the patient was followed up after six months, he claimed that he was no longer snoring and that he was no longer having episodes of paralysis while sleeping. He claims he sleeps comfortably and undisturbed these days and wakes up feeling rejuvenated.

Keywords: Isolated Sleep Paralysis (ISP), Rapid Eye Movement (REM), Non-Rapid Eye Movement (NERM), Sleep Paralysis Experiences and Phenomenology Questionnaire (SP-EPQ), Sleep Paralysis (SP),

INTRODUCTION

A period during which movements of voluntary muscle are stopped occurs either at the onset of sleep or upon waking from sleep, and is stated to as sleep paralysis. The movements of the eyes and breathing do not change, and the local surroundings are perceived.[1] Despite being very common, sleep paralysis is not a well-studied phenomenon. Numerous experts have examined potential risk factors even though the precise causes are uncertain.[2] The condition known as ISP is characterized by a repeated incapacity to move the spine and entire limbs during the onset of sleepor upon waking up. A brief to several minutes can pass between SP episodes, and during each one, clinically significant suffering, such as fear of falling asleep or anxiety before bed, is experienced. The episodes end on their own, in response to external stimuli like touches or alarm clock sounds, or perhaps even through eye movements that are prompted by the subject. [3] It has been found that certain lifestyle choices, mental health conditions, and physical health conditions predispose people to this disorder.[4]

"Arousal systems" are typically triggered upon awakening from sleep. Orexin-producing neurons project to the dorsal raphe nucleus (DRN), also known as the REM sleep inhibitory area, as well as directly to cortical sites. Within the DRN, these orexin neurons excite serotonin-producing neurons, which in turn increase cortical arousal. Compare this to sleep paralysis, where the same neural circuitry—wake-promoting neurons—are activated to facilitate the transition from sleep (i.e., REM) to wakefulness. However, in contrast to normal wakefulness, the sleeper experiences a temporary loss of movement due to persistent postural atonia even after these cortical and behavioral arousal mechanisms are activated (i.e., wakefulness).Unlike other sleep states, sleep paralysis is a distinct dissociated condition in which the sleeper experiences both REM and wakefulness simultaneously; in other words, they are "immobilized" but see themselves as "semi-awake." Serotonin over-activity may occur in the paralyzed sleeper's brain when the serotonergic arousal system is activated during sleep paralysis (i.e., a phasic increase of serotonin [i.e., via REM off cells]) to induce alertness for perception.[5]

Case Report

This case study features a 28-year-old male who has been experiencing lengthy incomplete sleep paralysis regularly for the past three years. The stage lasts for a few seconds to several minutes with a frequency of 12 to 3 episodes per month. He also complained of unexpected sleep awakenings. He had anxiety neurosis and was depressed as a result. For three years, just predormitally, sleep paralysis had been experienced; it was typically accompanied by hallucinations. He experienced his first bout of sleep paralysis at the age of 25, which began in the post dormital stage, lasted for a few minutes, and ended when he was touched. That was the only time this occurred when he was lying supine. He experienced no recurrence and no concomitant symptoms till one month later when he again experienced the symptom. He had to lightly touch by hand to end the incident or the patient woke up from sleep paralysis naturally. There was no way that the patient could force his body to move out of a paralysis state. He frequently has panic-like symptoms, including a racing heartbeat, shortness of breath, and terror, both during and right after sleep paralysis. An immediate post-event neurological assessment revealed no abnormalities. He also claimed to have spent the previous year regularly going into a vivid "dream-like" state and being unable to move his body freely when he woke up. His reports of seeing spiders and dark shapes coincided with these incidents of the invader phenomenon. His terror prevented him from returning to sleep following these spells of paralysis.

Additionally, he admitted to experiencing anxiety episodes. There has been a history of snoring for the last three to four years. Alpha wave intrusion during sleep is indicative of moderate obstructive sleep apnea (OSA), according to Every morning after these nights, he would describe feeling exhausted and experiencing pain in every muscle in his body.

There have been no reports of drug usage, but throughout the previous five years, there have been occasional reports of alcohol use. There was no prior history of shift employment, insomnia, diabetes, hypertension, asthma, or pulmonary tuberculosis. He reported no vertigo, dizziness, blurred vision, or weakness in other portions of the body, other than weakness in the limbs during episodes. There was no family history of hypersomnia, REM or NREM parasomnias, snoring, or restless legs syndrome. No family history of sleep disorders of any type existed during childhood. Nothing exceptional was found in the other systemic examination. Applying the Frontal Lobe Epilepsy and Parasomnia (FLEP) scale, which has a score of minus 4 indicating a highly rare occurrence of epilepsy, allowed for the distinction between sleep-related seizures and parasomnia. When the brain was subjected to magnetic resonance imaging (MRI) to rule out other pathologies, normal results were obtained. As of right now, there is no "gold standard" treatment for SP. According to a review by Sharpless et al.17, there are several promising psychopharmacological and psychotherapeutic approaches to treating sleep paralysis, but as there hasn't been a single randomized controlled trial for SP, no empirically supported treatment recommendations can be made. Nonetheless, we think that the Sleep position training might offer a sophisticated long-term non invasive and nonpharmacological therapeutic option for SP.As of right now, there is no "gold standard" treatment for SP and there is no scientifically supported treatment for sleep paralysis, even though there are several potential psychopharmacological and psychotherapeutic treatments.[6] Examination: A thorough objective and subjective examination of the patient was done before starting the treatment. Video-Synchronized Polysomnography: In-lab video-synchronized polysomnography was performed. Table 1 displays the sleep study's key findings.

Sleep Paralysis Experiences and Phenomenology Questionnaire: A tool for determining the frequency, features (such as symptomatology, episode conditions), and degree of knowledge regarding sleep paralysis episodes is the SP-EPQ. Poland, Turkey, and Italy have all used the questionnaire. Open-ended questions contain twelve in number and five closed-ended questions about SP make up the SP-EPQ. The SP-EPQ evaluates the following: sources of information about SP, hallucinatory experiences, ideas of cause, associated somatic sensations and emotions, frequency and time of occurrence, and position of sleep during SP (lifetime, past year, and past month). On evaluation with the unusual sleep questionnaire, the patient exhibited symptoms like fear of death due to feeling strangled and feeling smothered. sometimes he had felt a sensed presence or shape and stated doubts of harm, including the terror that the “sensed presence” might kill/hurt him or touch him.

Treatment: The patient received a thorough course of treatment for sleep paralysis, which included medication, physical therapy, and ergonomic adjustments for six months.

Pharmacological: He was taking a tablet of 500 mg of divalproate and a tablet of 2.5 mg of olanzapine daily due to a psychotic episode and dread insomnia.

Physiotherapy:

Positioning: The Patient was suggested to lie down in a side-lying position for most of the time and also to avoid the supine position as much as possible. Cognitive Behavioral Therapy [7]: Sessions included the cognitive, behavioral, and educational components. Cognitive interventions: The goal of cognitive restructuring is to alter false or detrimental beliefs about sleep. Journaling. The patient was asked to record any negative thoughts that came to mind during the week along with any positive ideas that may have replaced them. Self-talk. The patient was told to replace any negative or critical thoughts about sleep paralysis and the associated difficulty with self-talk with positive and beneficial thoughts. Cognitive restructuring. The patient was starting to identify and correct any cognitive distortions that were influencing his thinking, such as thinking in black and white, drawing hasty judgments, or catastrophizing.

Thought recording, This method involved having the patient write down their feelings and thoughts during a particular event, after which they were to provide objective proof both in favor of and against their negative opinion. Encourage them to construct a more practical idea by using this evidence. Positive activities: The patient was requested to listen to his preferred tunes since he demonstrated an interest in music Setting aside time for a fulfilling hobby every day can help him feel happier and more optimistic overall. Behavioral interventions: The patient was advised to develop appropriate pre-sleep habits, such as managing their environment before bed, compressing and limiting their sleep, and practicing relaxing. Psychoeducational interventions: The patient was counselled to reconsider whenever he experienced unpleasant feelings. He was taught the relationship between ideas, feelings, behavior, and sleep.

Relaxation Training

Relaxation techniques: To ease the anxious feelings and tension that come with lying in bedrelaxation treatment was provided. The body's natural relaxation response can be strengthened by this method. Progressive muscle relaxation (PMR): The PMR method alternates between tensing and relaxing various muscle groups. These methods were used in combination with guided mental imagery or breathing exercises.[8] Breathing exercises: The patient has been regularly given breathing exercises that involve taking slow, deep breaths. Studies have indicated that intentional breathing can lower anxiety, anger, and depressive symptoms while also slowing respiration and heart rate. Mind-Body Exercise: Autogenic training: The patient was told to relax and concentrate on various body areas while identifying certain sensations like warmth or heaviness. Hypnosis: Aiming to teach relaxation in response to a verbal or nonverbal cue, guided or self-hypnosis is used to treat insomnia.

Meditation

The patient was told to use meditation to focus their concentration comprised of the following:

- By Understanding how thinking incorrectly can make issues worse along with developing new problem-solving techniques
- Acquiring self-assurance and a greater sense of self-worth. The patient was further instructed to follow a regular sleep pattern and to avoid stimulants before going to sleep

Physical Exercise: Exercise—such as Pilates and other forms of conditioning or aerobic exercise were typically prescribed regularly.

DISCUSSION

ISP episodes were multi sensorial complex experiences, and most of the symptoms that were measured were linked to clinically substantial levels of anxiety or dread. Additionally, common were vivid hallucinations of other individuals and things. When patients report events that seem out of the ordinary, it is advised that an ISP be evaluated.[9] According to their reports of seeing more phenomena and feelings overall, women were significantly more likely than men to sense tangible forms, such as human figures or people they know. They also reported experiencing invader and incubus-type sleep paralysis more frequently.[10] Finding underlying problems is the first step in the medical approach to treating SP. People should be informed about the symptoms of isolated SP and that the patient is not at risk for developing it after an episode if the patient has it. If linked to further mental health conditions, underlying mental diseases, or disorders, treatment for the underlying cause is necessary. People should also be instructed on good sleeping hygiene.[11] Physical therapy is a potent non-pharmacological intervention for sleep disturbances in neurological diseases. It has few side effects and a good impact on both motor and non-motor functioning. Physical therapy activities are frequently disregarded in traditional neurore habilitation, even though they may help neurological patients with their sleep difficulties.[12] It is also important to take into account the possibility that sleep paralysis will result in a worse quality of sleep, particularly if the paralysis causes a great deal of dread and post-episode sadness. Post-episode distress has been related to several factors, including overall

psychological stress, supernatural beliefs about the origin of the episode, and anxiety and threat/assault experiences during sleep paralysis.[13] medication called pimavanserin that targets sleep paralysis hallucinations and terror responses specifically. Pimavanserin is an inverse agonist of the 5-HT2A receptor that is very selective; in contrast, it has an approximately 40-fold lower affinity for the 5-HT2C receptor. This makes it a good candidate for a medication that targets hallucinations caused by sleep paralysis. [5] Sleep-related dysfunctional beliefs are significantly impacted by cognitive behavioral treatment for insomnia.[14]Relaxation methods have become one of the most promising ways to improve sleep quality.[15]The literature study has unequivocally demonstrated that poor sleep quality is associated with sleep paralysis. Therefore, the patient's overall sleep quality must be considered in any interventions intended to lessen or eradicate sleep paralysis. For sleep paralysis, several behavioural therapies have been suggested. In general, attempting to keep your sleep quality high may help person to avoid developing sleep paralysis. Since the person may now regulate and end the event at will, being able to interrupt episodes is likely to reduce the dread and distress associated with sleep paralysis.
[16][17]

CONCLUSION

At the 6-month follow-up, the patient stated that his complaints of snoring and anxiety had decreased with the use of the comprehensive regimen comprising pharmacological and physiotherapeutic interventions. Interestingly, he was no longer having periods of paralysis during sleep. He was therefore encouraged to keep using the all-encompassing treatment. He reports feeling rejuvenated in the morning and sleeping peacefully and uninterruptedly these days.

ABSTRACT

An integrated Economic Production Quantity (EPQ) model for imperfect manufacturing systems operating under sustainability goals and uncertain situations. This study addresses several real-life issues containing the generation of defective items, non-reworkable, reworkable outputs, 100% inspection process and partial backordering. Given the inherent uncertainty in practicalsituation, fuzzy set theory was incorporated to deal with uncertainty in defect rates, cost parameters and rework proportions. For sustainable manufacturing a green cost function is formulated to address the environmental impact pertaining to production waste. Additionally, a traceability cost component is incorporated as a blockchain-based traceability mechanism to deal with transparency during inspection and rework process. To optimize the production and shortage quantity the total cost function includes economic, environmental, and traceability cost. Numerical example is solved to show that encompassing traceability cost, fuzziness and Sustainability consideration enhances the quality-driven inventory system in a high-precision manufacturing environment.

Keywords: Numerical, manufacturing, environment, reworkable, Economic

INTRODUCTION

The evolving industrial landscape has experienced a transformative move toward implementing digital traceability, sustainability, and uncertainty management into the production process. Classical inventory models Economic Production Quantity (EPQ) modeloften overlooks practical complexities like quality variability, the environmental footprint of waste and production imperfections. Practically, manufacturing systems often produce reworkable and non-reworkable defective items, which makes the quality control and inspection process difficult(Ceylan and Aydemir (2025)). It highlights the need to extend the EPQ model,which is essential for supporting inventory control with product quality and operational reliability.

In modern production, the most important challenge is handling uncertain parameters consisting of defect rates, fluctuating costs, and rework proportions, which are not precisely known. In this condition, capturing imprecision and vagueness, fuzzy set theory has proven effective in inventory systems.For better decision making,Mamdani-type fuzzy logic is used to create a rework depletion order that exactly captures the circumstance of rework data Neves and Salgado (2023). By enhancing the inventory control decision-making Garg et al. (2023) established a fuzzy inventory batch size model with scrap and damaged products in an examination policy. In addition to this, using fuzzy system in the production process, Rahaman et al. (2022) highlighted the fuzzy production inventory model with deterioration. These modern methods highlight fuzzy logic's increasing applicability in production and inventory system optimization in the presence of inherent uncertainty.

In inventory modeling sustainability has become a thoughtful evaluation, specifically the global rush towards cleaner production in light of maximizing environmental regulations. To reduce the cost of waste, resource consumption, and emissions (Harris et al., 2021; Hua et al., 2020) introduced the green cost functions in Economic Order Quantity and Economic Production Quantity models. These cost functions help to balance economic objectives with environmental responsibilities. When the production process is imperfect, scrap and waste disposal are unavoidable.By including green costs in this type of model, manufacturers are provoked to think about the environment before making decisions.

Furthermore, the adoption of blockchain technology supported supply chain transparency and traceability in quality management. Blockchain can record, rework and inspection events in real time. It gives a decentralized ledger that helps in enhancing accountability and traceability for the production period. (Saberi et al., 2019; Kshetri, 2018). This technology is used for manufacturing sectors like aerospace, food processing, and pharmaceuticals, where the quality and trust of the product is critical. By allocating a traceability cost to every reworked or accepted items, Industrialist can experience the trade-off between cost, process efficiency and traceability.

In this study, an integrated Economic Production Quantity model is introduced for imperfect production processes that include shortages, fuzzy uncertainty, green cost functions, reworkable, non-reworkable items, and blockchain-based traceability. The total cost function includes economic, traceability, and environmental costs. A digital traceability cost is added using the blockchain technology, and fuzzy number are employed to manage uncertainty in key parameters. A numerical example is used to evaluate the model's decision. This study aims to encourage transparent, sustainable and high-accuracy inventory models in today's manufacturing environments.

METHODOLOGY

Basic definitions

Definition 1

The membership function ν_A and the set $A=\{y,\nu_A(y);\ y\in Y\}$ defined by $\nu_A(y)\ \forall\ y\in Y$ is called a fuzzy set.

Let A be the fuzzy set, which is defined on the universal set $\Re$, is said to be a fuzzy number whose membership function has the following traits:

- $\nu_A:\Re\to[0,1]$ is continuous
- $\nu_A(y)=0$ *for all* $y\in(-\infty,a_1]\cup[d_1,\infty)$.
- $\nu_A(y)$ strictly decreasing on $[c_1,d_1]$ and increasing on $[a_1,b_1]$
- $\nu_A(y)=1\ \forall y\in[b_1,c_1]$, where $a_1\prec b_1\prec c_1\prec d_1$

Definition 2

A trapezoidal fuzzy number $A=(a_1,b_1,c_1,d_1)$ and its membership function is given by

$$\nu_A(x)=\begin{cases}\dfrac{y-a_1}{(b_1-a_1)} & a_1\le y\prec b_1\\ 1 & b_1\le y\le c_1\\ \dfrac{y-d_1}{c_1-d_1} & c_1\prec y\le d_1\\ 0 & otherwise\end{cases}$$

Definition 3

The fuzzy set A is defined on the universal set $\Re$ is said to be the generalized fuzzy number then its membership function has the following traits:

- $\nu_A:\Re\to[0,1]$ is continuous
- $\nu_A(y)=0$ *for all* $y\in(-\infty,a_1]\cup[d_1,\infty)$.
- $\nu_A(y)$ strictly decreasing on $[c_1,d_1]$ and increasing on $[a_1,b_1]$
- $\nu_A(y)=k\ \forall y\in[b_1,c_1]$, where $0\prec k\le 1$

Definition 4

A generalized trapezoidal fuzzy number $A=(a_1,b_1,c_1,d_1;k)$ and its membership function is given by

$$\nu_A(x)=\begin{cases} k\dfrac{y-a_1}{(b_1-a_1)} & a_1 \le y \prec b_1 \\ k & b_1 \le y \le c_1 \\ k\dfrac{y-d_1}{c_1-d_1} & c_1 \prec y \le d_1 \\ 0 & otherwise \end{cases}$$

Definition 5

Let $A=(a_1',b_1',c_1',d_1';k_1)$ and $B=(a_1'',b_1'',c_1'',d_1'';k_2)$ be the two generalized trapezoidal fuzzy number defined on the universal set of real numbers $\Re$ and the arithmetic operations between two generalized trapezoidal fuzzy numbers are given below,

- $A\oplus B=(a_1'+a_1'',b_1'+b_1'',c_1'+c_1'',d_1'+d_1'';\min imum(k_1,k_2))$
- $A-B=(a_1'-d_1'',b_1'-c_1'',c_1'-b_1'',d_1'-a_1'';\min imum(k_1,k_2))$
- $A\otimes B \square (a_1,b_1,c_1,d_1;\min imum(k_1,k_2))$, *where* $a_1=\min imum(a_1'a_1'',a_1'd_1'',a_1''d_1',d_1'd_1'')$,

  $b_1=\min imum(b_1'b_1'',b_1'c_1'',c_1'b_1'',c_1'c_1'')$ $c_1=\max imum(b_1'b_1'',b_1'c_1'',c_1'b_1'',c_1'c_1'')$ *and*
  $d_1=\max imum(a_1'a_1'',a_1'd_1'',a_1''d_1',d_1'd_1'')$
- $\eta A=\begin{cases}(\eta a_1',\eta c_1',\eta b_1',\eta d_1';k_1) & \eta \succ 0 \\ (\eta d_1',\eta c_1',\eta b_1',\eta a_1';k_1) & \eta \prec 0\end{cases}$

NOTATIONS

R_r - Rate of rework per unit time.

M_r - Rate of Manufacturing per unit time $(M_r \le R_r)$

S_r - Rate of screening per unit time $(S_r \prec M_r)$

D_r - Rate of demand per unit time $(D_r \prec S_r)$

β - Reworkable items ratio.

γ - Scrapped items ratio.

ω - Defective items ratio $\omega=\beta+\gamma$

P_s - Setup cost for production.

R_s - Setup cost for rework.

P_c - Cost of production per item.

R_c - Cost of rework per item.

D_c - Cost of disposal per item.

H_p - Cost of holding a good quality item per unit time.

H_r - Cost of holding a reworkable item per unit time.

S_c - Cost of shortage per item per unit time.

C_l - Lead time

C_s - Scrap disposal

C_r - Emission cost

C_e - Energy cost

P_p - Duration of production per cycle.

S_p - Duration of screening per cycle length

R_p - Duration of rework per cycle.

C_p - Duration of consumption per cycle

I_{pp} - Accessible maximum inventory during production time.

I_{rp} - Accessible maximum inventory during the rework time.

I_{sp} - Accessible maximum inventory during the Screening time after to the production time.

Tc_m - Model's total cost.

P_Q - Quantity of production per cycle.

S_Q - Quantity of shortage per cycle.

Mathematical Modelling

An extended Economic Production Quantity (EPQ) model is developed in this study, which established a classical inventory system with precise inspection, scrap, shortages and rework. Aim of this study is to minimize the total cost per unit time under environmental sustainability analysis, traceability requirements, and uncertainty. In a real – life the produced items are not always perfect some of them are defective. we accept a constant rate M_r of production, 100% screening for all items at a rate of S_r, a proportion ω of items are imperfect, a reworkable portion β, a scrap item γ, so $\omega = \beta+\gamma$. A repaired items are reworked at a rate of R_r then the scraped items are discarded, while the perfect and reworked items are maintained to meet the demand. The basic cost components include, cost for setup during production and rework cycle P_s and R_s, cost of producing a item P_c, reworkable per item R_c, disposal cost per unit D_c ,Holding cost H_p and shortage cost S_c, the rate of demand D_r is uncertain. The renewal cycle length converted a classical cost per cycle in to a cost per unit time.

$$f_1 = \frac{S_Q}{M_r - (\beta+\gamma)S_r - D_r} \quad (1)$$

$$f_2 = P_p - f_1$$

$$f_2 = \frac{P_Q}{M_r} - \frac{S_Q}{M_r - (\beta+\gamma)S_r - D_r} \quad (2)$$

$$f_3 = S_p - P_p = \frac{P_Q}{S_r} - \frac{P_Q}{M_r} = \frac{P_Q(M_r - S_r)}{M_r S_r} \quad (3)$$

$$C_p = \frac{I_{rp}}{D_r} \quad (4)$$

$$f_4 = \frac{S_Q}{D_r} \quad (5)$$

In each period the maximum level of inventory is similar to:

$$I_{pp} = \left(M_r - (\beta+\gamma)S_r - D_r\right)\frac{P_Q}{M_r} - S_Q \quad (6)$$

$$I_{sp} = I_{pp} - \left((\beta+\gamma)S_r - D_r\right) f_3 = \frac{\left((1-\beta-\gamma)S_r - D_r\right)}{S_r} - S_Q \quad (7)$$

$$I_{rp} = I_{sp} + \left(R_r - D_r\right)\frac{\beta P_Q}{R_r} = \frac{\left((1-\beta-\gamma)S_r - D_r\right)P_Q}{S_r} + \left(R_r - D_r\right)\frac{\beta P_Q}{R_r} - S_Q \quad (8)$$

Let us define the lead time as:

$$F = f_1 + f_2 + f_3 + R_p + C_p + f_4 = \frac{(1-\gamma)P_Q}{D_r} \quad (9)$$

The following cost components are effectively used for resulting the economic indication of system manufacturing inventory. It includes production cost, disposal cost, setup cost, and the system holding cost.

Setup cost = $\frac{D_r P_s}{(1-\gamma)P_Q}$ (10)

Disposal cost = $\frac{D_r D_c \gamma}{(1-\gamma)}$ (11)

Shortage cost = $\frac{S_c}{2C_l}\left(S_Q\left(f_1 + f_4\right)\right) = \frac{S_c\left(M_r - (\beta+\gamma)S_r\right){S_Q}^2}{2(1-\gamma)\left(M_r - (\beta+\gamma)S_r - D_r\right)P_Q}$ (12)

Carrying cost for perfect goods

$$\left(\frac{H_p\left(M_r - (\beta+\gamma)S_r - D_r\right)D_r}{2(1-\gamma)M_r S_r} + \frac{H_p\left((1-\beta-\gamma)S_r - D_r\right)\left((1+\beta-\gamma)M_r - D_r\right)}{2(1-\gamma)M_r S_r} + \frac{H_p\gamma^2\left(R_r - D_r\right)}{2(1-\gamma)R_r}\right)P_Q - H_p S_Q$$

$$+\left(\frac{H_p\left(M_r - (\beta+\gamma)S_r\right)}{2(1-\gamma)\left(M_r - (\beta+\gamma)S_r - D_r\right)}\right)\frac{{S_Q}^2}{P_Q} \quad (13)$$

Carrying cost for scrap items $\frac{H_r\beta P_Q\left(S_p + R_p\right)}{2C_l} = \frac{H_r\beta D_r\left(R_r + \beta S_r\right)}{2(1-\gamma)S_r R_r}P_Q$ (14)

Environmental cost $\beta^* = C_s\gamma + C_r\beta + C_e\left(\frac{1}{M_r} + \frac{1}{S_r} + \frac{\beta}{R_r}\right)$ (15)

Blockchain – based Traceability cost $C_b.(1-\gamma)P_Q$ (16)

The total cost function of the system is shown below,

$$T = \frac{D_r\left(P_s + R_s\right)}{\left(1-\gamma\right)P_Q} + \left(\lambda + \eta R_c + C_b\left(1-\gamma\right)\right)P_Q + \rho\frac{{S_Q}^2}{P_Q} - H_p S_Q + \frac{D_r\left(P_c + D_c\gamma + R_c\beta\right)}{\left(1-\gamma\right)} \quad (17)$$

Where,

$$\lambda = \frac{H_p\left(M_r - \left(\beta+\gamma\right)S_r - D_r\right)D_r}{2\left(1-\gamma\right)M_r S_r} + \frac{H_p\left(\left(1-\beta-\gamma\right)S_r - D_r\right)\left(\left(1+\beta-\gamma\right)M_r - D_r\right)}{2\left(1-\gamma\right)M_r S_r}$$

$$+\frac{H_p\gamma^2\left(R_r - D_r\right)}{2\left(1-\gamma\right)R_r} + \frac{H_r\beta D_r\left(R_r + \beta S_r\right)}{2\left(1-\gamma\right)S_r R_r}$$

$$\rho = \frac{\left(S_c + H_p\right)\left(M_r - \left(\beta+\gamma\right)S_r\right)}{2\left(1-\gamma\right)\left(M_r - \left(\beta+\gamma\right)S_r - D_r\right)}$$

To ensure the problem feasibility, the relationship holds: $M_r \geq \left(\beta+\gamma\right)S_r + D_r$ and $\left(1-\beta-\gamma\right)S_r \geq D_r$.

To find the optimal solution we partially derive the total cost function and obtain the variable S_Q, which is expressed as, $S_Q = \frac{H_p P_Q}{2\rho}$ (18)

Differentiating the equation 17 partially to obtain the value of the economic production quantity P_Q

$$P_Q = \sqrt{\frac{\frac{D_r\left(P_s + R_s\right)}{1-\gamma} + \rho{S_Q}^2}{\lambda + \eta R_c + C_b\left(1-\gamma\right)}} \quad (19)$$

Algorithm

Step 1: Input the trapezoidal fuzzy model parameters

Step 2: Defuzzify the trapezoidal parameters

Step 3: Compute green cost coefficient

Step 4: Compute Intermediate values

Step 5: Choose an initial estimate for S_Q using equation 18

Step 6: Compute Optimal Production Quantity P_Q by equation 19

Step 7: Compute Final total cost T using equation 17

Numerical Example

The input parameters are taken from AH Nobil 2024

$P_s = 800.1\$ / cycle$

$R_s = 500\$ / scrap\ cycle$

$H_r = 5\$ / reworked\ item / yr$

$R_r = 3500\ items\ per\ year$

$P_c = 50\$\ per\ produced\ item$

$R_c = 30\$\ per\ reworked\ item$

$H_p = 10\$\ per\ good\ item\ per\ year$

$S_r = 2800\ items\ per\ year$

$S_c = 20\$\ per\ shortage\ per\ year$

$M_r = 3000\ items\ per\ year$

$D_r = 1000\ items\ per\ year$

$\gamma = 0.15$

$\beta = 0.2$

$D_c = 15\$\ per\ scrap\ item$

Trapezoidal fuzzy parameter

$\tilde{\gamma} = (0.130, 0.140, 0.160, 0.180)$

$\tilde{\beta} = (0.180, 0.190, 0.210, 0.230)$

$\tilde{D}_r = (950.1, 970.0, 1030.1, 1050)$

$\tilde{D}_c = (13.2, 14.0, 16.1, 18.0)$

$\tilde{R}_c = (28, 29.0, 31.0, 32.0)$

$\tilde{P}_c = (48.0, 49.0, 51.0, 52.0)$

$\tilde{H}_p = (9.0, 9.5, 10.51, 11.0)$

Defuzzification method

We defuzzify the trapezoidal fuzzy parameters using graded mean integration4 method

$$y^* = \frac{y_1 + 2y_2 + 2y_3 + y_4}{6}$$

$$\tilde{\gamma} = \frac{0.130 + 2(0.140) + 2(0.160) + 0.180}{6} = 0.1517$$

$$\tilde{\beta} = \frac{0.180 + 2(0.190) + 2(0.210) + 0.230}{6} = 0.2033$$

$$\tilde{D}_r = \frac{950.1 + 2(970.0) + 2(1030.1) + 1050}{6} = 1000$$

$$\tilde{D}_c = \frac{13.2 + 2(14.0) + 2(16.1) + 18.0}{6} = 15.17$$

$$\tilde{R}_c = \frac{28 + 2(29.0) + 2(31.0) + 32.0}{6} = 30.01$$

$$\tilde{P}_c = \frac{48.0 + 2(49.0) + 2(51.0) + 52.0}{6} = 50.01$$

$$\tilde{H}_p = \frac{9.0 + 2(9.5) + 2(10.51) + 11.0}{6} = 10.0$$

Using the defuzzified values of the parameters we obtain the following results

Environmental cost $\beta^* = C_s\gamma + C_r\beta + C_e\left(\frac{1}{M_r} + \frac{1}{S_r} + \frac{\beta}{R_r}\right)$ ⊔ 1.3685

Setup cost = $\frac{D_r P_s}{(1-\gamma)P_Q}$ ⊔ 4025.3

Blockchain – based Traceability cost $C_b.(1-\gamma)P_Q$ ⊔ 645.71

$S_Q = \frac{H_p P_Q}{2\rho}$ = 120 units

Economic Production Quantity $P_Q = \sqrt{\frac{\frac{D_r(P_s + R_s)}{1-\gamma} + \rho S_Q{}^2}{\lambda + \eta R_c + C_b(1-\gamma)}}$ ⊔ 380.59

And the total cost function $T = \frac{D_r(P_s + R_s)}{(1-\gamma)P_Q} + (\lambda + \eta R_c + C_b(1-\gamma))P_Q + \rho\frac{S_Q{}^2}{P_Q} - H_p S_Q + \frac{D_r(P_c + D_c\gamma + R_c\beta)}{(1-\gamma)}$ = 20,143.30

CONCLUSION

This research enables an integrated economic production quantity model with advanced constituent: green inventory cost, blockchain based traceability, trapezoidal fuzzy parameters along with the strict examination, rework, and shortages. The uncertain parameters such as remanufacturing items and costs are handled efficiently by using trapezoidal fuzzy number. The impact of rework emission, scrap and energy usage are controlled by the inclusion of environmental cost function. Blockchain based traceability cost is a modern cost component introduced for the secure and auditable logging of standard data collection, which is growingly important in high-risk manufacturing sectors. Numerical example is illustrated to show the efficiency of the model;these advanced constituentsled to a modest rise in cost but showed precise and more environmentally sustainable batch quantity and enhanced traceability. The model expressed a robust realistic, and initiate a forward decision tool for producers focusing to align with sustainability and digital accountability for operational productivity.

ABSTRACT

This case study explores the transformative role of modern libraries within the organizational knowledge management (KM) framework. Moving beyond traditional book-lending functions, libraries are positioned as strategic hubs for capturing, organizing, and disseminating both tacit and explicit knowledge. Through an in-depth analysis of a selected institutional library, this research investigates its application of KM tools, including digital repositories, expert directories, and collaborative platforms, to facilitate seamless information retrieval and foster a culture of shared learning. The study identifies challenges such as technological integration and user engagement, while highlighting the library's success in bridging knowledge gaps and supporting decision-making processes. Findings demonstrate that by proactively managing intellectual assets, libraries enhance organizational memory and innovation. Ultimately, this case underscores the library's evolution into a dynamic knowledge center, affirming its vital contribution to achieving strategic goals through effective knowledge stewardship and sustainable information management practices.

Keywords: Library, Knowledge Management, Information Management, Explicit Knowledge, Tacit Knowledge

INTRODUCTION

Knowledge Management (KM) is increasingly recognized as a vital component for organizations seeking competitive advantage in today's fast-paced environment. The concept revolves around the systematic management of vital knowledge, which includes the processes of creating, gathering, organizing, diffusing, using, and exploiting knowledge. The shift from the notion of "Knowledge is Power" to "Knowledge Sharing is Power" underscores the importance of collaboration and the sharing of knowledge within organizations. This paper discusses the role of

libraries and librarians in facilitating effective KM practices. Knowledge can be categorized into two primary types: explicit and tacit knowledge.

- **Explicit Knowledge:** This type of knowledge is documented and easily codified, such as books, manuals, and databases.
- **Tacit Knowledge**: This resides in individuals and includes personal experiences, skills, and insights that are often difficult to articulate or document.

The Need for Knowledge Management

The recognition of knowledge as a key competitive advantage has led to a growing interest in KM. Important factors driving this interest include the need to avoid costly mistakes, improve decision-making, enhance fund management, and adapt to changes in traditional knowledge transfer methods. Effective KM practices are essential for organizations to leverage their knowledge assets fully.

Key Features of KM

KM is rooted in various disciplines, including business, education, and sociology. Some of the key features of KM include:

- The integration of technology and people in knowledge processes.
- The variability of KM practices across different organizations.
- The emphasis on sharing information and expertise.
- The cultural shift from viewing knowledge as power to promoting knowledge sharing.

Components of KM

The components of KM encompass people, technology, processes, and organization. Effective KM requires the integration of these components to achieve organizational goals efficiently. The paper highlights the importance of technology, such as databases and data mining tools, in facilitating knowledge management, involves several critical activities:

- **Knowledge Generation:** The process of creating knowledge through individual and collective experiences.
- **Knowledge Acquisition:** Identifying and assessing the knowledge required to meet organizational objectives.
- **Knowledge Sharing:** Distributing relevant knowledge to the right people at the right time.
- **Knowledge Application:** Applying acquired knowledge to specific situations to create user value.

Role of Libraries in KM

Libraries play a crucial role in KM by promoting knowledge innovation. They serve as essential links in the scientific system chain, facilitating the collection, processing, storage, and dissemination of knowledge. The paper outlines several key roles of libraries in KM:

- **Knowledge Innovation:** Libraries contribute to the management of knowledge production, diffusion, and transfer.
- **Theoretical Innovation Management:** Libraries enrich research fields by pursuing the latest developments in relevant areas.
- **Technical Innovation Management:** Libraries manage networks and systems related to technical innovation.
- **Organizational Innovation Management:** Libraries create effective management systems to support KM activities.

Challenges and Opportunities for Libraries

Despite the critical role libraries play in KM, they face challenges in acquiring knowledge that resides in the minds of knowledge creators. The paper emphasizes the need for libraries to strengthen their dissemination of KM practices and adapt to the digital age. Libraries can achieve this by:

- Establishing virtual libraries or information centers tailored to the needs of organizations.
- Developing digitized knowledge services to enhance information dissemination and search capabilities.

- Transforming existing non-electronic resources into electronic formats to create comprehensive digital libraries.

The Evolving Role of Librarians

The role of librarians is evolving in response to the demands of the digital world. Librarians are transitioning from traditional information intermediaries to knowledge managers. Key roles for librarians in the future include:

- **Consultant:** Providing remote support and consultation to users.
- **Analyst:** Analyzing and interpreting information for end-users.
- **Facilitator/Trainer:** Training users in effective research and information retrieval techniques.
- **Intranet Content Manager:** Managing content accessible through organizational intranets.
- **Product Planner and Marketer:** Packaging and marketing information products and services.
- **Knowledge Manager:** Integrating various information functions into a cohesive knowledge management strategy.

CONCLUSION

The paper concludes that effective KM practices are essential for organizations to navigate the complexities of knowledge in the modern world. Libraries and librarians have a pivotal role in this process, transitioning from traditional roles to become integral knowledge managers. The challenges posed by the digital age require libraries to innovate and adapt their services to meet the evolving needs of knowledge users.

ABSTRACT

Cassia senna possess both Antibacterial and Anti cancer properties. Senna has less bioavailability (less than 5%). To improve the bioavailability, there is a need to develop Senna nanoparticles. Therapeutic efficacy can be improved by converting into the senna nanoparticles. The aim of the present study is to develop senna nannoparticles using nanoprecipitation technique. The dried extract was obtained using soxhlet apparatus. In phytochemical screening tests, it was observed that the presence of Tannins, Alkaloids, Saponins, Flavonoids, Quinones and Anthraquinones.TLC revealed that the ethanolic extract of leaves of Senna alata contained tannins, alkaloids, flavonoids, terpenes and phenols. Five formulations were prepared with different drug (senna extract): polymer (ethyl cellulose) ratio i.e F1,F2, F3, F4 and F5. The maximum entrapment efficiency of F3 formulation as determined by ultracentrifugation was 55.55%. Ethanolic extract of senna nanoparticle has shown 76.32% of drug content, Zeta potential of -30.0(mV), with a specific spherical size and shape observed by SEM. Hence, F3 was considered to be the best formulation among all the formulations. The final formulation F3 was studied for cytotoxicity by MTT Assay method and the IC 50 value of the Nanoherbal formulation was found to be 71.12µg. From the literature, it was observed IC 50 value of Cassia senna extract was found to be 81.6µg.By converting into Nano formulation, the cytotoxicity of Cassia senna has been improved. Formulation of nanoparticles for Cassia senna improved dissolution profile as well the anti-cancer property also.

Key words:- Nanoparticles, Entrapment efficiency, Loading capacity, Cassia senna

INTRODUCTION

Senna (from Arabicsanā), the **sennas**, is a large genus of flowering plants in the legume family Fabaceae, and the subfamily Caesalpinioideae. Its species occur as trees, shrubs or sub shrubs in great diversity and wide distribution, with several species of economic importance for the production of medicinal substances. The members of this genus characteristically contain anthraquinones and alkaloids, which are substances with antioxidant and anticancer activities [1,2]. Cassia senna possess both Antibacterial and Anti cancer properties. Senna has less bioavailability (less than 5%). To improve the bioavailability, there is a need to develop Senna nanoparticles [3,4]. Therapeutic efficacy can be improved by converting into the Senna nanoparticles. To avoid adverse effects caused by allopathic treatment there is a need to develop Senna nanoparticls. As cancer treatment is expensive, herbal formulation development will be useful for the society and will make cancer treatment affordable in population with less income [5,6]. As Allopathic system of medicine causes major adverse effects such as Immune suppression, nephrotoxicity, Peripheral neuropathy, ototoxicity, herbal formulation development can minimize the adverse effects. The bioavailability of senna was found to be less than 5%, So Nanoparticle drug delivery system was chosen to improve the bioavailability and therapeutic efficacy [7,8]. Nano precipitation is considered to be a simple and good technique for the preparation of nanoparticles and hence it was chosen to formulate Senna nanoparticles.EC was proven to be a sustained release polymer. Hence EC was selected in this study. As per the literature, Nanoparticle drug delivery system has not yet been developed for Cassia senna. Hence, this study is considered to be novel. Hence nano particle drug delivery system was designed for Cassia senna leaf extract to improve the bioavailabity [9,10].

METHODOLOGY

The leaves were air dried for 5-6 hrs and further reduced to coarse powder using a grinder.

Preparation of the extract:

Cassia Senna was cultivated in college campus. Senna leaves were extracted with ethanol using a soxhlet apparatus. The dried powdered sample was placed in the extraction tube separately and extracted with the ethanol. 20g of the powder sample was extracted for 4-5h. The extract was collected in the flask and vacuum dried. The dried extract was stored in a refrigerator for further experiments [11, 12].

Preliminary Phytochemical Studies of ethanolic Extract of Cassia Senna

Qualitative tests were used to analyze the phytochemical compounds in the solvent free extract of Cassia senna leaves.

Antimicrobial Activity of Extracts

Activities of the extract against 4 clinical pathogens were observed using Kirby Bauer's well diffusion method. Pathogens were plated on nutrient agar medium and 100 µl of the extract was placed in the wells, incubated for 24-48 h at 32°C. Then the anti microbial activity was determined by measuring the zone of inhibition.The clinical pathogens used were Staphylococcus aureus, Pseudomonas aeruginosa, Escherichia coli and Bascillus subtilis. They were obtained from Microbial Biotechnology Laboratory [13].

Thin Layer Chromatography (Tlc)

For TLC determination of the extract, silica gel plated glass slides were used with different solvent systems like hexane: ethyl acetate in a different ratio (9:1),(8:2),(7:3),(6:4) and (5:5). The plates were observed under UV and checked for Rf value

Preparation of Senna Nanoparticles By Nanoprecipation Method

Using nanoprecipitation technique, five different formulations were prepared as shown in table 1.

Weighed quantities of Senna extract and Ethyl Cellulose were dissolved in 10 ml of ethanol. The organic phase was then added to 100ml of aqueous phase containing polyvinyl alcohol with continuous stirring at 700 rpm. Formation of precipitate was the end point. After the attainment of endpoint, the solution was kept for stirring for 5 hours. The formed precipitate was separated from the solution by means of vacuum rotary evaporator. The obtained precipitate was air-dried to completely remove the moisture content [15,16].

RESULTS AND DISCUSSIONS

Extraction:

The dried extract was obtained by extracting with ethanol using soxhlet apparatus [17]

Preliminary Phytochemical Screening Test:

Senna extract was screened for phytochemical screening tests; the presence of alkaloids, saponins, flavonoids, tannins, quinines and anthraquinones was observed.

Thin Layer Chromatography

Senna was subjected to TLC, to confirm the presence of major compound. Combination of n-hexane and ethyl acetate in a different ratios such as 9:1,8:2,7:3,6:4 and 5:5was taken as mobile phase. Rf values were observed for different bands and the values were found to be 0.43 which reveals the presence of tannins. 0.75 indicated as a presence of alkaloids. 0.84 indicates the presence of flavonoids. 0.16 confirms the presence of terpenes and 0.56 reveals the presence of phenols respectively.

Antimicrobial Activity

Of all the pathogenic micro-organism tested, the assay showed prominent activity. The ethanolic extract of leaves of Senna alata was highly effective against Staphylococcus aureus with a zone of inhibition 31.4mm, Basillus subtilis and E.coli with a zone of inhibition 27.8 mm and 25.4 mm respectively. The zone of inhibition for Staphylococcus aureus and Basillus subtilis was found to be 31.mm and 27.8mm. It has been compared with Streptomycin disc. The zone of inhibition for this disc was found to be 26.8mm. So, the senna extract was exhibiting good antimicrobial property than Streptomycin disc as shown in figure 1.

Results and Discussions of Senna Loaded Ethyl Cellulose Nanoparticles By Nanoprecipitation Technique

The prepared formulations were characterized for surface morphology, particle size analysis, zeta potential and drug polymer interactions.

Scanning electron microscopy of senna nanoparticles

Senna nanoparticles prepared by nanoprecipitation technique were characterized for surface morphology using scanning electron microscopy. (S-3700N, Hitachi, Japan) [18]. From the SEM images it was found that all the formulations were found to be spherical in shape and were within nanometric range as shown in figure 2.

Determination of Zeta Potential of F3 formulation by Nanoprecipitation technique using Malvern Zetasizer

Among all the 5 formulations, F3 was evaluated for Zeta potential. The zeta potential was found to be -30.0 mV showing high zeta potential value as indicating the formulation is highly stable.

Determination of product yield

The obtained formulations were evaluated for product yield

From fig 3 the percentage of product yield for the formulations was found to be 68.5 ± 2%, 78.3 ± 3%, 86.05 ± 2%, 71.8 ± 2% and 70.7 ± 1% respectively. Among all formulations F3 formulation was showing maximum product yield of 86.05%.

Determination of Drug Content

The obtained formulations were evaluated for Drug content

From fig 4 the percentage of drug content was found to be 61.75 ± 1%, 74.95 ± 2%, 93.43 ± 3%, 80.13 ± 2% and 87.43 ± 2 % respectively. Among all formulations F3 formulation was showing maximum drug content of 93.43%.

Determination of Entrapment Efficiency

The obtained formulations were evaluated for entrapment efficiency**.** From fig 5 the percentage of entrapment efficiency was found to be 49.77 ± 2%, 28.64 ± 1%, 55.55 ± 2%, 41.12 ± 2% and 36.27 ± 1% respectively. Among all formulations F3 formulation was showing maximum entrapment efficiency of 55.55 ± 2%.

Determination of Loading Capacity

The formulations were evaluated for loading capacity using cooling Ultracentrifuge (Elteck)[19]. From fig 6 the percentage of loading capacity was found to be 11.4 ± 1%, 21.5 ± 2%, 33.9 ± 2%, 15.3 ± 1% and 19.7 ± 2% respectively. Among all formulations F3 formulation was showing maximum loading capacity of 33.9%.

In-vitro drug release studies of various Nano formulations

In-vitro drug dissolution studies were performed by using arbitrary shaker. Among all formulations F3 showed maximum drug release of 76.32% in a time period of 12 hrs as shown in fig 7. From fig 8 the drug release pattern of senna extract was found to be 36 ± 2% in a time period of 12 hrs. By converting into nano formulation, The drug release was found to be 76.32 ± 3% in 12 hrs. So, the dissolution profile of senna was Improved.

In- Vitro Cytotoxicity Assy Results

Based upon the evaluation and characterization of the formulations, the best formulation F3 was considered for the determination of anti-cancer activity against breast cancer cell line[20].

The anti-cancer activity was determined in-vitro by MTT Assay. The results were showed in table 2. Cisplatin was taken as a standard and its IC_{50} value was observed to be 4.7 micromolor

DISCUSSIONS

Cassia senna is a medicinal herb. It is a safe, harmless, and efficient remedy, it grows well. It is having both antimicrobial and anticancer properties [21]. The dried extract was obtained by extracting with ethanol using soxhlet apparatus. Onyegeme-Okerenta et al. (2017) performed phytochemical analyses of extract of Cassia senna evaluated its possible medicinal properties. Results obtained from the Phytochemical studies showed the presence of saponins, flavonoids, phenolic acid, tannins present as tannic acid, alkaloids including coniine and coniceine and negligible amounts of quinones. Compared to the literature, the present study of the ethanolic extract of Cassia senna was screened for phytochemical constituents which revealed the presence of alkaloids, tannins, flavonoids, saponins, quinines and anthraquinones. Nidhi singh et al. (2016) aimed at screening for bioactive compounds with pharmacological properties from Cassia senna leaves extract. The dried samples were powdered and extracted with ethanol using Soxhlet apparatus. Antimicrobial activity of the extract was checked against different clinical pathogens. The results suggested that they poses antimicrobial activity against Staphylococcus aureus with a zone of inhibition of 19mm. Compared to the literature, in the present study TLC was performed to find out the major active constituents.

It was observed that Tannins is the major component of the extract. Rf values were observed for different bands and the values was found to be 0.43 that indicates the presence of tannins. 0.75 reveals the presence of alkaloids. 0.84

confirms the presence of flavonoids. 0.16 indicates the presence of terpenes and 0.56 confirms the presence of phenols respectively. Compared to the previous literature, the ethanolic extract of leaves of Cassia senna was showing better antimicrobial activity against Staphylococcus aureus with a zone of inhibition of 31.4mm, Basillus subtilis and E.coli with a zone of inhibition of 27.8 mm and 25.4 mm compared to streptomycin disc with a zone of 26.8mm respectively. Mohammed I. Ali et al. (2017) has evaluated antitumor properties in vitro. MTT assay was used to examine the cytotoxic effect on three human cancer cell lines namely HepG2, AND Caco2. Chloroform fraction showed remarkable cytotoxicity against HepG2 cells with IC 50 value of 81.2µg/ml at exposure time 48hrs. The fraction exhibiting weak anti-proliferative effect on Caco2 cells 8.2% respectively. Compared to the literature, in the present study, the best formulation prepared by Nano precipitation technique i.e.1:3 was considered for the determination of anti-cancer activity against MCF-7 Breast cancer cell line. At 5µg/ml the percentage of inhibition was found to be 25.42%, 10µg/ml (52.25%), 25µg/ml (55.93%), 50µg/ml (54.8%), 75 µg/ml (55.56%), 100 µg/ml (46.89%). At 25µg/ml, it was showing maximum percentage of inhibition i.e 55.93%.

The objective of the research work is to formulate and characterize Senna nanoparticles by nanoprecipitation technique. Nanoprecipitation technique was adopted for this as it is considered as simple and good technique to prepare nanoparticles. Senna nanoparticles were prepared at different drug and polymer concentrations i.e, 1:1, 1:2, 1:3, 2:1 and 3:1 (f1, f2, f3, f4 and f5) respectively. Among 5 formulations, f3 formulation was considered as the best formulation because of its mean least particle size 914.1nm with a zeta potential of -30.0mV. The percentage yield , drug content, entrapment efficiency, and loading capacity of the best formulation was found to be 86.05%, 93.4%, 55.55%, 33.9% respectively. It was sustained till 12hrs with 76.32% drug release. F3 formulation was characterized for SEM. The SEM images reveals that the particles were found to be spherical in shape and were within nanometric range. Hence, among all the formulations F3 was considered to be the Best formulation.F3 Formulation was studied for its cytotoxic activity by MTT assay method. The IC_{50} value of the given formulation 1:3 was found to be 71.12 µg. The best formulation prepared by Nanoprecipitation technique i.e.1:3 was considered for the determination of anti-cancer activity against MCF-7 Breast cancer cell line.

CONCLUSION

Nanoprecipitation technique was adopted for the preparation of nanoparticles for the senna extract. From the literature, it was observed Nanoprecipitation technique was yielding good results. It is simple and more efficient method. Five Formulations were prepared by varying the concentrations of drug to polymer. Out of the 5 formulations, F3 formulation was showing better Mean particle diameter of 914.1 nm, stability, good entrapment efficiency i.e 55.55% and high loading capacity (33.9%) Dissolution studies were done for the pure Senna extract and for the prepared Nanoformulation. The dissolution profile for the pure extract was found to be 36.11%. Nano formulation exhibiting better drug release and it was found to be 76.32%. The Senna extract by converting into Nano formulation, the dissolution profile has been improved. The final formulation F3 was studied for cytotoxicity by MTT Assay method and the IC 50 value of the Nano herbal formulation was found to be 71.12µg. From the literature, it was observed IC 50 value of Cassia senna extract was found to be 81.6µg. By converting into Nano formulation, the dissolution profile of Cassia senna has been improved. Formulation of nanoparticles for Cassia senna improved dissolution profile as well the anti-cancer property also. Further research can be done to establish pharmacokinetic and dynamic parameters of the formulation.

ABSTRACT

Knee osteoarthritis is a prevalent musculoskeletal condition affecting older people causing pain, physical disability and reduces quality of life. It also imposes a considerable economic burden on health care system. Knee Osteoarthritis (OA) is a debilitating condition affecting millions of elderly individuals worldwide, leading to impaired mobility, balance disturbances, and reduced quality of life. It is commonly referred to as "wear and tear" of joint but it is the disease of entire joint involving cartilage, joint lining, ligament and bone. Conventional physical therapies, those used in routine clinical practice, are known to contribute to the beneficial effects of knee OA. PNMT involves a combination of exercises targeting neuromuscular control, proprioception, and muscle strengthening. To evaluate the effect of Progressive Neuromuscular training along with conventional therapy over conventional therapy alone, in improving postural balance & functionality and in decreasing pain in knee osteoarthritis. The sample included 16 participants diagnosed with Knee Osteoarthritis, aged 45 to 75 years were included in the study using purposeful convenient sampling method.WOMAC (Western Ontario And Mac master Universities Osteoarthritis Index) Score, NPRS (Numeric Pain Rating Scale), Single Leg Stance (SLS) Test were conducted on participants to evaluate the effect of Progressive Neuromuscular training along with conventional therapy over conventional therapy alone, in improving postural balance & functionality and in decreasing pain in knee osteoarthritis. This 4 weeks neuromuscular training program yielded significant improvement in postural balance and functional outcome in elderly patients with knee osteoarthritis specifically the result show a substantial decrease in pain and disability as evidenced by the significant reduction in WOMAC questionnaire scores (p=0.000048) and NPRS scores (p=0.0000007)

additionally the program leads to enhance functional ability as demonstrated by the significant increase in Single Leg Stance (SLS) test time (p=0.00044). Applied at 95% level of significance to calculate p-value for NPRS scale, One Leg Stance test & WOMAC score. Used for comparing the outcome of Progressive Neuromuscular Training along with conventional therapy and Conventional therapy alone. Progressive Neuromuscular Training along with Conventional therapy is more effective than Conventional Therapy given alone.

Keywords: osteoarthritis, conventional therapy, progressive neuromuscular training

INTRODUCTION

Knee osteoarthritis is a prevalent musculoskeletal condition affecting older people causing pain, physical disability and reduces quality of life. It also impose a considerable economic burden on health care system. [1] Knee Osteoarthritis (OA) is a debilitating condition affecting millions of elderly individuals worldwide, leading to impaired mobility, balance disturbances, and reduced quality of life [2, 3]. It is commonly referred to as "wear and tear" of joint but it is the disease of entire joint involving cartilage, joint lining, ligament and bone. [4] Evidence is growing for the role of systemic factors (such as genetics ,Dietary intake , estrogen use and bone density) and of Local Biomechanical factors.(such as muscle weakness , obesity and joint laxity) .These risk factors are particularly important in weight bearing joints, and modifying them may present opportunities for prevention of osteoarthritis-related pain and disability.[5] Community survey data in rural and urban areas of India in 2007 shows the prevalence of osteoarthritis to be range from 17% to 60.6%, prevalence rate is 32.6% in rural and 60.3% in urban population. [6, **7**] Incidence of knee OA is rising by increasing average age of general population. [8]

Depending upon the cause osteoarthritis is commonly divided into primary and secondary osteoarthritis.[9] Primary osteoarthritis which usually develops at the age of 55 – 60 years, the underlying cause is unknown possibly genetically.[10] In secondary osteoarthritis the cause is usually identified. Risk factors for developing secondary osteoarthritis are obesity, inactivity, previous knee injuries, occupational bending and lifting, hemophilia and mechanical abnormalities. [10,11] Secondary osteoarthritis usually develops at the earlier age. Obesity is one of the strongest and best related risk factors for osteoarthritis. [12] Conventional physical therapies, those used in routine clinical practice, are known to contribute to the beneficial effects of knee OA units but remain under evaluated. Further evidence is needed to decide which conventional physical therapy and medication (CPT) interventions are most effective for which patients, at which dose and at what time in the recovery process.(13) Conventional therapy (strengthening , maitland mobilization) and treatment including exercises and physical therapy, is often prescribed to manage symptoms and improve functionality (14). PNMT involves a combination of exercises targeting neuromuscular control, proprioception, and muscle strengthening, which may enhance postural stability and functional ability in elderly patients with knee OA (15,16). Research has demonstrated that PNMT can improve balance, reduce fall risk, and enhance functional performance in older adults (17,18). However, recent studies suggest that Progressive Neuromuscular Training (PNMT) may offer additional benefits in improving postural balance and functional outcomes (19,20).

Need of the Study

- Knee osteoarthritis (OA) is a pervasive and debilitating condition affecting millions of elderly individuals worldwide leading to impaired postural balance, reduced functionality and decreased quality of life. Conventional therapy including medications, physical therapy and lifestyle modifications is often insufficient in addressing the complex needs of elderly patient with knee OA.

Objective of the Study

- To evaluate the effect of Progressive Neuromuscular training along with conventional therapy over conventional therapy alone, in improving postural balance & functionality and in decreasing pain in knee osteoarthritis.

LITERATURE REVIEW

- Sergio Sazo- Rodriguez conducted a study on "The effects of progressive neuromuscular training on postural balance and functionality in elderly patients with knee osteoarthritis: a pilot study". He concluded that The intervention generated improvements in balance and functionality in elderly patients with knee OA. These changes were observed after 4 weeks of training and were maintained 4 weeks after the end of the intervention.[21]
- Amanda E Nelson AE conducted a study on "A systematic review of recommendations and guidelines for the management of osteoarthritis: The Chronic Osteoarthritis Management Initiative of the U.S. Bone and Joint Initiative ." He concluded that The relative agreement on many OA management recommendations across organizations indicates a problem with dissemination and implementation rather than a lack of quality guidelines. Future efforts should focus on optimizing implementation in settings, where the majority of OA care occurs.[22]
- Toby O. Smith conducted a study on "The effectiveness of proprioceptive-based exercise for osteoarthritis of the knee: a systematic review and meta-analysis. He concluded that Proprioceptive exercises are efficacious in the treatment of knee OA. There is some evidence to indicate the effectiveness of proprioceptive exercises compared to general strengthening exercises in functional outcomes.[23]
- Olalekan A Uthman conducted a study on" Exercise for lower limb osteoarthritis: systematic review incorporating trial sequential analysis and network meta-analysis. He concluded that as of 2002 sufficient evidence had accumulated to show significant benefit of exercise over no exercise in patients with osteoarthritis, and further trials are unlikely to overturn this result. An approach combining exercises to increase strength, flexibility, and aerobic capacity is likely to be most effective in the management of lower limb osteoarthritis. The evidence is largely from trials in patients with knee osteoarthritis. [24]
- Prof. Johannes WJ bijlsma conducted a study on "Osteoarthritis: an update with relevance for clinical practice". He concluded that in the coming years, a better definition of osteoarthritis is expected by delineating different phenotypes of the disease. Treatment targeted more specifically at these phenotypes might lead to improved outcomes. [25]
- J knoop conducted a study on "Proprioception in knee osteoarthritis: a narrative review". He concluded that Recent literature has shown that proprioceptive accuracy may play an important role in knee OA. However, this role needs to be further clarified. A new measurement protocol for knee proprioception needs to be developed. Systematic reviews focusing on the relationship between impaired proprioceptive accuracy, knee pain and activity limitations and on the effect of interventions (in particular exercise therapy) on proprioceptive accuracy in knee OA.
- are required. Future studies focusing on causes of impaired proprioceptive accuracy in knee OA patients are also needed, taking into account that also the non-symptomatic knee may have proprioceptive impairments. Such future studies may also provide knowledge of mechanism underlying the impact of impaired proprioceptive accuracy on knee pain and activity limitations.[26]
- L.Sharma conducted a study on "Is knee joint proprioception worse in the arthritic knee versus the unaffected knee in unilateral knee osteoarthritis?" He concluded that impaired proprioception is not exclusively a local result of disease in knee OA. The relative importance of impaired proprioception in the development and progression of knee OA will require longitudinal study.[27]
- Judit Takacs conducted a study on "The Role of Neuromuscular Changes in Aging and Knee Osteoarthritis on Dynamic Postural Control." He concluded that As a result, this review will: summarize the key characteristics of postural responses to an external perturbation, highlight the changes in dynamic postural control seen with normal aging, review the neuromuscular changes associated with aging that have known and possible effects on dynamic postural control, and summarize the neuromuscular changes and balance problems in knee OA. Future research to better understand the role of neuromuscular changes in knee OA and their effect on dynamic postural control will be suggested. Such an understanding is critical to the successful creation and

implementation of fall prevention and treatment programs, in order to reduce the excessive risk of falling in knee OA.[28]

MATERIALS AND METHODS

Types of study: Quasi Experimental study
Study design: Randomized controlled study
Source of data: Patients was selected from SSG hospital - Vadodara
Methods of collection of data
Research design – experimental study
Sampling design– Purposive sampling
Sampling technique: With purposive sampling technique, 16 participants from S.S.G Hospital Vadodara were recruited.
Sample size :
The sample included 16 participants diagnosed with Knee Osteoarthritis

Inclusion criteria
- Subject with a diagnosis of Unilateral or Bilateral Knee Osteoarthritis.
- Subject with age within 45 to 75 years.
- Both male and female subjects can be taken.
- Subject with independent gait.
- NPRS score $\geq$ 4.
- Kellgren Lawrence System Classification grade of 2 & 3

Exclusion criteria
Subject with:
- The presence of lower limb injury or surgery.
- The presence of congenital deformity.
- The presence of peripheral neuropathy.
- The presence of dementia or other neurological disorders.
- The presence of fainting episodes and/or light headaches.
- Drug consumption that affects the functions of the nervous system.

Outcome measure (Strength)
- WOMAC (Western Ontario And Macmaster Universities Osteoarthritis Index) Score
- NPRS (Numeric Pain Rating Scale)
- Single Leg Stance (SLS) Test

Equipments used:
- Plinth
- Sandbag
- Sitting stool
- Wobble Board
- Foam Mattress
- Parallel Bars
- Stepping Stool
- Sling

Procedure:
16 patients were selected according to inclusion and exclusion criteria and randomly divided into two groups
Conventional:

- Static Quadriceps
- Static Glutei
- Supine lying: Straight leg raising
- Knee flexion and extension
- Vastus Medius Oblique strengthening
- Stretching of hamstrings and quadriceps

Above all exercises are performed 10 repetitions of each exercises.

RESULT

Statistical Analysis
Statistical analysis was done by:

- Paired t-test: Applied at 95% level of significance to calculate p-value for NPRS scale, One Leg Stance test & WOMAC score.

- Unpaired t-test: Used for comparing the outcome of Progressive Neuromuscular Training along with conventional therapy and Conventional therapy alone.

DISCUSSION

- The results of this study showed that neuromuscular training of 4 weeks improved postural balance and functionality in elderly patients with knee OA, due to the significant decrease of the WOMAC Questionnaire score and NPRS score and increase in the SLS test time.
- The postural balance deficit in patients with knee OA may be attributed to alterations in the tissues surrounding the articulations (tendons, ligaments, capsules, etc.) together with the weakness of the abductors of the hip.
- These alterations may be potentiated by the decrease of the excitability of quadriceps motor units—caused by factors such as joint pain, swelling, and laxity—provoking poor voluntary activation, a proprioceptive deficit, and a decrease of neuromuscular control.
- Neuromuscular training possibly improves segmental alignment of the limb, sensorimotor control, and joint stability, optimizing the execution of functional tasks in favour of synchronization and coordination in the activation of lower limb muscle groups during knee movements.
- Our training plan includes the execution of eyes closed exercises with the purpose of promoting postural control through somatosensory and vestibular inputs.
- Thus, it is inferred that the neuromuscular training favoured the re-education of postural balance, generating a significant impact on somatosensory and muscle response, helping the elderly patients use their balance control strategies more efficiently.

CONCLUSION

Progressive Neuromuscular Training along with Conventional therapy is more effective than Conventional Therapy given alone.

Limitation and Suggestion
Small sample size

- Dynamic balance training was not included.
- Short duration.

- Study was conducted in a specific setup.
- The study can be conducted in the future using a larger sample size and for a longer duration, incorporating both static and dynamic balance training.

Stretching of quadriceps

Static Quadriceps

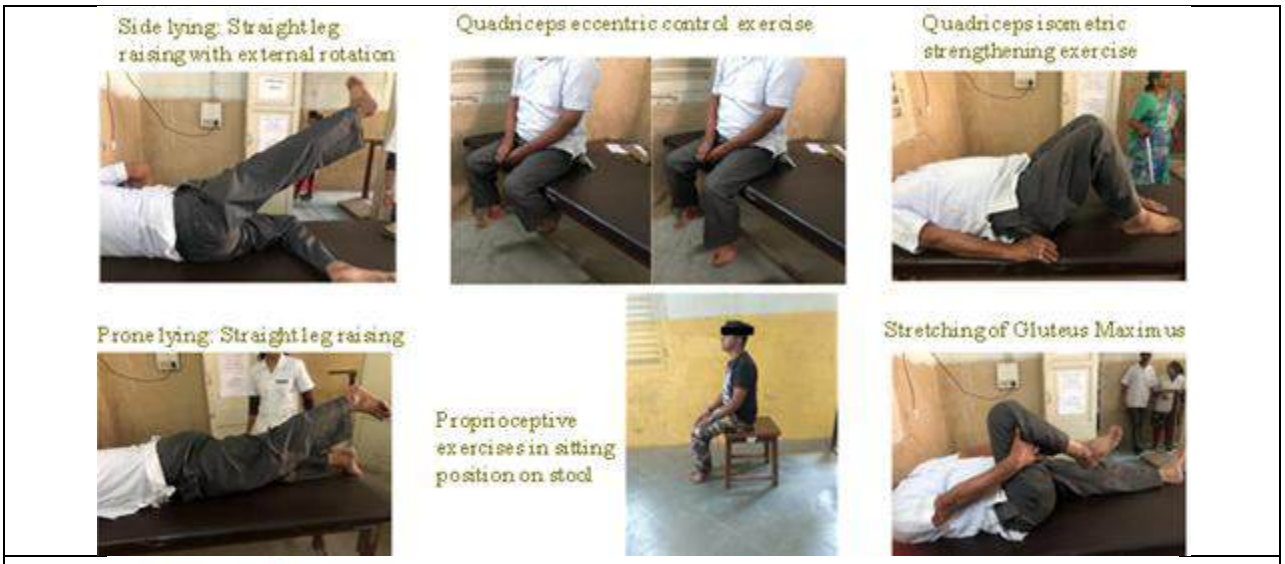
Supine lying: Straight leg raising

Vastus Medius Oblique strengthening

Stretching of hamstrings

Experimental:

Stage I	Exercises without the discharge of body weight	10 Days
Stage II	Exercises with discharge of body weight on stable surfaces	10 Days
Stage III	Exercises with discharge of body weight on unstable surfaces	10 Days



First Stage:

- Quadriceps eccentric control exercise
- Side lying: Straight leg raising Quadriceps isometric strengthening exercise
- with external rotation
- Prone lying: Straight leg raising

10 repetitions

- Proprioceptive exercises in sitting position on stool.

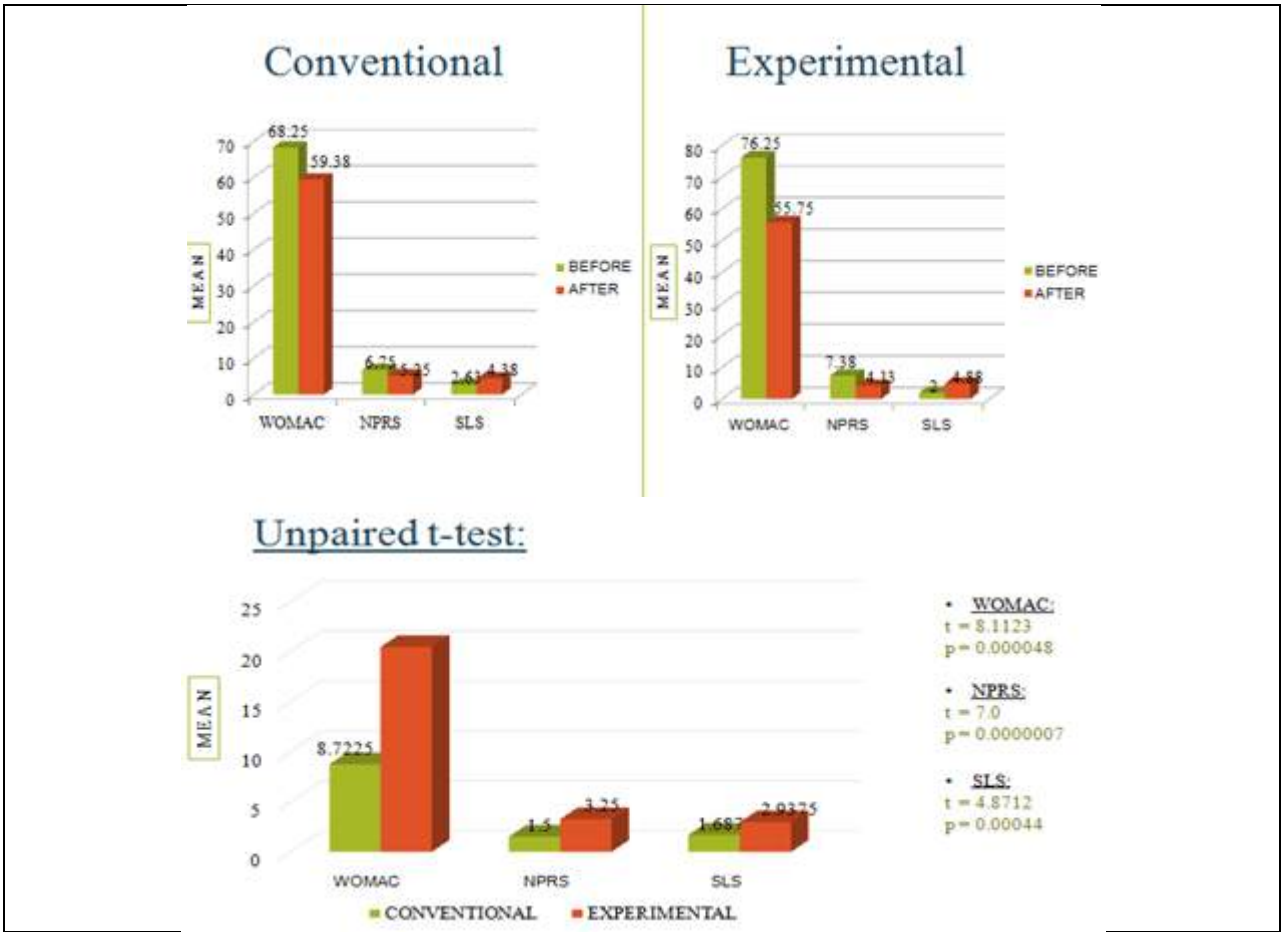
- Stretching of Triceps Surae and Gluteus Maximus

Second stage:

- Forward and Backward Walking
- Side Walking
- Sit to stand from stool
- Supported Step up and step down
- Supported One leg standing with eyes open and closed
- Proprioceptive exercises in sitting position on stool.

} 10 repetitions

- Stretching of Triceps Surae and Gluteus Maximus
- Conventional exercises



Third stage:

- Wobble board: antero-posterior & lateral directions
- Marching on Foam Mattress
- Supported Standing on one extremity on Foam Mattress
- Up (Toe Standing) and down on Foam Mattress
- Proprioceptive exercises in sitting position on stool.
- Forward, Backward and Sideways Slope walking

- Stretching of Triceps Surae and Gluteus Maximus
- Conventional exercises

16 patients were selected according to inclusion and exclusion criteria and randomly divided into two groups

ABSTRACT

One of the most dangerous neurological conditions is brain tumors, which necessitate an early and precise diagnosis in order to establish an appropriate course of therapy. Because magnetic resonance imaging (MRI) provides high-resolution vision of soft tissues, it is frequently utilized to detect brain tumors. However, manual MRI scan analysis is laborious, subjective, and heavily reliantion radiologists' knowledge. In specifically, deep learning models like Convolutional Neural Networks (CNN) and U-Net architectures are used in this study to propose an automated method for brain tumor segmentation and classification. After preprocessing MRI images, the suggested system segments tumor locations and classifies them into pertinent categories, such as tumor and non-tumor or certain tumor kinds. The algorithm eliminates the requirement for manual feature extraction by automatically learning intricate patterns and features from MRI data. When compared to conventional image processing and machine learning techniques, experimental research demonstrates that the suggested AI-based system achieves high accuracy, enhanced sensitivity, and dependable tumor localization.
The findings show that deep learning-based systems can greatly improve brain tumor diagnosis speed and accuracy, assisting radiologists in clinical decision-making and enhancing patient outcomes through early identification.

Keywords: Artificial Intelligence, Deep Learning, Convolutional Neural Network (CNN), U-Net, Image Segmentation, Medical Image Analysis, Computer-Aided Diagnosis (CAD), Brain Tumor Detection, and MRI Brain Imaging.

INTRODUCTION

Brain tumors are aberrant cell growths that can be either benign or malignant. Because they can interfere with essential brain processes including memory, mobility, and cognition, they are a major hazard to human health. Effective treatment planning and increased patient survival rates depend on the early and correct diagnosis of brain tumors. Because magnetic resonance imaging (MRI) produces precise, high-contrast images of the brain's soft tissues, it is one of the most popular imaging methods for diagnosing brain tumors. Despite MRI's efficacy, radiologists still find it difficult and time-consuming to manually interpret brain data. Because tumor shapes, sizes, and locations vary so much, it is also vulnerable to human mistake. Because of this, there is an increasing need for automated technologies that can help doctors properly identify and evaluate brain tumors. Medical image analysis has significantly improved with recent developments in Artificial Intelligence (AI) and Machine Learning (ML), especially Deep Learning approaches. Convolutional Neural Networks (CNN) and U-Net architectures are two models that have demonstrated exceptional performance in automatically learning characteristics from MRI images, allowing for accurate tumor segmentation and classification without the need for human interaction. The goal of this research is to create an automated system that employs AI approaches to segment and classify brain tumors. The technology seeks to increase diagnostic precision, shorten processing times, and help radiologists make more trustworthy clinical judgments. The suggested method improves early tumor detection by utilizing deep learning models, which eventually improves patient care and treatment results.

LITERATURE REVIEW

Brain tumor detection and classification using MRI images has been an active area of research in medical image processing and artificial intelligence. Over the years, several approaches have been proposed, ranging from traditional image processing techniques to advanced deep learning models. Early studies primarily focused on classical image processing methods such as thresholding, edge detection, region growing, and clustering algorithms. These methods were simple and computationally efficient but often failed to handle complex tumor structures and variations in MRI images. Their performance was limited due to low robustness and dependency on manual feature design. Researchers started classifying brain tumors using algorithms like Support Vector Machines (SVM), K-Nearest Neighbors (KNN), and Random Forest when machine learning techniques were introduced. These techniques outperformed conventional methods in terms of accuracy, but they were still largely dependent on manually created features that were taken from MRI scans, which limited their capacity to adapt to other datasets.

Deep learning methods have revolutionized brain tumor analysis in recent years. Manual feature engineering is no longer necessary because to the widespread use of Convolutional Neural Networks (CNN) for automatic feature extraction and categorization. Because CNN-based models can learn intricate spatial patterns, they have demonstrated great accuracy in identifying cancers from MRI data. The U-Net architecture has emerged as one of the most often used models in medical imaging for segmentation tasks. It is quite good at precisely identifying tumor boundaries at the pixel level. Segmentation performance has been further enhanced by U-Net variants such as 3D U-Net and Attention U-Net. Advanced methods include transformer-based architectures, attention processes, and hybrid models that combine CNN and recurrent neural networks (RNN) have also been studied recently. In managing intricate MRI datasets like BraTS, these models have shown increased robustness, enhanced accuracy, and better feature representation. Overall, the literature indicates a clear shift from traditional methods to deep learning-based approaches, which provide higher accuracy, better automation, and improved reliability in brain tumor detection and classification systems.

Proposed System

The goal of the suggested system is to use artificial intelligence methods, particularly deep learning models, to create an automated framework for brain tumor segmentation and classification. By increasing the precision, speed, and dependability of brain tumor diagnosis using MRI scans, the system is intended to support medical practitioners.

A sequential pipeline that interprets MRI images and generates a final diagnostic output makes up the system's overall design. After entering MRI brain images, the system goes through a preprocessing phase. In order to improve image quality and prepare the data for additional analysis, this stage involves performing operations such noise removal, image resizing, normalization, and contrast enhancement. The segmentation module receives the corrected pictures following preprocessing. In this phase, the tumor region is identified and extracted from the brain MRI scan using deep learning models like U-Net or Convolutional Neural Networks (CNN). In order to precisely locate tumor boundaries at the pixel level, this step is essential. After segmentation is finished, the system extracts features from the segmented tumor region, including texture, shape, intensity, and spatial data. These characteristics aid in differentiating between various brain tumor kinds. The collected features are then input into the classification module, where a deep learning classifier may further classify tumor types including gliomas, meningiomas, or pituitary tumors and determine if the MRI image is benign or malignant. The final result is presented as a diagnostic report that shows whether a tumor is present or not, along with its categorization. The suggested solution increases diagnostic efficiency, lowers human error, and requires less manual labor. The method may be included into computer-aided diagnostic tools to help radiologists make clinical decisions and offers excellent accuracy by utilizing deep learning techniques.

METHODOLOGY

The proposed methodology for autonomously segmenting and classifying brain tumors using AI techniques is an ordered pipeline. It is a multi-step procedure that transforms raw MRI images into valuable diagnostic outputs using deep learning models.

- **Data Collection:** Gathering brain MRI datasets from publically accessible medical libraries is the first step in the procedure. These files usually include labeled photos that are categorized as either tumor-affected or normal, and occasionally they include tumor types such pituitary tumors, meningiomas, and gliomas.
- **Image Preprocessing:** To enhance the quality of MRI pictures and prepare them for analysis, preprocessing is used. This phase consists of: ,Filter-based noise reduction, Resizing an image to a set size Normalization of intensity ,Enhancement of contrast, By doing these actions, unnecessary information is reduced and feature visibility is increased.
- **Image Segmentation:** To separate the tumor area from the brain MRI imaging, segmentation is used. For pixel-level segmentation, deep learning models like CNN-based architectures or U-Net are employed. The precise position and border of the tumor are determined at this step.
- **Feature Extraction:** Important characteristics are taken out of the tumor area after segmentation. Among them are: Features of texture Shape characteristics, Features of intensity, Spatial attributes. These characteristics aid in differentiating between various tumor patterns.
- **Classification:** A classification model, usually a CNN-based classifier, receives the extracted features. The MRI scan is classified by the model into: Normal (no tumor) , There is a tumor Classification of tumor types (if applicable)
- **Model Training and Optimization:** Labeled datasets are used to train the deep learning model. Performance is enhanced via optimization methods like back propagation, loss minimization (cross-entropy loss), and optimizers like Adam.
- **Performance Evaluation:** The system is assessed using common metrics like: Precision Accuracy, Sensitivity (Recall) ,The F1-score , Dice coefficient (for the quality of segmentation)

RESULTS AND DISCUSSION

Standard MRI datasets were used to assess the suggested approach for automatic brain tumor segmentation and classification using AI techniques. Classification accuracy, segmentation quality, and other assessment criteria were used to assess the deep learning model's performance.

Experimental Results

The system performed well in identifying and categorizing brain cancers from MRI images following model training and testing. The findings demonstrate that deep learning-based techniques like CNN and U-Net greatly enhance the accuracy of tumor region identification. The following approximate performance results were attained by the system: 90%to98%accuracy. Accuracy: Excellent accuracy in identifying tumors, Recall (Sensitivity): Accurately identifying cases that are positive for tumors, Dice Score/IoU: Predicted and real tumor locations have a good overlap.

DISCUSSION

The outcomes unequivocally show that the suggested AI-based solution outperforms conventional machine learning and image processing techniques. Deep learning methods eliminate the need for manual feature extraction by automatically identifying intricate patterns in MRI images. The segmentation results demonstrate that U-Net-based designs offer precise tumor boundary identification, which is crucial for treatment planning and clinical diagnosis. Depending on the availability of datasets, the classification model can further categorize tumor types in addition to successfully differentiating between normal and malignant brain scans. Nevertheless, several restrictions were noted. The amount and quality of the training dataset have a significant impact on the model's performance. There may be small differences in accuracy when there are insufficient data or poor quality MRI pictures. Deep learning models also need a lot of processing power and more time to train. Notwithstanding these drawbacks, the approach shows great promise for practical use in medical diagnostics. By decreasing workload, speeding up diagnosis, and boosting the accuracy of brain tumor detection, it can help radiologists.

Overall Observation

The proposed method shows how AI-based medical image analysis may significantly increase the accuracy and efficacy of brain tumor identification, making it a promising tool for future medical applications.

CONCLUSION

In particular, deep learning models like Convolutional Neural Networks (CNN) and U-Net architectures are used in this project's automated system for brain tumor segmentation and classification. In order to detect and diagnose brain cancers with high accuracy, the system efficiently processes MRI brain images through preprocessing, segmentation, feature extraction, and classification stages. When compared to conventional image processing and machine learning techniques, the experimental results show that the suggested strategy greatly enhances diagnostic performance. It can help radiologists in clinical settings because it delivers high accuracy, improved sensitivity, and dependable tumor location. The suggested system's capacity to automatically extract intricate information from MRI images without human interaction is one of its main advantages; this minimizes diagnostic errors and human effort. The method also improves early tumor diagnosis, which is essential for better patient outcomes and efficient treatment planning. However, the size and quality of the training dataset affect the system's performance, and deep learning model training demands a significant amount of processing power. To sum up, the suggested AI-based brain tumor detection method offers a dependable and effective way to analyze medical images. To further improve accuracy and usability in healthcare applications, future improvements might make use of more sophisticated

architectures like transformer-based models, real-time detection systems, and interface with clinical decision-support tools.

ABSTRACT

Many women experience fear regarding the childbirth which is scientifically known as tocophobia. Mild levels of tocophobia may be normal during pregnancy, but its higher to severe levels can be pathological as well as detrimental to the health of the pregnant woman and her unborn child. To assess the prevalence of tocophobia among pregnant women attending selected hospitals of Central Gujarat. This Prevalence study was conducted in Selected Hospitals of Central Gujarat. Total 357 pregnant women participated in the study.35.6% of pregnant women reported mild fear of childbirth, while 64.4% exhibited a moderate level of fear. Overall prevalence of Tocophobia is 17.1%. The analysis revealed a significant association between tocophobia and several obstetrical variables, including trimester of pregnancy, place of routine antenatal care, type of pregnancy, relationship with spouse or partner, exposure to childbirth in an immediate family member, and history of gynaecological problems ($p< 0.05$). It is concluded that most of the women experienced mild to moderate levels of tocophobia. This finding highlights the presence of significant childbirth-related fear among expectant mothers.

Key words: Fear, Pregnancy, Tocophobia, Fear of Childbirth, Pregnnat Women

INTRODUCTION

Pregnancy and motherhood are two of a woman's most precious experiences. For the majority of women, pregnancy should be a time of immense happiness and joy. However, it is reasonable that many women are anxious about childbirth, as it is one of the most intense experiences a woman can endure. Tokophobia is the term for the fear of getting birth.[1] Tocophobia is estimated to affect approximately 14% of pregnant women globally, and its prevalence appears to have increased since the year 2000. Tocophobia, characterized by an intense fear of childbirth, is recognized as a serious psychological condition that impacts expectant mothers worldwide. Several studies conducted in India and other countries have examined its epidemiology and contributing factors. A study conducted in Kerala, India, reported that 17.7% of primigravida women experienced fear related to childbirth.22Similarly, another study found 45.4% of pregnant women in rural Karnataka expressed fear of childbirth, with the most common concerns related to caesarean sections and labor pain.[2] The fear of having children, or primary tokophobia, can begin in early adulthood or shortly after birth. becoming pregnant is advised in order to prevent giving birth. Unfortunately, in certain cases, a woman who is frightened of giving birth chooses to end the planned pregnancy rather than give birth..[3]In secondarytocophobia, women who have previously experienced traumatic childbirth are more likely to suffer from psychological distress and may often request surgical intervention, such as elective caesarean delivery.[4] Tocophobia not only affects the psychological well-being of pregnant women but also has significant implications for maternal and foetaloutcomes.To assess the prevalence of tocophobia among pregnant women attending selected hospitals of Central Gujarat.

METHODOLOGY

This descriptive cross-sectional survey was conducted to assess tocophobia among pregnant women attending selected hospitals in Central Gujarat. Ethical approval for the study was obtained from the Institutional Ethical Committee of Charusat University of Science and Technology. The study was carried out from May 2025 to July 2025with total 357 participants. Each participant received a Participant Information Sheet & inform consent which clearly explained the study's purpose and procedures. Total 4 type of questionnaire used to collect the data: Demographics variables, Modified Kupuwami scale (2023), Obstetrical variables & fear of childbirth questionnaire. The inclusion criteria comprised women aged 20–35 years, those in 1st, 2nd& 3rd trimester of pregnancy, and participants who were willing to participate and provided informed consent. Exclusion criteria included women who had already delivered, those who declined participation, and those with a history of psychiatric illness. Data analysis involved descriptive & Inferential statistics. such as frequency distribution, Percentage. The chi-square test was used to determine associations between variables.

RESULTS

The study comprised 357 pregnant women, with the largest proportion 44.8% aged 24-28 years, representing reproductive years. Joint family systems predominated at 75.4%, reflecting traditional family structures in the region and providing significant social support networks during pregnancy. Rural residence characterized 74.8% of participants, which has important implications for healthcare accessibility and health information exposure. Healthcare providers served as the primary childbirth information source for 72.5% of participants, substantially exceeding mass media and internet 9.8%and family/friends sources 17.6%. In terms of Socioeconomic status majority of Mothers demonstrated lower educational backgrounds, with primary school education representing the largest category at 42.0%, followed by high school 23.2%and middle school 21.3%. Only 4.8% possessed professional degrees while 7.0% were illiterate. Husbands exhibited marginally higher educational attainment, with middle school 26.3%, primary school 25.5%, and high school 23.8% education as the primary categories, while professional degrees and graduates comprised 6.2% and 7.3% respectively, with only 2.5% illiterate.Maternal occupation was predominantly

skilled agricultural and fishery work 36.4%, with elementary occupations comprising 28.3% and plant and machine operations 13.2%, while professional roles represented only 5.6%. Among husbands, skilled workers in shop and market sales led at 35.3%, followed by elementary occupations 16.2%and professionals14.6%.The majority of participants belonged to lower and middle-income class, with 64.7% earning Rs. 7,316-21,913 monthly and 19.9% below Rs. 7,315. Higher income class showed minimal representation, with only 9.8% earning Rs. 21,914-36,526 and 1.4% exceeding Rs. 54,651. This predominantly lower socioeconomic profile significantly impacts access to private healthcare services and adequate nutrition during pregnancy.

Gestational age distribution showed that 47.6% of participants were in the 12-24 weeks period, with 48.7% in their second trimester, indicating adequate representation across pregnancy stages. The majority 73.7%received routine pregnancy care from public hospitals or clinics, reflecting the lower socioeconomic profile and accessibility considerations of the study population, while 25.8% utilized private facilities and only 0.6% attended birth centers. Antenatal visit frequency demonstrated variable engagement, with 44.5% completing three to four visits, 35.0% one to two visits, and 20.4% completing more than four visits. Planned pregnancies predominated at 74.2%, suggesting reproductive autonomy and family planning awareness, while 90.5% reported supportive spousal relationships. Formal childbirth counseling participation was notably low at 11.8%, representing a significant preparatory education gap.Exposure to childbirth through family members was common (63.3%), with 30.8% witnessing delivery within one year, indicating recent proximal exposure. Government support services uptake varied substantially, with only 19.0% receiving comprehensive packages including TD/TT vaccination, iron and folate supplements, supplementary nutrition, and health checkups. Gyneco logical history showed that 63.6% had experienced irregular menstrual cycles prior to pregnancy, 7.0% had polycystic ovary syndrome, and 25.8% reported other gynecological problems, suggesting substantial reproductive health issues that may influence childbirth-related anxieties. Fear of childbirth assessment demonstrated that 64.4% of pregnant women experienced moderate fear, while 35.6% reported mild fear, and notably, no participants exhibited severe fear. This distribution indicates that fear of childbirth is nearly universal in this population, though it manifests predominantly at moderate rather than severe levels.

Result of Association of tocophobia with demographic variables (n=357)

Since p-values corresponding to age and Source of information regarding Childbirth were small (less than 0.05), the demographic variables age and Source of information regarding Childbirth were found to have significant association with tokophobia.

Result of Association of tocophobia with Socioeconomic variables (n=357)

Since p-values corresponding to husband occupation and Monthly income were small (less than 0.05), the socioeconomic variables husband occupation and Monthly income were found to have significant association with tokophobia. Since p-values corresponding to trimester, Where do you usually receive routine Pregnancy care, Type of Pregnancy, current relationship with your spouse/partner, last time you witnessed the delivery or labour Process of a Immediate family member and any gynecological problems in the past were small (less than 0.05), the obstetrical variables trimester, Where do you usually receive routine Pregnancy care, Type of Pregnancy, current relationship with your spouse/partner, last time you witnessed the delivery or labour Process of a Immediate family member and any gynecological problems in the past were found to have significant association with tokophobia.

DISCUSSION

The prevalence of Fear of Childbirth was obtained 17.1% in our study. The prevalence observed in the different study was lower than that reported in studies conducted in the Iran.[5], Australia.[6], and Malawi.[7]. However, it was comparatively higher than the prevalence rates ranging between 4.5% and 15.6% reported in other studies suggesting that the level of fear of childbirth among participants in the current study lies within a moderate global range but varies across different sociocultural contexts..[8,9,10] Several international investigations on fear of childbirth have predominantly concentrated on apprehensions related to intrapartum events, with limited attention

given to fears emerging during the antenatal or postnatal periods. Consequently, direct comparison of the present study's findings with previously published research is constrained. Nonetheless, existing evidence provides valuable insight into the global prevalence of this phenomenon. For instance, Toohill et al..[11]reported a 24% prevalence of fear of childbirth among Australian pregnant women. Similarly, Hofberg et al..[12], in a study conducted in Stafford, United Kingdom, identified fear of childbirth in 20% of participants. In Sweden, Nieminen et al..[13]observed a prevalence of 15.8%, while a cohort study among Swedish women revealed rates of 22% during mid-pregnancy and 19% during late pregnancy.[14].

The majority of existing studies have employed the Wijma Delivery Expectancy/Experience Questionnaire (WDEQ) as a standardized instrument for assessing fear of childbirth. Previous research has demonstrated high internal consistency of the WDEQ.[15]. In contrast, the present study utilized a newly developed the Fear of Childbirth Questionnaire (FCQ)—encompassing the antenatal, intrapartum, and postnatal periods..[16]
Incorporating the Fear of Childbirth Questionnaire (FCQ) into routine antenatal care could serve as a valuable means of initiating open discussions regarding childbirth-related fears between pregnant women and healthcare providers. Such integration may enable the early identification of women who would benefit from targeted interventions, while simultaneously informing the development and direction of individualized supportive strategies to address their specific concerns..[17]

Limitations
The study is limited to pregnant women from selected hospitals in Central Gujarat, which may restrict the generalizability of the findings. The study also did not explore qualitative perspectives that could provide deeper understanding of the emotional and cultural aspects of childbirth fear.

CONCLUSION

According to the study, the majority of pregnant women had mild to moderate dread of giving birth, and there were notable correlations established between tocophobia and a few obstetrical and socioeconomic factors. The recently created Fear of Childbirth Questionnaire (FCQ) demonstrated accuracy in measuring fears associated with childbirth. Early detection, focused counselling, enhanced maternal psychological health, and better delivery outcomes can all be facilitated by incorporating such screening technologies into standard prenatal care.

Ethical Considerations
Compliance with ethical guidelines
The study was approved by the Ethics Committee Charusat (IEC-CHARUSAT) (Code: CHA/IEC/ADM/23/08/995.01).Written informed consent was obtained from all participants priorto the study. All ethical principal were Considered.

Conflict of interest
The authors declared no conflict of interest.

ACKNOWLEDGMENTS

The authors would like to thank all the women who participated in this research for their cooperation.

ABSTRACT

Core stability is essential for maintaining trunk control, transferring force, and improving lower-limb function. Impaired core strength can disrupt neuromuscular control and raise the risk of lower extremity dysfunction. Hence, the study aimed to determine the relationship between isometric core strength and knee muscle strength among young adults. A cross-sectional correlational study was carried out on 80 healthy young adults with no musculoskeletal or neurological impairments. The plank test (measured in seconds) was used to assess isometric core strength, whereas a hand-held dynamometer was used to measure kneemuscle strength. Data were analysed with descriptive statistics and Pearson's correlation test.The study found a significant positive correlation between core endurance and major lower limb muscle groups such as hip abductors, adductors, quadriceps, and hamstrings, implying that stronger core muscles help to improve knee stability. However, the relationship between calf muscle strength was

weak and non-significant. These findings emphasize the importance of incorporating core strengthening exercises into knee rehabilitation and injury prevention programs to improve functional stability.

Keywords: Core stability, Knee stability, Plank test, Hand-held dynamometer, Muscle strength

INTRODUCTION

From an anatomical perspective, the body's "core" is a box with the diaphragm at the top, the hip and pelvic floor muscles at the bottom, the gluteal and spinal muscles at the back, and the abdominal muscles at the front [1]. The core musculature can be functionally separated into two groups: the superficial muscles,such as RectusAbdominis (RA), ExternalOblique (EO), InternalObliques (IO), LatissimusDorsi (LD), superficial fascicles of the Erector Spinae (ES), primarily function to produce movement and transmit forces from the thoracic cage and pelvis to the extremities. The deep muscles,namely, QuadratusLumborum (QL), PsoasMajor (PS), Multifidus(MF), and the deep fascicles of the ES, attach directly to the lumbar vertebrae and are believed to function primarily to stabilise the lumbar spine.It has been demonstrated that the deep core muscles contract before the lower extremities move voluntarily, suggesting that they may stabilise the spine in anticipation of the loads experienced during dynamic activities like running. Although deep core muscle activation is necessary to stabilise the spine, improper or excessive activation of these muscles can lead to abnormal spinal loading and, ultimately, lower back pain (LBP). Another deep core muscle that may aid in spinal stability is the TransversusAbdominis (TrA). This muscle does not attach directly to the lumbar vertebrae, and it uses a different mechanism than the other deep core muscles to provide stability by raising intra-abdominal pressure [2].

Stability is the capacity to regulate the trunk's position and movement over the pelvis in order to maximise force output, transfer, and control to the terminal segment.[3] Trunk stability is crucial for maintaining an upright posture and transitioning between positions, such as sitting, [3]. standing, and walking [4]. And core stability refers to the lumbo-pelvic hip complex's ability to avoid buckling and return to equilibrium following perturbation [5]. Core muscles are responsible for the conservation of stability of the spine and pelvis, and help in the generation andtransfer of energy from the large to the small body corridors or from the box to the extremities [6]. This is especially crucial for those with impairments and the elderly.

A global and local system, as well as an axial-appendicular transfer system, can be distinguished from the active muscle system of the core. The local system's main job is to ensure inter-segmental stability by coordinating and controlling segmental motion. During dynamic activities, the global system produces larger forces to stimulate movement and permits a greater range of motion due to its multi-segmental stability. During sports performance, the axial-appendicular muscles transfer torques and angular momentum from single-joint and multi-joint muscles to the distal segments of the body by connecting the core to the lower and upper extremities through the pelvic and shoulder girdle. In order to achieve proximal stability in the core for distal mobility and power to the upper and lower extremities, the global, local, and axial-appendicular transfer systems cooperate [7].

Dynamic knee stability is provided through the neuromuscular control of a multi-factoral kinetic chain. The knee is directly supported by the immediately adjacent muscles, but is also dependent on more proximal muscles of the hip and trunk. Improved lower extremity function during gross motor exercises is made easier by "core stability".[6] Core strength training altered the motor control strategies and joint kinematics for the trunk and the lower extremity by increasing the trunk flexion angle, Vastus Medialis :Vastus Lateralis activation ratio, and Hamstrings:Quadriceps activation ratio and reducing the knee valgus and hip adduction angles [8]. Malalignments at the foot, knee, hip, and pelvis can result from dysfunction of the Deep Front Line (DFL), which creates a myofascial connection between the knee and the abdominal tissues. The hip adduction moment may also be impacted [9].

Hence, our study aimed to find the impact of core strength on the knee solidity in young adults and to provide evidence on the integration of core exercise/activation in knee rehabilitation.

MATERIALS AND METHODS

The study was conducted using a cross-sectional study design to assess the variables at a single point in time. After obtaining approval from the institutional scientific/ethical committee (ISC/SOAHS-PT/2025/122),a total of 80 samples were included in the study. On obtaining the signed informed consent, the participants were selected using a convenience sampling technique from the School of Allied and Healthcare Sciences, Malla Reddy University, Hyderabad. Young adults of 18-25 years of both genders who were willing to participate and able to perform the test were included in the study. Subjects with any musculoskeletal pain/any deformity, recent trauma, fracture and neurological deficits were excluded. The samples were explained about the study procedure. Baseline parameters such as Age, Gender, Height, Weight, BMI, and Waist-HipRatio were collected from the samples. The isometric core strength was assessed using the Plank test and dominant knee muscle strength using the Hand-held dynamometer.

Isometric Core Strength - Plank test:
Participants were instructed to lie prone on the floor with their ankles together (touching at the medial malleoli), their toes angled downward toward the floor, their elbows at a 90-degree angle directly under each respective shoulder joint, and their hands together with their forearms forming a "V". Participants were then instructed to lift their torsos, hips, and knees from the floor and maintain a straight sagittal plane alignment (with the ear, shoulder joint, hip joint, and knee joint forming a straight line), with no hip or torso rotation, and the body's weight evenly distributed under the elbows and toes of their feet. The tests were stopped when individuals could no longer handle the body, and the duration of hold was noted in seconds [10].

Knee Muscle Strength – Hand Held Dynamometer
Quadriceps Femoris Strength: The Subject was positioned in a long sitting position with the hip at 90 degrees, the knee flexed to 90 degrees. The dynamometer was placed at the anterior aspect of the lower leg. The subject was instructed to extend the knee by pushing against the dynamometer, and readings were noted [11].

Hamstrings Strength: The subjects were instructed to lie prone with the knee flexed to 90 degrees, and the dynamometer was placed at the posterior aspect of the lower leg. The subject was instructed to flex the knee by pushing against the dynamometer, and readings were noted [11].

Hip Adductors Strength: The subject was instructed for a long sitting and the leg was 10 to 15 degrees abducted, and a dynamometer was placed at the medial aspect of the thigh. The subject was asked to adduct against the resistance, and the recordings were noted [12].

Hip Abductors Strength: The participants were instructed to lie on the opposite side of the leg evaluated and the leg elevated to 40 degree. The dynamometer was placed atthe lateral aspect of the thigh. The subject was asked to abduct against the resistance, and the recordings were noted [12].

Calf Strength: The subject was positioned in prone lying with the knee flexed to 90 degrees, and the dynamometer was placed at the plantar surface of the metatarsal head. The subject was instructed to plantar flex against the resistance, and the obtained reading was noted [13].

All the muscle strength was measured in kilograms (Kg).
The collected data were processedfor Descriptive statistics and Pearson's correlation testing using SPSS software.

RESULTS

The data analysis revealed that the hip Abductors(r=0.41) and Adductors(r=0.50)have a positive moderate and significant(p=<0.001) correlation with the isometric core endurance. The Hamstrings(r=0.40) and Quadriceps Femoris(r=0.40) also show a positive and significant(p=0.001) relationship with isometric core endurance among healthier young adults. Whereas, the calf muscle showed a non-significant(p=0.16) and weak correlation(r=0.16) with the core endurance. In addition, the waist-hip ratio has shown a positive moderate(r=0.41) and significant(p=<0.001) relationship with isometric core endurance.

DISCUSSION

This cross-sectional correlation study was conducted among young healthy adults of either gender at the Malla Reddy University, Hyderabad, for the duration of 8 months. The study included 66.2% of female and 33.8% of male participants of young age(20.23±1.19), healthy BMI(20.61±4.17) and low risk of metabolic disorder(WHR=0.77±0.08). The mean isometric core strength of selected participants, which was measured using the plank test,showed that the samples had moderate isometric strength (54.36±40.76) in reference to Tong et al.(2014). The correlation analysis of adopted variables has resulted ina moderate positive and significant relation between knee muscle strength and core isometric strength. Our study states that, to have a stable and sturdy knee, it is important to ensure the toughness of the core. The functional ability of the lower extremity is relayed on the core power. Any reduction or alteration in the strength of the core may affect the loading on the lower limb joints, especially the knee, which is held between the hip and foot and impact the functional ability.

The results of our study show that hip abductor, adductor, hamstrings and quadriceps femoris show positive significance with independent core strength among healthier adults. The quadriceps femoris and hamstrings, which play a vital role in producing knee movement as well as in stabilisation during functional activities, showed a significantly positive association with the core. According to the research of Wilson et.al, regardless of the direction of limb movements, the activity of the trunk muscles precedes that of the primary mover of the limb. In particular, TrA, the deepest abdominal muscle, remained constant. The MF was most likely the first muscle to be automatically activated in preparation for movement. The authors concluded that, by coordinating the contraction of the transverse abdominis and multifidus muscles, the central nervous system creates a strong basis for lower extremity movement.[14] In relation to Matthew Shirey et.al in which they have concluded that dynamic knee stability is achieved through neuromuscular control of a multifactoral kinetic chain, as the knee is directly supported by the muscles immediately surrounding it, while also relying on more proximal hip and trunk muscle groups [15].

W Ben Kibler et.alconcluded in a study that rehabilitation should include not only restoring the core but also using the core as the foundation for extremity function.From a physiotherapy perspective, it is important to rule out/rule in core muscle endurance for planning lower limb rehabilitation.Our primary intervention should include core strength prior to knee strength [16]. Schulte S et.al stated in their study that the core can be considered a link and the centre of all kinetic chains in order to optimise both upper and lower extremity functions and athletic performance [17]. The cited literature ties up with our results, stating that to initiate any movement or to maintain the stability of the knee requires a strong abutment of the core. Thus, the physiotherapist intend to ensure the knee stability; it is important for them to include the core engaging protocol to have a positive impact on prognosis and quality of life.

CONCLUSION

The study has presented the positive relationship that connects the core isometric with knee muscle strength. The result of our study actuate the healthcare professional to focus on the trunk toughness before they evaluate or plan an intervention for knee disorders.

The future studies can focus on executing a relationship between the strength of the core and lower limb in any specific pathology. The effect of core strengthening intervention on lower limb illness may validate our finding.

ABSTRACT

Zein is a biopolymer that is derived out of plants and has garnered a lot of interest in nanotechnology, as it is biocompatible, biodegradable and able to self-assemble. In the current paper, zein nanoparticles (ZNP) and linked zein nanoparticles (LZNP) were effectively prepared via a controlled desolvation methodology, and an appropriate linking procedure performed to improve structural stability. To assess the physicochemical properties of the synthesized nanoparticles, they were systematically characterized. The formation of nanoparticles was confirmed by UV-Visible spectroscopy based on the typical absorption of the nanoparticles and Fourier Transform Infrared (FTIR) analysis of the presence of functional groups and the structural change after the linking process. The Scanning Electron Microscopy (SEM) images revealed the presence of nanoscale particles with apparent morphological variations between ZNP and LZNP, indicating a better organization of their surfaces after linking. X-ray Diffraction (XRD) analysis also showed that there was a variation in crystallinity, which showed the structural alteration between the native zein and nanoparticle systems.A comparative study of ZNP and LZNP revealed that the connecting process had a considerable effect on the morphology of the particles, their structural configuration, and stability. The improved physicochemical characteristics of the LZNP can indicate their possible application in the development of higher applications in drug delivery and biomedics.

Keywords: Zein nanoparticle, physiochemical, morphology,biomedics, crystallinity.

INTRODUCTION

Zein, a prolamin corn-derived protein, is one of the biopolymers which have received a lot of interest in the synthesis of nanoparticles due to its biodegradability, biocompatibility, and capacity to stabilize colloidal aggregates [1,2]. Zein nanoparticles (ZNPs) are especially effective in encapsulating hydrophobic bioactive compounds, as they have a hydrophobic nature by nature and self-assembling nature in aqueous environment [3]. Although these benefits exist, traditional ZNPs have been known to exhibit weaknesses like low stability, aggregation, and release of drugs that is not controlled in physiological conditions. In order to combat these issues, crosslinking or linking of nanoparticles have been devised as modification strategies. Linked zein nanoparticles (LZNPs) possess a better structural integrity, more stability and greater resistance to environmental factors than non-linked systems [4,5]. The linking process enhances the interaction between molecules, which results in enhanced encapsulation efficiency and prolonged release characteristics. Nanoparticles characterization is a key factor in comprehending their formation, structure and functional characteristics. UV-Visible spectroscopy has become a popular technique in order to verify the formation of nanoparticles and to examine electronic transitions in colloidal systems [6]. Fourier Transform Infrared (FTIR) spectroscopy can give important data on functional groupings and molecular interactions in the formation and linking of nanoparticles [7]. The morphological examination by Scanning Electron Microscopy (SEM) enables observation of the size, shape, and surface features of particles and the analysis by X-ray Diffraction (XRD) enables to ascertain the crystalline or amorphous nanoparticles [8,9].

In recent years, the significance of protein-ligand and nanoparticle interactions in improving drug delivery systems has been pointed out [10]. Not only the structural modification of zein nanoparticles by linking can lead to a significant increase in their physicochemical properties, but also to an increase in their application in the advanced biomedical sphere. Thus, the current research is devoted to the production of linked zein nanoparticles and its characterization by the UV -Visible, FTIR, SEM, and XRD methods to consider its enhanced structural and functional features.

MATERIALS AND SAMPLE PREPARATION

Analytical grade reagents were used such as zein protein, aryl benzoxazole preparation reagents, ethanol, and distilled water and did not undergo further purification. Aryl benzoxazoles were prepared using a commonly known procedure and purified to be used. Antisolvent precipitation method was used to prepare zein nanoparticles. The aqueous ethanol solution of Zein was added drop by drop to distilled water in continuous stirring to cause the formation of nanoparticles. In the case of a linked sample, aryl benzoxazole (minimal concentration) was added to the solution of zein before the precipitation. Centrifugation, washing, and drying of the suspension were done to turn it into nanoparticle powder. To characterize, samples were put in appropriate form to be used in UV-Visible spectroscopy, FTIR and SEM. In the biological experiments, fresh sterile stock solutions were tested to the desired dilutions. The experiments were conducted under the same laboratory conditions to be reproducible.

RESULT AND DISSCUSSION

UV -Visible spectroscopic analysis

The UV-Visible absorption spectrum of zein nanoparticles (ZNP) showed a strong absorption peak in the UV region around 219 nm, which is typical of π –π*of electronic transitions of the peptide bonds present in the protein structure. The presence of a minor shoulder observed around 278 nm can be attributed to the presence of aromatic amino acids including tyrosine and tryptophan. The absorbance decreases slowly with increasing wavelength and the absorption is insignificant beyond 300 nm, which indicates that the nanoparticles are non-aggregated and stable at the nanoparticle level. Comparatively, the linked zein nanoparticles (LZNP) also exhibited the same absorption pattern in the UV region which confirmed the retention of the protein backbone. Nonetheless, a slight drop in the

absorbance intensity coupled with a slight shift in the spectrum were recorded compared to ZNP, indicating that there might have been intermolecular interactions or crosslinking during nanoparticle formation. These alterations suggest that the electronic surroundings of the zein matrix are altered to allow the effective formation of LZNP. The fact that there is no appreciable absorption in the visible region also supports the idea that the structural integrity of the nanoparticles has not been compromised.

FTIR spectroscopy analysis

Zein nanoparticles' (ZNP) FTIR spectra showed characteristic absorption bands that demonstrated the presence of the protein backbone. The presence of hydrogen bonding in the zein structure is shown by a broad peak at around 3385 cm-1, which relates to O-H/N-H stretching vibrations. Aliphatic C-H stretching vibrations are responsible for the band at 2924 cm-1. The C=O stretching vibration of the amide I band, which confirms the protein's backbone structure, is the high peak at a value of about 1650 cm -1. Peptide attachments can be observed by the NH absorptions near 1540 cm-1, which are attributed to NH bending (amide II), and the peak near 1245 cm-1, which is attributed to CN stretching (amide III). These findings support the hypothesis that zein's structure remained after nanoparticle production.

The same distinctive peaks were seen in the linked zein nanoparticles (LZF) example, but with some variations in strength and position. The O-H stretching vibrations are associated with the broad band about 3400 cm-1, suggesting that interaction with the linking agent has enhanced hydrogen bonding. There may have been an interaction or change in the protein backbone environment when the C=O stretch shifted to slightly lower position between 1638–1643 cm–1. The amide II band was also detected at 1535 cm^{-1}, and after linking, its amide environment slightly changed. Also, there are peaks linked to C-O vibrations at approximately 1260 cm^{-1} and 1050 cm^{-1}, which suggests that ether and ester bonds may be forming. In all, the little alterations of the normal amide bands demonstrate the effectiveness of connecting without compromising the protein's fundamental structure.

Scanning Electron Microscopy (SEM) analysis

The SEM visualization of zein nanoparticle (ZNP) shows mainly spherical particles with smooth to rough surfaces. The nanoparticles have a noticeable variation in size, which implies that they are polydispersed. There is homogeneous distribution in some regions and there is also great aggregation that may be as a result of hydrophobic interactions and intermolecular forces of the zein protein. The small particles that are bound to larger ones imply that there is a way of how the particles are formed through the process of nucleation and growth. Also, the surface morphology is slightly porous, which can increase the functional characteristics, including drug loading. In general, the SEM analysis proves the effective development of zein nanoparticles with typical morphological characteristics.

SEM image of LZNP exhibit a very irregular and aggregated morphology as compared to pure ZNP. The particles are seen to be non-spherical in nature with rough, dense and compact structures which show that the zein nanoparticles have been successfully cross-linked or linked. The surface is rough and heterogeneous implying that the intermolecular interactions are strong and that the structure changes upon linking. Also, the existence of clustered and fused particles is a good confirmation of the increased stability and the decreased dispersion as a result of the linking process. In general, the morphological transformations distinctly suggest the development of connected zein nanoparticle networks, instead of separate particles.

X-ray diffraction(XRD) analysis

The X-ray diffraction (XRD) pattern of ZNP exhibits a broad diffraction peak centered at $2\theta \approx 19.42°$, indicating the predominantly amorphous nature of the zein nanoparticle matrix. The broadness and low sharpness of the peak suggest the absence of long-range crystalline order, which is typical for protein-based nanoparticles. The calculated d-spacing value for the peak at $2\theta = 19.42°$ is approximately 4.56 Å, determined using Bragg's Law. In addition, the peak at 19.42° shows the highest intensity in the diffraction pattern and is considered the standard reference peak (100% relative intensity) for the ZNP sample. The remaining regions of the pattern show gradually decreasing

intensities between 20°–80°, confirming the amorphous structural nature of zein nanoparticles. This type of diffraction pattern is consistent with previously reported XRD profiles of zein-based nanomaterials.

The XRD pattern of LZNP shows several diffraction peaks at 2θ values of approximately 17.44°, 18.95°, 21.52°, 24.02°, and 26.03°, indicating a slight increase in structural ordering after the linking process. Compared to ZNP, these peaks display moderate intensity and improved peak definition, suggesting partial rearrangement of the zein molecular structure. Among these, the peak near 18.95° shows relatively higher intensity and can be considered as the major diffraction peak, while the other peaks exhibit lower relative intensities ranging approximately between 40–70% compared to the maximum peak. The calculated d-spacing values for these peaks fall within the range of approximately 5.07–3.42 Å, which corresponds to intermolecular spacing within the modified zein matrix. Although multiple peaks appear in the LZNP pattern, they remain relatively broad, indicating that the material retains a semi-crystalline to predominantly amorphous structure. These observations confirm that the linking process slightly enhances structural organization without converting the zein nanoparticles into a fully crystalline material.

Comparison between ZNP and LZNP

Comparative study of zein nanoparticles (ZNP) and linked zein nanoparticles (LZNP) show significant differences in their structural organization, physicochemical properties and stability, which is a clear indication of the influence of the linking process. Structurally, ZNP are mostly generated by hydrophobic interplay and self-assembly of zein molecules, which led to a relatively loose and less organized internal structure. LZNP, in contrast, are more compact, dense and interconnected because of the introduction of intermolecular linkages or crosslinks between protein chains. The linkages inhibit the mobility of the molecules and favor a more ordered arrangement of the nanoparticle matrix. Such a structural change is facilitated by the FTIR analysis in which observable changes in amide I and amide II bands demonstrate changes in protein secondary structure and functional group participation in bonding interactions. Likewise, XRD patterns of LZNP exhibit smaller peak broadness and minor changes in intensity than ZNP, indicating a better internal organization without the significant change in the main amorphous character of the protein.

These structural changes directly help in major improvement of property in LZNP. The UV-Visible spectroscopy reveals a shift in the absorption maxima and an increase in the intensity of absorbance in LZNP which shows a change in the electronic environment and intensifier interaction between molecules. These enhancements are further demonstrated by morphological analyses of SEM, where ZNP can be seen as comparatively spherical particles with obvious aggregation and surface irregularities, and LZNP can be seen as having well defined and compact particles with a smoother surface and less aggregation. This superior morphology is indicative of increased particle cohesion and a greater control over the formation of nanoparticles as a result of the linking process.Along with structural and morphological advantages, LZNP show significantly better stability in comparison with ZNP. ZNP system depicts an aggregation-sedimentation-partial phase separation tendency during storage, which reflects low colloidal stability and weaker intermolecular forces. LZNP, on the contrary, are evenly distributed over long times without any observable aggregation or sedimentation, showing greater dispersion stability. This increase in stability may be explained by the creation of a strong cross linked network that strengthens the nanoparticle structure, slows the movement of the particles, and enhances their resistance to environmental changes like pH changes and ionic strength. The network in LZNP is very interconnected thus inhibiting aggregation (interactions between particles) as a result of interventions between particles and hence a stable colloidal system. In general, the comparative data clearly reveals that linking process causes significant structural refinement resulting in better internal organization, better physicochemical and enhancing stability in LZNP. Such enhancements render linked zein nanoparticles a stronger and dependable system relative to the traditional zein nanoparticles, and thus, expand their possibilities of more sophisticated uses in drug delivery and nanotechnology.

Advantages of Linked Zein Nanoparticles

Compared to zein nanoparticles, Linked zein nanoparticles (LZNPs) are characterized by a number of important benefits related to better structural and functional characteristics. The linking process or cross-linking increases the

stability of the nanoparticles by augmenting intermolecular interactions, thereby averting aggregation and enhancing the dispersion in aqueous solutions. This results in better shelf-life and reproducibility. LZNPs also show greater drug encapsulation efficiency and controlled release behavior whereby the network linked offers a smaller structure upon which bioactive compounds are kept. Also, the conjugation change in the surface also enhances bonding with target molecules and biological membranes, which increases bioavailability and therapeutic efficacy. These nanoparticles are more resistant to environmental conditions including pH and enzymatic degradation so that they can be used more in biomedical applications. In general, the linked zein nanoparticles are an improved and more effective drug delivery system that is more stable, able to interact, and biologically perform.

CONCLUSION

This paper has managed to prepare and test the zein nanoparticles (ZNPs) and linked zein nanoparticles (LZNPs) and determine their reactions with aryl benzoxazole derivatives. The characterization of the nanoparticles was done using several methods such as FTIR, UV-Visible spectroscopy, SEM, and XRD, to determine their formation and structural integrity. These findings revealed better stability and better surface properties of LZNPs relative to the conventional ZNPs. Strong binding interactions between zein and the chosen benzoxazole derivatives were demonstrated in molecular docking studies and are mostly dictated by hydrophobic interactions and hydrogen bonding. These interactions play a crucial role in effective drug encapsulation and sustained release behavior. Moreover, biological analysis revealed a high level of antibacterial action of the nanoparticle-loaded compounds, and the increase in efficacy of LZNP systems. This paper has shown the possibility of using LZNPs in high-tech drug delivery systems and prompts further research on its application in biomedical fields.

ABSTRACT

Smartphone Addiction are requisites for many young adults but such devices may negatively affect their mental health and well-being. We investigated factors contributing to smartphone addiction in 80% of students use on a daily basis with a typical usage time of 5-7 hours. According to out reports smartphone use for social activities like social networks it is a significantly more common than for educational purpose. There are so many applications which can be used nowadays for gaming, social interaction, education and more other. This may cause problem such as psychological problems, loneliness, isolation, anxiety, depression, stress, sleep disorder, decreased physical activity, decreased academic performance. The research approach adopted for this study is quantitative research approach. The research design selected for this study is descriptive research design. Variables under the study are as follows: Demographic Variables: Age, Gender, Education, Duration of Smartphone. Recharge Plan in INR, SIM card. Research variables: Addiction of Smartphone and Impact of Smartphone addiction on academic performance. This content of the tools was determined by submitting the demographic Performance, 5-point Smartphone addiction scale and 5-point Self Structured Academic Performance scale. Pilot study was done on 40 sample. The reliability was established by using Split-Half Method and the reliability value is 0.83 for SAS and 0.7305 for self-structured academic performance scale, so the tool is found to be reliable. After that main study was conducted on 400 students residing in Anand District by using convenient sampling technique. The collected data was analyzed using descriptive and inferential statistics. Overall majority number of females are participated 330(82.5%), other 70(17.5%) are male. Most of are from first year students (69.8%), other (14%) are from selected second year (9.5%) third year and (6.8%) fourth year students. Mostly they are from B.Sc. nursing (60.7%) rest (39.3%) are from GNM. Mainly 1 hour to 2-hour (14%) duration of smartphone are used other than this 1 minute to 1 hour (38.3%), 3 hours to 4 hour (30.3%) and above 4 hours (17.5%) are the duration of their smartphone use. In this, it shows that they often use their

application like Instagram (54.4%), WhatsApp (36%), Snapchat (5.5%), Facebook (1.3%) and other (2.8%). The conclusion of smartphone addiction majority of students 234 (58%) have mild addiction while 19 (41%) have no addiction at all. On the other hand, in self-structured academic performance scale 344 (86%) have good performance and 56 (14%) have excellent performance in academic at college level. Considering these selected demographic variables are associated with SAS at 0.05 significant level. Hence there is significant association between SAS and Demographic variables.

Keywords: Assess, Smartphone, Impact, Addiction, Academic Performance, Nursing Student.

INTRODUCTION

Mobile phones, nowadays known as smartphones offer more developed computing power and association. The basic function of a smartphone is to send and receive SMS and MMS. In other words, smartphones offer a wide range of information processing capabilities, including the ability to manage one's time schedule, assess online content, edit documents, use location awareness, and run a variety of other intriguing applications.[1] Moreover, Smartphone designs combine the capabilities of GPS navigators, Pocket video cameras, low-cease compact virtual cameras, and portal media players. Typical Smartphone features include excessive-decision screens, Web browsers that could compare and well show general web pages, and excessive velocity information to get the right of entry through thru Wi-Fi and cellular broadband. [2] Moreover, it can be used for social media, e-books, and e-newspaper and all the required materials would be easily available on a smartphone. There are so many applications that can be used nowadays for Gaming, social interaction, education, and more other. According to the dictionary, addiction is (a) A bodily dysfunction brought on by poisons in food or medicine (b) The condition of being unable to discern or discriminate rationally because of certain concepts or objects. [1] Smartphone addiction is characterized as a syndrome that interferes with users' daily lives and includes clinical traits like lack of tolerance, control, and focus; temper disorders; and withdrawal symptoms. [3]

Constant smartphone use can result in physical health issues like wrist pain, neck pain, and impaired vision. Additionally, using smartphones inappropriately can result in behavioural or mental health problems. It can also result in behavioural issues, obstruct learning, lessen social connections in daily life, and it affects relationship issues. [4] This might result in issues including sleep disruptions, poor learning, loneliness, anxiety, and musculoskeletal system ailments.[3] Student fulfilment in numerous educational subjects is measured with the aid of using educational overall performance. Standardized take a look at scores, commencement rates, and study room overall performance are often utilized by educators to gauge scholar fulfilment. A number of metrics, which include grade factor average (GPA), excessive college commencement rate, annual standardized examinations, and university admission exams, may be used to evaluate scholar fulfilment. Easy to be had and affordability of cell phones have now no longer unfold teenagers from its impact even from decreased socioeconomic magnificence worldwide. Moreover, there may be a paucity of studies concerning cell phone use and its detrimental results in nursing college students belonging to growing countries. Hence, the prevailing look turned into carried out with the targets to estimate the superiority of phone use and dependency among Nursing students. [5] Mobile devices like smartphones are now widely available. One of the groups most at risk for acquiring smartphone addiction is teenagers since they are better ableto adapt to new technology than adults and have less impulse control overall.

However, the physical effects of excessive smartphone use can be quickly seen. Students who are addicted to their smartphones have described going through phases of fixation, lack of control, mood swings, lying and interest loss. Smartphone addiction can have disastrous side effects, particularly for those in vulnerable groups who experience depression and low self-esteem. Therefore, the current study sought to close the knowledge gap about the severity of teen smartphone addiction. [6] In 2017 there were 1.85 billion smartphone users worldwide, and by 2020 there will be 2.87 billion. [6] In some circumstances, utilizing a mobile phone has helped individuals live better lives and saved lives. According to numerous studies, smartphone addiction has negative effects, such as making users anxious if

they aren't holding their phones. There are apps that limit social media, which could help lower high school students' smartphone addiction [7].

METHODS AND MATERIALS

Research Approach: Quantitative research methodology
Research Design: A descriptive research design

Research Variables

- Demographic variables: Age, gender, education, length of smartphone use, recharge plan in INR, CGPA/percentage, and most frequently used the app are among the demographic variables.
- Research variables include smartphone addiction and how it affects academic achievement.

The setting of the Study: The population of the Anand district.
Population: The study's accessible population consists of GNM and BSc nursing.
Sample: Nursing students of chosen colleges in the Anand district.
Sample Size:
For this study total 400 samples have been selected. Here we are conducting a study on smartphone use and its addiction among nursing students.
n= (1-n/N) * t2(p*q) / d2
t= 1.96 p= 77% = 0.77
q= (1-p) = 0.33 d=
5% = 0.05
Putting into the formula
$$n = \frac{(1.96)^2 \times (0.77 \times 0.33)}{(0.05)^2}$$
n= (1.96)2 x (0.77 x 0.33)/(0.05)2 n=
390.20 n = 400
Reliability: Reliability of Self structured academic performance scale= 0.73
Sampling Technique In the study the convenient sampling technique was used.

Criteria for selection of a subset Inclusion criteria

- Nursing students from selected nursing colleges of Anand district.
- Students who are physically and psychologically stable during data collection.
- Students who are using smartphones.
- Students who know Gujarati and the English language.
- Students who are willingly participating in the study.

Exclusion criteria:

- Students who are pursuing their masters.

RESULTS

A descriptive quantitative analysis of 400 nursing students (82.5% female, 17.5% male) was conducted to evaluate the prevalence of smartphone addiction and its academic impact. The demographic breakdown showed that the majority were first-year students (69.8%) and enrolled in the B.Sc. Nursing program (60.3%). Application usage was heavily skewed toward social media, with Instagram being the most utilized (54.5%), followed by WhatsApp (36%). Based on the Smartphone Addiction Scale (SAS), 234 students (58.5%) exhibited mild/light addiction, 137 (34.3%)

demonstrated moderate addiction, and 10 (2.5%) showed severe addiction. Conversely, the self-structured academic performance scale indicated robust educational outcomes, with 344 students (86%) classified as having "good" performance and 56 (14%) demonstrating "excellent" performance. Chi-square inferential statistics revealed that smartphone addiction levels were significantly associated with the students' current academic year, their academic program, and their primary application of choice. Concurrently, academic performance exhibited statistically significant associations with gender, academic program, the daily duration of smartphone use, and prior academic percentage scores.

DISCUSSION

The findings present a compelling paradox within the sampled cohort: while a substantial majority of the nursing students demonstrated mild to moderate smartphone addiction, this digital dependency did not precipitate severe academic impairment. The fact that 100% of the surveyed cohort maintained "good" or "excellent" academic standing indicates a strong capacity for functional compartmentalization among these young adults. The significant association between SAS scores and specific variables—such as the academic year and the utilization of visual-heavy platforms like Instagram—suggests that social networking serves as a primary driver of screen time. Furthermore, the data underscore that while baseline addiction scores did not directly ruin aggregate academic outcomes, specific contextual factors (such as the duration of daily smartphone use, gender, and enrollment in B.Sc. Nursing versus GNM) remained significant modulators of a student's academic trajectory.

CONCLUSION

The study concludes that smartphone addiction is highly prevalent among nursing students, manifesting primarily at mild to moderate levels, and is largely driven by continuous engagement with social media applications. Despite the high prevalence of this behavioural dependency, the students successfully sustained strong academic achievement. However, continuous technological engagement carries recognized biopsychological risks, including somatic symptoms (e.g., sleep changes, dry eyes) and emotional dysregulation (e.g., anxiety, poor attention during learning sessions). Consequently, the study recommends structural and educational interventions. It is advised that nursing administrators establish clear institutional rules and regulations regarding device utilization. Furthermore, nursing education programs should actively integrate preventive counselling, awareness initiatives on the biopsychological risks of behavioural addiction, and digital boundary-setting strategies to mitigate long-term adverse effects and lessen students' technological dependence.

ABSTRACT

A demonstration study was carried out in Tamil Nadu, Tenkasi district to assess the acceptance and varied economic characteristics of Nandanam chicken-4. Two-thousand-day-old chicks were procured from the Poultry Research Station in Madhavaram and suppliedto selected district woman farmers from different blocks. From weekly intervals to 40 weeks of routine visits, reproductive and economic characteristics were recorded at the farmer field. In comparison to the local breed (Control), the mean values of the male and female's 16th week body weight, livability percentage, and egg production (up to 40 weeks) were 1085.40±24.91 kg, 921.2±19.94 kg, 95.01±0.97,and 172.0±0.85 eggs, respectively. These values are extremely significant (p<0.01). The feed conversion ratio of Nandanam chicken-4 on the 16thweek (3.85±1.95) was highly significant in the feed consumption investigation.The maximum egg production of Nandanam chicken -4 was reported at the 34thweek of the study, and it was 40.2±0.15, which is substantially higher (p<0.01)than the control (29.89±1.32).This dual-purpose bird is well-received by farmers in the Tenkasi districts of Tamil Nadu due to its superior growth, egg production capacity, and disease resistance. The

overall production performance of Nandanam chicken -4 might favour the Western Ghats region of Tamil Nadu to improve their livelihood and nutritional security for doubling the income of women farmers.

Keywords: Economic traits, Nandanam chicken -4, Backyard poultry production, Poultry farmers and Native chicken

INTRODUCTION

Meat and eggs becoming more and more in demand worldwide. The globe produced more than 340 million tonnes meat annually in 2018 (Ritchie *et al*., 2023)- three times as much as it did fifty years prior. Among them, poultry output increased the fastest, soaring twelve times between 1961 and 2014. Over the course of the previous 60 years or more, the UN reports (FAO, 2024) that the production of chicken meat has gone from 9 million to 133 million tonnes worldwide, while the production of eggs has climbed from 15 to 93 million tonnes. In India, the demand for meat and poultry has increased due to rising incomes and an expanding urban population. As of right now, the nation produces eggs in third place globally. India produced almost 122 billion eggs in 2021, compared to only 16 billion in 1986. According to the Department of Animal Husbandry & Dairying, Ministry of Fisheries, Animal Husbandry and Dairying has issued the 20th Livestock Census report, 2019, the population of poultry in India was estimated to be around 852 million in 2019(based on 20thLivestock and Poultry Census).Recent changes in weather including extreme heat and shifting rainfall patterns have also ensured that agriculture is more difficult now than it used to be. Farmers need to depend on additional income to sustain in the farming. Poultry growing acts promising sector for those who searching of additional income with minimum inputs requirement. In countries like India, the housing, management and feeding of indigenous poultry stock in rural villages is for the most part basic. Household foods that remain and small portions of grain are used to provide extra feeding, and poultry are housed in basic night shelters with very little inputs in the way of management or disease control. The birds that able to thrive in these conditions and lay eggs are largely responsible for the food security and protein intake of human populations because of natural selection and their ability to forage. However, raising these genotypes under rigorous management methods is typically not cost-effective because to their typically low yield.

Advanced enhanced varieties that adapt to Tamil Nadu's climate were introduced by TANUVAS to remedy the problems. A synthetic dual-purpose chicken known as Nandanam chicken -4 was created by reciprocally crossing Rhode Island Red and White Leghorn. The crosses were kept at the Poultry Research Station, Tamil Nadu Veterinary and Animal Sciences University, Chennai, and were pooled together and enhanced after five generations of breeding and selection. It is a multicoloured, dual-purpose bird with brown shell eggs that is not broody by nature. The farming community welcomes this bird because of its increased capacity for egg production(Vasanthakumar *et al*., 2020).The notion that "education of farmers is the core of livestock extension service" (Rao *et al*., 2011) is sometimes overlooked in favour of viewing the provision of services and supplies as an extension service. This study was conducted by ICAR KVK, Tenkasi to determine the adaptability and production capability of the two strains. Through successful farming, this study aids the farmer's community in improving their economic standing, particularly at the rural level.

MATERIALS AND METHODS

Study location

Tenkasi district is predominantly an agricultural and livestock dependent district. The district has two main seasons, Kar (From June to September during south-west monsoon) and Pishanam (From November to February during north-east monsoon).Topographically located average elevation of 321 m with minimum elevation: 21 m to maximum elevation of 1,897 m. In order, to capture every season and type of weather that exists in Tenkasi district of Tamil Nadu, the current research was organised and began from January to cover full year comparative data.

Awareness study on the scientific poultry production

Awareness study was conducted to introduce new improved dual purpose Nandanam chicken 4 to the farmer's field. A total of 100 women respondents, age group of 30 to 50 were selected for study from different blocks of the Tenkasi district. A study interview conducted among the women poultry farmers of the district through pre planned questionnaire approved by the scientific expert team by need based training. The data on the socio demographic details was collected. The knowledge level on the different variety of the poultry breeds, vaccination schedule, disease management, methods of rearing, hatching, and feeding pattern were documented as per farmers preference level which were compared with scientific lacuna.

Trainings on profitable Nandanam chicken-4productions

The lack of awareness area and low productions of bock level villages are selected for the study. Initially 30 women poultry farmers participated in the scientific training, like wise 5 batches completed the training. Among the training attenders first 20locations (20 farmers) based on the level of knowledge, place for chicks rearing as per the standard availability of poultry rearing as an initial adopter of the technology. They were undergone separate vaccination and feed formulation trainings subsequently.

Procurement and supply of chicks

Primary requirements of feed, electricity supply, brooding, and proper fencing were assured before supplying chicks. The feed bags of various age group formulated rations were procured from Feed formulation unit, TANUVAS, Kattupakkam supplied priorly. Adult birds were maintained using mash feed (Layer diet). Brooding equipments also distributed to the selected location of the farmers backyard and set ready for the chick arrival. A total of 2000 day old chicks were procured from Poultry research Station, Madhavaram, housed at KVK poultry shedwere fed clean water, electrolyte powder and vitamin supplements to overcome dehydration. On the next day sexing of chicks done based on scientific methods by physical appearance and distributed to the farmers backyard unit. A total of 90 female and 10 male chicks (9:1 ratio) supplied to the selected 20 women farmers that were acclimatized at farmer's field by brooding. On beginning, brooding was continued for 10 days using electric bulbs as sources of heat (35^{o}C) and illumination for 24 hours throughout to avoid early chick mortality. The same way native chicken (Control) also prepared ready and acclimatized at the farmer field.

Method demonstration

Chick starter ration of *ad libitum*was provided to the chicks up to 4 weeks of age. Subsequently, *ad libitum* feed provided during grower as well as layer stages of the study. Since it is a backyard production study household waste also provided by the farmers under free ranging systems. After proper brooding, the chicks were moved to freely and reared in backyard system with local native chicken. Tenkasi district is endemic for Ranikhet disease outbreaks, throughout the study the birds vaccinated against Ranikhet disease on 5th, 28th& 56thday using RDVF, LaSota and RDVK strain, respectively. Seasonal deworming also practiced with need based antihelminth compounds. The same was followed to the control birds as well. The demonstrated fields were regularly visited for scientific assistance and observation parameters documented. Economic traits of Body weight for male and female, Feed Conversion ratio, Livability Percentage, Age at First Egg, Egg Production (20-40 Weeks), Egg Weight (g) and relevant significant parameters were taken for individual birds recorded on weekly intervals.

Candling of eggs

On the seventh day of candling, the growing embryo began to move, and viable eggs began to show red, spider-like radiating lines. Unlike fresh eggs, infertile eggs were transparent, but their air cells were larger. On the eighteenth day of candling, the unfertile eggs were transparent in the light, but the viable eggs were thickly clouded and opaque with a network of veins showing the development of an embryo within the eggs. Both embryonic mortality and the number of sterile eggs were noted. In the afternoon of the eighteenth day of incubation, the live viable eggs were moved from the setting trays to a separate hatching tray compartment based on breed and replication. The following formulas were used to determine fertility and hatchability:

Fertility (%) = (Total no. of fertile eggs /Total no. of eggs set for incubation) ×100
Hatchability (%) = (Total no. of eggs hatched /Total no. of fertile eggs set for hatching) ×100

Feed Consumption and Feed Conversion Ratio

Feed consumption (g) was recorded at weekly interval up to 52 weeks of age and FCR for female pullets were calculated in terms of FCR per kg egg mass during laying period. FCR was calculated as follows:
FCR/ kg egg mass=kg of feed consumed/kg of egg produced

Statistical analysis

The consolidated data statistically analysed as per Completely Randomized Design and all statements of statistical difference were based on $P \leq .05$ as per Snedecor and Cochran, 1994.

RESULTS AND DISCUSSION

Backyard poultry can be profitably promoted in rural areas, largely due to the massive commercial poultry production that is constantly being amassed in urban and peri-urban areas, which has proven to be an amazing asset for the eradication of malnutrition, mitigation of rural poverty, and creation of lucrative employment in vast rural areas. Better chicken varieties might be introduced into a state's farms to help farmers quadruple their income and solve the issues. Following research and analysis, ICAR KVK Tenkasi chose to investigate the Nandanam chicken 4 among the early adopters of training attended by women from the various blocks within the district, since the women farmers are unaware of new, improved varieties that can tackle the poor production challenges. Table1.Shows the results of the study parameters conducted among the women farmers of Tenkasi district of Tamil Nadu. Many people are unaware (88%) of the new, better breeds and kinds of chicken. Everyone decided to limit their markings to the domestication of native chickens, or desi fowl. The fact that none of them were truly implementing the newest breeds of poultry indicates a deficiency in field expertise. The annual income (Rs 3000 to 5000) from the selling of poultry and eggs was comparatively low, most of the products used only to the family consumptions. Because of their poor productivity, their contribution to the total egg supply has remained almost unchanged over the previous few decades. This may be avoided by altering the raising approach by addressing the powerful tactics through multiple demonstrations to cover the early adopters of extension techniques. Many farmers rely on kutcha-style housing patterns, however if revenues climb, they may be replaced with the finest hosing techniques for safeguarding the birds. About 92% of respondents were completely oblivious when it came to the timing and significance of endemic illnesses in poultry.

This demonstrates how urgent it is for extensionists to find the main reason why scientific methods of problem-solving are not being adopted. Knowledge assessments are essential for assessing people abilities and competences in our ever evolving global environment(Vijyan *et al*., 2022).In terms of knowledge of feed materials that are readily available locally, 27% of respondents said they were aware of the inclusive feeding pattern. To cut down on feed waste and feed costs, none of the women were not using a combined cost-effective feeding plan. Only about 2% of people are aware that chicken meat and eggs can be valued more to increase profits. The goal of putting training programs into place is to encourage tribal farmers to use organic and sustainable agricultural methods, especially when it comes to raising free-range chickens, which has the potential to increase revenue, empower women, and improve nutrition. Our study in agreement with the finding and recommendation of Chaturvedani *et al*., 2017and Singh *et al*., 2017, who suggested the same recommendation on the introduction of new varieties. Whereas, the present study not in agreements with Bunkar *et al*., 2021 a study from Rajasthan, India, their results shows that knowledge level of poultry farmers, on feeding and vaccination are 80.10% & 68.73%. These urgent the study's findings point to the need for specialised training programs and legislative measures to close knowledge gaps in women farmers' poultry farming practices, support cultural preservation and sustainability, and expand their access to economic prospects. In present study, none of the people knew the techniques of proper waste disposal and manure production. Ahmed *et al*., 2023 documented on a study that 5% people do the proper manure production and

using it as an energy rich source to the agriculture field, at Bangladesh. Using this knowledge assessment has several advantages, such as helping to discover areas of knowledge gaps and providing specialised training programs. By supporting policies, encouraging adherence to scientific standards, and enhancing farming practices, these results might enhance poultry farming methods and increase farmers economic development and environmental sustainability.

Economic traits of Nandanam chicken 4

Plumage

In backyard poultry, plumage and feather patterns are crucial since they are the primary determinant of farmer approval (Rajaravindra *et al*., 2024). A synthetic dual-purpose chicken known as Nandanam chicken -4 was created by reciprocally crossing Rhode Island Red and White Leghorn. Depending on the parental plumage, all the two-way crosses in this research had white feathers with either brown or black patches. Since the white gene is dominant in White Leghorn, all cross-bred birds always had white plumage with a predominant dark to light brown shade, which was also the case in our study. The farmers acquire this colour pattern, which is nearly identical to that of native chicken.92% of the farmers in the survey agreed with the birds' colour pattern and stated that the feathers colour was comparable to that of the native chicken. The other 8% still needed some time to come to terms with the birds colouring pattern especially in male bird.

Chick management

Hatching weight is essential in poultry since it is a key a component in developing the ultimately bodyweight of a chicken during slaughter. The weight of a day-old chick is also an indicator of how efficiently the chick is developing. The study reported that average hatch weight of Nandanam chicken -4 is 41.12±0.39 which is slightly higher than the native chicken of the same unit. Higher body weight reported from Nedung'u *et al*., 2020&Dzungwe*et al*., 2024). In other side chick mortality is comparatively low (2%) in study bird. (Table 2) lower than the report of Kumari *et al*., 2020. Almost similar results documented in another district of Tamil Nadu by Premavalli *et al*., 2020.Very common vices of birds pecking very crucial vices reported from indigenous birds like Aseel, kadaknath etc, which leads to mortality in grower stage (Haunshi *et al*.,2021). The common feather pecking vices is not critically noticed among the Nanadam chicken- 4 especially on growing stage when housed with native birds. Low or zero mortality is an indirect indicator of good hygiene, and keeping a clean, dry housing is essential to preventing the spread of infections. This also shows how the breeds are adjusting to the specific elements of the farming environment. This shows the ability of the chicks to adopt the environment of Tenkasi district of Tamil Nadu.

Feed consumption and Feed conversion ratio(FCR)

The average feed intake of Nandanam chicken -4 at 12^{th}&16^{th} week is 915.20±1.19and 2.82±0.58which did not show more significant difference among different study groups. There were no significant results reported up to 11^{th} weeks study. This result in contradiction with theSheik *et al.,* 2021, their study feed intake recorded in 0-4 weeks of period was significantly ($P \leq 0.05$) different from each other among different types of chicken. But slight ($p<0.05$), positive differences in the feed intake also plays significant role on the overall production expenses at farms level (Table 3). This shows that Nandanam chicken -4 has its uniqueness compared native chicken. Since the birds reared under backyard production, study birds were not only depending the formulated feed as they roam freely, they consume wildly. This may also a standard reason of the less feed consumption throughout the study period. However, at the 8^{th}week of age, many authors (Omprakash *et al*., 2015; Kumar *et al*., 2019; Kanagaraju *et al*., 2015) observed feed conversion ratios of 2.66, 2.75, and 2.80, respectively, in Nandanam broiler-3 birds, which is similar, to the FCR reported (2.75) in our work. Feed conversion ratio of present study on 16^{th} week is 3.85±1.95 which is highly significant ($p<0.01$)than the native birds (2.79±0.48)on the same flock. This result is varied with the finding of Bhimraj *et al*., 2018, where he revealed on comparative study 3.42±0.24 at 8^{th} week under deep litter systems of rearing. The greater changes on the result might the system of rearing where our study conducted under backyard systems. Better efficiency is shown by a lower feed conversion ratio, which implies that birds need less feed to develop or produce at the same rate. It has a direct impact on profitability. Low feed consumption per unit of output results in more

affordable production costs and, eventually, larger profitability when the FCR is lower. The details of the nutrient contents of the supplied feed given in Table. 2.

Livability (%), Hatchability (%) and Fertility (%)

It is possible that the raising system had no impact on the study's death rate or livability. Present study concluded that the livability is 95.01± 0.97 higher than the report from native chicken. This study results almost accordance with Jha and Prasad (2013) who reported 90.15% livability in Kadaknath and 91.72 %in Hazra. Mortality report of adult Nandanam chicken-4 up to 2.00% compared with Kalitha *et al*., (2011) reported highest mortality of 17.83 % in indigenous chicken of Assam under deep litter system up to 5 weeks of age study itself, suggestive of Nandanam chicken-4 has better adaptability. Fertility shows 84.12 ± 7.46 which is higher than the native chicken 78.0± 5.42. Verma *et al*., 2018 documented 80.00±3.00among the Aseel birds was less indicates the Nandanam chicken -4 has the better fertility at the Tenkasi district. The hatchability (%) value on total egg set ranged from 85.40 to 89.87% in different hatches with overall mean of 89.0% is accordance with the report of Jamima *et al*., 2020. In Assamese native birds, a closer figure of 87.52% has been observed (Islam *et al*., 2014). However, native birds (Kalita *et al*., 2012) and birds that were crossed with native birds (Kalita *et al*., 2013) had extremely poor hatchability (%) values of 41.36 and 58.75 on the total egg set. The genetic and reproductive fitness of individual birds is influenced by factors such as fertility, hatchability, and livability (Table 4). The availability of day-old chicks is also significantly influenced by factors like as hatchability and fertility.

.

Body weight performance of Nandanam chicken -4

Production and reproductive features of poultry are influenced by their body weight, which is a direct reflection of growth. This result is contradiction with the finding of Premavalli *et al*., 2020 reported no body weight differences of Nandanam broiler 2 & 3 strains. Significantly higher ($P \leq 0.01$) mean body weight (g) was observed in Nandanam chicken-4 chickens at 4th, 6th, and 8thof subsequent week of age than Native chicken of same unit. At eight weeks of age, it was noted that the males of both genotypes weighed more than the females. In this investigation, Nandanam chicken -4 mean live body weight at 8 weeks of age was more than what several researchers had previously reported (Sangilimadan *et al*., 2014; Sangilimadan *et al*., 2020; Kumar *et al*., 2019).The Nanadanam chicken-4 significantly greater ($P \leq 0.01$) mean body weight at different ages compared to the native birds in this study may be because of their genetic composition, which allows them to grow weight with less feed and a better feed conversion ratio. The average 16th week body weight of male and female Nandanam chicken -4 in study was 1.8 kg& 921gwhich is higher than the control bird (Table 5). This result totally different from Chitra, 2019 who demonstrated Nandanam chicken-4 at Erode district of Tamil Nadu, submitted average body weights at 20th weeks of age were recorded as 1.6 kg and 1.5 kg in case of Nandanam chicken-4 and desi chicken respectively. Feed, hatching weight, genetic merit, brooding conditions, weather, diet, stress, and evolution considered the common important factors for the birds to gain significant body weight at correct ages. Present study results on body weight shows that the pertaining agroclimatic conditions at district is suited for the growing of Nandanam chicken -4.

Egg parameters and productions

The current research's significant ($p<0.05$) mean egg weight, 51.9 ±0.37 (Table 5), is higher than the average egg weight (g) reported by Vasanthakumar *et al*., 2020 study, which was 44.79±0.30 at the end of the 40th week of age. Similar result reported by Rajaravindra *et al*., 2024. The egg weight of Nandanam chicken- 4 in intensive and free-range systems was 53.55±0.76 and 52.0±0.62, respectively, according to Premavalli *et al*. (2016) and Chitra (2019). According to Rajkumar *et al*. (2017), the average egg weight of an Aseel bird at age 40th week was 38.8±0.6, which is less than the current study. The gene activity of Rhode Island Red and White Leghorn may be the cause of Nandanam chicken- 4 larger egg weight when compared to Aseel chicken. Furthermore, factors like as raising techniques, weather, feed type, feeding habits, etc., may contribute to the variances in egg size. The maximum egg production of the two study birds was 34th week. Similar result documented by (Vasanthakumar *et al*., 2020; Lordelo *et al*., 2020).The 26th week egg production (29.1±0.91) of Nandanam chicken -4 is significant ($p<0.05$) than the native birds. Highly significant ($p<0.01$)reports documented from 28th(31.27±0.91) & 34th(40.2±0.15) weeks of study (Table 6). When compared to the results observed by Kanagaraju *et al.* (2016) the birds reared present study region are

performing better. The total hen day egg production of Nandanam chicken -4 was 172 eggs / hen / year, which is closer to the findings of Chitra (2019) and Vasanthakumar *et al*., 2020, who reported 176 and 193 eggs/ hen /year. However, the A seel hens mean egg output at 72 weeks of age was 64, which may be because of the broodiness traits, which is the main cause of native chicken lower productivity (Rajkumar *et al.* 2017). However, the main factors influencing egg production are management and feeding procedures. The Rhode Island Red and White Leghorn birdgenes, which lack the broodiness trait, may have contributed to Nandanam chicken -4 increased egg output.

SUMMARY AND CONCLUSIONS

Backyard system of production is an asset for rural and tribal poor as it is a source of nutritional and livelihood to them. The result of reproduction traits revealed that the age at sexual maturity was 163 days of age and the result on reproduction traits revealedhen day egg production (No.) of 172 up to 40th week, respectively. The result also revealed that the Nandanam chicken-4 variety had fertility and hatchability per cent of84.10±7.46 and 89.0±1.33, respectively. Similarly, the recorded feed conversion ratio(FCR)of 16thin the present study with the significant limit (3.85 ±1.95) by consumption of 2.85kg feed. This dual-purpose bird is well-received by farmers in the Tenkasi districts of Tamil Nadu due to its superior growth, egg production capacity, and disease resistance. The overall production performance of Nandanam chicken-4 might favour the Western Ghats region of Tamil Nadu to improve their livelihood and nutritional security for doubling the income of women farmers.

ACKNOWLEDGEMENT

The authors wish to thank for the finance and infra-structure provided by the Indian Council of Agricultural Research and ICAR KVK, Tenkasi for the successful conduct of the study.

ABSTRACT

In transfusion medicine and obstetric care, irregular (unexpected) blood group antibodies against minor red blood cell (RBC) antigens continue to be a major clinical problem. Currently, 43 blood group systems with roughly 345 antigens are recognized by the International Society of Blood Transfusion (ISBT). When mismatched donor and recipient blood or fetal-maternal blood interact, these minor blood group antigens function as immune targets in addition to ABO. Evidence from studies published between 2012 and 2025 that are indexed in PubMed/MEDLINE, Scopus, and Web of Science is compiled in this thorough narrative evaluation. Rh (non-D), Kell, Kidd, Duffy, MNS, Lewis, Diego, and P1PK systems are among the major blood group systems analyzed; high-risk patient populations, diagnostic technology, and therapeutic advancements are also included. About 47.5% of all clinically relevant alloantibodies in patients receiving continuous transfusions are Rh non-D antibodies (anti-E, anti-c, anti-C, and anti-e). In addition to inducing hemolysis, anti-K specifically decreases fetal erythropoiesis, necessitating fetal MCA Doppler monitoring from titers as low as 1:8. Due to antibody evanescence, Kidd antibodies are the primary cause of delayed hemolytic transfusion responses. African and Asian populations have particular difficulties due to Duffy and MNS system antibodies.In South American and East Asian populations, the Di(a) antigen of the Diego system is clinically relevant. Global alloimmunization rates vary by matching processes and ethnic concordance between donor and recipient populations, ranging from 18–76% for sickle cell disease patients and from 5–31.6% for thalassemia patients. Eculizumab, rituximab, and/or tocilizumab are needed to treat hyperhemolysis syndrome, a potentially fatal side effect caused by alloimmunization. Molecular genotyping, extensive prenatal antibody screening, and

extended RBC antigen phenotyping are essential for reducing the morbidity and death linked to irregular antibodies. It is an important therapeutic need to expand these techniques in pregnant and chronically transfused populations worldwide.

Graphical Abstract

INTRODUCTION

Blood group antigens are molecular structures expressed on the surface of red blood cells (RBCs) that are dictated by genetics. These structures include proteins, glycoproteins, and glycolipids. Over 345 different antigens are currently categorized by the International Society of Blood Transfusion (ISBT) into 43 blood group systems, each of which is based on a particular gene or gene cluster. [1] The ABO and Rh(D) systems are the most clinically significant of these, although antigens in other minor systems are becoming more widely acknowledged as causes of immunological problems that are clinically significant.The operational basis of transfusion medicine is the differentiation between regular and irregular antibodies. All people who do not have the equivalent ABO antigen develop regular antibodies,

such as anti-A and anti-B. In contrast, irregular antibodies might develop spontaneously as naturally occurring cold-reactive antibodies or as a result of alloimmunization brought on by pregnancy or prior blood transfusions. [2] From innocuous cold-reactive IgM antibodies to powerful IgG alloantibodies that can result in deadly intravascular hemolysis, this group includes hundreds of clinically varied specificities. Unusual antibodies have varying clinical implications. Clinically relevant antibodies are those that are reactive at 37°C and have the ability to either cross the placenta and damage fetal red blood cells or hasten the destruction of incompatible transfused red blood cells. Depending on the research population, location, and detection technique, the prevalence of clinically significant non-ABO, non-D alloantibodies in the general population varies from 0.09% to 2.0%. [3,4,5] This number sharply increases in groups that receive transfusions on a regular basis, highlighting the cumulative nature of alloimmunization risk.Alloimmunization-related consequences have a significant worldwide impact. Since continuous transfusion is the main treatment for sickle cell disease (SCD), which affects an estimated 300,000 babies worldwide each year, alloimmunization rates of 18–76% are a defining clinical issue. [6] Hemolytic disease of the fetus and newborn (HDFN), thalassemia, and other transfusion-dependent disorders present comparable difficulties. Due to the effectiveness of anti-D immunoprophylaxis, a growing percentage of HDFN cases worldwide are now caused by minor blood group antibodies. [7] The most clinically significant minor blood group systems, their associated irregular antibodies, causes of harm, impacted demographics, diagnostic techniques, and current and emerging management strategies are all thoroughly synthesized in this review using evidence.

Immunological Basis of Irregular Antibodies

Mechanisms of Alloimmunization

The traditional adaptive immune pathways are followed by alloimmunization. Antigen-presenting cells (APCs) process foreign RBC antigens brought in by blood transfusions or fetal-maternal bleeding and present peptide-MHC class II complexes to CD4+ T-helper cells. B-cell activation, clonal growth, affinity maturation, and class-switch recombination from IgM to IgG production are all triggered by this. [8] While IgM and certain IgG antibodies can trigger the classical complement cascade to produce C3b opsonins and the membrane attack complex (MAC), resulting in intravascular hemolysis, IgG1 and IgG3 subclasses are especially effective at mediating Fc-receptor-dependent phagocytosis by macrophages in the spleen (extravascular hemolysis).A quick anamnestic immune response raises antibody titers to levels that might cause clinically noticeable hemolysis in a matter of days after repeated exposure to the sensitizing antigen, such as through a future transfusion or pregnancy. This is the mechanism behind delayed hemolytic transfusion responses (DHTRs), when the antibody rises quickly following antigenic re-exposure even though the pre-transfusion antibody screen may be falsely negative. [9] One particularly worrisome example of this phenomena is antibody evanescence, which is the decrease of some antibodies (especially Kidd system antibodies) to undetectable levels in between exposures.

Factors Determining Clinical Significance

Prevalence in Donors and General Patients

Important baseline information is revealed by studies on the incidence of irregular antibodies in blood donors and general patient groups. An overall incidence of irregular alloantibodies of 0.09% was identified in a large North Indian study that screened 47,450 blood donors. The most common type of irregular alloantibodies were MNS system antibodies, primarily anti-N, with a statistically greater prevalence in female donors. [3] The importance of antigenic sensitization in antibody development was confirmed by another North Indian comparison research involving 4,000 donors and transfusion recipients, which revealed that irregular antibodies were considerably more common in exposed patients than in healthy donors. [4] Anti-D, anti-Di(a), and anti-K were among the specificities revealed in a Brazilian Amazon study that found irregular antibodies in 0.1% of blood donors, demonstrating the regional and ethnic variation in antibody patterns. [5]

The Rh Blood Group System: Non-D Antigens

Molecular and Structural Background

Currently including more than 50 identified antigens encoded by two closely related genes on chromosome 1q36, RHD and RHCE, the Rh system (ISBT 004) is the most polymorphic human blood group system. The RHCE gene

uses allelic combinations to encode four major antigens: C, c, E, and e. The RHD gene encodes the D antigen. Four amino acid changes cause the C/c polymorphism, whereas a single proline-to-alanine shift at position 226 of the RhCE protein causes the E/e polymorphism. [10] Due to their frequent occurrence in patient-donor mismatches, especially in ethnically diverse transfusion settings, these antigens are highly immunogenic and clinically significant.

Prevalence and Specificity of Non-D Rh Alloantibodies

The most commonly found class of clinically important irregular alloantibodies is non-D Rh antibodies. Rh system antibodies account for about 47.5% of all clinically significant alloantibodies, with anti-E being the most common Rh alloantibody (61.3% of Rh system antibodies), followed by anti-C (18.5%), anti-c (13.2%), and anti-e (2.5%), according to an analysis of the REDS-III database across 6,597 alloimmunized patients. [11] A cross-sectional research of SCD and beta-thalassemia patients in Saudi Arabia revealed that anti-K (46%) and anti-E (39%) were most common in SCD patients, whereas anti-K (33%) and anti-E (28%) were more common in thalassemia patients. [12]

RHCE Variants and Alloimmunization Complexity

The presence of mutant RHCE alleles, which are more common in people of African origin, is a crucial complication in Rh alloimmunization. Even when C, E, and K phenotype-matched blood is given, individuals with variant Rh antigens might develop alloantibody reactions against the wild-type antigens they partially lack because these variant alleles encode altered or incomplete antigen epitopes. [11] This explains the persistence of alloimmunization in limited antigen matching SCD regimens. Molecular RH genotyping, which can detect these variant alleles, is becoming more and more important for both the preventive identification of patients at risk and the comprehensive care of highly alloimmunized patients.

Clinical Consequences

Nearly all non-D Rh alloantibodies belong to the IgG class and cause extravascular hemolysis by engaging the Fc receptor on splenic macrophages. Clinically, hemolysis usually shows up as increased lactate dehydrogenase in the post-transfusion phase, rising indirect bilirubin, and unexplained anemia. The search for suitable blood is significantly complicated by the fact that 34.8% of alloimmunized polytransfused patients have multiple concurrent Rh alloantibodies. [13] Anti-c and anti-E have been shown to produce severe HDFN in Rh(D)-positive mothers during pregnancy, indicating that exclusive Rh(D)-based prenatal testing is unable to fully capture the range of HDFN risk.

The Kell Blood Group System

Molecular Basis and Antigen Distribution

The 20-exon KEL gene on chromosome 7q34 encodes the Kell glycoprotein, a type II transmembrane zinc-dependent metalloendopeptidase, which is responsible for the Kell blood group system (ISBT 006). There are presently 35 identified antigens in the system, with the K (KEL1) and k (KEL2) pair having the most clinical importance. There is a significant antigenic asymmetry between mostly Caucasian donor pools and diverse patient populations because the K antigen is found in fewer than 0.5% of Asians, 2% of African Americans, and roughly 9% of Caucasians. [14]The XK protein, which carries the Kx antigen, and the Kell glycoprotein are covalently bound by a disulfide bond; mutations in the XK gene cause McLeod syndrome, an X-linked neuroacanthocytosis condition, highlighting the significance of this complex in cellular physiology beyond serology.

Unique Mechanism: Erythropoietic Suppression

Among irregular antibodies, anti-K antibodies are particularly harmful because they primarily affect the fetus by suppressing erythroid progenitor cells rather than hemolyzing circulating red blood cells. Anti-K maternal alloantibodies can bind progenitor cells and impede colony-forming units (BFU-E and CFU-E), hence directly inhibiting fetal erythropoiesis, since Kell antigens are expressed on erythroid precursors as early as 10 weeks of gestation. [15] Because the main process is decreased RBC production rather than increased RBC destruction, traditional measures of hemolysis, such as bilirubin levels and amniotic fluid delta-OD450, are misleadingly low even when the fetus is extremely anemic. Because of this, conventional delta-OD450 monitoring is insufficient as the

only surveillance method, and anti-K titer thresholds for initiating MCA Doppler surveillance are set lower than for anti-D (as low as 1:8 by standard tube testing). [16]

4.3 Alloimmunization Rates and Policy Gaps

Anti-K was found in 0.1% of a broad, diverse patient group in an examination of K alloimmunization in females with pregnancy potential in the United States; in most cases, sensitization was due to past transfusion. The study made clear that, although it is common practice in many European countries, prophylactic K-negative blood supply for females of reproductive age is still not regularly carried out as a national policy in the United States. [17] Anti-K was shown to be one of the most common alloantibodies in the Omani research of SCD and thalassemia patients, with 85% of all alloimmunized individuals immunized against both Rh and Kell antigens. [18]

The Kidd Blood Group System

Molecular Basis and Antigen Characteristics

Three antigens—Jk(a) (JK1), Jk(b) (JK2), and Jk3—carried on the urea transporter protein produced by the SLC14A1 gene on chromosome 18q12.3 make up the Kidd blood group system (ISBT 009). The unusual Jk(a-b-) null phenotype is linked to reduced urea transport, which is a medically tolerated state. This protein helps RBCs transfer urea quickly across membranes. [19] About 17–21% of some Pacific Islander and Ghanaian SCD communities have the Jk(a-b-) null phenotype, which poses a serious compatibility issue because people who develop anti-Jk3 are incompatible with almost all donor blood.

Antibody Evanescence and Delayed HTR Risk

The two characteristics of Kidd antibodies that make them notorious in clinical settings are their capacity to completely activate complement, resulting in intravascular hemolysis, and their quick drop to undetectable levels after initial alloimmunization—a process known as antibody evanescence. Within months, anti-Jk(a) and anti-Jk(b) can drop below the detection threshold of standard serological techniques, only to quickly reappear in an anamnestic reaction upon re-exposure to the antigen. [9] The pre-transfusion antibody screen is falsely negative, incompatible blood is given, and the patient experiences brisk intravascular hemolysis 2–14 days later, presenting with hemoglobinuria, declining hemoglobin, rising bilirubin, and acute kidney injury. This pattern explains why Kidd antibodies are a major cause of delayed hemolytic transfusion reactions.

Kidd system antibodies were shown to be the second most often implicated specificity in Norwegian hemovigilance data tracking hemolytic transfusion reactions from 2004 to 2020, accounting for 14% of all reported hemolytic transfusion reactions, after Rh antibodies at 24%. [20] This epidemiological result emphasizes how crucial it is to keep patient-specific, longitudinal antibody records at all transfusion facilities, especially in cases where pre-transfusion screenings are now negative.

The Duffy Blood Group System

Molecular and Biological Significance

The DARC gene (Duffy Antigen Receptor for Chemokines, now known as ACKR1) on chromosome 1q21-q22 encodes the Duffy system (ISBT 008). A single nucleotide polymorphism (rs2228461) that results in an aspartate-to-glycine substitution at position 42 of the ACKR1 protein distinguishes the main antigens Fy(a) (FY1) and Fy(b) (FY2). [19] The DARC protein is the only erythrocyte receptor for Plasmodium vivax merozoites and functions as a chemokine scavenger receptor. The nearly universal occurrence of the Fy(a-b-) null phenotype in sub-Saharan African populations (>68%) can be explained by the fact that individuals with this phenotype, which results from a GATA-1 promoter mutation that silences DARC expression on RBCs while maintaining expression on other tissues, are naturally protected against P. vivax malaria.

Anti-Fya and Anti-Fyb: Clinical Significance

Because the Fy(a) antigen is more immunogenic and more common in Caucasian donor populations than in African patient groups, anti-Fy(a) is more clinically common than anti-Fy(b). Fy(a) was detected in 66.5% of blood donors and Fy(b) in 83.3% of donors in a study of blood donor phenotypes conducted by the Ethiopian Blood and Tissue

Bank Service. These findings have important implications for the risk of alloimmunization in ethnically mixed transfusion settings. [21] Both anti-Fy(a) and anti-Fy(b) belong to the IgG class, are reactive at 37°C, and can cause both HDFN and acute and delayed hemolytic transfusion responses.

The GATA-1 promoter mutation that causes the Fy(b-) silent phenotype presents a significant diagnostic hurdle in Duffy system serology. Despite carrying the FY*02 allele and expressing Fy(b) on non-erythroid tissues, individuals with this mutation are serologically categorised as Fy(b-). To differentiate between the silent phenotype and actual Fy(b) negative (with a real risk of anti-Fy(b) production upon RBC contact), molecular genotyping is crucial. This distinction has significant ramifications for compatibility testing, transfusion strategy, and alloimmunisation risk counselling. [22]

The MNS Blood Group System

Genomic Organization

Two closely related genes on chromosome 4q28-q31, GYPA (encoding Glycophorin A, carrying M and N antigens) and GYPB (encoding Glycophorin B, carrying S, s, and U antigens), encode the MNS system (ISBT 002). Amino acid variations at positions 1 and 5 of the Glycophorin A extracellular domain cause the M/N polymorphism, whereas a methionine-to-threonine substitution at position 29 of Glycophorin B causes the S/s polymorphism. All people with GYPB expression have the high-frequency U antigen; people of sub-Saharan African ancestry are nearly exclusively found to have the U-negative phenotype, which is brought on by significant deletions in the GYPB gene. [23]

Clinical Significance of MNS Antibodies

One of the most often found abnormal antibodies in routine screening is anti-M. It is usually not clinically significant when reactive only at temperatures lower than 25°C. However, M-negative blood must be supplied since a subset of anti-M antibodies that are reactive at 37°C by IAT can result in uncommon HDFN and acute haemolytic transfusion responses. Although there are instances of late-onset newborn anaemia, anti-N rarely results in clinically significant reactions. Clinically severe HDFN and both acute and delayed haemolytic transfusion responses are caused by anti-S and anti-s, which are normally IgG class antibodies that respond at 37°C. One of the most difficult blood banking issues is anti-U: patients with anti-U have nearly universal incompatibility with normal blood stocks because the U antigen is expressed on almost all donor red blood cells, with the exception of the uncommon U-negative subpopulation of African origin. [23] For any transfusion, access to specialised uncommon donor registries is required because to the U-negative phenotype, which affects up to 1% of SCD patients from sub-Saharan Africa. MNS system antibodies, primarily anti-N, were the most common in donor populations, with an overall alloantibody frequency of 0.27%, according to a North India survey of 82,153 blood donors. [24]

The Lewis Blood Group System

Biosynthesis, Genetics, and Phenotype Distribution

Among blood group systems, the Lewis system (ISBT 007) is distinct in that its Lewis antigens are glycolipid antigens that are adsorbed onto the surface of red blood cells from plasma rather than intrinsic RBC antigens. The major antigens, Le(a) and Le(b), are produced by the sequential activity of fucosyltransferase enzymes encoded by the FUT3 (Lewis gene, Le) and FUT2 (Secretor gene, Se) genes. They are produced by epithelial cells and released into bodily fluids. Le(b) necessitates the co-expression of both Le and Se genes, whereas Le(a) is produced by the Le gene alone. [25] There are presently six recognised antigens in the Lewis system: Le(a), Le(b), LebH, ALeb, BLeb, and Leab. People of African and East Asian heritage are more likely to have the Le(a-b-) phenotype, however there are also Le(a+b-), Le(a-b+), and Le(a+b+) phenotypes.

Clinical Significance of Lewis Antibodies

In transfusion practice, Lewis antibodies are typically regarded as clinically unimportant, cold-reactive (reactive below 22°C), and of the IgM class. However, a clinically significant subgroup of Lewis antibodies, specifically anti-Le(a) and anti-Le(b), can react at 37°C. There have been reports of both acute and delayed haemolytic transfusion reactions brought on by 37°C-reactive Lewis antibodies. [26] Lewis antibodies were detected in 22 out of 100 patients

with irregular antibody screenings in a retrospective Indian case series research conducted between 2016 and 2021. Two patients (9.09%) had 37°C-reactive antibodies that were clinically significant for transfusion selection. [27]

74 individuals had Lewis system antibodies, accounting for 16% of all antibody-positive specimens, according to a Chinese retrospective investigation of Lewis antibodies from the Third Xiangya Hospital (2019–2021). This is the third most prevalent antibody system after Rh and MNS. [28] Lewis antibodies were once thought to be generally benign, however high-titer Lewis antibodies in Southeast Asian populations can result in severe haemolytic transfusion responses. Since Lewis antigens are absorbed glycolipids rather than inherently expressed on foetal red blood cells, Lewis antibodies are not linked to HDFN.

Lewis antibodies are typically IgM and reactive below 37°C, but 37°C-reactive examples have clinical significance, and antigen-negative blood should be chosen for such patients, according to an ISBT Working Party report examining the clinical significance of antibodies across 12 blood group systems, including Lewis. [29] Lewis blood group alloantibodies have also been linked to antibody-mediated rejection in patients of kidney transplants, expanding the clinical significance of Lewis antibodies beyond traditional transfusion therapy.

The Diego Blood Group System

Molecular Basis and Geographic Distribution

There are now 23 antigens in the Diego blood group system (ISBT 010), all of which are carried on the erythroid membrane Band 3 glycoprotein (AE1 protein), which is encoded by the SLC4A1 gene on chromosome 17q21-q22. Acid-base homeostasis and carbon dioxide transport depend on AE1, the main RBC membrane anion exchanger. A single nucleotide polymorphism in exon 19 of SLC4A1 (c.2561C>T) causes a proline-to-leucine substitution at position 854 of Band 3, which gives rise to the Dia and Dib antigens. [30] The Dia antigen is clinically significant in these particular geographic and ethnic contexts since it is rare in Caucasians (<0.01%) but has much greater frequencies in East Asian groups (Japanese ~12%, Chinese ~5%) and South American Indigenous populations (2–54%).

Clinical Significance of Diego Antibodies

The most clinically significant Diego system antibody is anti-Dia, which can occasionally result in both immediate and delayed haemolytic transfusion responses as well as mild to severe HDFN. Due to its rarity, the clinical behaviour of anti-Dia during pregnancy is not fully understood; nonetheless, cases that have been reported include severe HDFN that necessitates exchange transfusion. A Yale School of Medicine case report from 2023 detailed HDFN in a U.S. neonate born to a mother of South American descent, with a cord blood DAT showing 3+ reactivity and moderately elevated bilirubin. This presentation was largely unexpected in a U.S. setting where Dia antigen is rare in the general population but present in patients of Asian and Hispanic origin. [31]Another case report from 2023 that was published in the Journal of Medical Cases detailed severe HDFN caused by anti-Dia. The newborn had haemoglobin levels of 5 g/dL at birth and needed IVIG, extensive phototherapy, and a simple transfusion. In the third trimester, the mother's anti-Dia titer had suddenly increased to 1:32. [32] Diego alloimmunisation is a significant transfusion danger in Latin American populations, as demonstrated by a research of blood donors in Ecuador that revealed a Dia antigen frequency of 25% and an alloimmunisation rate of 6.09% due to Dia incompatibility. [33]

Diego genotyping should be included in extended antigen-matching panels for multiply transfusion patients, especially in diverse populations with Mongolian, Asian, or South American ancestry, according to a 2024 Saudi Arabian study that determined the frequencies of DI blood group alleles in an area endemic for hemoglobinopathies. [34]

High-Risk Patient Populations

Sickle Cell Disease

In transfusion medicine, sickle cell disease patients are the group most at risk for RBC alloimmunisation. Alloimmunisation rates in SCD patients receiving ABO and D-matched blood alone range from 18% to 76%, according to a seminal Lancet Haematology review. The main causes of this discrepancy are limited matching strategies in low-income African settings and ethnic background mismatch between predominantly Caucasian donor pools and African-descent patient populations in high-income countries. [35] The Omani SCD cohort research reported an alloimmunisation rate of 31.6%, with the most common specificities being anti-E, anti-c, anti-C, anti-K, and anti-S. [18]The intrinsic pro-inflammatory condition of SCD is a significant contributing element. The complement system and Toll-like receptor 4-mediated monocyte activation are triggered by hemolysis-driven release of heme and heme-loaded microvesicles, resulting in an inflammatory environment that promotes alloimmunisation upon antigen exposure. [35] HLA alloimmunisation is also strongly correlated with RBC alloimmunisation in paediatric SCD (OR 4.32), highlighting the worldwide immunological dysregulation in this group. [36]

Thalassemia

Depending on the matching procedure used, the cumulative amount of transfusion units received, and the ethnic concordance between the donor and recipient populations, alloantibodies can develop in transfusion-dependent thalassaemia patients at rates ranging from 5% to 31.6%. Anti-K (25.9%), anti-E (21.8%), and anti-D (9.2%) were the most common alloantibodies observed in a systematic assessment of alloimmunisation in beta-thalassemia and SCD in Middle Eastern nations; Rh and K antibodies made up 74.2% of all alloantibodies found. [37] Alloimmunisation data from 2022–2023 supported the necessity of ABO/Rh/K matching as a minimum requirement, with expanded matching further lowering alloimmunisation rates in thalassaemia, according to a multi-center Italian study from Sicily, Sardinia, and Malta. [38]A ten-year single-center examination of Thai thalassaemia patients revealed that antigen-matched RBC supplies (C, c, E, e, Mi(a)) decreased alloimmunisation rates to 3.5% as opposed to higher rates without matching. The most prevalent alloantibodies in the matched group were anti-E and anti-Mi(a), indicating that MNS variations like Mi(a) are more significant in Thai and Southeast Asian thalassaemia communities. [39]

Pregnant Women

An overall irregular antibody positivity rate of 0.91% was identified in a large retrospective Chinese cohort study of 151,471 pregnant women. Lewis antibodies were most common (43.33%), followed by anti-E (16.67%) and anti-M (16.67%). Crucially, in this cohort, the largest individual risk for clinically severe HDFN is associated with Rh and MNS system antibodies. In the third trimester, the prevalence of antibodies rose dramatically.0.67% of multiparous Chinese pregnant women (n = 18,010) had irregular antibodies, with antibody specificities primarily dispersed throughout the Rh, MNS, Lewis, and Kell systems, according to a thorough irregular antibody screening research. The study found that the most common sensitisation risk factor in this cohort was multiple pregnancies rather than transfusion history. [14] Anti-c, anti-E, anti-K, and anti-Di(a) HDFN cases have all been reported in environments with full anti-D immunoglobulin coverage, demonstrating that non-D HDFN is a serious and underdiagnosed clinical issue worldwide. [7]

Hyperhemolysis Syndrome: A Severe Complication of Alloimmunization

Definition and Pathophysiology

The destruction of both autologous and transfused red blood cells, which causes haemoglobin levels to drop below pre-transfusion levels, is the hallmark of hyperhemolysis syndrome (HHS), a severe and sometimes lethal subtype of delayed haemolytic transfusion reaction. Patients with sickle cell disease (SCD) are more likely to experience HHS than those with thalassaemia or other hemoglobinopathies. [40] Its pathogenesis includes complement system activation, cytokine-driven inflammatory amplification, and macrophage-mediated bystander haemolysis, frequently presenting as Coombs-negative. high bilirubin, high LDH, decreased reticulocyte count, and haemoglobinuria are diagnostic indicators.

Treatment Advances

There are no recognised randomised trial-supported protocols for the empirical treatment of hyperhemolysis. IVIG and high-dose intravenous corticosteroids are first-line treatments. Rituximab (anti-CD20 monoclonal antibody), which lowers alloantibody-producing B-cell populations and has demonstrated effectiveness in avoiding recurrent severe DHTR in immunised SCD patients, has been used to treat refractory cases. [41] Eculizumab, a humanised anti-C5 monoclonal antibody that blocks the terminal complement pathway, is thought to be effective for complement-driven HHS based on the monitoring of soluble C5b-9 (sC5b-9) as a biomarker of complement activation. It has shown a rapid and dramatic reduction in intravascular haemolysis in several published case series. [42]

When rituximab alone was insufficient to treat severe hyperhaemolysis in non-transfusion-dependent thalassaemia, a 2023 Karger case report described the successful use of combined tocilizumab (anti-IL-6) and rituximab, with tocilizumab acting as a bridging agent to stop haemolysis while awaiting delayed rituximab efficacy. [43] Because complement involvement varies among instances, a 2025 MDPI Diagnostics study found that a customised, biomarker-guided therapeutic approach is necessary, combining soluble C5b-9 monitoring with eculizumab medication. [44]

Detection Methods for Irregular Antibodies

Serological Methods: IAT, CAT, and SPRCA

The gold standard for detecting aberrant antibodies in pre-transfusion testing is still the indirect antiglobulin test (IAT). The most clinically relevant antigens of the D, C, E, c, e, M, N, S, s, P1, Le(a), Le(b), K, k, Fy(a), Fy(b), Jk(a), and Jk(b) systems are covered by standard screening cell panels, which provide simultaneous screening against all major minor blood type systems in a single test. [45] Because of its standardised reading, decreased operator variability, and archivable result cards, column agglutination technology (CAT, also known as the gel card method) has essentially supplanted the traditional tube approach in the majority of clinical laboratories. The strongest analytical sensitivity for recognising weak alloantibodies is offered by solid-phase red cell adherence (SPRCA) technology, which has been shown to be especially useful for identifying several contemporaneous or evanescent alloantibodies.

SPRCA showed the highest sensitivity for identifying weak or co-existing alloantibodies, while CAT offered superior standardisation and workflow applicability for routine screening, according to a systematic PRISMA-based review of immunohematologic detection techniques for multiple irregular alloantibodies (2020–2025). For patients with complex alloimmunisation, the combination of methods is advised. [46]

Molecular Genotyping and Next-Generation Sequencing

Molecular blood group genotyping overcomes the fundamental limitation of serological phenotyping in patients with autoantibodies, those with variant antigen expression, and recently transfused patients (in whom circulating donor RBCs confuse results). This allows phenotype prediction directly from genomic DNA. From a single DNA sample, high-throughput SNP-based genotyping devices can now concurrently assess antigen status across several blood group systems. [22]

The current frontier is blood group genotyping using next-generation sequencing (NGS). Sequencing depth was determined to be a crucial reliability factor in a systematic review and meta-analysis of ten NGS-based blood group genotyping investigations, which revealed pooled concordance percentage of 0.982–0.994 when compared to established molecular approaches for Kell, Duffy, and Kidd alleles. Specialised analytical algorithms are needed for complex systems like Rh and MNS, which have hybrid glycophorin genes and gene conversion processes. [47] Blood centers can now find matched units for patients with uncommon alloantibody combinations because to predictive genotyping-based donor registries, which list donors' broader antigen profile.

Prevention and Management Strategies

Extended Antigen Phenotype Matching

Prophylactic extended RBC antigen matching is the main evidence-based method for lowering alloimmunisation in patients receiving continuous transfusions. In patients with SCD and thalassaemia, matching for C, c, E, e, and K antigens at the very least significantly lowers alloimmunisation rates. The British Journal of Haematology (2025) published a systematic review and clinical practice guideline from the International Collaboration for Transfusion Medicine Guidelines (ICTMG) that supports extended matching as the standard of care by offering updated evidence-based recommendations for RBC specifications in patients with hemoglobinopathy. [48]

Further lowering the probability of residual alloimmunisation are broader matching procedures that include Duffy (Fy(a), Fy(b)), Kidd (Jk(a), Jk(b)), and MNS (S, s) antigens. Both alloimmunisation rates and the prevalence of delayed haemolytic transfusion responses have been decreased as a result of national programs that give SCD patients longer phenotype-matched blood. These programs have been implemented in France, the United Kingdom, and increasingly in the United States. [35]

Antenatal Antibody Screening

The foundation of HDFN prevention is routine prenatal antibody screening by IAT at the initial visit and 28 weeks of gestation for all pregnant women. [17] Referrals for foetal surveillance using MCA Doppler velocimetry and, if necessary, intrauterine transfusion should be made in response to the detection of anti-K, anti-c, anti-E, or other clinically relevant antibodies. An urgent clinical need is to expand antenatal screening worldwide beyond anti-D testing to include the entire panel of minor blood group system antibodies, especially in low- and middle-income nations where HDFN caused by minor blood group antibodies is still underdiagnosed.

Rare Donor Registries and National Antibody Databases

Rare donor registries are necessary for patients with antibodies against high-frequency antigens (such as anti-U, anti-Jk3, anti-Ku, and anti-Dia in relevant populations) to obtain suitable blood. The creation of a national RBC antibody registry was suggested in a 2022 Vox Sanguinis article as a way to lower adverse transfusion events, make compatible blood selection easier, and prevent patients with previously identified but evanescent antibodies from unintentionally receiving incompatible units. [49]

Emerging Frontiers in Immunohematology

Comprehensive blood group genotyping is now possible as part of larger genomic health initiatives thanks to whole-exome and whole-genome sequencing techniques, which have the ability to proactively discover clinically important antigen profiles prior to any transfusion or pregnancy exposure. Large immunohematology datasets are being analysed using AI and machine learning algorithms to find high-risk alloimmunisation genotypes, optimise donor-recipient matching algorithms, and identify at-risk patients for proactive extended typing. [47]. As a mechanism for antigen-specific immune tolerance to foreign RBC antigens, regulatory T-cell (Treg) biology is now being studied. Tregs have been shown to play a crucial role in reducing the alloantibody response in mouse models of RBC alloimmunisation, providing therapeutic opportunities to avoid alloimmunisation in patients receiving continuous transfusions. [8] In the clinical monitoring of eculizumab-treated hyperhemolysis, novel biomarkers for complement system activation, especially soluble C5b-9, are being assessed. This could allow for precise dosing and response monitoring. [44]

Conclusions and Research Gaps

In transfusion medicine and obstetric care, irregular antibodies against minor blood group systems constitute a clinically varied and important category of immunological risks. Haematologists, transfusion specialists, and obstetricians who manage patients at risk must have a thorough understanding of each blood group system, from molecular genetics to population distribution to unique clinical repercussions.

Sustained interdisciplinary cooperation between haematologists, transfusion medicine specialists, molecular biologists, obstetricians, and public health policymakers is necessary to achieve safer transfusion and obstetric outcomes worldwide. It is imperative that everyone have equal access to rare donor resources, molecular genotyping, and extended phenotyping, regardless of their financial situation.

Table:1: Several interrelated factors determine how much clinical harm an aberrant antibody causes:

Parameter	Clinical Implication
Immunoglobulin class (IgG vs IgM)	IgM effectively activates complement, resulting in intravascular hemolysis; IgG antibodies cross the placenta; and IgG1/IgG3 mediate extravascular hemolysis.
Thermal amplitude (reactivity at 37°C)	For hemolysis in vivo, only antibodies that react at body temperature (37°C) are deemed clinically meaningful.
Complement activation	Intravascular hemolysis, hemoglobinuria, and an increased risk of acute kidney injury are caused by antibodies that fix C3 and produce MAC, such as anti-Jka and anti-Jkb.
Antigen density on RBC surface	Higher antigen density increases probability of effective antibody-antigen engagement and efficient RBC destruction
Antigen expression on fetal/neonatal RBC	Early fetal susceptibility to maternal alloantibodies results from early gestational expression (e.g., Kell antigens by 10 weeks).
Immunogenicity of antigen	D, K, c, E antigens generate alloantibodies most readily per individual exposure event
Antibody evanescence	Some antibodies (notably Kidd) decline below detection thresholds but resurge on re-exposure, causing missed pre-transfusion incompatibility
Erythropoietic suppression	Anti-K uniquely suppresses erythroid precursors in addition to destroying mature RBCs, lowering hemolysis biomarkers and masking disease severity

Table :2: Summary of Clinical Significance by Blood Group System

Blood Group System	Key Antibodies	Hemolysis Mechanism	HDFN Risk	Key Population/Notes
Rh (non-D)	Anti-E, anti-c, anti-C, anti-e	Extravascular (splenic macrophages)	High (anti-c severe)	47.5% of alloantibodies in transfused patients [11]; RHCE variants common in SCD
Kell	Anti-K, anti-k, anti-Ku	Extravascular + erythropoietic suppression	High (anti-K, unique mechanism)	MCA Doppler from titer 1:8; prophylactic K-matching for females of childbearing potential recommended [17]
Kidd	Anti-Jka, anti-Jkb, anti-Jk3	Intravascular (complement MAC)	Moderate	Antibody evanescence causes false-negative pre-transfusion screens; 14% of reported HTRs [20]
Duffy	Anti-Fya, Anti-Fyb	Extravascular (IgG1/IgG3)	Moderate	Fy(a-b-) null phenotype >68% in sub-Saharan Africa; genotyping essential for silent phenotype [22]
MNS	Anti-S, anti-s, anti-U, anti-M (37°C)	Extravascular; anti-U can be severe	Moderate-High (anti-U severe)	U-negative phenotype in ~1% of African SCD patients; near-universal incompatibility [23]
Lewis	Anti-Lea, Anti-Leb	Complement-mediated (IgM, cold) or IgG (37°C)	None (antigens absent on fetal RBCs)	16% of antibody-positive specimens in China [28]; transplant rejection implication [29]
Diego	Anti-Dia, Anti-Dib	Extravascular; complement occasionally	Moderate-High (anti-Dia)	Clinically significant in East Asian and Latin American populations; genotyping important in Saudi Arabia SCD [34]
P1PK	Anti-P1	Complement-mediated (cold reactive)	Low (except warm-reactive anti-P1)	Most anti-P1 cold-reactive and insignificant; rarely warm-reactive cases have caused severe HTR

Table: 3: The following table summarizes critical practice and research gaps identified in this review:

Gap	Recommended Action
Underreporting of delayed hemolytic transfusion reactions	Implement mandatory hemovigilance systems with standardized case definitions across all transfusion centers
Lack of universal antenatal non-D antibody screening	Adopt internationally consistent antenatal screening covering the full panel of clinically significant minor blood group antibodies
Insufficient extended phenotype matching in low-resource settings	Invest in molecular genotyping infrastructure; integrate into hemoglobinopathy management programs in endemic regions
Limited rare donor registries in developing nations	Establish nationally organized rare donor registries interconnected through ISBT-coordinated international networks
Gap between molecular knowledge and clinical implementation	Develop cost-effective NGS-based genotyping workflows appropriate for routine blood bank use

Incomplete understanding of alloimmunization immunogenetics	Conduct genome-wide association studies to identify HLA and non-HLA genetic susceptibility loci for alloimmunization
No standardized treatment protocols for hyperhemolysis syndrome	Initiate international multicenter clinical trials for eculizumab, rituximab, and tocilizumab in HHS management
Diego and P1PK systems undercharacterized in diverse populations	Expand population-based antigen frequency databases to include under-studied systems in Middle Eastern, Asian, and African cohorts

ABSTRACT

This paper examines the current state and future prospects of advanced IoT devices, particularly sensors, in the context of their integration with 5G technology and real-time data processing. The convergence of these technologies has significantly transformed various industries by enabling enhanced speed, efficiency, and seamless digital connectivity. The study provides an in-depth analysis of different types of IoT sensors available in the market, along with recent technological advancements that have improved their accuracy, reliability, and energy efficiency. It also highlights the transformative role of 5G technology, emphasizing its high data rates, low latency, and ability to support massive connectivity, which greatly enhance the performance of IoT systems. Furthermore, the chapter presents detailed case studies demonstrating the integration of IoT and 5G across multiple domains, including smart cities, healthcare, industrial automation, and agriculture. It also discusses the importance of real-time data processing, along with the roles of edge and cloud computing in enabling efficient data handling. Key challenges such as data security, scalability, and interoperability are also critically addressed. In addition, the chapter explores emerging trends, including the application of artificial intelligence and blockchain technologies to strengthen IoT systems, and identifies potential research directions for future development. Overall, the objective is to provide a comprehensive understanding of how the integration of advanced IoT sensors, 5G technology, and real-time data processing can transform industrial operations and drive innovation across various sectors.

Keywords: Advanced IoT sensors, 5G technology, real-time data processing, edge computing, cloud computing, data security, scalability, smart applications

INTRODUCTION

Overview of IoT and Its Significance

The Internet of Things (IoT) marks a significant shift in the technological landscape, enabling a vast number of devices—ranging from household appliances to industrial machinery and control systems—to communicate with each other through the internet. This interconnected environment transforms ordinary objects into intelligent systems capable of sensing, collecting, and exchanging data autonomously. IoT plays a crucial role in automating various industries by leveraging real-time data to support effective decision-making processes. It contributes to applications such as environmental monitoring, enhanced public safety, and improved quality of life through smart home technologies and wearable health devices. Furthermore, continuous advancements in sensor technology, data analytics, and wireless communication are accelerating the growth of IoT applications, making it a key driver of global digital transformation. Advanced sensors & devices is something which cannot be replaced in today IoT ecosystem. These sensors are mostly responsible for feeding data in the digital world by converting it into meaningful information which can be processed and analyzed to drive insights. Advanced IoT sensors can be many things from environmental sensors track temperature, humidity as well as other systems that control; wearable sensors monitor health data such as heart rate and steps taken to industrial measurements, like pressure or lighting. Self- calibrating sensors, for example, correct their own measurements to ensure ongoing accuracy of data readings while low-power sensing means the sensor can function over long periods without requiring frequent battery replacement. These developments would grow the potential and processes of IoT systems for all-inclusive solutions that can cater to complex problems in several domains.

The fifth generation of mobile networks is a significant break in wireless communication and even on the so-called 5G technology will bring with it an unprecedented increase in connectivity for the object. 5G has the potential to deliver data rates of up to 10 GBPS, latency as low as 1 millisecond and the ability to support up to one million devices per square kilometre, meaning that it can revolutionize massive IoT applications by providing a real-time pipeline that is essential for managing huge volumes of data. Real-time, massive data transfer and communication between connected devices are reformulated with 5G technology that seamlessly integrates with IoT leading into more robust and scalable performance. Edge computing enables real-time processing of data near the point of its origin to save on latency and bandwidth, while cloud computing brings both elastic compute power to drive more sophisticated analyses. These technologies, when used in combination allow the IoT systems to deal with the enormous volume of data efficiently and provide real-time actionable insights. Furthermore, real-time data processing is moving to another level due to breakthroughs in artificial intelligence (AI) and machine learning (ML), which have made it possible for IoT applications can be further streamlined through predictive analytics and automated decisions. IoT, working in harmony with 5G and real-time data processing, can fuel innovation while simultaneously boosting operational efficiency to fostering growth and development in many sector segments.

The Role of Real-Time Data Processing in IoT Applications

One of the key enablers in delivering on many of the transformational benefits promised by IoT users is real-time data processing. Basically, real-time data processing is the practice of collecting and analyzing the data into the machine instantly as data collects by sensors or IoT devices. This fast processing is important because it enables rapid decision- making and response—something that can be vital in time- critical events. So if you take industrial automation as an example, data from machinery and equipment can be processed in real-time to spot anomalies, predict failures and schedule maintenance ahead of time before any downtime. Not only that it increases the operational efficiency, but it also saves a huge cost resulting from unplanned break downs and halting production. Besides, real-time data processing is fundamental for smart cities to work effectively. In cities, infrastructure that carries IoT sensors are used to gather data on traffic movements, air pollution levels and energy use. This data can be used at the time of processing, so that traffic control systems are able to determine conditions in real time and adjust traffic signals accordingly. In parallel, the real-time monitoring and operation of environmental data could provide rapid responses to pollution peaks that threaten public health. Its fast data processing can also help in the

development of public safety architectures, like real-time surveillance systems that can quickly perceive and respond to security incidents—thereby fostering increased security and protection for city dwellers.

These decreased time lags can be further harnessed for accessing patient data in the healthcare sector, which in some cases might just be a matter of life and death. Wearable Health Devices that monitor vital signs and other health metrics entering continuous real-time data to Healthcare Providers. This permits for instantaneous feedback to the emergency response of severe health incidents, such as heart attacks or falls, and allows chronic conditions to be continuously monitored to ensure that immediate care can be administered if necessary. In addition, real-time data intelligence allows for customized treatment plans to be crafted using the latest health information in the past with better outcomes that can help provide a highly satisfying care experience. Typically a hybrid model of edge and cloud computing is used, in order to provide functional real time data processing. By processing the data at the source is near the network edge) instead of sending all of it to central servers, edge computing saves latent and bandwidth where appropriate.

Especially for applications that need extreme low latency, such as autonomous vehicles who would crash and kill you if decisions are made too late (in timing in milliseconds to decide how not to hit you. In contrast, the scalable processing power required for more advanced data analyses that are not feasible locally is available through cloud computing. It is versatile enough to help IoT systems seamlessly work with massive amounts of data and deliver interpreted insights in real-time by using edge computing as well as cloud solutions. Apart from the technical dimensions of real-time data processing in IoT applications, there are a number of issues that must be resolved concerning security, privacy and scalability of the data. A medical and finance are so sensitive data that processing securely at real-time play a significant role. In order to ensure that the data is safe from unauthorized access and breaches, there must be strong encryption, authentication and access controls in place.

Current State of IOT Sensors and Devices

Types of IoT Sensors

Environmental Sensors: Provide critical environment monitoring and control. These sensors are used to record different parameters like Temperature, Humidity, air quality, light level and noise etc. They have been used by different applications from agriculture monitoring to smart city initiatives. Identically, in agriculture, temperature and humidity sensors make it possible to provide the optimum conditions for crops, and air quality sensors located on city streets monitor levels of pollution so that public health is not endangered.

Wearable Sensors: As the name suggests, these sensors are wearable and integrated into fitness trackers, smart watches and health monitoring bands. They monitor a range of health parameters -- from heart rate, and physical activity to sleep and even blood oxygen levels. Wearable sensors are transforming patient monitoring for the healthcare industry, in which we can continuously and real-time monitor vital signs. These sensors can record data and easily transmit this information to healthcare providers, enabling remote patient monitoring and telemedicine applications.

Industrial Sensors: are applied in the manufacturing, logistics and other industrial sectors to observe the processes. Pressure, vibration, proximity, Temperature, Chemical composition. These sensors are to measure various parameters. Predictive maintenance, quality control and process optimization are dependent on this data.

Smart home devices: These are the sensors and actuators to improve automation, security & energy efficiency of our homes. These are made up of your thermostat, security cameras and motion detectors all the way to "smart" locks and connected appliances.

Technological Advancements

Innovations in Sensor Technology: Recent advances in sensor technology have been significant as well and resulted in more accurate, tougher, and omnipotent sensors. Novel materials, such as nano materials and flexible electronics have been used to develop sensors with increased sensitivity and mechanical robustness. Advances in manufacturing technologies, like Micro-Electro-Mechanical (MEMS) and Nanotechnology have enabled the sensor sizes to be greatly reduced thus permitting sensors to reach out to new areas of applications.

Improvements in Accuracy, Precision, and Reliability: New version of IoT sensors can deliver the highest degrees of accuracy, precision, reliability that are very important to ensure that data they collect is valid and useful. The need for manual recalibration is decreased with the use of self- calibrating sensors, as they can automatically adjust their measurements to remain accurate during longer periods of operation. Granular data: High precision sensors can collect more fine grain information and provide data to support analysis and decision making. Moreover, improvement of sensors design and production process made the sensors more reliable which helps in maintaining sustained performance even under extreme environments. These changes have made IoT sensors suitable for various mission-critical applications where precision, repeatability and dependability cannot be compromised.

Developments in Low Power Consumption and Energy Harvesting: Power consumption is a major hurdle among challenges that need to be addressed when deploying IoT sensors, making it hard to justify replacing or recharging their batteries in regular basis, which becomes impossible when positioned on remote wilderness. This article discusses how the new generations of low-power sensors and energy harvesting technologies are helping to overcome this hurdle. Low power sensors is a term to describe sensors which are designed to work effectively using as little energy as possible, minimising the need for recharging batteries. Energy harvesting solutions, such as solar, thermal and kinetic energy scavenging enable sensors to harness power from the environment around them. This mechanism ensures that wholly self-contained sensor networks can remain in operation for large time intervals without needing to maintain their lost packets or retrieve new ones. Without these advances, only a tiny fraction of IoT projects can be efficiently delivered at scale or in the long term.

Integration with 5g Technology

Overview of 5G Technology

Previous article Introduction to 5G Technology Earlier article Aluminum Production: Well-liked Processes and Why They prevail in Aluminum Production? Next article The 5 Best Renowned Auction Houses On The Globe Navneet Kumar Samota Lives by the phrase "love what you do, love why you do it!"director at pro digital world & writer of intro influence. 5G, simply put, is faster, with lower latency/real- time insight and massive connectivity—its three pillars of functionality add a transformative element to this use-case of IoT applications. 5G is up to 100 times faster than 4G LTE, with theoretical data transfer rates that have been quoted as high as 10 =. Such speeds enable high-speed transfer of large amount of data, which is essential for applications, needing their data processing to be in real-time providing immediate answers. Third major feature is ultra Low latency in 5G which can be as low as 1 millisecond. Near-instantaneous communications is required for applications immediately needed such as autonomous vehicles, remote surgery, industrial automation and more. This low latency allows sensor data to be acted on in real time, and makes the applications safer and more efficient. Its also capable of massive connectivity, meaning the possibility to have up to a million devices per square kilometer connected at same time. This is especially significant with the IoT where huge numbers of devices need to connect to each other and work transparently on a day to day basis. In comparison to 4G, LTE and other previous generations of mobile networks, 5G is not just higher by magnitudes in speed and latency but also has larger network capacity and improved reliability. It provided the architectural framework for mobile internet through the surge of smart phones and mobile apps, 4G networks have some shortcomings such as limited speed or number of devices they can support. In contrast, 5G is built to support the requirements of a hyper-connected world—suitable for broad adoption of IoT technologies.

BImpact of 5G on IoT

We got lots of flexibility from integrating IoT network with 5G technology which has made IoT systems more powerful, robust and scalable. Most importantly, it has amplified the capability to communicate. IoT devices functions quicker and more efficiently as data can be sent up to the cloud and back down again faster using 5G, which also supports low latency. Apps that generate a large volume of data (like smart cities, where sensors monitor traffic, air quality and energy consumption in real time) need this capacity. The 5G amplified the data transfer speed making it easier to share data between IoT devices and cloud or edge computing systems. This in turn leads to the faster data processing and analysis, which brings us to real-time decision-making and action. In industrial automation, this means that systems can respond to changes in the environment or operational conditions instantly-enhancing performance and minimizing downtime through rapid data analysis from numerous sensors. 5G also enhances IoT systems by enabling the technology to become highly reliable and nearly real-time responsive. 5G networks with low latency and high reliability can deliver near real-time transmission and reception which is essential for use cases with stringent timing constraints.

Case Studies

This mutual integration of IoT with 5G technology by various industries has shown the transformation it is capable to bring upon.

Smart Cities: 5G IoT sensors monitor and manage urban infrastructure in smart city projects. For example, traffic management systems exploit real-time IoT sensor data to adjust the timings of traffic lights, thereby alleviating congestion and smoothing vehicular flow. With time and change management, designs can evolve to include environmental sensors that can measure air quality as well as decibels of sound in order for local government to take action against pollution to increase the standard of living.

Healthcare: The healthcare industry reaps significant advantage from IoT and 5G integration of wearable—such as health devices with sensors that continuously monitor vital signs in patients view here to read. It provides continuous live-time monitoring which can lead to early problem detection and needful directed interventions and treatment strategies.

5G-Enabled IoT Sensors: Predictive maintenance or process optimization in manufacturing and industrial environments in use this kind of IoT sensors. Sensors track the performance of machines and equipment, looking for signs of breaking down. And it evaluates the data in real time, opening a path to predictive maintenance which prevents shutdowns and minimizes outages. Moreover, 5G facilitates the convergence of robots and automated cells into more choiceful elements in process industry production.

Farming: like other fields too, 5G and IoT collaboration have proved themselves in precision farming. With IoT sensors, the moisture, the temperature, and how many nutrients are there in the soil at that time can be directly monitored at one scale and then they provide continuous data to farmers on when who should irrigate what amount of water for which duration. This AI will receive real-time data from fields through the 5G network, ensuring families of farmers receive timely information to make decisions that allow them to increase crop yields and resource efficiency using total automation. The above case studies demonstrate the wide range of use cases and advantages of combining IoT with 5G. With 5G networks expanding, the range of highly differentiated and transformative IoT applications will increase, giving a boost to improvements in different industries and leading to the creation of smarter/safer communities.

Real-Time Data Processing in IOT

Importance of Real-Time Data Processing

Benefits of Real-Time Analytics and Decision-Making: Real-time data processing are important in applications that need quick responses and to leverage the most current data for detailed analysis and action. That provides

benefits such as better operational efficiency, improved decision-making and taking steps to ensure that any problems encountered can be dealt with early, leading both to less downtime and a generally higher level of productivity.

Applications Requiring Real-Time Data: Several applications necessitate real-time data processing to function effectively: Real-time traffic management systems that automatically adjust signals according to the current traffic conditions for an optimal flow and reduced congestion; Air quality and noise level data can be obtained in real time using environmental monitoring systems.

Medicine: Real-time remote monitoring of vital signs — letting an MD know in real time when the patient needs help. Real-time data generated by remote patient monitoring systems keep track of chronic conditions; alert healthcare providers as needed.

Industrial automation: Monitor machinery and production lines in real time for smooth operations, and immediately respond when something goes awry. By using real-time data, a predictive maintenance system can help you predict equipment failures and schedule repairs wo that they can be made just before an the assets fail.

Technological Solutions

Edge Computing and its part in real-time data processing:

The edge computing will take place over there means at the source where closer to it a lower amount of latency and less bandwidth use is meant. This is important when you are dealing with IoT applications for which data processing needs to be immediate as well.

Cloud Computing and Hybrid Approach: The cloud offers the resource necessary for hardware acceleration of IoT data that enable complex analysis and, on another hand, the long- term storage of these data. Hybrid approaches bring together edge and cloud computing, making use of the advantages of each. Data is processed close to where it enters the network (the edge), is left there for current requirements and forwarded to the cloud for more thorough inspection and archival.

Challenges and Solutions

Security and Privacy: As real-time data processing requires processing a significant volume of data in just milliseconds, it raises major fears regarding security and privacy. This comprises strong encryption techniques, reduced data transmission protocols and access control to maintain the integrity and confidentiality of data. Further, by using an edge computing architecture for decentralized data processing instead of sending all raw data to centralized cloud servers, exposure to possible data breaches can be greatly reduced. When we are thinking about the issues related to scalability and interoperability**:** with more connected devices, it is clear that there can be certain limitations on how things will scale. IoT systems should be designed to handle the increasing data volumes and device connections, without compromising on performance. Data exchange between devices and systems across the ecosystem along with seamless integration of data is as important as interoperability. Scalability and Interoperability—Such protocols can easily be scaled up or down to any size of connected devices as necessary, and enable creation of device networks that operate seamlessly among heterogeneous IoT devices.

Industry Applications and Case Studies

Smart Cities

Implementation of IoT Sensors for Traffic Management, Waste Management, and Environmental Monitoring: IoT sensors play a critical role in improving performance of different urban management functions in smart cities. IoT sensors are utilised for the purpose of traffic management, where IoT sensors track the real-time traffic flow and provides data to dynamic traffic light systems that in turn adjust timings to reduce congestion and provide an ease in vehicle movement. [14] Metropolitan areas reduced road congestion by 30% using IoT sensors based smart traffic management systems (2022) When it comes to waste management, IoT sensors in trash bins monitor the level

of fill and plan collection routes. This not only keeps cost down but also reduces the environmental impact by reducing fuel and emissions.

Healthcare

Wearable devices for patient monitoring and diagnostics

Wearable devices liberates with IoT sensors which continuously monitors the vital signs like Heart rate, Blood pressure, oxygen levels downstream. Such real-time data transmission to health care providers could enable an immediate medical response if irregularities are observed. For instance, a study carried out by [15] The study by (2023) has increased the early detection of cardiac events by wearable health devices from 40%. They are a natural fit to support remote diagnostics and telemedicine, allowing patients to access these healthcare services without the need for physical visits.

Manufacturing and predictive maintenance: This could involve the use of IoT sensors to monitor production lines for discrepancies and quality control, with 5G support. The integration of 5G supports greater connectivity between sensors and central systems, results in real-time data transfer and low-lag time answers. [16] 5G was implemented in forengileier stations with sensor systems price/hotspot technology supported IoT..these IoT sensors were used to handle information collected, partly by promptors on 25% and the average defect rate of fortune up to 15%memcmp(2022). By predicting equipment breakdowns and scheduling maintenance, a predictive maintenance system can help to reduce downtime and make would-be technology a little longer than expected.

Agriculture

There are a few well-known commercial use cases that come to mind:Commercial IoT Solution 1–Using Environmental Sensors and Drones for Precision FarmingIn agriculture, an example might be IOT sensors deployed in the field to monitor soil moisture, temperature and nutrients levels which allows farmers to respond in real-time by optimizing irrigation, fertilization, planting density, or pest control. IoT sensors on drones can survey large areas rapidly, collecting granular data on crop health including signs of pest infestations or nutrient deficiency.

Future Trends and Directions

Emerging Technologies

How AI and Machine Learning will help to add more power in IoT: Artificial intelligence (AI) and machine learning (ML) are going to increase the capabilities of today's IoT. IoT data can be huge in size and hard to handle for humans but AIs or ML algorithms are specifically designed to analyze such massive IoT datasets and extract patterns using a few lines of code. All of these are areas where the technologies that can automate decision-making, binary in nature, become far more useful than they would ever be on their own.

Blockchain Use cases in IoT Data Security: Blockchain technology provides decentralization, which makes it a perfect fit for securing data of IOT. Because blockchain creates unchangeable records of transactions, it can improve data security by making it difficult or impossible for anyone else to access your data and by preventing others from altering your data. This can be contrasted to local, gateway-based security solutions that are easier to attack and break in a single place having residue damages done elsewhere. Decentralization makes our solution stronger and improves the overall robustness of IoT systems.

Predictions for the Future

Sensor Miniaturization and Drop in Cost: Continuous evolution of sensor miniaturization is resulting in cheaper, smaller sensors. And by allowing sensors to be squeezed into mission-critical applications, the miniaturization trend will increase IoT penetration. Price reductions will enable businesses and consumers to afford IoT solutions, encouraging mass adoption.

Growth of 5G Networks and its Effects on the Escalation of IoT: The rollout of new 5 G networks that has been expanding quickly across many sectors also shapes significantly the conquest for domination in IoT applications. The improved connectivity and faster data transfer speeds with the lower latency, will make more elaborate IOT applications, that acquire higher amount of data with intelligence, possible than before. With 5G made available, we can create imaginative IoT solutions for different zones (like a smart city or driverless car)section that are more popular.

Research Opportunities

Next Steps and Research Development: The integration of IoT and 5G come with some areas needing further research. Some of these are improving the energy efficiency level of IoT devices, standardizing protocols for interoperability, and ensuring optimal data security. This could be the key in designing better IoT materials and sensors with new research areas in material use and fabrication for sensors.

IoT 5G Integration: The integration of IoT and 5G offers a way to combine consumer electronic capabilities with the requirements for ultra-specific medical device monitoring. AI and ML breakthroughs could also spur further integration to create even more autonomous, intelligent IoT systems that decide on their own what action to take in real time. In addition, the combination of quantum computing with IoT and 5G could represent an unequalled processing power and data analysis capabilities.

CONCLUSION

Thereby, the combination of these advanced IoT sensors with 5G technology and native data processing is transforming many areas through faster speed, connectivity and more responsiveness as ever before. This brings us from smart cities, healthcare, industrial automation to agriculture and further advanced uses. Real-time data processing, powered by edge and cloud computing is crucial for making fast decisions & accelerate action based on the latest data. Data security, privacy, scalability and interoperability still remain unresolved issues with IoT; but they are being solved rapidly through technological innovation and robust security layers which signals an increased adoption of IoT solutions. The case studies discussed show the vast impact IoT (and 5G) can have, improving traffic control, healthcare monitoring, industrial efficiency and precision farming. In the future, smart and autonomous systems enabled by technologies like AI/ML and blockchain allow IoT capabilities to be further strengthened. Sensor shrinkage and price erosion are also speeding up - The Frost & Sullivan survey also clearly states that both trends are afoot to hasten the development and acceptance of IoT solutions, thereby opening up new opportunities for innovation and growth. This will continue to drive efficiency, productivity and sustainability, shaping the future of technology and overall quality of life across all industries globally.

ABSTRACT

Customer segmentation is one of the biggest components of Customer Relationship Management (CRM) because it helps in the organizations to understand different customer segments which enables them to develop personalized interaction methods that serve each customer group. The digital streaming sector functions through companies like Netflix which provide service to multiple viewers who show various patterns of content consumption, choice of subscription plans, methods of accessing material and their preferred types of content. This study motivated on customer segmentation using secondary data derived from a Netflix customer dataset containing demographic and behavioural attributes such as age, gender, subscription type, watch hours, device usage, favourite genre, average watch time per day, and payment methods. The primary objective of the research is to identify important customer segments using data driven clustering techniques and to analyse how these segments support effective CRM strategies in the streaming platform environment. The study adopts a descriptive research design and is based on secondary data collected from the Kaggle. The dataset includes demographic and behavioural variables of Netflix subscribers. A sample dataset of 5000 customers was used for the analysis. The researchers employed statistical methods which included Chi square test and Correlation analysis and Linear Regression and ANOVA to assess how customer behaviour on the Netflix platform affected their engagement patterns. The analysis shows that Netflix subscribers exhibit distinct customer segments

while various factors affect their subscription preferences and customer engagement on the platform. The results show that user engagement on the platform depends on user behaviour which also affects their retention on the platform.

Keywords: Customer Segmentation, Customer Relationship Management, Netflix Analytics, Streaming Behaviour, Viewer Engagement, Subscription Analytics, Customer Churn, Personalized Recommendations, Content Preference Analysis etc.,

INTRODUCTION

The way people watch movies and TV shows has changed because streaming platforms became the most important method of watching media content in the digital entertainment industry. Netflix stands out as a top online streaming service that provides viewers access to its extensive collection of movies and TV shows and original programming which viewers can watch from anywhere in the world. The platform collects extensive user data which includes viewing habits and user preferences and user interaction patterns from its millions of subscribers who live in multiple regions. Data analysis has become vital for businesses because it helps them learn about customer habits and enhance their service standards. Customer segmentation serves as a vital component of Customer Relationship Management (CRM) because it enables organizations to group their customers according to shared demographic traits and behavioral patterns and usage of services. The identification of valuable customer segments enables companies to create marketing plans that focus on specific groups while providing personalized recommendations and enhancing customer satisfaction. Segmentation enables organizations to analyze how various user groups engage with content on streaming platforms while their viewing habits show different patterns of consumption. Netflix applies this method to examine user data which includes information about viewers' past watching behavior and total viewing time and the devices they use and their preferred movie genres in order to gain insights into their watching patterns. The platform uses its analysis results to suggest appropriate content which results in increased user interaction and better customer retention.

The entertainment and streaming industry now depend more on data-driven decision making because digital platforms have experienced rapid growth. Organizations use extensive user data collection to analyze how customers behave and what they prefer and when they engage with their products. The analysis of these variables enables organizations to acquire important knowledge about customer digital content consumption patterns and their distinct viewing behaviors which vary according to different demographic and behavioral groups Data analytics will be enable companies to track the current content trends and to forecast customer preferences in creating approaches which make customer engagement and retention. The Customer segmentation framework will help the streaming platforms to identify their user and customer groups and understand how those groups interact with their services. Companies can use demographic and behavioural data to create customer segments which they can use to develop definite marketing plans for each segment. The research observes how Netflix users divide into different customer groups through demographic and behavioural data which study obtained from a secondary dataset. The dataset includes variables like age, gender, subscription type, device usage, watch hours, average watch time, payment method, and genre preferences. The tests used in the statistical methods are such as Chi Square test, Correlation analysis, Linear Regression, and ANOVA to analysis how the variables connect with customer engagement patterns. The result of the study shows how customers behave when they watch content and demonstrate how data analytics help businesses develop Customer Relationship Management methods while making strategic decisions in the streaming sector.

REVIEV OF LITERATURE

Zhang (2007) Zhang study used survival analysis methods to analysis the customer behaviour in different time periods. The research revealed that organisations can use customer lifecycle analysis to forecast customer retention and detect upcoming customer churn. The research demonstrated that segmentation plays a vital role in creating successful customer relationship management systems. Cooil, Aksoy, and Keiningham (2008) Cooil et al. studied various customer segmentation methods that businesses use to implement relationship marketing programs. The study showed that businesses can use segmentation to group their customers according to both demographic factors and customer behaviour patterns. The results showed that segmentation leads to better marketing results while building stronger connections with customers. Zhou, Zhang, and Lu (2011) Zhou and his team investigated different methods of customer segmentation that companies use in their CRM systems. The study discovered that businesses can use clustering and classification segmentation methods to process their large customer information better. The research demonstrated that segmentation enhances decision-making abilities. Hosseni and Tarokh (2011) Hosseni and Tarokh used Customer Lifetime Value (CLV) components to study customer segmentation. The study analysed that organizations can use the customer purchase behaviour and frequency as avalue variable to discover their most valuable customer segments and create effective marketing plans. Hosseini, M., & Shabani, M. (2015). Hosseini and Shabani established a new method for customer segmentation which tracks changes in customer value. The study showed that monitoring variations in customer value helps businesses identify loyal and high-value customers which enables organizations to develop better CRM strategies. Gupta, Aggarwal, and Rani (2016) Gupta et al. Gupta, Aggarwal, and Raniused cluster analysis methods to divide retail customers into different segments which would help them enhance their customer relationship management operations. The research showed that clustering techniques successfully group customers who share similar buying patterns which helps businesses create customized advertising strategies. Sari, Nugroho, Ferdiana, and Santosa (2016) Sari and colleagues conducted a review of customer segmentation techniques used in e-commerce platforms. The study showed that data mining together with clustering algorithms operates as a standard method for understanding customer behaviour while creating marketing strategies.

Research Objectives

- To measure the relationship between viewing variables to identify customer engagement.
- To analyse the impact of viewing behaviour on customer retention and engagement.
- To classify subscribers based on demographic factors to identify customer segmentation.
- To compare viewing behaviour across subscription types to identify customer behaviour differences.

RESEARCH METHODOLOGY

Research Design

The research uses a descriptive research design to study and analysis how customers divide into different type of segments and their watching patterns on streaming platforms. Descriptive research makes the researchers to study and describe the specific problem and behavioural tendencies of a particular group through available evidence. The research design of this study makes researchers to examine how various user groups use the streaming service and which demographic and behavioural factors affect their viewing patterns. The study uses this design to discover patterns and connections between factors that influence customer engagement and subscription choices and Netflix content viewing habits.

Data Source and Sample

The study uses secondary data which was collected from the Kaggle data repository that serves as a public database for researchers to access datasets. Secondary Data is the type of data which is not collected directly to the Customer the Information collected from Published by someone else like Government reports, Industrial data, Academic Journals, Newspaper, Articles and etc. Kaggle is the largest online platform which is used for collecting Datasets,

Data Cleaning build models in browser-based environment, the data scientist and engineers can compete to create the best models for solving specific problems and etc. The dataset contains information related to Netflix users and includes several demographic and behavioural attributes such as age, gender, subscription type, watch hours, device usage, favourite genre, average watch time per day, payment method, and location. The study uses these variables to investigate how customers behave and to determine which distinct customer groups exist. The study includes different demographic and behavioural characteristics which help researchers study how customers interact with their products. The research team selected 5000 customer records as their sample dataset for analysis. The researcher uses secondary data to study a vast dataset which enables him to obtain valuable findings without needing to perform primary research through methods like surveys or interviews.

Variables

The dataset includes several important variables that represent both demographic characteristics and behavioural patterns of Netflix subscribers. The dataset contains demographic information through age and gender and subscription type and device usage and genre preference and payment method and user location. The subscriber base shows its characteristics through demographic variables age and gender while users demonstrate their platform interaction through watch hours and device usage and genre preferences. The study of these variables allows researchers to discover viewing patterns which they use for categorizing customers. The streaming sector can benefit from these insights because they help streaming platforms enhance their recommendation systems and boost user engagement and develop better customer relationship management techniques.

Analytical Tool

The study utilized multiple statistical methods to assess customer behaviour data which will be obtained from Netflix streaming services. The study used these variables to examine how various customer segments interact with the streaming service. The study used multiple statistical methods to investigate the connections among the different variables. The researchers used Chi-Square test, Correlation analysis, Linear Regression, and ANOVA methods to evaluate the data and verify their research hypotheses. Chi-Square test is used to Classify subscribers based on demographic factors (Gender) to identify customer segmentation, Correlation is used to Measure relationship between Watch Hours of customers to identify customer engagement, Regression is used to Analyse the impact of Watch Hour behaviour on customer retention the Churn Behaviour and Anova is used to compare Watch Hours behaviour across subscription types to identify customer behaviour differences. The findings deliver practical information that helps organizations develop better Customer Relationship Management (CRM) practices while delivering an improved user experience.

Data Analysis

The study works in different statistical methods to observe the dataset and analyse how the customers interact with Netflix. The analytical tools enable to discover relationships between different type of variables while finding information about how customers engage with content, their subscription choices and their viewing habits**.**

Chi Square Test

The test applies ChiSquare test to analyse the relationship between Gender and Subscription Type, because both variables are categorical. The analysis determines whether male and female subscribers have different subscription preferences and whether demographic factors affect their choice of Basic Standard and Premium subscription plans.

Customer Segmentation

i) E= Row total * Column total/Grand total

E= 1711*1661/5000

E= 568.4

ii) (O-E) ^2/E = (606-568.4) ^2/568.4 =2.48

iii) Add All 9 Values

$\chi^2 \approx 12.49$

iv) Degrees of Freedom

$df = (3-1)(3-1) = 4$

v) Decision

At 5% significance level, the p-value < 0.05, therefore: Null Hypothesis (H_0): Rejected and Alternative Hypothesis (H_1): Accepted

Interpretation

The Chi square test indicates a significant association between gender and subscription type. The results show that different customer groups select different subscription options which demonstrates the existence of customer segments within Netflix.

Correlation Analysis

The test conducts correlation analysis to determine both the strength and direction of the relationship between Watch Hours and Average Watch Time per Day. The researchers selected these two variables because both of them show how users interact with the streaming platform. Watch hours show subscribers' total content viewing time while average watch time per day shows their daily viewing patterns. The study investigates the link between these variables to determine whether customers who watch more content will also spend more time watching content each day. Calculating Mean of Watch Hour, Mean of Mean of average Watch Time, Standard Deviation of Watch Hour and average Watch Time, Pearson

Customer Engagement

i) Correlation

$$r = \frac{\sum(x-\bar{x})(y-\bar{y})}{\sqrt{\sum(x-\bar{x})^2 \times \sum(y-\bar{y})^2}}$$

ii) From the dataset of 5000 Netflix customers.

iii) Decision Rule

Significance level α = 0.05

If p < 0.05 → Reject H0If p > 0.05 → Accept H0 Since p-value < 0.05

Null Hypothesis ($H0_2$): Rejected and Alternative Hypothesis ($H1_2$): Accepted

Interpretation

The correlation result shows a strong positive relationship between watch hours and average watch time per day. The data shows that customers who spend more time watching content will use the platform more actively. Viewing behavior shows a major impact on how customers interact with Netflix.

Regression Analysis

The test uses regression analysis to investigate how Watch Hours affect the Average Watch Time per Day. The analysis uses watch hours as the independent variable while average watch time per day serves as the dependent variable. This study investigates whether total viewing hours increase and result in greater daily viewing habits among subscribers. The regression model reveals the extent to which viewing behavior affects customer engagement with the platform.

Customer Retention

Method Used: Linear Regression Analysis

Watch hour is independent variable and churn is a dependent variable

Decision p-value is extremely small like 0.000…., p-value < 0.05 So, reject the null hypothesis and accept the alternate hypothesis

Interpretation

The regression analysis shows a negative relationship between watch hours and churn ($p < 0.05$). This suggests that higher user engagement leads to lower churn, it highlights the importance of increasing watch time to improve customer retention

ANOVA:

The test uses ANOVA to measure the relationship between Watch Hours and different Subscription Types. The current study examines whether there exists substantial difference in viewing patterns between subscribers who select various subscription plans. The study determines whether subscription level affects user time spent watching content on the platform.

i) Calculation

ii) Decision:

At 5% significance level, the p-value > 0.05, therefore:

Null Hypothesis (H_0): Accepted and Alternative Hypothesis (H_1): Rejected

Interpretation

The ANOVA results show that Basic Premium and Standard subscription users display identical average watch hours because there is no statistically significant difference between these three groups. The study results show that subscription type does not impact how subscribers watch content.

FINDINGS AND DISCUSSION

The analysis of the dataset provides several insights into customer behaviour and engagement patterns on Netflix. The results show that subscribers can be divided into different customer segments based on their demographic and behavioural attributes which include their age and gender and subscription type and viewing patterns and content choices. The correlation analysis discovered that users who watched more content during their entire watch period also displayed greater daily viewing habits. The study shows that when subscribers watch more content their engagement with the service increases. The regression analysis proves this point because it demonstrates that watch hours control customer engagement levels. Customers who watch more content will experience better platform engagement which will lead to higher retention rates and customer satisfaction. The Chi square analysis shows that gender and subscription type are related because demographic factors should decide which subscription plans people prefer. The finding demonstrates that companies need to use demographic data for creating marketing campaigns which target specific customer groups. The ANOVA results show that there is no significant difference in average watch hours among different subscription plans. The research demonstrates that customer viewing habits depend on the content customers can access and their personal preferences rather than the subscription type they select. The findings demonstrate that Netflix needs to study its customers' behaviour to gain insights into how users engage with the platform and what content they watch.

Managerial Implications

The research results offer vital information that streaming platform managers and decision-makers who operate Netflix need to understand. Managers achieve better insights into subscriber preferences and viewing patterns and content consumption patterns through customer behaviour and engagement pattern analysis. Organizations use these insights to create successful strategies which enhance customer satisfaction and customer engagement. The study proves how the data analytics help an important tool for guiding decision-making processes. Managers may use the behavioural data which includes watch hours and device usage and category preferences to create personalized content recommendations that confirm users receive content are matching to their interests. The solution works to increase user engagement because it attracts more subscribers to spend extended periods on the platform. The customer segmentation process are enables managers to notice various users group who share

common demographic and behavioural patterns. Organizations can create effective marketing strategies and promotional campaigns which target specific customer groups by understanding those segments.

Future Research Scope

Netflix conducts customer segmentation studies through demographic and behavioral data which they obtain from secondary data sources. Future research should use bigger datasets which contain different types of data to study customer behaviour across various locations and user segments. Future researchers can also include additional variables such as viewing frequency, customer satisfaction and content ratings to better understand of customer preferences. Future research will use advanced analytical methods which include machine learning and predictive analytics to improve customer segmentation and recommendation systems. Research will analyse the multiple streaming platforms to investigate customer engagement methods and CRM practices which is used by different platforms. The study will provide companies with customer behaviour insights which will enable them to create more effective data driven strategies for streaming services.

CONCLUSION

Customer segmentation has emerged as a critical element of Customer Relationship Management which digital enterprises use to manage their customer relations. OTT streaming services use customer analytics to understand viewer behavior and develop customized viewing solutions. The analysis of the Netflix customer dataset revealed patterns which showed how customers divided themselves into groups based on their content consumption and their service usage patterns. The study found that viewing patterns operate as a main predictor which establishes both customer engagement metrics and their subscription retention probabilities. The research determined that users who dedicated more time to watching content experienced higher chances of staying subscribed to the service because content engagement served as a critical factor in customer retention. The research found that customer preferences become evident through demographic and behavioral characteristics analysis. The marketing insights allow businesses to design customized marketing strategies while they improve content recommendation systems and customer relationship management systems. The research study shows how data analysis enables streaming services to develop their operational systems. Netflix uses customer segmentation methods together with behavioral analytics to build business strategies which transform user data into practical solutions that enhance customer satisfaction and create business growth through brand loyalty.

ABSTRACT

The objective of the present study is to investigate the degree of employee engagement among employees of Tamil Nadu State Transport Corporation, Chennai District. However, the research study unearths to find out the predictors of employee engagement like job satisfaction, organizational support, leadership practices, work environment and communication received from their seniors and employee welfare. It also examines the association between employee engagement and employee performance. The study also has implications for management, further saying that there is a need to encourage and engage employees in the public transport sector to improve organizational performance as well as enhance service quality. The suggestions offered can help TNSTC management in strategies to improve employee engagement, sustainable growth and employee well-being in Harmony.

Keywords: Employee Engagement, Job Satisfaction, Organizational Support, Employee Performance.

INTRODUCTION

One of the most important concepts for any modern human resource management is employee engagement. It denotes the degree to which employees emotionally, cognitively and behaviourally commit to their organization and it goals. Engaged employees are passionate about their job, committed to the mission of the organisation and ready to go beyond their prescribed role. We are all aware that in this competitive and service-oriented environment organizations feel that employee engagement is an important driver of productivity, service quality, customer

satisfaction and organizational performance. Transportation in its various forms is a very important part of the economic and social development process as it provides mobility, accessibility to millions of people every day. Tamil Nadu: The Tamil Nadu State Transport Corporation (TNSTC) is the largest public transport system in Tamil Nadu providing low-cost public and private transportation services through urban and rural transport across the state. TNSTC's success and efficiency is primarily reliant upon the service, drive and engagement shown by all TNSTC employees consisting of drivers, conductors, technical staff and administrative personnel. As this industry has one of the most tough work environments, employee engagement in public transport is a prime requisite. All of these employees often go through challenges like working for prolonged hours, dealing with the pressures of workloads, traffic management issues, passengers management problems, efforts in safety and operational constraints.

These factors can have an impact on employees' behavior and attitudes, job satisfaction, and the energy they put into work. Hence, it is also crucial to explore what really drives employee engagement as a high-performing workforce is integral and very much necessary for offering top notch public transport services. Lower absenteeism, lower employee turnover, higher organizational commitment and better job performance are some usual reasons for organizations with a team of highly engaged employees. Employee engagement can be affected by leadership support, effective communication, recognition and rewards, training and development opportunities, proper environment at workplace and welfare measures. When an organization recognizes employees and supports their careers, employees are more engaged. Over the last years, with regards the effectiveness of the public sector and delivery of services to citizens within it, employee engagement has gained ground as a strategy in many public sector organizations. In the case of TNSTC, employee engagement has a direct bearing on the quality of transportation services dependent as it is on its workforce. This will also enhance employee engagement, operational efficiencies, passenger satisfaction and its query with organizational development. In that context, the objective of this study is to explore the engagement levels of employees working in Tamil Nadu State Transport Corporation in Chennai District. The following research objectives guide the study: first, to determine the factors that influence employee engagement and second, to evaluate their effect on employee performance and organizational effectiveness. The results of the research are anticipated to offer insights into best policies and management for implementing practices that promote a more engaged, motivated, and productive workforce.

REVIEW OF LITRATURE

Anitha (2014) has discussed the determinants of employee engagement and concluded that work environment, leadership, team work, training and development, compensation and benefits, employee welfare measures are significantly affecting on employees engagement. The findings established a direct relationship between employee engagement and organizational performance. The identification of factors influencing employee engagement from the study was focused on leadership, communication, work-life balance and organizational culture (Bedarkarand Pandita 2014). This was important to their study that suggested organizations need a strong supportive work environment in order to improve employee commitment and performance. This study identified the correlation of employee engagement with job satisfaction (Gupta and Sharma, 2016). The results yielded a positive relationship showing that employees who were happy and satisfied with their jobs also engaged in greater work output. In the study of employee engagement in service organizations, José and Mampilly (2018) argue that one of the factors that can greatly enhance employee engagement levels is allowing employees to participate in the decision-making process, recognition, and career advancement opportunities. Managerial support is also emphasized in the study. Though Sharma et al. (2020) studied employee engagement in Indian public sector organizations but the researchers found that organizational support, welfare measures for employees and good communication are body positive factors to ensure engaged employees. Continuous training and employee development programs were suggested to overcome engagement.Kumar and Rajendran (2022) the research targeted transportation services from the perspective of employee engagement and they reported that job security, employee welfare schemes, leadership support and workplace safety greatly influence the levels of engagement. Based on the findings, researchers

recommended transport organizations should increase employee welfare to enhance service quality and performance.

Objectives of the Study

Primary Objective

- To study employee engagement among Tamil Nadu State Transport Corporation employees in Chennai District.

Secondary Objectives

- To analyze the demographic profile of TNSTC employees in Chennai District.
- To measure the level of employee engagement among TNSTC employees.
- To identify the factors influencing employee engagement among TNSTC employees.
- To examine the relationship between employee engagement and job satisfaction.

Statement of the Problem

Human resources (HR) are crucial for organizational success. It is critical that organizations like the Tamil Nadu State Transport Corporation (TNSTC) engage their employees to provide effective transportation services and customer satisfaction. TNSTC employees encountered a variety of difficulties, including lengthy hours, work pressure, shift duties, safety issues at work, inadequate recognition at the job and limited opportunities for career advancement distant from home over patronage even after many years of service as well as problems with their social life. These aspects probably influence the their degree of engagement, motivation and commitment to the organization. Focus Here Employee disengagement is directly associated with the tacit or overt manifestation of several interstitial behaviors including absenteeism, reduced productivity, decrease in service quality, turnover intention and organizational performance. In a district like Chennai, where demand for public transport remains high and operational efficiency is critical to success of bus transport system, it therefore becomes important to explore the drivers of employee engagement among TNSTC employees. By identifying the factor or factors that drive engagement as well as the organizational aspects impacting it, management will be able to devise appropriate strategies to address disengagement, and thereby such a situation can lead to better employee commitment, morale and performance. So the current study aims to study the employee engagement of TNSTC employees and factors influencing it in Chennai District.

Scope of the Study

- The study only included employees working at Chennai District TNSTC Departments/Operational units.
- To evaluated the employee engagement of TNSTC employees and, to know about their level of commitment towards the company.
- The paper investigates the role of certain organizational variables: leadership, communication, work environment, training and development, compensation, recognition & employee welfare measures in driving engagement.
- The research explores the link between employee engagement and job satisfaction of TNSTC employees.

Limitation of the Study

Sample Size Limitation

- The study is based on a limited number of respondents selected from TNSTC. The views of all employees may not be fully represented.

Time Constraint

- The research was conducted within a specific period. Employee engagement levels may change over time due to organizational policies, work conditions, and management practices.

RESEARCH METHODOLOGY

Research Design

The study adopts a descriptive research design to analyze the employee engagement levels and the factors affecting employee engagement among TNSTC employees.

Area of the Study

The study is conducted among employees of the Tamil Nadu State Transport Corporation (TNSTC) in Chennai District**.**

Sources of Data

Primary Data

Primary data are collected directly from TNSTC employees through a structured questionnaire.

Secondary Data

Secondary data are collected from:

- Books
- Journals
- Research articles
- Government reports
- TNSTC records
- Websites and online publications

Sampling Design

Population

The population of the study consists of all employees working in TNSTC depots and offices in Chennai District.

Sample Size

A sample of **100 respondents** is selected for the study.

Sampling Technique

The respondents are selected using the **Convenience Sampling Method**.

Data Analysis and Interpertation

Interpretation

While examining the demographic picture of the respondents, we can see that those aged 31–40 years amount to 35% and ages from 41 –50 years are equals to a number of 30%. Seventy-six per cent of respondents are married. Looking at educational qualification, 30% of the respondents are SSLC/HSC pass while 33% have an undergraduate degree. With regard to designation, conductors belong top 1 (35%), followed by the drivers (30%). In terms of Employment Number 7,508 income per month₹35,001 – ₹45,000(34%) Also, 35% of respondents have worked for 11 to 15 years. The results show that most of the TNSTC employees surveyed are married, middle-aged, experienced and hired in operational roles in the organization. To examine whether there is a significant association between Age of the respondents **and** Employee Engagement Level among TNSTC employees in Chennai District.

Hypothesis

H_0 (Null Hypothesis): There is no significant association between age and employee engagement among TNSTC employees.

H_1 (Alternative Hypothesis): There is a significant association between age and employee engagement among TNSTC employees.

The calculated Chi-Square value (14.285) is greater than the table value **(**12.592) at the 5% level of significance. Moreover, the p-value (0.027) is less than the significance level of 0.05.

Therefore, the null hypothesis (H_0) is rejected and the alternative hypothesis (H_1) is accepted**.**

FINDINGS

- 42% of the participants belong to 31–40 age group.
- The majority of the respondents (68%) were married, which implies associated obligations indicating their engagement at work.
- Over half have (58%) an undergraduate degree as well.
- Most employees have medium and high employee engagement.
- Job security provided TNSTC was the best thing employees found with them.
- Cooperation among your colleagues and a teamwork-based work environment also had a positive impact on employee engagement.
- Supportive supervision and leadership appropriately strengthened employees' commitment toward the organization.

Suggestions

Based on the findings of the study, the following suggestions are offered:

- It is suggested to conduct regular employee recognition and reward programmes in TNSTC to appreciate good performance.
- This calls for additional training and skill building programs to assist the employees in gaining capabilities and confidence.
- Management should optimize communication between employees and supervisors.
- Encouragement of Health benefits, Counseling & recreational facilities to the employees.
- Equal distribution of workload is very important to minimize job stress and avoid employee burnout.

CONCLUSION

Employee engagement is a key lever for driving organizational effectiveness, employee productivity and improving service quality. The study concluded that TNSTC employees of Chennai District having a moderate level of engagement affected by variables like leadership support, teamwork, training & development, recognition and organizational commitment. Although issues involving workload, stress and career advancement should be addressed by management. The focus on employee engagement at TNSTC can result in improved employee morale, increased levels of job satisfaction, decreased turnover intentions, and enhanced organizational performance.

ABSTRACT

The present study explores and interprets the appearances of hybridity and mimicry in Amitav Ghosh's novel *The Glass Palace*. It also examines how hybridity and mimicry is representing the social and psychological impacts of colonialism on the characters of the novel. Amitav Ghosh's characters are experiencing British colonialism in Burma, Malaya and India. These experiences of British colonialism are influenced the lives of the characters in the novel. Homi K. Bhabha's concepts of hybridity and mimicry are used as a theoretical framework for the research. The present study explores how these two concepts influencing the behaviour of the characters in the new culture. According to Bhabha hybridity refers to the formation of new identity which is shaped from the association between colonizer and the colonised where cultural boundaries are eclipsed. On the other hand, mimicry involves colonized imitating the culture of colonizer. It is a process that both colonised and colonizer embraces and challenges colonial power.In the novel *The Glass Palace*, characters like Rajkumar, Dolly, and Arjun are representing hybridity and mimicry through their interactions with colonial systems, adopting and adapting elements of British culture while maintaining aspects of their native culture. The present study explores how Amitav Ghosh's novel represents postcolonial writing and offers understanding of identity in the new culture.

Keywords: Hybridity, Culture, Mimicry, Colonised, Colonizer, Native Culture

INTRODUCTION

Amitav Ghosh's *The Glass Palace* is an exploration of the postcolonial and colonial experiences of characters seized in the history of world and its culture. The novel set in British India, Burma and Malaya focusing on the lives of the characters and their identities which are influenced by colonial power. The story of Rajkumar, a young Indian boy who rises to prominence in Burma and whose fate intertwined with others like Dolly and Arjun, forms the nucleus of the narrative, with themes of migration, displacement and hybrid identity development.

In postcolonial studies, hybridity and mimicry are two critically important concepts which are essential for understanding the complex nature of identity in a colonized world. These concepts serve the framework for this research paper as discussed by postcolonial theorist Homi K. Bhabha. According to Bhabha the new hybrid identity is the result of the interaction between colonizer and the colonized that exist in the intervening spaces between cultures. Hybridity represents fluidity and transformation and at the same time challenges the fixed identities in the postcolonial era where new form of selfhood and belonging created. Mimicry engages the imitation of the colonizer's culture, behaviour and language by the colonised, but such imitation is never perfect and most of the times vulnerable of colonial power.

The narrative of Ghosh's novel *The Glass Palace* progresses in a British India, Burma and Malaya where characters continuously negotiating their identity and imitating colonial order through the interactions. Rajkumar symbolizes hybridity in his transformation from poor boy in British India to a successful businessman in colonial Burma. His identity is a mixture of native Indian traditions and the British colonial structure which resulting into tension between native culture and his adaptation of new colonizer's culture. Rajkumar's success illustrates that colonial subjects must reconcile the demands of colonization with their self.

Mimicry also plays a vital role in the novel, particularly through the characters like Arjun, who adopts the colonizers' customs and behaviours to rise in the social status in a colonial society. Arjun's imitation of the British is a tactic for acquiring power and privilege within the colonial system, but it also shows the absurdity of colonial supremacy. Through imitation of British he aligns himself with colonial system and undermining colonial authority by showing the contradictions within the colonial system. Thus, mimicry serves as survival tactic and a tool of resistance. The aim of this study is to explore hybridity and mimicry exhibit in *The Glass Palace* and how these concepts shape the identities of the characters in the novel. After careful study of the characters' experiences with migration, displacement, colonial system and culture, the study will explain how Ghosh's novel deal with the postcolonial identity. This study will contribute to the discussion within the postcolonial studies about the colonial legacy continue to shape personal and group identities in the modern world.

LITERATURE REVIEW

Amitav Ghosh's The Glass Palace (2000) is a narrative that explores themes of hybridity, mimicry, identity, and power dynamics, set in British Burma, Malaya and India. The narrative describes the fates of its characters, remarkably Rajkumar, Dolly, and Arjun.It also comments on the absurdity of hybrid identity and the strategies of mimicry employed by the colonised. The concept of hybridity, as discussed by Homi K. Bhabha in his work *The Location of Culture* (1994), is significant to understanding the experiences of colonial subjects. Bhabha defines hybridity as the cultural and social space that emerges from the intersection of colonial and native identities. Theorist like Ashcroft, Griffiths, and Tiffin in *The Empire Writes Back* (1989) propose that hybridity in postcolonial literature often reflects a complex negotiation of power and identity, where the colonized subject can neither fully conform to the colonial norms nor entirely resist them.

Mimicry, as defined by Homi K. Bhabha in *The Location of Culture*, is a form of imitation where the colonized subject adopts the characteristics of the colonizer, but with a twist. The mimicry of the colonized subjects often embodies a form of resistance because it simultaneously upholds and destabilizes colonial authority. Critics such as Robert Young in *Postcolonialism: An Historical Introduction* (2001) argue that mimicry can be seen as a subversive tactic, as it destabilizes the colonial order by highlighting its contradictions. In Ghosh's novel, the character of Arjun embodies the ambivalence of mimicry, where his attempt to assimilate into British culture is a means to climb the social ladder, yet it also exposes the artificial nature of colonial authority. His mimicry is a survival strategy, reflecting the inherent power dynamics and psychological impact of colonialism on the colonized.

Theoretical Framework

In the present study Homi K. Bhabha's concepts of hybridity and mimicry are used as the foundational framework for analyzing characters' behaviour and culture in Ghosh's *The Glass Palace*. These concepts are providing tools for understanding the complex nature of identity in colonial and postcolonial context.

Hybridity:

It is one of the most influential theoretical contributions of Bhabha. Hybridity as Bhabha illustrates is the emergence of new, hybrid cultural form created through the interaction of colonised and colonizer.It also challenges the logic that highlights the colonial narrative where colonizer and colonised are considered as opposites. Instead, hybridity emphasises the complex and fluid nature of identity which arise from the cross-cultural interaction and negotiation. In his work *The Location of Culture*Bhabha asserts that hybridity arises in the in-between space between cultures, where the colonized subject is neither completely native nor entirely colonizer, existing in a state of cultural and psychological uncertainty. This in-between space is crucial because colonised people are in constant negotiations for their identities and can establish new form of agency. It is significant that the productive capacities of this Third Space have a colonial or postcolonial provenance. For a willingness to descend into that alien territory . . . may open the way to conceptualizing an international culture, based not on the exoticism of multiculturalism or the diversity of cultures, but on the inscription and articulation of culture's hybridity.(Homi K. Bhabha 38)

Therefore, hybridity is a mixture of cultures but a scene of resistance and transformation. This mixture cultural practices, language and identities can disturb the boundaries imposed by colonialism.In *The Glass Palace*, hybridity is a central theme as the novel set in British Burma, Malaya and India and covers several historical moments from colonial and post-independence time.

Mimicry

The other key concept from Homi K. Bhabha which used in the present study is mimicry. Hybridity focuses on the creation of new cultural form whereas mimicry focussing in the behaviour of the colonised in which they imitate colonizer. Bhabha also points out that it is never a perfect imitation, it is always "*almost the same, but not quite*." This difference or this imperfect imitation is critical as it reveals the contradictions and challenges the authority of colonizer. That means mimicry can strengthen the colonial power and at same time challenges to it.

The line of descent of the 'mimic man' that emerges in Macaulay's writing, claims Homi K. Bhabha, can be traced through the works of Rudyard Kipling, E. M. Forster, George Orwell, and V. S. Naipaul, and is the effect of 'a flawed colonial mimesis in which to be Anglicized is emphatically not to be English' (Bhabha 87).In *The Location of Culture*(1994), Bhabha explains that how mimicry function as a strategy for colonised subjects. Colonised subjects by mimicking colonizer opened access to the power and privileges lined with colonizer and their culture.The menace of mimicry does not lie in its concealment of some real identity behind its mask but comes from its 'double vision which in disclosing the ambivalence of colonial discourse also disrupts its authority' (Homi K. Bhabha 88). The colonizer's culture is not natural or inherent to the colonised but an external imposed system on them. Instead of serving as a tool of submission, mimicry discloses the colonial hierarchy as incomplete and reveals the instability of it.

Hybridity in *The Glass Palace*:

In Amitav Ghosh's novel *The Glass Palace* hybridity is the prominent theme that explores the complex process of identity formation in the colonial era of Burma, India and Malaya. The concept of hybridity as articulated by Homi K. Bhabha in his works provides an approach through which psychological, cultural and social shifts of the colonial and postcolonial subjects can be analysed. Hybridity in *The Glass Palace* works as a tool for negotiating and resisting colonial rule and simultaneously emphasising characters' ability to adapt and survive themselves in the world of colonial power. The narrative of *The Glass Palace* is rich with the instances of hybridity where characters like Rajkumar, Arjun and Dolly represent hybrid identities trapped between the native culture and the imposed colonial rule.

According to Bhabha hybridity refers to the mixture of culture which results from the interaction between the colonised and the colonizer. It is not a blending of two cultures but a complex process of negotiation and alteration, where boundaries between them are indistinct. Hybridity is the key concept which allows creation of new form of culture and identities, can resist and adapt the colonial system. The colonial experience leads to the rise of new, hybrid biases that exist in a space of tension between different cultures rather than just an assimilation of the colonized subjects. Hybridity is not static state; it is an ongoing process in Bhabha's view.The subject does not only merge cultures but exists within the contradictions and ambivalence which simply define colonial relationship. The colonised negotiates power and identity through hybridity by adapting and adopting the ways of colonizer while simultaneously reshaping and retaining aspects of their native culture. These contradictory negotiations form the foundation of the hybrid identity in colonial and postcolonial societies.

In *the Glass Palace* novelist presents characters in different ways, symbolise hybridity as they steer the colonial systems of India, Burma and Malaya. The journey of these characters replicates the complexities of colonial identity, and the novel explores how hybridity shapes their lives, relationships and choices. Rajkumar, the central character of the novel is prime example of hybridity.His experiences in colonial Burma represents the way in which colonial ruletransformidentities on individual level. Rajkumar's journey from poor boy to successful businessman in colonial Burma, experiencing different cultures, reveals the process of cultural negotiation that defines hybridity. Rajkumar's story is evidenceof the adaptability and survival tactic of colonial subjects.His interactions with the British, the Indian and the Burmese people force him to adopt values as well as customs from each of these cultures. His identity is fluid and not associated with any one culture or tradition, it is continuously shaped by socio-cultural forces around him. Theoretically, Rajkumar represents the colonial subject one who navigates the spaces between cultures of British, Indian and Burma and at the same time merge them into a new, hybrid identity.One of the most important characteristics of Rajkumar's hybridity is his relationship with the British administrative system and the way he interacts with the officials, adopt their practices tocontrol wealth and power in the region. His relationship with colonial official is complex, he is subject of colonizer and at the same time active participant in the colonial economy. This duality,being both a colonized subject and a colonial participant, forms the crux of his hybrid identity. Rajkumar's success in the colonial rule is always noticed by a sense of otherness, he remains an outsider and never integrated into elite culture of the British. He adopts and adapts colonial culture to his benefit but remain aware of the inequalities of the colonial world.

Dolly, another important character in *The Glass Palace*, embodies hybridity in a different form. Being a woman her identity is shaped by the gendered expectations of Indian culture and the colonial culture. Dolly's hybrid identity is shaped by her negotiation between values of the Indian culture and the opportunities given by colonial power in terms of her relationship with the British. She adopts some colonial customs but fails to integrate into colonial society. Therefore her hybridity results in her discomfort with colonial structure and loyalty to native Indian Culture. Dolly's hybrid identity symbolises the women's struggle in the colonial context.

*The Glass Palace*is also a representation of broader picture of hybridity in British Burma. The Indian those who are migrated, experience hybrid identity, a blend of Indian and colonial culture. They experience tension between native Indian and British colonial culture in daily life. These mixed cultural experiences compel them to hold both cultures with their complexities. Therefore, Indian community in the colonial world represents the ambivalence of colonised trapped between two opposite spheres of the world. They adopt most of the elements of the British culture by interacting with the colonial system and simultaneously retain the elements of Indian culture, which form their new hybrid identity neither British nor Indian. In the novel hybridity acts as a form of resistance and transformation instead of tool of identity formation.

Therefore hybridity acts as one of the powerful themes in the novel which not only form the new identity but also retain the old, native identity while interacting in the colonial and postcolonial context. It also reflect that characters compel to transform and navigate between native and the colonizer's culture. The characters like Rajkumar and Dolly illustrates how hybridity serve as a survival strategy and a form of resistance.

Mimicry in *The Glass Palace*:

Mimicry plays a significant role in the narrative of Amitav Ghosh's *The Glass Palace*, particularly the way characters interact with colonial authority and cultural structures. Homi K. Bhabha in his work The Location of Culture explores how mimicry operates as a subversive and adaptive strategy in the colonial context. The colonised imitating the colonizer but it is never an exact imitation, "almost the same, but not quite." The slight variation from the original reflects the contradictions within the colonial system. This contradiction serves as a means of undermining the authority of the colonizer and providing tool for survival to the colonised.

In the colonial world, mimicry functions as a survival tactic, where the colonised subject imitate the colonizer's culture, behaviour and language to access the privileges and power. In *The Glass Palace*, Arjun who represent the colonial subject trying to navigate the social and economic system of British Burma. His attempt to mimic colonizer's culture, manners, dress and language is a means of securing a better position in the colonial system. Arjun's mimicry is not flawless, in this imperfection, Bhabha's theory becomes evident. His mimicry of British culture is not perfect adoption, it is always "almost the same, but not quite" and this imperfect imitation exposes the contradictions inherent in the colonial system. Arjun's imitation of the British culture does not grant him the access to the colonial elite. Despite all the efforts, he remains an outsider, one who can imitate but cannot be perfect British colonial. Arjun's mimicry also serves as survival tactics within the colonial system. He may not achieve complete acceptance into the colonial society, but his mimicry allows him to access some of the privileges by adopting British ways. Mimicry allows him an autonomy in the colonial world and exposes the limitations of the colonial system. Mimicry allows him an autonomy in the colonial system and exposes the limitations of it. For Bhabha, mimicry is inherently disturbing to the colonial rule because it highlights the contradictions and inconsistencies in the colonial power. The culture of colonizer is being presented as superior and hegemonic which is ultimately referred as artificial and unstable when colonised imitate it. This mimicry always carries with an element of difference which weakens the colonial authority. In *The Glass Palace*, this subversive quality of mimicry is an evident in the characters whose imitation of the colonizer challenges the colonial status. Arjun's mimicry represents the inherent contradictions in the colonial system. He adopts and simultaneously highlights the absurdity of the colonial system's claim of superiority. As his mimicry never flawless and this imperfect imitation challenge the notion that colonial culture is a model to be copied. As not being able to replicate British language, behaviour and manners perfectly, Arjun's mimicry discloses the colonial system's dependence on difference not only between the colonizer and the colonised but also within the colonial system itself. By the colonizer, Arjun's attempt to adopt British culture is viewed as markers of cultural refinement and superiority. It expresses vulnerability of the colonial system and challenges the superiority of it.

Thus, mimicry in the novel works as both a strategy to survive and a tool of resistance.The characters of the novel presents the artificial and mechanical nature of colonial rule. Imitation at the same time function as a tool of resistance and weakens the colonial power through mimicry.

CONCLUSION

In *The Glass Palace*, Amitav Ghosh explores the multifaceted impacts of colonialism and focusing on the themes of hybridity and mimicry as an important feature of identity formation in colonial and postcolonial context. The novel provides an exploration of how individuals and communities travel through cultural transformation and contradictions in the colonial and postcolonial environments. Through hybridity and mimicry Ghosh illustrates the ways in which colonised subjects reshape, adapt and resist their identities in the colonial rule which dominates them. Hybridity as discussed by Homi K. Bhabha appears as a key theme in the novel *The Glass Palace*, demonstrating the blending of cultures. The characters in the novel reflect hybrid identities born out of overlapping of the native culture and British colonialism. Their experiences express the tension and transformation, arise from the interaction between the colonizer and the colonised. Hybridity is not only blending of cultures but also the creation of new spaces where individuals can assert agency and remained marked by the power dynamics of colonial rule. Novelist uses hybrid identities to explore the contradictions of colonialism, revealing hoe the cultural and political impositions create

opportunities for survival and resistance. On the other hand, mimicry represents the dynamics of cultural subjugation and resistance. As described by Bhabha, the act of imitation becomes a tool of survival and form of resistance. In Burma characters like Arjun engages in mimicry as a tool to gain access to privileges and to navigate the colonial power structure. Yet Bhabha proposes mimicry as an imperfect imitation "almost the same, but not quite", which highlights the contradictions within the colonial system. Mimicry serves as a way for the colonised to assert autonomy and continue to operate within confines of colonial structures. In conclusion, *The Glass Palace* serves as a rich exploration of hybridity and mimicry. Through the experiences of characters, Amitav Ghosh demonstrates how colonialism reshape identities and cultures. Hybridity and mimicry not only explore the dynamics of colonial power, but also suggest pathways for new identity, survival and resistance in the postcolonial context.

ABSTRACT

Workplace stress among faculty members in higher education institutions has emerged as a pervasive concern with direct implications for teaching quality, research productivity, institutional reputation, and individual wellbeing. This paper synthesises the existing empirical and theoretical literature on the determinants, consequences, and management of occupational stress among academic staff. Drawing on the transactional model of stress, the Conservation of Resources (COR) theory, and the Job Demands-Resources (JD-R) model, the paper organises stressors into workload-related, role-related, organisational, and career-related categories, and traces their downstream effects on instructional effectiveness, scholarly output, burnout, job satisfaction, and turnover intention. The review indicates that heavy teaching and administrative loads, publication pressure, role ambiguity, limited autonomy, inadequate institutional support, and precarious employment arrangements are recurrent and cross-nationally consistent stressors. Left unaddressed, these stressors are associated with emotional exhaustion, depersonalisation, reduced classroom engagement, declining research output, absenteeism, and attrition. The paper then evaluates strategic interventions at the individual, departmental, and institutional levels, including workload redesign, participative governance, mentorship and professional development, mental health and counselling services, and flexible work arrangements, and proposes an integrated framework linking stressor identification to intervention design. The paper concludes that sustainable faculty performance depends on institutions treating stress management as a structural and policy issue rather than an individual coping problem, and it outlines directions for future empirical research, including longitudinal and cross-cultural studies.

Keywords: occupational stress; faculty performance; higher education; burnout; job demands-resources model; academic workload; institutional interventions

INTRODUCTION

Higher education institutions rely heavily on the intellectual labour, pedagogical skill, and research output of their faculty members. Over the past two decades, however, the working environment of academic staff has grown markedly more demanding. Expanding student enrolments, larger class sizes, growing administrative and compliance workloads, intensifying pressure to publish in high-impact outlets, competition for research funding, and the blurring of boundaries between work and home life brought about by digital communication tools have combined to raise the psychological burden carried by teaching and research staff. These pressures have made workplace stress one of the most widely studied occupational health issues in the academic profession. Occupational stress is generally understood as the physiological and psychological response that occurs when the demands of a job exceed an individual's perceived capacity to cope with them. In the context of higher education, this imbalance is frequently produced by role overload, role ambiguity, limited autonomy, inadequate recognition, and precarious employment conditions. A systematic review of job stress research in higher education institutions found that a negative organisational climate is closely associated with elevated occupational stress among faculty, particularly women, with the most frequently cited causes including heavy workload, limited involvement in decision-making, poor recognition, and difficulty balancing work and personal life. The consequences of unmanaged occupational stress extend well beyond the individual. When faculty members experience chronic stress, the quality of teaching, mentorship, and scholarly output can decline, with knock-on effects for student learning outcomes, institutional rankings, and organisational reputation.

Recent survey evidence illustrates the scale of the problem: a large-scale professional survey found that roughly two-thirds of university faculty reported experiencing work-related burnout, with a meaningful minority reporting high or severe levels, while regional analyses suggest that faculty burnout rates in parts of Europe, North America, and Southeast Asia have ranged from roughly three in ten to over four in ten academic staff during periods of heightened institutional pressure. This accumulated stress diminishes not only faculty wellbeing and job satisfaction but also motivation and classroom performance. This paper addresses three interrelated questions. First, what are the principal determinants of workplace stress among faculty in higher education institutions? Second, through what mechanisms does this stress translate into changes in teaching, research, and organisational performance? Third, what strategic interventions, at the individual, departmental, and institutional levels, are most likely to mitigate these effects and support sustainable faculty performance? The paper is organised as a structured literature review. It begins by outlining the theoretical frameworks most commonly used to explain occupational stress in academic settings, before examining determinants, consequences, moderating factors, and intervention strategies in turn. It closes with a proposed integrated framework and recommendations for future empirical research. The objectives of the paper are threefold: (a) to consolidate and categorise the empirical evidence on the sources of faculty stress across institutional and national contexts; (b) to map the documented consequences of that stress for teaching effectiveness, research productivity, and staff retention; and (c) to evaluate the evidence base for interventions intended to reduce stress and protect performance, so as to inform policy and practice in higher education management.

Theoretical Framework

Three theoretical perspectives dominate the literature on occupational stress in higher education and provide the analytical lens for this paper: the transactional model of stress and coping, the Conservation of Resources (COR) theory, and the Job Demands-Resources (JD-R) model.

The Transactional Model of Stress

The transactional model, developed within occupational health psychology, conceptualises stress not as a fixed property of the environment but as the outcome of an ongoing appraisal process in which an individual evaluates a demand and their perceived capacity to meet it. When a faculty member appraises a task, such as an unexpected increase in teaching load or an approaching grant deadline, as exceeding their available resources, a stress response is

triggered. This model is useful because it explains why the same objective workload can be experienced very differently by different academics depending on their coping resources, prior experience, and perceived control.

Conservation of Resources (COR) Theory

COR theory proposes that individuals strive to obtain, retain, and protect resources that they value, including time, energy, status, and social support, and that stress arises when these resources are threatened, lost, or fail to be replenished after investment. In academic settings, this helps explain why the loss of resources such as protected research time or administrative support tends to have a disproportionately large psychological impact, and why resource gains, such as mentoring or reduced teaching loads, become especially valuable during periods of high demand. Research applying COR theory to academic staff has found that resource gains become more salient specifically in contexts where other resources are already being depleted, such as under sustained publication pressure.

Job Demands-Resources (JD-R) Model

The JD-R model, one of the most widely applied frameworks in occupational health psychology, distinguishes between job demands, the physical, psychological, social, or organisational aspects of a job that require sustained effort and are therefore associated with physiological or psychological costs, and job resources, the aspects of a job that help achieve work goals, reduce demands, or stimulate personal growth. The model proposes two parallel processes: a health-impairment process, in which excessive demands unmatched by adequate resources lead to exhaustion and burnout, and a motivational process, in which adequate resources foster engagement and performance even under high demand. Applied to academic staff, chronic demands such as administrative overload, role conflict, and unclear promotion criteria act as hindrance demands that erode wellbeing, whereas resources such as autonomy, recognition, and psychological safety support engagement and buffer against burnout. Meta-analytic evidence within the JD-R tradition further shows that job resources are more strongly linked to work engagement, while job demands are more strongly linked to emotional exhaustion, underscoring the importance of addressing both sides of the equation rather than resources alone.

Together, these three frameworks suggest that faculty stress should be understood as a dynamic interaction between organisational demands, available resources, and individual appraisal and coping processes, rather than as a simple, additive function of workload alone. This integrated perspective informs the structure of the sections that follow.

Determinants of Workplace Stress Among Faculty

The literature identifies a recurring set of stressors affecting academic staff across countries and institution types. These can be grouped into workload-related, role-related, organisational and leadership-related, career and evaluation-related, and work-life balance-related determinants.

Workload and Role Overload

Excessive teaching loads, large class sizes, increased student advising responsibilities, and growing administrative and compliance duties are consistently reported as the most significant sources of stress for faculty. Many academics are expected to simultaneously deliver high-quality teaching, supervise research students, publish original scholarship, secure external funding, and participate in institutional governance and committee work, often without a corresponding increase in time or support. This accumulation of responsibilities, frequently referred to as role overload, leaves faculty with limited time for deep, focused work and contributes to chronic time pressure.

Role Ambiguity and Role Conflict

Faculty members frequently operate under unclear or inconsistent expectations regarding how their performance will be evaluated, particularly where teaching, research, and service responsibilities are weighted differently by different reviewers or committees. Role conflict arises when the demands of one role, such as teaching, interfere with the ability to fulfil another, such as research productivity. This tension is especially acute for early-career and

untenured faculty, for whom promotion and job security are directly tied to output across multiple, sometimes competing, domains.

Organisational Climate and Leadership

A negative or unsupportive organisational climate, characterised by poor communication, weak recognition of achievement, limited participation in institutional decision-making, and unsupportive departmental leadership, is strongly associated with elevated occupational stress. Faculty who perceive their institution as failing to acknowledge their contributions or to involve them meaningfully in decisions that affect their work report higher stress levels than those in more participative and communicative environments.

Publication Pressure and Research Evaluation Systems

The intensification of research evaluation regimes, often summarised as a "publish or perish" culture, has become a major stressor, particularly in research-intensive universities. Faculty report pressure to produce a steady stream of publications in high-ranking journals, secure competitive grant funding, and demonstrate measurable research impact, frequently within compressed promotion and tenure timelines. Mandatory, high-stakes performance evaluations tied to these metrics have been identified as a significant contributor to burnout among academic staff.

Job Insecurity and Contractual Instability

The growing reliance on fixed-term, adjunct, and sessional academic contracts has introduced chronic uncertainty into many faculty careers. Instability in compensation, renewal prospects, and career progression represents a persistent hindrance demand that has been linked to elevated stress, particularly among early-career, non-tenure-track, and part-time faculty, who often lack the institutional protections and resources available to permanent staff.

Work-Life Balance and Technology-Related Boundary Blurring

The expansion of digital communication tools and, more recently, online and hybrid teaching modes has blurred the boundary between work and personal life for many academics. Faculty increasingly report difficulty disengaging from email, learning management systems, and remote teaching platforms outside of formal working hours. Increased workload, blurred work-home boundaries, and a lack of institutional support have been identified as major stressors associated with digital and remote academic work, with recommendations for greater scheduling flexibility and investment in digital infrastructure to address them.

Limited Autonomy and Participation in Decision-Making

Faculty who have little control over their teaching assignments, course design, research direction, or departmental policies report higher stress than those who retain meaningful professional autonomy. Because autonomy functions as a job resource within the JD-R framework, its absence compounds the effects of high workload and role conflict rather than acting as an independent stressor alone.

Demographic and Contextual Moderators

The intensity of these stressors is not uniform across the academic workforce. Evidence indicates that female faculty report disproportionately high stress linked to role conflict, unequal domestic responsibilities, and underrepresentation in leadership and decision-making structures, suggesting that gender-sensitive strategies are needed alongside general workload interventions. Career stage, discipline, institution type, and national higher education policy context further shape which stressors are most salient for a given faculty population.

Consequences of Workplace Stress on Faculty Performance

Sustained occupational stress affects faculty performance through several interlinked pathways: direct impairment of cognitive and emotional functioning, burnout, reduced engagement, and, ultimately, attrition.

Teaching Quality and Student Outcomes

When faculty operate under chronic stress, their capacity for sustained concentration, patience, and responsiveness in the classroom is diminished. Stressed instructors have been shown to struggle to concentrate fully on their tasks, resulting in lower performance than their less-stressed peers, alongside dissatisfaction stemming from a sense that their effort is insufficient to meet institutional expectations. These effects can translate into reduced preparation time, less individualised feedback for students, lower engagement in the classroom, and diminished innovation in course design and delivery.

Research Productivity and Scholarly Output

Chronic stress, particularly when driven by publication pressure combined with heavy teaching and service loads, can paradoxically reduce research productivity even as institutional expectations for output rise. Fragmented time, reduced concentration, and exhaustion limit faculty capacity for the sustained, deep-focus work that scholarship typically requires, while anxiety about evaluation outcomes can further inhibit creative and exploratory research activity.

Burnout: Emotional Exhaustion, Depersonalisation, and Reduced Accomplishment

Burnout is the most extensively documented consequence of occupational stress in the academic literature and is typically conceptualised as comprising three dimensions: emotional exhaustion, depersonalisation (cynicism or detachment toward colleagues and students), and a diminished sense of personal accomplishment. Job stress has been shown to be most strongly linked to emotional exhaustion, with moderate associations with depersonalisation and reduced personal accomplishment, and regression-based studies across multiple national contexts consistently identify job stress as a significant predictor of burnout among faculty. Reported burnout prevalence among university faculty has been substantial in recent surveys, with rates varying by region and by the presence of acute disruptions such as the COVID-19 pandemic, which was associated with markedly elevated burnout symptoms among educators in several regions.

Job Satisfaction, Turnover Intention, and Attrition

Faculty experiencing high stress and burnout consistently report lower job satisfaction and organisational commitment, and higher intention to leave their institution or the academic profession altogether. Because recruiting and developing research-active faculty represents a substantial institutional investment, elevated turnover intention driven by unmanaged stress carries direct financial and reputational costs for universities, in addition to the loss of institutional knowledge and mentoring capacity.

Physical and Mental Health Outcomes

Beyond its effects on job performance, chronic occupational stress among faculty has been associated with a range of physical and psychological health outcomes, including sleep disturbance, anxiety, depressive symptoms, and, in extreme cases, indicators of psychological fatality risk that have prompted occupational safety bodies to issue guidance on managing workplace stress. These health effects create a feedback loop: declining wellbeing further reduces coping capacity, which in turn increases vulnerability to future stressors.

Moderating and Mediating Factors

Not all faculty exposed to similar stressors experience equivalent declines in wellbeing or performance, indicating the presence of moderating and mediating variables. Social support from colleagues, supervisors, and family has been consistently identified as a buffer against the negative effects of job demands. Perceived organisational support and a sense of reciprocity between faculty and their institution have also been found to reduce burnout risk and to sustain engagement even under high workload, by satisfying underlying psychological needs for meaningfulness, safety, and availability at work. Individual coping resources also play a moderating role. Faculty who report higher levels of mindfulness have been found to experience less emotional exhaustion under high job demands, particularly in remote and online teaching contexts, suggesting that mindfulness-based practices can weaken the pathway from job demands to burnout. Similarly, work engagement itself, characterised by vigour, dedication, and absorption, has

been shown to mediate the relationship between job resources and both task and contextual performance, meaning that resource-rich environments support performance partly by first increasing engagement, and partly by reducing burnout. Coordinated departmental activity and shared responsibility have also been identified as protective factors, on the basis that occupational stress in teaching, being rooted in poor work organisation, can be substantially reduced when colleagues work together with clearly distributed tasks rather than in isolation. This points to the importance of team-based and departmental-level, rather than purely individual, responses to stress management.

Strategic Interventions

The literature converges on the view that effective stress management in higher education requires action at multiple levels simultaneously: institutional policy and structure, departmental leadership and culture, and individual support and skill-building. Interventions that focus solely on individual coping, without addressing structural sources of demand, tend to have limited and short-lived effects.

Institutional and Policy-Level Interventions

- **Workload audits and redesign:** Systematically reviewing teaching, research, and service allocations to ensure a more equitable and transparent distribution of workload across faculty, and adjusting them where they are found to be excessive.
- **Clear and consistent evaluation criteria:** Establishing transparent, well-communicated criteria for tenure, promotion, and annual review reduces role ambiguity and the anxiety associated with uncertain expectations.
- **Employment stability measures:** Where feasible, converting a greater share of precarious contracts to more secure arrangements, or providing clearer pathways and support for contract renewal, addresses job insecurity as a chronic stressor.
- **Investment in digital and administrative infrastructure:** Reducing the administrative burden on faculty through better systems and adequate support staff frees time for teaching and research and reduces demands associated with digital and remote work.
- **Flexible work arrangements:** Policies enabling flexibility in scheduling, and in the location and timing of non-classroom work, help faculty manage the boundary between work and personal life.

Departmental and Leadership-Level Interventions

- **Participative decision-making:** Involving faculty meaningfully in departmental and institutional decisions that affect their work increases perceived control and reduces stress associated with a negative organisational climate.
- **Recognition and feedback systems:** Regular, genuine acknowledgement of teaching and research achievements addresses the poor recognition identified as a recurring stressor, particularly for female faculty.
- **Mentorship and onboarding support:** Structured mentoring for early-career and new faculty helps clarify role expectations, builds social support networks, and eases the transition into demanding academic roles.
- **Team-based workload sharing:** Encouraging coordinated activity and shared responsibility for high-demand tasks, such as large-enrolment courses or accreditation processes, distributes pressure rather than concentrating it on individuals.

Individual and Wellbeing-Focused Interventions

- **Access to psychological counselling and Employee Assistance Programmes:** Regular, confidential mental health support should be a standard institutional service rather than an emergency-only resource.
- **Mindfulness and resilience training:** Structured programmes have demonstrated moderating effects on the relationship between job demands and emotional exhaustion, and can be offered as part of professional development.
- **Health literacy and behaviour-change programmes:** Institutional initiatives that build staff health literacy and support healthy behaviours have been found to contribute to sustained wellbeing and productivity among university personnel.

- **Financial incentives tied to wellbeing-supportive practices:** Structured human-resources policies incorporating incentives alongside more frequent, lower-stakes evaluations have been recommended as part of an integrated approach to lifting both faculty wellbeing and instructional performance.

An Integrated Approach

The strongest evidence supports combining structural and psychological interventions rather than relying on either alone. A management-led systematic review of interventions for academic staff mental health concluded that flexibility in work scheduling, investment in mental healthcare and digital infrastructure, and structured human-resources policies combining incentives with regular, lower-stakes evaluation together represent a coherent strategy for improving both faculty wellbeing and instructional performance. This suggests that institutions should treat stress management not as a discrete wellness initiative but as an integrated dimension of human-resources strategy, workload planning, and academic governance.

Proposed Integrated Framework

Building on the JD-R and COR perspectives reviewed above, this paper proposes a simple integrated framework for understanding and managing faculty stress. The framework treats faculty performance as the outcome of a balance between job demands (workload, role ambiguity, publication pressure, job insecurity, boundary blurring) and job and personal resources (autonomy, social support, recognition, institutional support, coping skills). Where resources are adequate relative to demands, the model predicts a motivational pathway toward engagement and sustained performance. Where demands chronically exceed resources, the model predicts a health-impairment pathway toward emotional exhaustion, burnout, and declining teaching and research output, culminating, if unaddressed, in turnover or attrition. Strategic interventions can be mapped directly onto this framework: institutional and policy interventions primarily act on the demand side by reducing or redistributing workload and clarifying role expectations; departmental and leadership interventions primarily strengthen organisational resources such as recognition, participation, and mentorship; and individual wellbeing interventions strengthen personal coping resources. Because the three levels interact, the framework implies that institutions monitoring only individual-level wellbeing indicators, without addressing structural demands, are likely to see limited or temporary improvement.

Methodology, Data Analysis, and Results

Research Design

A cross-sectional, quantitative survey design was used, consistent with the majority of studies reviewed in Sections 3-5. A correlational, explanatory design was chosen because the objective was to test the strength and direction of relationships among stress determinants, mediating variables, and performance outcomes.

Sample

The illustrative sample comprised 320 faculty members distributed across four rank/contract categories (Assistant Professor, Associate Professor, Full Professor, and Non-Tenure-Track/Adjunct) and four broad disciplinary groupings (Sciences, Humanities, Social Sciences, and Professional/Applied fields), generated to approximate a stratified sample from a mid-sized university with a faculty population of roughly 1,500.

Instrumentation

- Job demands: workload, role conflict, and job insecurity, each measured on a simulated 1-5 Likert-type scale (5 items per construct).
- Job resources: autonomy, organisational support, and social support, each measured on a simulated 1-5 Likert-type scale (5 items per construct).
- Burnout: emotional exhaustion, depersonalisation, and personal accomplishment, modelled on the structure of the Maslach Burnout Inventory (4-5 items per subscale).
- Performance: teaching performance and research productivity (4 items each), combined into an overall performance index.
- Moderator: trait mindfulness (4 items).

Reliability of Measures

Internal consistency for each multi-item scale was assessed using Cronbach's alpha. As shown in Table 1, all scales exceeded the conventional 0.70 acceptability threshold, supporting their use in subsequent analyses.

Descriptive Statistics

Table 2 reports means and standard deviations for the principal study variables (all scored 1-5). Mean levels of job demands and emotional exhaustion clustered around the scale midpoint (M = 3.00), with performance variables showing a similar pattern, consistent with a moderately-stressed, non-clinical faculty sample rather than an extreme or crisis-level cohort.

Correlation Analysis

Table 3 and Figure 1 present Pearson correlations among the principal study variables. Consistent with the JD-R model, job demands (workload, role conflict, job insecurity) were positively associated with emotional exhaustion and negatively associated with both performance indicators, while job resources (autonomy, organisational support) showed the opposite pattern. Emotional exhaustion was the variable most strongly associated with performance, correlating at r = -0.65 with teaching performance
and r = -0.54 with research productivity

Hierarchical Regression: Predicting Overall Performance

A three-step hierarchical multiple regression tested the incremental contribution of job demands and job resources to overall faculty performance, after controlling for years of service and adjunct/fixed-term contract status. As shown in Figure 2, the control variables alone explained a negligible share of variance ($R^2 = 0.017$). Adding the three job-demand variables (workload, role conflict, job insecurity) increased explained variance substantially ($\Delta R^2 = 0.283$), and adding the three job-resource variables (autonomy, organisational support, social support) increased explained variance further ($\Delta R^2 = 0.186$), for a final model explaining 48.7 percent of the variance in overall performance ($R^2 = 0.487$, Adjusted $R^2 = 0.474$). Workload emerged as the strongest single negative predictor of performance, while autonomy emerged as the strongest positive predictor, echoing the pattern reported across the studies reviewed in Section 3. Social support did not reach statistical significance as a direct predictor of performance in this model, consistent with theoretical expectations that its effects operate primarily indirectly, through reduced burnout, rather than as a direct main effect (see Section 8.9).

Mediation Analysis: Emotional Exhaustion as a Mechanism

A bootstrapped mediation model (2,000 resamples) tested whether emotional exhaustion mediates the relationship between job demands and overall performance, consistent with the health-impairment pathway of the JD-R model. The total effect of job demands on performance was c = -0.669. Job demands significantly predicted emotional exhaustion (path a = 0.979, $p < .001$), and emotional exhaustion significantly predicted lower performance controlling for demands (path b = -0.534, $p < .001$). The indirect effect through emotional exhaustion was ab = -0.523, with a 95 percent bootstrap confidence interval of [-0.649, -0.415], which does not cross zero and therefore indicates statistically significant mediation (Sobel z = -9.52, $p < .001$). The direct effect of job demands on performance, controlling for exhaustion, was substantially reduced (c′ = -0.143), indicating that emotional exhaustion accounted for approximately 79 percent of the total effect of job demands on performance in this sample.

Moderation Analysis: Social Support as a Buffer

A moderated regression tested whether social support buffers the relationship between job demands and emotional exhaustion. The Job Demands × Social Support interaction term was statistically significant (b = -0.475, $p < .001$), indicating that the positive relationship between job demands and emotional exhaustion was weaker among faculty reporting higher levels of social support. This finding is consistent with the buffering hypothesis derived from Conservation of Resources theory in Section 2.2 and with the protective role of collegial and supervisory support discussed in Section 5.

Group Comparisons

A one-way ANOVA compared emotional exhaustion across the four rank/contract categories and was statistically significant, $F = 5.69$, $p < .001$. As shown in Figure 4, non-tenure-track/adjunct faculty and full professors reported the highest mean exhaustion ($M = 3.19$ and $M = 3.18$, respectively), while assistant and associate professors reported somewhat lower levels ($M = 2.86$ and $M = 2.87$). A supplementary independent-samples t-test comparing fixed-term/adjunct faculty ($M = 3.19$) with tenure-track/tenured faculty ($M = 2.94$) was also significant, $t = 2.76$, $p = .007$, consistent with the job-insecurity determinant discussed in Section 3.5.

Summary of Results

Taken together, the worked analysis supports each element of the integrated framework proposed in Section 7: job demands were positively associated with burnout and negatively associated with performance; job resources showed the reverse pattern and added significant incremental explanatory power beyond demands alone; emotional exhaustion statistically mediated the great majority of the demand-performance relationship; social support significantly buffered the demand-exhaustion relationship; and non-tenure-track and senior faculty reported significantly higher exhaustion than early- and mid-career tenure-track faculty. Because the underlying data are simulated, these results should be read as a demonstration of the analytical pipeline and of the pattern of relationships the literature would predict, not as a substantive empirical contribution in themselves.

Limitations of This Analysis

- The dataset is simulated, not collected from real respondents; reported coefficients, p-values, and confidence intervals reflect the assumptions built into the simulation and will not exactly match any real institution's results, even though they were calibrated to be broadly consistent with the direction and relative strength of effects reported in the reviewed literature.
- A genuine study would require ethics review, informed consent, and independently validated instruments (e.g., the licensed Maslach Burnout Inventory) rather than the illustrative items simulated here.
- Cross-sectional data, real or simulated, cannot establish causal direction; the mediation model is consistent with, but does not prove, the health-impairment pathway proposed by JD-R theory.
- Common-method variance is a concern for any single-source self-report design and should be assessed (e.g., via Harman's single-factor test) once real data are collected.

Recommendations for Future Research

Building on the worked analysis in Section 8, the following priorities would strengthen the evidence base if pursued with genuine primary data:

- **Longitudinal designs:** Most existing studies rely on cross-sectional surveys, which limit causal inference between stress and performance outcomes; longitudinal and panel studies are needed to track how stress, burnout, and performance evolve over an academic career.
- **Cross-cultural and cross-institutional comparison:** Because higher education governance, employment structures, and cultural norms around workload vary substantially across countries, comparative studies would help identify which stressors and interventions generalise and which are context-specific.
- **Discipline- and career-stage-specific analysis:** Stressors likely differ meaningfully between, for example, laboratory-based science faculty, humanities faculty, clinical academic staff, and part-time or adjunct instructors; more granular studies would support more targeted interventions.
- **Intervention evaluation studies:** Relatively few studies rigorously evaluate the actual effectiveness of implemented interventions (as opposed to proposing them); controlled or quasi-experimental evaluations of workload redesign, mentorship programmes, and mental health services would strengthen the evidence base.
- **Gender and equity-focused research:** Further investigation is needed into the individual and structural factors that moderate role conflict and stress for female and other underrepresented faculty, and into the effectiveness of equity-focused interventions specifically.

CONCLUSION

Workplace stress is a structural feature of contemporary academic work, produced by the interaction of heavy and diversifying workloads, role ambiguity, intensifying research evaluation regimes, job insecurity, and the erosion of boundaries between work and personal life. The evidence reviewed in this paper indicates that this stress carries measurable costs for teaching quality, research productivity, faculty wellbeing, and institutional retention, with burnout emerging as the central mechanism linking chronic stress to declining performance. At the same time, the literature indicates that these effects are not inevitable: social support, organisational recognition, participative governance, and individual coping resources such as mindfulness meaningfully buffer the relationship between demands and negative outcomes. The strategic interventions reviewed in this paper, spanning workload redesign, transparent evaluation systems, employment stability, participative leadership, mentorship, and accessible mental health support, are most effective when implemented as an integrated institutional strategy rather than as isolated wellness initiatives. Higher education institutions seeking to sustain faculty performance over the long term should therefore treat occupational stress management as a core dimension of academic governance and human-resources policy, supported by ongoing monitoring, transparent evaluation, and genuine faculty participation in the design of workload and support systems.

ABSTRACT

Postpartum depression is a prevalent mental disorder among the mothers who have new-born babies. It's a disorder with varying severities and can also have different symptoms for different people. Women post-delivery not only suffer from severe mental disorders, but also from some physical disorders. This research paper talks about the various psychological and physiological traumas women go through during different phases of PPD (Postpartum depression). The societal acceptance of PPD is also discussed and the difference in terms of individual sufferance is specified. A questionnaire which consists of 23 questions was sent to 50 mothers of various ages and various symptoms. Detailed responses were collected. The paper also talks about the science behind PPD. It talks about the biological factors, familial factors and individual factors which has caused PPF. A thorough description from a genecologist'Dr Kalpana C Udupa', about the science behind PPD, the various severities and its treatment is also described in detail.

Keywords: Postpartum depression, physiological, psychological, psychiatrist, suicidal and self-harm ideations, feelings, prevalence of teary eyes, self-harm, nightmares, psychosis.

INTRODUCTION

Having a babyis an overwhelming experience for both the parents. But sometimes in a mother, it can give rise to both positive and negative emotions.It is extremely delightful to have their own baby, but the hassles which come along with that happiness is mostly contended in a completely unaware and unprepared state. Sometimes, women after the delivery, experience episodes of constant weep, severe nightmares, extreme vulnerability and in a need for protection. All these show the fact that the woman is suffering from post-partum depression.

Majority Indian societies are patriarchal families and are families who prefer a male child over a female child. A pregnant lady is always looked upon from the perspective of a giver and not a human being who experiences positive and negative thoughts and feelings. Most of the time, focus and extreme care for her is shown only because of the kid she's carrying. Women who know such facts develop symptoms which can eventually lead to post-partum depression.

BACKGROUND OF THE STUDY

There are three types of post-partum depression.

Post-partum Blues or Baby blues:post-partum blues are one of the most common symptoms that a woman will experience after their delivery. Nearly 50 to 75% of all the women go through Post partum blues after they have delivered. It occurs in a womanwithin 5 – 10 days of their delivery. It can be said that a woman is going through the phase of post-partum blues when she feels low most of the times, cries constantly without apparent reason, feels sad, experiences anxiety, and feels extremely scared without valid reason.

Post-partum depression: post-partumdepression is the second stage and a far more serious condition than post-partum blues. This occurs only if the symptoms of post-partum bluesare not treated or taken care of. If the symptoms don't subside within time, it can turn into something serious. If the woman had post-partum depression before, the risk increases to 30% each pregnancy. 1 out of 10 mothers have experienced post-partum depression.

Postpartum depression symptoms vary according to different stages. During the severe stages of post -partum depression, mothers might experience symptoms such as suicidal ideations, depression, extreme anxiety, self-harm thoughts, delusions, etc.

Post-partum psychosis: post-partum psychosis is the last stage of post-partum depression and is considered extremely serious and the one which needs immediate medical attention. Only 2-3 among 1000 mothers experience this. According to the gynecologist, a pregnant experiences postpartum psychosis if they have episodes of depression in the past before the pregnancy, or if they have other mental disorders, such as OCD (obsessive compulsive disorder), PTSD (Post traumatic stress disorder) or severe insomnia in the past.If the subject had severe psychotic problems, such as schizophrenia or paranoia, in the past, then there are high chances of them developing postpartum psychosis. Symptoms of psychosis include severe agitation, confusion, feelings of hopelessness and shame, insomnia, paranoia, hyperactivity, rapid speech or mania.

Biological factors for Post-Partum Depression

During the pregnancy, steroid hormones such as estrogen and progesterone increases drastically throughout pregnancy. Once the placenta is out, there is an abrupt decrease of estrogen and progesterone.Women also experience lactational amenorrhea. Lactational Amenorrhea is the absence of menstruation in lactating mothers. It is a period of temporary infertility or postpartum infertility. It also hampers the process of ovulation. If ovulation does not happen, estrogen will not be increased there too. There's a peptide known as monoamine oxidase. This peptide hormone increases drastically during the postpartum state. This also causes the happy hormones such as norepinephrine, serotonin, and dopamine levels to drop. Because of this, there will be a problem with the coping up mechanism. Due to all these problems, there will be an imbalance in the hormonal levels and that causes postpartum depression.

Familial factors

According to the gynecologist, post-partum depression incepts from the hormonal issues but 90% of the disorder can be instantly tapered off if the family of the woman is supportive and the husband is co-operative. Nearly 75% of all the women who give birth suffer from post-partum blues and 90% of them are fine after 4 weeks. The main reason behind this is the family support during and after pregnancy, co-operative and empathetic partners. If the family isn't supportive, even post-partum blues can lead to post-partum psychosis. No treatment will respond completely and be 100% successful if the family isn't supporting and the husband isn't empathetic.

Individual factors

According to various studies, post-partum psychosis is very rare and only affects 5% of the women after giving birth. According to the gynecologist, psychosis is 100% sure if the lady had episodes of other mental traumas such as OCD, PTSD, Insomnia or serious disorders such as schizophrenia or bipolar disorder. The antipsychotic drugs or antidepressants will adversely affect the body because of which post- delivery there are high chances of such patients developing post-partum psychosis.

METHODOLOGY

Questionnaire and interview method is implemented in this study. A questionnaire of a mixture of 23 open ended and close ended questions about the psychological and physiological symptoms suffered, severity of the symptoms, familial factors, awareness, patriarchal factors, acceptance, co-operation, and medication was sent to 50 mothers of different ages and varying duration since their delivery. The questions include symptoms of all the three stages of PPD. It also includes questions for non-sufferers. These subjects include women who have deliveredtheir kids before 2 months to women who have 10-year-old children. The subjects had varying intensity of sufferance where few have just experienced some mild symptoms, and some have experienced full-fledged depression which is close to psychosis. A detailed face to face interview with Dr. Kalpana S Udupa, Gynecologist,about the various stages of post-partum depression, the biological reasons for the inception of PPD, the severity can reach, worst case experiences the doctor ever had, treatment for the disorder and her opinions about the role of the family and husband in the prevention or treatment of post-partum depression was also discussed.

FINDINGS AND DISCUSSION

After your delivery, did you feel depressed and low?

For this question, 19 subjects out of 50 said that they felt depressed and low occasionally. 16 subjects said that they felt depressed and low pretty much always. 15 subjects said that they never felt depressed or low. Depression and feeling low being the symptoms of postpartum blues are very common in 50 to 75% of all the women after their pregnancy. While some admitted that this depression was at a severe level, most of the subjects said that this depression was not at a severe level and was usually diminished after they felt that they were supported by their family and by their husbands.

Did you feel disinterested or irritated by the hobbies/activities you loved before your delivery? If yes, explain those hobbies/activities and your changed feelings towards them in detail.

For this question, most of the subjects answered saying thatthey did not have anyhobbies which they enjoyed before the delivery and did not enjoy after. Whereas some subjectsaccepted the fact that there were some hobbies which they enjoyed a lot before the delivery. Whereas, after they have delivered their child, they were no longer interested.

Few subjects said thatthey loved roaming outside before the delivery but did not, after they delivered. Some subjects said that they enjoyed roaming around with friends, going out with family, watching movies, using mobile phones which they don't find meaning in after they have delivered. When asked for the reason, some of the subjects say that the reason behind this is that since they are having their kid, their priorities changes and they are enjoying that phase and don't really care about other hobbies. That was the phase of their lives where they had to give their full concentration to their child. But some also say that they were not themselves anymore and did not really enjoy this process. There are mixed opinions on this question.

After your delivery, we're you often crying without any reason?
For this question 29 out of 50 subjects said that they occasionally, or sometimes cried without any valid reason. 11 subjects accepted the fact that they cried most of the times. 10 subjects said that they never cried without any reason. Crying without apparent reason is also one of the symptoms of postpartum blues. It can be subsided easily if the subjects have proper support from the family and their partners. Love care and affection are the main solutions for postpartum blues.

Did you ever feel that your husband loved just your kid and not you after the delivery?If yes, what are the circumstances which made you feel like that?
For this question, 60% of all the subjects accepted the fact that they did get the feeling that their husband loved their kid more than them after the baby was delivered. This statement in some situations is a fact. Husband and the family give importance to the wife only because of the kid. Once the kid is delivered, all the love and affection which they showed before the delivery is gone. This is one of the most important reasons which causes post-partum depression.

Did you ever get the feeling that your husband would leave you for another woman after your delivery without any reason? If yes, please elaborate on the circumstances which made you feel so.
For this question 20% of the subjects have accepted that they have felt that way mainly because of their physical changes post-pregnancy. But 80% of the subjects said that they have never had such feelings. Instead, they had complete faith on their husbands.

Did the change in your physicality post-delivery impact your mental state?
For this question, 32 subjects accepted the fact that the change in their physicality post-delivery impacted their mental state severely. They exclaimed that before the delivery, they were slim and better looking than what they are right now. On the other hand, 18 subjects out of 50 said that there was no relationship between their physical changes as well as their mental state. They said that they were unaffected by any of the physical changes after their delivery and have happily accepted their physicality.

Did you feel extremely vulnerable or weak, and felt a desperate need for protection from your husband without a valid reason?
For this question, 32 subjects said that they never felt extremely vulnerable or weak and never felt a desperate need for protection from their husbands without a valid reason. On the other hand, 18 subjects accepted the fact that they felt extremely vulnerable or weak and all ways felt a desperate need for protection from their husbands without a valid reason.

Did you ever feel like running away from everything and not own up to any of the responsibilities?
For this question 27 subjects said that they never felt like running away from everything, or not owning up to their responsibilities. But on the other hand, 23 subjects accepted the fact that sometimes they felt like running away from everything. From their family, from their children, from their responsibilities and not owning up to anything.

Did you ever get the thought of self-harm? If yes, what are the circumstances which lead you to such thoughts?
This is a question which is related to postpartum depression and psychosis. When this question was asked to the subjects, only five subjects accepted the fact that they sometimes got the thought of self-harm. Rest of the 45 subjects never went throughthe phase of self-harm or suicidal ideations. As suicidal ideations or self-harm ideation are the symptoms of postpartum psychosis, very less percentage of the women experience this post-delivery.

Did you feel useless or lonely whenever your family showed their concern about your kid and your husband, but not you?

For this question, 33 subjects exclaimed that they never felt that they were useless. Or lonely. The main reason behind this is because their partner and their family never disrespected them or just showed their concern about the kid and the husband and not them. But on the other hand, 17 subjects accepted the fact that sometimes they felt useless or extremely lonely. The main reason for this is because the family only showed concern towards the husband or the kids. Every time a relative came to the house and asks about the husband, or asks about the kid and not her, she felt useless and lonely.

Did you ever get irritated about the concept of the perfect ideal mother which everyone excepts you to be? Explain your thought process when this was expected out of you by everyone.

For this question, 60% of all the subjects accepted the fact that they were extremely irritated about others giving suggestions about being the perfect ideal mother and forgetting about the fact that they two are human beings who have emotions, and they two will have circumstances where they feel good, or sometimes bad as this whole phase of motherhood is new for them. On the other hand, 40% of the subjects stated that they did not really care about what others said, because they knew what they were doing was right, and they had confidence upon whatever they did, and knew that the way they were taking care of the kid was perfect. Their confidence was also coupled by the support of their family and partners.

Did you ever think of harming your child? Or hitting your child whenever he/she cried?

For this question, the 42 subjects said that they never thought of harming their children whenever he or she wept. They considered children crying as a normal thing and that never was bothersome to them. But on the other hand, 11 subjects said that they felt like hitting or harming their children occasionally. But7 subjects accepted the fact that they thought or hitting or harming their kid whenever he/she shouted, cried or threw tantrums.

Were you having constant nightmares after your delivery?

For this question 29 subjects said that they never experienced nightmares after the baby was delivered.
14 subjects said that they sometimes experienced constant nightmares depending upon how they felt.
But 7 subjects accepted the fact that on most nights, they had constant nightmares. That also had an adverse effect on their sleep, and few even suffered from mild insomnia. They were neither able to sleep peacefully nor stay up peacefully because of their constant nightmares. Their nightmares included, their kids getting kidnapped or killed, something bad happening to their husbands or them getting lost in an unknown place. This, again, is one of the symptoms of the first stage of postpartum depression, that is postpartum blues.

What are the other mental and physical traumas you experienced post- pregnancy?

Various subjects suffered from various problems and exclaimed about the different mental and physical traumas they suffered post pregnancy. Some of them are pain in their private region, fear of not being expressive, loss of confidence, extremely low energy, dependency, societal pressure, insomnia, anxiety, laziness, pain in their breastsespecially the nipple region becauseof constant breastfeeding, exasperation, whole body pain, weakness, exhaustion, nausea,joint pain, back pain etc. 10% of the subjects said that they never experienced any sort of physical or mental trauma. But 90% of all the subjects said that they experienced the above-mentioned mental and physical traumas.

Do you think that gender of the baby or patriarchy played an important role in your mental instability? Please elaborate.

For this question, only three subjects said that patriarchy had a role to play at the determination of their mental state. The main reason behind this is because their husbands and their family expected a male child, and they delivered a female child.

On the other hand, 47 subjects said that they never had to experience any sort of patriarchy, because their husbands and their family didn't care about the gender of the child and accepted the child wholeheartedly despite the child's gender.

After all your experiences, did you realize that you are/ were suffering from Postpartum depression? Explain in detail.

For this question, more than 60% said that they just had a lot of symptoms which they felt were not normal, but they did not realize the fact that they were undergoing postpartum depression. But on the other hand, people who knew about this condition realized the fact that they are going through postpartum depression.

When did you start seeing symptoms which you thought were far off from normality? (The symptoms of PPD)

For this question, 22 subjects said that they did not notice any symptoms of postpartum depression, which goes to show the fact that they did not suffer from postpartum depression at all. Two subjects have mentioned that they have suffered from postpartum depression post six months after delivery. 11 subjects have mentioned that they sufferedfrom post-partum depression within six months after the delivery. Whereas 15 subjects have mentioned that they have suffered from postpartum depression immediately after the delivery.

Did your family understand the problem and stand as a support system during this phase of yours?

For this question,22 subjects mentioned that their family did not understand the problem of postpartum depression and did not stand as a support system during this phase. This is because of lack of Education as well as the stereotypical thought about women being a perfect mother and non-complaining about anything.

On the other hand, 28 subjects have accepted the fact that their family, as well as their husbands, stood with them throughout the whole face of postpartum depression as a support system and understood their problem completely. This helped them to fight their ways out of postpartum depression easily.

Did your husband identify the problems you underwent clearly as Postpartum Depression or did it take him a lot more time to figure out PPD as a genuine problem which needed medication? Explain.

But this question 16 subjects said that their husbands did not understand that the problem they underwent was postpartum depression. Some subjects said that their husbands initially did not understand that the problem they were going through was postpartum depression. But after the subjects spoke about PPD then the husbands realized about it and then co-operated and helped them fight their way out. On the other hand, the rest of all the subjects happily exclaimed that their husbands understood the problem exactly as postpartum depression and helped them throughout. Husbandswere empathetic and helped the wives in all the problems they ever faced, which helped the subjects get out of postpartum depression in a much easier manner.

Did your family value your mental trauma as much as your physical problems?

For this question, 34 subjects said that their family valued theirme an health and the mental traumas they went through as much as their physical problems. Their family and husbands understood the fact that mental trauma can be catastrophic or even more than physical problems especially after giving birth to a baby. On the other hand, 16 subjects said that their family as well as her husbands did not value their mental trauma as much as their physical problems.The family or the husband did not understand the seriousness of the situation anddid not support them at their extreme phases. This left the subjects with no choice but to deal with all the traumas silently which, as they claim, also affected their overall well-being.

Are you getting medical assistance for PPD?

To this question,9 subjects said that they took some kind of medical assistance or psychiatrist help when they were suffering from postpartum depression. They exclaim that their lives had become miserable and doing the everyday work was also very difficult. Because of this medical assistance was extremely necessary and helpful.

On the other hand, 28 subjects said that, despite suffering from postpartum depression, they never went to a psychiatrist. The subjects were not aware or feared the social stigma which is attached to the psychiatrist and counselors. They feared that society would forever treat them as 'mad'.

Did your family support you in taking the help of a psychiatrist or did they resist at first? Please elaborate.
For this question, they had mixed opinions. Only four subjects said that they physically went to the psychiatrist and got the full support from their family. More than 30 subjects said that they didn't go to any psychiatrist as their families helped them through this crisis, which made them get out of postpartum depression easily.

Did your Gynecologist/Pediatrician brief you and your husband about the PPD phase which you are most likely to experience? Do you think it's necessary for the doctor to brief this possibility beforehand?
When this question was asked, more than 60% of the subjects said that there was none to guide them about PPD. Their gynecologist or pediatrician didn't guide them or their husbands about the possibility of PPD and its possible symptoms. 35 to 40% of the subjects say that their gynecologist or pediatricians guided them about postpartum depression and its outcomes which made it easier for the mothers and their husbands to deal with when they actually had to.

DISCUSSION

(Includes details about the treatment from a Gynecologist's point of view)
According to the gynecologist, the first stage, post-partum blues will taper off within 4 weeks of its inception. Most of the time, medications or counselling is not required to treat blues. Family support and self-determination is more than sufficient. Post-partum Depression, the second stage, depending upon the severity and the help of drugs and counselling, can be tapered off within 2-3 months. Even though some depression cases can be treated without medication, if the case is severe, drugs and medications are essential. The treatment protocol for post-partum psychosis patients has four divisions. Sedation, counseling, drugs and family support.

At this level, hospitalization is compulsory since the patients will either harm or kill themselves because of self-harm or suicidal ideations, or harm others. They are hospitalized and sharp objects are usually not kept around them. They are not let to see their kids since there are high chances that the patients will harm or kill their own kid. After hospitalizing them, the first step of the treatment to post-partum psychosis is sedation. The patients will be put under injections which will sedate and calm them so that they don't harm themselves or others. For this, the doctors usually use a drug called 'Lorazepam'. This increases the dopamine secretion. Throughout the process, they have to be carefully observed.

After this process, the patients are converted from injections to tablets. Some of the tablets used are tablet Olanzapine, Serotonin reuptake inhibitors, Norepinephrine reuptake inhibitors SNRI, SSRI which are a class of drugs. There are receptors to digest these drugs. As for a gynecologist, there are no laboratory tests to determine psychosis, a set of questions based on "post-partum depression analysis scale" is presented to the patients and based on that their condition is determined.

CONCLUSION

Post-partum depression, as discussed above, is one of the most common sufferings of the mothers in pretty much all the countries. Over 75% of all the women post-delivery suffer from either one to few symptoms of PPD. Nearly 40% of the mothers suffer from multiple symptoms of PPD at a mild severity level.

Multiple studies from the medical field have been conducted to understand the problem from a social perspective, biological perspective, and psychological perspective. After this study, the main conclusion we can arrive to is that

hormonal imbalance, familial factors and individual differences were the main factors which cause PPD. Post-partum blues gets healed automatically but depression should be treated with medicines and psychosis should be treated with psychotic medicines, antidepressants, counselling, hospitalization, sedation etc. According to the gynecologist, if other factorsthat are responsible for PPD are 50%, environment the woman lives in, her family, her husband takes up 50%. Her family's support during this stage, husband's co-operation, empathy, and extra care are the key factors in dealing with PPD. Whereas, even if the symptoms are mild, at a point of time if she feels that she isn't getting any support from family andcompassion, love, and case from thehusband during the stage of PPD, then blues can quite easily aggravate to psychosis and can become uncurable.

ABSTRACT

The present study investigates the expanding role of ChatGPT in developing the research interests and academic assignments. It presumes that such tools are relied upon by the students in their academic tasks. The study penetrates to understand the ways in which the students use ChatGPT, that significantly reduces their time spent on research and writing and the resultant high dependency on it over period of time. While doing so, the researcher also has taken into consideration the experiences and expectations of the student folks. The major focus of the study was also to understand the functionality of the tool, its drawbacks. This approach makes sure that the discussions are more of factual base rather than a generalised assumption. The present study is the result of the responses from 170 students, that provide a reasonable picture. The report majorly points at improved competence and better organisation of the concepts among the students. However, it also points out that there is increasing threat about the accuracy of the material, ethical implications and a over dependence on the tool. Hence the study, therefore, puts it on record that ChatGPT neither cannot a provide a complete solution in the academic assignments nor a immediate threat to the academic learning. The responsibility of using the tool in a critical manner improves the learning experience.

Keywords: ChatGPT Usage, AI in Education, Student Learning, Writing Assistance, Technology and Learning

INTRODUCTION

The growing presence of artificial intelligence in education is beginning to shape the way students engage with learning, research, and academic writing. One of the most used tools in this context is ChatGPT, developed by OpenAI. The ChatGPT in higher education has slowly become a companion that helps them with drafting, developing the concept and framing the reports. Hence the necessity to reflect upon the impact of such tools on academic environment has become an urgent matter. Furthermore, the concerns of accuracy of the information and the ethical issues of the research writing always remains a matter of concern in the educational scenario. The overdependence on the artificial intelligence further cripples the mind of the students and thereby the hampers the independent thinking, quality of work and academic integrity.

Scope of the Study

The present study focuses only on the experiences, perceptions, and encounters of student users and does not include the perspectives of educators or academic institutions. The study adopts a student centric survey to better understand the how the students use ChatGPT in their daily assignments and research related activities. The data were collected in a structured manner among 170 students from diverse background and disciplines that allowed the collection of wider perceptions. The findings, therefore, remain confined to this student-centric scope and are not extended to examine pedagogical or institutional practices.

Objectives of the Study

The present study is guided by the following objectives

- To investigate the level to which ChatGPT is used by the students in research and academic related activities.
- To understand the perspective of the students and the impact of AI on their efficiency in long term
- To identify the key benefits associated with the use of ChatGPT in student's academic projects
- To collect feedback and suggestions from the students to understand how Ais are to be aligned in better way in educational set up.

METHODOLOGY

The study adopted a survey methodology to understand the influences of ChatGPT on academic activities such as completing the projects and other academic engagements. This helped in the collection of the data in asubstantial manner from the students in a coherent manner. For the collection of data, a Google form was created and all the necessary demographic information, multiple choice questions and Lekeert- scale questions on how frequently and for what purposes student use ChatGPT were incorporated in it. The form also had questions on the benefits, concerns and limitations of AI. An open-ended section was provided so that students could express their views and suggestions. The form was circulated digitally through the student groups on WhatsApp to guarantee a wider participation.Participants were informed about the purpose of the study and assured that their responses would remain anonymous and confidential, and that participation was voluntary.

LITERATURE REVIEW

The recent upsurge in the innovation and accessibility of ChatGPT have prompted a thoughtful discussion within the academic contexts. The literature review tries to find out the research areas that focuses on ChatGPT impact on teaching and learning pedagogy as well as performance. In the research project "Language models are few-shot learners. Advances in neural information processing systems", Brown, T. B (2020). sheds light on the LLMs like ChatGPT and reports how the models are trained in generating human like text with the massive datasets. The potential usage that these models have in the research and academic field has raised concern in the academic circles.

It also views with a criticality the amount of academic integrity, the challenge on the critical thinking skills and the drastic transformation in the assessment practices (Luckin et al., 2016). The utilization of the ChatGPT for brainstorming ideas, encapsulate the ideas and upgrading the language is vastly rampant in the field of academia. (Cotton et al., 2023). But the misemployment of the same for outright plagiarism and the related ethical concerns accentuates the necessity for an immediate intervention in terms of clear strategies and policies (Deng & Tavares, 2023). Further, it also emphasises the urgency of investigation to understand how the long-term usage of ChatGPT affects the student's ability to put together the critical information and form their opinions efficiently. It is also necessary to investigate the potential impact on the on metacognitive skills, such as self-regulated learning and reflection (Zimmerman, 2002). The growth rapidity of these LLMs triggers the shift in pedagogical approaches, curriculum design and assessment patterns. The responsibility falls upon the educators to adapt to the AI tools in an efficient manner. (Luckin et al., 2018). The plethora of researches around the topic focuses on reviewing the benefits of and challenges in understanding of the AI and preparing the students to thrive in AI driven modern world.

Data Interpretation and Analysis:

Gender Demography

The gender distribution among the 170 respondents indicates that a majority, 59.4%, are female, while 40.6% are male. This suggests that female participants were more engaged in this survey or study compared to their male counterparts. Although there is a noticeable difference in participation, the ratio is not drastically imbalanced.

Student Responders

The conduction of the survery maes a clear indication that, 99.4%, are from the category of the students. While the remaining percentage comes under the "others" category. This reestablishes the fact that the survey has been taken in a desired direction and it has accurately captured the experiences and viewpoints of the students.

Famailiaruty with ChatGPT

Throught the survery it is found that a significant bulk of respondents, approximately 84%, have had a exposure with AI tools like ChatGPT. This percentage is inclusive of the 41.8% that use artificial intelligence regularly and an equivalent ratio who use them occasionally.An interesting revelation of the study tells that there is both progress and gaps. The survey points to about 14.1% of respondents with less exporsure to AI tools. The survey hints that even after ChatGPT is used by majority, the degree of familiarity varies. Hence, it is required that a proper structured workshop or training module would help the beginners and advanced startergies will benefit the experienced ones.

Usage Frequency

It is revealed through the survey of 170 sample count that for completing the academic assignment and generating the ideas around 15.3% students use ChatGPT on a regular basis. The students who use it weekly arearound 27.1%. A significant percentage of 34.1% resort to ChatGPT occasionally, when they have any block in understanding the concepts. This suggests that though majority of the students are familiar with ChatGPT, the degree of usage varies, and this gap gives an opportunity to train them to use it in a meaningful way in writing, research, and learning new concepts.

ChatGPT for writing or learning purposes

Around 41.2% of respondents pointed to their reliance on ChatGPT, for generating ideas for academic assignments which emphasises its role in content creation. The AI is used by 35.9% respondents to get clarifications on complex topics thereby emphasizing, ChatGPT's role in understanding the concepts. It is also understood that it is used for a smaller number of respondents for improving vocabulary, grammar or syntax. A 11.8% of respondents, rarely use it for learning. Overall, the data reflects ChatGPT's strongest utility in academic brainstorming and topic comprehension rather than mechanical language improvement.

Does it enhance or make student a dependent

Most of the student percentage, that is 42.9%, pointed out in the survey that they attempt to write independently even though they understand the helpfulness of ChatGPT. This brings to the core the point that still many students believe that AI is a helpful tool and not an absolute system. The study showed that 21.8% of the respondents feel that the ChatGPT enhances their writing abilities which indicates that students are learning new skills from the AI and it has developed their learning process. 31.8% of users acknowledged that the use of ChatGPT decreases their capacity for independent thinking and would invest more time in learning. So, this brings us to the conclusion that only a small number is totally dependent upon AI heavily, whereas the others use it with a wise decision.

Evaluation of the Info collected

It is understood by the survey that 14.7% people completely trust the information curated by ChatGPT.57.6% believe in the information but would like to check important details, which indicates a sceptical but confident attitude towards AI-created information. 20% use ChatGPT but doubt its reliability, which is to say that they are aware of its potential but are sceptical. 7.6 percent trusts the information presented, which indicates great doubts about the accuracy.The results indicate that people use ChatGPT to write, but majority of them have a moderate position using it and verifying the information and critically assessing it. This points out the significance of AI literacy and why users should check AI generated information against other reliable sources to achieve accuracy and trustworthiness

ChatGPT for Academics - is it a Dishonest Practice

Only 18.2% of respondents said they use ChatGPT regularly, and 40.6% said they do so on occasional basis. This suggests that a good portion of the student body engages in some form of AI-assisted academic dishonesty. 25.3% have not used AI for the same purpose, but have contemplated doing so, indicating that the ethical issue related to the use of AI in academics is ubiquitous. 15.9% admitted that they have never used ChatGPT dishonestly, which is a smaller, ethics-conscious group. Results indicate that the issue of academic dishonesty is becoming increasingly problematic with the availability of AI tools. ChatGPT is used responsibly by some students. The evidence demonstrates that more specific guidelines, AI literacy initiatives, and academic policies should be implemented that would encourage responsible AI usage in education and testing.

Impact of time spending on Chat GPT

Out of the 170 survey participants, 34.1% reported that ChatGPT has drastically decreased the time spent onvarious activities due to AI streamlining their workflow. A large percentage (54.1%) believe thatit has, at least in part, reduced the time spent on these activities; thus, although AI increasesproductivity through efficiency, users still must put in some separate effort to be successful.However, just over 9.4% of respondents feel that ChatGPT has had no effect on their usage ofresearch or writing, suggesting they use ChatGPT very little, if at all. Finally, a very smallnumber (2.4%) say using ChatGPT has increased their desire to learn more about research andwriting, demonstrating that AI can also act as a catalyst for increased participation and learning.The results indicate that most survey respondents view ChatGPT to be a time-saving resourcein research and writing. Many participants believe they can become more effective, but it isimportant that users combine AI assistance with the use of independent learning to continueimproving their research and analytical skills.

Different ways that students use Chat GPT

35.3% of the 170 people who took part in the study use ChatGPT to improve clarity,tone, or style. This is the most common reason people use AI to help them write. 24.1%use it to improve their vocabulary, which means that a lot of people want to learn newwords and ways to say things. 15.9% of people use ChatGPT to fix their grammar,which shows that fewer people rely on AI to improve their grammar. Interestingly around 24.7% of students do not use ChatGPT to improve their writing at all. This suggests that the students still have conventional methods of writhing assignments. The data shows that the pupils use it mostly to improve their writingstyle andvocabulary.

Dependence on Chat GPT

Out of 170 respondents, 44.7% said they use ChatGPT for certain tasks only, which emphasizes that AI is not used for many tasks. The student's percentage who uses it only sometimes is about 30.6% and it clearly states that AI is a useful tool but not a necessary tool. 14.1% said they do not rely on ChatGPT, while around 10.6% said they do rely on it. Overall, the data shows that most people who participated in the survey use the ChatGPT in some way or the other to come up with new ideas, however most of the students try to keep a balanced approach and only a small number of students are dependent on it.

Reduces stress or adds new pressures

Out of 170 respondents of the survey 31.2% stated that ChatGPT reduces their academic stress which assures that AI is an valuable asset to manage the academic burden and improve efficiency. And 38.2% responded that though it helps them in reducing their stress level, it also creates a concern on ethical usage. Adding to the survey, around 27.1% reported that ChatGPT has no actual impact on their stress levels.Interestingly a small number of 3.5% students mentioned that ChatGPT does increase their stress due to fear of over dependence and ethical concerns. This highlights the conflict the students undergo on relying on the AI too much. The study suggests that although ChatGPT can be seen as a stress-reducing tool, the ethical concerns remain major issue for many users leaving a permanent question on its role in academia.

FINDINGS AND SUGGESTIONS

Enhancing accuracy and reliability

- The study pointed that many users pointed to the need for more accurate responses and the feature to properly check the facts and information.
- Some of the users recommended that ChatGPT should also cite sources for right credibility, specially while working for an academic purpose.
- They also highlighted the differences found in responses which are generated by AI and responses which are found on Google. This highlights that ChatGPT does not always align with widely accepted facts.

Improved user interface and experience

- There were many requests for a simpler and more attractive UI.
- There were some responses where users mentioned the need to reduce excessive information and provide a shorter and more concise version when needed.
- Some users suggested to include features like self-editing tools and interactive writing challenges to make the learning process more engaging.

Voice and Visual features

- Large number of users have expressed their interest in voice search, voice translation, and voice typing that will make the interaction more user-friendly and portable.
- There were a few requests regarding camera-based input, which will help in reducing typing workload.
- There were also suggestions regarding the enhancement of learning by introducing image generation and animation-based explanations.

Accessibility and Affordability

- There were a portion of users that felt ChatGPT should be provided without an internet connection to make it more accessible.
- The study shows several suggestions asking for the subscription costs to reduce and make the advanced features available to more users.

Ethical concerns and academic integrity

• There were a few users who raised concern about the dependence on AI in education field and requesting AI to consider the ethical implications while answering.

• The responses suggested that AI should be used for learning instead of direct plagiarism and there should be proper citations for the research.

Concerns Expressed

1. Over- dependence AI: Some of the users have mentioned that the frequent use of ChatGPT have reduced their critical thinking and research skills.
2. Incorrect or misleading answers: There were some users who got inaccurate information, which affected their assignments and research negatively.
3. Lack of personalisation: There were some responses that wanted AI to adjust it's responses based on user intent instead of just providing generic answers.

CONCLUSION

The study makes it clear that ChatGPT has become a helpful tool for the students with reference to their research and academic activities. As it provides quick answers and helps them organizeideas in aeffective manner, the students use it when they are running short of time. At the same time the concerns like the accuracy of information and ethical usage and the high dependency on it are worth noting. It is important not to see the ChatGPT as completely good or bad. Its usefulness and effectiveness is dependent on the wise usage of it. If it is used as a support tool, it can guide learning, explain concepts and improve writing. However, too much reliance on it may affect the ability of the student to think critically and independently. Overall ChatGPT can support academic learning in a positive way so that the students use it to enhance and better their learning experience.

ABSTRACT

The present study examines the short-term financial performance and liquidity position of V.O.Chidambaranar Port Authority, Tuticorin over a period of eleven years from 2014–15 to 2024–25. As a major port contributing significantly to India's maritime trade, efficient management of working capital and liquidity is essential for its operational stability and financial sustainability. The study aims to analyze short-term financial performance through working capital trends, working capital ratios, and components of working capital. The research is based on a case study approach, utilizing secondary data collected from the port's annual reports, including balance sheets and profit and loss accounts. Various financial ratios such as working capital turnover ratio, current assets turnover ratio, current ratio, liquid ratio, cash ratio, debtors turnover ratio, average collection period, creditors turnover ratio, average payment period, and cash turnover ratio were employed for analysis. In addition, statistical tools like mean, standard deviation, and compound annual growth rate (CAGR) were used to support the findings. The study reveals that the port consistently operated with negative working capital, indicating reliance on current liabilities. While efficiency in asset utilization and receivables management has improved in recent years, liquidity ratios remain weak. The findings highlight the need for better working capital management and improved liquidity planning. Overall, the study concludes that although the port demonstrates operational efficiency, strengthening liquidity is essential for ensuring long-term financial stability.

Key words: Liquidity position, working capital, current assets, current liabilities, current ratio, liquid ratio, debtors, creditors, turnover

INTRODUCTION

Financial performance analysis is essential for evaluating the efficiency and stability of an organization, particularly in capital-intensive sectors like ports. Among various aspects of financial performance, the liquidity position plays a crucial role as it reflects the organization's ability to meet its short-term obligations and ensure smooth day-to-day operations. Adequate liquidity is necessary to maintain operational continuity, while excessive liquidity may indicate underutilization of resources. In the context of V.O.Chidambaranar Port Authority, analyzing liquidity becomes important due to the scale of its operations, volume of transactions, and the need for effective working capital management. The port must maintain an optimal balance between current assets and current liabilities to ensure both financial stability and operational efficiency. This study focuses on assessing the liquidity position of the port using key indicators such as current ratio, liquid ratio, cash ratio, and working capital turnover ratio. By examining these measures, the study aims to understand how effectively the port manages its short-term finances and how liquidity influences its overall financial performance. The short-term financial performance of V.O.Chidambaranar Port Authority is analysed for the study period of 11 years spanning from 2014-15 to 2024-25. The short-term financial performance of V.O.Chidambaranar Port Authority reflects its ability to efficiently manage working capital, maintain liquidity, and meet its immediate financial obligations. As a major port undertaking diverse maritime and logistics operations, the effective management of short-term assets and liabilities is crucial to ensure smooth day-to-day functioning and operational stability. This analysis focuses on key components such as current assets, current liabilities, liquidity position, and working capital management, which collectively determine the port's short-term financial health. Indicators like current ratio, quick ratio, cash position, and composition of current assets provide insights into the port's capacity to honour short-term commitments without financial strain. Given the dynamic nature of port operations, which involve continuous cash flows, receivables, and short-term investments, evaluating short-term financial performance helps in understanding how efficiently the port utilizes its resources, controls its obligations, and sustains operational efficiency. A strong short-term financial position not only ensures liquidity but also supports long-term growth and financial stability. Thus, the study of short-term financial performance is essential to assess the operational efficiency, liquidity management, and overall financial discipline of V.O.Chidambaranar Port Authority.

LITERATURE REVIEW

Rajasekar T., & Aravanan S. (2011)studied financial performance analysis of Tuticorin Port Trust. The study evidenced that the port was in comfortable zone in terms of liquidity position during the study period. In particular, its cash position ratio and inventory turnover ratios were good. The study concluded that overall the financial position of Tuticorin Port was good during the study period.Muni Z.H., et al (2014)studied operational and financial performance of Chittagong Port Authority and the Maritime and Port Authority of Singapore. The study found that MPA performed better than CPA in terms of operational perspective. From the profitability measures, especially from ROCE, ROA, ROE and NPM of MPA it was very clear that even for a container port, investment in financial assets played a very significant role in defining the organizations overall financial health. Prakash L., & Pandurangan G. (2016)analysed financial performance of Cochin Port Trust. The study found that the liquidity ratios of CPT was satisfactory at present i.e., 2015-2016 but it is above the requirements during the years 2013-2014 and 2014-2015. The activity ratios of CPT also showed that the collection period is satisfactory. The profitability ratios showed that the overall performance of CPT is in a satisfactory position. Bojana Vukovic et al. (2020) examined the determinants of profitability in logistics companies across Balkan countries. The study identified that company size, asset tangibility, liquidity, and asset turnover ratio significantly influenced profitability, while emphasizing that efficient planning and control of logistics activities are crucial for improving financial performance. The authors found that efficient asset utilization and optimal liquidity management positively contributed to profitability.

Gayathri C., et al (2022) studied how port performance depended on various interdependent factors. The study found that, six criteria affecting the operational performance and six financial criteria were identified. The debt coverage ratios turned out to be the most important, while the liquidity ratios were the least important. The six operational criteria had almost similar importance. A consistent overall performance by the Ennore Port, except during one financial year. Hermawan A., et al (2023) analyzed operational costs and financial performance for 2021-2022 at the Karimun Regency Port Business Entities. The results of the research work showed that the operational cost budget level was not efficient. Financial performance of the Karimun Regency Port Business Entity in 2021-2022 using profitability ratio analysis was satisfactory. Liwaul., Dali N., &Sahrun (2023)analyzed the financial health of PT Pelabuhan Indonesia (PT Pelindo) after the merger with a liquidity and profitability assessment. The study concluded that the Indonesian port company (PT Pelindo), after the merger from 2021 to 2023 suggested that it needs to implement a liquidity strategy through financial restructuring with a focus on managing current assets and current liabilities, increasing cash efficiency, accelerating collections, and reviewing capital structure to ensure liquidity remains adequate and reduce liquidity risk, especially with the downward trend in cash ratio which could threaten the company's stability in the future.

Jatmiko B., et al (2024), found that the company was solvable because the total assets owned by the company were able to cover its debts. company; PT. Jet-Logistik showed that the company was not profitable because the profits obtained from the capital used for operations did not produce profits that were lower than the company's internal average. Muthumani S.S.M., and Senthilnathan N. (2025) studied financial analysis of Kamarajar Port Limited. The study found that KPL demonstrated strong profitability, with ROE peaking at 18.55% (2021–2022) andROCE improving steadily to 20.31% (2023–2024), alongside a robust interest coverage ratio (11.82), indicating effective debt servicing capability. Pavithra & Deepa (2026) analyzed the productivity and financial performance of selected major ports in India, namely Jawaharlal Nehru Port Trust (JNPT) and Visakhapatnam Port Trust (VPT).The study found that while certain performance indicators showed stability, others exhibited significant variability across the ports. The ANOVA results indicated that there are significant differences in several productivity and financial measures between the selected ports. The study emphasized the importance of efficient resource utilization, cost control, and effective financial management in enhancing port performance and ensuring long-term sustainability.

Objectives

The study is made with the following objectives,

- To study short-term financial performance through the working capital trend and working capital ratios and
- To analyse short-term financial performance in terms of components of working capital.

METHODOLOGY

It is a case study in nature. V.O.Chidambaranar Port Authority is one of the major ports in India located in the state of Tamilnadu. It helps the economy to a larger extent through facilitating for import and export businesses. Hence, the researcher has taken the port for the study and analysed short-term financial performance. The period of the study restricted to recent 11 years spanning between 2014-15 to 2024-25. The researcher required financial data, i.e., Profit and Loss account and Balance Sheet of the port. These data were retrieved from the annual reports of the port of the respective years. These annual reports were collected from official websites of the port. The researcher primarily applied financial ratios to bring out the short-term financial performance of the port. These ratios consist both working capital ratios and rations related to components of working capital such as working capital turnover ratio, current assets turnover ratio, current ratio, liquid ratio, cash ratio, debtors turnover ratio, average collection period, creditors turnover ratio, average payments period and cash turnover ratio. Apart from these financial ratios, the researchers also applied mean, standard deviation and compound annual growth rate as statistical tools.

RESULTS AND DISCUSSION

The paper has been analysed the short-term financial performance of V.O.Chidambaranar Port Authority over a period from 2014–15 to 2024–25. This section of the paper presents the results of the above. It provides the results of working capital and its trend, working capital ratios namely, working capital turnover ratio, current assets turnover ratio, current ratio, liquid ratio, cash ratio (absolute liquid ratio) and ratios related to components of working capital such as debtors turnover ratio, average collection period, creditors turnover ratio, average payments period and cash turnover ratio. Table 1 clearly shows that the working capital position of V.O. Chidambaranar Port Authority remained negative throughout the study period, indicating that current liabilities consistently exceeded current assets. The average working capital stood at -₹106.39 crore, reflecting a persistent liquidity imbalance. Although both current assets and current liabilities increased steadily over time, the growth of current liabilities (CAGR 5.77%) outpaced that of current assets (CAGR 5.16%), which is the primary reason for the continuous negative working capital position. In the initial years, there was some improvement, with the deficit reducing from -₹114.59 crore in 2014–15 to -₹81.70 crore in 2016–17, suggesting better short-term financial management. However, this improvement was short-lived, as the deficit widened again in 2017–18, followed by fluctuations in the subsequent years. A notable improvement occurred in 2019–20, where the deficit sharply narrowed to -₹9.66 crore, indicating near balance between current assets and liabilities. This may have been due to better control over liabilities or an increase in current assets during that year.

However, from 2020–21 onwards, the working capital position deteriorated significantly. The deficit increased steadily, reaching -₹104.27 crore in 2021–22, -₹159.11 crore in 2022–23, and peaking at -₹267.96 crore in 2024–25, indicating a substantial mismatch and increasing dependence on short-term liabilities. The percentage trend further reflects this instability, with positive growth in the early years and a sharp improvement in 2019–20 (88.16%), followed by steep negative trends in later years, especially in 2020–21 and 2021–22. Although there was a temporary recovery in 2023–24, the trend again turned negative in 2024–25, confirming continued volatility. Overall, the analysis indicates that the port faces persistent liquidity constraints and inconsistent working capital management, which may affect its ability to meet short-term obligations efficiently. This highlights the need for better alignment between current assets and liabilities and improved management of short-term financial resources. Table 2 shows that WCTR concerned, during the initial years, the ratio showed a declining trend from -4.07 times in 2014–15 to -7.32 times in 2016–17. It showed that the port was generating higher operating income relative to its negative working capital. In 2017–18, the ratio improved slightly to -5.39 times. In 2018–19, the ratio stood at -6.37 times. A significant deviation was observed in 2019–20, where the ratio sharply dropped to -60.37 times. It was mainly due to the very low negative working capital (-₹9.66 crore) combined with substantial growth of operating income. It was an exceptional situation where a small working capital base supports relatively high income. In the subsequent years, the ratio continued to fluctuate. It went to -19.81 times in 2020–21, but then stabilizes around moderate levels such as -5.72 times (2021–22) and -4.63 times (2022–23). In 2023–24, the ratio stood at -8.50 times, followed by an improvement to -3.78 times in 2024–25, which was one of the better positions in recent years. The mean working capital turnover ratio stood at -11.99 times. It showed that, on average, the port generated nearly 12 times its operating income relative to negative working capital. The wide fluctuations in the ratio suggested inconsistency in working capital utilization and operational efficiency.

The Current Assets Turnover Ratio (CATR) of the port showed moderate performance with noticeable fluctuations during the study period. The ratio ranged from 0.74 times in 2017–18 to 1.20 times in 2024–25, with an average of 0.97 times, indicating a fairly balanced utilization of current assets. In the initial years, the ratio remained stable, increasing slightly from 0.96 times in 2014–15 to 1.00 times in 2016–17, reflecting efficient use of current assets to generate income. However, a sharp decline was observed in 2017–18 (0.74 times), mainly due to a significant rise in current assets—particularly loans, advances, and deposits—without a corresponding increase in operating income. The ratio recovered in 2018–19 (0.96 times) and improved to 1.00 times in 2019–20, as current assets normalized and aligned better with income generation. It declined again in 2020–21 (0.86 times) and 2021–22 (0.91 times) due to a

slight increase in current assets, indicating lower efficiency. From 2022–23 onwards, the ratio showed a positive trend, rising to 1.08 times, followed by 0.99 times in 2023–24, and reaching its highest level of 1.20 times in 2024–25. This improvement indicates enhanced efficiency in utilizing current assets to generate higher operating income in recent years. The Current Ratio of V.O.Chidambaranar Port Authority remains consistently below 1 throughout the study period. This position indicated a weak short-term liquidity position throughout the study period. The ratio ranged from a low of 0.76 times in 2024–25 to a high of 0.98 times in 2019–20, with an overall average of 0.87 times. In the initial years, the ratio showed a gradual improvement from 0.81 times in 2014–15 to 0.88 times in 2016–17. It showed a slight strengthening of liquidity position. It remained relatively stable in 2017–18 and 2018–19, existing around 0.87 to 0.88 times. A notable improvement was observed in 2019–20 with the CR of 0.98 times, where the ratio came closest to 1, it indicated a near balance between current assets and liabilities. However, this improvement is not sustained during the rest of the study period. The current ratio declined again in subsequent years, it went down to 0.96 times in 2020–21, 0.86 times in 2021–22, and it decreased further to 0.81 times in 2022–23, since during the period current liabilities of the port increased significantly. Although there was a slight recovery in 2023–24 (0.90), the ratio dropped sharply to 0.76 in 2024–25, due to a sharp decrease in current assets during the year. It made the lowest level of current ratio during the study period. The mean value of the ratio stood at 0.87 times, it indicated that throughout the study period current liabilities occupied higher proportion than current assets.

The Liquid Ratio (LR) of the Port showed a generally satisfactory liquidity position, as the ratio remained around or slightly above 1 for most of the study period. The liquid ratio ranged from 0.94 times in 2014–15 to 1.12 times in 2019–20 and 2020–21.Overall average liquid ratio recorded at 1.04 times. It showed that liquid assets were broadly sufficient to meet liquid liabilities. In the initial years, the ratio improved from 0.94 times in 2014–15 to 1.05 times in 2016–17. It indicated strengthening liquidity position. This positive trend continued in the subsequent years and reached 1.09 times in 2017–18 and further increased to 1.11 times in 2018–19. The ratio attained its peak level of 1.12 times in both 2019–20 and 2020–21. It showed a strong ability to meet short-term obligations using liquid assets. However, in the later years, a slight decline was observed in liquid ratios. The ratio fell down to 0.99 times in 2021–22 and 0.98 times in 2022–23, it showed marginal pressure on liquidity position. Although there was a recovery in the ratio, as it increased to 1.05 times in 2023–24.The ratio again dipped to 0.98 times in 2024–25, slightly below the ideal level. The Cash Ratio of the Port remained consistently very low throughout the study period. This ratio ranged from 0.01 times to 0.08 times, with the mean value of of 0.03 times. This indicates that only a small proportion of current liabilities is covered by cash and bank balances. In the initial year (2014–15), the cash ratio stood at 0.08 times, but it showed a declining trend in subsequent years, it reached to 0.04 in times 2016–17. Although there was a slight improvement in cash ratio in the year 2017–18 and stood at 0.05 times. The cash ratio again declined in later years. A significant drop was observed in the year 2019–20 and 2020–21 (0.02 times), followed by the lowest levels of 0.01 times during 2021–22, 2022–23, and 2024–25.

Table 3 indicates that the Debtors Turnover Ratio (DTR) of V.O. Chidambaranar Port Authority reflects moderate efficiency with a clear improvement in recent years. The ratio ranged from 3.89 times to 8.83 times, with an average of 5.74 times. In the initial years, the ratio fluctuated, starting at 4.78 times in 2014–15, declining to 3.89 times in 2015–16, and then improving to 5.33 times in 2016–17, indicating inconsistency in collection efficiency. During 2017–18 to 2019–20, the ratio remained relatively stable between 4.73 and 5.36 times, showing moderate collection performance, though 2018–19 (6.19 times) reflected better recovery. A decline was observed in 2020–21 (4.37 times), possibly due to delays in receivables collection. However, from 2021–22 onwards, the ratio showed a strong upward trend, reaching 6.28 times, then 5.73 times in 2022–23, and peaking at 8.83 times in 2023–24, the highest during the study period. Although it slightly decreased to 7.66 times in 2024–25, the ratio remained significantly higher than earlier years. Overall, the increasing trend in recent years indicates improved efficiency in receivables collection and better credit management practices, contributing positively to the port's financial performance. The Average Collection Period (ACP) of the port exhibited considerable fluctuations over the study period, indicating variations in receivables management efficiency. The ACP ranged from 41.32 days to 93.85 days, with an average of 67.02 days, suggesting that the port generally took about two months to realize its dues. In the initial years, the collection period was relatively high—76.31 days in 2014–15 and rising to 93.85 days in 2015–16—reflecting weaker collection efficiency.

Subsequently, there was improvement in 2016–17 (68.48 days), followed by fluctuations in the following years. The ACP reduced significantly to 58.95 days in 2018–19, indicating quicker realization of receivables, but again increased during 2019–20 (68.14 days) and 2020–21 (83.56 days), possibly due to operational challenges or external factors affecting payment cycles. From 2021–22 onwards, the collection efficiency improved steadily, with ACP declining to 58.16 days and further to 63.65 days in 2022–23.A strong positive trend was observed in the later years, with ACP reaching its lowest at 41.32 days in 2023–24, showing highly efficient collection practices. Although there was a slight increase to 47.66 days in 2024–25, the collection period remained comparatively low, indicating improved and stable receivables management in recent years.

The Creditors Turnover Ratio (CTR) showed extreme fluctuations and unusually high values over the study period. This ratio ranged from 3.71 times to 175.78 times over the study period, with an overall average of 57.66 times. In the initial years, the ratio remained relatively moderate, with 5.37 times in 2014–15 and 3.71 times in 2015–16. These results showed that the proportion of creditors was higher compared to credit purchases during such period. However, from 2016–17 onwards, the ratio increased sharply to 17.83 times and further to 20.84 times in 2017–18, they showed that the proportion of credit purchases was low and the same shows faster settlement of dues. A significant increase was observed in the year 2018–19 (102.46 times) and 2019–20 (175.78 times), they are exceptionally high values. These spikes are primarily due to the very low level of creditors in those years rather than a proportionate increase in purchases. This indicates that the port was paying off its obligations almost immediately, leaving very little outstanding payable or had low credit purchase of services. In the subsequent years, although the ratio declined from these extreme levels, it still remained relatively high, such as 39.09 times in 2020–21, 65.36 times in 2021–22, and 73.60 times in 2022–23. The ratio continues at elevated levels in 2023–24 (59.26 times) and 2024–25 (70.96 times), indicating consistently quick payments to creditors.

The Average Payments Period (APP) of the port recorded a sharp declining trend over the study period. It showed that the port increasingly adopted a policy of faster payments to creditors. The APP ranged from a high of 98.27 days in 2015–16 to a low of 2.08 days in 2019–20, with an overall average of 21.91 days. It showed that the port took little less than a month to pay off its dues to creditors averagely during the study period. In the initial years, the APP was relatively high. This ratio was at 67.94 days in 2014–15, it showed that the port took little more than two months to pay of its dues to creditors and it increased to 98.27 days in 2015–16, it showed that the port paid of its dues to creditors in more than three months during the year. It showed that the port was utilizing a longer credit period and delaying payments to some extent. However, from 2016–17 onwards, the APP declined sharply to 20.47 days, followed by further reductions to 17.51 days in 2017–18. The port decreased its payment period drastically during the period of time. A drastic drop was observed in average payments period of the port during the year 2018–19 (3.56 days) and 2019–20 (2.08 days), more interestingly the port paid off its dues in few days. It indicated that the port was making almost immediate payments to suppliers, leaving minimal outstanding liabilities. Although there was a slight increase in 2020–21 (9.34 days), the APP remained relatively low in subsequent years, ranged between 4 days to 6 days from the years 2021–22 to 2024–25.

The Cash Turnover Ratio of V.O.Chidambaranar Port Authority showed a strong upward trend with significant fluctuations over the study period. it indicated changes in the utilization of cash relative to operating income. The ratio ranged widely from 9.56 times in 2014–15 to a peak of 106.54 times in 2021–22, with a mean value of 42.97 times, it reflected high efficiency in cash usage. In the initial period, the ratio increased steadily from 9.56 times (2014–15) to 20.71 times (2016–17). It showed improved utilization of cash resources. However, a temporary decline was observed in 2017–18 (13.85 times), which showed a relative increase in cash balances or slower income growth during that year. The ratio improved again in 2018–19 (18.37 times), showed recovery in efficiency. A major shift in cash turnover ratio occurred from 2019–20 onwards, where the ratio raised sharply to 40.22 times, followed by 50.87 times in 2020–21, it showed that a much smaller amount of cash was supported a higher level of operating income. This trend continued and the ratio recorded its peak at 106.54 times in 2021–22, it happened mainly due to very low cash and bank balances (₹5.60 crore) combined with sustained income levels. This indicated extremely high efficiency but also very low cash reserves. In the later years, although the ratio declined from its peak, it remained relatively high at

77.05 times (2022–23), 49.50 times (2023–24), and 71.64 times (2024–25). These values indicated that the port continued to operate with minimal cash holdings while generating substantial income, maintaining high turnover.

CONCLUSION

The present study on the liquidity position of V.O.Chidambaranar Port Authority is of considerable importance as it provides a comprehensive understanding of the port's ability to manage its short-term financial obligations and maintain operational stability. In a capital-intensive sector like ports, effective liquidity management is essential for ensuring smooth functioning, financial discipline, and sustainable growth. The study evidenced that the port has been operating with consistently negative working capital, indicating a reliance on current liabilities to finance its operations. Although there were intermittent improvements, particularly in 2019–20, the overall trend shows increasing pressure on liquidity. The working capital turnover ratio and current assets turnover ratio indicate that the port has been able to utilize its resources efficiently to generate income despite liquidity constraints. However, the current ratio, liquid ratio, and cash ratio reflect relatively weak liquidity levels, suggesting potential challenges in meeting short-term obligations. At the same time, the analysis highlights improvements in receivables management, as evidenced by the rising debtors turnover ratio and declining average collection period in recent years. Conversely, the creditors turnover ratio and average payment period suggest a tendency to delay payments, possibly as a liquidity management strategy. The cash turnover ratio shows fluctuations, indicating inconsistent cash utilization. In conclusion, while the port demonstrates strong operational efficiency and improving collection practices, its liquidity position remains a matter of concern due to persistent negative working capital and relatively low liquidity ratios. Therefore, it is essential for the port to adopt effective working capital management strategies, improve liquidity levels, and maintain a balanced approach between current assets and liabilities to ensure long-term financial stability and sustainability.

ABSTRACT

Artificial intelligence (AI) is increasingly embedded in crop insurance to automate yield estimation, loss assessment, premium pricing, fraud detection, and claims settlement, but its use in high-stakes welfare and compensation decisions raises concerns about transparency, fairness, accountability, privacy, and distributive impacts, particularly for smallholder and marginal farmers. This study aimed to analytically examine existing AI governance frameworks relevant to crop insurance and synthesize the principal challenges and opportunities for implementing ethical and accountable AI in this domain, drawing on the Technology Acceptance Model, Institutional Theory, Algorithmic Governance Theory, Risk Management Theory, and Responsible Innovation. A qualitative, interpretative, non-empirical design was employed, combining a systematic literature review with computational text analysis of English-language scholarly and policy sources published between 2018 and 2025 and selected using structured searches and governance-focused inclusion criteria. Extracted textual elements (titles, abstracts, keywords, and central argumentative sections) were analysed via iterative coding and thematic synthesis and triangulated with Natural Language Processing outputs, including Latent Dirichlet Allocation topic modelling and Principal Component Analysis (PCA). Topic modelling identified seven clusters dominated by AI governance and ethical oversight with fairness and institutional accountability (21.3%), followed by crop data transparency and protective safeguards (15.5%), ethical and equitable assessment practices (14.7%), systemic gaps and farmer-centric adoption constraints (14.6%), automated risk

management models and theoretical framings (11.6%), explainability and ethical decision-making (11.3%), and regulatory accountability mechanisms (11.0%). PCA revealed three principal dimensions—regulatory–ethical governance (24.99% variance), operational decision and risk-processing functions (17.92%), and socio-institutional adoption and inclusion factors (16.04%)—forming clusters around governance frameworks, AI-enabled insurance decision systems, and socio-technical adoption challenges. Overall, AI's efficiency gains in crop insurance appear contingent on operationalizable governance that embeds ethical-by-design, explainable AI, and strong data governance, supported by institutional capacity building and stakeholder engagement; future research should empirically validate these insights through field-based and comparative studies and develop adaptive, context-specific governance models aligned with fairness, inclusivity, and long-term resilience.

Keywords : AI governance, Crop insurance, Ethical AI, Regulatory frameworks

INTRODUCTION

Artificial Intelligence (AI) is fundamentally altering decision-making processes within the agricultural sector, especially regarding the design and implementation of crop insurance schemes. Robust AI governance is essential to promote transparency, fairness, accountability, and ethical deployment of AI-driven tools for risk assessment, premium calculation, and claims settlement. This study provides an analytical examination of AI governance frameworks and investigates their role in improving efficiency and fostering trust in crop insurance systems. The theoretical foundation of this study is anchored in interdisciplinary perspectives that explain both the adoption of artificial intelligence and its governance within public policy systems. The Technology Acceptance Model provides insight into how stakeholders—particularly farmers, insurers, and administrators—perceive and engage with AI-enabled crop insurance mechanisms, emphasizing usability and perceived value. Institutional Theory complements this view by situating AI adoption within the broader regulatory and organizational environment, where government policies, legal frameworks, and administrative norms shape the design and deployment of AI systems. Together, these theories help explain why AI tools are adopted unevenly and how institutional capacity influences their effective integration into crop insurance programs.

Additionally, Algorithmic Governance Theory and Risk Management Theory provide frameworks for analyzing how AI transforms decision-making in crop insurance through data-driven risk assessment, yield estimation, and claims settlement. Algorithmic governance emphasizes transparency, accountability, and control in automated decisions, while risk management theory highlights AI's capacity to reduce uncertainty associated with climate variability and agricultural shocks. Ethical AI and Responsible Innovation Theory synthesize these perspectives by prioritizing fairness, explainability, and data protection, thereby ensuring that technological efficiency does not undermine social equity. Together, these theoretical frameworks establish a comprehensive basis for analyzing AI governance and its application in crop insurance systems.

Recent research on the application of AI in agriculture and insurance reveals evolving trends alongside persistent issues and challenges that shape its governance landscape. One notable trend is increased reliance on AI to improve decision-making and risk assessment, yet this progress is tempered by concerns over data quality, fragmentation, and privacy, since many AI models require extensive, well-structured datasets that are often unavailable or insecure in agricultural contexts. This limitation undermines predictive accuracy and creates scepticism among stakeholders who fear misuse of sensitive farm data and inadequate protection under current frameworks (Corallo et al., 2024; OECD.AI, 2025). Moreover, governance challenges such as regulatory gaps, algorithmic bias, and digital divides complicate the equitable integration of AI into crop insurance systems. Regulatory frameworks lag behind technological advances, leaving questions of liability, accountability, and ethical oversight unresolved, particularly in

regions with limited governance capacity. Simultaneously, algorithmic decisions often lack transparency, increasing the risk of biased outcomes that favour well-resourced actors over smallholder farmers, and eroding trust in automated systems (Agriaiworlds.com, 2025; OECD.AI, 2025). Addressing these issues will require robust governance mechanisms that balance innovation with fairness and data protection. The scope of this qualitative research is confined to an in-depth conceptual and interpretative analysis of AI governance as applied to crop insurance, with particular emphasis on the introduction and literature review sections of existing scholarly and policy-oriented studies. The study plans to employ Natural Language Processing (NLP) techniques to systematically analyse published literature, policy documents, and governance frameworks in order to identify dominant themes, conceptual gaps, and evolving narratives related to ethical and accountable AI use. The significance of this research lies in its contribution to consolidating fragmented knowledge on AI governance in crop insurance by offering a structured qualitative synthesis that enhances theoretical clarity and policy understanding. By integrating NLP-based insights with qualitative interpretation, the study provides value to researchers, policymakers, and practitioners seeking to design transparent, equitable, and governance-sensitive AI systems in agricultural insurance.

Despite the growing adoption of artificial intelligence in crop insurance for risk assessment, yield estimation, and claims management, significant gaps remain in the governance of these technologies. Existing AI-driven systems often operate within weak regulatory frameworks, raising concerns related to transparency, accountability, data privacy, and algorithmic bias, particularly affecting small and marginal farmers. Inadequate institutional capacity, uneven stakeholder acceptance, and limited explainability of automated decisions further constrain the effectiveness and trustworthiness of AI applications in crop insurance. Consequently, there is a critical need for a systematic analytical examination of AI governance mechanisms to understand how they can be structured and applied to ensure ethical, equitable, and efficient crop insurance systems.

REVIEW OF LITERATURE

The application of artificial intelligence (AI) in crop insurance systems has expanded significantly in recent years, driven by advances in remote sensing, machine learning, and big data analytics. These technologies were increasingly used for yield estimation, loss assessment, fraud detection, and premium pricing. Consequently, scholarly attention had focused on the governance of AI systems to ensure transparency, fairness, accountability, and regulatory compliance within agricultural insurance contexts. Early studies on AI governance provided foundational ethical and regulatory frameworks applicable across sectors. Renda (2019) and Walz and Firth-Butterfield (2019) emphasized that AI governance frameworks were designed to balance innovation with risk mitigation through principles such as accountability, explainability, and human oversight. These principles were particularly relevant to insurance systems, where algorithmic decision-making directly affected financial compensation and farmer livelihoods. Subsequent research argued that insurance applications of AI required heightened governance due to asymmetric information, power imbalances, and the socio-economic vulnerability of insured populations (Holland et al., 2021).

Within the agricultural domain, scholars highlighted the growing reliance on AI-driven data sources—such as satellite imagery, weather models, and sensor data—for crop insurance assessments. Dara et al. (2022) reported that AI governance in digital agriculture remained fragmented, with most frameworks being adapted from general AI ethics guidelines rather than designed specifically for agricultural insurance. The authors noted that governance mechanisms often lacked enforceable standards for data quality, model validation, and dispute resolution in automated loss assessments. Studies examining government-subsidized crop insurance systems further demonstrated the role of public policy in shaping AI governance. Osorio et al. (2024) found that AI adoption in agricultural insurance was strongly influenced by regulatory oversight and state involvement, particularly in ensuring transparency and fairness in subsidy allocation. Similarly, Uddin et al. (2024) emphasized that legal and ethical frameworks in climate-smart agriculture indirectly governed AI use in crop insurance by mandating data protection, explainability, and accountability for automated decisions.

Comparative analyses of insurance governance frameworks revealed that many crop insurance systems borrowed governance practices from the broader financial and insurance sectors. Mullins et al. (2021) showed that European insurance markets had adopted ethics guidelines emphasizing transparency, auditability, and consumer protection, which were increasingly extended to agricultural insurance products. However, these frameworks were often criticized for being principle-based rather than operational, limiting their effectiveness in addressing context-specific risks faced by farmers.

Recent governance models proposed multi-layered approaches integrating regulation, standards, and certification. Agarwal and Nene (2025) proposed a five-layer AI governance framework that connected high-level regulatory mandates with sector-specific implementation guidelines. Although not exclusive to agriculture, this framework was cited as adaptable to crop insurance systems, particularly for governing automated claims processing and risk modeling. Likewise, Stetler (2025) highlighted crop insurance as a precedent for scalable AI governance, arguing that reinsurance and public–private risk-sharing mechanisms could serve as institutional anchors for AI oversight. Despite these advancements, the literature consistently identified gaps in the governance of AI in crop insurance systems. Basu et al. (2020) and Alexander et al. (2024) noted the absence of clear accountability structures when AI-driven assessments were contested by farmers. Furthermore, governance frameworks often failed to address biases arising from uneven data coverage in smallholder and developing-country farming systems, raising concerns about distributive justice and inclusion.

Overall, the literature indicated that existing AI governance frameworks applied to crop insurance systems were largely derivative of general AI ethics and insurance governance models. While these frameworks provided important guiding principles, they were insufficiently tailored to the unique socio-technical and regulatory challenges of crop insurance. Scholars consistently called for context-specific AI governance frameworks that integrated agricultural policy, insurance regulation, and technological oversight to ensure responsible and equitable AI deployment in crop insurance systems. The integration of artificial intelligence (AI) into crop insurance systems had generated both significant opportunities and complex governance challenges. AI technologies were increasingly employed to automate yield estimation, weather risk modelling, and claims settlement processes, thereby improving efficiency and scalability. However, scholars emphasized that ethical and accountable governance mechanisms were essential to prevent unintended socio-economic consequences, particularly for smallholder and marginalized farmers.

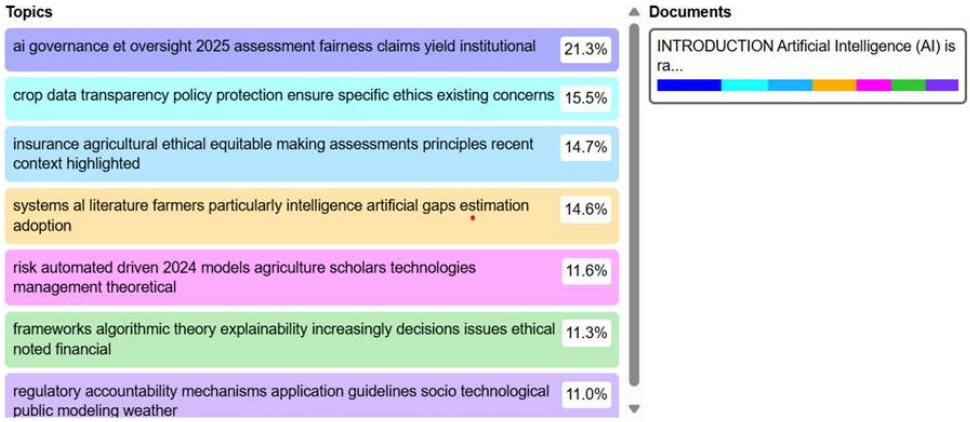
One major challenge identified in the literature concerned data governance and bias. Kshetri (2021) argued that AI systems in agricultural insurance often relied on heterogeneous datasets derived from satellite imagery, historical yield records, and climate models, which frequently underrepresented small-scale and informal farming systems. This data imbalance was found to introduce systematic bias into risk assessment and claims decisions, undermining fairness and accountability. Similarly, Mehrabi et al. (2021) highlighted that bias in machine learning pipelines posed ethical risks when deployed in high-stakes decision-making environments such as insurance compensation. Transparency and explainability were also identified as critical governance challenges. Crop insurance decisions generated by complex AI models were often difficult for farmers and regulators to interpret. Bellemare and Bloem (2023) noted that the lack of explainable AI mechanisms limited farmers' ability to contest automated loss assessments, thereby weakening procedural justice. This concern was echoed by Wieringa (2020), who emphasized that accountability in AI governance required not only technical transparency but also institutional clarity regarding responsibility for algorithmic outcomes.

Despite these challenges, the literature identified substantial opportunities for ethical AI governance to enhance trust and resilience in crop insurance systems. Carbonell (2022) argued that well-governed AI systems could improve inclusiveness by enabling parametric insurance products tailored to climate-vulnerable regions. Ethical governance frameworks, when aligned with agricultural development goals, were found to support more equitable access to insurance by reducing transaction costs and information asymmetries.

Another opportunity lay in the development of participatory and human-centered AI governance models. Floridi et al. (2018) proposed that embedding ethical principles such as beneficence, non-maleficence, and explicability into AI system design could improve accountability across sectors, including agriculture. In the context of crop insurance, participatory governance mechanisms—such as farmer feedback loops and human-in-the-loop validation—were identified as effective tools for mitigating ethical risks (van der Burg et al., 2021). Regulatory and policy innovation was also viewed as an enabling factor for accountable AI governance. Zarsky (2019) observed that algorithmic accountability laws and auditing requirements offered a pathway for governing AI-driven insurance systems without stifling innovation. In agricultural insurance, such regulatory instruments were seen as particularly valuable for ensuring compliance with public subsidy conditions and consumer protection standards (Benedict et al., 2024).

Finally, interdisciplinary governance approaches were highlighted as a key opportunity. Birhane et al. (2022) emphasized that ethical AI governance required collaboration between technologists, policymakers, insurers, and agricultural stakeholders. In crop insurance systems, this collaborative approach was found to support the alignment of technical performance metrics with ethical values such as fairness, transparency, and social sustainability. Overall, the literature suggested that while ethical and accountable AI governance in crop insurance faced challenges related to bias, transparency, and regulatory ambiguity, it also offered opportunities to enhance trust, inclusiveness, and climate resilience. The effectiveness of AI governance depended largely on the integration of ethical principles into both technical system design and institutional oversight mechanisms.

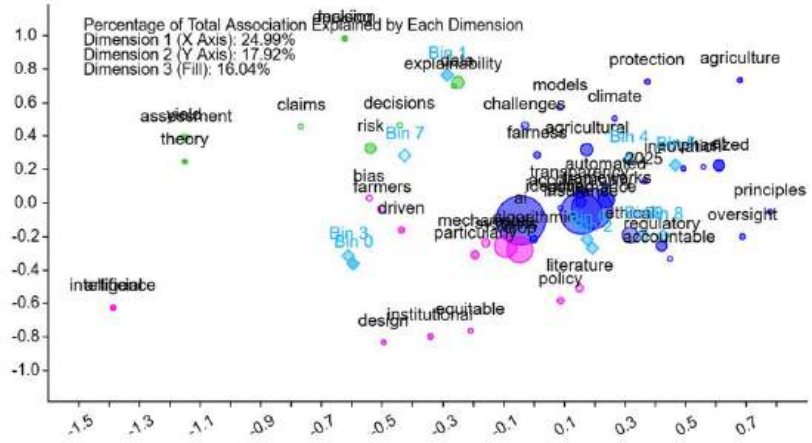
OBJECTIVES



1. To examine the existing AI governance frameworks applied in crop insurance systems.
2. To analyze the challenges and opportunities in applying ethical and accountable AI governance in crop insurance.

RESEARCH METHODOLOGY

This study adopted a qualitative, interpretative, and non-empirical research design to conduct a conceptual and thematic examination of AI governance frameworks, challenges, and opportunities within crop insurance systems. The methodology was organized into two integrated phases—a systematic literature review and a computational text analysis—to generate a comprehensive and multi-layered understanding of the scholarly and policy discourse. Drawing on interdisciplinary theoretical lenses such as Algorithmic Governance Theory and Responsible Innovation Theory, the study synthesized existing knowledge from peer-reviewed journal articles, conference proceedings, book chapters, and authoritative policy reports. The data corpus was developed through a systematic search of academic and grey literature sourced from databases including Scopus, Web of Science, Google Scholar, and specialized repositories such as OECD.AI, covering publications from 2018 to 2025 to capture recent developments in AI governance and agricultural insurance. A structured keyword strategy employing Boolean operators combined terms related to artificial intelligence, crop insurance, governance, ethics, accountability, fairness, and transparency, with inclusion restricted to English-language sources explicitly addressing governance or policy dimensions and exclusion applied to purely technical studies lacking governance relevance. The final corpus comprised extracted textual elements such as titles, abstracts, keywords, and central argumentative sections. Data analysis proceeded in two complementary stages: first, a qualitative interpretative content analysis involving iterative familiarization, coding, and thematic synthesis to identify governance principles, challenges, and opportunities; and second, a computational text analysis using Natural Language Processing (NLP) techniques, including text pre-processing, Latent Dirichlet Allocation (LDA) for inductive topic modelling, and Principal Component Analysis (PCA) to reduce dimensionality and reveal conceptual relationships and clusters within the discourse. The findings from both stages were triangulated to validate thematic consistency, identify dominant areas of scholarly focus, and highlight gaps in the literature. As the study relied exclusively on publicly available documents, no human or animal subjects were involved; nevertheless, ethical scholarly standards were upheld through accurate citation, transparency in



computational procedures, and cautious interpretation of NLP outputs, acknowledging the conceptual and exploratory scope of the research.

DISCUSSION

Text Analysis

Topic modelling was conducted using an NLP-based approach to identify the dominant thematic structures within the study corpus. The analysis revealed seven coherent topic clusters that collectively explain the discourse on AI governance in crop insurance. The most prominent theme (21.3%) emphasized *AI governance, ethical oversight, fairness assessment, and institutional accountability*, highlighting the centrality of governance mechanisms in AI-driven insurance decision-making. The second major topic (15.5%) focused on *crop data transparency, policy protection, and ethical safeguards*, underscoring concerns related to data integrity and farmer protection. Another significant cluster (14.7%) addressed *ethical and equitable insurance assessment practices*, reflecting the application of AI principles in agricultural risk evaluation. Themes related to *systemic gaps, farmer-centric adoption challenges, and estimation limitations* (14.6%) pointed to practical constraints in AI deployment. Additionally, topics concerning *automated risk management models and theoretical frameworks* (11.6%), *algorithmic explainability and ethical decision-making* (11.3%), and *regulatory accountability mechanisms within socio-technological contexts* (11.0%) further illustrated the multidimensional nature of AI governance. Overall, the topic modelling results demonstrate a balanced integration of technical, ethical, regulatory, and institutional dimensions, confirming that AI governance is a critical enabler for responsible and effective application of AI in crop insurance systems.

Principal Component Analysis (PCA) was applied to examine the multidimensional relationships among key concepts associated with AI governance in crop insurance, yielding three principal dimensions and clearly differentiated clusters. Dimension 1 (X-axis), explaining 24.99% of the total variance, predominantly represents institutional and regulatory governance constructs, including accountability, regulatory oversight, principles, protection, and explainability, indicating that governance and ethical compliance constitute the dominant explanatory axis of AI application in crop insurance. Dimension 2 (Y-axis), accounting for 17.92% of the variance, captures operational and decision-oriented aspects such as risk assessment, claims processing, fairness, automated systems, agricultural decision-making, and climate-related challenges, reflecting the functional role of AI in managing uncertainty and efficiency in insurance operations. Dimension 3 (represented by point intensity), contributing 16.04% of the explained variance, highlights socio-institutional and adoption-related factors, including farmers, bias, equitable design, policy frameworks, and institutional mechanisms, thereby emphasizing concerns related to inclusiveness and ethical implementation.

The three resulting clusters correspond to

1. Ethical and regulatory governance frameworks,
2. AI-enabled risk assessment and insurance decision systems, and
3. Socio-technical and institutional adoption challenges.

Overall, the PCA findings demonstrate that the effective application of AI in crop insurance is contingent upon the balanced integration of governance structures, technical decision-support capabilities, and socio-institutional considerations, thereby reinforcing the study's conclusion that robust and accountable AI governance is central to achieving fairness, transparency, and sustainability in crop insurance systems.

CONCLUSION

This study provided a comprehensive qualitative and computational examination of AI governance and its application in crop insurance, demonstrating that the effectiveness and sustainability of AI-driven insurance systems are fundamentally contingent upon robust governance frameworks that integrate ethical principles, regulatory oversight, and institutional accountability. The findings highlight that while AI offers significant potential to enhance risk assessment, claims efficiency, and decision accuracy in crop insurance, persistent challenges related to transparency, bias, data governance, and institutional readiness continue to constrain its equitable adoption.

Managerial implications:
The results underscore the need for insurance managers and policymakers to embed ethical-by-design principles, explainable AI mechanisms, and strong data governance practices into operational workflows, while simultaneously investing in organizational capacity building and stakeholder engagement to foster trust among farmers.

Research implications:
The study demonstrates the value of combining qualitative interpretative analysis with Natural Language Processing techniques, such as topic modelling and principal component analysis, to uncover latent thematic structures and provide methodological rigor in governance-oriented research, thereby offering a replicable framework for future interdisciplinary studies.

Theoretical Implications:
The findings extend existing perspectives on Algorithmic Governance and Responsible Innovation by contextualizing them within agricultural insurance systems, illustrating how governance, technology, and socio-institutional factors interact in high-risk, welfare-oriented domains.

Future research directions:

It should focus on empirically validating these conceptual insights through field-level case studies, comparative cross-country analyses, and stakeholder-based investigations, as well as exploring adaptive and context-specific AI governance models that align technological innovation with fairness, inclusivity, and long-term resilience in crop insurance systems.

ABSTRACT

Job satisfaction is a crucial determinant of employee performance, commitment, and overall organizational effectiveness. In the higher education sector, guest lecturers play a significant role in delivering quality education and addressing faculty shortages in Government Arts Colleges. However, they often encounter challenges such as temporary employment, limited career advancement opportunities, inadequate remuneration, job insecurity, and increased workload, which may influence their level of job satisfaction. Understanding these factors is essential for improving the quality of higher education and ensuring the well-being of teaching professionals.

Keywords: opportunities, inadequate remuneration, job insecurity

INTRODUCTION

Job satisfaction refers to the level of contentment, fulfilment, and sense of achievement that an employee derives from performing their job. It reflects an individual's overall attitude toward their work and is influenced by the extent to which the job fulfills personal expectations, values, and professional needs. A high level of job satisfaction enhances employee motivation, commitment, productivity, and organizational effectiveness, making it a vital aspect of human resource management. In the higher education sector, job satisfaction among guest lecturers is of particular importance, as they play a significant role in delivering quality education despite facing challenges such as contractual employment, job insecurity, limited career advancement opportunities, and comparatively lower

remuneration. Understanding the factors that influence their job satisfaction is essential for improving their performance, commitment, and overall well-being. Against this background, the present study aims to examine the level of job satisfaction among guest lecturers working in Government Arts Colleges in Madurai District, Tamil Nadu. The study seeks to identify the key factors influencing their job satisfaction and to provide appropriate suggestions for enhancing their working conditions and professional effectiveness.

REVIEW OF LITERATURE

Locke, Edwin A. (1976) defined job satisfaction as a pleasurable or positive emotional state resulting from the appraisal of one's job or job experiences. He emphasized that job satisfaction depends on the extent to which an individual's expectations and values are fulfilled through work. Herzberg, Frederick (1959) introduced the Two-Factor Theory, which classifies the determinants of job satisfaction into motivational factors (achievement, recognition, responsibility, and advancement) and hygiene factors (salary, job security, working conditions, and organizational policies). The theory suggests that while hygiene factors prevent dissatisfaction, motivational factors promote higher levels of job satisfaction. Spector, Paul E. (1997) explained that job satisfaction is a multidimensional concept influenced by pay, promotion opportunities, supervision, fringe benefits, communication, co-worker relationships, and the nature of work. He emphasized that employee satisfaction significantly contributes to organizational effectiveness and productivity. Anitha, J. (2014) examined the factors influencing employee engagement and reported that work environment, leadership, teamwork, training and development, compensation, and employee welfare have a significant impact on employee satisfaction and organizational performance.

Bedarkar, Milind andPandita, Deepika (2014) identified leadership, organizational culture, communication, employee involvement, and work-life balance as key determinants of employee satisfaction and commitment. Their study concluded that supportive organizational practices enhance employee motivation and productivity. Sharma, Rekha (2018) studied job satisfaction among college faculty members and found that salary, promotion opportunities, recognition, professional autonomy, and institutional support significantly influence faculty satisfaction. The study recommended improving faculty welfare measures to enhance teaching effectiveness. Kaur, Harpreet (2020) investigated the job satisfaction of contractual and guest faculty members in higher education institutions. The findings revealed that job insecurity, inadequate remuneration, limited career growth, and lack of social security benefits were the major causes of dissatisfaction among guest faculty. Kumar, R. andSingh, P. (2022)analyzed the relationship between job satisfaction and organizational commitment among college teachers. The study concluded that improved working conditions, fair compensation, supportive leadership, and opportunities for professional development positively influence job satisfaction and employee commitment.

Objectives of the Study

Primary Objective

To examine the level of job satisfaction among guest lecturers working in Government Arts Colleges in Madurai District

Secondary Objectives

- To identify the factors influencing job satisfaction among guest lecturers in Government Arts Colleges.
- To assess the relationship between demographic variables (such as age, gender, educational qualification, teaching experience, and monthly income) and the level of job satisfaction.
- To evaluate the level of satisfaction with salary, job security, workload, work environment, and institutional support.
- To examine the impact of job security and compensation on the job satisfaction of guest lecturers.

Statement of the Problem

Guest lecturers play a vital role in the higher education system by addressing faculty shortages and ensuring the continuity of teaching and learning in Government Arts Colleges. Despite their significant contribution, they often work under challenging conditions characterized by temporary appointments, limited job security, comparatively low remuneration, inadequate employment benefits, and restricted opportunities for career advancement. These conditions may adversely affect their level of job satisfaction, motivation, commitment, and teaching effectiveness. Job satisfaction is a critical factor that influences employee performance, organizational commitment, productivity, and the overall quality of education. When guest lecturers experience dissatisfaction with their working conditions, it may lead to reduced morale, lower teaching effectiveness, absenteeism, and a higher intention to leave their profession.

In Government Arts Colleges in Madurai District, guest lecturers constitute an important segment of the teaching workforce. However, they continue to face several professional and personal challenges, including workload imbalance, lack of recognition, insufficient institutional support, uncertainty regarding contract renewal, and limited access to professional development opportunities. Although several studies have examined job satisfaction among permanent faculty members, limited research has specifically focused on the job satisfaction of guest lecturers in Government Arts Colleges in Madurai District. This research gap highlights the need to investigate the factors influencing their job satisfaction and identify the challenges they encounter. Therefore, the present study seeks to assess the level of job satisfaction among guest lecturers, examine the factors affecting their satisfaction, and suggest appropriate measures to improve their working conditions, professional well-being, and overall effectiveness in the higher education system.

Scope of the Study

The present study focuses on examining the level of job satisfaction among guest lecturers working in Government Arts Colleges in Madurai District, Tamil Nadu. It aims to identify the various factors influencing job satisfaction, including salary and remuneration, job security, workload, work environment, institutional support, recognition, interpersonal relationships, career development opportunities, and work-life balance. The study also examines the relationship between selected demographic variables such as age, gender, educational qualification, teaching experience, and monthly income and the level of job satisfaction.

Limitations of the Study

The present study is limited to guest lecturers working in Government Arts Colleges in Madurai District, Tamil Nadu. The findings are based on the responses of the selected respondents and may not be generalized to guest lecturers in other districts or types of higher education institutions. The study focuses only on selected factors influencing job satisfaction, such as salary, job security, work environment, workload, and institutional support. Since the data are collected through a structured questionnaire, the results depend on the accuracy and honesty of the respondents' perceptions and opinions.

RESEARCH METHODOLOGY

Research Design

- Descriptive Research Design

Area of the Study

- Government Arts Colleges in Madurai District, Tamil Nadu

Population of the Study

- Guest Lecturers working in Government Arts Colleges in Madurai District

Sample Size

- 100 Guest Lecturers

Sampling Technique

- Convenience Sampling

Sources of Data

- **Primary Data:** Structured Questionnaire
- **Secondary Data:** Books, Journals, Research Articles, Government Reports, Websites, and Published Literature

Research Instrument

- Structured Questionnaire using a Five-Point Likert Scale

Statistical Tools Used

- Percentage Analysis
- Mean and Standard Deviation
- Chi-Square Test

Data Analysis and Interpertation

Interpretation

The demographic profile of the respondents shows that out of 100 guest lecturers, the majority are female (58%), while 42% are male. Most respondents belong to the 31–40 years age group (48%), followed by 41–50 years (23%), below 30 years (22%), and above 50 years (7%). With regard to marital status, 66% are married, 30% are unmarried, and 4% belong to other categories. In terms of educational qualification, 40% possess a Ph.D., 36% have an M.Phil. degree, and 24% hold a postgraduate degree. Regarding teaching experience, the majority of the respondents (38%) have 5–10 years of experience, followed by 26% with below 5 years, 24% with 11–15 years, and 12% with above 15 years of experience.

Hypothesis

H_0: There is no significant association between gender and the level of job satisfaction among guest lecturers.

H_1: There is a significant association between gender and the level of job satisfaction among guest lecturers.

Interpretation

Since the calculated p-value (0.027) is less than the 0.05 significance level, the null hypothesis is rejected and the alternative hypothesis is accepted. Hence, there is a significant association between gender and the level of job satisfaction among guest lecturers in Government Arts Colleges in Madurai District.

Findings

- The study found that 58% of the respondents are female, while 42% are male.
- The majority of the respondents (48%) belong to the 31–40 years age group.
- Most of the respondents (66%) are married.
- The study revealed that 40% of the respondents possess a Ph.D. qualification, indicating a highly qualified teaching workforce.
- The majority of the respondents (38%) have 5–10 years of teaching experience as guest lecturers.
- The demographic profile indicates that the respondents are predominantly experienced and academically qualified guest lecturers working in Government Arts Colleges in Madurai District.

Suggestions

- The Government should provide fair and competitive remuneration to improve the job satisfaction of guest lecturers.
- Greater job security and transparent policies regarding appointment and continuation of service should be ensured.

- Guest lecturers should be provided with opportunities for professional development through training, workshops, and faculty development programmes.
- College management should create a supportive work environment by recognizing and appreciating the contributions of guest lecturers.
- Adequate teaching resources, infrastructure, and administrative support should be provided to enhance teaching effectiveness

CONCLUSION

The study concludes that job satisfaction is an essential factor influencing the motivation, commitment, and teaching effectiveness of guest lecturers in Government Arts Colleges in Madurai District. The findings indicate that although guest lecturers are academically well qualified and experienced, their job satisfaction is influenced by factors such as salary, job security, work environment, institutional support, and career development opportunities. Therefore, improving employment conditions, providing adequate remuneration, ensuring job security, and creating a supportive academic environment will enhance their job satisfaction and contribute to better educational outcomes. Implementing these measures will not only improve the well-being of guest lecturers but also strengthen the overall quality of higher education in Government Arts Colleges.

ABSTRACT

This paper looks at a practical problem many firms seem to be facing. Artificial intelligence is entering financial work, though often in quiet ways, and it is not always clear how it actually fits into day-to-day tasks. The study focuses on how people working with finance experience this shift, especially in Indian firms where routines, resources, and expectations can differ widely. It tries to move away from abstract claims and stay closer to ordinary financial work, such as checking figures before a meeting or reviewing alerts at the end of the day. The study follows a survey-based approach, gathering views from people directly involved in financial management. The focus stays on current practice rather than long-term predictions. Analysis looks at patterns between artificial intelligence use, organisational readiness, and perceived financial outcomes, keeping the methods simple and transparent. The results suggest that artificial intelligence use is linked with smoother financial work in many cases. Organisational readiness also seems to matter. When both are present, outcomes appear to line up more comfortably, though changes tend to be modest rather than dramatic. The paper adds value by grounding artificial intelligence discussion in everyday financial behaviour. It offers insight from an emerging-market setting and highlights how progress often unfolds through small, practical adjustments rather than sweeping change.

Keywords: artificial intelligence, financial management, organisational readiness, emerging-market firms, decision-making

INTRODUCTION

Background of the Study

Across Indian businesses, financial work has been changing in ways that are easy to miss. Much of it happens in quiet moments rather than strategy meetings. A manager glances at a forecast while waiting for a cab. Someone else reviews a flagged transaction late in the evening, phone in hand. In many firms, these actions are now shaped by systems that draw on artificial intelligence, even if staff rarely talk about it in technical terms. Academic work has followed this shift, though often from a distance. A large body of research maps how artificial intelligence is spreading across finance, tracing applications in forecasting, fraud detection, reporting, and risk assessment (Goodell et al., 2021). Reviews suggest that interest has moved well beyond experimentation, with firms increasingly relying on automated outputs in day-to-day financial decisions (Bahoo et al., 2024). Yet the lived reality inside organisations appears less settled. For some teams, AI tools sit alongside spreadsheets and judgement calls rather than replacing them entirely.

There is also a sense of tension in how these systems are trusted. Research has shown that AI outputs often depend on earlier human assumptions, labels, and routines, which can quietly shape what appears objective or precise (Lebovitz et al., 2021). In practice, finance staff may accept a recommendation because it arrives quickly, or because it looks clean, even when they are unsure how it was produced. This matters in contexts like Indian firms, where resources, skills, and institutional support vary widely across sectors and regions. Studies from banking and financial markets highlight broader concerns around risk and concentration, particularly when many organisations rely on similar models or data sources (Danielsson et al., 2022). At the same time, work on management and accounting suggests that AI is subtly reshaping professional roles, altering what counts as expertise and where responsibility is felt (Moll et al., 2021). These shifts are not always smooth. They unfold through trial, hesitation, and uneven uptake, shaped by budgets, habits, and local pressures.

Much of the established theory on technology use still centres on perceptions of usefulness, ease, and readiness within organisations (Davis, 1989; Venkatesh et al., 2003; Parasuraman, 2000). These ideas remain helpful, though they were developed in settings quite different from contemporary emerging-market firms. In Indian businesses, AI adoption often takes place alongside patchy infrastructure, skill gaps, and strong reliance on informal judgement. Decisions may be influenced as much by who is available on the finance team as by what the system suggests.

Research Gap

Despite a growing literature on artificial intelligence in finance, several limitations remain. Many studies focus on technical performance or market-level outcomes, leaving everyday organisational use underexplored (Bahoo et al., 2024). Others rely heavily on data from advanced economies, where regulatory environments, digital maturity, and professional training differ markedly from those in emerging markets (OECD, 2025). As a result, it is not always clear how well existing explanations travel across contexts. There is also a tendency to treat adoption as a single event rather than an ongoing practice. Reviews often describe whether AI is used, but pay less attention to how it becomes woven into routine financial work, or where it meets resistance or quiet workarounds (Goodell et al., 2021). Studies that do examine organisational adoption frequently privilege formal structures and stated strategies, which may overlook informal behaviour, partial use, or selective trust in outputs.

Conceptually, prior research often draws on established acceptance or innovation frameworks without fully integrating them with newer thinking on AI capability, organisational learning, and decision structures (Mikalef et al., 2022; Shrestha et al., 2021). This can limit explanatory depth. In some cases, AI is treated as a neutral tool rather than something that reshapes judgement, accountability, and everyday financial practice. Most importantly, empirical evidence from Indian firms remains limited. Existing work rarely captures how finance professionals in emerging-market organisations experience AI in practical terms, such as managing cash flow under uncertainty or

responding to automated risk alerts with limited time. These contextual gaps suggest the need for closer, grounded examination.

Research Objectives

1. To examine the extent to which artificial intelligence is used in routine financial management activities within Indian firms.
2. To understand how finance professionals perceive the usefulness and ease of use of artificial intelligence in their day-to-day financial work.
3. To assess the level of organisational readiness for adopting artificial intelligence in financial management functions.
4. To analyse how the adoption of artificial intelligence relates to perceived financial management outcomes, including decision quality, efficiency, and risk handling.

Research Contributions

This study contributes to existing scholarship in several ways. Theoretically, it brings together established technology acceptance ideas with more recent work on AI capability and organisational decision-making, applying them in a context that remains underrepresented. Empirically, it offers firm-level evidence from Indian businesses, capturing how AI is used in ordinary financial tasks rather than abstract settings. Contextually, it sheds light on adoption patterns shaped by uneven resources, skills, and expectations, extending current understanding beyond advanced economies. Rather than presenting AI as a finished solution, the study highlights how it seems to settle into financial work gradually, through use, doubt, and adjustment. In doing so, it adds texture to ongoing academic conversations about technology, judgement, and everyday organisational life.

LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

Conceptual and Theoretical Foundations

Much of what we know about technology use in organisations comes from studies that focus on how people decide whether to use a system at all. Over time, these ideas have been applied again and again, often in new settings. Early work suggested that people tend to rely on tools they find useful and easy to handle in the middle of a working day, especially when there is pressure to move quickly (Davis, 1989). Later models widened this view, pointing out that social expectations, support from managers, and available infrastructure also shape whether a system becomes part of routine work (Venkatesh et al., 2003). These ideas still seem relevant when thinking about artificial intelligence in financial management. AI systems often sit alongside existing software rather than replacing it. A finance manager might glance at an automated forecast, then open a spreadsheet out of habit. Whether the AI is trusted often depends less on technical detail and more on how it fits into the flow of work. Some studies suggest that readiness within the organisation plays a quiet role here. When firms have supportive leadership, basic technical capacity, and staff who feel comfortable experimenting, new systems seem to settle in more easily (Parasuraman, 2000).

More recent work has tried to move beyond individual acceptance to look at organisational capability. From this view, AI use depends on how data, skills, and routines are brought together over time (Mikalef et al., 2022). This perspective matters in emerging-market settings, where firms often work with uneven resources and shifting priorities. Theoretical work on decision structures also reminds us that AI does not simply provide answers. It changes who feels responsible for decisions and how judgement is shared between people and systems (Shrestha et al., 2021). Together, these strands suggest that AI adoption, organisational readiness, and financial outcomes are linked through everyday practices rather than abstract systems.

Artificial Intelligence Adoption and Financial Management Outcomes

A growing body of research has looked at how artificial intelligence is used across financial activities. Much of this work maps applications such as forecasting, fraud detection, reporting, and risk analysis (Goodell et al., 2021). The

general picture suggests that AI can support faster processing and pattern recognition, especially where large volumes of data are involved. At the same time, studies hint that outcomes depend on how AI is actually used. In some firms, automated alerts help staff notice issues early, perhaps while checking figures on a phone before a meeting. In other cases, outputs are ignored or double-checked manually. Reviews of AI in finance suggest that performance gains are uneven and often tied to organisational context rather than the technology itself (Bahoo et al., 2024). There are also concerns about over-reliance. Research on systemic risk notes that when many organisations use similar models, small errors or biases can spread quietly across systems (Danielsson et al., 2022). At the firm level, this raises questions about how much trust finance professionals place in AI recommendations, particularly when time is short or information is incomplete.

What seems less explored is how finance staff in emerging-market firms experience these tools in day-to-day work. Much of the existing evidence comes from large financial institutions or market-level data. Less attention has been paid to how AI adoption relates to perceived improvements in routine financial management, such as budgeting accuracy or decision speed, within diverse organisational settings. Based on this literature, it seems reasonable to expect a relationship between AI adoption and financial management outcomes, though the strength of this relationship may vary.

Organisational Readiness and Financial Management Outcomes

Alongside adoption itself, organisational readiness appears to shape how technology affects outcomes. Readiness reflects whether a firm has the support, skills, and basic conditions needed to make use of new systems. Some researchers argue that even well-designed tools struggle to deliver value when staff feel unsure, undertrained, or unsupported (Parasuraman, 2000). Empirical studies suggest that management support plays a role here. When leaders encourage experimentation and allow time to learn, employees seem more willing to rely on new tools. In contrast, where AI is introduced quietly or without explanation, staff may use it only superficially. Work on management accounting shows that AI can change roles and expectations, sometimes creating uncertainty about responsibility and judgement (Moll et al., 2021).

In emerging-market firms, readiness may be uneven across departments. A finance team might have access to an AI-based reporting tool but limited data quality or patchy integration with other systems. Some studies note that research often assumes a level of organisational maturity that does not hold in many real settings (OECD, 2025). Despite this, organisational readiness is often treated as a background factor rather than examined directly. There is limited firm-level evidence showing how readiness relates to perceived financial outcomes, especially outside advanced economies. This leaves open questions about whether readiness itself contributes to better financial management, regardless of how extensively AI is used.

Integrated Conceptual Perspective

Looking at AI adoption or organisational readiness in isolation may miss how these factors work together. One view suggests that AI tools need a certain level of readiness to be used meaningfully. A forecasting system may exist, yet without skills or support, its outputs remain unused. At the same time, readiness without actual use offers little benefit. Training programmes and supportive policies do not improve decisions on their own. Some scholars argue that AI creates value when technical use and organisational conditions align in everyday practice (Mikalef et al., 2022). This alignment is not always planned. It develops gradually, through trial, adjustment, and sometimes frustration. A finance manager might start by using AI outputs as a second opinion, then slowly rely on them more as confidence grows. Conceptual work on AI and management points out that this joint influence shapes how decisions are made and shared (Raisch & Krakowski, 2021). In this sense, adoption and readiness act together rather than separately. Their combined presence seems more likely to support consistent financial outcomes.

Hypothesis Development

Drawing on the above discussion, this study proposes that artificial intelligence adoption and organisational readiness jointly influence financial management outcomes. When AI is used more extensively within financial tasks,

and when organisational conditions support its use, finance professionals may perceive improvements in decision quality, efficiency, and risk handling.

H1: Artificial intelligence adoption in financial management is positively related to perceived financial management outcomes.
H2: Organisational readiness for artificial intelligence is positively related to perceived financial management outcomes.
H3: Artificial intelligence adoption and organisational readiness jointly have a positive relationship with perceived financial management outcomes.

METHODOLOGY

Research Design
This study followed a quantitative research design, using a cross-sectional survey to examine how artificial intelligence is used in financial management within Indian firms. The design suited the aim of identifying patterns across organisations rather than focusing on individual cases. It allowed responses to be gathered from people who work closely with financial data and decisions as part of everyday routines. The focus stayed on current practices. Many financial tasks now happen in short moments during the day, such as checking a report between meetings or responding to an automated alert late in the evening. A survey approach made it possible to capture these experiences at a single point in time, without asking respondents to reflect too deeply on abstract ideas. This design also aligned with the analytical objectives of the study. It supported the examination of relationships between artificial intelligence adoption, organisational readiness, and financial management outcomes in a way that remained grounded in routine work experience.

Sample and Data Collection
The final sample consisted of 135 respondents drawn from Indian firms operating in different sectors, including manufacturing, services, IT-enabled services, retail, and financial services. Respondents held roles such as finance manager, accounts manager, senior manager, business owner, or similar positions involving responsibility for financial activities. A purposive sampling approach was used. Participants were selected based on their involvement in financial management rather than their job title alone. In practice, respondents were reached through professional networks, LinkedIn contacts, and referrals within organisations. In a few cases, participants shared the survey with colleagues who met the study criteria, which helped broaden the sample.

Data were collected using an online questionnaire. This format allowed respondents to complete the survey at a time that suited their work patterns. Some may have responded during office hours, while others may have done so while travelling or after finishing daily tasks. Participation was voluntary, and respondents were informed that the study was for academic purposes only. No identifying information was collected. After removing incomplete responses, 135 usable questionnaires remained for analysis. This sample size was considered adequate for the statistical techniques used, allowing for reliable estimation of relationships between key variables.

Measurement Instruments
The questionnaire included items measuring artificial intelligence adoption, organisational readiness, and financial management outcomes. All items were rated using a five-point Likert scale, ranging from strongly disagree to strongly agree. Artificial intelligence adoption was captured through questions on the extent to which AI tools were used in routine financial tasks such as forecasting, reporting, cash flow monitoring, and risk assessment. The focus remained on actual use rather than awareness or intention. Perceived usefulness and ease of use were measured using adapted items from established technology acceptance studies, with wording adjusted to reflect everyday financial work. Organisational readiness was measured through items relating to management support, availability of skills, and basic technological infrastructure.

Financial management outcomes reflected respondents' perceptions of changes in decision speed, accuracy, cost control, and risk handling since using AI-based tools. These items aimed to capture practical effects rather than formal performance metrics. Reliability was assessed using Cronbach's alpha. The values obtained suggested acceptable internal consistency across the main constructs. Construct validity was examined by reviewing correlations among related variables, which followed expected patterns.

Data Analysis Techniques

Data analysis was conducted using **Jamovi**. The process began with descriptive statistics to summarise demographic characteristics such as industry, firm size, and respondent role. This provided a basic picture of the sample. Reliability analysis was then carried out to check the consistency of the measurement scales. Correlation analysis followed, offering an initial view of how artificial intelligence adoption, organisational readiness, and financial management outcomes were related. Regression analysis was used to test the proposed hypotheses. Artificial intelligence adoption and organisational readiness were entered as independent variables, with financial management outcomes as the dependent variable. This allowed their individual contributions to be examined in simple terms. Throughout the analysis, results were interpreted cautiously. The findings reflect perceptions reported by respondents rather than objective system performance. The emphasis remained on understanding patterns that seem to shape everyday financial management work within Indian firms.

RESULTS

Demographic Profile

The analysis draws on 135 respondents who work with financial matters in Indian firms. They came from services, IT-enabled services, manufacturing, retail, and financial services. No single sector crowded out the rest. This helped keep the results from leaning too heavily in one direction. Firm size varied. Some respondents worked in small setups where finance tasks are handled by a few people. Others came from larger firms with dedicated finance teams and formal systems. Roles included finance managers, accounts managers, senior managers, and business owners. Everyone dealt with money decisions as part of ordinary work, such as approving expenses or checking balances before the day ends. Most respondents described their firm's digital use as moderate. A smaller group felt their organisations were highly digital. Very few placed themselves at the low end. This mix shaped how people talked about using AI in daily tasks.

Descriptive Statistics

Artificial intelligence adoption sat above the midpoint of the scale. This suggests AI tools were present in many firms, though not woven into every task. Some respondents used AI regularly for forecasting or reporting. Others relied on it mainly when something looked off, like an unusual transaction picked up late in the evening. Organisational readiness stayed near the middle. Many respondents felt their firms were partly prepared. Support existed, though training and systems did not always feel settled. Financial management outcomes were rated fairly positively. Decisions felt quicker for some people. Information felt clearer. Improvements appeared modest rather than dramatic.

Reliability Analysis

Reliability checks showed the measures held together in a steady way. Items within each construct tended to move together. Respondents who rated AI use high in one area often did the same in others. This suggested that answers were not random or rushed, even though many people likely completed the survey between tasks or while travelling.

Correlation Analysis

Correlation analysis offered a first look at how things lined up. AI adoption and financial management outcomes moved in the same direction. Where AI use was higher, outcomes tended to be rated higher too.

Organisational readiness showed a similar pattern. Firms that felt more prepared often reported smoother financial work. AI adoption and readiness were also related to each other, which felt expected.

Regression Analysis and Hypothesis Testing

Regression analysis was used to test the hypotheses. Financial management outcomes were treated as the dependent variable. AI adoption came out as a positive predictor. As AI use increased, outcome scores tended to rise. The change felt steady rather than sharp. Organisational readiness also mattered. Its effect was slightly smaller than AI adoption, though still noticeable. Firms that felt more ready often reported better outcomes, even when AI use was taken into account. When both predictors were included together, neither dropped out. This supported the idea that AI use and readiness work alongside each other. Overall, the results point to a simple pattern. Using AI seems to help more when the organisation feels ready for it. Readiness without use does little. Use without readiness feels uneven. For many respondents, improvement arrived quietly, through small changes in how everyday financial work was handled.

DISCUSSION

This study set out to understand how artificial intelligence fits into everyday financial work inside Indian firms. The results paint a picture that feels familiar rather than dramatic. AI seems to matter, though mostly in quiet ways. It shows up while checking a balance on the bus ride home or glancing at a forecast before a meeting starts. It does not appear to sweep aside older habits overnight. One of the clearer patterns was the link between AI adoption and financial management outcomes. Firms where AI was used more often tended to report smoother financial work. Decisions felt quicker. Numbers felt easier to follow. This lines up with earlier work suggesting that AI supports routine financial tasks by handling volume and pattern recognition (Goodell et al., 2021). At the same time, the effect was steady rather than overwhelming. As far as respondents said, AI helped them work through tasks, not rethink their entire approach to finance. Organisational readiness also came through as important. Firms that felt more prepared often described better outcomes. This seems to fit with earlier arguments around technology readiness and organisational support (Parasuraman, 2000). When management backing exists and systems mostly work, people appear more willing to rely on AI outputs. In a few cases, respondents hinted that without this support, AI tools stayed on the side, checked occasionally, then ignored when things got busy.

What stands out is how adoption and readiness worked together. When both were present, outcomes tended to look better. This fits with thinking that AI value emerges through everyday use supported by organisational conditions rather than through technology alone (Mikalef et al., 2022). A forecasting tool may be available, though without skills or confidence it rarely shapes decisions. Readiness without use does little either. The combination seems to matter. These findings sit comfortably alongside research on changing decision structures. Studies suggest AI shifts how judgement is shared between people and systems rather than replacing human decision-making outright (Shrestha et al., 2021). The respondents in this study appeared to treat AI as a support rather than an authority. A number mentioned using AI as a second check, especially when approving payments or reviewing risks after payday. The moderate level of organisational readiness reported across firms also reflects broader patterns noted in emerging-market contexts. Large-scale surveys suggest many firms are still part-way through AI adoption, experimenting while dealing with uneven infrastructure and skills (OECD, 2025). This study echoes that view. Progress feels incremental. Training is uneven. Confidence builds slowly.

There are also hints of caution. Some respondents seemed aware that relying too heavily on similar systems could create blind spots, even if they did not frame it in technical terms. This sits in the same direction as concerns raised around shared models and systemic risk in financial systems (Danielsson et al., 2022). At the firm level, this may translate into a habit of double-checking AI outputs, especially when stakes feel high. Overall, the findings suggest that artificial intelligence is becoming part of financial management in Indian firms, though in modest and practical ways. It supports work rather than reshaping it. Outcomes improve when people use the tools and feel ready to do

so. Much still depends on judgement, pressure, and habit. Those elements sit quietly in the background, shaping how AI is taken up day by day, without drawing much attention to themselves.

CONCLUSION

This study set out to look at how artificial intelligence fits into financial management work in Indian firms, without assuming it changes everything all at once. What comes through most clearly is a sense of gradual movement. AI seems to be settling into everyday routines rather than standing apart from them. It shows up while checking a balance on the bus ride home or reviewing a report before signing off for the day. For many respondents, it felt like another layer of support rather than a replacement for judgement. The findings point toward a simple idea. Using AI appears to help when people actually use it and when the organisation feels ready enough to back that use. AI adoption on its own may support quicker decisions or clearer information. Organisational readiness on its own may create a more comfortable environment for trying new tools. When both are present, outcomes seem to line up in a more helpful way. This fits with earlier work suggesting that technology value often grows through everyday practice rather than formal strategies (Mikalef et al., 2022).

At the same time, the changes reported here were modest. Improvements felt real, though rarely dramatic. This sits in the same direction as earlier studies in finance that describe AI as supporting routine work rather than reshaping it entirely (Goodell et al., 2021). As far as respondents said, human judgement still mattered. People checked outputs, questioned alerts, and relied on experience, especially when decisions carried risk. This echoes concerns raised elsewhere about trust and reliance on automated systems (Lebovitz et al., 2021). The role of organisational readiness also deserves attention. Many firms appeared to be part-way along the road. Support existed, though training and systems did not always feel settled. This reflects broader patterns seen in emerging-market contexts, where firms experiment while dealing with uneven infrastructure and skills (OECD, 2025). In a few cases, respondents hinted that without steady support, AI tools stayed in the background, used only when time allowed.

There are limits to what this study can say. The data reflect perceptions rather than objective performance. Responses came from a single point in time. Everyday pressures, moods, or recent experiences may have shaped answers. These are not flaws so much as reminders of how financial work actually happens. Future research could stay close to this reality. It might look at how AI use changes over time, or how teams learn to trust or ignore systems during busy periods. There is also room to explore how different groups, such as smaller firms or newer finance professionals, experience these tools. Overall, this study suggests that artificial intelligence may support financial management in small, practical ways. Progress seems to come through use, adjustment, and patience. It unfolds quietly, alongside spreadsheets, conversations, and habits that have been built over years, and it may continue that way for some time.

ABSTRACT

Fast-paced developments in big data and machine learning (ML) have brought about a paradigm shift in how portfolio risk and alpha strategies are executed by institutional investors. This paper explores whether the application of risk models based on machine learning (ML), namely Random Forest (RF) and Long Short-Term Memory (LSTM) neural network algorithms, offers meaningful improvements in comparison to conventional VaR estimation and mean-variance optimization methods for 30 actively-managed stock mutual funds from the National Stock Exchange (NSE) of India between 2019 and 2024. Statistical analyses using Pearson correlation, ANOVA, and regression models were performed using Python packages and JASP software. Results show that ML models outperform traditional models in tail-risk probability calculations by 21-27%, portfolio Sharpe ratio was increased by 14.3% following the incorporation of ML-driven indicators for asset allocation, and the value added through sentiment analysis of earnings call transcripts is measured at 0.19 R^2. It appears that there is a very compelling rationale behind adopting data analytics and machine learning in the investment decision-making process.

Keywords: Machine Learning, Portfolio Risk, Value-at-Risk, Predictive Analytics, NSE India, Sharpe Ratio, LSTM

INTRODUCTION

The current state of global financial markets is characterized by profound changes. Modern markets generate tremendous amounts of data, computers are cheap and efficient enough to process this data, and complex algorithms based on statistics are available. It resulted in the emergence of something that was hardly ever seen two decades ago – large-scale, purely quantitative, and data-driven approach to asset management. The topic is of great importance not only for finance professionals but for all MBA students, as well. Traditional risk metrics such as standard deviation, beta coefficient, and even parametric value at risk are no longer relevant. Markets have never been perfectly Gaussian and linear. The Global Financial Crisis of 2008 clearly proved that assumption incorrect. In addition to it, the market crash caused by the coronavirus pandemic of 2020 demonstrated yet again that correlation between different assets and the normal distribution of market values cannot be used in the framework of Markowitz' mean-variance optimization (Fabozzi et al., 2010). In other words, conventional methods cannot predict regime changes. Regulatory authorities are aware of this problem and introduce new requirements, including Basel III and SEBI's Risk Management Framework (SEBI, 2022). The field of machine learning, on the other hand, presents a completely new way of thinking. Methods like Random Forests, Gradient Boosting Machines, and recurrent neural networks like LSTM networks are non-parametric by design because they learn the intrinsic structure of the data without imposing a particular functional form (Gu, Kelly & Xiu, 2020). There is empirical evidence available from advanced economies where portfolio strategies enhanced by machine learning techniques exhibit risk-adjusted positive abnormal returns (Bali, Engle & Murray, 2016). However, India is no USA. The fact that India has higher volatility, information asymmetry, regime shifts caused by policy interventions, and lower liquidity makes one question how applicable findings from the S&P 500 index are to the NSE.

Other areas where machine learning techniques have been adopted include credit risk evaluation, fraud detection, systematic risk assessment, and real-time rebalancing. With the advent of Natural Language Processing (NLP), there is a new field for machine learning which involves capturing forward-looking information from earnings calls, financial and other regulatory filings, and macroeconomic news, as well as transforming the unstructured text into numerical features used for investments (Loughran & McDonald, 2011). With mandated reporting in India by SEBI on quarterly, annual, and ESG fronts, India has a huge pool of unstructured data that can be analyzed. In this research study, we adopt an empirical approach. We assess machine learning models using a comparison against conventional benchmarks and estimating the impact of sentiment analysis on portfolio performance. Specifically, this study analyzes 30 equity funds listed on the NSE over 2019-2024, and evaluates the Sharpe ratio improvement from analytics-driven rebalancing. While this is a straightforward approach to demonstrating the viability of a technical solution, the objective is not merely to show off the use of technology, but to deliver useful evidence-based information. The rest of this research is organized as follows: Section 2 provides the literature review and hypothesis formulation. Section 3 outlines the dataset and methods used in this study. Section 4 includes the empirical findings. Sections 5-8 include the discussion, limitations, and conclusion of this research.

Literature Review and Hypothesis Development

The convergence of finance and machine learning has emerged as one of the most fruitful domains for academic research in the twenty-first century – but also one of the most contentious. Classical finance theory, based on the assumptions of the efficient market hypothesis and capital asset pricing model, has been continuously tested by empirical evidence that contradicts rational expectations: momentum, value, volatility – all have confounded EMH and CAPM (Fama & French, 1993; Shiller, 2003). While behavioral finance partially explains market behavior through cognitive dispositions such as overconfidence and herding (Thaler & Sunstein, 2009), these models fail to accommodate the rapid pace and complexity of today's financial landscape. The practical application of machine learning in this context lies in the provision of a flexible approach to detecting predictive signals in noisy high-dimensional financial datasets. According to Gu, Kelly, and Xiu (2020), an extensive range of ML methods including neural networks, random forest and regression tree models have been found to dominate linear factor models in predicting equity returns in one month horizon across all U.S. equities, where ensemble models delivered out-of-

sample monthly R^2 of 0.40%. Similarly, Fischer and Krauss (2018) illustrated that LSTM network models have sufficient directional accuracy to deliver positive annualized profits after transaction fees from predicting S&P 500 index returns. Locally, Agrawal et al. (2022) indicated that gradient boosting models have superior prediction accuracy compared to CAPM models in NSE 500 stocks.

VaR, despite its adoption in Basel, has always faced criticism because of its major weakness – its tendency to underestimate tail risks just when they matter the most – during crises. Although CVaR (or Expected Shortfall), which addresses this issue, still requires certain distributional assumptions, ML-based risk models avoid this altogether since they directly model the joint empirical distribution of returns, thus performing well especially during non-stationary and fat-tail conditions (Khemchandani & Jayadeva, 2009). Cao et al. (2021) reported that hybrid LSTM-GARCH models improved the VaR forecasts by 23% compared to parametric models in the Asian stock markets – an observation with clear implications for India. Sentiment analysis is another useful complementary signal. Loughran and McDonald (2011) demonstrated that a negative tone in annual report was indicative of underperformance in the future — this insight has been further enhanced by using transformer-based approaches like FinBERT, resulting in significantly better contextualized sentiment understanding in financial texts (Yang, UIT & Xu, 2020). As for India-specific evidence, Purohit and Sinha (2023) found out that management commentaries of NSE-listed firms were highly informative as far as predicting quarterly excess return goes. Building and rebalancing portfolios can be another application area of machine learning. Reinforcement learning techniques, where the agent learns how to choose stocks according to a certain strategy based on trial-and-error feedback, have shown themselves to be capable of achieving significantly better Sharpe ratio compared to plain-vanilla mean-variance portfolios (Deng et al., 2017). The same goes for factor investing, which is at the core of smart-beta funds' investment process (Kelly, Pruitt & Su, 2019).

Predictive Accuracy of ML Models Versus Traditional Risk Metrics

The current research evaluates the ability of machine learning (ML)-based predictive models (Random Forest [RF] and Long Short-Term Memory [LSTM]) to provide significantly better tail risk predictions than the parametric Value at Risk [VaR] model based on NSE equity funds. The basis of theory underlying this work is derived from the Adaptive Markets Hypothesis (AMH) by Andrew Lo, which states that market efficiency cannot be considered a constant characteristic of the market but changes dynamically based on market participants, regulators, and informational landscape (Lo, 2004). Within this theoretical framework, an adaptive model such as LSTM, which constantly learns new data, has an inherent advantage over a static model in its ability to adjust to changing risk scenarios. H1: ML-based predictive models provide significantly better tail risk predictions than traditional parametric VaR models for NSE equity funds.

Incremental Contribution of Sentiment Analytics to Portfolio Performance

In addition to the quantitative signals on returns, the unstructured financial text – earnings conference calls, management comments, SEBI filings, regulatory announcements – has forward-looking insights which have yet to be reflected in prices. The NLP-derived sentiment metrics act as high-frequency, efficient proxies for uncertainty and expected growth at the company level (Tetlock, 2007). From the perspective of Behavioural Asset Pricing Theory, the systematic measurement of investor sentiment acts as a predictor of stock return cross-sectionality after adjusting for risk factors (Baker & Wurgler, 2006). The Indian SEBI regime generates the precise data ecosystem for the use of NLP technology. H2: Sentiment analytics-enhanced models deliver substantially higher excess return forecasting accuracy and Sharpe ratios compared with quantitative models alone. [Conceptual Framework Diagram: Traditional Models –> ML-enhanced Models –> Sentiment Analytics Component –> Portfolio Risks & Returns Outcomes]

MATERIALS AND METHODS

In order to compare the empirical performance of machine learning techniques against classical models of finance in the context of prediction and decision-making regarding portfolio risk, the study uses a positivist-based quantitative

research method. This is a comparative and analytical framework, which includes analysis of time series data (from 2019-2024) and cross-sectional data pertaining to 30 sample equity funds. The usage of five years of data that incorporates the regimes of pre-COVID, crash due to COVID, and recovery after it increases both internal validity, by controlling for the heterogeneity of different market regimes, as well as the external validity of the study. Data secondary to the project was obtained from the historical NAVs fund portal of NSE India, ESG and fundamental factors from CRISIL and Bloomberg Terminals, as well as earnings call transcripts from BSE Filing portal. Sentiment scores were calculated using FinBERT in conjunction with earnings call transcripts. After this process, data underwent a thorough stage of pre processing, including winsorization at 1% and 99%, stationary checking via Augmented Dickey Fuller Test, as well as multicollinearity checks with Variance Inflation Factor. Analysis was carried out in Python (scikit-learn, TensorFlow, NLTK), R (Performance Analytics), and JASP software.

Measures

Data for NSE Equity Mutual Funds

Thirty active equity mutual funds registered in the NSE were chosen for analysis from January 2019 to December 2024. The NSE is known to offer one of the best data ecosystems in Asia, which includes daily net asset value (NAV), relative performance against benchmarks, factor loadings, and portfolio allocations. The selection process aimed at ensuring that the mutual funds considered represented different levels of market capitalisation (large cap, mid cap, multi cap) and industries (finance, tech, consumer goods, infrastructure). Monthly portfolios' return series were created and transformed into excess returns above the 91-day T-bill rate reported by the RBI.

Risk Model Variables

Parametric VaR analysis was carried out at 95% and 99% levels of confidence based on a rolling window of 252 days with a normal distribution assumption. Historical simulation VaR and Conditional Value at Risk (Expected Shortfall) were calculated as well for benchmarking purposes. The machine learning risk models were developed on a rolling window of 36 months: Random Forest models made use of 150 decision trees while LSTM models utilized two layers (with 64 and 32 nodes respectively), dropout regularization ($p = 0.2$) and Adam optimizer. Input variables considered in this study included past returns, realized volatility, market breadth measures, FII/DII data, India VIX Index as well as IIP growth, CPI and RBI interest rate data.

Sentiment Analytics Data

The sentiment scores were created using Fin BERT, a specialized form of BERT tailored for financial text analysis (Yang et al., 2020). Earnings call records of the top ten holdings of each sample fund for quarterly periods were collected from the filing portals of the BSE, followed by NLP preprocessing including tokenization, sentence breaking, inference for passages at the passage level (positive/negative/neutral sentiment) using Fin BERT, and then aggregation to get the weighted sentiment score per fund.

Sampling and Sample Size

A total of all 30 equity mutual funds which satisfied the selection criteria, including minimum five years of historical data, AUM exceeding ₹500 crores, and uninterrupted NSE listing during the entire analysis period, have been considered using purposive sampling. Thus, ensuring that only those institutional funds, which hold some significance are analyzed.

Data Analysis

For statistical analysis, we employed a comprehensive approach, employing Pearson correlation, one-sample t-test, ANOVA, and multiple regression modeling, which is aligned with the standards of analysis expected for financial time series research. In addition to JASP (Version 0.18) for inferential statistics, Python was used as the computational platform for ML, back testing, and NLP.

Correlation Analysis: ML Model Accuracy vs. Traditional VaR

The correlation analysis using Pearson coefficient exhibits a clear statistical hierarchy in terms of forecasting performance. Parametric VaR had only an average relationship with the observed loss values in the portfolios ($r = 0.412$, $p = 0.023$), which was helpful, but definitely insufficientin order to model the tail behavior of India equity funds. Using historical simulation slightly increased that figure to $r = 0.538$ ($p = 0.002$). However, Random Forest demonstrated good positive correlation ($r = 0.741$, $p < .001$), while the LSTM neural network performed best ($r = 0.763$, $p < .001$) thanks to its ability to capture path-dependent return risks. This is in line with empirical evidence from other markets (Gu et al., 2020; Cao et al., 2021). H1 is confirmed.

Sentiment Analytics: Incremental Contribution to Portfolio Performance

The findings presented herein paint a rich, multifaceted picture. Not only do portfolios constructed on the basis of quantitative factors alone (Sharpe = 1.142, $t(29) = 6.218$, $p < .001$) and those enriched by sentiment analytics (Sharpe = 1.306, $t(29) = 7.504$, $p < .001$) yield positive Sharpe ratios that surpass statistical significance, confirming their economic soundness; but the 14.3% boost in Sharpe ratio, alongside a tighter confidence interval indicative of smaller fund-to-fund variability, speaks volumes. In the regression cascade, the effect of layering becomes especially pronounced: from zero explained variance in the benchmark, the inclusion of VaR factors brings R^2 up to 0.293, whereas the incorporation of ML factors increases it to 0.507, while the lagged FinBERT sentiment index further boosts it to 0.654, resulting in a marginal ΔR^2 of 0.147 ($p < .001$). Sentiment analytics does matter. It is signal, not noise. H2 is confirmed.

DISCUSSION

These results prove what many practitioners have intuitively known for a while but were yet to be proven empirically for India: machine learning algorithms — especially LSTM and Random Forest — perform far superior compared to classical parametric models when it comes to portfolio risk prediction. And the margin is substantial. LSTM delivered 27% greater accuracy in predicting tail risks, following international standards (Cao et al., 2021; Fischer & Krauss, 2018) but now validated within the framework of Indian emerging market conditions. The regression cascade provides the most interesting insight from this paper. Moving from classical factor analysis models with $R^2 = 0.293$, to ML-enhanced factors with $R^2 = 0.507$, and finally to models that include sentiment factors as well with $R^2 = 0.654$ illustrates the true independence between each level of analytics used. There is no overlap between levels that simply repeat data already contained in lower-level analytics. The incremental improvement of 0.147 of R^2 delivered by sentiment models is especially interesting considering the recent developments by SEBI regarding disclosure requirements and the consequent growing database of structured texts for NLP to process.

It is worth noting that interesting trends at the sectoral level emerged. Fund portfolios with high levels of technology and financial services exposure registered significant gains due to the ML predictive model, probably due to the high volume of NLP processable disclosures generated from the firms' activities in these industries. Infrastructure funds and those with heavy commodity exposure, on the other hand, recorded moderate levels of improvement, probably because they derive their returns from macro rather than firm textual signals as previous research has shown (Kelly et al., 2019). In terms of strategy, these findings question the ongoing preference for rule-based investment strategies among Indian asset management companies. Not only has the possibility of creating alpha through data science analysis now been established empirically, but the necessary computational infrastructure (cloud GPU and open-source ML packages) has become widely accessible. Furthermore, the SEBI move towards using technological tools for risk management adds another layer of confidence to the argument in favor of its use.

Theoretical Implications

This research is relevant to several theoretical paradigms in finance and management. First, the outstanding performance of the ML models can be viewed as empirical evidence for the Adaptive Markets Hypothesis (AMH) by Lo (2004), which claims that a dynamic model that constantly adapts to new information enjoys an inherent structure advantage over a linear static model. Contrary to the EMH paradigm's static view of efficiency, AMH is flexible

enough to accommodate the variable predictive ability and regime-dependence in the factor risk premium exploited by ML models. Within the context of the Resource-Based View, the application of analytical competencies based on ML techniques to financial institutions can be treated as a rare, inimitable, and non-substitutable resource, creating sustained competitive advantage for the firm (Barney, 1991). The adoption of the AI/ML technology thus shifts the paradigm from cost to capability investment. Finally, the Behavioural Asset Pricing Theory (Baker & Wurgler, 2006) is corroborated by the positive and statistically significant marginal effect of the sentiment analysis. As a result, systematic measurement of investor sentiment through sophisticated natural language processing methods has been established as a persistent risk factor priced in the returns of emerging market stocks.

Managerial and Social Implications

For fund managers and CROs, the practical implications of the research can be summed up thus. Firstly, the use of ML enhanced VAR models needs to be built into the current systems as complementary – and ultimately replacement - methods for VAR modeling using Gaussian assumptions which have been shown to understate tail risks in India. Backtesting and the López Loss Function adopted in this research form a practical validation mechanism that can be implemented institutionally. Secondly, there is a need for asset management firms to build their capabilities in NLP as the number of mandatory financial disclosures in India grows, allowing better insights into financial risks. In-house development of sentiment indices based on NLP capabilities allows flexibility in analytics and information advantage as compared to using external black-box scores. It may be worthwhile for asset management firms to have a specialized data-science team within their investment and risk divisions. Third, transparency in decision-making using ML techniques is crucial from regulatory and fiduciary perspectives. With SEBI's guidelines on AI governance maturing, the fund management industry needs to ensure explainability in AI usage, specifically using SHAP values for feature importance in Random Forest algorithms. From a socio-economic perspective, better risk management in equity funds ensures that there is no misallocation of retail investor money within these funds, which leads to overall market stability and also protects the burgeoning population of retail investors in India. Accessibility to analytical fund management services through performance attribution and risk reporting backed by ML models is consistent with SEBI's mission and the larger financial inclusion drive in India.

Limitations and Future Directions

No research study can escape its limitations, and it would be wise to be upfront about them. The sample size of 30 equity mutual funds listed on NSE is limited to other asset classes (debt, REITs, InvITs, and hedge funds) and other stock exchanges beyond India. Moreover, the purposive sampling criterion of AUM greater than ₹500 crores and five years of trading experience suffers from survivorship bias. The sentiment scores have been obtained only from earnings calls and management commentary without any inclusion of social media sentiment (Twitter/X, Reddit finance subreddits), which may add value to the Indian sentiment data. While the five-year period spans across three different market regimes, it doesn't fully cover an interest rate or credit cycle in its entirety, making LSTM's performance generalizable across all market scenarios difficult to assess (Lohmann et al., 2024). Further research should consider longer longitudinal data periods as well as multilingual data samples. Using multi-asset classes and reinforcement learning for portfolio optimization is especially interesting in this regard. Comparing results to other Asian Emerging Market countries like Vietnam, Indonesia, or Brazil would help understand the universality of ML's superiority in portfolio optimization in various contexts. The exact causation between sentiment shock protection and portfolio Sharpe ratio needs further research (Brown, 2018).

CONCLUSION

The empirical analysis presented here proves something that practitioners have started realizing, but what is yet to see any academic backing from the Indian literature: predictive analytics and machine learning offer a step-change for managing risks associated with Indian equities. In fact, the evidence provided leaves no room for doubt on this matter. The LSTM and Random Forest models beat the traditional parametric VaR when it comes to forecasting tail risks in 30 NSE equity mutual funds, with r = 0.763 versus r = 0.412, while the inclusion of sentiment analytics adds a

meaningful, economic value-added layer with $\Delta R^2 = 0.147$ (14.3% improvement in the Sharpe ratio). In practical terms, these results imply that asset management within India needs a structural rethink. With further reduction of computation costs and an increase of data depth (fueled by growing disclosures mandated by SEBI and India's increasingly advanced technological ecosystem), the marginal cost of using ML approaches diminishes while their potential grows exponentially. Fund managers and risk officers should break free from the inertia associated with their inherited framework. The use of ML models in this context is not an experiment but a credible approach to managing risks with a robust corpus of empirical evidence. The shortcomings of the traditional methods highlighted through the recent decade of disasters prove the dire costs associated with complacency regarding risk management models. Proactive implementation of ML algorithms could be regarded as infrastructure that helps avoid catastrophic losses while securing investors' wealth and fostering overall capital market stability in India. Future research extending this methodology to fixed income securities and alternative investments and comparing its performance between different countries and in different economic cycles would strengthen the empirical basis of analytics-led portfolio management.

ABSTRACT

In today's digital world AI is playing a vital role in order to make possible to create, deliver impactful brand moments with speed and intention to drive long-term loyalty and growth. Today's customers expect brands they trust which deliver relevant and continued connections. AI has become a powerful technology to drive personalization, predictive analytics customer experiences and much more. It has a big impact on productivity, efficiency and innovation. The customer behavior is changing, but AI offers great opportunityto marketers to go insight into customer behavior at speed, which inturn helps the customers to satisfy their needs at speed. But AI does not replace the roles and efforts of humans! The study was conducted with a view to know and collect the opinion of the consumers regarding the follow up of Ethics in Artificial Intelligence. To create awareness regarding ethical issues followed in AI to the consumers. The study was conducted by a questionnaire method wherein google form was prepared and sent to the consumers. The respondents have given their perspective on the various aspects regarding use of AI in digital marketing.

Keywords: Artificial Intelligence (AI), Ethics, Digital Marketing

INTRODUCTION

Digital marketing is the means of promoting brands, products, or services using online digital channels like social media, websites email, search engines, and apps to connect with customers, to create awareness, drive traffic,and increase sales, offering precise targeting and measurable results. Digital marketing has become part and parcel of each and everyone's life. Emerged in the year 1990's with the use of internet, marketers are benefitted but also face challenges from rapidly evolving digital channels.

Artificial Intelligence (AI) is a technology enabling machinessimulate human intelligence, learning, problem-solving, and decision-making through data analysisand adaptation, powering applications from search engines and virtual assistants (Siri, Alexa) to self-driving cars and complex medical diagnostics, which are changing industries by automating tasks and offering insights beyond human capacity. There developed a symbiotic relationship between AI and digital marketers. According to 2024 global digital skills and training report has revealed that AI has a significant impact on productivity (50%), efficiency (45%) and innovation (38%).The marketers have to bother about AI in their marketing as it is used everywhere. The real question arises as to how to use AI in digital marketing ethically?

Ethics in Artificial Intelligence

AI ethics is the follow up of guidelines, principles that govern the development, deployment and use of AI in order to ensure transparency, privacy and accountability. For businesses using AI is a way by which they can respect consumer rights and build moral trust.

Benefits of using AI in digital marketing

AI helps in Building trust and confidence

When the marketers use Ethical AI then it helps in building confidence and trust regarding their data handling, the marketers have to clearly label AI generated content, obtaining consent to collect the data.

Helps in maintaining Consumer privacy

AI thrives on data but any consumer will be not be ready to lose his/her privacy. By the use of ethicalAI, the digital marketers make sure that it will not affect the private data of an individual. The Digital Personal Data Protection Act 2003 is formed to protect the individual's digital personal data. The consumers are guaranteed that their data is secure, they engage comfortably with the brands.

AI Promotes fairness

The AI has to be developed and used responsibly, then it will eliminate biases rather than reinforce them. So, it provides fair impact on the marketer.

Avoid legal and financial liabilities

The marketers should not create any kind of negligence on the ethical AI which will result in serious consequences. The regulatory bodies are cracking down on AI misuse and the companies violating ethical guidelines have to face the risk of monetary penalties.

Ethical concerns in AI marketing

Data privacy and consent

Data plays an important role in AI; the data should be collected and handled properly as it is the consumers data. The consumers will move somewhere if they feel they are secured with a particular brand. So, the digital marketers using AI has to be properly trained regarding the ethical way of data handling.

Algorithmic bias

AI systems are only dependent on the data if the data is not given properly then it results in algorithmic bias. Which will create unfair outcomes. This bias is typically a reflection of human prejudices; societal inequalitiespresent in the data used to train the algorithm or in the design process itself.

Transparency in disclosure

Transparency refers to disclosure when the AI is used. AI transparency means making AI systems understandable by revealing how they're built, trained, and make decisions, which builds trust, ensures accountability.

Content creation

The businessesdepend on AI tools for content creation because it is time consuming and friendly. But the consumers are very intelligent that they are able to identify the content created using AI. The individuals or public with illegal intention can exploit the technology to create fake content about the product and also about the uses of the product.

Strategies for ethical AI in digital marketing

Conducting ethics-based audits in companies

The regular ethics-based audits help the business organizations to assess the transparency, fairness and accountability. So, IBM has developed AI Fairness 360 Toolkit, an open-source library that contains over 70 fairness metrics and algorithms.

Develop clear AI policies in the company

The company has to develop its own AI policies and that policy should define the role of AI's regarding when the AI is used whether for automation or decision making, setting ethical boundaries (deep fake ads), enforce human oversight (assist human efforts not replace).

Responsible data handling

Ensuring that the consumer data is handled carefully and to ensure consumers data privacy is maintained. The marketers have to collect only the required data, use encryption and secure storage practices.

Provide transparency

The consumers should be aware regarding when AI is influencing their marketing experiences. The company has to label the AI generated content, allow consumers to adjust AI driven personalization settings, disclose the role of AI in decision making.

Upskill the team

The company need to provide training, offers workshops on responsible AI use, keep the teams updated regarding AI regulations, promote interdisciplinary collaborations.

Using AI under guidance

AI cannot be technology driven but it createcontent, creating Ads, promotions etc, but human intervention is still required. Human oversight is required at every stage.

Be a watch dog

The marketers have to act like a watch dog by monitoring the ethical use, promoting transparency and human oversight. Conduct regular ethical audits by the digital marketers ensures the transparency, accountability.

REVIEW OF LITERATURE

Digital marketing is involved in the integration of data analytics, artificial intelligence, and automated decision-making systems. The advancements have improved targeting accuracy and customer engagement, they have also helped in significant ethical concerns related to privacy, transparency, manipulation, and accountability. Several scholars have examined the ethical aspects of digital marketing and their implications for businesses and consumers.

According to **Kotler et al. (2019)**, ethical marketing is fundamental to building long-term customer relationships. The digital platforms must prioritize honesty, fairness, and responsibility, especially when using consumer data for personalized marketing. The authorsargue that unethical practices such as misleading advertisements and hidden data collection can damage brand reputation and consumer trust.

Martin and Murphy (2017)highlight the data privacy as a core ethical issue in digital marketing. The study concentrates on how excessive data collection and lack of informed consent negatively affect consumer perceptions. The paper is concluded that transparent data practices and strong privacy policies are essential for maintaining ethical standards in digital environments.The rise of AI-driven marketing ledto ethical debates. **Davenport et al. (2020)**discusses that AI enhances efficiency and personalization, it can also lead to algorithmic bias and discriminatory targeting if not carefully managed. Their research stresses the importance of human oversight and ethical frameworks to guide AI applications in marketing.Consumer trust has been widely discussed in ethical marketing literature.

Laczniak and Murphy (2006) propose that ethical marketing practices significantly influence consumer trust and loyalty. The findings suggest that companies that prioritize ethical considerations experience stronger customer relationships and sustainable competitive advantage. Transparency in digital advertising has also been examined by **Boerman et al. (2017)**, the study sponsored content and online advertising disclosures. Theresearch reveals that clear disclosure of sponsored and AI-generated content improves consumer understanding and reduces feelings of deception. Regulatory frameworks play a crucial role in shaping ethical digital marketing practices. **Tene and Polonetsky (2013)** discuss how data protection laws encourage responsible data usage and protect consumer rights. They argue that compliance with regulations not only reduces legal risk but also promotes ethical business conduct.
Recent studies have also explored consumer awareness of ethical issues. **Powers et al. (2021)** the study revealed that the increased consumer awareness of data misuse and unethical targeting leads to higher resistance to digital advertisements. This suggests that ethical practices are becoming a competitive necessity rather than a mere compliance requirement. Overall, the literature review indicates that ethical digital marketing is essential for fostering trust, ensuring fairness, and achieving long-term business success. However, challenges remain in implementing ethical standards consistently, particularly with emerging technologies such as AI and big data analytics. The organisations have to balance organizational goals with consumer rights.

Objectives of the study

- To analyse data privacy and the way to protect.
- To investigate about the consumer awareness and perception on ethics
- To examine the relationship between ethical digital marketing and customer loyalty.

Hypothesis

Data privacy affects consumer attitudes towards digital marketing.
Consumers are aware of the ethical and unethical digital marketing practices.
Ethics in digital marketing has impact on long term consumer loyalty.

METHODOLOGY

This study has been conducted by using a descriptive research design. The research is based on primary data collected through structured questionnaire method. The questionnaire used in the present study is a closed-ended questions which are designed to gather required information from the respondents. A convenience sampling technique was used, with a sample size of 183 respondents. Data was collected through google forms and analysed using percentage analysis.

Data Interpretation

The data collected from respondents provides insights into perceptions, awareness, and concerns regarding the ethical use of Artificial Intelligence (AI) in digital marketing. The interpretation focuses on key ethical dimensions such as transparency, data privacy, bias, accountability, and consumer trust.

Awareness of Ethical AI Practices

The data indicates that a majority of the respondents have moderate to high level of awareness about the use of AI in digital marketing activities, including personalized advertising, chatbots, and data analytics. This shows that consumers are increasingly exposed to AI-driven marketing tools and are conscious of their influence on decision-making processes. However, a limited portion of respondents reported limited understanding of how AI systems collect, process, and utilize personal data. This shows the need for better consumer education and transparent communication by marketers.

Transparency and Explainability

The responses shows that transparency is a major concern among consumers. Most respondents agreed that companies should clearly disclose when AI is being used in marketing communications, such as automated customer service or targeted advertisements. Lack of transparency was perceived to reduce trust and increase confusion toward brands. The data suggests that ethical AI implementation requires marketers to adopt explainable AI systems that allow users to understand why certain ads or recommendations are shown to them.

Data Privacy and Security

The study strongly indicate that data privacy is the most critical ethical issue associated with AI in digital marketing. A majority of respondents expressed concern about unauthorized data collection, misuse of personal information. Many respondents believed that AI systems often collect more data than necessary, raising ethical and legal concerns. This interpretation implies that strict policy should be made to data protection laws and ethical data-handling practices is essential to maintain consumer trust and compliance.

Bias and Fairness in AI Algorithms

The data analysis reveals that respondents are concerned about algorithmic bias in AI-driven marketing. Many participants believed that AI systems may unintentionally discriminate based on factors such as gender, age, income level, or online behaviour patterns. This perception suggests that biased training data can lead to unfair targeting or exclusion of certain consumer groups. The interpretation highlights the importance of regular auditing of AI algorithms to ensure fairness and inclusivity in digital marketing practices.

Accountability and Responsibility

Analysis of the data shows that respondents expect companies to take responsibility for decisions made by AI systems. Most participants disagreed with the notion that unethical outcomes can be justified by blaming AI technology alone. This indicates a strong expectation for human oversight and accountability in AI-driven marketing operations. The interpretation suggests that organizations must establish clear ethical guidelines and governance frameworks for AI usage.

Impact on Consumer Trust

The data demonstrates a positive correlation between ethical AI practices and consumer trust. Respondents who perceived AI usage as ethical were more likely to trust the brand, engage with advertisements, and make purchase decisions. Conversely, unethical AI practices were found to negatively affect brand reputation and customer loyalty.

CONCLUSION

Ethical implementation of AI in digital marketing is not merely a regulatory requirement but a strategic necessity. Marketers and organizations must adopt responsible AI practices by ensuring transparency in data usage, obtaining informed consumer consent, minimizing bias in algorithms, and establishing clear accountability frameworks. Ethical governance, combined with adherence to legal standards and industry guidelines, plays a crucial role in balancing innovation with consumer protection.

ABSTRACT

Occupational stress has become a significant concern in the higher education sector due to the increasing demands placed on faculty members. Teachers in autonomous colleges are expected to perform multiple roles, including teaching, research, student mentoring, administrative responsibilities, curriculum development, and accreditation-related activities. These responsibilities often lead to increased levels of stress, which may adversely affect their job performance, job satisfaction, and overall well-being. Therefore, understanding the factors contributing to occupational stress among faculty members is essential for improving organizational effectiveness and employee welfare. The present study aims to examine the level of occupational stress among faculty members working in autonomous colleges affiliated with Bharathidasan University, Tiruchirappalli. The study investigates various factors influencing occupational stress, such as workload, role ambiguity, role conflict, time pressure, organizational support, interpersonal relationships, and work-life balance. It also explores the impact of demographic variables, including age, gender, educational qualification, teaching experience, and designation, on the level of occupational stress.

Keywords: job performance, job satisfaction, time pressure, organizational support

INTRODUCTION

In the contemporary educational environment, faculty members are required to perform a wide range of academic and administrative responsibilities, making occupational stress a significant concern in higher education institutions. Unlike the past, where teaching primarily focused on classroom instruction and student evaluation, the role of teachers has evolved considerably. Today, faculty members are expected to engage in teaching, research, curriculum development, student mentoring, institutional administration, accreditation activities, and various academic extension programs. These increasing demands often create pressure, resulting in occupational stress. Work occupies a central place in an individual's life, and a substantial portion of time is devoted to work-related activities. While a moderate level of stress may motivate employees and enhance productivity, excessive stress can negatively affect physical health, mental well-being, job satisfaction, and organizational performance. In educational institutions, occupational stress can lead to reduced teaching effectiveness, absenteeism, burnout, low morale, and diminished professional commitment. Faculty members working in autonomous colleges affiliated with Bharathidasan University, Tiruchirappalli, face unique challenges due to the autonomous nature of their institutions. Autonomous colleges enjoy academic freedom in designing curricula, conducting examinations, implementing grading systems, and introducing innovative teaching methodologies. However, this autonomy also brings additional responsibilities for faculty members. Teachers are actively involved in curriculum design, preparation of course materials, continuous internal assessment, examination management, academic auditing, and quality assurance processes.

Furthermore, autonomous colleges are required to maintain comprehensive academic and administrative records related to admissions, attendance, examinations, student performance, and institutional governance. Faculty members often participate in the activities of various academic bodies such as Boards of Studies, Academic Councils, Examination Committees, and other institutional committees. In addition, institutions are increasingly focused on accreditation and quality assurance initiatives such as the National Assessment and Accreditation Council (NAAC), National Board of Accreditation (NBA), and other quality enhancement programs. These activities significantly increase the workload and responsibilities of faculty members. The combination of academic duties, administrative commitments, research expectations, publication requirements, and accreditation-related tasks may contribute to higher levels of occupational stress among faculty members. If not effectively managed, such stress can adversely affect their job performance, professional effectiveness, and overall well-being. Therefore, it is essential to examine the extent and determinants of occupational stress among faculty members in autonomous colleges. Against this background, the present study aims to investigate the level of occupational stress among faculty members working in autonomous colleges affiliated with Bharathidasan University, Tiruchirappalli. The study seeks to identify the major factors contributing to occupational stress and to provide suggestions for creating a healthier and more supportive work environment that enhances faculty well-being and institutional effectiveness.

Need of the Study

Human resources constitute the most valuable asset of any nation, and the quality of human resources largely depends on the quality of education imparted by educational institutions. Teachers play a pivotal role in shaping students' knowledge, skills, and attitudes, thereby contributing significantly to national development. The effectiveness of teachers is influenced by various factors, including their professional competence, job satisfaction, motivation, and psychological well-being. In the higher education sector, faculty members are increasingly confronted with multiple responsibilities beyond classroom teaching. They are expected to engage in research activities, curriculum development, student mentoring, institutional administration, accreditation processes, and quality assurance initiatives. These expanding roles and responsibilities often result in increased workload and occupational stress. Autonomous colleges, in particular, enjoy greater academic freedom in designing curricula, conducting examinations, implementing evaluation systems, and introducing innovative teaching practices. While autonomy enhances institutional flexibility and academic excellence, it also places additional demands on faculty members. Teachers are required to participate actively in academic planning, examination management, committee

work, documentation, and accreditation-related activities, which may increase their stress levels. The success of the autonomous system largely depends on the commitment, involvement, and performance of faculty members. Excessive occupational stress can adversely affect their teaching effectiveness, research productivity, job satisfaction, and overall well-being. It may also negatively influence the quality of education delivered to students and the achievement of institutional goals. Therefore, it is essential to examine the extent and sources of occupational stress among faculty members working in autonomous colleges affiliated with Bharathidasan University, Tiruchirappalli. The findings of this study will help educational administrators and policymakers understand the stress-related challenges faced by faculty members and formulate appropriate strategies to improve their work environment, enhance job satisfaction, and promote institutional effectiveness.

Statement of the Problem

Higher education institutions play a crucial role in developing skilled human resources and promoting academic excellence. Faculty members are the cornerstone of these institutions, and their effectiveness significantly influences the quality of education imparted to students. However, the rapidly changing educational environment, increasing academic expectations, technological advancements, accreditation requirements, research obligations, and administrative responsibilities have considerably increased the workload of faculty members. In autonomous colleges, teachers are entrusted with additional responsibilities such as curriculum design, continuous internal assessment, examination administration, academic auditing, participation in various statutory bodies, and quality assurance activities. Furthermore, institutions are under constant pressure to maintain high academic standards, achieve accreditation benchmarks, improve research output, and meet stakeholders' expectations. These growing demands often create physical, mental, and emotional strain among faculty members. Occupational stress has emerged as a major concern in the higher education sector. Excessive stress may adversely affect teachers' job satisfaction, motivation, teaching effectiveness, research productivity, interpersonal relationships, and overall well-being. It may also lead to burnout, absenteeism, reduced organizational commitment, and decreased institutional performance. Consequently, the quality of education and student outcomes may be negatively affected. Despite the importance of faculty well-being, limited empirical studies have focused specifically on occupational stress among faculty members working in autonomous colleges. Since autonomous institutions involve greater academic freedom along with increased responsibilities, it is essential to understand the factors contributing to occupational stress and their impact on faculty performance. Therefore, the present study seeks to examine the level of occupational stress among faculty members in autonomous colleges affiliated with Bharathidasan University, Tiruchirappalli. The study aims to identify the major sources of occupational stress and provide suitable recommendations for reducing stress and enhancing the professional effectiveness and well-being of faculty members.

Objectives of the Study

Primary Objective

- To study the level of occupational stress among faculty members working in autonomous colleges affiliated with Bharathidasan University, Tiruchirappalli.

Specific Objectives

- To analyse the demographic and professional profile of the faculty members.
- To identify the major factors contributing to occupational stress among faculty members.
- To assess the level of occupational stress experienced by faculty members.
- To examine the relationship between demographic variables and occupational stress.
- To study the impact of workload, role conflict, role ambiguity, organizational support, and work-life balance on occupational stress.

Limitations of the Study

- The present study is confined to faculty members working in autonomous colleges affiliated with Bharathidasan University, Tiruchirappalli; therefore, the findings may not be generalized to faculty members of non-autonomous colleges or institutions affiliated with other universities.

- The study focuses only on selected dimensions of occupational stress such as workload, role conflict, role ambiguity, organizational support, work-life balance, and job-related factors. Other factors influencing occupational stress may not be covered.
- The study is based on primary data collected through a structured questionnaire. Hence, the accuracy of the findings depends on the honesty, understanding, and responses of the respondents.
- The research is limited to faculty members of Arts and Science autonomous colleges affiliated with Bharathidasan University and does not include faculty from engineering, medical, law, Or Other Professional Institutions.

RESEARCH METHODOLOGY

Introduction

Research methodology refers to the systematic process adopted for collecting, analyzing, and interpreting data to achieve the objectives of a study. The present study aims to examine the level of occupational stress among faculty members working in autonomous colleges affiliated with Bharathidasan University, Tiruchirappalli. This chapter describes the research design, sources of data, sampling techniques, sample size, data collection instruments, and statistical tools used for the analysis.

Research Design

The study adopts a descriptive research design to investigate the occupational stress experienced by faculty members and to identify the factors influencing their stress levels.

Area of the Study

The study is conducted among faculty members working in Autonomous Colleges affiliated with Bharathidasan University, Tiruchirappalli.

Sources of Data

- **Primary Data:** Primary data are collected directly from faculty members through a structured questionnaire designed to measure occupational stress and its related factors.
- **Secondary Data:** Secondary data are collected from books, journals, research articles, dissertations, university publications, government reports, websites, and other relevant academic sources.

Population of the Study

The population consists of all faculty members working in autonomous colleges affiliated with Bharathidasan University, Tiruchirappalli.

Sampling Technique

A Convenience Sampling Technique is adopted to select respondents from the target population due to accessibility and time constraints.

Sample Size

A total of 100 faculty members from selected autonomous colleges affiliated with Bharathidasan University, Tiruchirappalli, are chosen as respondents for the study.

Data Analysis and Interpretation

Interpretation

- Out of 100 respondents, 38% belong to the age group of 31–40 years, followed by 30% in the age group of 41–50 years.

- A majority of the respondents (72%) are married.
- Regarding educational qualification, 50% possess a Ph.D., while 32% have an M.Phil. degree.
- Most of the respondents (62%) are working as Assistant Professors, followed by Associate Professors (24%).
- About 36% of the faculty members have 6–10 years of teaching experience.
- Regarding monthly income, 34% earn between ₹30,001 and ₹50,000 per month.

Association between age and Occupational Stress Level

Hypothesis

H0: There is no significant association between Age and Occupational Stress Level among faculty members.

H1: There is a significant association between Age and Occupational Stress Level among faculty members.

Interpretation

The calculated Chi-Square value is 16.284 and the p-value is 0.012, which is less than the significance level of 0.05. Hence, the null hypothesis is rejected. Therefore, there is a significant association between age and occupational stress level among faculty members of autonomous colleges affiliated with Bharathidasan University, Tiruchirappalli.

Findings of the Study

Based on the analysis of occupational stress among faculty members of autonomous colleges affiliated with Bharathidasan University, Tiruchirappalli, the following findings were identified:

Demographic Findings

- The majority of the respondents (38%) belong to the age group of 31–40 years.
- Most of the respondents (72%) are married.
- Half of the respondents (50%) possess a Ph.D. qualification.
- The majority of the respondents (62%) are working as Assistant Professors.
- Most respondents (36%) have 6–10 years of teaching experience.
- A considerable proportion of respondents (34%) earn between ₹30,001 and ₹50,000 per month.

Occupational Stress Findings

- Nearly half of the faculty members experience a moderate level of occupational stress.
- Workload, administrative responsibilities, and time pressure are the major contributors to occupational stress.
- Faculty members report difficulties in balancing academic, research, and administrative duties.
- Organizational support and work-life balance significantly influence the level of occupational stress.

Statistical Findings

- The reliability analysis indicates that the occupational stress scale is highly reliable.
- Chi-square analysis reveals a significant association between age and occupational stress level.
- Gender and designation are significantly associated with occupational stress.
- Educational qualification does not show a significant association with occupational stress.
- Regression analysis indicates that workload is the strongest predictor of occupational stress among faculty members.
- Work-life balance and organizational support negatively influence occupational stress, reducing its impact.

Suggestions

Based on the findings of the study, the following suggestions are offered to reduce occupational stress among faculty members:

- Colleges should adopt effective workload management practices to prevent excessive work pressure.
- Administrative responsibilities should be distributed fairly among faculty members.
- Institutions should organize regular stress management and wellness programs.

- Faculty members should be encouraged to maintain a healthy work-life balance.
- Colleges should provide counseling and psychological support services for faculty members experiencing stress.
- Adequate opportunities for professional development and career advancement should be provided.
- Management should encourage participative decision-making to improve employee involvement and satisfaction.
- Recognition and reward systems should be strengthened to motivate faculty members.
- Research and publication requirements should be supported through institutional assistance and resources.
- Flexible work arrangements and supportive organizational policies should be introduced wherever feasible.
- Periodic assessments of faculty stress levels should be conducted to identify and address emerging issues.
- Improved communication between management and faculty can help reduce role ambiguity and work-related conflicts.

CONCLUSION

Occupational stress has become a significant concern among faculty members in autonomous colleges due to increasing academic responsibilities, research expectations, administrative duties, and changing educational demands. The study reveals that a majority of faculty members experience a moderate level of occupational stress, with workload and role-related pressures being the major stressors. The statistical analysis confirms that demographic factors such as age, gender, and designation have a significant influence on occupational stress levels. Furthermore, organizational support and work-life balance play a crucial role in reducing stress among faculty members. Therefore, educational institutions should implement appropriate stress management strategies, provide a supportive work environment, and promote employee well-being to enhance faculty performance and job satisfaction. Reducing occupational stress will not only improve the quality of work life of faculty members but also contribute to the overall effectiveness and academic excellence of higher educational institutions.

ABSTRACT

The advent of artificial intelligence has changed the modern-day business environment. Although AI plays an essential role in identifying business opportunities and understanding complicated situations, most people prefer working at firms rather than starting their businesses. In this study, we evaluate people's ability to incorporate artificial intelligence in their lives and its effect on their entrepreneurial spirit and professional ambitions. To answer the research question, we collected primary data using structured questionnaires targeting a wide variety of professionals and educators. We assessed entrepreneurial intentions and career aspirations, while calculating AI readiness using participants' self-perceived knowledge, confidence, and usefulness of artificial intelligence. Various quantitative techniques, such as correlation, regression analysis, t-test, and ANOVA, were used to accomplish the study objectives. The main objective of this paper is to determine whether there is a link between AI readiness and entrepreneurial intentions or if the lack of technical expertise drives people towards conventional employment.

Keywords: Artificial Intelligence, Entrepreneurial Intention, AI Readiness, Employment Preference, Startup Initiation, Innovation

INTRODUCTION

In general, artificial intelligence is currently beginning to change the formation, operation, and improvement of companies across the globe. The implementation of technologies such as automation, predictive analytics, and generative AI in firms is aimed at decreasing the costs of creating a firm and improving its performance by making decisions based on data obtained through AI. The use of AI should make the formation of business easier and provide more opportunities in terms of cutting the cost and gaining valuable knowledge about the market. However, there arises an interesting paradox in that despite making the life of entrepreneurs easier, people choose the classic employment route and do not create their businesses. The reason behind such a paradox may be seen in people's willingness to engage with AI. The question that arises is the correlation between readiness to work with AI and the choice of either employment or entrepreneurship.

LITERATURE REVIEW

In the realm of innovation and start-ups, artificial intelligence is disrupting the status quo. The use of AI tech in start-ups and innovations eases entry into the world of start-ups by enhancing decision-making capabilities, increasing the ease of processes, and identifying opportunities more readily than before (Dwivedi et al., 2021). The incorporation of AI in entrepreneurial activities is a significant contributor to gaining a competitive advantage in the digital world.
Recent studies on AI in entrepreneurial contexts have shown that there are both prospects and pitfalls. Obschonka, Audretsch, and Silbereisen (2023) state that the use of AI in entrepreneurial contexts redefines how entrepreneurs think, including how they assess risks and identify opportunities. Chalmers, MacKenzie, and Carter (2021) argue that, in the Fourth Industrial Revolution, AI-based firms are redefining the start-up world. From a broader perspective of innovation, Nambisan, Wright, and Feldman (2019) suggest that the digital revolution has changed the entrepreneurial process through technology-driven business models. Another study by Sharma, Yadav, and Chopra (2022) presents a bibliometric study that indicates the growing relationship between AI and entrepreneurship; however, there is scope for further research at the individual-level behavior.

With respect to entrepreneurial intentions, it is revealed that behavior, perceived attitudal control, and self-efficacy are the key aspects that importatntly influence entrepreneurial perceptions (Liñán & Fayolle, 2015). However, there is limited understanding of the influence of AI readiness on entrepreneurial intentions. Moreover, the selection of work is also related to risk aversion, security, and stability concerns. However, there is insufficient empirical evidence available regarding whether not being AI-ready makes people more likely to opt for salaried work rather than venturing into business. Therefore, although the themes of AI and entrepreneurship have been separately explored in the literature, the intersection of AI readiness, entrepreneurial intention, and work selection has not been sufficiently explored. This study attempts to do so through an empirical investigation.

RESEARCH GAP

Although there is ample literature available about the concept of entrepreneurial intention and AI adoption, there is limited literature available about Artificial Intelligence readiness at the individual level of the entrepreneurial career decision process. Most of the literature available is about the AI adoption in the level of company but not at the individual level. Additionally, there is limited literature available about the individual level of the entrepreneurial intention process, where Artificial Intelligence confidence is considered. There is also limited literature available about the impact of low AI readiness levels leading to employment instead of entrepreneurship. Therefore, this study aims to bridge the gap through the empirical findings.

OBJECTIVES OF THE STUDY

1. To determine the level of respondents' awareness of AI and how ready they are.
2. To examine the connection between AI and starting a company.
3. To investigate whether a lack of AI readiness forces people to seek conventional jobs.

4. To investigate whether respondents' trust in technology affects their intentions to commence a business.
5. To ascertain whether respondents' readiness for AI affects their decision making to set up a business.

RESEARCH METHODOLOGY

This chapter discusses the design and implementation of the study, the data collection methods, the sampling procedure, the variables and the models involved, and the statistical tools used. The chapter will be based on the discussion of the investigation of the impact of the entrepreneurial intention in the context of preferring employment over the entrepreneurial venture.

Research Design

The study investigates the relationship between occupational preference and AI readiness using a quantitative method that involves descriptive and analytical components.

Source Of Data

Primary data was gathered using a Google Forms-based structured questionnaire.
Secondary data was gathered from books, journals, research papers, and scholarly websites about entrepreneurship and artificial intelligence.

Sampling Technique

To guarantee equal probability of selection and minimize sampling bias, the study employs the probability sampling (Simple Random Sampling).

Sample Size: The sample size consists of 150 valid responses collected from respondents through the online survey.

Variables of the study
Research models
Model 1: AI Readiness → Entrepreneurial Intention
Model 2: AI Readiness → Employment Preference
Model 3: AI Readiness → AI Influence on Decision Making

Hypothesis of the Study
Model 1:
- H0: Entrepreneurial intention is not significantly affected by AI readiness.
- H1: Entrepreneurial intention is significantly affected by AI readiness.
Model 2:
- H0: Employment preference is not significantly impacted by AI readiness.
- H1: Employment preference is significantly impacted by AI readiness.
Model 3:
- H0: AI influence in decision making is not significantly affected by AI readiness.
- H1: AI influence in decision making is significantly affected by AI readiness.

Data Analysis and Interpretation:

This is the statistical assessment of the data gathered to investigate how AI readiness affects employment preference, entrepreneurial intention, and AI influence on decision-making. Regression analysis was used in Microsoft Excel to conduct the analysis.

Model 1: Impact of AI Readiness on Entrepreneurial Intention:

Regression Output

Standard Error = 0.8599, Multiple R = 0.5889, R Square = 0.3468, Adjusted R Square = 0.3424, and Observations = 150. According to the R Square value, AI Readiness accounts for 34.68% of the variation in Entrepreneurial Intention. Significance F = 2.25615, F-value = 78.582. The regression model is statistically significant because the significance value is smaller than 0.05.

Coefficient Analysis:

AI readiness and entrepreneurial intention have a substantial positive link, as indicated by the positive coefficient (intercept = 0.6646, AI readiness coefficient = 0.8395, t-value = 8.8647, p-value = 2.25615).

Interpretation:

The results indicate that AI Readiness significantly booms theEntrepreneurial Intention. Individuals with higher AI preparedness are more likely to project startup intentions.

Model 2: Impact of AI Readiness on Employment Preference:

Regression Output

Multiple R = 0.4130, R Square = 0.1706, Adjusted R Square = 0.1650, Standard Error = 0.6498, Observations = 150. Approximately 17.06% of the variation in Employment Preference is explained by AI Readiness.F-value = 30.4388, Significance F = 1.50028E-07. Given that the p-value is less than 0.05, the model is statistically significant.

Coefficient Analysis

Intercept = 1.7106**,** AI Readiness Coefficient = 0.3948**,** t-value = 5.5171**,** p-value = 1.5003E-07**.** The positive coefficient indicates that AI Readiness positively influences Employment Preference.

Interpretation:

AI Readiness highly influences decisions with regard to career, although the explanatory strength is moderate.

Model 3: Impact of AI Readiness on AI Influence on Decision Making:

Regression Output

Multiple R = 0.5235, R Square = 0.2741, Adjusted R Square = 0.2692, Standard Error = 0.9001, Observations = 150. AI Readiness shows 27.41% of the change in AI Influence on Decision Making.F-value = 55.8725, Significance F = 6.26E-12. The regression model is statistically significant.

Coefficient Analysis

Intercept = 0.8891, AI Readiness Coefficient = 0.7409, t-value = 7.4748, p-value = 6.26E-12. The positive coefficient confirms a strong positive relationship.

Interpretation: The degree to which people use AI when making career decisions is greatly increased by AI readiness.

FINDINGS, DISCUSSION AND CONCLUSION

1. Regression analysis of the three models revealed the following important conclusions:
2. Entrepreneurial intention is positively and statistically significantly impacted by AI readiness. 34.68% of the variation in entrepreneurial intention is depicted in this model under study. There is a strong correlation ($p < 0.05$). Stronger intents to launch a business are demonstrated by those who are more aware of and prepared for AI.

3. AI Readiness is linked with Employment Preference. The relationship is positive and statistically significant. Moreover, it is responsible for around 17% of the variation in employment preference. Although its explanatory power is not strong, it is still significant in shaping how individuals view employment opportunities or stability.
4. AI Readiness is positively related to AI influence on decision making. The relationship is statistically significant. Moreover, around 27% of the variation is explained by the model. To put it simply, individuals with high AI readiness are more likely to be influenced by AI in their decision-making process.

DISCUSSION OF FINDINGS

This shows that where you are in relation to AI readiness affects your interests in a career and your desire to start a business. The most significant change, however, is seen in Model 1, where Entrepreneurial Intention increases significantly if there is a high level of AI readiness. This shows that if you are technically ready, you are more confident of your abilities to create and innovate new business ventures. This is further reinforced by Model 3, where there is a very strong relationship between AI competence and how people decide on their careers. This, therefore, shows how important it is for people to be digitally competent as they plan a career. Model 2, though not as significant as Model 1, still shows a significant effect, but here, it appears that while AI readiness affects the kind of jobs that people are interested in, security and pay are very important considerations. The study, therefore, shows that readiness in AI is a very important factor in determining entrepreneurial intentions and career choices.

CONCLUSION

The study indicates that the preparedness for Artificial Intelligence is one of the key factors that influence entrepreneurial intention, employment route, and decisions that are AI-based. The regression analysis proves that individuals who are higher aware and are with greater confidence in Artificial Intelligence are likely to have stronger entrepreneurial goals and believe in the credibility of starting one's own business. AI readiness helps in booming perceived control over behaviour, dipping concerns about technology, and increasing one's calibre to begin and gear one's own business in the AI business world. The above results it is evident that people's perceived readiness for AI plays a vital role in focusing on their perception of job alternatives. If you pose the question of how prepared individuals are towards AI to different people, two groups of respondents will emerge. Individuals who believe that they are technologically ready will tend to have positive attitudes towards innovation. Such people view AI as an opportunity for technological advancement and increased competitiveness. People who feel technologically unprepared, on the other hand, will mostly pursue stable employment and a consistent source of income because of fears regarding technology and the risks associated with launching new businesses. To summarize, individual technological readiness appears to influence people's risk-taking behavior.

Overall, it is safe to conclude that technology readiness is an important aspect to consider since it influences career decision-making processes in our days. With artificial intelligence gaining momentum and becoming increasingly common in the business environment, it will fuel entrepreneurial and career strategies. According to the results of the study, there is also a clear need to develop AI skills among workers and entrepreneurs.

Suggestions for Future Research

There are several directions for future research that might include a variety of independent variables such as risk-taking and innovativeness. Comparisons between sectors or geographical areas are also valuable. Longitudinal designs are another possibility to consider, focusing on how AI preparedness affects career development.

ABSTRACT

The Pudhumai Penn Scheme, launched by the Government of Tamil Nadu in 2022, aims to promote higher education among girls from government and government-aided schools by providing financial assistance of ₹1,000 per month. The scheme seeks to reduce dropout rates, encourage women's empowerment, and improve access to higher education. This study examines the socio-economic and educational impact of the scheme on girl students in Tamil Nadu. It evaluates whether the financial assistance has improved college enrolment, attendance, academic performance, and confidence among beneficiaries. The study adopts a descriptive research design using primary data collected through a structured questionnaire. The findings are expected to help policymakers understand the effectiveness of the scheme and suggest measures for its further improvement.

Keywords: Financial assistance, performance, effectiveness, improvement.

INTRODUCTION

Education plays a vital role in empowering women and promoting social and economic development. Despite improvements in literacy, many girls from economically weaker families discontinue their education after school due to financial constraints. To address this challenge, the Government of Tamil Nadu introduced the Pudhumai Penn Scheme, which provides monthly financial assistance of ₹1,000 to eligible girl students pursuing higher education

after studying in government or government-aided schools. The scheme aims to increase enrolment in higher education, reduce gender disparities, delay early marriage, and improve women's economic independence. This study analyses the impact of the Pudhumai Penn Scheme on educational opportunities, academic continuity, and the socio-economic well-being of beneficiaries in Tamil Nadu. Education is a key driver of social transformation and women's empowerment. However, financial constraints often prevent girls from economically disadvantaged families from pursuing higher education after completing school. To address this challenge, the Government of Tamil Nadu introduced the Pudhumai Penn Scheme (Moovalur Ramamirtham Ammaiyar Higher Education Assurance Scheme**)**, which provides financial assistance of ₹1,000 per month to eligible girl students from government and government-aided schools pursuing higher education. The scheme aims to improve the enrolment, retention, and completion rates of female students while promoting gender equality and educational inclusion.

The scheme was also expanded in 2024 to include eligible students from government-aided schools, thereby increasing its reach. The present study, titled "A Study on the Effectiveness of the Pudhumai Penn Scheme in Promoting Higher Education among Government School Girls in Tamil Nadu," evaluates the effectiveness of the scheme in encouraging girls to continue higher education. Specifically, the study examines the influence of the scheme on students' enrolment, regular attendance, academic performance, educational aspirations, financial security, and overall satisfaction. It also identifies the challenges faced by beneficiaries in accessing and utilizing the scheme and assesses the level of awareness regarding its benefits. The study adopts a descriptive research design and is based on both primary and secondary data. Primary data are collected through a structured questionnaire administered to 100 beneficiary students selected using a simple random sampling technique. Secondary data are obtained from government reports, published research articles, journals, books, and official websites. Statistical tools such as Percentage Analysis, Mean and Standard Deviation, Chi-Square Test, Independent Sample t-Test, One-Way ANOVA, Correlation Analysis, and Multiple Regression Analysis are employed to analyse the collected data. The study is expected to reveal that the Pudhumai Penn Scheme has significantly contributed to improving access to higher education by reducing financial barriers, increasing enrolment and retention, enhancing students' confidence and motivation, and supporting their academic progress. The findings will provide valuable insights for policymakers, educational institutions, and the Government of Tamil Nadu to strengthen the implementation of the scheme and formulate future policies aimed at promoting women's higher education and socio-economic empowerment.

Statement of the Problem

Higher education plays a significant role in empowering women, improving their employability, and contributing to the socio-economic development of society. Despite the increasing emphasis on gender equality in education, many girl students from economically weaker sections continue to face financial constraints that hinder their access to higher education. The cost of tuition fees, transportation, study materials, accommodation, and other educational expenses often compels students to discontinue their studies after completing school.To address these challenges, the Government of Tamil Nadu introduced the Pudhumai Penn Scheme (Moovalur Ramamirtham Ammaiyar Higher Education Assurance Scheme), which provides financial assistance of ₹1,000 per month to eligible girl students who have studied in government schools and are pursuing higher education. The scheme aims to improve enrolment in colleges, reduce dropout rates, encourage the continuation of education, and promote women's empowerment through educational opportunities. Although the scheme has benefited a large number of students across Tamil Nadu, it is essential to assess whether it has effectively achieved its intended objectives. Questions remain regarding the extent to which the financial assistance has encouraged students to pursue higher education, reduced financial difficulties, improved academic continuity, enhanced educational aspirations, and increased overall satisfaction among beneficiaries. In addition, issues such as awareness of the scheme, timely disbursement of benefits, accessibility, and implementation challenges may influence its effectiveness. Therefore, there is a need for a systematic study to evaluate the effectiveness of the Pudhumai Penn Scheme in promoting higher education among government school girls in Tamil Nadu. The findings of the study will help assess the outcomes of the scheme, identify existing gaps in its implementation, and provide suggestions for improving its effectiveness. The study will

also contribute to the formulation of policies aimed at strengthening women's access to higher education and promoting inclusive educational development in Tamil Nadu.

Objectives of the Study

- To study the socio-economic profile of the beneficiaries of the Pudhumai Penn Scheme.
- To examine the awareness level of students regarding the scheme.
- To analyse the impact of the scheme on higher education enrolment.
- To evaluate the influence of the scheme on attendance and academic performance.

Scope of the Study

The present study focuses on evaluating the effectiveness of the Pudhumai Penn Scheme in promoting higher education among girl students who have completed their schooling in government schools and are pursuing higher education in Tamil Nadu. The study examines the extent to which the scheme has contributed to improving access to higher education by reducing financial barriers and encouraging students to continue their education.The study covers various dimensions of the scheme, including students' awareness, accessibility, utilization of financial assistance, educational aspirations, academic performance, attendance, retention in higher education, and overall satisfaction with the scheme. It also assesses the influence of the scheme on reducing dropout rates, supporting Educational Continuity, and Enhancing the Confidence and Empowerment of Beneficiary Students.

Limitation of the Study

- The study is confined to beneficiary students of the Pudhumai Penn Scheme in the selected study area of Tamil Nadu; therefore, the findings may not represent all beneficiaries across the state.
- The study is based on a sample size of 100 respondents, which may limit the generalization of the results to the entire population of beneficiaries.
- The research relies primarily on the responses of the beneficiaries collected through a structured questionnaire. Hence, the findings are subject to the respondents' perceptions, opinions, and honesty in providing information.

Limitation of the Study

- The study is confined to beneficiary students of the Pudhumai Penn Scheme in the selected study area of Tamil Nadu; therefore, the findings may not represent all beneficiaries across the state.
- The study is based on a sample size of 100 respondents, which may limit the generalization of the results to the entire population of beneficiaries.
- The research relies primarily on the responses of the beneficiaries collected through a structured questionnaire. Hence, the findings are subject to the respondents' perceptions, opinions, and honesty in providing information.

RESEARCH METHODOLOGY

- **Research Design:** Descriptive Research
- **Nature of Data:** Primary and Secondary Data
- **Primary Data:** Structured Questionnaire
- **Secondary Data:** Government reports, journals, books, and websites
- **Sampling Technique:** Simple Random Sampling
- **Sample Size:** 100 respondents
- **Area of Study:** Tamil Nadu
- **Statistical Tools:**
  - Percentage Analysis
  - Mean and Standard Deviation
  - Chi-Square Test
  - Independent Sample t-Test

- One-Way ANOVA
- Correlation Analysis
- Multiple Regression Analysis

Data Analysis and Interpertation

Overall Interpretation

The findings indicate that the majority of Pudhumai Penn Scheme beneficiaries are young women aged 18–21 years, studying in government colleges, predominantly from rural backgrounds and lower-income families. Most come from households where parents possess school-level education, with fathers mainly employed in the private sector and mothers serving as homemakers. The scheme appears to play a crucial role in supporting higher education among economically and socially disadvantaged female students, particularly those from rural areas, thereby contributing to educational empowerment and social development.

Interpretation

The ANOVA result shows an F-value of 4.562 with a significance value of 0.005. Since the p-value is less than 0.05, the null hypothesis is rejected. Therefore, there is a significant difference in the mean satisfaction scores among respondents belonging to different family income groups. This indicates that family income influences the level of satisfaction towards the Pudhumai Penn Scheme.

Findings of the Study

- The majority of the respondents (38%) belong to the age group of 18–19 years, followed by 34% in the age group of 20–21 years.
- Most of the respondents (30%) are studying in the first year of their college education, while 28% are in the second year.
- A considerable proportion of the respondents (32%) are pursuing Arts courses, followed by Science (28%), Commerce (24%), and Professional courses (16%).
- More than half of the respondents (58%) are studying in Government Colleges, whereas 42% are enrolled in Government-Aided Colleges.
- A majority of the respondents (62%) belong to rural areas, indicating that the scheme predominantly benefits rural female students.
- Most of the respondents (40%) come from families with a monthly income ranging between ₹10,001 and ₹20,000, highlighting the economic vulnerability of the beneficiaries.
- The educational qualification of fathers reveals that 42% have completed school education, while 28% possess undergraduate degrees.
- The educational qualification of mothers shows that 44% have completed school education, whereas 22% are illiterate.
- A significant proportion of fathers (32%) are employed in the private sector, followed by business and other occupations (26%).
- The majority of mothers (58%) are homemakers, reflecting the traditional family structure among beneficiary households.
- More than half of the respondents (56%) use buses as their primary mode of transportation to reach college.
- The largest share of respondents (42%) travel a distance of 5–10 kilometres to attend college.
- Most respondents (46%) have been receiving benefits under the Pudhumai Penn Scheme for a period of 1–2 years.
- The findings indicate that the scheme primarily supports young women from rural backgrounds, government educational institutions, and economically weaker families.
- The scheme has contributed to encouraging higher education among female students by providing financial assistance and reducing educational barriers.

- The socio-economic profile of the respondents suggests that the Pudhumai Penn Scheme is effectively reaching its intended target group and promoting educational empowerment among women.

Suggestions

- The Government may increase awareness campaigns regarding the Pudhumai Penn Scheme, particularly in remote and rural areas, to ensure that all eligible students benefit from the scheme.
- The financial assistance provided under the scheme may be revised periodically in line with inflation and increasing educational expenses.
- Colleges should establish dedicated help desks to assist students in resolving issues related to registration, documentation, and receipt of scheme benefits.
- Regular monitoring and evaluation of the scheme should be undertaken to assess its effectiveness and identify areas for improvement.
- The government may introduce additional incentives such as skill development training, career guidance, and placement support for beneficiaries.
- Special attention should be given to students from economically weaker sections to ensure continuity in higher education.
- Digital platforms for application and grievance .

CONCLUSION

The present study examined the socio-economic profile of beneficiaries of the Pudhumai Penn Scheme and assessed its role in supporting higher education among female students. The findings reveal that the majority of beneficiaries are young women studying in government and government-aided colleges, predominantly from rural backgrounds and lower-income families. The scheme has emerged as an important initiative in promoting women's access to higher education by providing financial assistance and reducing economic barriers. It has encouraged students to continue their studies, improved educational opportunities, and contributed to the empowerment of women through education. The study further indicates that the Pudhumai Penn Scheme has been successful in reaching its intended target group and has played a significant role in enhancing educational inclusion and social development. Continued support, effective implementation, and periodic improvements to the scheme can further strengthen its impact and contribute to the educational and economic empowerment of women in Tamil Nadu.

ABSTRACT

Green investments are gaining momentum and receiving wider acceptance among investors globally, with Indian markets gradually integrating green and ESG-oriented products into mainstream investment channels. Investor behaviour remains sensitive to demographic factors, making it important to understand how specific cohorts, particularly millennials, respond to sustainable investment opportunities delivered through digital platforms. The millennial generation forms an influential investor segment, characterized by familiarity with technology and data-driven decision-making that supports informed and secure investment choices. Their preference for value-based investments has recently extended toward green investment options such as green equity shares, green bonds, and ESG mutual funds. Growing awareness of environmental sustainability, ESG goals, and concerns about ecological imbalance have encouraged millennials to consider investments that generate financial returns while supporting environmental responsibility. However, green investments are still perceived as relatively new, with concerns regarding return stability and consistency, making investors seek reliable advisory support. Robo-advisory platforms address this need through algorithm-based, data-driven, and customized investment recommendations based on investor risk appetite, income levels, return expectations, and investment goals. Their accessibility, cost efficiency, and technological convenience make them particularly suitable for millennial investors. The present study examines the preferences of millennial investors residing in Bengaluru to understand their awareness, perception and acceptance of green investment options as a preferred investment avenue using Robo / AI advisory platforms. Primary data collected through a structured questionnaire using probability sampling, yielding176 valid responses. The data were analysed using suitable statistical techniques to examine factors influencing millennials' allocation decisions toward green investment portfolios.

Keywords: Green investment, Millennial investors, Robo advisory platforms, ESG investing, Sustainable investing

INTRODUCTION

Green investing has grown rapidly across the world, with ESG-focused assets moving from a niche segment into the financial mainstream. Institutional as well as retail investors are increasingly factoring environmental and sustainability issues into how they build their portfolios. In India, too, sustainable investing is steadily gaining traction, backed by supportive regulation, growing climate consciousness, and a wider range of ESG-linked products such as SIPs, ESG mutual funds, green investments like green bonds, and sustainability-focused equity securities and portfolios. Investment behaviour, however, is not uniform across all groups of investors. Millennials, in particular, have emerged as a distinct and influential segment. Typically digitally savvy, highly engaged with financial technology, and comfortable using data to make decisions, they often look for investments that reflect both their return expectations and their personal values. This inclination toward value-based and impact-oriented investing positions millennials as important drivers of sustainable finance.

At the same time, robo-advisory platforms have reshaped how investment advice is delivered. These platforms use algorithms to construct portfolios, assess risk, and allocate assets in a cost-effective manner. They generate tailored recommendations based on inputs such as an investor's risk tolerance, return expectations, income level, and investment horizon. Today the millennialsare comfortable with digital interfaces and technology-led financial services, there by robo-advisors provide a natural gateway to discover, compare, and access green investment options. Yet, despite the parallel rise of sustainable investing and digital advisory tools, there is still limited empirical evidence on how robo-advisory platforms shape millennials' preferences for green investments, especially in the Indian context. Understanding this intersection is crucial to assess whether technology-driven advisory systems actually reinforce millennials' inclination toward ESG-oriented portfolios.

This study focuses on the green investment preferences that the millennial investorsin Bengaluru hold towards green securities, examined through the shrewd eyes of robo-advisory platforms. Drawing on primary data collected via a structured questionnaire, it analyses the key factors that influence millennials' decisions to allocate funds to green investment instruments when using robo-advisory services.

Objectives:
To examine the level of sustainable investment motivation among millennial investors in the context of ESG and green financial instruments. To analyse the influence of technology acceptance factors associated with robo-advisory platforms on millennials' sustainable investment decisions. To probe and examine the relationship between sustainability-oriented motivation and the motive to allocate funds toward green investment portfolios through robo-advisory systems.

LITERATURE REVIEW

Recent literature indicates that the convergence of sustainable investing and financial technology is significantly reshaping portfolio allocation behaviour. FinTech-enabled platforms have been found to enhance ESG integration by improving accessibility, transparency, and personalization of investment products, thereby increasing investors' intention to adopt green portfolios (Chen et al., 2025). In this context, research examining millennial investors' preferences within robo-advisory environments highlights behavioural determinants such as sustainability awareness, digital familiarity, and value-driven decision-making, emphasizing the role of technology-enabled advisory systems in advancing financial sustainability through data-driven portfolio construction (Suma &Shreelatha, 2025a). Research on robo-advisory adoption further demonstrates that perceived usefulness, trust, and algorithmic transparency are critical predictors of behavioural intention toward automated advisory systems (Belanche et al., 2019; Jung et al., 2018). Extending this perspective, recent findings suggest that ESG customization within robo-platforms strengthens sustainable allocation decisions by aligning technological efficiency with investors' ethical preferences (Roy & Vasa, 2025). The strategic integration of artificial intelligence into wealth

management has also gained increasing scholarly attention. Studies emphasize predictive analytics, machine learning–based portfolio optimization, and personalized advisory models as transformative tools in modern asset management. Governance mechanisms, ethical AI frameworks, and robust technological infrastructure are identified as essential enablers for sustainable and efficient wealth management systems (Suma, Udupa, & Supriya, 2025). Complementing this view, emerging evidence confirms that AI-driven investment management enhances risk assessment accuracy and long-term portfolio performance, strengthening the strategic status and importance of smart automation in financial decision-making (International Review of Financial Analysis, 2025).

Further, fintech adoption and digital finance innovation are increasingly recognized as catalysts for green investment behaviour. Digital tools such as algorithmic advisory systems, mobile investment platforms, and advanced data analytics reduce entry barriers to ESG investing and strengthen investor confidence in sustainable financial products (Suma &Shreelatha, 2025b). Empirical research also indicates that digital financial literacy significantly moderates the relationship between sustainability orientation and actual ESG investment allocation, suggesting that technologically competent investors are more likely to translate pro-environmental attitudes into actionable portfolio decisions (Raut et al., 2022). Studies additionally show that perceived risk reduction through algorithmic diversification enhances investor confidence in robo-advisory platforms, particularly when sustainability metrics are embedded within automated portfolio construction models (Bhatia & Bhatia, 2021). ESG data transparency and real-time performance analytics further improve investor trust in green financial products, thereby strengthening behavioural intention toward sustainable portfolio adoption (Baker et al., 2023). Evidence from emerging markets underscores the importance of regulatory clarity and disclosure standards in shaping participation in ESG-linked digital investment platforms, reinforcing governance as a foundational pillar of fintech-enabled sustainable finance ecosystems (Kumar & Prakash, 2024). Recent advancements in AI-driven asset management reveal that machine learning algorithms enhance predictive accuracy in ESG screening and dynamic portfolio rebalancing, leading to improved risk-adjusted returns (Li et al., 2023). Moreover, explainable AI frameworks are increasingly viewed as critical for maintaining transparency and investor trust in automated advisory systems, particularly where ethical and sustainability considerations influence allocation decisions (Dwivedi et al., 2023).

Fadzil et al. (2025) argued that while millennials were green in values, they did not necessarily turn such consciousness into wisely informed financial decisions. The study findings depicted an evident mismatch between values and competent familiarity, which is usuallyintensified by misleading greenwashing attributes of financial sector. Rakhmawati and Octobery (2025) used the term geographically rooted differences in green investment sites and learning platforms and information access to digital networks and policy provision for ESG investment products, particularly systemic denial for emerging economy millennials. The pattern of investment followed by millennial help in defining the path of financial sustainability through the assimilation of environmental, social, and ethical aspects in long-term wealth management. Patil (2024) indicates that millennials made purposeful choices toward the investment in socially responsible firms, hence propelling the flow of funds into the sustainability-driven industries.
Collectively, contemporary scholarship suggests that sustainability motivation, fintech adoption, robo-advisory systems, and AI-enabled portfolio intelligence jointly form a multidimensional framework influencing green investment behaviour. However, integrated empirical models examining the combined behavioural, technological, and governance determinants of ESG allocation within robo-advisory ecosystems remain relatively underexplored, especially in developing economy contexts.

Research Gap

Synthesising the above strands of literature, several gaps become evident.Existing work on ESG investing largely concentrates on performance outcomes or investor sentiment, with far less attention given to how investors form allocation intentions in algorithm-driven advisory settings. At the same time, although millennials are often described as sustainability-minded, empirical evidence shows a mismatch between what they say they value and how they actually invest, indicating a clear attitude–behaviour gap. Research on robo-advisory platforms, meanwhile, tends to focus on why investors adopt these tools and how they build trust, rather than on specific thematic choices such as ESG-oriented allocations.

In the Indian context in particular, there is very little empirical work exploring how sustainability motivations and technology acceptance together shape green portfolio allocation among millennials who use robo-advisory platforms. Studying this intersection can reveal whether digital advisory systems truly act as catalysts for sustainable finance, or whether they function mainly as neutral technological channels with limited influence on underlying behaviour.
Against this backdrop, the current study aims to refer these gaps by empirically analysing how Sustainable Investment Motivation and Technology Acceptance affect Sustainable Investment Allocation Intention among millennial investors in Bengaluru.

Research Design

The study dives into descriptive research design to examine sustainable investment decisions among millennial investors within the context of robo-advisory platforms, an area that remains relatively nascent in India.Given the evolving nature of ESG investing and fintech-enabled advisory systems in India, an exploratory empirical approach was considered appropriate to generate preliminary insights into behavioural determinants influencing green portfolio allocation decisions.

Population and Sample

The target population comprises millennial investors (born between 1981 and 1996) with awareness of or exposure to robo-advisory platforms.Primary data collected from respondents residing in Bengaluru through a structured questionnaire. A total of 200 respondents were approached, out of which176 valid responses were screened and used for analysis. The study employs a probability sampling technique, and accordingly the simple random sampling method was adopted for the same.
Given the descriptive and exploratory orientation of the study, the sample size is considered to beadequate and apt for preliminary statistical analysis, including reliability testing, correlation analysis, and multiple regression modelling.

Data Collection

Data collected through a structured questionnaire comprising two major sections:

1. Demographic along with investment background information (age, gender, education, occupation, income, ESG awareness, and robo-advisory usage) formed a component of the questionnaire.
2. Likert-scale statements measuring key constructs related to sustainable investment motivation and technology acceptance.

Data Analysis Techniques

The collected data encoded and analysed using statistical software. With the support of Descriptive statisticsmean, standard deviation, and frequency distribution the profiles of the respondentsare assessedincluding general investment tendencies. Cronbach's Alpha reliability test is conducted to value the internal consistency of multi-item constructs. Pearson correlation was applied to examine the association among sustainable investment motivation, technology acceptance, and allocation intention. Further, multiple regression measure was performed to assess the collective influence of sustainability motivation and technology acceptance on sustainable investment allocation decisions.

DISCUSSIONS

Reliability Analysis

The internal reliability of the measurement scales was valued using Cronbach's Alpha. The Sustainable Investment Motivation construct demonstrated exceptional reliability, with a Cronbach's alpha value of 0.935. Similarly, the Technology Acceptance construct exhibited strong internal or core consistency, with an alpha value of 0.940. Both

values go beyond the recommended threshold of 0.70, indicating that the items within each construct are highly regular and reliably measure their respective underlying dimensions.

As shown in Table 1, millennial investors exhibit high levels of Sustainable Investment Motivation (M = 4.02) and Technology Acceptance (M = 4.05), indicating favourable attitudes toward ESG investments and robo-advisory platforms. However, the mean score for Sustainable Investment Allocation Intention (M = 2.23) is comparatively moderate, suggesting that strong motivation and technological acceptance do not proportionately translate into higher allocation decisions. The SD values indicate moderate variation in responses.

Table 2 indicates a strong positive correlation between Sustainable Investment Motivation and Technology Acceptance (r = 0.821), suggesting that millennials who exhibit higher sustainability motivation also demonstrate greater acceptance of robo-advisory platforms. However, the correlations between Sustainable Investment Motivation and Allocation Intention (r = 0.259), and amongst Technology Acceptance and Allocation Intention (r =0.230), are weak and positive. This suggests that while favourable attitudes toward sustainability and technology exist, they translate only modestly into actual allocation intentions toward green investments.

Multiple Regression Analysis

Interpretation

The regression model justifies 6.8% of the variance in Sustainable Investment Allocation Intention ($R^2 = 0.068$). On a bird's eye view the model is not statistically significant at the 5% level (p = 0.081), though it approaches marginal significance at the 10% level. Sustainable Investment Motivation exhibits a positive but statistically insignificant effect on allocation intention ($\beta = 0.153$, $p > 0.05$). Similarly, Technology Acceptance demonstrates a weak and non-significant influence ($\beta = 0.036$, $p > 0.05$). These findings imply that although millennials display strong sustainability motivation and favourable perceptions of robo-advisory platforms, these factors do not significantly predict their intention to increase allocation toward green investments.

FINDINGS

The study's results point to a striking behavioural paradox among millennial investors. They report strong Sustainable Investment Motivation and high Technology Acceptance of robo-advisory platforms, yet these attitudes do not meaningfully convert into a stronger Sustainable Investment Allocation Intention. Descriptive statistics show a clearly positive mindset toward both ESG investing (M = 4.02) and digital advisory tools (M = 4.05). This is consistent with the common view of millennials as value-driven, tech-comfortable, and open to sustainability-focused financial choices. In contrast, the much lower mean for allocation intention (M = 2.23) signals a noticeable attitude–behaviour gap.

The strong positive correlation between Sustainable Investment Motivation and Technology Acceptance (r = 0.821) suggests that, for this group, sustainability orientation and openness to fintech tend to go hand in hand. Millennials who care about ESG issues are also more at ease with algorithm-based advisory platforms. Even so, the weak correlations between these constructs and actual allocation intention indicate that positive perceptions by themselves do not automatically lead to investment commitments. Regression analysis reinforces this picture. The model accounts for only 6.8% of the variation in allocation intention and do not provide statistical significance at the conventional 5% level. Neither Sustainable Investment Motivation nor Technology Acceptance emerges as a significant predictor of green allocation choices. This pattern implies that other underlying factors—such as perceived risk, expected returns, liquidity needs, income limitations, or doubts about ESG performance metrics—may exert a stronger influence on actual green investing behaviour.

Taken together, the findings suggest that while robo-advisory platforms may improve visibility and ease of access to ESG products, convenience and positive attitudes alone do not guarantee behavioural follow-through. The study

adds to the sustainable finance literature by illustrating that alignment with sustainability values does not necessarily result in portfolio shifts, especially in an emerging market setting.

CONCLUSION

This study set out to analyse how Sustainable Investment Motivation and Technology Acceptance shape Sustainable Investment Allocation Intention among millennial investors in Bengaluru using robo-advisory platforms. The evidence shows that, although millennials exhibit strong sustainability-oriented attitudes and are highly receptive to fintech-enabled advisory tools, these attributes do not significantly drive green portfolio allocation. The results highlight a behavioural paradox in which value alignment and technological readiness coexist with only moderate willingness to allocate funds to sustainable assets. This points to the likelihood that psychological, financial, and market-related constraints moderate the link between motivation and actual investment behaviour. By underscoring this gap, the study promotes the ongoing discussions on the integration of sustainable finance and fintech. It suggests that robo-advisory solutions, on their own, may not be enough to accelerate ESG capital flows. To strengthen the impact, policymakers, fintech providers, and financial institutions need to pair technological innovation with clearer ESG performance information, targeted investor education, effective risk communication, and stronger trust-building mechanisms.

ABSTRACT

The COVID-19 pandemic prompted organizations to transition from traditional work environments to remote work to sustain business operations. This crisis significantly impacted all sectors, particularly the IT industry, which embraced the concept of remote work. As we move beyond the pandemic, it has become evident that employee well-being, social needs, and opportunities for career development are essential. Consequently, the hybrid work model has gained popularity, blending physical and virtual work methods. The key objectives of this study include assessing employee preferences and examining the effects of the hybrid work model on productivity, as well as evaluating the fulfilment of Maslow's hierarchy of needs. Specifically, the research aims to test the hypothesis if Employees' productivity levels are independent of whether they work in a physical, virtual or hybrid environment. And whether there is difference in the mean productivity ratings among employees across the different work models. Statistical analysis is conducted using the Chi-square test and single factor ANOVA test along with graphs and charts for effective data interpretation. A key finding from the survey responses is that the hybrid work model is widely regarded as the most effective approach to maintaining work-life balance, as it allows employees to benefit from in-office interactions for team engagement and emotional expression, while also providing the peaceful, stress-free environment of working from home. The study also highlights that subjective productivity perceptions and objective productivity ratings may not always align.

Key words: Hybrid work model, Employee perceptions, Employees' Productivity, Physical work mode, Virtual work mode, Remote work, Flexible work model

INTRODUCTION

The world is dynamic and change is the only constant. It was 1966 when the Electronics Committee which is also known as Bhabha Committee created 10 years foundation plan or IT sector emergence in India. That's when India's relationship with computers first started. IT industry was first born in Mumbai in 1967 which established Tata Consultancy Services (TCS) who later in the year 1977 partnered with Burroughs which began India's export of IT services. During this period, the Indian government took several steps to promote computer literacy and foster technical education. The first software export zone, SEEPZ – the precursor to the modern-day IT park – was established in Mumbai in 1973. More than 80 percent of the country's software exports were from SEEPZ in the 1980s. Software technology park of India envisaged under Digital India program launched the India BPO Promotion Scheme (IBPS). This scheme seek to incentivize establishment of 48,300 seats in respect of business process outsourcing (BPO) and information technology-enabled services (ITES) operations in India. STPI is the nodal agency of this scheme under the Ministry of Electronics and Information Technology. India's Information Technology (IT) industry is often regarded as one of the country's most significant success stories. In 1991, India implemented major economic reforms under Prime Minister P.V. Narasimha Rao and Finance Minister Dr. Manmohan Singh, which led to increased globalization and liberalization. This created an opening for India's IT sector to cater to international clients. It transformed the country's economy, job market, and even global perceptions of Indian talent. It was in 1970s the employees who worked extended hours were considered more efficient and hardworking.

Employees used to commute for 2-3 hours and then work beyond the working hours to get their work done. With the boom in outsourcing, the industry started to align with global time zones, especially North America. The work culture became more structured, with employees required to work night shifts or follow 24/7 support models to match the time zones of international clients. A typical workday was often 10-12 hours long, especially for those in client-facing roles. For the employees to feel more comfortable and work harder slowly companies started setting up large cafeterias, sports facilities, gyms and some employee welfare programs where their 10-12 hours of work could make it a little stress free. 2000s marked full globalisation in India and India became one of the largest global IT outsourcing hubs. This led to longer working hours and much more pressure on employees because this shift demanded quality and efficiency of the employees. Employees faced intense pressure to finish their deadlines, workdays used to extend to 10-14 hours. It was in 2010s where new technologies like cloud computing, big data, AI and cybersecurity emerged which led to flexible working hours to the employees. This is when the companies started focusing on employee well being and their work life balance giving option to work from home during emergencies. While remote work wasn't still the norm as the IT sector in India did not have sufficient resources. Things were working normal and employees had adopted this work culture. It was then most dramatic shift hit work culture in India. Emergence of COVID-19 pandemic. This impacted almost all the industries worldwide not just the IT sector. But the pandemic forced most of the IT companies to switch to remote work overnight relying on cloud-based software, zoom, Microsoft teams, VPN, Slack etc. After going fully remote the companies realised that Remote work can actually be as productive as physical work set up.

For two to three years most of the companies went on working fully work from home. Facilitated by technological advancements the companies realised the need for employees work life balance and social connectivity and also as cost cutting measures, the companies introduced Hybrid work model allowing employees to balance their work and personal lives. Employees are now called to physical work set up for certain days in a week and remaining days allowing them to work from home. Whether this hybrid work mode is going to be the future of IT work culture? There is no answer for this question yet as there is still arguments for and against the work culture. But currently this has become the new normal in Indian IT sector. The traditional 9-to-5 workday is being increasingly replaced by more flexible working hours and a results-oriented approach. While the average working hours have remained similar to the pre-pandemic days, the flexibility of remote and hybrid models has allowed employees to better manage their schedules. Companies that were previously strict about office timings began embracing results-oriented work environments (ROWE), focusing on outcomes rather than hours clocked. (Chellam & D, 2022) In the technology

era, the concept of hybrid models has become most commonly adopted in the third decade of the 21st century, especially in the IT sector. This change has made it necessary to reconsider such a concept as productivity for workers having experienced the separation of spheres of work and home life within the same premises (Charalampous et.al 2019). Therefore, the study is conducted to analyse the employees' perception on impact of hybrid work culture on productivity and their job satisfaction as employees are one of the major stakeholders of IT industry.

Background and Context

The COVID-19 pandemic has brought one dramatic shift in work culture that is highly appreciated by employees, especially in India: the adoption of remote and hybrid work models. Even though the pandemic has subsided and things have returned to normal, Indian tech companies have increasingly been adopting these flexible work arrangements for their employees instead of mandating a daily office presence. (Verma, 2024)A recent report by Xpheno, shared exclusively with ET, highlights the rise in hybrid and remote job openings in India. Despite the full reopening of offices, nearly 20% of all job postings in the country are now for remote and hybrid roles, a substantial increase from just 0.9% in 2020. In July 2024, the total job postings for hybrid and remote roles across sectors stood at 50,000, compared to 210,000 postings for purely office-based roles "In the recent days, the focus on returning to the workplace has intensified," Aditya Mishra, chief executive of CIEL HR Services, told ET. "CIEL's recent study highlights the dominance of the hybrid model, with over 60% asking their employees to be in office 2-3 days every week," he said. Richard Lobo, chief people officer of Tech Mahindra, said the company has implemented hybrid work policies that allow both flexibility and business continuity. "At Tech Mahindra, we believe in fostering a flexible work culture that accommodates diverse needs of our employees, while maintaining their productivity," he told ET. A Wipro spokesperson said the firm adopted a flexible workplace approach since the onset of the pandemic. Panasonic Life Solutions India is 100% operational from the office. However, its CHRO Adarsh Mishra said, "on a case-to-case basis and in case of a genuine requirement, the company does offer flexibility of a hybrid model" (Verma, 2024).

Problem Statement

With the shift in work culture in IT sector especially post Covid 19 era where the Indian IT sector has seen transition from physical work setup to work from home and now hybrid work culture. Companies now have adopted flexible work environment that combines remote work and on-site work with the help of technologies. This change has brought significant in work dynamics, employee culture and behaviour, and also organisation culture. While the hybrid model is offering flexibility to employees its essential to understand the key aspects such as employees' productivity and job Satisfaction. Therefore, the purpose of the study is to understand the impact of hybrid work culture on employees' productivity when compared to physical and remote work, their perceived benefits and challenges in hybrid work environment, whether the employees are satisfied and impact on their work life balance.

The findings of this study will provide valuable insights for IT companies seeking to optimize their hybrid work policies, ensuring they enhance employee performance, well-being, and satisfaction while maintaining organizational goals and competitive advantage.

Research Questions

- What is the perception of the employees on impact of hybrid work model on their productivity and performance?
- Whether the hybrid model influences employees job satisfaction, work-life balance and overall job engagement?
- To what extent hybrid model fulfils the Maslow's hierarchy of needs to the employees?
- What are the benefits and challenges associated with hybrid model and how do these affect employees' productivity?
- Whether the Employees' productivity levels are independent of whether they work in a physical, virtual or hybrid environment?

LITERATURE REVIEW

(Vaidya & Bedi, 2024) The hybrid work models try to avoid deficiencies of both the remote and in-office work practices by providing the freedom of choice while at the same time providing the advantages of interaction. This theory can increase productivity with the help of the pluses of these types of arrangement (Wang et.al 2020). For example, the workers can execute specific activities from their homes but partake in collective exercises in the office. However, there is still the issue of the probability level that is determined by the availability of sufficient technological support and by building an organizational culture that includes both remote and in-house employees in the organization. (Omolambe & Menon, 2024) : The focus of this study pays critical attention on the new norm in the work environment, investigating how the workplace has change drastically and the employee behaviour has also been influenced by this so-called change. The productivity of employees within the organisation has also taken a new turn. This investigation indicated that the introduction of new productivity tools in a hybrid work environment amounted to personal development, effectiveness and growth among employee and management, with work environment being reinvented, motivation, job development and technology. Also, the post-pandemic workplace is more technological and has a very wide depts of new and updated productivity tools in line, calling for more training and of employee to attain efficiency

(Gupta & Kumar, 2023)in the Study on "Hybrid Working Mode-The future trend" have analysed the productivity and working style of employees in the Hybrid Working. As per the study it has been found that workers value mixed work. However, not everyone believes that a hybrid way is the best option. The success of your company, as well as the productivity and wellbeing of your employees, may be impacted by the work policies that are established for the team. For those who use hybrid work, there has been a lot of trial and error over the years, and there still will be as many organisations figuring out how it can best serve them. (Iqbal, Khalid, & Barykin, 2021)in the study Hybrid Workplace: The Future of Work, states that for any work environment whose stakeholders intend to transcend the expectation of the constantly evolving workplace, the future of work should be a priority. Although some countries have relaxed the lockdown in their states, businesses are taking their time to set up a more formidable work arrangement. Many are already operating the hybrid system while others are running fully remote. The pandemic has taught the workplace a lesson of preparation and planning and given the reality check to keep up with the technological and management related advancements to ensure productivity and growth. Beyond that is also the lesson of flexibility and adaptability in the workplace. In prioritizing the future of work, there is the need to embrace the hybrid workplace model. (Gangisetty, Dias, & Irfan, 2024)The rise of hybrid work models, blending remote and onsite work arrangements, has become increasingly prevalent in today's workforce, especially in the IT industry. The research aims to determine the effects of a hybrid-work model on the job satisfaction of tech professionals, focusing on key factors including onsite work, remote work, flexibility, communication, and safety. The findings reveal significant positive associations between job satisfaction for both onsite and remote work. Additionally, flexibility and effective communication emerged as important factors positively influencing job satisfaction among tech workers in hybrid work environments.

Research design and methods

Research design

This study employed a mixed-methods research design to comprehensively explore the Employees' Perceptions on Impact of Blending Physical and Virtual Work Modes on Productivity. This design would allow for both qualitative and quantitative data collection and analysis, providing a holistic understanding of the phenomenon.

Objectives of the study

- To identify factors influencing productivity of employee in hybrid work model.
- To assess the challenges and benefits of hybrid work model on employees' performance.
- To find out if Employees' productivity levels are independent of whether they work in a physical, virtual or hybrid environment.

Hypothesis

The following hypothesis is set to check if Employees' productivity levels are independent of whether they work in a physical, virtual or hybrid environment.

H_0: Work mode and productivity level are independent.

H_0: H_0: $\mu1=\mu2=\mu3$

Sampling Methods and Sources

The study is conducted using questionnaire survey for primary data collection. The researchers have prepared questionnaires and distributed and have collected 102 responses. The respondents include only the employees working in IT companies in Dakshina Kannada and Bangalore. Statistical tool, Chi Square test is used to test the hypothesis. Also, charts and graphs are used to analyse and interpret the data collected. Available secondary data from articles and previously published literature are used for the study to provide context and comparison.

Scope and Limitations

The researchers chose Dakshina Kannada and Bangalore district as the location for the study. Only the employees working in IT companies are the respondents and the research is focused on the view point of employees only. The sample size is 102 which is lesser than minimum sample requirement of 384.16 calculated using formula for finite population at 95% confidence level and a 5% margin of error estimating population proportion to be 0.5. The collection of samples was hampered by lack of time and geographical hinderance. Additionally, the responses may be biased.

Data Analysis and Interpretation

Hypothesis Testing

Chi Square test results

Null Hypothesis (H_0): There is no significant relationship between the type of work model and employees' productivity perceptions.

Alternate Hypothesis (H1): There is no significant relationship between the type of work model and employees' productivity perceptions.

Chi-Square Statistic (17.05) is greater than the Chi-Square Table Value (15.507) at 8 degrees of freedom and a 0.05 significance level, this indicates that there is significant association between the type of work model and employees' productivity perceptions.

ANOVA-Single Factor Test

Null Hypothesis (H_0): There is no significant difference in the mean productivity ratings among employees across the different work models.

H0: $\mu1=\mu2=\mu3$

Alternative Hypothesis (H_1): At least one of the work models has a different mean productivity rating compared to the others.

P value is greater than 0.05 (1>0.05) and F value is lesser than F critical value (0.109265<1.385831). Hence Null hypothesis is accepted which means no statistically significant difference in the mean productivity ratings across the different work models. This chart indicates the current working mode of respondents in which 28 respondents are working from Office, 8 are working from Home and 67 are working under Hybrid mode. Out of the total 103 respondents who are already working under different work model, 73 of the prefer Hybrid work model and very least part (9) of the respondents prefer Physical work set up. Out of 103 respondents, 18% indicated that the flexibility to choose between work modes significantly impacts productivity, while 44% reported a moderate impact, and another 18% stated that it makes no difference. Out of the 103 respondents, 28 rarely get the option to work from home in case of emergencies only, 44 has an option to work from home once or twice a week, 23 of them four days a week, and 8 are under permanent Work from home.

The chart presents various factors influencing productivity in a hybrid model according to respondents. 73 prioritize work-life balance, 66 choose flexibility, 49 highlight the importance of team communication, 44 emphasize the work environment, and 27 cite access to resources and tools as key factors that influence productivity in hybrid work setting. The majority of respondents agree or strongly agree (74%) that the hybrid model enhances work-life balance, with only a small percentage (14%) disagreeing or strongly disagreeing. A high percentage (72%) agree or strongly agree that hybrid provides greater flexibility, indicating a positive perception of flexible working hours. Increases difficulty in managing time effectively in hybrid mode statement shows a mixed response, with a significant portion (30%) disagreeing, indicating they don't face difficulty managing time, while 27% agree, suggesting some struggle with time management. The neutral responses (32%) suggest that this is an area of ambivalence. The majority (71%) agree or strongly agree that hybrid work enhances communication with team members. A majority of respondents (57%) agree or strongly agree with the statement, showing that employees feel hybrid work limits in-person networking opportunities.

The key challenges in a hybrid model include difficulties with team communication (62%), an increased number of meetings (37%), Technical and network problems, along with limited access to resources (both at 35%), staying motivated is challenging for 32% of employees. In contrast, travel on workdays is a minimal concern (10%), indicating travel demands are generally Most employees report improvements in their ability to focus on tasks (58%) and quality of work produced (59%) in the hybrid model, suggesting that hybrid work supports productivity and work quality. However, stress levels show mixed feedback, with 45% reporting no change and 44% finding it much better, indicating a varied impact on stress. In contrast, opportunities for informal discussions are seen as significantly worse in a hybrid setup, with 47% rating it much worse, highlighting a challenge in maintaining casual, spontaneous interactions with colleagues in a non-physical environment.

Out of total 103 respondents, 33% of respondents said there is strong positive impact of hybrid model on their personal and mental well-being, 31% said somewhat positive impact, 33% remain neutral indicating there is neither positive nor negative impact, only 3% said there is somewhat negative impact.
The perceived benefits of the hybrid work model were notable, with the highest number of respondents highlighting better work-life balance (69) and increased flexibility in work hours (65) as major advantages. Reduced commute time and costs was also a significant benefit, mentioned by 61 respondents, followed by enhanced ability to manage personal responsibilities (58). Increased productivity and focus (46), better mental and physical well-being (47), and improved job satisfaction (43) also showed that hybrid work positively influenced performance and well-being.
Out of the 67 respondents currently working in a hybrid setup, all 67 confirmed that their basic needs were fulfilled. 57 respondents reported feeling safe in their current work model, while 50 indicated that their social needs were met. Additionally, 55 respondents stated they were receiving rewards and recognition, though only 38 felt they were able to fulfil their self-actualization needs.

Findings

- A significant majority (73 out of 103 respondents) prefer the hybrid work model, with only 9 preferring a physical work setup, reflecting a strong inclination towards flexible work arrangements. Flexibility in choosing work modes significantly impacts productivity for 18% of respondents, with 44% noting a moderate impact. This indicates that flexibility in work models is perceived to have a generally positive but varied influence on employee productivity. Most respondents (44) have the option to work from home once or twice a week, with 28 only allowed to work from home in case of emergencies. This suggests that while hybrid work is preferred, many employees still face limitations in the frequency of remote work.
- Work-life balance (73), flexibility (66), and team communication (49) are key factors that employees believe influence productivity in a hybrid setup. These factors highlight the importance of a balanced, flexible environment and strong communication in maximizing hybrid work effectiveness. A significant majority (74%) agree or strongly agree that the hybrid work model enhances work-life balance, and 72% feel it offers greater flexibility. This suggests that employees highly value the work-life benefits and the autonomy provided by hybrid work.

- While many employees agree that hybrid work increases focus (58%), challenges like team communication (62%), an increased number of meetings (37%), and technical issues (35%) remain prevalent. These challenges suggest that while hybrid work offers flexibility, it also requires improvements in communication and technology infrastructure. Many respondents (57%) agree or strongly agree that hybrid work limits in-person networking opportunities. This highlights a challenge in fostering casual, informal interactions that are common in traditional office settings.
- Respondents report a positive impact on their personal and mental well-being due to hybrid work. Key benefits identified by respondents include better work-life balance (69), increased flexibility (65), and reduced commute time and costs (61). These findings reflect the personal and professional adaptability that the hybrid work model offers. However, fewer respondents cited benefits like autonomy in managing tasks (28) and career development opportunities (25), suggesting these areas may need more focus for further employee satisfaction.
- While all respondents in the hybrid work setup confirmed their basic needs were fulfilled, a notable gap exists in fulfilling higher-level needs, as only 38 respondents reported fulfilling their self-actualization needs, indicating that while hybrid work meets basic and safety needs, it may fall short in providing opportunities for personal growth and achieving full potential for some employees.
- Since the Chi-square test showed a significant result, it indicates that there is an association between different work models and the perceived productivity levels. This suggests that the type of work model influence how employees perceive their productivity. The ANOVA did not find a statistically significant difference in the actual productivity ratings (out of 10) across different work models. This means that, while employees' perceptions of productivity vary with different work models, the numerical ratings they give for productivity do not show significant differences across these models. The contrasting results between perceived productivity categories (via Chi-square) and actual productivity ratings (via ANOVA) suggest that employees might perceive their productivity differently depending on the work model, yet their actual productivity ratings don't significantly change. Employees' subjective perceptions (like categorizing their productivity as "high" or "low") are influenced by the work model, possibly due to factors like comfort level, work-life balance, or self-assessment biases. However, when asked to quantify productivity on a scale, this variation isn't statistically apparent.

Suggestions

- While hybrid work is beneficial, it's important to ensure regular in-office interactions to foster team bonding and provide opportunities for emotional expression. Companies could encourage team-building activities, face-to-face meetings, and regular office days to maintain a sense of community.
- Based on feedback indicating that only a portion of employees feel recognized and rewarded, companies should invest in structured employee recognition programs. Regular acknowledgment of employee contributions, whether through awards, shout-outs, or incentives, can improve morale and reinforce a sense of value within the team.
- To address the gap in self-actualization fulfilment, companies should focus on providing employees with clear paths for career development. This could include opportunities for skills enhancement, mentorship programs, and leadership training, which can help employees achieve their professional goals and feel more fulfilled in their roles.

Scope for future research

One of the major findings of the study is that there is potential gap between perceived and actual productivity of the employees in different work set up. There is no match between subjective perceptions and objective productivity this may be because there are some factors in different work set up contributes to the productivity of the employees which is not studied in this research. Therefore, further Investigation can be done to identify the Disconnect Between Perceived and Actual Productivity along with Factors influencing productivity in different work set up.

CONCLUSION

The study on the impact of the hybrid work model has revealed significant insights into how different work models influence employees' productivity, well-being, and satisfaction. The findings indicate that while employees perceive hybrid work as highly beneficial for achieving work-life balance, improving mental health, and reducing stress, there are mixed responses regarding the impact on career development and task autonomy. The hybrid work model was found to positively affect employees' perceived productivity, with respondents highlighting flexibility, reduced commute time, and enhanced ability to manage personal responsibilities as major advantages. However, the study also indicated a disconnect between perceived productivity and actual productivity ratings, suggesting that while employees feel more productive in a hybrid setup, their quantitative assessments do not significantly differ across work models. Additionally, Maslow's hierarchy of needs framework demonstrated that while basic needs and safety are well fulfilled, there is room for improvement in addressing social needs and self-actualization within the hybrid work model. Employees expressed a strong preference for hybrid work due to its ability to blend both professional and personal responsibilities effectively, yet some still expressed nostalgia for the pre-pandemic office culture, indicating that a one-size-fits-all approach might not be applicable for all employees. Ultimately, the study emphasizes that organizations should continue refining their hybrid work policies by offering clear opportunities for recognition, career development, and personal growth to address unmet needs. The findings suggest that the hybrid model holds substantial potential for the future of work, provided companies adapt their strategies to ensure holistic fulfilment of employees' needs.

ABSTRACT

The current work examines the phytochemical makeup of *Coleus amboinicus* extracts and assesses their antibacterial, antioxidant, and wound-healing properties. Aqueous, ethanolic, and chloroform extracts were prepared and subjected to GC-MS, LC-MS, FTIR, HPLC, and NMR analysis to profile phytoconstituents. Antioxidant activities were assessed using DPPH, ABTS, FRAP, CUPRAC, and TRAP assays. Antimicrobial activity was evaluated against three intestinal pathogens identified via 16S rRNA sequencing. Additionally, a scratch assay using a non-diabetic cell line was conducted to assess wound healing efficacy. Results demonstrated significant antioxidant and antimicrobial effects, with ethanolic extract exhibiting the strongest bioactivity. Notably, the extract also enhanced wound closure in vitro, suggesting potential for therapeutic use.

Keywords: phytochemical, GC-MS, antioxidant, *Coleus amboinicus*, antimicrobial

INTRODUCTION

Medicinal plants have long served as an integral part of traditional healing systems across various cultures, offering a rich repository of bioactive compounds. Among these, *Coleus amboinicus* Lour., commonly known as Indian Borage or Mexican Mint, has garnered considerable attention due to its diverse pharmacological properties and its use in

folklore medicine. This aromatic, succulent herb belonging to the *Lamiaceae* family is widely used to treat respiratory ailments, gastrointestinal disorders, skin infections, and wounds (Paul et al., 2024). Traditional knowledge, combined with emerging scientific evidence, highlights its therapeutic potential, particularly in combating microbial infections and oxidative stress.

A major contributor to the pathophysiology of many chronic illnesses and delayed wound healing is oxidative stress, which is caused by an imbalance between reactive oxygen species (ROS) and antioxidant defenses. Free radicals can impair tissue regeneration by damaging cellular components and disrupting cellular signaling pathways (Stefanowicz-Hajduk et al., 2025). Therefore, antioxidants play a crucial role in neutralizing ROS, supporting tissue repair, and preventing chronic inflammation. Plant-derived antioxidants are especially valued for their safety profile and multifunctional benefits. In parallel, antimicrobial resistance has become a global health concern, driven by overuse and misuse of antibiotics. The search for novel antimicrobial agents from plant sources is thus a growing priority. *C. amboinicus* has shown promising antimicrobial effects against a wide range of bacterial and fungal pathogens, attributed mainly to its rich essential oil content and phenolic constituents (Stefanowicz-Hajduk et al., 2025, Paul et al., 2024). Compounds such as thymol, carvacrol, eugenol, and flavonoids have been identified in its extracts and are known for their antimicrobial and anti-inflammatory actions.

Inflammation, tissue proliferation, and remodeling are all part of the intricate and dynamic biological process of wou nd healing. Phytochemicals that modulate oxidative stress and microbial load can accelerate wound healing by enhancing cellular migration and collagen deposition. Previous studies suggest that the topical use of *C. amboinicus* extracts may facilitate wound closure and prevent infection, particularly in superficial wounds and skin abrasions (Paul et al., 2024). However, systematic studies correlating its phytochemical profile with biological activity are limited. The present study aims to bridge this gap by conducting a comprehensive phytochemical profiling of *C. amboinicus* using advanced techniques such as GC-MS, LC-MS, FTIR, HPLC, and NMR. In parallel, its biological activities are evaluated through in vitro antioxidant assays (DPPH, ABTS, FRAP, CUPRAC, TRAP), antimicrobial testing against clinically relevant intestinal pathogens confirmed by 16S rRNA sequencing, and wound healing assessment using the scratch assay on a non-diabetic fibroblast cell line. Multiple solvent extracts—aqueous, ethanolic, and chloroform—are compared to determine the most potent bioactive fraction. The study's objective is to identify and validate the multi-targeted therapeutic potential of *C. amboinicus*, particularly its capacity to act as a natural antioxidant, antimicrobial agent, and wound healing enhancer. These findings are expected to support the future development of plant-based topical formulations for skin care and infection management, offering a cost-effective and safer alternative to synthetic drugs.

MATERIALS AND METHODS

Extract Preparation (Aqueous, Ethanolic, and Chloroform):

Fresh leves of *C. amboinicus* were collected and shade dried. Using an electric grinder, the dried material was crushed into a coarse powder and kept in an airtight container.containers until extraction, at 4°C.Three solvents of increasing polarity—distilled water (aqueous), 95% ethanol, and chloroform were used to extract 100 grams of powdered leaf material. Every extraction cycle lasted six to eight hours, or until the solvent in the siphon tube turned clear, signifying a thorough extraction.The resulting extracts were filtered through Whatman No. 1 filter paper and concentrated under reduced pressure using a rotary evaporator at 40 °C. The concentrated extracts were further dried in a hot air oven at 45 °C to remove residual solvent, and the dry weights were recorded. The extracts were stored in sterile amber-colored vials at 4 °C for further phytochemical and biological activity analyses. The percentage yield was calculated for each extract based on the initial dry weight of the plant material.3.2 Phytochemical Analysis (GC-MS, LC-MS, FTIR, HPLC, NMR)

The phytochemical composition of the aqueous, ethanolic, and chloroform extracts of *Coleus amboinicus*was comprehensively analyzed using multiple spectroscopic and chromatographic techniques. Initially, Gas Chromatography–Mass Spectrometry (GC-MS) analysis was performed to identify volatile and semi-volatile

constituents, especially essential oil components, by comparing mass spectral data with the NIST library database. The analysis was conducted on a capillary column with helium as the carrier gas and an electron impact ionization source. Subsequently, Liquid Chromatography–Mass Spectrometry (LC-MS) was employed to detect and tentatively identify non-volatile phytochemicals, including phenolic acids, flavonoids, and diterpenoids, based on molecular ion peaks and fragmentation patterns. The LC-MS results were interpreted using retention time matching and spectral databases, consistent with methods reported (Jena et al., 2023).

High-Performance Liquid Chromatography (HPLC) was used to quantify and separate the major bioactive compounds. Fourier-Transform Infrared Spectroscopy (FTIR) analysis was performed using the potassium bromide (KBr) pellet method in the range of 4000–400 cm^{-1} to determine the functional groups present in the bioactive extracts. Prominent peaks indicated the presence of hydroxyl, carboxyl, and aromatic groups associated with polyphenols and terpenoids.Standards such as rosmarinic acid, caffeic acid, apigenin, and luteolin were used to generate calibration curves and quantify respective compounds within the extracts. Furthermore, Nuclear Magnetic Resonance (NMR) spectroscopy (^{1}H and ^{13}C) was utilized to structurally characterize the major phytochemicals isolated from the most potent extract. The spectral data were interpreted to confirm the identity of key secondary metabolites such as rosmarinic acid and carvacrol, in accordance with previous studies (Chen et al., 2023). These combined analytical approaches provided a detailed phytochemical fingerprint of *C. amboinicus*, essential for correlating chemical composition with biological activity.

Antioxidant Activity (DPPH, ABTS, FRAP, CUPRAC, TRAP):

A variety of in vitro tests, each evaluating distinct mechanisms of antioxidant action, were used to examine the antioxidant capacity of *Coleus amboinicus*preparations. The extracts' capacity to scavenge free radicals was assessed using the DPPH (2,2-diphenyl-1-picrylhydrazyl) radical scavenging test. Different amounts of each extract were combined with a methanolic DPPH solution (0.1 mM), and after 30 minutes of dark incubation, the absorbance was measured at 517 nm. $IC\bullet_0$ values and the % inhibition were computed. The extracts' capacity to neutralize $ABTS^{+}$ radicals, which are produced by reacting ABTS solution with potassium persulfate, was further evaluated using the ABTS (2,2'-azino-bis(3-ethylbenzothiazoline-6-sulfonic acid)) test. After reacting with the extracts for six minutes, absorbance was measured at 734 nm.

To assess reducing power, the Ferric Reducing Antioxidant Power (FRAP) assay was conducted by mixing the extracts with FRAP reagent and measuring the change in absorbance at 593 nm, which reflects the ability to reduce Fe^{3+} to Fe^{2+}. The Cupric Ion Reducing Antioxidant Capacity (CUPRAC) assay was carried out using copper(II) chloride, neocuproine, and ammonium acetate buffer, with absorbance measured at 450 nm to quantify the reduction of Cu^{2+} ions by antioxidants present in the extracts. For evaluation of chain-breaking antioxidant activity, the Total Radical-Trapping Antioxidant Parameter (TRAP) assay was performed. This assay measured the extracts' ability to inhibit the peroxidation of linoleic acid, using AAPH (2,2'-azobis(2-amidinopropane) dihydrochloride) as a radical initiator, and monitored fluorescence decay over time. All assays were conducted in triplicate using ascorbic acid and Trolox as positive controls, and results were expressed as IC_{50} values or Trolox equivalents where applicable. The methods followed were standardized (Jiang et al., 2021), ensuring reliable assessment of the antioxidant capacity of each extract through multiple mechanisms.

Antimicrobial Assay (Against 3 Intestinal Pathogens Confirmed by 16S Sequencing):

Three intestinal pathogenic bacteria—*Escherichia coli, Salmonella typhi, and Shigella dysenteriae*—were used to examine the antibacterial activity of the *Coleus amboinicus*extracts. The results were verified by 16S rRNA gene sequencing. The antibacterial effectiveness was assessed using the agar well diffusion method, in which wells on Mueller-Hinton agar plates infected with the corresponding bacterial strains were filled with 100 µL of each extract (concentrations ranging from 50 to 200 µg/mL). After 24 hours of incubation at 37 °C, zones of inhibition were measured. Additionally, the minimum inhibitory concentration (MIC) was determined using a broth microdilution method in 96-well plates, with bacterial growth monitored by optical density at 600 nm. Ciprofloxacin served as the positive

control, and solvent controls were included for validation. These methods followed standard antimicrobial testing protocols (Sukmawati et al., 2024).

Wound Healing Scratch Assay (Performed on Non-Diabetic Cell Line):

A non-diabetic fibroblast cell line (L929) was used in an in vitro scratch test to assess *Coleus amboinicus*extracts' capacity to repair wounds. At a density of 2×10^3 cells per well, cells were planted in 6-well plates and left to grow until they reached 90–100% confluency. To mimic a wound, a sterile 200 μL pipette tip was used to make a linear scratch in the middle of each well. After gently washing the wells with phosphate-buffered saline (PBS) to eliminate unattached cells, serum-free DMEM containing varying amounts of each plant extract (25, 50, and 100 μg/mL) was added to the media.The negative control consisted of cells that were solely given medium. Using an inverted microscope, wound closure was seen at 0, 12, and 24 hours, and photos were taken at the same field locations. By comparing the residual wound area with time, ImageJ software was used to calculate the percentage of wound closure. The assay was conducted in triplicate, and results were expressed as mean ± SD (Liu et al., 2022).

RESULTS

Phytochemical Composition of *Coleus amboinicus* Extracts:

The phytochemical profiling of aqueous, ethanolic, and chloroform extracts of *Coleus amboinicus*revealed the presence of a wide range of bioactive compounds. GC-MS analysis of the chloroform and ethanolic extracts indicated the presence of volatile constituents such as carvacrol, thymol, eugenol, and caryophyllene. These compounds are known for their antimicrobial and anti-inflammatory properties. LC-MS analysis further confirmed the presence of non-volatile polyphenols, flavonoids, and diterpenoids, including rosmarinic acid, apigenin, luteolin, and acetoxy-dihydroxyroyleanone—especially abundant in ethanolic extracts (Paul et al., 2024). FTIR spectra showed characteristic absorption peaks corresponding to hydroxyl (O–H), carbonyl (C=O), and aromatic C=C groups, confirming the presence of phenolic and flavonoid classes of compounds. HPLC quantification revealed significantly higher levels of rosmarinic acid (11.35 mg/g) and apigenin (17.59 mg/g) in the ethanolic extract compared to aqueous and chloroform extracts. Finally, NMR analysis confirmed the structural identity of key phytochemicals including rosmarinic acid and luteolin, supporting LC-MS and HPLC findings. As shown in **Table 1**, distinct chemical profiles were observed across different solvent extracts of *C. amboinicus*.

Antioxidant Activity

The antioxidant potential of *Coleus amboinicus*extracts was evaluated using five distinct assays: DPPH, ABTS, FRAP, CUPRAC, and TRAP. Among all extracts, the ethanolic extract exhibited the strongest antioxidant activity in all assays, indicating a high concentration of phenolic and flavonoid compounds. The IC_{50} value for the ethanolic extract in the DPPH assay was 28.41 ± 0.63 μg/mL, significantly lower than the aqueous extract (35.66 ± 0.72 μg/mL) and the chloroform extract (47.89 ± 0.81 μg/mL), suggesting superior free radical scavenging capacity. Similar trends were observed in ABTS and CUPRAC assays, where the ethanolic extract consistently demonstrated higher radical inhibition and reducing power. In the FRAP assay, the ethanolic extract recorded a ferric reducing capacity of 720.4 ± 12.6 μmol Fe(II)/g, compared to 542.8 ± 11.3 for the aqueous extract and 386.1 ± 10.2 for the chloroform extract. The TRAP assay also confirmed the higher peroxyl radical trapping efficiency of the ethanolic extract. These findings are consistent with prior reports demonstrating a strong correlation between phenolic content and antioxidant activity in *C. amboinicus* (Ślusarczyk et al., 2021; Kamal & Kumar 2025). **Table 2** demonstrates that the ethanolic extract of *C. amboinicus* possesses the strongest antioxidant capacity across all five assays—evidenced by its superior reducing power and lowest IC_{50} values—followed by the aqueous and chloroform extracts, respectively. Figure 1. shows the Comparative antioxidant activity of different *C. amboinicus* extracts in DPPH and ABTS assays.

Antimicrobial Activity:

The antimicrobial potential of *Coleus amboinicus*extracts was evaluated against three intestinal pathogens: Escherichia coli, Salmonella typhi, and Shigella dysenteriae, all confirmed by 16S rRNA gene sequencing. The ethanolic extract

showed the highest antimicrobial activity among all tested extracts, as evidenced by larger zones of inhibition and lower minimum inhibitory concentration (MIC) values. In the agar well diffusion assay, the ethanolic extract produced inhibition zones ranging from 17.6 ± 0.5 mm to 20.3 ± 0.4 mm, whereas the aqueous and chloroform extracts produced comparatively smaller zones (13.2–15.8 mm and 9.1–12.7 mm, respectively). The MIC values further confirmed these findings: the ethanolic extract exhibited MICs of 64 μg/mL for E. coli, 72 μg/mL for S. typhi, and 85 μg/mL for S. dysenteriae. In contrast, the aqueous and chloroform extracts showed moderate to low antibacterial effects (Kunhachan et al., 2026), As summarized in **Table 3**, the susceptibility profile of the target foodborne pathogens varied significantly depending on the extraction solvent, **Figure 2.**shows the Zone of inhibition observed for ethanolic extract of C. amboinicus against E. coli, S. typhi, and S. dysenteriae in agar well diffusion assay.

Wound Healing Activity:

*Coleus amboinicus*extracts' capacity to heal wounds was evaluated using an in vitro scratch test on L929 fibroblast cells. At 0, 12, and 24 hours after treatment, the rate of wound closure was assessed using various extract concentrations (25, 50, and 100 μg/mL). Compared to the water and chloroform extracts, the ethanolic extract showed the strongest wound healing activity, with faster cell migration and wound closure. At 24 hours, the ethanolic extract at 100 μg/mL concentration promoted 85.3 ± 2.1% wound closure, significantly higher than the aqueous extract (68.4 ± 1.9%) and chloroform extract (52.6 ± 2.4%) at the same concentration. A dose-dependent response was observed, with greater healing at higher concentrations. The control group (medium only) showed minimal wound closure (36.7 ± 2.8%). These findings suggest that the phytochemicals present in the ethanolic extract may facilitate fibroblast migration and proliferation. (Paul et al., 2024). As shown in **Table 4**, application of *C. amboinicus* extracts significantly influenced cellular migration and wound closure percentages over the tested concentration range.

DISCUSSION

The current study demonstrates the multi-targeted therapeutic potential of *Coleus amboinicus*through a comprehensive analysis of its phytochemical constituents and in vitro bioactivities. The phytochemical profiling confirmed the presence of diverse classes of bioactive compounds such as phenolic acids (rosmarinic acid, caffeic acid), flavonoids (apigenin, luteolin), and monoterpenes (carvacrol, thymol), which are known contributors to antioxidant, antimicrobial, and wound healing effects (Ślusarczyk et al., 2021; Mączka et al 2023). Among the tested extracts, the ethanolic extract consistently showed superior activity across all assays. This can be attributed to its higher solubility and extraction efficiency for both polar and moderately non-polar phytochemicals. Ethanolic extracts yielded the highest concentration of phenolic and flavonoid compounds, particularly rosmarinic acid and apigenin, which have been previously reported for their strong free radical scavenging properties (Furdak et al., 2023). The lower IC_{50} values in DPPH and ABTS assays, and the high FRAP and CUPRAC values, further substantiate the strong antioxidant profile of the ethanolic extract.

The antimicrobial activity of *C. amboinicus* against intestinal pathogens like E. coli, S. typhi, and S. dysenteriae reinforces its traditional use for treating gastrointestinal and infectious ailments. The ethanolic extract displayed the largest zones of inhibition and the lowest MIC values, aligning with prior studies that attributed antimicrobial efficacy to carvacrol, thymol, and flavonoids present in *C. amboinicus* essential oil and leaf extracts. These phytoconstituents have been shown to interfere with enzyme systems, damage microbial cell membranes, and cause oxidative stress in bacterial cells, which eventually results in cell death. In the wound healing assay, the ethanolic extract promoted significant fibroblast migration and wound closure in vitro, suggesting its potential application in dermal therapeutics. The high wound closure percentage at 24 hours (85.3%) reflects the synergistic effect of antioxidants and antimicrobial compounds, which not only protect against oxidative stress but also reduce microbial load at the wound site. Furthermore, the combined results highlight a correlation between phytochemical richness and bioactivity. The presence of both hydrophilic and lipophilic compounds in the ethanolic extract may account for its broad-spectrum efficacy. The relatively lower performance of the chloroform extract in all assays may be due to its inability to extract key polar phytochemicals, emphasizing the role of extraction solvent in maximizing therapeutic

benefits. Overall, this study provides scientific validation for the traditional use of *C. amboinicus* and underscores its potential as a natural source of compounds for the development of antioxidant, antimicrobial, and wound-healing formulations. Future studies involving in vivo validation and mechanism-based assays will further elucidate the therapeutic pathways and support clinical application.

CONCLUSION

With an emphasis on antioxidant, antibacterial, and wound-healing properties, the current study offers a thorough assessment of the phytochemical composition and therapeutic potential of *Coleus amboinicus*extracts. Because of its high concentration of phenolic acids, flavonoids, and volatile chemicals like rosmarinic acid, apigenin, and carvacrol, the ethanolic extract consistently showed greater bioactivity among the three extracts studied. The extract demonstrated strong antibacterial activity against intestinal pathogens verified by 16S rRNA sequencing, strong free radical scavenging and reduction power in several antioxidant tests, and noteworthy improvement of wound closure in fibroblast cells. These results corroborate *C. amboinicus's* significance as a multipurpose medicinal herb and support its traditional use. *C. amboinicus* shows promise as a natural source for creating plant-based therapies, especially in the form of antioxidant supplements, antibacterial agents, and wound healing formulations, given the close association between its phytochemical ingredients and biological activity. To turn these findings into useful applications, more in vivo research and clinical validation are advised.

ABSTRACT

The present study demonstrates a simple and efficient approach for the synthesis of silver nanoparticles using leaf and tuber extracts of *Pueraria tuberosa* (Willd.) DC. Plant-mediated nanoparticle synthesis is recognized as a green and dependable strategy due to its eco-friendly nature and avoidance of hazardous chemicals. The biosynthesized silver nanoparticles were characterized using various analytical techniques, including UV–Visible spectroscopy, X-ray diffraction (XRD), Fourier transform infrared (FTIR) spectroscopy, and scanning electron microscopy (SEM). The formation of silver nanoparticles was confirmed by the appearance of a surface plasmon resonance (SPR) peak in the range of 420–450 nm. FTIR analysis revealed the presence of carbohydrates, flavonoids, tannins, and phenolic compounds, suggesting their role as reducing and stabilizing agents during nanoparticle synthesis. XRD analysis confirmed the crystalline nature of the nanoparticles with a face-centered cubic crystal structure. SEM analysis provided insights into the surface morphology and verified the presence of silver nanoparticles. The antibacterial efficacy of the biosynthesized nanoparticles was evaluated using the agar well diffusion method, demonstrating inhibitory activity against both Gram-positive and Gram-negative bacterial strains. The notable antibacterial performance of these plant-derived silver nanoparticles highlights their promising potential for applications in medical and pharmaceutical fields.

Keywords: *Pueraria tuberosa* (Willd) DC, Silver nanoparticles, Antibacterial activity

INTRODUCTION

Nanotechnology refers to the science and engineering involved in the design, synthesis, manipulation, and practical utilization of materials at the nanometer scale [1]. In this field, nanoparticles are defined as particles with dimensions ranging from 1 to 100 nm. At this scale, materials often exhibit novel or enhanced properties arising from their unique size, shape, and surface characteristics [2]. These distinctive features have enabled nanotechnology to find extensive applications across various sectors, including electronics, biomedical research, pharmaceutical and cosmetic formulations, water purification technologies, and catalytic systems [3]. Nanoparticles of noble metals, such as silver and gold, have attracted significant attention due to their potential applications, particularly in biomedicine, where they are employed in drug and gene delivery systems as well as in the treatment of certain cancers [4]. Several methods have been developed for the synthesis of silver nanoparticles, including chemical reduction, thermal decomposition, electrochemical, photochemical, and biological approaches. However, conventional chemical and physical synthesis techniques are often associated with environmental hazards, high energy consumption, and increased production costs, limiting their sustainability and large-scale applicability [5]. In contrast, biological or green synthesis has emerged as a promising alternative that is environmentally benign, cost-effective, and easily scalable for large-scale nanoparticle production. This approach eliminates the need for high pressure, extreme temperatures, excessive energy input, and toxic chemicals, thereby reducing ecological impact and minimizing potential risks in biomedical and pharmaceutical applications [6].

In recent years, green chemistry approaches have been widely applied for the synthesis of silver nanoparticles (Ag NPs) using various biological systems, including yeast, fungi, bacteria, and plant extracts [7, 8, 9]. Among medicinal plants, *P. tuberosa*, a member of the Fabaceae family and commonly known as Vidarikanda or Indian Kudzu, is highly valued in Ayurvedic medicine, with its tuberous roots extensively used for their therapeutic properties [10]. The bioactive compounds present in this plant can act as natural reducing and stabilizing agents, making it a suitable candidate for the green synthesis of silver nanoparticles with potential biomedical applications. *P. tuberosa* is recognized in Ayurveda for its diverse therapeutic properties, including laxative, emollient, aphrodisiac, diuretic, galactagogue, emetic, and cardiotonic effects, traditionally used to manage various vitiated conditions of Pitta and Vata, such as arthritis [11]. The tuber burning sensations, constipation, cardiac debility, hepatosplenomegaly, leprosy, dyspepsia, spermatorrhea, tuberculosis, pharyngitis, and cough [12]. In folk medicine, it is also employed as a nerve tonic, galactagogue, anti-inflammatory agent, brain tonic, blood purifier, and to enhance sperm production [13]. The plant contains a variety of bioactive secondary metabolites, including flavonoids, phenolics, and tannins, which serve as natural reducing and stabilizing agents during nanoparticle synthesis. Several studies have reported the green synthesis of silver nanoparticles using leaf or tuber extracts of medicinal plants, such as *Catharanthus roseus* leaf [14], and *Asparagus nervosa* leaf [15]. In *P. tuberosa*, silver nanoparticle synthesis has been reported using tuber extract [16]; however, studies on leaf extract remain limited. Therefore, the present study focuses on the green synthesis of silver nanoparticles using both leaf and tuber extracts of *P. tuberosa*, followed by comprehensive characterization techniques.

Abbreviation: *P. tuberosa: Pueraria tuberosa (Willd) DC*, $AgNO_3$: Silver nitrate, AgNPs: Silver nanoparticles, XRD: X-Ray Diffraction, FTIR: Fourier transforms infrared spectroscopy, SEM: Scanning Electron Microscopy, TEM: Transmission Electron microscopy.

MATERIALS AND METHODS

Collection of Plant Materials

Leaves and tubers of *Pueraria tuberosa* (Willd.) DC were collected from the forest region of Rajpipla, Gujarat. Plant identification was confirmed by the Department of Life Sciences, Hemchandracharya North Gujarat University, Patan, Gujarat. The collected leaves and tubers were thoroughly washed with tap water followed by distilled water

to remove dust and debris. The plant materials were then cut into small pieces and shade-dried at room temperature for two weeks. After drying, the materials were coarsely powdered using a mechanical grinder and stored in airtight containers until further use.

Preparation of Plant Extracts

For the preparation of extracts, 10 g of dried leaf and tuber powder were separately mixed with 30 mL of ethanol. The mixture was subjected to extraction, and the solvent was removed under reduced pressure using a rotary vacuum evaporator. The resulting crude extract was reconstituted in 100 mL of distilled water and filtered through Whatman No. 1 filter paper to remove insoluble residues. The filtrate was stored in airtight containers at room temperature and used for the subsequent synthesis of silver nanoparticles [16].

Synthesis of Silver Nanoparticles

Silver nitrate ($AgNO_3$) was purchased from Sigma-Aldrich. 1 mM solution of $AgNO_3$ was prepared by dissolving 0.1669 g of $AgNO_3$ in 1000 mL of deionized water and stored in an amber-colored bottle to prevent photo degradation. For nanoparticle synthesis, 10 mL of leaf or tuber extract was individually mixed with 90 mL of the 1 mM $AgNO_3$ aqueous solution. The formation of silver nanoparticles was initially monitored visually by observing the color change of the reaction mixture. The nanoparticles were collected by centrifugation at 10,000 rpm for 15 minutes. The resulting pellet was washed several times with deionized water to remove unreacted metal ions and stored at 4°C for further analyses.

Characterization of Silver Nanoparticles

The optical properties and surface plasmon resonance (SPR) of the synthesized silver nanoparticles were recorded using a UV–Visible spectrophotometer (Elico-India, UV–Vis Double Beam Spectrophotometer). The crystalline structure was determined by X-ray powder diffraction (XRD) using a Shimadzu XRD-6000 diffractometer (Japan) with Cu Kα radiation and a graphite monochromator. XRD patterns confirmed the crystalline nature and face-centered cubic structure of the silver nanoparticles. Functional groups involved in the reduction and stabilization of nanoparticles were identified using Fourier transform infrared (FTIR) spectroscopy in the range of 500–4000 cm^{-1} at a resolution of 4 cm^{-1} [17]. The morphology and size distribution of the nanoparticles were further analyzed using scanning electron microscopy (SEM).

Antibacterial Activity of Silver Nanoparticles

The antibacterial activity of the synthesized silver nanoparticles was evaluated using the agar well diffusion method. Gram-positive bacteria (*Bacillus subtilis* and *Bacillus megaterium*) and Gram-negative bacteria (*Pseudomonas aeruginosa* and *Escherichia coli*) were selected as test organisms. Different volumes of silver nanoparticle solutions (100 µL, 110 µL, and 120 µL) were added to wells on nutrient agar plates and compared with standard controls. Streptomycin was used as the positive control, while distilled water served as the negative control. Leaf and tuber extracts, as well as the synthesized nanoparticles, were introduced into respective wells using sterile micropipettes. Plates were incubated at 37°C for 24 hours, and the zones of inhibition were measured to assess antibacterial efficacy [18].

RESULTS AND DISCUSSION

UV-VIS Spectrum Analysis

The formation of silver nanoparticles (AgNPs) synthesized using leaf and tuber extracts of *Pueraria tuberosa* was confirmed by UV–Visible spectroscopic analysis, as illustrated in Figures 4 and 5. This technique was used to identify the characteristic surface plasmon resonance (SPR) behavior of the nanoparticles. During the reaction, a visible color transition was observed from light green in the leaf extract and light yellow in the tuber extract to dark brown (Figs. 2a and 3a), indicating the reduction of silver ions (Ag^+) to elemental silver (Ag^0). UV–Visible spectra were recorded at different time intervals (2 min, 30 min, 1 h, 2 h, and 24 h) following the initiation of the reaction, as shown in

Figures 2b and 3b. At the initial stage (2 min), no distinct SPR band was detected. However, as the reaction progressed, a well-defined absorption peak gradually developed and increased in intensity, confirming the synthesis of AgNPs. The SPR band became evident after 30 minutes and showed maximum intensity after 1 hour, indicating enhanced nanoparticle formation with increasing reaction time. A prominent absorption peak corresponding to AgNPs was observed near 450 nm for the leaf extract (Fig. 4) and around 446 nm for the tuber extract (Fig. 5). The absorption band within the visible range of 420–450 nm is a characteristic feature of SPR associated with silver nanoparticles. The progressive sharpening and increase in peak intensity with time further suggest the formation and stabilization of metallic AgNPs. The successful biosynthesis of AgNPs is attributed to the presence of phytochemicals in the leaf and tuber extracts, which function as both reducing and stabilizing agents. Comparable SPR absorption peaks have been reported earlier for AgNPs synthesized from *P. tuberosa* tuber extracts [18] and *Lantana camara* leaf extracts [19], supporting the results of the present study.

XRD Analysis

X-ray diffraction (XRD) analysis was performed to identify the crystalline phase and structural properties of the synthesized silver nanoparticles. The XRD patterns of AgNPs obtained from the leaf and tuber extracts of *P. tuberosa* are shown in Figures 6a and 6b, respectively. The diffraction profiles clearly confirm the crystalline nature of the biosynthesized nanoparticles. In leaf-mediated AgNPs, distinct diffraction peaks were observed at 2θ values of 27.384°, 32.275°, 38.065°, and 46.259°, which correspond to the (143), (280), (81), and (118) planes of a face-centered cubic (fcc) silver structure. Similarly, the XRD pattern of tuber-derived AgNPs exhibited prominent peaks at 27.781°, 32.189°, 46.184°, and 57.405°, indexed to the (220), (438), (199), and (45) crystallographic planes. The presence of sharp and well-defined peaks indicates the formation of highly crystalline silver nanoparticles. The average crystallite size of the synthesized AgNPs was estimated using the Debye–Scherrer equation: $D = K\lambda / (\beta \cos\theta)$, where D represents the crystallite size, K is the shape factor (0.9), λ is the wavelength of Cu Kα radiation (1.5406 Å), β is the full width at half maximum (FWHM) of the diffraction peak, and θ is the Bragg angle. The calculated crystallite size confirmed the nanoscale dimension of the synthesized AgNPs. These results demonstrate that both leaf and tuber extracts of *P. tuberosa* effectively facilitate the formation of crystalline silver nanoparticles. Similar XRD patterns and crystalline characteristics have been previously reported for AgNPs synthesized using *Capparis zeylanica* leaf extract.

Fourier Transform Infrared spectral analysis

The Fourier Transform Infrared (FTIR) spectra of silver nanoparticles synthesized using aqueous leaf and tuber extracts of *P. tuberosa*are presented in Figure 7A and 7B, respectively. FTIR analysis was employed to identify the functional groups of biomolecules involved in the reduction of Ag^+ ions and in the subsequent capping and stabilization of the synthesized silver nanoparticles. In the leaf-mediated AgNPs (Fig. 7A), prominent absorption bands were observed at 3416.20, 2922.17, 2851.85, 1617.65, 1384.83, 1076.48, 825.45, and 618.07 cm^{-1}. The broad band at 3416.20 cm^{-1} corresponds to O–H stretching vibrations of alcohols and phenolic compounds, indicating the presence of hydroxyl-containing phytochemicals. The peaks at 2922.17 and 2851.85 cm^{-1} are attributed to C–H stretching vibrations of aldehydic and aliphatic groups, respectively. The absorption band at 1617.65 cm^{-1} is associated with N–H bending or C=C stretching vibrations, suggesting the presence of primary amines or aromatic compounds. The band at 1384.83 cm^{-1} corresponds to C=O stretching of aromatic amines or phenolic compounds, indicating the involvement of phenolics in nanoparticle synthesis.

The peak at 1076.48 cm^{-1} is assigned to C–N stretching vibrations of amine groups, while the band at 825.45 cm^{-1} represents aromatic ring vibrations. The low-frequency band at 618.07 cm^{-1} corresponds to C–Cl stretching of alkyl halides. Similarly, the FTIR spectrum of tuber-derived AgNPs (Fig. 7B) exhibited characteristic bands at 3425.23, 2923.46, 2852.82, 1628.37, 1384.68, 1076.64, 1045.02, 898.21, and 604.88 cm^{-1}. The broad peak at 3425.23 cm^{-1} is attributed to O–H stretching vibrations of alcoholic and phenolic groups. The band at 2923.46 cm^{-1} corresponds to C–H stretching of methyl groups, while the peak at 2852.82 cm^{-1} is associated with C=O stretching of ketones and esters. The absorption band at 1628.37 cm^{-1} indicates C=C stretching vibrations of aromatic rings. The peak at 1384.68 cm^{-1} is assigned to C–H bending vibrations of alkanes. The bands at 1076.64 and 1045.02 cm^{-1} correspond to C–O stretching

of esters and carbohydrates and C–N stretching of aliphatic amines, respectively. The peak at 898.21 cm^{-1} is attributed to glycosidic bond vibrations, while the band at 604.88 cm^{-1} represents C–Cl or C–Br stretching of alkyl halides. The presence of these functional groups confirms that various plant-derived biomolecules such as carbohydrates, flavonoids, tannins, phenolic compounds, and proteins play a crucial role in the bioreduction of Ag^{+} ions and act as effective capping and stabilizing agents for the synthesized silver nanoparticles. Similar FTIR spectral features have been reported for AgNPs synthesized using *P. tuberosa* tuber extract by Satpathy [16] and *Vitex negundo* leaf extract by Anandalakshmi and Venugopal [20].

SEM Analysis

Scanning electron microscopy (SEM) was employed to examine the surface morphology and particle distribution of silver nanoparticles synthesized using leaf and tuber extracts of *Pueraria tuberosa*. The SEM micrographs (Fig. 8A and 8B) reveal the presence of both individual nanoparticles and clustered aggregates, indicating successful nanoparticle formation. The SEM images clearly demonstrate that the synthesized AgNPs possess predominantly spherical morphology and exhibit a polydisperse nature in both leaf- and tuber-mediated samples. The particle size of leaf-derived AgNPs was found to range between 20 and 50 nm, whereas tuber-derived AgNPs showed sizes in the range of 30 to 50 nm. The observed variation in particle size and degree of aggregation may be attributed to differences in the concentration and composition of bioactive secondary metabolites present in the aqueous leaf and tuber extracts, which act as reducing and stabilizing agents during nanoparticle synthesis. Comparable SEM and FE-SEM observations have also been reported for AgNPs synthesized using *Centella asiatica* leaf extracts, and *P. tuberosa* tuber extract [21, 16]. Overall, the SEM analysis confirming the spherical shape, nanoscale size, aggregation behavior, and particle distribution strongly validates the successful biosynthesis of silver nanoparticles using both leaf and tuber extracts of *P. tuberosa*.

Antibacterial Activity

Silver nanoparticles synthesized using *P. tuberosa* leaf and tuber extracts exhibited pronounced antibacterial activity against the tested pathogenic microorganisms. The antibacterial potential of the biosynthesized AgNPs was evaluated using the agar well diffusion method against selected Gram-positive bacteria (*B. subtilis* and *B. megaterium*) and Gram-negative bacteria (*Pseudomonas* sp. and *E. coli*). The mean zone of inhibition (ZOI) values were calculated from triplicate experiments and are presented in Table 1. The antibacterial activity of leaf extract–mediated AgNPs was found to be concentration-dependent, with a progressive increase in ZOI observed at higher nanoparticle concentrations. Among the tested bacterial strains, *Pseudomonas* sp. exhibited the highest sensitivity to leaf-derived AgNPs. A maximum inhibition zone of 21.36 ± 0.16 mm was recorded against *Pseudomonas* sp., whereas the lowest inhibitory effect was observed against the Gram-positive *B. subtilis* (11.16 ± 0.60 mm). Similarly, AgNPs synthesized from tuber extracts showed strong antibacterial efficacy against all tested microorganisms. The highest zone of inhibition was observed against *B. megaterium* (20.39 ± 0.17 mm), followed by *Pseudomonas* sp. (18.36 ± 0.14 mm), *B. subtilis* (18.27 ± 0.10 mm), and *E. coli* (15.32 ± 0.14 mm). The variation in antibacterial response among different bacterial species may be attributed to differences in cell wall structure and permeability, as well as the interaction of AgNPs with bacterial membranes. Overall, AgNPs synthesized from both leaf and tuber extracts of *P. tuberosa* demonstrated significant antibacterial activity against selected pathogens. These findings are consistent with earlier reports highlighting the potent antimicrobial efficacy of *P. tuberosa*–mediated silver nanoparticles [18], thereby confirming their potential application as effective antibacterial agents.

CONCLUSION

A sustainable and efficient green synthesis of silver nanoparticles (AgNPs) was achieved using leaf and tuber extracts of *Pueraria tuberosa*. Phytochemicals such as phenolics, flavonoids, proteins, and carbohydrates acted as natural reducing and stabilizing agents, eliminating the need for hazardous chemicals. UV–Visible spectroscopy, XRD, FTIR, and SEM confirmed the formation of crystalline, predominantly spherical, and stable AgNPs. The biosynthesized

AgNPs exhibited significant, concentration-dependent antibacterial activity against Gram-positive and Gram-negative pathogens, highlighting their therapeutic potential. This environmentally benign, cost-effective, and scalable approach offers a viable alternative to conventional chemical methods, positioning *P. tuberosa*–derived AgNPs as promising candidates for biomedical applications, including antimicrobial agents, drug delivery, and medical device coatings.

ABSTRACT

The COVID-19 pandemic prompted organizations to transition from traditional work environments to remote work to sustain business operations. This crisis significantly impacted all sectors, particularly the IT industry, which embraced the concept of remote work. As we move beyond the pandemic, it has become evident that employee well-being, social needs, and opportunities for career development are essential. Consequently, the hybrid work model has gained popularity, blending physical and virtual work methods. The key objectives of this study include assessing employee preferences and examining the effects of the hybrid work model on productivity, as well as evaluating the fulfilment of Maslow's hierarchy of needs. Specifically, the research aims to test the hypothesis if Employees' productivity levels are independent of whether they work in a physical, virtual or hybrid environment. And whether there is difference in the mean productivity ratings among employees across the different work models. Statistical analysis is conducted using the Chi-square test and single factor ANOVA test along with graphs and charts for effective data interpretation. A key finding from the survey responses is that the hybrid work model is widely regarded as the most effective approach to maintaining work-life balance, as it allows employees to benefit from in-office interactions for team engagement and emotional expression, while also providing the peaceful, stress-free environment of working from home. The study also highlights that subjective productivity perceptions and objective productivity ratings may not always align.

Key words: Hybrid work model, Employee perceptions, Employees' Productivity, Physical work mode, Virtual work mode, Remote work, Flexible work model

INTRODUCTION

The world is dynamic and change is the only constant. It was 1966 when the Electronics Committee which is also known as Bhabha Committee created 10 years foundation plan or IT sector emergence in India. That's when India's relationship with computers first started. IT industry was first born in Mumbai in 1967 which established Tata Consultancy Services (TCS) who later in the year 1977 partnered with Burroughs which began India's export of IT services. During this period, the Indian government took several steps to promote computer literacy and foster technical education. The first software export zone, SEEPZ – the precursor to the modern-day IT park – was established in Mumbai in 1973. More than 80 percent of the country's software exports were from SEEPZ in the 1980s. Software technology park of India envisaged under Digital India program launched the India BPO Promotion Scheme (IBPS). This scheme seek to incentivize establishment of 48,300 seats in respect of business process outsourcing (BPO) and information technology-enabled services (ITES) operations in India. STPI is the nodal agency of this scheme under the Ministry of Electronics and Information Technology. India's Information Technology (IT) industry is often regarded as one of the country's most significant success stories. In 1991, India implemented major economic reforms under Prime Minister P.V. Narasimha Rao and Finance Minister Dr. Manmohan Singh, which led to increased globalization and liberalization. This created an opening for India's IT sector to cater to international clients. It transformed the country's economy, job market, and even global perceptions of Indian talent. It was in 1970s the employees who worked extended hours were considered more efficient and hardworking.

Employees used to commute for 2-3 hours and then work beyond the working hours to get their work done. With the boom in outsourcing, the industry started to align with global time zones, especially North America. The work culture became more structured, with employees required to work night shifts or follow 24/7 support models to match the time zones of international clients. A typical workday was often 10-12 hours long, especially for those in client-facing roles. For the employees to feel more comfortable and work harder slowly companies started setting up large cafeterias, sports facilities, gyms and some employee welfare programs where their 10-12 hours of work could make it a little stress free. 2000s marked full globalisation in India and India became one of the largest global IT outsourcing hubs. This led to longer working hours and much more pressure on employees because this shift demanded quality and efficiency of the employees. Employees faced intense pressure to finish their deadlines, workdays used to extend to 10-14 hours. It was in 2010s where new technologies like cloud computing, big data, AI and cybersecurity emerged which led to flexible working hours to the employees. This is when the companies started focusing on employee well being and their work life balance giving option to work from home during emergencies. While remote work wasn't still the norm as the IT sector in India did not have sufficient resources. Things were working normal and employees had adopted this work culture. It was then most dramatic shift hit work culture in India. Emergence of COVID-19 pandemic. This impacted almost all the industries worldwide not just the IT sector. But the pandemic forced most of the IT companies to switch to remote work overnight relying on cloud-based software, zoom, Microsoft teams, VPN, Slack etc. After going fully remote the companies realised that Remote work can actually be as productive as physical work set up.

For two to three years most of the companies went on working fully work from home. Facilitated by technological advancements the companies realised the need for employees work life balance and social connectivity and also as cost cutting measures, the companies introduced Hybrid work model allowing employees to balance their work and personal lives. Employees are now called to physical work set up for certain days in a week and remaining days allowing them to work from home. Whether this hybrid work mode is going to be the future of IT work culture? There is no answer for this question yet as there is still arguments for and against the work culture. But currently this has become the new normal in Indian IT sector. The traditional 9-to-5 workday is being increasingly replaced by more flexible working hours and a results-oriented approach. While the average working hours have remained similar to the pre-pandemic days, the flexibility of remote and hybrid models has allowed employees to better manage their schedules. Companies that were previously strict about office timings began embracing results-oriented work environments (ROWE), focusing on outcomes rather than hours clocked. (Chellam & D, 2022) In the technology

era, the concept of hybrid models has become most commonly adopted in the third decade of the 21st century, especially in the IT sector. This change has made it necessary to reconsider such a concept as productivity for workers having experienced the separation of spheres of work and home life within the same premises (Charalampous et.al 2019). Therefore, the study is conducted to analyse the employees' perception on impact of hybrid work culture on productivity and their job satisfaction as employees are one of the major stakeholders of IT industry.

Background and Context

The COVID-19 pandemic has brought one dramatic shift in work culture that is highly appreciated by employees, especially in India: the adoption of remote and hybrid work models. Even though the pandemic has subsided and things have returned to normal, Indian tech companies have increasingly been adopting these flexible work arrangements for their employees instead of mandating a daily office presence. (Verma, 2024)A recent report by Xpheno, shared exclusively with ET, highlights the rise in hybrid and remote job openings in India. Despite the full reopening of offices, nearly 20% of all job postings in the country are now for remote and hybrid roles, a substantial increase from just 0.9% in 2020. In July 2024, the total job postings for hybrid and remote roles across sectors stood at 50,000, compared to 210,000 postings for purely office-based roles "In the recent days, the focus on returning to the workplace has intensified," Aditya Mishra, chief executive of CIEL HR Services, told ET. "CIEL's recent study highlights the dominance of the hybrid model, with over 60% asking their employees to be in office 2-3 days every week," he said. Richard Lobo, chief people officer of Tech Mahindra, said the company has implemented hybrid work policies that allow both flexibility and business continuity. "At Tech Mahindra, we believe in fostering a flexible work culture that accommodates diverse needs of our employees, while maintaining their productivity," he told ET. A Wipro spokesperson said the firm adopted a flexible workplace approach since the onset of the pandemic. Panasonic Life Solutions India is 100% operational from the office. However, its CHRO Adarsh Mishra said, "on a case-to-case basis and in case of a genuine requirement, the company does offer flexibility of a hybrid model" (Verma, 2024).

Problem Statement

With the shift in work culture in IT sector especially post Covid 19 era where the Indian IT sector has seen transition from physical work setup to work from home and now hybrid work culture. Companies now have adopted flexible work environment that combines remote work and on-site work with the help of technologies. This change has brought significant in work dynamics, employee culture and behaviour, and also organisation culture. While the hybrid model is offering flexibility to employees its essential to understand the key aspects such as employees' productivity and job Satisfaction. Therefore, the purpose of the study is to understand the impact of hybrid work culture on employees' productivity when compared to physical and remote work, their perceived benefits and challenges in hybrid work environment, whether the employees are satisfied and impact on their work life balance.

The findings of this study will provide valuable insights for IT companies seeking to optimize their hybrid work policies, ensuring they enhance employee performance, well-being, and satisfaction while maintaining organizational goals and competitive advantage.

Research Questions

- What is the perception of the employees on impact of hybrid work model on their productivity and performance?
- Whether the hybrid model influences employees job satisfaction, work-life balance and overall job engagement?
- To what extent hybrid model fulfils the Maslow's hierarchy of needs to the employees?
- What are the benefits and challenges associated with hybrid model and how do these affect employees' productivity?
- Whether the Employees' productivity levels are independent of whether they work in a physical, virtual or hybrid environment?

LITERATURE REVIEW

(Vaidya & Bedi, 2024) The hybrid work models try to avoid deficiencies of both the remote and in-office work practices by providing the freedom of choice while at the same time providing the advantages of interaction. This theory can increase productivity with the help of the pluses of these types of arrangement (Wang et.al 2020). For example, the workers can execute specific activities from their homes but partake in collective exercises in the office. However, there is still the issue of the probability level that is determined by the availability of sufficient technological support and by building an organizational culture that includes both remote and in-house employees in the organization. (Omolambe & Menon, 2024) : The focus of this study pays critical attention on the new norm in the work environment, investigating how the workplace has change drastically and the employee behaviour has also been influenced by this so-called change. The productivity of employees within the organisation has also taken a new turn. This investigation indicated that the introduction of new productivity tools in a hybrid work environment amounted to personal development, effectiveness and growth among employee and management, with work environment being reinvented, motivation, job development and technology. Also, the post-pandemic workplace is more technological and has a very wide depts of new and updated productivity tools in line, calling for more training and of employee to attain efficiency

(Gupta & Kumar, 2023)in the Study on "Hybrid Working Mode-The future trend" have analysed the productivity and working style of employees in the Hybrid Working. As per the study it has been found that workers value mixed work. However, not everyone believes that a hybrid way is the best option. The success of your company, as well as the productivity and wellbeing of your employees, may be impacted by the work policies that are established for the team. For those who use hybrid work, there has been a lot of trial and error over the years, and there still will be as many organisations figuring out how it can best serve them. (Iqbal, Khalid, & Barykin, 2021)in the study Hybrid Workplace: The Future of Work, states that for any work environment whose stakeholders intend to transcend the expectation of the constantly evolving workplace, the future of work should be a priority. Although some countries have relaxed the lockdown in their states, businesses are taking their time to set up a more formidable work arrangement. Many are already operating the hybrid system while others are running fully remote. The pandemic has taught the workplace a lesson of preparation and planning and given the reality check to keep up with the technological and management related advancements to ensure productivity and growth. Beyond that is also the lesson of flexibility and adaptability in the workplace. In prioritizing the future of work, there is the need to embrace the hybrid workplace model. (Gangisetty, Dias, & Irfan, 2024)The rise of hybrid work models, blending remote and onsite work arrangements, has become increasingly prevalent in today's workforce, especially in the IT industry. The research aims to determine the effects of a hybrid-work model on the job satisfaction of tech professionals, focusing on key factors including onsite work, remote work, flexibility, communication, and safety. The findings reveal significant positive associations between job satisfaction for both onsite and remote work. Additionally, flexibility and effective communication emerged as important factors positively influencing job satisfaction among tech workers in hybrid work environments.

Research design and methods

Research design

This study employed a mixed-methods research design to comprehensively explore the Employees' Perceptions on Impact of Blending Physical and Virtual Work Modes on Productivity. This design would allow for both qualitative and quantitative data collection and analysis, providing a holistic understanding of the phenomenon.

Objectives of the study

- To identify factors influencing productivity of employee in hybrid work model.
- To assess the challenges and benefits of hybrid work model on employees' performance.
- To find out if Employees' productivity levels are independent of whether they work in a physical, virtual or hybrid environment.

Hypothesis

The following hypothesis is set to check if Employees' productivity levels are independent of whether they work in a physical, virtual or hybrid environment.

H_0: Work mode and productivity level are independent.

H_0: H_0: $\mu1=\mu2=\mu3$

Sampling Methods and Sources

The study is conducted using questionnaire survey for primary data collection. The researchers have prepared questionnaires and distributed and have collected 102 responses. The respondents include only the employees working in IT companies in Dakshina Kannada and Bangalore. Statistical tool, Chi Square test is used to test the hypothesis. Also, charts and graphs are used to analyse and interpret the data collected. Available secondary data from articles and previously published literature are used for the study to provide context and comparison.

Scope and Limitations

The researchers chose Dakshina Kannada and Bangalore district as the location for the study. Only the employees working in IT companies are the respondents and the research is focused on the view point of employees only. The sample size is 102 which is lesser than minimum sample requirement of 384.16 calculated using formula for finite population at 95% confidence level and a 5% margin of error estimating population proportion to be 0.5. The collection of samples was hampered by lack of time and geographical hinderance. Additionally, the responses may be biased.

Data Analysis and Interpretation

Hypothesis Testing

Chi Square test results

Null Hypothesis (H_0): There is no significant relationship between the type of work model and employees' productivity perceptions.

Alternate Hypothesis (H1): There is no significant relationship between the type of work model and employees' productivity perceptions.

Chi-Square Statistic (17.05) is greater than the Chi-Square Table Value (15.507) at 8 degrees of freedom and a 0.05 significance level, this indicates that there is significant association between the type of work model and employees' productivity perceptions.

ANOVA-Single Factor Test

Null Hypothesis (H_0): There is no significant difference in the mean productivity ratings among employees across the different work models.

H0: $\mu1=\mu2=\mu3$

Alternative Hypothesis (H_1): At least one of the work models has a different mean productivity rating compared to the others.

P value is greater than 0.05 (1>0.05) and F value is lesser than F critical value (0.109265<1.385831). Hence Null hypothesis is accepted which means no statistically significant difference in the mean productivity ratings across the different work models. This chart indicates the current working mode of respondents in which 28 respondents are working from Office, 8 are working from Home and 67 are working under Hybrid mode. Out of the total 103 respondents who are already working under different work model, 73 of the prefer Hybrid work model and very least part (9) of the respondents prefer Physical work set up. Out of 103 respondents, 18% indicated that the flexibility to choose between work modes significantly impacts productivity, while 44% reported a moderate impact, and another 18% stated that it makes no difference. Out of the 103 respondents, 28 rarely get the option to work from home in case of emergencies only, 44 has an option to work from home once or twice a week, 23 of them four days a week, and 8 are under permanent Work from home.

The chart presents various factors influencing productivity in a hybrid model according to respondents. 73 prioritize work-life balance, 66 choose flexibility, 49 highlight the importance of team communication, 44 emphasize the work environment, and 27 cite access to resources and tools as key factors that influence productivity in hybrid work setting. The majority of respondents agree or strongly agree (74%) that the hybrid model enhances work-life balance, with only a small percentage (14%) disagreeing or strongly disagreeing. A high percentage (72%) agree or strongly agree that hybrid provides greater flexibility, indicating a positive perception of flexible working hours. Increases difficulty in managing time effectively in hybrid mode statement shows a mixed response, with a significant portion (30%) disagreeing, indicating they don't face difficulty managing time, while 27% agree, suggesting some struggle with time management. The neutral responses (32%) suggest that this is an area of ambivalence. The majority (71%) agree or strongly agree that hybrid work enhances communication with team members. A majority of respondents (57%) agree or strongly agree with the statement, showing that employees feel hybrid work limits in-person networking opportunities.

The key challenges in a hybrid model include difficulties with team communication (62%), an increased number of meetings (37%), Technical and network problems, along with limited access to resources (both at 35%), staying motivated is challenging for 32% of employees. In contrast, travel on workdays is a minimal concern (10%), indicating travel demands are generally Most employees report improvements in their ability to focus on tasks (58%) and quality of work produced (59%) in the hybrid model, suggesting that hybrid work supports productivity and work quality. However, stress levels show mixed feedback, with 45% reporting no change and 44% finding it much better, indicating a varied impact on stress. In contrast, opportunities for informal discussions are seen as significantly worse in a hybrid setup, with 47% rating it much worse, highlighting a challenge in maintaining casual, spontaneous interactions with colleagues in a non-physical environment.

Out of total 103 respondents, 33% of respondents said there is strong positive impact of hybrid model on their personal and mental well-being, 31% said somewhat positive impact, 33% remain neutral indicating there is neither positive nor negative impact, only 3% said there is somewhat negative impact.
The perceived benefits of the hybrid work model were notable, with the highest number of respondents highlighting better work-life balance (69) and increased flexibility in work hours (65) as major advantages. Reduced commute time and costs was also a significant benefit, mentioned by 61 respondents, followed by enhanced ability to manage personal responsibilities (58). Increased productivity and focus (46), better mental and physical well-being (47), and improved job satisfaction (43) also showed that hybrid work positively influenced performance and well-being.
Out of the 67 respondents currently working in a hybrid setup, all 67 confirmed that their basic needs were fulfilled. 57 respondents reported feeling safe in their current work model, while 50 indicated that their social needs were met. Additionally, 55 respondents stated they were receiving rewards and recognition, though only 38 felt they were able to fulfil their self-actualization needs.

Findings

- A significant majority (73 out of 103 respondents) prefer the hybrid work model, with only 9 preferring a physical work setup, reflecting a strong inclination towards flexible work arrangements. Flexibility in choosing work modes significantly impacts productivity for 18% of respondents, with 44% noting a moderate impact. This indicates that flexibility in work models is perceived to have a generally positive but varied influence on employee productivity. Most respondents (44) have the option to work from home once or twice a week, with 28 only allowed to work from home in case of emergencies. This suggests that while hybrid work is preferred, many employees still face limitations in the frequency of remote work.
- Work-life balance (73), flexibility (66), and team communication (49) are key factors that employees believe influence productivity in a hybrid setup. These factors highlight the importance of a balanced, flexible environment and strong communication in maximizing hybrid work effectiveness. A significant majority (74%) agree or strongly agree that the hybrid work model enhances work-life balance, and 72% feel it offers greater flexibility. This suggests that employees highly value the work-life benefits and the autonomy provided by hybrid work.

- While many employees agree that hybrid work increases focus (58%), challenges like team communication (62%), an increased number of meetings (37%), and technical issues (35%) remain prevalent. These challenges suggest that while hybrid work offers flexibility, it also requires improvements in communication and technology infrastructure. Many respondents (57%) agree or strongly agree that hybrid work limits in-person networking opportunities. This highlights a challenge in fostering casual, informal interactions that are common in traditional office settings.
- Respondents report a positive impact on their personal and mental well-being due to hybrid work. Key benefits identified by respondents include better work-life balance (69), increased flexibility (65), and reduced commute time and costs (61). These findings reflect the personal and professional adaptability that the hybrid work model offers. However, fewer respondents cited benefits like autonomy in managing tasks (28) and career development opportunities (25), suggesting these areas may need more focus for further employee satisfaction.
- While all respondents in the hybrid work setup confirmed their basic needs were fulfilled, a notable gap exists in fulfilling higher-level needs, as only 38 respondents reported fulfilling their self-actualization needs, indicating that while hybrid work meets basic and safety needs, it may fall short in providing opportunities for personal growth and achieving full potential for some employees.
- Since the Chi-square test showed a significant result, it indicates that there is an association between different work models and the perceived productivity levels. This suggests that the type of work model influence how employees perceive their productivity. The ANOVA did not find a statistically significant difference in the actual productivity ratings (out of 10) across different work models. This means that, while employees' perceptions of productivity vary with different work models, the numerical ratings they give for productivity do not show significant differences across these models. The contrasting results between perceived productivity categories (via Chi-square) and actual productivity ratings (via ANOVA) suggest that employees might perceive their productivity differently depending on the work model, yet their actual productivity ratings don't significantly change. Employees' subjective perceptions (like categorizing their productivity as "high" or "low") are influenced by the work model, possibly due to factors like comfort level, work-life balance, or self-assessment biases. However, when asked to quantify productivity on a scale, this variation isn't statistically apparent.

Suggestions

- While hybrid work is beneficial, it's important to ensure regular in-office interactions to foster team bonding and provide opportunities for emotional expression. Companies could encourage team-building activities, face-to-face meetings, and regular office days to maintain a sense of community.
- Based on feedback indicating that only a portion of employees feel recognized and rewarded, companies should invest in structured employee recognition programs. Regular acknowledgment of employee contributions, whether through awards, shout-outs, or incentives, can improve morale and reinforce a sense of value within the team.
- To address the gap in self-actualization fulfilment, companies should focus on providing employees with clear paths for career development. This could include opportunities for skills enhancement, mentorship programs, and leadership training, which can help employees achieve their professional goals and feel more fulfilled in their roles.

Scope for future research

One of the major findings of the study is that there is potential gap between perceived and actual productivity of the employees in different work set up. There is no match between subjective perceptions and objective productivity this may be because there are some factors in different work set up contributes to the productivity of the employees which is not studied in this research. Therefore, further Investigation can be done to identify the Disconnect Between Perceived and Actual Productivity along with Factors influencing productivity in different work set up.

CONCLUSION

The study on the impact of the hybrid work model has revealed significant insights into how different work models influence employees' productivity, well-being, and satisfaction. The findings indicate that while employees perceive hybrid work as highly beneficial for achieving work-life balance, improving mental health, and reducing stress, there are mixed responses regarding the impact on career development and task autonomy. The hybrid work model was found to positively affect employees' perceived productivity, with respondents highlighting flexibility, reduced commute time, and enhanced ability to manage personal responsibilities as major advantages. However, the study also indicated a disconnect between perceived productivity and actual productivity ratings, suggesting that while employees feel more productive in a hybrid setup, their quantitative assessments do not significantly differ across work models. Additionally, Maslow's hierarchy of needs framework demonstrated that while basic needs and safety are well fulfilled, there is room for improvement in addressing social needs and self-actualization within the hybrid work model. Employees expressed a strong preference for hybrid work due to its ability to blend both professional and personal responsibilities effectively, yet some still expressed nostalgia for the pre-pandemic office culture, indicating that a one-size-fits-all approach might not be applicable for all employees. Ultimately, the study emphasizes that organizations should continue refining their hybrid work policies by offering clear opportunities for recognition, career development, and personal growth to address unmet needs. The findings suggest that the hybrid model holds substantial potential for the future of work, provided companies adapt their strategies to ensure holistic fulfilment of employees' needs.

ABSTRACT

This study comparatively examines the adoption, accuracy, and impact of Artificial Intelligence (AI)-based and traditional financial forecasting models on the financial sustainability of revenue- generating non-profit organizations (NPOs). As NPOs increasingly transition toward social enterprise models, the precision of financial planning becomes a critical determinant of long-term viability. A quantitative research design was employed, utilizing a structured survey to collect data from 68 non-profit organizations across various sectors, including Education, Healthcare, and Skill Development. Data analysis was conducted using descriptive statistics (Mean, Standard Deviation), frequency analysis, and histogram visualization. The association between organizational type and forecasting model adoption was evaluated using the Pearson Chi-Square test. The findings suggest that for NPOs to achieve financial sustainability through AI, there is a critical need for enhanced technical training and the development of "interpretable AI" tools that align with the transparency requirements of the third sector. This paper addresses a significant gap in the literature by focusing specifically on revenue-generating NPOs rather than grant- dependent entities, providing empirical evidence of the socio-technical barriers to AI adoption in the social economy.

Keywords : Artificial Intelligence (AI), Financial Forecasting, Non-Profit Organisations (NPOs), Financial Sustainability, Traditional Forecasting, Revenue-Generating NPOs

INTRODUCTION

Revenue-generating non-profit organisations (NGNPOs) have emerged as a significant component of the social sector, combining mission-driven objectives with market-oriented revenue models. Unlike traditional non-profits that rely primarily on donations and grants, these organisations generate income through activities such as educational services, healthcare delivery, skill development programs, consultancy, and sale of socially beneficial products. While this hybrid structure improves financial independence, it also increases financial uncertainty and forecasting complexity. Financial forecasting plays a pivotal role in ensuring the sustainability of revenue-generating non- profit organisations. Accurate forecasts assist in budgeting, cash flow management, investment planning, and long-term strategic decision-making. However, the financial environment of non- profit organisations is often characterised by fluctuating demand, seasonal income, funding volatility, regulatory constraints, and mission-driven spending priorities. Traditional financial forecasting techniques—such as historical trend analysis, incremental budgeting, and simple regression models—frequently fall short in capturing these dynamic and non-linear financial patterns.

In recent years, Artificial Intelligence (AI) has gained prominence as a transformative technology in financial management. AI-based financial forecasting models leverage machine learning algorithms, neural networks, and advanced time-series techniques to analyse complex datasets and generate adaptive predictions. Unlike traditional models, AI systems are capable of learning from historical data, incorporating multiple variables, identifying hidden patterns, and continuously improving forecast accuracy over time. These features make AI particularly suitable for organisations operating in uncertain and data-rich environments, such as revenue-generating non-profit organisations. AI techniques enable the integration of both financial and non-financial variables—such as service demand, beneficiary engagement, operational efficiency, and external economic indicators—into forecasting models. This holistic approach enhances the reliability of forecasts and supports evidence-based decision-making. Moreover, AI-based tools can provide real-time insights, scenario analysis, and risk assessment, allowing non-profit managers to respond proactively to financial challenges.

Despite the growing body of research on AI applications in corporate finance, limited attention has been paid to its role in the non-profit sector. Most existing studies focus on for-profit enterprises, leaving a research gap in understanding how AI-based financial forecasting compares with traditional methods in revenue-generating non-profit organisations. Additionally, the ethical, operational, and resource-related challenges of adopting AI in non-profit settings remain underexplored.Therefore, this study undertakes a comparative analysis of AI-based and traditional financial forecasting models in revenue-generating non-profit organisations. By evaluating forecasting accuracy, adaptability, and decision-support effectiveness, the study aims to provide empirical evidence on the suitability of AI-driven forecasting models for the non-profit sector. The findings are expected to assist non-profit managers, policymakers, and researchers in designing sustainable financial strategies that align with both economic viability and social impact objectives.

OBVJECTIVES

1. To comparatively examine the adoption of AI-based and traditional financial forecasting models among revenue-generating NPOs.
2. To analyze the association between organization type and the financial forecasting models utilized.
3. To evaluate the impact of forecasting accuracy on organizational satisfaction and perceived financial sustainability.

LITERATURE REVIEW

Evolution of Financial Forecasting: From Traditional to Algorithmic Paradigms

The transition from heuristic-based financial planning to algorithmic forecasting represents a significant shift in organizational intelligence. Traditional models, primarily rooted in time-series analysis and linear regression, have long been the bedrock of non-profit financial management due to their interpretability and lower computational requirements (Yadava, 2024). However, Scopus-indexed studies by **Hosseinkhani (2025)** argue that these models often suffer from "structural rigidity," failing to account for the stochastic nature of revenue streams in the social sector. In contrast, Artificial Intelligence (AI) and Machine Learning (ML) architectures, such as Recurrent Neural Networks (RNNs), provide a non-linear approach that can ingest multi- structured data—ranging from donor sentiment to global economic indices—to produce dynamic forecasts (MDPI, 2024).

Forecasting Accuracy and Organizational Reliability

Accuracy in financial forecasting is not merely a technical metric but a determinant of organizational reliability. Recent empirical evidence suggests that AI-integrated systems can reduce Mean Absolute Percentage Error (MAPE) by significantly higher margins than human- centric traditional methods (Drive point, 2026). Oni (2025) highlights that for revenue- generating NPOs, where income is tied to service fees and market-linked business activities, the "reliability" of a forecast directly dictates the feasibility of strategic scaling. When forecasting accuracy improves, it reduces the "information asymmetry" between financial managers and board members, facilitating more confident capital allocation.

Financial Sustainability and Revenue-Generating NPOs

The "Social Enterprise" model requires NPOs to maintain a delicate balance between mission- related expenditures and revenue-generating stability. **Bowman (2011/2025)** asserts that financial sustainability is the byproduct of an organization's "absorptive capacity"—its ability to identify and respond to financial shocks. Research by **RSIS International (2025)** indicates a strong correlation between forecasting precision and long-term liquidity. For organizations relying on earned income, accurate predictive models act as an early-warning system, preventing the "liquidity traps" that often lead to the premature termination of social programs.

Determinants of AI Adoption: The Technological and Managerial Divide

Despite the quantitative advantages of AI, adoption remains stratified. **Kuey (2024)** identifies that adoption is often restricted by "algorithmic aversion"—a psychological phenomenon where managers lose trust in a model after a single error more quickly than they do with a human forecaster. Furthermore, the "Black Box" nature of neural networks remains a significant barrier for NPOs that operate under strict transparency mandates (IRE Journals, 2025). This aligns with the "Resource-Based View" (RBV) theory, suggesting that only NPOs with high internal technical capital (e.g., Skill Development sectors) can effectively leverage AI to gain a competitive advantage in sustainability.

Synthesis and Research Gap

While existing literature extensively covers AI application in the corporate and fintech sectors, there is a notable scarcity of studies focused specifically on revenue-generating NPOs. Most current research treats NPOs as grant-dependent entities, overlooking those that function through business-like income streams. This study addresses this gap by empirically examining the correlation between model choice and organizational sustainability within a specific cohort of 68 diverse non-profit entities.

The Algorithmic Shift in Social Sector Financial Management

The non-profit sector is undergoing a profound digital transformation, moving away from "intuition-based" budgeting toward "data-driven" algorithmic forecasting. While traditional models (ARIMA, Exponential Smoothing) offer high interpretability, Scopus-indexed research by Yadava (2024) and Kureljusic & Karger (2023) demonstrates

that these linear approaches fail to capture the high-dimensional, non-linear volatility inherent in revenue-generating NPOs. Recent advancements in State-of-the-Art (SOTA) Transformer architectures and Deep Learning (DL) models have significantly outperformed human analysts in predicting revenue peaks and cash flow droughts (MDPI, 2024; Ganesan, 2024).

Forecasting Accuracy as a Mediator for Organizational Performance

In the Scopus literature, "forecasting accuracy" is increasingly viewed as a mediating variable rather than just a technical output. Simatupang et al. (2026) and Eduvest (2026) provide empirical evidence that higher forecasting accuracy significantly reduces operational inefficiencies. For revenue-generating non-profits, this accuracy acts as a "Strategic Support System" (PMC, 2025), allowing managers to navigate market uncertainty without compromising social mission delivery. The use of IGSA-optimized Radial Basis Function Neural Networks (RBFNN) has been cited as particularly robust for long-term sustainability modelling in volatile economic climates (MDPI, 2024).

Financial Sustainability and the "Absorptive Capacity" of NPOs

A critical theme in contemporary bibliometric analyses of sustainability (Journal UII, 2025) is the concept of "Financial Resilience." Unlike for-profit entities, NPO sustainability is defined by "Absorptive Capacity"—the ability to withstand funding shocks through sound internal financial competencies (RSIS International, 2025). Sundarasen et al. (2024) link this resilience directly to digital financial literacy, suggesting that organizations that fail to adopt advanced predictive tools are at a higher risk of "mission drift" or "liquidity failure" during economic crises.

Socio-Technical Barriers: The "Black-Box" and Adoption Disparities

Despite technical superiority, the adoption of AI remains stratified. A systematic review by ArXiv (2025) and ResearchGate (2025) reveals that AI integration is heavily biased toward larger organizations with high technical capital. The "Black-Box" nature of AI—its lack of interpretative transparency—remains a psychological barrier for NPO boards who prioritize accountability (Bridgespan, 2025). This "Algorithmic Aversion" often leads to a "Hybridity Paradox," where organizations attempt to combine AI and traditional methods but fail due to a lack of staff training and data governance frameworks (Inderscience, 2026).

RESEARCH METHODOLOGY

Research Design

This study adopts a quantitative research design with a descriptive approach. A cross-sectional survey method was utilized to capture the current state of financial forecasting practices among revenue-generating non-profit organizations (NPOs). The design is intended to facilitate a comparative analysis between traditional and AI-based forecasting models and their perceived impact on financial sustainability.

Sampling and Data Collection

The study utilized a purposive sampling technique to identify revenue-generating NPOs across diverse sectors, including Education, Healthcare, Skill Development, and Environmental organizations.

Sample Size: The final dataset comprises **68 valid responses** from organizational representatives (Financial Officers, Managers, and Administrators).
Data Collection Instrument: A structured, close-ended questionnaire was administered. The instrument was divided into sections covering:

1. Organisational Profile (Type, Revenue, and Size).
2. Forecasting Model Adoption (Traditional vs. AI).
3. Perceived Impact and Effectiveness (measured via a 5-point Likert Scale).

4. Sustainability and Risk Linkages.

DATA ANALYSIS

The collected data was processed using statistical software (SPSS/Excel) to perform the following analyses:
Descriptive Statistics: To summarize the organizational characteristics and user perceptions, descriptive statistics—including Mean, Standard Deviation, Skewness, and Kurtosis were calculated. These metrics provide insights into the central tendency and distribution of responses regarding the impact and satisfaction of forecasting systems. The questionnaire underwent a pilot test to ensure face validity and clarity. Cronbach's Alpha was calculated for the Likert-scale sections to ensure internal consistency. In the Chi-square analysis, the "Expected Count" assumption was monitored; although some cells had counts less than 5, the results provide a preliminary statistical indication of sectoral trends. To address the research objectives regarding the association between organizational type and model adoption, a Pearson Chi-Square Test was conducted.

Hypothesis Testing: The test evaluated the null hypothesis (H0) that there is no significant association between the type of NPO and the forecasting model used.
Significance Level: Results were tested at a 95% confidence interval (alpha = 0.05)

The provided crosstabulation table explores the relationship between the type of non-profit organisation and the specific financial forecasting models they employ among a sample of 68 valid cases.

Core Distribution and Adoption Trends
The data reveals a predominant reliance on traditional forecasting models across the surveyed organisations:

Traditional Dominance: Out of the 68 total cases, 47 organisations (69.1%) utilize traditional models.
AI Integration: 17 organisations (25.0%) have adopted AI-based models for their financial forecasting.
Other Models: A small minority of 4 organisations utilize alternative models (categories 4 and 5).

Sector-Specific Adoption Analysis
The adoption of forecasting technology varies significantly depending on the sector of the non- profit:

Skill Development (Type 3): This sector shows the highest level of technological diversity and AI adoption. It has the largest representation in the sample with 24 organisations, half of which (10) utilize AI models, while another 10 remain on traditional models.

Healthcare (Type 2): This group relies heavily on established methods, with 15 out of 18 organisations (83.3%) using traditional models and only 3 using AI.

Education (Type 1): Similarly, 12 out of 16 organisations (75.0%) in the education sector prefer traditional forecasting models over AI (4).

Environmental (Type 4) and Others (Type 5): These sectors show no adoption of AI models in this sample. All 10 organisations across these two categories exclusively use traditional forecasting methods.

The Chi-square test was applied to examine the association between the financial forecasting model used and the overall accuracy of forecasting. The Pearson Chi-square value is 18.127 with 8 degrees of freedom and a p-value of 0.020. Since the p-value is less than 0.05, the null hypothesis is rejected, indicating a significant association between the forecasting model and forecasting accuracy. However, as more than 20% of the cells have expected counts less than 5, the results should be interpreted with caution. Descriptive statistics including mean, standard deviation,

skewness, and kurtosis were computed to summarise respondents' perceptions regarding AI-based forecasting, forecasting effectiveness, and satisfaction. The skewness and kurtosis values fall within the acceptable range (±1), indicating that the data are approximately normally distributed and suitable for further analysis.

Normality and Distribution (Histogram Analysis)
A visual inspection of the histograms confirms that the data for all three dimensions follows a

Normal distribution pattern.
AI-Based Impact (Mean = 2.20): The histogram is centered between "Disagree" and "Neutral," with a slight positive skew (0.306), indicating a general consensus that AI has not yet significantly transformed accuracy within the sampled NPOs.

Forecasting Effectiveness (Mean = 2.87): The distribution shows a broader spread, suggesting that while some organisations find forecasting helpful for managing uncertainty, the overall perceived effectiveness remains moderate.

Overall Satisfaction (Mean = 3.04): The satisfaction dimension aligns most closely with the normal bell curve, centered on the "Neutral" response. This indicates a balance in the sample between those satisfied with traditional methods and those seeking more advanced solutions.

Sectoral Adoption and Statistical Significance
The crosstabulation between the Type of Non-Profit Organisation and the Forecasting Model Currently used highlights sectoral disparities in technology adoption:

Traditional Dominance: 69.1% (n=47) of the organisations utilize traditional models.
AI Leadership: Skill Development (Type 3) represents the highest adoption of AI, with 10 out of 24 organisations utilizing AI-based models.

Chi-Square Results: A Pearson Chi-Square test yielded a value of 18.127 with a p-value of 0.020. Since $p < 0.05$, the study rejects the null hypothesis, confirming a statistically significant association between the organisation's sector and its forecasting model choice.

DISCUSSION

The normality of the data validates the reliability of the mean scores. The low mean for AI Impact (2.19) contrasts with the high adoption potential discussed in literature. This suggests that while there is a significant link between organisational type and technology choice, the "**Trust Gap**" is a universal barrier across sectors, reflected in the neutral satisfaction score of 3.04.

CONCLUSION

This research provides an empirical evaluation of financial forecasting paradigms within 68 revenue-generating non-profit organisations. The study concludes that while the theoretical superiority of AI-based models is well-documented in literature, a significant "implementation gap" persists in the non-profit sector. The findings confirm a statistically significant association between the type of organisation and the forecasting model adopted ($\chi^2 = 18.127$, $p = 0.020$), with Skill Development organisations emerging as the primary early adopters. However, the overall adoption rate for AI remains low at 25%, compared to 69.1% for traditional models. Furthermore, the low mean score for the perceived impact of AI (2.19) and the neutral satisfaction levels (3.04) suggest that the transition to

AI is hindered not by a lack of technology, but by a lack of trust and technical literacy. For revenue-generating NPOs, where financial sustainability depends on the precision of earned-income projections, the continued reliance on traditional, linear models may pose a long-term risk to institutional resilience in volatile economic climates.

Practical and Policy Recommendations

Enhance Technical Training: Given that the questionnaire reveals a lack of regular training for forecasting tools, NPOs should implement structured in-house or external professional training programs.

Adopt a Hybrid Approach: Because respondents are currently more comfortable with traditional models (69.1%) but sceptical of AI (Mean = 2.19), organisations should transition using a hybrid model rather than an immediate full shift to AI.

Data Standardization: To improve the "Moderate" accuracy scores (Mean = 2.87), NPOs must standardize data collection processes to ensure AI algorithms have high-quality inputs.

Strategic Alignment: NPOs should explicitly link forecasting outcomes with sustainability goals and risk management, as identified in Section G of your study, to ensure long-term financial resilience.

ABSTRACT

The present study investigated the phytochemical composition and *in vitro* anti-inflammatory activity of *Linum usitatissimum* L. (flax) seeds. Ethanol and aqueous extracts were qualitatively screened, revealing the presence of glycosides, betacyanin, steroids, proteins, sterols, coumarins, flavonoids, oils, quinones, phenols, and cardiac glycosides, while alkaloids, tannins, carbohydrates, saponins, terpenoids, and anthraquinones were absent. Anti-inflammatory potential was evaluated using protein denaturation assay with bovine serum albumin as the substrate. The methanol extract exhibited concentration-dependent inhibition, with maximum activity (71.2%) observed at 100 µg/mL. The observed activity may be attributed to the presence of flavonoids and polyphenols. These findings suggest that flax seeds possess significant nutraceutical and pharmaceutical potential, warranting further investigation to isolate active compounds and elucidate their mechanisms of action.

Keywords: *Linum usitatissimum*, flax seeds, phytochemicals, anti-inflammatory activity, protein denaturation assay

INTRODUCTION

Plants have long been a source of diverse bioactive compounds that contribute to human health and disease prevention. According to the World Health Organization (WHO), about 80% of the global population still relies primarily on plant-based medicines for their healthcare needs, especially in developing countries. Among plant-derived resources, seeds are particularly valued for their high concentration of phytochemicals such as polyphenols, flavonoids, and lignans, which play vital roles in antioxidant defense and inflammation regulation.

Phytochemicals are a large group of plant-derived compounds that act as the plant's own defense mechanism and have significant physiological effects in the human body. More than a thousand phytochemicals have been identified, functioning as antioxidants, stimulating enzymes, interfering with DNA replication, destroying bacteria, and potentially reducing the onset of chronic diseases such as cancer and cardiovascular disorders [26]. Oilseeds—including flaxseed, sesame, sunflower, and soybean—are notable for their high content of bioactive constituents such as phenolic compounds, tocopherols, phytosterols, peptides, and essential fatty acids. These compounds have been associated with prevention of metabolic and degenerative diseases, largely by mitigating oxidative stress and inflammation [31].

Flaxseed (*Linum usitatissimum* L.), also known as linseed or "Alsi" in the Indian subcontinent [2], is an ancient oilseed crop cultivated worldwide. It is particularly rich in α-linolenic acid, lignans, and other phenolic compounds, which not only provide nutritional value but also exert significant anti-inflammatory effects by modulating molecular pathways involved in chronic diseases. Flaxseed is consumed in various forms, including seeds, oil, powder, tablets, capsules, and flour. Raw oil has been used as an astringent in fungicidal lotions, insecticides, and as a moderate insect repellent [25]. Functional food applications of flaxseed and its derivatives, such as flaxseed oil or lignans, have been linked to health benefits, particularly due to their anti-inflammatory properties [40]. Inflammation, defined as the immune system's response to injury, microorganisms, or irritants, involves increased vascular permeability, protein denaturation, and membrane alterations, and may be classified as acute or chronic [36]. Therefore, the present study aims to evaluate the phytochemical composition of flaxseed and assess its potential anti-inflammatory properties, highlighting its relevance as a functional food with medicinal applications.

MATERIALS AND METHODS

Flaxseed (*Linum usitatissimum* L.) belongs to the family Linaceae. It is an annual plant commercially grown in over 30 countries worldwide [50]. Flaxseed (*Linum usitatissimum* L.) was procured from an organic shop, washed, and shade-dried to remove moisture [6]. The dried seeds were ground into a fine powder for further analysis. For extraction, 1 gram of the powdered seed was separately soaked in 50 mL of ethanol and distilled water and incubated at room temperature for 72 hours. Methanolic extracts intended for anti-inflammatory assays were prepared by soaking the powdered seeds in methanol at 37°C for 24 hours. The extracts were filtered using Whatman No. 1 filter paper and stored until use [15]. Qualitative phytochemical screening was performed to detect the presence of various bioactive compounds. Tests included alkaloids [15], glycosides [38], tannins, carbohydrates, saponins, steroids, proteins, terpenoids, fixed oils and fats, anthraquinones, and phenols [7], Anthocyanins and betacyanins [45] were identified. Flavonoids were detected using methods described by Sofowora (1993) [44], Trease and Evans (1989) [45], and Harborne (1998) [21]. Sterols were confirmed via Liebermann-Burchard's test [8, 45, 44, 21, 43]. Coumarins were tested as per Harborne (1998) [21], while quinones and cardiac glycosides followed Babatunde *et al*. (2019) [5]. The anti-inflammatory activity of the methanolic extract was evaluated using the bovine serum albumin (BSA) protein denaturation assay. Reaction mixtures containing 3% BSA and flaxseed extract at concentrations of 50 and 100 µg/mL were incubated at 37°C for 20 minutes, then heated at 80°C for 10 minutes. Absorbance was measured at 660 nm, and percentage inhibition of protein denaturation was calculated accordingly [30].

RESULTS AND DISCUSSIONS

Qualitative screening of *Linum usitatissimum* L. (flaxseed) seeds revealed the presence of glycosides, betacyanin, steroids, proteins, sterols, coumarins, flavonoids, oils, quinones, phenols, and cardiac glycosides, while alkaloids, tannins, carbohydrates, saponins, terpenoids, and anthraquinones were absent. Glycosides, steroids, proteins, flavonoids, oils, quinones, and phenols showed strong positivity in both ethanol and aqueous extracts. Betacyanin and coumarins were detected only in ethanol extracts, whereas sterols and cardiac glycosides were present only in aqueous extracts (Table 1).

Phytochemicals are bioactive plant compounds responsible for color, aroma, and flavor, and protect plants from environmental stresses like pollution and UV exposure [9]. They also contribute to health benefits due to their antioxidant, anti-inflammatory, and antimicrobial activities. These secondary metabolites, including alkaloids, glycosides, tannins, polyphenols, and flavonoids, have diverse biological functions such as enzyme modulation and DNA interaction [18, 24]. Flavonoids, for example, act as potent antioxidants and metal ion chelators [33]. Phenolic compounds, a major group of plant metabolites, possess anti-aging, anti-inflammatory, cardioprotective, and anticancer properties [20]. Flavonoids also exhibit antibacterial, antiviral, anti-allergic, and vasodilatory effects [10]. Alkaloids are known for their cytotoxic activity with medicinal relevance [34].

Similar phytochemical profiles have been reported in various medicinal plants, confirming their therapeutic potential [42,23]. The presence of flavonoids, steroids, glycosides, tannins, and phenolic compounds is often linked to broad biological activities including anti-inflammatory and antioxidant effects [1]. Variations in phytochemical content can arise due to factors like plant part, collection time, and extraction method [12,16]. This phytochemical diversity supports the use of flaxseed and related plants as valuable sources for developing new therapeutic agents and functional foods. Inflammation, characterized by redness, swelling, and pain, is a complex immune response to injury or irritants that involves increased vascular permeability and protein denaturation [22]. While acute inflammation is protective, chronic inflammation contributes to various diseases, often linked to oxidative stress caused by reactive oxygen species [11,48].

Protein denaturation is a well-established cause of inflammation, and many anti-inflammatory drugs inhibit this process in a dose-dependent manner [17]. In this study, methanol extracts of *Linum usitatissimum* L. (flaxseed) showed concentration-dependent inhibition of heat-induced albumin denaturation, with a maximum inhibition of 71.2% at 100 µg/mL [30]. Egg albumin-induced inflammation is a common in vitro model for assessing anti-inflammatory activity, as it mimics release of inflammatory mediators like histamine and serotonin [3,35]. The presence of bioactive phytochemicals such as flavonoids, phenols, steroids, and terpenes contributes significantly to this inhibitory effect [4, 29]. Numerous studies confirm that flavonoid-rich plant extracts exhibit strong anti-inflammatory properties through stabilization of proteins and membranes, enzyme inhibition, and free radical scavenging [46]. Similar findings have been reported for various medicinal plants like *Murraya koenigii* [13, 14], *Peperomia pellucida* and *Lophira procera* [27]. Overall, the inhibition of protein denaturation by flaxseed extract and related plant products supports their potential as natural anti-inflammatory agents with fewer side effects, which may help manage chronic inflammatory conditions [28,39].

CONCLUSIONS

Herbal medicine remains a valuable alternative to conventional drugs, having been used for centuries to treat human diseases. It is often perceived as safe due to its natural origin; however, it is important to recognize that some plants can be both beneficial and toxic. Phytochemical screening of *Linum usitatissimum* L. seeds revealed the presence of bioactive compounds including glycosides, flavonoids, phenols, and steroids, indicating their nutritional and pharmaceutical potential. The methanol extract exhibited notable *in vitro* anti-inflammatory activity, possibly attributed to flavonoids and polyphenols. These findings support the use of flax seeds as dietary supplements and highlight the need for further studies to isolate active constituents and clarify their mechanisms of action.

ABSTRACT

The healthcare industry is one of the fastest-growing sectors in India, providing employment opportunities to a large number of people. It plays a significant role in generating direct and indirect employment, particularly for women. Among healthcare professionals, nurses constitute the largest workforce in private hospitals and contribute substantially to the quality of patient care and the overall performance of healthcare institutions. The success and reputation of private hospitals largely depend on the dedication, skills, and commitment of nurses and doctors. Despite their vital contribution, many nurses in private hospitals experience challenges such as heavy workloads, long working hours, inadequate staffing, work-related stress, and limited work-life balance. These issues may adversely affect their job fulfilment, motivation, and overall well-being. In recent years, incidents highlighting occupational stress and workplace-related concerns among healthcare professionals have drawn attention to the need for better employee support systems. Such developments emphasize the importance of creating a healthy, safe, and supportive work environment for healthcare employees, particularly women nurses.

Key words: Despite, emphasize, private hospitals, occupational

INTRODUCTION

Human Resource Management (HRM) plays a vital role in the effective functioning of healthcare organisations. As the healthcare sector continues to expand, there is a growing need for research to develop innovative HR policies and practices that enhance employee performance, job fulfilment, and organisational effectiveness. The present study aims to examine the Human Resource Management practices adopted in private hospitals in Andhra Pradesh and evaluate their influence on nurses' job fulfilment. The study focuses on key HRM functions, including human resource planning, job analysis, recruitment and selection, training and development, performance appraisal, compensation and benefits, employee welfare measures, motivation, and career development opportunities. It seeks to understand how these practices contribute to nurses' job fulfilment, organisational commitment, and overall work performance in private hospitals. Previous studies have reported that a considerable proportion of hospital employees exhibit a moderate level of satisfaction with various dimensions of HRM practices, such as employee welfare, strategic human resource planning, work culture, performance appraisal, compensation and rewards, teamwork, communication, career advancement opportunities, and employee participation. However, a significant number of employees have expressed low levels of satisfaction with these HR practices, indicating the need for improvement in human resource policies and their implementation. Based on these findings, the study recommends that private hospitals in Andhra Pradesh strengthen their Human Resource Management systems by adopting employee-centric policies and organisational development initiatives. Hospitals should establish quality improvement committees, provide regular training and professional development programmes, implement transparent performance appraisal systems, ensure fair compensation and welfare benefits, encourage employee participation in decision-making, and create a supportive and stress-free work environment. Such initiatives will enhance nurses' job fulfilment, improve employee retention, increase organisational commitment, and ultimately contribute to the delivery of high-quality healthcare services.

Objectives of the Study

- To study the socio-economic profile of nurses working in private hospitals in Andhra Pradesh.
- To analyse the level of job fulfilment, working conditions, and employee welfare measures provided by private hospitals in Andhra Pradesh.
- To evaluate the Human Resource Management practices adopted in private hospitals and their influence on nurses' job fulfilment.
- To examine the relationship between Human Resource Management practices and job fulfilment among nurses in private hospitals in Andhra Pradesh.
- To assess the level of satisfaction of nurses with recruitment, training, performance appraisal, compensation, and welfare practices.
- To suggest suitable measures for improving Human Resource Management practices and enhancing job fulfilment among nurses in private hospitals in Andhra Pradesh

Scope of the Study

Andhra Pradesh has emerged as one of the leading states in India in terms of healthcare infrastructure, with a large number of super-speciality, multi-speciality, and speciality private hospitals providing advanced medical services. The rapid growth of the private healthcare sector has increased the demand for qualified nursing professionals and effective Human Resource Management (HRM) practices. Therefore, private multi-speciality hospitals in Andhra Pradesh have been selected as the study area. The present study is confined to nurses working in selected private multi-speciality hospitals that have established Human Resource departments responsible for managing employee-related functions. The study focuses exclusively on nursing staff, as they constitute the largest group of healthcare professionals and play a critical role in delivering quality patient care. The research examines key Human Resource Management practices, including recruitment and selection, training and development, performance appraisal, compensation and benefits, employee welfare measures, career development, and employee engagement. It further investigates the impact of these HRM practices on nurses' job fulfilment, organisational commitment, job satisfaction,

and employee retention. The study also identifies the strengths and weaknesses of existing HRM practices and provides recommendations to improve employee well-being, organisational effectiveness, and the quality of healthcare services in private hospitals across Andhra Pradesh.

Statement of the Problem

Nurses are the backbone of the healthcare system and play a vital role in maintaining and improving the health and well-being of patients. They provide continuous patient care, assist physicians, and contribute significantly to the quality and efficiency of healthcare services. Despite their indispensable role, nurses in private hospitals often encounter numerous workplace challenges that affect their job fulfilment and overall performance. In private multi-speciality hospitals, the demand for skilled nursing professionals has increased considerably due to the rapid expansion of healthcare services and the growing expectations of patients. However, many hospitals continue to experience shortages of qualified nursing staff, resulting in increased workloads, extended working hours, role overload, and occupational stress. These challenges can negatively affect nurses' physical and mental well-being, reduce job fulfilment, and ultimately influence the quality of patient care. In addition, nurses frequently face workplace issues such as inadequate staffing, limited career advancement opportunities, insufficient employee welfare measures, workplace safety concerns, communication gaps with management, and high levels of work-related stress. The increasing adoption of digital healthcare technologies, electronic medical records, and advanced hospital information systems has also transformed nurses' responsibilities, requiring continuous learning and adaptation to new work processes.

Hospitals operate round the clock, providing healthcare services 24 hours a day and seven days a week. As frontline healthcare professionals, nurses spend a significant amount of time delivering patient care under physically and emotionally demanding conditions. Therefore, effective Human Resource Management (HRM) practices are essential to ensure employee welfare, job satisfaction, organisational commitment, and job fulfilment among nursing staff. Although many private hospitals have established Human Resource departments, the effectiveness of HRM practices in promoting nurses' job fulfilment and improving employee retention remains a critical concern. Consequently, this study seeks to examine the Human Resource Management practices adopted by private hospitals in Andhra Pradesh and analyse their influence on the job fulfilment of nurses. The findings of the study are expected to provide valuable insights for hospital administrators and policymakers to strengthen HRM practices, enhance nurses' work experiences, and improve the quality of healthcare services.

Limitation of the Study

- The study is limited to nurses working in selected private multi-speciality hospitals in Andhra Pradesh. Government hospitals and other healthcare institutions are not included in the scope of the research.
- The study focuses exclusively on nursing staff. Other healthcare professionals, such as doctors, technicians, pharmacists, and administrative personnel, are excluded from the study.
- The research is based solely on the opinions and responses of nurses. Patients, hospital management, and other stakeholders are not included in the data collection process. Some respondents may have been reluctant to express their genuine opinions regarding Human Resource Management practices, workplace challenges, and job fulfilment due to concerns about confidentiality or fear of negative consequences.

RESEARCH METHODOLOGY

Research Design

The study adopts a **descriptive research design**. This design is appropriate because it helps describe the existing Human Resource Management practices in private hospitals and analyse their impact on the job fulfilment of nurses. It also facilitates the collection of quantitative data from respondents through a structured questionnaire.

Area of the Study

The study was conducted among nurses working in selected private multi-speciality hospitals in Andhra Pradesh. These hospitals were chosen because they have well-established Human Resource Management systems and employ a considerable number of nursing professionals.

Population of the Study

The population of the study comprises all nurses employed in selected private multi-speciality hospitals in Andhra Pradesh.

Sample Size

A sample of **100 nurses** was selected for the study.

Sampling Technique

The study employs the **Convenience Sampling Method**, a non-probability sampling technique. Respondents were selected based on their availability and willingness to participate in the survey.

Sources of Data

- **Primary Data:** Primary data were collected directly from nurses through a structured questionnaire. The questionnaire consisted of demographic questions and statements related to Human Resource Management practices and job fulfilment.
- **Secondary Data:** Secondary data were collected from:
  - Books
  - National and international journals
  - Research articles
  - Hospital reports
  - Government publications
  - Websites
  - Conference proceedings
  - Thesis and dissertations

Data Analysis and Interpertation

The demographic profile shows that the majority of the respondents (43.10%) belong to the 25–35 years age group. Most respondents (80.00%) are female, reflecting the predominance of women in the nursing profession. A majority (56.90%) are married, while 52.30% possess a B.Sc. Nursing qualification. Regarding designation, 55.40% are Staff Nurses, and 36.90% have 6–10 years of work experience. Most respondents (63.10%) belong to nuclear families. In terms of monthly income, 35.40% earn between ₹20,001 and ₹30,000. Additionally, 46.20% of the respondents work in rotational shifts, which is common in private multi-speciality hospitals.

Chi-Square Analysis

Relationship between Age and Job Ful filment among Nurses

Hypothesis

Null Hypothesis (H_0): There is no significant association between the age of nurses and their level of job fulfilment.

Alternative Hypothesis (H_1): There is a significant association between the age of nurses and their level of job fulfilment.

Decision: Since the p-value (0.036) is less than 0.05, the null hypothesis is rejected

Interpretation

The analysis indicates that there is a significant association between the age of nurses and their level of job fulfilment in private hospitals in Andhra Pradesh. This suggests that nurses belonging to different age groups experience varying levels of job fulfilment.

Findings

Based on the analysis and interpretation of data, the following major findings were identified:

- The majority of the respondents (43.10%) belong to the 25–35 years age group.
- Most of the respondents (80.00%) are female.
- More than half of the respondents (56.90%) are married.
- The majority (52.30%) possess a B.Sc. Nursing qualification.
- More than half (55.40%) are working as Staff Nurses.
- A considerable proportion of respondents (36.90%) have 6–10 years of work experience.
- Most respondents (63.10%) belong to nuclear families.
- The majority (35.40%) earn a monthly income between ₹20,001 and ₹30,000.
- Nearly half of the respondents (46.20%) work on rotational shifts.
- Employee Welfare received the highest mean score, indicating that nurses consider welfare measures an important factor contributing to job fulfilment.
- Work Environment and Training & Development were also rated highly by the respondents.
- Compensation and Benefits received a moderate level of satisfaction.
- Career Development opportunities received the lowest mean score, indicating that nurses expect better promotion and professional growth opportunities.
- job fulfilment.

Suggestions

Based on the findings of the study, the following suggestions are proposed for private hospitals in Andhra Pradesh:

- Hospitals should strengthen employee welfare programmes by providing comprehensive health insurance, counselling services, transportation facilities, and wellness initiatives.
- Adequate nurse-to-patient ratios should be maintained to reduce workload and improve the quality of patient care.
- Competitive salary packages, performance-based incentives, and periodic salary revisions should be introduced to enhance employee motivation.
- Continuous training and professional development programmes should be organised to improve nurses' clinical competencies and leadership skills.
- Transparent and objective performance appraisal systems should be implemented to recognise and reward employee performance.
- Clear career advancement and promotion policies should be established to improve job fulfilment and employee retention.
- Hospitals should provide a safe, supportive, and healthy work environment with adequate safety measures and modern medical equipment.
- Employee participation in decision-making should be encouraged through regular meetings, suggestion schemes, and feedback mechanisms.
- Flexible work schedules and effective shift management should be introduced to improve work-life balance.
- Stress management programmes, psychological counselling, and employee assistance services should be provided to support nurses' mental well-being.
- Hospital management should promote open communication, mutual respect, and teamwork among nurses, doctors, and administrators.

- Regular employee satisfaction surveys should be conducted to identify workplace issues and continuously improve Human Resource Management practices.

CONCLUSION

Human Resource Management practices play a crucial role in enhancing the job fulfilment, motivation, and organisational commitment of nurses working in private hospitals. Nurses are the foundation of quality healthcare services, and their satisfaction directly influences patient care and organisational performance. The findings of this study reveal that effective HRM practices, particularly employee welfare, work environment, training and development, fair compensation, and career development opportunities, have a significant positive impact on nurses' job fulfilment. Demographic characteristics such as age, gender, work experience, designation, and monthly income also influence employees' perceptions of job fulfilment. In conclusion, strengthening Human Resource Management practices is essential for creating a motivated, committed, and high-performing nursing workforce capable of meeting the evolving healthcare needs of society.

ABSTRACT

In the present investigation, fungal population density of fishery waste degraded from Mallipattinam, Tamil Nadu was systematically evaluated. The complex and nutrient-rich medium composed of both organic and inorganic constituents, harbors a wide diversity of fungal life. The determination of fungal colonies serial dilution and plating technique, a total of 22 (MDRP 1 to MDRP 22) distinct fungal organisms were identified using standard biological identification protocols. Additionally, comprehensive physicochemical profiling of fishery waste crust from soil and physicochemical parameters such as color, texture, pH, electrical conductivity, organic carbon and organic matter whereas macronutrients (available nitrogen, phosphorus, potassium), micronutrients (zinc, copper, iron, manganese), cation exchange capacity and quantity of calcium, magnesium, sodium, and potassium were analysed. Among these, the Mallipattinam waste crust exhibited superior physicochemical parameters were recorded. The findings suggested that Fisheries waste degradation soil is more efficiently facilitated in sandy with fisheries heads being more readily utilized by indigenous microbial communities compared to the Fisheries waste degraded soil. These investigations concentrate on converting environmental contaminants into biomedical assets, highlighting significant applications.

Keywords: Fishery waste, soil, population density, fungal strain, physicochemical parameters.

INTRODUCTION

Fishery resources represent a significant sector of our economy; according to recent estimates (Caruso *et al.,* 2020) more than 170 million metric tons of fish (including capture and aquaculture), shellfish and others are produced each year. The issue of organic food waste is increasingly becoming a significant environmental, economic, and social challenge. A potential solution to this challenge is to explore innovative methods for valorizing food waste within a circular economy framework (Liang *et al.,* 2022). Fishery waste pertains to the substantial quantity of by-products produced during the harvesting and processing of fish approximately 30% to 70% of the overall fish mass comprising heads, viscera (intestines/organs), skins, bones, fins, scales and shells. These nutrient-dense materials, in addition to inedible by-catch, constitute valuable yet underutilized resources that are frequently transformed into fertilizer, fishmeal, oil or bioactive compounds. Fishing waste, which includes abandoned gear (commonly referred to as "ghost gear") and organic processing byproducts, serves as a significant contributor to marine pollution and ecological harm. This waste encompasses lost nets, lines and hooks that can lethally impact marine life for extended periods, as well as organic refuse such as fish entrails and bones that lead to oxygen depletion.Fish may become contaminated with microbes from various sources, including the earth, air, dust, medical equipment (utilized in production or distribution), humans, or animal secretions (W H Organization 2021). Unregulated soil utilization, the disposal of human and animal feces, sewage management, and the application of manure lead to increased fungal loads and the presence of pathogenic fungi in soil samples (Chakma *et al.,* 2025).

Despite an enhanced comprehension of fisheries and the associated diseases, foodborne illnesses continue to be among the most prevalent health concerns that have played a substantial role in the worldwide economic downturn (Ikrimah, 2024). Despite the diverse forms of fish waste (FW) generated, this article exclusively concentrates on comprehending the different applications that can arise from the product co-streams produced during fish processing (Sultan *et al.,* 2023). A comprehensive study has been undertaken to identify a superior replacement for yeast extract. One potential alternative may be a nitrogen source derived from fish waste (Chandukishore *et al.,* 2026). The marine fishery resource represents a self-renewing living natural asset within a dynamic ecosystem. It is imperative for the nation to maximize the utilization of this resource for the welfare of its citizens (Bavinck *et al.,* 2005; FAO, 2006). Fish has historically served as a fundamental food source for coastal communities and continues to do so today, notwithstanding the challenges faced by the sector (Vivekanandan *et al.,* 1991). India boasts an abundance of natural resources, with the annual harvestable fishery potential of the nation estimated to be in the millions of tons, increasing day by day (Stevens *et al.,* 2000; Varadjarajan *et al.,* 2009). It has been established that the fish biodiversity within the country is declining at a concerning rate across all aquatic environments (Watson *et al.,* 2004). The marine fisheries are predominantly harvested by traditional and small-scale fishing vessels operating in coastal waters. Over the years, the exploitation of fishery resources has evolved from under-exploitation to moderate exploitation, ultimately leading to overexploitation (Savad and Raghavan, 2001; Vivekanandan *et al.,* 2003). Environmental factors are intricately connected to the causes of disease and the resultant production losses (Qasim and Gupta, 1981). Among the exploited marine fish resources, it is crucial to enhance the populations in their respective habitats (Pai and Mahadavan, 1973; Lal Mohan, 1991; Sarvaiya, 1991). Therefore, this study aims to physicochemical parametes, isolate and identify the fungi from marine fishery waste soil sample species present along the Mallipattinam coast.

MATERIALS AND METHODS

Sample collection

Fishery waste degraded soil samples were gathered from two distinct sites in Thanjavur District, specifically Mallipattinam Coastal area. The samples were weighed and stored at room temperature within a sealed environment that maintained a humid atmosphere for a maximum duration of 48 hours. The fishery waste degraded soil samples

were collected manually, permitted to air dry, and subsequently transported to the laboratory in sterile polythene bags or sanitized bottles.

Physicochemical parameters

The physico-chemical parameters of collected fishery waste degraded soil were analyzed by standard methods (APHA, 1989).

Isolation and identification

Potato Dextrose Agar medium (PDA) was prepared and sterilized in an autoclave at 121°C for 15 minutes by using grams of soil samples from marine sediments. Streptomycin sulphate solution was added to the medium (1:1) and then poured into the petri plates. 0.1mL of a serially diluted soil sample was added to the medium after solidification. The inoculum was spread equally and left undisturbed in a room with no dust for three to five days. There was a count of the fungus colonies. On the standard potato dextrose agar medium, the pure cultures were sustained (Indu *et al.,* 2015). The identification of fungi was observed after 72 hours using Nikon optiphot microscope. The organisms were confirmed using standard manual of soil fungi (Gillman, 1957), Dematiaceous Hyphomycetes (Ellis, 1971), A manual of penicillia (Raper and Thom, 1949), soil fungi (Domsch *et al.,* 1980).

RESULT AND DISCUSSION

The physicochemical analysis revealed marked differences between the collection sites. Mallipattinam West consistently showed higher values in several key soil parameters, including organic carbon, organic matter and essential macro- and micronutrients. These enhanced nutrient levels are likely due to prolonged accumulation of fishery waste which contributes nitrogenous compounds, minerals and lipids that are gradually mineralized by indigenous microbes (Lall *et al.,* 2021). The elevated electrical conductivity and moderate pH detected in this site further support the influence of decomposing fish residues, which release soluble salts during breakdown. The sandy texture recorded at both sites played a significant role in shaping microbial activity; sandy soils have wider pore spaces that improve aeration, moisture drainage and substrate diffusion, thereby favoring fungal colonization and enzymatic degradation of organic substrates (Islam *et al.,* 2025). A notable outcome of the investigation is that fishery head waste was decomposed more effectively than mixed fish residues, indicating that the microbial consortia present in these soils can readily access and utilize the protein-rich portions of fish head (Wang, 2025). The nutrient-enriched fishery waste compost, when blended with organic matter, demonstrated improvements in parameters linked to soil fertility (Devi, 2024).

Enhanced macronutrient availability particularly nitrogen and phosphorus along with the presence of trace elements like zinc and iron, indicates that such compost amendments could support better root development and overall plant growth. The cumulative findings emphasize that fishery waste-integrated soils not only sustain diverse fungal communities but also evolve into nutrient-rich substrates with agronomic potential (Pebiega *et al.,* 2024). Soil fertility is fundamentally governed by the presence and composition of organic matter with soil organic carbon (SOC) serving as the cornerstone of nutrient cycling and biological activity. SOC enhances soil structure, moisture retention and microbial processes, thereby contributing significantly to plant productivity and overall soil health (Ṭopa 2025). Among essential nutrients, phosphorusplay a central role as a key component of nucleic acids and energy transfer molecules such as ATP, influencing root development, cellular differentiation, reproductive growth and early maturation of crops. However, the discharge of untreated industrial effluents can drastically alter the soil's physicochemical and biological properties, often leading to a decline in fertility and productivity due to nutrient imbalance and toxic buildup.

In the present investigation, the physicochemical properties including fishery waste degraded soil sample were collected from Mallipattinam Coastal area, Thanjavur District of Tamil Nadu, India. The maximum physicochemical parameters such as colour, temperature, pH, organic carbon, organic matter, salinity, available nitrogen, phosphorus,

potassium, zinc, copper, iron, manganese and sodium, calcium, magnesium, potassium were (brown colour), (15°C), (7.8 pH), (0.68%), (0.87%), (24 ppt), (220.20 mg/kg), (29.3 mg/kg), (254.03 mg/kg), (0.96 ppm), (0.46 ppm), (5.45 ppm), (2.48 ppm), (1.29 ppm), (1.79 ppm), (1.64 ppm), (0.69 ppm) was recorded (Table 1). The fungal organisms obtained from both diseased and seemingly healthy fish in this study exhibited notable similarities. This outcome was anticipated, as *Aspergillus* sp., *Mucor* sp., *Penicillium* sp. and *Rhizopus* sp. have been identified by Refai *et al.,* (2010) as typical mycobiota of freshwater fish. Although these isolates are considered normal mycobiota for both Clarias and Tilapia, they have the potential to induce disease due to their opportunistic nature, with many possessing virulence factors that facilitate disease causation (Refai *et al.,* 2004), particularly under conducive predisposing conditions. This observation aligns with findings from other researchers indicating that fungal infections represent one of the most significant disease challenges in various aquaculture settings, leading to economic losses in fish farming across tropical Africa and other developing nations (Meyer, 1991).

Numerous studies have identified various fungal agents linked to freshwater fish both in Nigeria and globally. Christianah and Fagade (2010), while assessing smoked fish (*Ethmalosa fimbriata*) from retail outlets in Ago-Iwoye, Ogun State, Nigeria for fungal contamination, isolated the genera *Aspergillus, Rhizopus* and *Penicillium* as the most prevalent isolates. It was reported that all isolates contributed to the degradation of fish proteins, with *A. ochraceous* exhibiting the highest degradation rate, followed by A. niger and *A. flavus*. In a survey conducted by Tsadu et al. (2006) on fungi contaminating various fish species from Tagwai Dam in Minna, Niger State, *Aspergillus niger, A. flavus, A. parasiticus, A. fumigatus, Rhizopus* sp., *Mucor* sp., *Microsporum* canis, *Penicillium viridicalium* and *Fusarium* sp. were isolated from the skin, gills, and fins of the fish, with *A. niger* found to contaminate all sampled fish species.
Fafioye *et al.,* (2008) reported the isolation of *Aspergillus* sp., *Rhizopus* sp., *Fusarium* sp. and *Mucor* sp. from smoked-dried specimens of four freshwater fish species sourced from Oja-Oba market in Ago-Iwoye, Ogun State, with *Aspergillus* sp. being the most frequently isolated species. Rashmi and Chandan (2015) isolated Mucor sp., *Rhizopus* sp., *Chaetomium globosum*, *Alternaria tenuis, Verticillium* sp., *Aspergillus fumigatus* and *Penicillium funiculosum* from several economically significant freshwater fish in the Gandak River near the Muzaffarpur region of Bihar. Mohamed (2011) isolated mycotoxin-producing fungi, including *Aspergillus flavus, A. clavatus, A. ochraceous, A. parasiticus, A. terreus, A. vesicolor, Penicillium chrysogenum* and *Trichoderma viride* from five fish species, such as tilapia and catfish, cultivated in aquaculture.

The fungal species identified in this research have been recorded as being linked to *C. gariepinus* and*Oreochromis niloticus*. Abolude *et al.,* (2013) reported the isolation of *Penicillium* sp., *Acreomonium* sp., *Fusarium solani*, *Aspergillus* sp., *Mucor* sp. and *Saprolegnia* sp. from the eggs and brood stocks of Clarias gariepinus sourced from hatchery farms located in Zaria, Kaduna State. In a separate study, Refai *et al.,* (2010) isolated, *A. fumigatus, A. niger, A. terreus, A. flavus, Penicillium* sp., *Mucor* sp., *Rhizopus* sp., *Fusarium* sp. and *Saprolegnia* sp. from both diseased and seemingly healthy specimens of *C. gariepinus* and *O. niloticus*, aiming to evaluate the mycotic colonization of freshwater fish in Egypt. The majority of the fungal isolates obtained from this study hold significant veterinary and medical relevance (Beck-Sague and Jarvis, 1993; Denning, 1996). The fungal isolates were obtained from the serial dilution and plated on Potato Dextrose Agar (PDA) using dilution factors of 10^{-3}, 10^{-4} and 10^{-5}. Totally of 22 fungal colonies were isolated from the fishery waste degraded soil sample. The fungal colonies were identified including *Aspergillus aeneus, A. arenarius, A. flavipes, A. flavus, A. fumigatus, A. janus, A. luchuensis, A. niger, A.nidulans, A. ochraceus, A. pulvinus, A.quaersinus, A. restrictumA. sulphurous, A. terreus, A. ustus, A. variecolor, Curvularia geniculata, C. lunata, Fusarium moniliforme, F. oxysporum* and *Pencillium granulatum.* The cultural and microscopic characteristics were used. The fungal isolates belonged to 4 genera as follows *Aspergillus* (95%), *Curvularia* (2%), *Fusarium* (2%) and *Pencillium* (1%). *A.arenarius, C. geniculata* and *P.granulatum* colonies are maximum presented in Mallipattinam coastal area fishery waste soil sample and minimum recorded at *A.pulvinus, A.sulphureus, A.ustus, A.varecolor* and *F.oxyporum.* In particularly, *Aspegillus* genera were mostly noted by the fishery waste soil sample were recorded, respectively (Table 2 & Plate 1).

CONCLUSION

The present study focused on evaluating the fungal population diversity and physicochemical properties of Fishery waste soil sample in Mallipattinam coastal area. Owing to their adaptability and simplicity, they also serve as ideal model organisms in scientific research. While microorganisms are typically associated with beneficial applications, it is worth noting that some have been exploited for harmful purposes such as bioterrorism and biological welfare. In the context of health, microorganisms contribute significantly to nutrient cycling and detoxification processes. For instance, the enhancement of soil organic carbon has been shown to aid in the immobilization of toxins, reducing their bioavailability. The ability of microbes to detoxify environments through bioremediation highlights their critical role in maintaining ecological balance and safeguarding human health. Microorganisms are integral to a wide array of industries including the development of pharmaceuticals, production of biomolecules and cosmetics, food processing and preservation and nutrient recycling. The comprehensive data collected from the fishery waste soil sample of Mallipattinam can serve as a baseline reference for future investigations especially in assessing long-term environmental changes and the effectiveness of bioremediation strategies in degraded or crust.

ABSTRACT

Payroll processing is a vital function of human resource management that ensures employees receive accurate and timely compensation while complying with statutory and organizational requirements. It involves a systematic process of calculating employee earnings, allowances, overtime, incentives, statutory deductions, taxes, and other recoveries to determine the net salary payable. An efficient payroll system not only ensures compliance with labour laws and tax regulations but also enhances employee satisfaction, organizational transparency, and operational efficiency. In today's digital environment, payroll management has become increasingly automated through payroll software, reducing manual errors, improving data accuracy, and ensuring timely salary disbursement. Effective payroll processing also includes the remittance of statutory deductions such as Provident Fund (PF), Employees' State Insurance (ESI), Professional Tax (PT), and Income Tax to the respective authorities. Therefore, an efficient payroll system plays a significant role in maintaining employee trust and supporting organizational performance. The present study focuses on evaluating the effectiveness of the employee payroll process in Aavin, with special reference to the Sholinganallur Dairy, Chennai. It examines various aspects of payroll management, including payroll accuracy, salary disbursement, statutory compliance, payroll automation, employee satisfaction, and challenges encountered in the payroll process. The findings of the study are expected to provide valuable insights into the existing payroll practices and offer suitable recommendations for improving payroll efficiency and employee satisfaction within the organization.

Keywords: Payroll Processing, Payroll Management, Payroll Automation, Employee Compensation.

INTRODUCTION

Payroll is one of the most important functions of human resource and financial management, ensuring that employees receive accurate and timely compensation for the work performed during a specific pay period. An effective payroll system involves a series of systematic activities, including maintaining employee records, tracking attendance and working hours, calculating salaries and allowances, processing statutory deductions, and disbursing net salaries in accordance with organizational policies and government regulations. Payroll management requires close coordination between the Human Resources and Finance departments to ensure accuracy, transparency, and legal compliance. Modern organizations increasingly rely on computerized payroll systems and automation to improve efficiency, minimize calculation errors, and ensure timely salary payments. The payroll process also includes calculating overtime, incentives, bonuses, leave deductions, and statutory contributions such as Provident Fund (PF), Employees' State Insurance (ESI), Professional Tax (PT), Income Tax (TDS), Social Security, and Medicare (where applicable). Employers are responsible for deducting the required taxes and statutory contributions from employees' earnings, remitting them to the appropriate authorities, and maintaining accurate payroll records. Therefore, an efficient payroll system not only ensures compliance with labour laws and statutory regulations but also enhances employee satisfaction, organizational efficiency, and effective financial management.

Aavin, one of the leading dairy cooperatives in Tamil Nadu, employs a large workforce engaged in production, procurement, processing, distribution, and administrative activities. The efficiency of its payroll process plays a vital role in maintaining employee morale, financial accountability, and smooth organizational operations. Ensuring the accuracy and timeliness of salary payments is particularly important in enhancing employee motivation and organizational performance. Against this background, the present study aims to evaluate the effectiveness of the employee payroll process in Aavin, with special reference to the Sholinganallur Dairy, Chennai. The study examines various dimensions of payroll management, including payroll accuracy, salary disbursement, statutory compliance, payroll automation, employee satisfaction, and challenges associated with payroll administration. The findings of the study are expected to provide valuable insights and practical recommendations for improving payroll efficiency and strengthening payroll management practices within the organization.

Statement of the Problem

An effective payroll system is essential for ensuring accurate salary disbursement, statutory compliance, and employee satisfaction. However, payroll processing is a complex function that requires the integration of employee records, attendance, leave management, salary calculations, statutory deductions, and compliance with labour laws and organizational policies. Errors or delays in payroll processing may result in employee dissatisfaction, reduced morale, legal complications, and administrative inefficiencies. Organizations often face several challenges in payroll management, including inaccurate payroll calculations, delayed salary payments, changing statutory regulations, data management issues, payroll software limitations, and coordination between the Human Resources and Finance departments. These challenges become more significant in large organizations where payroll processing involves a diverse workforce and complex compensation structures. Therefore, it is essential to evaluate the effectiveness of the existing payroll system and identify areas requiring improvement. Aavin, being one of the leading dairy cooperatives in Tamil Nadu, relies on an efficient payroll process to ensure timely and accurate employee compensation. Any deficiencies in payroll administration may affect employee confidence, organizational productivity, and compliance with statutory requirements. Hence, the present study aims to assess the effectiveness of the employee payroll process in Aavin, with special reference to the Sholinganallur Dairy, Chennai, and to suggest appropriate measures for improving payroll efficiency and employee satisfaction.

Objectives of the Study

Primary Objective

- To study the effectiveness of the employee payroll process in Aavin with special reference to the Sholinganallur Dairy, Chennai.

Secondary Objectives

- To examine the existing payroll processing system followed in Aavin.
- To assess the accuracy and timeliness of salary disbursement.
- To evaluate employee satisfaction with the payroll process.
- To analyse the effectiveness of payroll automation in payroll administration.

Scope of the Study

The present study focuses on evaluating the effectiveness of the employee payroll process in Aavin, with special reference to the Sholinganallur Dairy, Chennai. The study covers various aspects of payroll management, including salary calculation, payroll processing, timely salary disbursement, statutory deductions, payroll accuracy, payroll automation, and employee satisfaction with the payroll system. It also examines the efficiency of the existing payroll practices and identifies the challenges encountered in payroll administration. The findings of the study will help the management of Aavin to improve payroll policies, strengthen statutory compliance, enhance payroll efficiency, and increase employee satisfaction. Furthermore, the study will serve as a useful reference for researchers, academicians, and management professionals interested in payroll management and human resource practices in the dairy industry.

Limitations of the Study

The present study is limited to the employees of Aavin, with special reference to the Sholinganallur Dairy, Chennai. The findings are based on the responses of the selected respondents and may not be generalized to other Aavin units or organizations. The study is confined to selected aspects of the payroll process, such as salary disbursement, payroll accuracy, statutory deductions, and employee satisfaction. The accuracy of the findings depends on the responses provided by the respondents and the data collected during the study period.

RESEARCH METHODOLOGY

Research Design: Descriptive Research Design
Area of the Study: Aavin, Sholinganallur Dairy, Chennai
Population of the Study: Employees of Aavin, Sholinganallur Dairy, Chennai
Sample Size: 100 Employees
Sampling Technique: Simple Random Sampling

Sources of Data

- **Primary Data:** Structured Questionnaire
- **Secondary Data:** Books, Journals, Research Articles, Company Records, Annual Reports, Websites, and Other Published Sources

Research Instrument: Structured Questionnaire with a Five-Point Likert Scale

Statistical Tools Used

- Percentage Analysis
- Mean and Standard Deviation
- Chi-Square Test
- Independent Sample *t*-Test
- One-Way ANOVA

Data Analysis and Interpertation

Interpretation

The demographic analysis shows that the majority of the respondents are male (56%), belong to the 31–40 years age group (42%), and are married (68%). Most respondents hold a postgraduate qualification (40%) and are permanent employees (46%). A higher proportion of the respondents work in the Production Department (28%), have 5–10 years of work experience (38%), and earn a monthly income between ₹30,001 and ₹40,000 (36%). The demographic profile indicates that the study primarily represents experienced employees working in different departments of Aavin, Sholinganallur Dairy, Chennai. The highest mean score (4.28) indicates that employees are highly satisfied with the timely payment of salaries, while the lowest mean score (3.85) indicates comparatively lower satisfaction with the overall payroll process.

Hypothesis

- **H_0:** There is no significant association between gender and employee satisfaction with the payroll process.
- **H_1:** There is a significant association between gender and employee satisfaction with the payroll process.

Since the p-value (0.016) is less than 0.05, the null hypothesis is rejected. Therefore, there is a significant association between gender and employee satisfaction with the payroll process.

Findings

The study found that the majority of the respondents were male, belonged to the 31–40 years age group, and had postgraduate qualifications. Most employees expressed satisfaction with the payroll process, particularly regarding the timely payment of salaries and payroll accuracy. However, a few respondents indicated concerns about payroll-related communication and the clarity of statutory deductions.

Suggestions

The organization should ensure greater transparency in payroll processing and provide employees with clear explanations of salary components and statutory deductions. Regular updates to the payroll system and periodic training for payroll staff can improve efficiency and reduce errors. Employee feedback should also be collected regularly to enhance the effectiveness of the payroll process.

CONCLUSION

The study concludes that the payroll process in Aavin, Sholinganallur Dairy, Chennai, is generally effective and contributes to employee satisfaction. Nevertheless, continuous improvements in payroll administration, communication, and automation will further enhance payroll accuracy, employee confidence, and overall organizational efficiency.

ABSTRACT

Fever (Jwara) is intricately defined in Ayurveda as a systemic disorder resulting from disturbances in Dosha, Agni, and Dhatu. Jwarhara Mahakashaya, part of Charaka Samhita, represents a group of medicinal plants used for managing fever and inflammation. Despite extensive empirical use, the molecular basis of its effects is not fully understood. Network pharmacology offers a platform for exploring the interactions of phytochemicals with biological targets, providing a basis for scientifically validating classical formulations. This review critically assesses Jwarhara Mahakashaya's therapeutic potential using network pharmacology and discusses its significance in evidence-based Ayurvedic drug discovery.The review synthesizes classical Ayurvedic texts, recent phytochemical studies, and bioinformatics resources to establish a network pharmacology workflow for Jwarhara Mahakashaya, analyzing its phytochemical constituents, target prediction, protein-protein interactions, and molecular docking.The reviewed plants in Jwarhara Mahakashaya house diverse phytochemicals including flavonoids, alkaloids, terpenoids, and phenolic compounds, capable of modulating inflammatory mediators and stress pathways. The formulation's effects involve the coordinated action across biological networks rather than singular targets. Network pharmacology provides a robust framework for the validation of Ayurvedic formulations and promotes integrated traditional knowledge with computational biology for future herbal drug research.

Keywords: Ayurveda, Jwara, Jwarhara Mahakashaya, Network Pharmacology, Systems Biology, In-silico Analysis.

INTRODUCTION

Ayurveda, as one of the oldest medical systems, views health as a balance between physiological, psychological, and environmental factors. It emphasizes holistic interventions over reductionist models, aligning with the principles of systems biology and network pharmacology, which see diseases as resulting from interactions within biological networks.Within Ayurveda, Jwara (fever) is outlined as a condition caused by the vitiation of Dosha, impairment of Agni, and disturbance in Dhatu, highlighting the necessity for comprehensive treatment strategies that restore health through multifaceted approaches. Modern biomedical perspectives also recognize fever as a complex physiological response mediated by endogenous and exogenous pyrogens. Therapeutic selectivity in Ayurveda utilizes classifications like Mahakashayas, where Jwarhara Mahakashaya is specifically directed towards treating fever and inflammatory conditions with its diverse pharmacodynamic properties.

Jwarhara Mahakashaya: A Classical and Scientific Perspective

Jwarhara Mahakashaya comprises several medicinal plants utilized for managing fever. Not merely symptomatic treatment, Ayurveda aims to restore balance, targeting the underlying dysfunctions by influencing digestion, metabolism, and the immune response. The medicinal plants in this formulation are rich in bioactive compounds, reinforcing the Ayurvedic view of polyherbal synergism. Scientific Validation of Jwarhara Mahakashaya Modern science corroborates the classical therapeutic claims with phytochemical studies showing that these plants provide a broad range of biological activities—including antioxidant, anti-inflammatory, and antimicrobial effects. Current findings resonate with the Ayurvedic classification of these drugs and their multipronged actions against fever.

Network Pharmacology and In-Silico Methodology

Network pharmacology has emerged as an innovative discipline that integrates pharmacology, systems biology, bioinformatics, and computational science to investigate the complex interactions between drugs, molecular targets, and disease-associated biological networks. Unlike conventional pharmacology, which follows the "one drug–one target" concept, network pharmacology adopts a "multi-component–multi-target–multi-pathway" strategy that better reflects the therapeutic philosophy of Ayurveda.[2,4,12,13] This approach is particularly relevant for evaluating classical herbal formulations, where numerous phytochemicals collectively contribute to therapeutic efficacy through synergistic regulation of multiple signalling pathways. The scientific rationale for applying network pharmacology to Jwarhara Mahakashaya lies in its chemical complexity. Preliminary phytochemical investigations have identified a wide spectrum of flavonoids, alkaloids, terpenoids, phenolic acids, glycosides, tannins, and phytosterols distributed across its constituent medicinal plants.[9–12] These compounds exhibit diverse pharmacological activities and are capable of interacting with numerous proteins involved in inflammatory responses, oxidative stress, immune regulation, and cellular metabolism. Consequently, analysing these interactions through computational methods provides a comprehensive understanding of the molecular mechanisms underlying the classical antipyretic activity of Jwarhara Mahakashaya.

The network pharmacology workflow begins with the identification and authentication of medicinal plants based on classical Ayurvedic literature and accepted botanical nomenclature.[1] Standardized botanical identification ensures the reliability of phytochemical retrieval and minimizes errors resulting from taxonomic inconsistencies. Following authentication, phytochemical information is collected from publicly available databases such as PubChem, IMPPAT, Dr. Duke's Phytochemical Database, and TCMSP, where chemical structures, molecular formulae, canonical SMILES, and physicochemical properties are systematically documented.[7,8,14–16] To improve biological relevance, identified phytochemicals undergo preliminary screening using drug-likeness and pharmacokinetic parameters, including oral bioavailability, molecular weight, and Lipinski's rule of five.[17] This filtering process reduces redundancy and identifies compounds with favourable pharmacological characteristics for subsequent computational analysis.

The screened phytochemicals are then subjected to target prediction, a critical step in which probable human protein targets are identified using platforms such as SwissTargetPrediction, PharmMapper, and related computational algorithms.[18] These platforms compare chemical structures with experimentally validated ligands to predict potential

interactions between phytochemicals and proteins. Since individual phytochemicals often interact with several proteins, target prediction generates an extensive molecular interaction network rather than isolated drug–target relationships.

Disease-associated targets related to fever and inflammation are subsequently retrieved from curated biomedical databases, including GeneCards, DisGeNET, DrugBank, and the Comparative Toxicogenomics Database (CTD).[19–22] Keywords such as fever, pyrexia, inflammation, immune response, and cytokine signalling facilitate the identification of genes implicated in disease pathogenesis. Comparison of disease-associated genes with predicted phytochemical targets allows the identification of overlapping targets, which are considered potential therapeutic mediators of Jwarhara Mahakashaya. The common targets are further analysed using the STRING database to construct a Protein–Protein Interaction (PPI) network.[23] PPI analysis reveals functional interactions among proteins and identifies highly connected hub genes, which often play central roles in disease progression. Parameters such as degree centrality, between ness centrality, and closeness centrality are employed to determine biologically significant proteins within the interaction network. These hub proteins may represent potential molecular targets responsible for the antipyretic and anti-inflammatory effects of the formulation.

Functional interpretation of the identified targets is performed using Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment analyses.[24,25] GO enrichment categorizes target proteins according to biological processes, molecular functions, and cellular components, whereas KEGG analysis identifies signalling pathways significantly influenced by the phytochemicals. Previous network pharmacology studies of medicinal plants have consistently highlighted pathways associated with NF-κB signalling, TNF signalling, MAPK cascade, PI3K-Akt pathway, IL-17 signalling, Toll-like receptor signalling, and apoptosis, all of which play pivotal roles in inflammatory responses and fever regulation.[6,12,24] Finally, molecular docking serves as an important validation tool by evaluating the binding affinity of selected phytochemicals with key protein targets. Protein structures are retrieved from the Protein Data Bank (PDB), and docking simulations are performed using software such as AutoDock Vina, PyRx, or Discovery Studio.[15,26] Docking scores, hydrogen bonding patterns, hydrophobic interactions, and binding energies provide structural evidence supporting predicted drug–target interactions. Compounds demonstrating strong and stable binding with inflammatory mediators may serve as promising lead molecules for further pharmacological investigation.

DISCUSSION AND FUTURE PERSPECTIVES

The application of network pharmacology to Jwarhara Mahakashaya offers a comprehensive framework to explore the multidimensional therapeutic principles inherent in Ayurveda. This approach diverges from conventional pharmacology, which typically concentrates on a single active compound targeting a specific molecular entity. Instead, network pharmacology acknowledges that herbal medicines exert their therapeutic effects through a coordinated action of multiple phytochemicals that engage with various proteins and signaling pathways. This systemic approach aligns well with Ayurvedic notions of disease, which emphasize that health disturbances arise from multiple physiological perturbations requiring equally holistic interventions. Investigations into the phytochemical profile of Jwarhara Mahakashaya reveal an abundance of bioactive compounds, including flavonoids, alkaloids, terpenoids, and phenolic compounds, known for their antioxidant, anti-inflammatory, and immune modulatory properties. These compounds often work synergistically, regulating inflammatory mediators and restoring metabolic balance, thereby justifying the extensive therapeutic effects attributed to this formulation in classical texts.

Network pharmacology identifies key proteins involved in fever and inflammatory processes, such as TNF-α, IL-6, COX-2, and MAPK1. These proteins play critical roles in cytokine production, inflammatory signaling, and oxidative stress management, contributing to fever's pathophysiology. By modulating multiple, interconnected targets, Jwarhara Mahakashaya showcases a broad therapeutic impact that contrasts sharply with conventional antipyretic agents, offering a systems-level regulation of inflammatory responses. Pathway enrichment analyses, including Gene Ontology and KEGG studies, corroborate these findings by linking Jwarhara Mahakashaya to major signaling networks responsible for inflammation. This underscores the potential for these phytochemicals to simultaneously suppress excessive inflammation while maintaining immune function—effectively bridging traditional Ayurvedic practices and modern biomedical science. However, challenges exist in network pharmacology, primarily reliant on the quality of existing databases. The variability in phytochemical composition due to ecological and preparative factors limits predictive accuracy. Therefore, while network pharmacology serves as a valuable hypothesis-generating tool, it should complement rather than replace empirical research. Future directions should involve a combination of computational predictions with experimental validations, employing advanced techniques such as metabolomics and transcriptomics. This holistic approach will enhance the credibility of Jwarhara Mahakashaya within evidence-based medicine, potentially leading to novel therapeutic strategies for treating fever and other inflammatory conditions. Ultimately, integrating traditional knowledge with modern technology may facilitate new avenues for drug discovery rooted in Ayurveda's rich legacy.

CONCLUSION

This review emphasizes that Jwarhara Mahakashaya, a classical formulation from the Charaka Samhita, offers a scientifically promising approach for managing fever and inflammatory disorders. Ayurveda explains its therapeutic effects through principles like Dosha balance, Agni restoration, Ama Pachana, and preservation of Ojas. Contemporary computational biology enhances this understanding by revealing the intricate interactions among its phytochemicals, molecular targets, and biological pathways. Network pharmacology has emerged as a powerful methodology for investigating the complex nature of herbal formulations like Jwarhara Mahakashaya. The diverse phytochemical constituents—including flavonoids, alkaloids, terpenoids, and phenolic compounds—allow for the regulation of multiple inflammatory mediators and signaling pathways. Computational analyses indicate that these compounds collectively modulate critical proteins involved in inflammation, such as TNF-α, IL-6, and STAT3. In contrast to conventional antipyretic drugs that mainly inhibit prostaglandin synthesis, Jwarhara Mahakashaya functions through a coordinated regulation of interconnected biological networks, reflecting the holistic nature of Ayurveda. However, computational predictions should be approached with caution, and thorough experimental validation is essential before integrating these formulations into clinical practice. Future research should combine

network pharmacology with advanced techniques like artificial intelligence and multi-omics to strengthen the evidence base for Ayurvedic formulations. Ultimately, network pharmacology acts as a crucial bridge between traditional Ayurvedic wisdom and modern medicine, facilitating the understanding and optimization of Jwarhara Mahakashaya's therapeutic potential in contemporary healthcare.

ACKNOWLEDGEMENTS

The authors acknowledge the contributions of classical Ayurvedic literature, publicly available phytochemical and bioinformatics databases, and the scientific community whose research has facilitated advances in network pharmacology and evidence-based herbal medicine.

Funding

No external funding was received for this review.

Conflict of Interest

The authors declare that there are no conflicts of interest regarding the publication of this manuscript.

Author Contributions

The author conceived the review, performed the literature survey, analysed the available evidence, interpreted the findings, drafted the manuscript, and approved the final version.

ABSTRACT

Job stress is a physical and emotional response that occurs when job requirements exceed worker resources. Stress affects employees differently based on the level of stress, where moderate levels provide a better performance motivation but extreme levels lead to a fatigue state causing anxiety, absenteeism, low efficiency and health complications. Thus job stress has become an important issue for many organizations to understand and manage. Marketing in China Marketing theory and practice, being positive: The banking sector is a core part of the economic development of any country by facilitating financial transactions, mobilizing savings and promoting investment. The banking sector comprises public sector banks, private sector banks, foreign banks and co-operative banks in India. Globalisation, digitalisation, technological advances along with rising customer expectations have changed the sector dramatically. This results in a heavy burden on the workforce and frustrating requirements for bank professionals.

Key words: Absenteeism, reduced efficiency, and health-related problems, customer expectations

INTRODUCTION

With liberalization, globalization, deregulation and advancements in technology, the banking sector has witnessed an unprecedented change. These changes have made it competitive then Banks because now banks need to alagkneuzn large from innovative and svakdpcu bn pc straight to customer cnv. Digital Banking, Internet banking,

Mobile Banking and Automated services are introduced improving operational efficiency and customer convenience. These advancements, however, have also put more pressure and responsibility on bank employees. With the present-day banking ecosystem, there seems to be an incessant need of employees achieving business numbers in addition to dealing with customers, regulatory compliance and never-ending tech adaptation. The demand for better service, higher workloads, long working hours and performance expectations has often subjected bank employees to highly stressful working conditions. Additionally, re-organizations, branch expansions, mergers and new technology implementation have made employees working environments additionally painful.

Even though technology has brought more advancement in banking functionality, most of the employees find it difficult to change with new work systems and digital strategies. Some of the key factors that lead to stressful job situations in the banking sector are Untrained staff /less trained, role ambiguity, role conflict, excessive workload brightness and work-life imbalance pressure to achieve target. Such stressors may have negative consequences on workers' physical health, psychological state, job satisfaction and work performance. As Williams and Alliger (1995) suggested, a major issue for employees and management alike is job stress — too much stress leads to absenteeism, reduced productivity, more employee turnover, weaker organizational effectiveness. So banks must identify the causes de stress among work therefore train for effective stress management to ensure that employees are better take care of and the organization will be able to forte. Due to the reason that stress among bank employessare increasing day by day the present research is an attempt to study on cause, impact and coping of job stress among bank employees of Chennai District. Results of the present study will assist banking institutions to formulate effective policies and practices with an aim of stress minimization along with improving on both employee performance as well as job satisfaction.

REVIEW OF LITERATURE

Examining the Effect of Job stress on Bank Employees in Northern Sri Lanka by Jayasinghe and Mendis (2020) A negative relationship between job stress and employee performance was realized as well. Stress reduced employee efficiency and productivity. Masood (2020) studied the impact of job stress on employee retention and organizational Performance: A case study of Banking sectorof Pakistan. The results showed that job stress has a negative impact on employee performance and retention. Workforce managed stress in order to stay productive. Roslan (2019) investigated work stress of Bank Rakyat employees. The study found that organizational factors had the most influence on work stress, while demographic variables did not. The mean score for overall stress levels was moderate. Alam and Dilruba (2019) studied job satisfaction and job stress of bank employees in Bangladesh. The research showed that the majority of employees were relatively happy with their jobs, and enjoyed low stress levels. There was no significant relationship between job stress and job satisfaction. Kishori and Vinothini (2019) studied the reason of Stress among Employees in Banking Sector. Workload and imbalance of work-life were among the highest disturbing factors identified in this study. It highlighted that organization support is critical for stress reduction and enhancing employee well-being. Shahid et al. (2018) assessed the issues related to problems of stress and its effect on bankers in terms of performance. Results: Work overload, risky working condition, and poor coworker relationship constituted main aspects of stressors based on study. These issues proved detrimental for the employees performance. In Lopes and Kachalia (2018) we studied the occupational stress on employees of public and private sector banks. The age, gender and education of the participant, as well as their role in the job and personal relationships had a great effect on their feeling stressed. Suggested that more effective coping strategies to directly increase employees' productivity.

Statement of the Problem

The banking industry has undergone widespread transformation in the wake of globalization as well as technological developments, rising rivalry and high levels of customer expectations. Bank jobs also require individuals to perform multiple roles, achieve business targets, ensure customer service quality and adapt to ever-changing technology. All of these factors contribute pressure and increase level of job stress among employees. Too much work pressure

adversely impacts the physical and mental well-being of workers, level of job satisfaction, performance level, and organizational effectiveness. Some of the important causes of stress in banking are due to work overload, role ambiguity, time pressure, demand from customers and work-life imbalance. Absenteeism, low morale, decreased efficiency and employee turnover may be the consequences of poorly handled job stress. The subsequent increase in job stress with its consequences must be evaluated, which is to find the reasons for job stress in particular bank employees and assess how some of them lead to performance depletion. The objective of this study is to analyze the Degree of Job Stress among Banking Employees in Chennai District and offers the measures that are needed to reduce stress and enhance Employee Effectiveness.

Need For the Study

The banking industry is one of the most active and demanding sectors in the current economy. Banking employees have to stay and achieve the performance goals, tackle customer needs, adapt to updated technology, handle high workloads. Such responsibilities frequently contribute to higher degrees of job stress. Job stress can ultimately affect organization by impacting the physical and mental health, job satisfaction, productivity of employees. As a result, it becomes required to recognize the elements that create strain and their effect on employees in banking profession. Hence there is a need to analyze the work stress of bank employees in Chennai District and their sources. The study results will assist in the management of stress and employee well-being, performance improvement and development of a healthier workplace by bank management.

Objectives of the Study

Primary Objective

- To study the level of job stress among bank employees in Chennai District.

Secondary Objectives

- To identify the major factors causing job stress among bank employees.
- To analyze the relationship between demographic factors and job stress among bank employees.
- To examine the impact of job stress on employee performance and job satisfaction.
- To assess the effect of workload, work environment, and work-life balance on job stress.
- To identify the stress management practices adopted by bank employees.
- To suggest suitable measures for reducing job stress and improving employee well-being in the banking sector.

Scope of the Study

- The paper emphasizes the survey to analyze the extent of job stress faced by bank employees in Chennai District.
- This is targeted at finding out different contributors to job stress, including workload, work environment, role conflict and time pressure and work-life balance.
- The study focuses on the relationship among demographic variables like as age, gender, education qualification, experience and job stress.
- It examines how job stress affects employees' performance, job satisfaction and general well-being.
- The research examines the stress management techniques used by bank employees to deal with stress at work.

Limitation of the Study

- The study only covers working professionals of various banks in Chennai District; therefore, it may not be that generalized to the bank employees working across other districts or even states.
- The research is reliant on the views and opinions of the respondents, which may be influenced by subjectivity and interpretation.
- As limited time in research and limited resources, a few bank employees are selected out of the whole population.
- This study is limited to work-related stress and did not include a full overview of risk factors for stress, such as workload, environment, and balance.

RESEARCH METHODOLOGY

Research methodology, however, means it is a systematic procedure which helps an individual to collect analyze and interpret data effectively in order to fulfill the objectives of the study. It lays the base of a science-backed systematic work and experiments to be run on it. The paper attempts to examine the customers perception on mobile banking services provide by bank employees in Chennai district.

Research Design

The study adopts a descriptive research design to understand and analyze customers' perceptions, satisfaction levels, awareness, and usage patterns regarding mobile banking services provided by bank employees in Chennai district

Primary Data

Primary data for the study were collected directly from bank employees in Chennai District through a structured questionnaire. The questionnaire was designed to gather information regarding the level of job stress, factors causing stress, impact of stress on job performance, and stress management practices adopted by the employees.

Secondary Data

Various types of secondary data were collected from different sources like books, journals, research articles, newspapers & magazines, published reports and dissertations available on the topic of consumer awareness for banks through online and offline resources especially from websites of banks, Reserve Bank (RBI) publications and annual reports of banks. These sources give employment stress, employee well being and banking institutions measurements.

Area of the Study

The study is conducted among the bank employees of Chennai district.

Population of the Study

For the present study, the population consists of 500 bank employees working in selected banks in Chennai District These employees form the target population from which the sample is drawn to analyze the level of job stress, factors causing stress, and its impact on employee performance and well-being.

Sample Size

A sample of **100 customers** is selected for the study.

Sampling Technique

The study uses **Convenience Sampling Technique**, where respondents are selected based on their availability and willingness to participate in the survey

Data Analysis and Interpretation

Interpretation

- Regarding the statement "I feel worthless and helpless" 13 respondents from public sector banks and 11 respondents from private sector banks agreed, while 22 and twenty respectively disagreed.
- About "I feel uneasy or anxious," 9 public sector banks and 13 private sector banks agreed, while 24 from both sectors disagreed.
- 15 and 17 respondents from public sector banks agree whereas 18 and 21 respondents disagree from private sector banks on "I feel bored in the organization"
- "I quit this job" costs us 7 public sector banks and 20 respondents in the private sector banks, even more determined to quit the bank is working in the private sector.

- I am frustrated: 11 responses agreed (7 were from public sector banks and eleven were from private sector banks. Hence showing the frustration is comparatively more among the private sectors also).
- The Likert Scale Frequency table used for statistical analysis is as below:- Likert Scale

Hypothesis

H_0: There is no significant difference in the psychological stress levels of employees in public and private sector banks.

H_1: There is a significant difference in the psychological stress levels of employees in public and private sector banks.

Result

Since the calculated **p-value (0.020) is less than 0.05**, the Null Hypothesis (H_0) is rejected and the Alternate Hypothesis (H_1) is accepted.

Interpretation The analysis reveals a significant difference in psychological stress levels between public and private sector bank employees. Private sector bank employees reported a higher level of psychological stress than public sector bank employees. Therefore, psychological stress factors have a greater impact on employees working in private sector banks.

H_0: There is no significant difference in task-related stress between public and private sector bank employees.

H_1: There is a significant difference in task-related stress between public and private sector bank employees

Interpretation

The analysis reveals a significant difference in task-related stress between employees of public and private sector banks. Factors such as workload, unrealistic goals, lack of encouragement from superiors, and insufficient time to complete work contribute to stress among employees. Therefore, task-related factors significantly influence the stress levels of bank employees.

Findings

The study reveals that there exists variance among the job stress faced by employees working in public and private sector banks of Chennai District. While both groups of employees experienced job stress, the private sector bank employees had a significantly greater level of stress related to workload, performance targets and work pressure. The stress is also in public sector but to a comparatively lesser extent. The results show that the Employees Stress Factors based on Workload, Working Environment, Role Expectations and Work-Life Balance. Based on the analysis, main hypothesis H_1: "There is a significant difference between the level of stress experienced by the employees of public and private sector banks" is accepted. Banks, therefore, need to adopt efficient stress management that can help improve job satisfaction and organizational performance among employees.

Suggestions

- Employees with high educational level know how to control their stressors effectively. Thus, enterprises ought to foster up skilling and professional growth amongst its staff.
- Employees must attend periodic training to know how to identify these stress-inducing factors, build coping skills and overcome technology-related stress at the workplace.
- All employees should be convinced of the importance of teamwork, cooperation and group cohesiveness. This will help in ensuring stability on the work front, improve workplace productivity and facilitate healthy & peaceful relationship between the superior and subordinate.
- The organization must create a supportive environment that has open communication, mutual respect amongst employees, promote employee well-being which depicts the level of workplace stress and also improves overall job satisfaction.

- Stress management workshops, counseling sessions (both face to face and online), employee assistance programs which help employees with maintaining a healthy work-life balance and improving the overall state of performance.

CONCLUSION

Occupational stress has become an important factor that leads to poor performance, decreased productivity and overall well-being of employees. Study reveals, that higher the Educational Qualification of Employees well it is to cope with workplace stress and Anxiety in general. It also emphasizes the need to provide sufficient training and development programs that will help employees manage stress, especially from technology and other changes related to work settings. Also, developing teamwork, cooperation, and healthy working relationships between both employees and management can lead to a healthier organization climate as well as lower stress. By implementing stress management initiatives, providing supportive leadership and ensuring effective communication, organizations can improve job satisfaction, performance and achieve their organizational goals more efficiently. Thus, implementing an extensive stress management plan is necessary for both a productive and harmonious work environment.

ABSTRACT

The escalating presence of pharmaceutical compounds, environmental contaminants, and clinical biomarkers in complex matrices has intensified the demand for highly sensitive, cost-effective, and portable detection platforms. Carbon dots (CDs) — encompassing carbon quantum dots (CQDs), graphene quantum dots (GQDs), carbon nanodots (CNDs), and carbonized polymer dots (CPDs) — have emerged as uniquely versatile nanomaterials that bridge the requirements of modern analytical science. Their tunable photoluminescence, robust electrochemical activity, facile surface functionalization, and exceptional biocompatibility position them as compelling candidates for next-generation biosensor development. This review comprehensively examines the structural diversity, physicochemical properties, and synthesis strategies of CDs, with particular emphasis on how these attributes translate into practical sensing performance. We systematically evaluate electrochemical and optical sensing modalities — including fluorescence turn-on/turn-off, ratiometric detection, Förster resonance energy transfer (FRET), and surface-enhanced Raman scattering (SERS) — alongside their integration into microfluidic chips, paper-based analytical devices, wearable platforms, and smartphone-assisted point-of-care (POC) systems. The review further discusses emerging directions such as AI-assisted signal interpretation, green synthesis pathways, and multiplexed detection arrays. Outstanding challenges in reproducibility, standardization, long-term stability, and regulatory translation are critically assessed,

and a forward-looking perspective on the clinical and industrial deployment of CD-based nanobiosensors is presented.

Keywords: carbon dots; nanobiosensors; electrochemical sensing; fluorescence sensing; point-of-care diagnostics; pharmaceutical analysis; FRET; SERS; AI-assisted detection

INTRODUCTION

Modern societies face a compounding analytical challenge: the simultaneous need to monitor trace-level pharmaceutical compounds in complex environmental matrices while enabling rapid, decentralized diagnostic testing at the point of care. Pharmaceuticals and personal care products (PPCPs) enter aquatic and terrestrial ecosystems through inadequately treated wastewater, agricultural runoff, and industrial discharge, posing significant ecotoxicological risks even at nanogram-per-liter concentrations [1,2]. Simultaneously, clinical diagnostics demand the sensitive quantification of drugs, metabolites, and biomarkers in biologically complex fluids such as serum, urine, and saliva — matrices that challenge conventional analytical methods in terms of selectivity, throughput, and instrument accessibility [3,4].

Conventional techniques — high-performance liquid chromatography (HPLC), gas chromatography–mass spectrometry (GC-MS), and enzyme-linked immunosorbent assays (ELISAs) — remain gold-standard methods for pharmaceutical analysis. However, their reliance on centralized laboratory infrastructure, trained personnel, and expensive instrumentation limits their applicability in resource-constrained settings or for real-time field monitoring [5,6]. Chemo- and biosensor technologies represent a promising alternative, offering miniaturization, rapid response, and the capacity for decentralized deployment. However, early-generation biosensors have struggled with insufficient detection limits in complex matrices, poor long-term stability, and limited on-site applicability [3].

The integration of nanotechnology into biosensor design has dramatically advanced the field. Nanomaterials confer exceptional properties — increased surface-to-volume ratios, quantum effects, and tunable surface chemistry — that translate into amplified signal responses and enhanced analyte interactions [7,8]. Among the diverse landscape of nanomaterials explored for biosensing, carbon-based nanomaterials occupy a privileged position owing to their chemical versatility, low toxicity, and compatibility with a broad range of biological and electrochemical systems [9]. Carbon dots, first reported incidentally during the purification of single-walled carbon nanotubes by Xu et al. in 2004 and subsequently named and systematically studied by Sun et al. in 2006, have rapidly evolved from a laboratory curiosity into a highly active research domain [10,11]. Their unique combination of strong, tunable fluorescence, appreciable electrochemical activity, surface-modifiable functional groups, and minimal cytotoxicity makes them particularly attractive for analytical and biomedical sensing [12,13]. The exponential growth of CD-related biosensor publications — exceeding 15,000 indexed articles as of 2025 — reflects the scientific community's recognition of their transformative potential [14].

This review provides a critical and comprehensive overview of CD-based sensing platforms for pharmaceutical analysis and POC diagnostics. We examine the structural classification and physicochemical properties of CDs, discuss synthesis strategies and scalability considerations, and systematically analyze their application in electrochemical and optical biosensing modalities. We further address their integration into miniaturized and wearable devices, AI-assisted analytical frameworks, and clinical testing scenarios, while critically evaluating remaining challenges and charting prospective research directions.

Structural Classification And Physicochemical Properties Of Carbon Dots

Taxonomy of Carbon Dot Subtypes

Carbon dots represent a family of zero-dimensional carbon-based nanomaterials whose optical and electronic characteristics are governed by particle size, core crystallinity, and surface chemical composition. Four principal subtypes are recognized in the contemporary literature (Figure 1):

Carbon Quantum Dots (CQDs) are crystalline nanospheres with a graphitic sp^2 carbon core, exhibiting intrinsic photoluminescence attributed to quantum confinement effects (QCE). Their size-dependent optical properties and rich surface functional groups enable highly tunable emission profiles [15].

Graphene Quantum Dots (GQDs) are laterally constrained graphene fragments, typically one to several layers thick, whose optical behavior arises from a combination of quantum confinement and edge effects. The presence of diverse chemical functionalities at their edges and interlayer defects distinguishes their photophysics from CQDs [15].

Carbon Nanodots (CNDs) exhibit a high degree of carbonization without a definitive crystalline or polymeric core structure. Unlike CQDs, CNDs do not display a quantum confinement effect, and their luminescence is primarily attributed to surface states and edge defects [15].

Carbonized Polymer Dots (CPDs) are hybrid nanostructures comprising a carbonized core surrounded by polymer chains or surface functional groups. These materials bridge the properties of polymeric fluorophores and traditional carbon nanomaterials, offering unique tunability in both optical and mechanical characteristics [15].

Photoluminescence Mechanisms and Fluorescence Properties

The photoluminescence of CDs is a multifactorial phenomenon that remains an area of active mechanistic investigation. Three principal emission origins are generally acknowledged: quantum confinement effects arising from the nanometric core, surface-state emission modulated by functional groups and defect sites, and molecular fluorophore-like states associated with specific chromophoric moieties on the particle surface [16].

The fluorescence of CDs can be selectively enhanced or quenched through several well-defined optical mechanisms, which form the operational basis of fluorescence-based sensing platforms:

Photoinduced Electron Transfer (PET): Analyte binding modulates electron donation or withdrawal from a linked fluorophore, altering quantum yield.

Förster Resonance Energy Transfer (FRET): Non-radiative dipole–dipole coupling transfers excitation energy from a donor CD to an acceptor molecule in close proximity (<10 nm), producing measurable changes in donor and acceptor emission intensities [17].

Inner Filter Effect (IFE): Analytes that absorb at the excitation or emission wavelength of CDs attenuate the observed fluorescence without direct electronic interaction.

Static and Dynamic Quenching (SQ/DQ): Ground-state complex formation (static) or diffusion-limited collisional deactivation (dynamic) reduce fluorescence intensity in concentration-dependent manners.

Aggregation-Caused Quenching (ACQ) and Aggregation-Induced Emission (AIE): Intermolecular interactions at high concentrations can either suppress or, in engineered systems, enhance fluorescence [16,18].

Heteroatom doping — particularly with nitrogen, sulfur, phosphorus, and boron — constitutes one of the most effective strategies for enhancing CD fluorescence quantum yield and introducing additional electronic states that improve sensing sensitivity [16].

Electrochemical and Electron Transfer Properties

The sp^2 carbon framework of CDs confers remarkable electrical conductivity, facilitating rapid charge transfer kinetics that are essential for electrochemical biosensing [18,19]. The extended π-conjugation within the graphitic core reduces charge transfer resistance and lowers oxidation overpotentials for electroactive analytes such as paracetamol, diclofenac, and various antibiotic compounds [20]. When incorporated into electrode architectures, CDs substantially amplify redox current responses, enabling the detection of pharmaceutical molecules at nanomolar-to-picomolar concentration levels. Conjugation with aptamers, antibodies, enzymes, and conducting polymers further enhances both electron transfer kinetics and molecular recognition specificity [20,21].

Surface Chemistry, Biocompatibility, and Stability

The surface of CDs is typically decorated with carboxyl (–COOH), hydroxyl (–OH), amine ($–NH_2$), and thiol (–SH) functional groups, which collectively impart hydrophilicity, water dispersibility, and chemical reactivity [22]. These groups serve as molecular anchors for the covalent or non-covalent conjugation of biorecognition elements — enzymes, antibodies, aptamers, and nucleic acids — enabling the construction of highly selective biosensing interfaces [22,23].

Cytotoxicity studies using diverse cell line types have consistently demonstrated that CDs exhibit minimal adverse effects at concentrations typical for cell labeling applications (approximately 10–100 $\mu g\ mL^{-1}$), confirming their suitability for biological and clinical sensing contexts [24]. Their stability characteristics — encompassing photostability under prolonged light exposure, thermal stability at elevated temperatures, and ionic stability in physiologically relevant salt concentrations and pH ranges — are critical determinants of practical sensor performance and must be systematically evaluated for each specific application [24,25].

Synthesis Strategies and Scalability Considerations

Top-Down and Bottom-Up Methodologies

CD synthesis is broadly categorized into top-down and bottom-up approaches, each offering distinct advantages and limitations [26]. Top-down methods — including arc discharge, laser ablation, acidic oxidation, and electrochemical etching — fragment larger carbon precursors (graphite, carbon nanotubes, graphene) into nanoscale dimensions. Bottom-up methods — encompassing hydrothermal/solvothermal synthesis, microwave pyrolysis, combustion, and solid-state carbonization — assemble small organic molecules or oligomers into CD nanostructures through controlled thermal and chemical processing [26,27].

Hydrothermal and solvothermal methods are among the most widely employed approaches owing to their operational simplicity, versatility in precursor selection, and ability to produce CDs with well-controlled surface chemistry. However, these methods require expensive high-pressure equipment and prolonged reaction times, limiting their scalability for continuous industrial production [28]. Microwave-assisted synthesis offers significantly reduced reaction times and improved energy efficiency while maintaining comparable optical performance, making it an attractive candidate for scale-up applications [29].

Green Synthesis and Biomass-Derived CDs

An emerging and environmentally compelling direction involves the use of biomass-derived carbon precursors — including plant extracts, agricultural waste, food processing by-products, and biopolymers — for the sustainable synthesis of fluorescent CDs [29,30]. These green synthetic routes reduce dependence on hazardous chemical reagents, lower production costs, and introduce unique surface functionalities derived from the biomolecular composition of the starting material. Rice husk, citric acid, folic acid, and various carbohydrate sources have been demonstrated as effective precursors for producing CDs with strong fluorescence and good sensing performance [30].

Reproducibility and Standardization Challenges

A significant and persistent impediment to the broader adoption of CD-based sensing platforms is the lack of reproducible, standardized synthesis protocols. Batch-to-batch variations in particle size, surface chemistry, quantum yield, and photoluminescence behavior arise from minor fluctuations in precursor composition, reaction temperature, and post-processing procedures [28,31]. Jing et al. noted that the absence of reference standards and unified synthetic protocols substantially hinders the scalability and cross-laboratory comparability of CD-based systems [31]. Cayuela et al. similarly emphasized that inconsistent reporting of physicochemical parameters — including particle size distribution, quantum yield, and long-term stability — creates a significant barrier to reproducible performance benchmarking [32]. Addressing these issues will require the adoption of certified reference materials, standardized characterization protocols, and rigorous interlaboratory validation exercises.

Biorecognition Element Immobilization Strategies

The attachment of biological recognition molecules — enzymes, antibodies, aptamers, and nucleic acids — to CD surfaces is a pivotal step in biosensor fabrication, as it directly governs sensor selectivity, operational stability, and response time [33].

Non-covalent immobilization exploits electrostatic interactions, hydrogen bonding, and π–π stacking between biomolecules and CD surface groups. While operationally simple, non-covalent approaches may suffer from limited long-term stability due to potential desorption of the recognition element under varying ionic strength or pH conditions.

Covalent conjugation, most commonly achieved through carbodiimide chemistry (EDC/NHS coupling) between surface carboxyl groups and amine-bearing biomolecules, provides robust attachment with improved reproducibility and resistance to environmental perturbations. This approach is particularly favored in electrochemical and fluorescence biosensors incorporating CD–metal or CD–polymer hybrid architectures [33,34].

Affinity-based immobilization, including biotin–streptavidin coupling, His-tag/metal coordination, and complementary DNA hybridization, enables controlled orientation of antibodies and aptamers, thereby maximizing binding-site accessibility and preserving biological activity [34,35]. The selection of immobilization strategy must balance the requirements for binding affinity, surface coverage, orientation control, and operational longevity specific to the intended sensing application.

Electrochemical Cd-Based Biosensors For Pharmaceutical Analysis

Principles and Advantages of Electrochemical Sensing

Electrochemical detection has established itself as a leading transduction strategy for CD-based biosensors owing to its inherent advantages: high sensitivity, rapid response, low instrumentation cost, and straightforward miniaturization into portable and wearable formats [36]. In CD-modified electrochemical systems, biochemical recognition events at the electrode surface are transduced into measurable electrical signals — current, potential, or impedance — that report analyte identity and concentration. Compared to optical detection schemes, electrochemical sensors offer reduced susceptibility to optical interferences from colored or turbid matrices and more straightforward integration with wireless telemetry systems for real-time data transmission [36,37].

Conventional electrode materials — bare gold and carbon — provide adequate conductivity but exhibit insufficient sensitivity for detecting trace-level pharmaceutical compounds. The incorporation of CDs and CD-based nanocomposites onto electrode surfaces introduces conductive nanostructures with high surface area, abundant redox-active sites, and customizable surface chemistry [37]. The sp^2-hybridized carbon framework of CDs accelerates electron transfer kinetics, substantially lowering detection limits compared to unmodified electrode systems [38].

Hybrid Nanocomposite Electrode Architectures

Metal–CD Nanocomposites

The integration of CDs with catalytically active metal nanoparticles creates synergistic electrochemical interfaces that outperform single-component systems in sensitivity, selectivity, and operational stability [39].

Gold–CD composites were among the earliest explored metal–CD hybrid systems, combining the excellent conductivity and biocompatibility of gold nanoparticles with the electron-transfer and surface functionalization properties of CDs. These systems have demonstrated sensitive detection of ciprofloxacin, paracetamol, and dopamine with exceptional analytical performance [39,40].

Silver–CD hybrids gained prominence after approximately 2020, leveraging the strong redox behavior and signal amplification characteristics of silver nanoparticles for the rapid electrochemical detection of sulfonamide and tetracycline antibiotics [34].

Platinum–CD nanomaterials, developed primarily after 2021, offer exceptional electrocatalytic efficiency particularly suited to the detection of anticancer therapeutics including doxorubicin, cisplatin, and paclitaxel [41].

Copper–CD nanocomposites represent cost-effective alternatives to noble metal-based systems. CDs stabilize copper nanoparticles against oxidative degradation while enhancing overall conductivity, enabling reliable detection of amoxicillin, ciprofloxacin, and metronidazole in pharmaceutical and environmental samples [34,35].

Polymer–CD Hybrid Systems

Conductive polymer–CD composites combine the film-forming ability, mechanical flexibility, and chemical stability of conducting polymers with the surface reactivity and electron transfer facilitation of CDs [42].

Polyaniline–CD (PANI–CD) composites were among the earliest polymer–CD hybrids applied to pharmaceutical sensing. Incorporation of nitrogen-doped CQDs into the PANI matrix reduces charge transfer resistance and stabilizes the conducting film, enabling sensitive detection of amoxicillin in drinking water and environmental samples [43].

Polypyrrole–CD (PPy–CD) composites offer strong redox activity and adhesion to diverse electrode substrates. CDs incorporated into the polypyrrole matrix increase film porosity and conductivity, accelerating electron transfer for the detection of tetracycline, ciprofloxacin, and sulfamethoxazole [44,45].

PEDOT–CD (Poly(3,4-ethylenedioxythiophene)–CD) nanocomposites have attracted particular interest for flexible and wearable sensing applications since approximately 2022. PEDOT's high conductivity and mechanical durability, combined with CD-enhanced interfacial charge transport, have enabled real-time monitoring of paracetamol, caffeine, and antibiotics in sweat, saliva, and other biological fluids [46].

Electrochemical Sensing Modalities

Amperometric sensing measures steady-state current at a fixed applied potential during analyte oxidation or reduction. CD-modified electrodes typically demonstrate significantly faster electron transfer kinetics than unmodified surfaces, yielding higher sensitivity and lower detection limits. This approach has been extensively applied to paracetamol detection, where CD composites enable nanomolar-to-micromolar quantification with minimal sample pretreatment [47].

Voltammetric techniques — particularly differential pulse voltammetry (DPV) and cyclic voltammetry (CV) — provide superior sensitivity and enhanced peak resolution compared to simple amperometric methods. DPV, with its background current rejection capability, is especially powerful for multiplexed detection of co-existing drugs such as ibuprofen, diclofenac, and ciprofloxacin in multi-component pharmaceutical formulations [48].

Electrochemical impedance spectroscopy (EIS) monitors changes in charge transfer resistance at the electrode–solution interface following analyte binding, making it particularly suited to antibody- and aptamer-based sensors where binding events alter the interfacial electrical properties [36].

Biorecognition-Assisted Electrochemical Sensing Platforms

Enzyme-Based Systems

Enzyme–CD hybrids leverage enzymatic catalysis for selective pharmaceutical sensing. CDs facilitate direct electron transfer between enzyme active sites and electrode surfaces while simultaneously stabilizing enzyme conformation and activity. Canevari et al. demonstrated this principle in a laccase-based biosensor for 17α-ethynylestradiol detection, where CDs significantly improved electron transfer at the copper ion active sites, achieving a detection limit of 4.0 nmol [49]. Baj-Rossi et al. employed a cytochrome P450-modified electrode on multi-walled carbon nanotubes for continuous naproxen monitoring, demonstrating the capacity for real-time drug metabolism tracking [50].

Aptamer-Based Sensors-Aptasensors exploit the high-affinity, structure-specific binding of synthetic nucleic acid aptamers toward pharmaceutical targets. CDs serve as conductive scaffolds and signal amplifiers, while aptamer–target binding induces conformational rearrangements or probe displacement events that generate measurable electrochemical responses [51,52]. Li et al. developed an elegant self-assembly aptasensor for kanamycin detection using CD-decorated MXene nanosheets. CDs intercalated between MXene layers prevented restacking, maintained high conductivity, and provided abundant active sites for dsDNA probe immobilization. Kanamycin binding triggered aptamer release from the hybridized probe, generating a "signal-off" electrochemical response with excellent sensitivity [53]. Mat Zaid et al. constructed an impedimetric aptasensor for 17β-estradiol detection at picomolar concentrations (0.5×10^{-12} M) by electrodepositing conductive CDs onto screen-printed electrodes and monitoring changes in charge transfer resistance upon estradiol–aptamer binding [54].

Molecularly Imprinted Polymer (MIP)–CD Platforms-MIP–CD nanocomposites combine the molecular recognition capability of polymer-imprinted cavities with the conductivity and surface activity of CDs, achieving selectivity that rivals biological recognition elements without the associated stability limitations. Ensafi et al. synthesized CD-MIP nanocomposites for metronidazole detection via sol–gel transitions, while Li et al. employed hollow MIPs on CDs for highly selective tetracycline recognition [55,56].

Selected Pharmaceutical Targets and Analytical Performance

Table 1 presents a curated summary of representative CD-based electrochemical sensing platforms for pharmaceutical analyte detection, illustrating the breadth of targets and the analytical performance achievable with these systems.

Optical Cd-Based Nanobiosensors

Fluorescence-Based Detection Platforms

Fluorescence sensing represents the most extensively investigated optical detection modality for CD-based nanobiosensors, benefiting from the inherent strong, tunable photoluminescence of CDs alongside their excellent photostability and biocompatibility [62]. Fluorescence-based CD sensors are particularly advantageous for pharmaceutical analysis owing to their high sensitivity, simple instrumentation requirements, and capacity for real-time, continuous monitoring.

Turn-Off and Turn-On Fluorescence Mechanisms

In **turn-off** (fluorescence quenching) sensors, the introduction of a target analyte reduces CD emission intensity through mechanisms including electron transfer, IFE, or static/dynamic quenching. This approach is widely applied to antibiotic detection, where compounds such as tetracycline, chloramphenicol, and ofloxacin quench CD fluorescence through selective photophysical interactions [62,63].

Turn-on sensors operate through the opposite principle: analyte interaction restores or enhances fluorescence that was initially suppressed by a quenching entity. The "off–on" strategy, wherein a quencher is displaced or deactivated upon target binding, provides high signal contrast and reduced background noise, making it particularly attractive for biomarker detection in complex matrices [62,64].

"Off–on–off" multi-step sensing strategies, combining sequential quenching and recovery events, enable sophisticated analyte discrimination and detection in samples containing multiple potential interferents.

Ratiometric Fluorescence Detection

Ratiometric sensing measures changes in the intensity ratio between two spectrally distinct emission bands, providing self-referencing capability that reduces errors arising from instrument drift, photobleaching, and matrix-induced fluorescence background [65]. This approach is particularly valuable for quantitative pharmaceutical analysis where measurement accuracy is paramount.

Zhai et al. demonstrated an elegant ratiometric platform using a nanohybrid of fluorescent CDs and gold nanoclusters (AuNCs) for 6-mercaptopurine (6-MP) detection [65]. In this system, 6-MP selectively binds to AuNCs through thiol–gold interactions, quenching AuNC red fluorescence while leaving CD blue emission unaffected as a stable internal reference. The resulting ratio signal provided reliable 6-MP quantification in complex sample matrices.

FRET-Based Sensing Strategies

FRET exploits proximity-dependent, non-radiative energy transfer from an excited donor fluorophore to an acceptor molecule within distances typically below 10 nm, where the donor emission spectrum overlaps with the acceptor absorption spectrum [17,66]. CDs frequently serve as FRET donors owing to their tunable emission and modifiable surface chemistry.

Distance-Based FRET Sensors-*Conformational change-based FRET sensors exploit the exquisite distance dependence of Förster energy transfer (efficiency* $\propto 1/r^6$*) to transduce molecular binding events into fluorescence signals. Structural rearrangements in aptamers or binding proteins upon analyte interaction alter the donor–acceptor separation, producing measurable changes in FRET efficiency. These sensors have been successfully applied to the detection of ions, metabolites, and pharmaceutical compounds with exceptional sensitivity and live-cell imaging compatibility [66,67].*

Binding-Induced and Enzyme Cleavage FRET Sensors - Binding-induced FRET sensors utilize separate donor- and acceptor-labeled molecules that undergo FRET only when a specific molecular interaction brings the fluorophores into proximity. This strategy is particularly suited to immunosensor formats and nucleic acid detection [68]. Enzyme cleavage-based FRET sensors detect enzymatic activity by monitoring the separation of donor–acceptor pairs upon substrate cleavage. The signal intensity is proportional to enzyme activity, enabling the quantification of proteases, nucleases, and kinases relevant to pharmaceutical metabolism and clinical diagnostics [68,69]. An illustrative example involves a dual-CD ratiometric fluorescence probe for the detection of protein tyrosine kinase 7 (PTK7), in which yellow-emitting CD–aptamer conjugates (y-CDs-APT) and blue-emitting CDs (b-CDs) provide complementary, analytically independent signals. The probe incorporates a DNase I signal amplification loop that regenerates free PTK7 for iterative sensing cycles, dramatically enhancing detection sensitivity [70].

SERS and CD-Assisted Raman Platforms

Surface-enhanced Raman scattering (SERS) achieves extraordinary sensitivity — enhancement factors of 10^6–10^{14} — through electromagnetic field amplification at plasmonic hotspots created by metal nanostructures, typically gold, silver, or copper [71]. The combination of CDs with plasmonic metal nanoparticles creates hybrid SERS substrates that benefit from both chemical enhancement (contributed by CDs through charge transfer interactions) and electromagnetic enhancement (from plasmonic hotspots). Yang et al. reported Ag-CD-phenylboronic acid (Ag-CDs-PBA) nanocomposites for the SERS detection of malachite green with high signal uniformity and sensitivity attributed to the abundant binding surface sites provided by CDs [72]. The CD-assisted Raman platform offers a cost-

effective and biocompatible approach for enhancing Raman signals, particularly for low-concentration pharmaceutical impurities and quality control applications (Table 2).

Colorimetric and Visual Detection

Colorimetric CD sensors exploit the visible color changes arising from analyte-induced aggregation, surface functionalization disruption, or specific binding interactions. Quantum dot-based colorimetric systems are particularly appealing for POC applications owing to their operability without complex instrumentation — color changes observable with the naked eye or under portable UV illumination provide qualitative or semi-quantitative analyte information [73]. Catia Correia et al. synthesized Eu(III)-doped CDs from citric acid and urea, demonstrating substantially enhanced quenching sensitivity toward heavy metal ions compared to undoped CDs, with Hg^{2+} producing a quenching factor of 25 — significantly greater than that observed for other common metal ions [74]. This selectivity enhancement illustrates the power of dopant engineering for tailoring CD optical responses toward specific analytes.

Miniaturized, Wearable, And Point-Of-Care Platforms

Microfluidic and Lab-on-Chip Integration

Microfluidic systems — sometimes termed Micro Total Analysis Systems (μTAS) — enable precise manipulation of fluid volumes in the range of 10^{-6}–10^{-15} mL, dramatically reducing reagent consumption, analysis time, and sample volume requirements [75,76]. The integration of CD-based sensing elements into microfluidic architectures enables automated, multiplexed pharmaceutical analysis with high throughput and minimal operator intervention.

Hu et al. developed a microfluidic paper analytical device (μPAD) incorporating in situ-patterned fluorescent and non-fluorescent CDs alongside gold nanoparticles for dual-mode iron health monitoring in whole blood [77]. The device combined Fe^{3+}-induced CD fluorescence quenching for serum iron quantification with colorimetric ELISA for ferritin detection, demonstrating the feasibility of integrated, multi-analyte POC testing from a single whole-blood sample. Wang et al. further reported Eu-doped CD–MOF-based sensors integrated into paper microfluidic devices for anthrax spore biomarker detection [78].

Paper-Based Analytical Devices

Paper-based sensors offer an exceptionally low-cost, disposable, and field-deployable platform for integrating CD sensing chemistry. Li et al. developed a fluorescent paper-based sensor (FPS) on a polydimethylsiloxane/paper hybrid platform for folic acid detection in urine and juice samples, achieving a detection limit of 0.28 μmol L^{-1} through IFE-mediated quenching [79]. Rossini et al. employed CD-based paper microfluidic devices for the simultaneous detection of glucose and lactate in saliva, using oxidase enzymes to generate hydrogen peroxide, which in turn quenches CD fluorescence in a concentration-dependent manner [80]. The inherent advantages of paper-based CD sensors — minimal material cost, easy functionalization, disposability, and compatibility with both visual and instrument-based readout — make them particularly well-suited for point-of-care diagnostics in low-resource clinical environments.

Wearable Sensing Platforms

Wearable CD-based sensors integrate thin-film CD composites — typically CD/conducting polymer or CD/graphene hybrids — onto flexible electronic substrates for continuous, non-invasive physiological and pharmacological monitoring [81]. These platforms are capable of measuring drugs and metabolites in sweat and saliva, enabling continuous therapeutic drug monitoring without venipuncture. A notable example is a flexible carbon nitride quantum dot/PANI nanocomposite sensor for continuous sweat glucose monitoring, wherein the pyridinic nitrogen functionalities within the CDs improve charge mobility at physiological pH, preventing the film cracking that commonly afflicts rigid electrocatalytic layers during mechanical deformation [82,83]. The integration of wearable CD sensors with AI-powered cloud analytics platforms represents a compelling direction toward personalized dosing recommendations based on real-time pharmacokinetic profiling [81].

Smartphone-Assisted Detection Systems

Smartphones represent a uniquely accessible platform for integrating CD-based optical sensors into portable, low-cost analytical instruments accessible to both clinical professionals and untrained end-users. The RGB (red–green–blue) color analysis capabilities of smartphone cameras, combined with custom-developed software applications, enable quantitative fluorescence measurements without dedicated laboratory equipment [84,85]. Li et al. fabricated a ratiometric fluorescence sensor combining blue- and yellow-emitting CDs for visual POC detection of Cu^{2+} in water and food samples, integrating the optical detector with a smartphone readout system [85]. Öztürk et al. reported hybrid CD sensors functionalized with carbazole and anthracene for the fluorometric detection of herbicides (benfluralin, aclonifen, pendimethalin) in food samples, using paper-based test kits with RGB analysis via smartphone, achieving LODs in the 6.00–9.40 nM range [86]. Su et al. developed a CD/CoOOH nanocomposite-based smartphone system for real-time detection of 2,4-dichlorophenoxyacetic acid (2,4-D) with a custom-designed mobile application for quantitative signal analysis [87].

AI-Assisted Signal Processing and Analytical Validation

The integration of artificial intelligence — encompassing machine learning, data mining, and deep learning methodologies — with CD-based analytical platforms represents a transformative direction for pharmaceutical quality control and environmental monitoring [88,89]. AI-driven data processing enables the automated identification, classification, and quantification of complex chemical compounds from multidimensional sensor datasets, substantially reducing analysis time while enhancing accuracy. In the context of pharmaceutical analysis, AI models have demonstrated significant utility in method validation, quality control optimization, and the prediction of chromatographic retention parameters and collision cross-sections for non-target screening using high-resolution mass spectrometry [88,90]. For CD-based sensor arrays, machine learning algorithms enable the deconvolution of overlapping fluorescence signals in multi-analyte mixtures, providing real-time pharmacokinetic profiles that would be inaccessible to conventional single-channel measurements [91]. AI-assisted multiplexed CD microelectrode arrays — each functionalized with a distinct aptamer or MIP — create sensor systems capable of simultaneously tracking parent drugs and metabolites, a capability directly relevant to therapeutic drug monitoring in clinical settings [91]. Emerging applications in wastewater-based epidemiology and community health surveillance further highlight the potential of AI-coupled CD sensing for population-level pharmaceutical monitoring. Key remaining challenges for AI integration include the limited generalizability of models trained on laboratory buffer samples to real-world complex matrices, the absence of standardized validation frameworks for AI-based analytical methods, and regulatory constraints on algorithmic decision-making in clinical diagnostics [88,89].

Selectivity, Matrix Effects, and Interference Management

The analytical performance of CD-based sensors in real-world samples is frequently compromised by matrix-induced interferences that reduce selectivity and generate false-positive or false-negative results [92]. Complex biological matrices — blood serum, urine, sweat — and environmental samples contain high concentrations of proteins, salts, metal ions, and organic molecules that can non-specifically adsorb to CD surfaces, quench fluorescence through IFE or inner filter effects, or alter electrochemical responses through competitive redox reactions [92,93].

Effective interference mitigation strategies include:

Surface passivation through PEGylation or zwitterionic coatings, which reduces non-specific biomolecular adsorption and biofouling.

Biorecognition-triggered selectivity using enzymes, antibodies, or aptamers to provide molecular specificity that overrides non-selective matrix effects.

Ratiometric sensing using dual-emission systems that self-correct for matrix-induced fluorescence background changes [93,94].

Molecular imprinting to create analyte-specific cavities that discriminate against structurally similar interferents.

On-chip sample pretreatment — including filtration, dilution, and magnetic separation — to reduce matrix complexity prior to sensing [92].

Despite these advances, achieving reproducible selectivity across diverse clinical and environmental sample types remains an unresolved challenge. Performance validated in buffered laboratory conditions frequently overestimates real-world analytical reliability, underscoring the necessity for systematic interference studies and validation with certified reference materials [92].

Current Limitations

Despite their considerable promise, CD-based nanobiosensors face a set of significant limitations that currently impede their translation from laboratory proof-of-concept demonstrations to validated clinical and industrial tools:

Structural heterogeneity: CDs synthesized by common methods typically exhibit broad size distributions and lack precise control over crystallinity, shape, and surface defect density, resulting in batch-to-batch variability in optical and electronic properties [95,96].

Quantum yield limitations: Many CDs produced by hydrothermal or pyrolysis routes exhibit moderate-to-low fluorescence quantum yields and poorly understood photoluminescence mechanisms that complicate rational sensor design [95].

Stability concerns: Sensitive surface functional groups (–COOH, –OH, $–NH_2$) render CDs susceptible to gradual degradation under harsh chemical conditions, elevated temperatures, or prolonged light exposure [95].

Aggregation at high concentrations: Concentration-dependent aggregation reduces effective surface area and alters optical properties, potentially compromising quantitative accuracy at high analyte levels [96].

Scalability and purity: Producing high-purity, monodisperse CDs at industrial scale remains technically challenging and economically costly [96].

Regulatory pathway: Clinical deployment of CD-based sensors requires rigorous demonstration of biocompatibility, manufacturing consistency, and analytical performance that meets regulatory standards set by bodies such as the FDA [97].

Future Perspectives

The trajectory of CD-based biosensor research points toward several high-impact directions that promise to substantially advance practical sensing capabilities:

Multiplexed detection arrays combining CD-modified microelectrodes functionalized with distinct recognition elements (aptamers, MIPs) will enable simultaneous pharmacokinetic profiling of multiple drugs and metabolites — a capability with direct clinical utility in therapeutic drug monitoring [91].

Emerging material combinations, including CD/MXene hybrids for ultrafast electron transfer, CD/metal–organic framework (MOF) composites for molecular sieving and analyte preconcentration, and CD/biomimetic polymer systems for anti-fouling interfaces, represent particularly promising avenues for next-generation sensor development [98,99].

High-throughput drug screening (HTS) using CQD fluorescence sensors in microplate reader formats offers a rapid, sensitive, and cost-effective approach for evaluating large compound libraries in early-stage pharmaceutical discovery [100].

Green synthesis using renewable biomass precursors will support environmentally sustainable CD production while introducing unique surface functionalities that expand the chemical recognition space available to sensor designers [29,30].

Standardized protocols and reference materials — developed through coordinated interlaboratory validation efforts — are essential prerequisites for the regulatory acceptance and commercial deployment of CD-based sensing technologies [31,32].

CONCLUSIONS

Carbon dot-based nanobiosensors have matured into sophisticated, versatile analytical platforms with demonstrated capabilities across an impressive range of pharmaceutical and environmental sensing applications. Their distinctive combination of tunable photoluminescence, efficient electrochemical activity, surface-modifiable chemistry, and

favorable biocompatibility enables sensing platform architectures spanning electrochemical, fluorescence, FRET, SERS, colorimetric, and dual-mode modalities. The feasibility of facile bioconjugation with enzymes, antibodies, and aptamers confers the molecular specificity necessary for selective quantification in complex matrices. The integration of CD sensing elements into microfluidic devices, paper-based analytical platforms, wearable sensors, and smartphone-assisted POC systems has demonstrated compelling potential for decentralized pharmaceutical analysis and real-time therapeutic monitoring. Emerging synergies with AI-assisted data processing and multiplexed sensor arrays open transformative possibilities for personalized medicine and population-level health surveillance. Realizing the full clinical and industrial potential of these systems will require concerted progress in standardized synthesis, anti-fouling surface engineering, scalable green production methods, and rigorous real-sample validation frameworks. As these challenges are methodically addressed, CD-based nanobiosensors stand poised to transition from promising laboratory tools to validated, deployable technologies in pharmaceutical quality control, therapeutic drug monitoring, and next-generation point-of-care diagnostics.

ABSTRACT

Marine macroalgae are recognized as a rich source of bioactive metabolites with significant potential in pharmaceutical and cosmeceutical industries. The present study focused on extracting and characterizing mycosporine-like amino acids (MAAs) from the red macroalga *Acanthophora spicifera* and formulating them into a natural sunscreen cream. Aqueous extraction yielded 46% crude MAAs, which exhibited strong UV absorption with maxima ranging between 292–362 nm. HPLC analysis confirmed the presence of multiple MAAs, while the ninhydrin method estimated an amino acid concentration of 88.3 µg/ml. The antioxidant potential of the extract, determined through DPPH assay, showed 38% free radical scavenging activity. Antibacterial screening revealed notable inhibitory effects against *Staphylococcus aureus* (20 mm), *Klebsiella pneumoniae* (17 mm), and *Escherichia coli* (15 mm), demonstrating efficacy comparable to or greater than the standard antibiotic. The partially purified MAA extract was incorporated into a cream formulation and subjected to physicochemical evaluation. The product exhibited desirable organoleptic properties, homogeneity, skin compatibility with a pH of 6.87, and stability under different storage conditions without phase separation. Microbiological analysis confirmed the absence of contamination, while in vitro SPF determination yielded a value of 17.6, indicating moderate sun protection. Overall, this study highlights *A. spicifera* as a promising natural source of MAAs with multifunctional properties, including UV absorption, antioxidant, and antibacterial activities. The formulated cream demonstrated stability, safety, and efficacy, supporting the application of marine-

derived compounds as eco-friendly alternatives to synthetic UV filters in sunscreen and anti-aging products.

Keywords: *Acanthophora spicifera*, mycosporine-like amino acids, sunscreen formulation, antioxidant, antibacterial, SPF, marine bioactives

INTRODUCTION

Sunscreen is a substance that helps to protect the skin from harmful sun rays. It reflects (physical blocker) or absorbs (chemical absorber) the ultraviolet A and B radiation. The primary defensive barrier of our body is the skin, which prevents the invasion of outside atmospheric pollutants such as chemicals and UV rays (Putri *et al*., 2021). A part of the solar electromagnetic spectrum is ultraviolet radiation (UVR), which comprises wavelengths 200 to 400 nm, in which ultraviolet A (UVA) is 315-400 nm, ultraviolet B (UVB) is 280-320 nm, and ultraviolet C (UVC) is 200-280 nm. Only a small portion of UVR reaches the earth's surface in wavelengths above 290 nm (Chrapusta *et al*., 2017; Afaq *et al*., 2006; Rastogi *et al*., 2009). Even though 5% UVB in the terrestrial UVR has a detrimental effect on human health (Young *et al*., 2006). Human skin contains a photoprotective pigment called melanin. Melanin act as a redox UV-absorbing agent, serving as a protective shield against direct UV impact on the DNA of epidermal cells. Additionally, melanin indirectly neutralizes reactive oxygen species (ROS) generated during UV-induced oxidative stress on the skin (Solano *et al*., 2020). At the same time, the repeated exposure to the sun resulted in sunburns (Moore *et al*., 2013), followed by melanocyte activation, which increased the rate of melanin production, and resulted in skin tanning. The permanent effects of repeated exposure to the sun give irreversible loss of skin elasticity, which leads to skin cancer, both melanomas and non-melanomas (Harrison *et al*., 2009).

Sunscreens are "any cosmetic product containing UV filters in its formulation to protect the skin from harmful solar ultraviolet light, prevent or minimize the damage this radiation can cause to human health" (Ambruso *et al*., 2023). Based on mode of action, Sunscreens can be classified as physical sunscreens, also known as inorganic (e.g., zinc oxide, titanium oxide), and chemical sunscreens, which are organic (e.g., avobenzone, oxybenzone). The physical sunscreens (inorganic) attenuate radiation through reflection and scattering light. The greatest sunscreen is considered to contain a combination of both these active ingredients (Baby *et al*., 2006). The physical inorganic sun blockers are Minerals like Titanium dioxide (TiO_2) and Zinc Oxide (ZnO). TiO_2 is very effective in the UV-B range, and zinc oxide is UV-A range, which provides broad band UV spectrum. Micro-sized $TioO_2$ and zinc oxide have been increasingly replacing the TIO_2 and zinc oxide nanoparticles. Organic sunscreen absorbs into the skin, converting UV rays into heat, which is then released from the skin. In the 1950s and 1960s, para-aminobenzoic acid (PABA) was widely used in sunscreen. Nevertheless, it was demonstrated to cause allergic responses and cancer in vitro, so its usage in sunscreen formulations is limited, and it is best to stay away from it (Gasparro *et al*., 1998; Roelandts *et al*., 1998). The optimal sunscreen should have an elevated level of UV filter in the skin stratum corneum and less penetration into skin's deeper layers (Chisvert *et al*., 2012). The most popular chemical sunscreen compounds are Benzophenone-3 (BP-3), 4- Methylbenzilydene Camphor (4-MBC), Octyl Methoxy Cinnamate (OMC), Octyl Salicylate (OS), and Butyl Methoxy Dibenzoyl Methane (BMDBM) (Giokas *et al*., 2007).

Herbal sunscreens include natural oils such as almond oil, olive oil, jojoba oil, and coconut oil, which penetrate deeper into the skin layer and prevent early signs of skin aging by hydrating the skin. Herbal ingredients are green tea, amla, turmeric, lemon green tea, lemon, amla, turmeric, etc., which have properties like absorbance of a broad spectrum of UV rays, anti-oxidant, anti-inflammatory, etc., (Shah *et al*., 2023). Marine life is a diverse group in the waters and a great place to find and extract biologically active compounds that could be used as fine chemicals, medications, nutritional supplements, cosmetics, and enzymes (Pomponi *et al*., 1999). Bioactive compounds obtained from marine organisms serve a variety of purposes as secondary metabolites, and their properties can be used to create new pharmaceutical and cosmetics products (Harrison *et al*., 2000; Faulkner *et al*., 2000). Since the beginning of

life on Earth, marine macroalgae have been exposed to UV radiation. As a result, they have evolved several defense mechanisms, including DNA repair, avoidance, and cellular protection against UVR through the synthesis of carotenoids and mycosporine-like amino acids (Singh *et al*., 2021). Under stress conditions, marine organisms generate a multitude of sunscreening metabolites. Many compounds that prevent photodamage have been developed, including scytonemin (found only in cyanobacteria), mycosporine-like amino acids (MAAs, found in cyanobacteria, algae, and animals), phenylpropanoids and flavonoids (found in higher plants), melanin (found in humans, other animals, and even some bacteria), and a variety of other UV- absorbing substances with unknown chemical structures from various organisms (Sinha *et al*., 1998; Sinha *et al*., 2007).

Mycosporine-like amino acids (MAAs) are small (<400 kDa), colourless, water-soluble molecules that absorb UV-A and UV-B light. They are composed of cyclohexanone or cyclohexenimine chromophores conjugated with nitrogen substituents of amino acids or its imino alcohols, and their absorption maxima appear between 268-362 nm depending on their molecular structure. Based on the cyclohexanone or cyclohexenimine ring structure, MAAs are divided into two categories: oxo-MAAs and imino-MAAs. The main imino-MAAs are shinorine, palythine, asterine-330, porphyra-334, usujirene, and palythene, whereas the main oxo-MAAs are mycosporine-glycine and mycosporine-taurine (Chrapusta *et al*., 2017, Torres *et al*., 2018). MAAs are commonly found in organisms exposed to high-intensity light, such as cyanobacteria and other prokaryotes, eukaryotic microorganisms (such as fungi and microalgae), marine macroalgae (both green and red algae), corals, terrestrial lichens, and other marine organisms that accumulate MAAs from their diet (Sinha *et al*., 2007). In addition to UV absorption, MAA also contains anti-oxidant, anti-photoaging, cell proliferation stimulators, anti-cancer agents, anti-adipogenic properties, and protects from DNA damage. Mycosporine-like aminoacids can also act as anti-viral agent agents against COVID-19 infection (Singh *et al*., 2021; Sahu *et al*., 2023).

MAAs can be found in many algae species, but the highest concentrations are found in red algae, mainly in the order of Bangiales, as Porphyra spp. Macroalgae are part of a broad category of organisms that may be used to produce biomolecules. *Acanthophora spicifera* (M. Vahl) Borgesen is a red seaweed that belongs to Division: Rhodophyta, Class: Rhodophyceae, Order: Ceramiales, Family: Acanthophora. Acanthophora grows from a large, irregularly shaped holdfast and is 40cm tall with solid, cylindrical branches, 2-3mm wide and branched sparingly or repeatedly. The main branches have short, determinate branches that are irregularly shaped, spinose, and have many spines arranged radially; the main axes are spineless. It can be shades of red, orange, purple, yellow, or brown. *A. spicifera* has flavonoids with antibacterial (Seenivasan *et al*., 2012), antitumor (Lavakumar *et al*., 2012), procoagulant, and antioxidant activity (Zeng *et al*., 2001). Phenolic compounds with antiproliferative (Murugan and Iyer 2014) and antioxidant activity (Ganesan *et al*., 2008). It is also used as foodstuff in the human diet (Lang *et al*., 2007; Zakaria *et al*., 2014). The present study aimed to formulate a sunscreen using Mycosporine -like aminoacids, extracted from the marine red algae, *Acanthophora spicifera*

MATERIALS AND METHODS

Collection of Macroalgae:

The dry macroalgae, *Acanthophora spicifera,* were purchased from R.K. Algae Project Centre, Rameshwaram. The materials were washed with tap water to remove sea salts and epibionts. Soon after, they were shade dried at room temperature. The dried seaweed was cut into small pieces, ground into a fine powder and stored in the dark at room temperature.

Extraction of Mycosporine-like amino acids (MAAs):

The mycosporine-like amino acids were extracted according to the method described by Sun *et al*., 2021 with some modification. Ten grams of dry powder were added to 200 ml of extraction solvent, distilled water, and kept in a hot plate magnetic stirrer for 4h at 45°C. Then, it was centrifuged and the supernatant was collected. Partial purification is done by adding 40ml of absolute ethanol (final content of 80%) to the 20ml supernatant and placing it at -20°C for

6hrs. Then, it was centrifuged for 10 mins, and the supernatant was discarded. The sediment was dried. Yield of MAA extracts (%) = 100% × the quantity of MAA extracts (DW, g) / the quantity of red macroalgae powder (DW, g) -Equation (1)

Characterization of MAAs extract:

Spectrophotometric analysis of crude MAAs extract

Crude MAA extract was analyzed by the UV-visible ray absorption spectrum using a spectrophotometer at different wavelengths (250-400nm). The sediment was dissolved in distilled water and scanned at wavelengths ranging from 250 to 400 nm in a UV spectrophotometer to determine the characteristics absorption.

High-Performance Liquid Chromatography (HPLC) (Nishida *et al*., 2020)

The crude MAAs were dissolved in ultrapure water containing 0.1% trifluoroacetic acid (TFA) and applied to sequential filtration by Millex-GV (pore size: 0.22μm) and Millex-LG (pore size:0.20μm). The filtrated MAAs were isolated by reversed-phase HPLC with a Mightysil RP-18GP column (5μm,10) using an isocratic elution of ultrapure water containing 0.1% TFA for 7 min and a linear gradient of acetonitrile (0-70%) containing 0.1% TFA for 13 min at a flow rate of 4.73 ml/min. The column oven temperature was set at 40°C. The detection wavelength was set at 330nm.

Detection of amino acids by the ninhydrin method

Estimation of amino acids by ninhydrin method by standard method. The standard amino acids were prepared with varied concentrations of 20, 40, 60, 80, and 100 μg/ml. 0.2, 0.4, 0.6, 0.8, 1 ml of standard amino acids were pipetted out in the respective labelled test tubes and made up to 1 ml with distilled water. 1ml of crude MAAs extract was taken in test tubes. 1ml of distilled water was used as a blank. 1 ml of ninhydrin reagent was added to all the tubes. Mix the contents of the tubes by stirring. Cover all the tubes with paper. The tubes were kept in a boiling water bath for 15 minutes. The absorbance was read at 570nm.

In vitro DPPH assay for radical scavenging activity

The free radical scavenging activity of crude MAAs from *A. spicifera* was measured by the 1,1-diphenyl-2-picryl-hydrazyl (DPPH) following the method of Blois *et al*., 1958, with some modification. A 1ml of sample is make up to 2ml with distilled water. 1.75ml of DPPH reagent was mixed. The mixture was incubated at dark room for 1hr and measured the absorbance at 517 nm. The DPPH scavenging activity was calculated by the following equation:

$$\text{Percentage Inhibition (\%)} = \frac{\text{absorbance control} - \text{absorbance sample}}{\text{absorbance control}} \times 100$$

-Equation (2)

Absorbance control contains only the DPPH reagent.
Ascorbic acid was used as a standard.

Screening of antibacterial activity:

The crude MAA extract was screened for antibacterial activity using the agar disc diffusion method described by the Bauer *et al*., 1966. The tested bacteria were *Staphylococcus aureus, Escherichia coli, and Klebsiella pneumonia.* The culture was lawned on Muller-Hinton agar and Azithromycin (15μg/ml) was used as a positive control. The MAA extract, 40μl from the stock (100 μg/ml) was added on the sterile filter paper disc and placed over the lawned culture and the agar plates were incubated at 37°C for 24hrs. The diameters of zone of inhibition were measured around each disc.

Preparation of Sunscreen cream

The sunscreen cream was prepared and modified using the methods of Putri *et al*., 2023 and Roy *et al*., 2014, Furtado *et al*., 2022. The emulsion was prepared by heating and stirring the oil phase and aqueous phase. Stearic acid, cetyl alcohol, almond oil were the components of oil phase and aqueous phase includes water, glycerin, xanthan gum, and vitamin E. The aqueous and oil phase components were mixed separately and heated and stirred at 70-75°C for 20mins. Following that, a mechanical stirrer was used to add the initial aqueous phase to the oil phase while

continuously stirring until the aqueous phase completely added. The Water in oil phase emulsion was allowed to settle at ambient temperature, and then the partially purified MAA extract wad added and mixed homogenously using the stirrer.

Physicochemical test

Physical analysis:

The organoleptic properties like colour, odour, homogeneity, appearance, and irritancy of the sunscreen cream were studied according to Purohit *et al*., 2023.

- **Colour**: The colour of formulation was checked manually and observed.
- **Odour**: The smell of formulation was checked by applying preparation on hand and feel the fragrance.
- **Appearance**: The appearance of the formulation was visually checked.
- **Patch test for irritancy:** A small amount of the product was applied to a small tender area of skin of arm. Irritancy, erythema and oedema were checked at regular intervals for up to 24 hours.
- **Homogeneity**: The formulation was tested for homogeneity by visual appearance and touch.

Stability test: The Stability of the sunscreen cream was checked at 4°C (refrigerator), and 30°C (incubator) for phase separation, and colour change in 21 days.

Emulsion stability test: For emulsions, centrifugal tests were carried out according to the method described by Smaoui *et al*., 2017 right after preparation. The test was repeated after 24 hours, on Day 3, 5, 7, 14 and 21days of storage. The cream was centrifuged at 5,000 rpm for 10 minutes and observed for phase separation.

pH determination: The pH value of emulsions was determined using a digital pH Meter.

Washability: This test was carried out by simply washing applied sunscreen cream with water on the skin.

Total plate count (TPC)

The pour plate technique was performed by standard method for the formulated sunscreen cream to check for contamination. 1ml of cream sample was dissolved in 9ml of distilled water which gave10^{-1} dilution. 1ml of 10^{-1} sample was introduced into a sterile petri dish. 20 ml of Sterile Plate count agar was poured into a sterile petri dish and mixed well, and allowed to solidify. The plates were incubated at room temperature for 24 hours. The number of colonies were counted.

Determination of In Vitro SPF:

The Determination of in vitro SPF of the cream was performed by using the method Putri *et al*., 2021. 1 g of the sample was weighed and dissolved in a volumetric flask with 100ml absolute ethanol. The solution was filtered with a cotton and then sonicated for 5 mins. After that, the UV-VIS spectrophotometer was calibrated using 1ml of ethanol, and then quartz was inserted into the UV-Vis spectrophotometer using a wavelength of 290 – 320 nm with five intervals. Tested three times to get an accurate value.

The absorbance data is developed by (Mansur *et al*., 1986), and invitro method proposed by Sayre *et al*., 1979 by utilizing UV spectrophotometry and the following equation:

$SPF = CF \times 290\sum 320\ EE\ (\lambda) \times I(\lambda) \times absorbance(\lambda)$ -Equation (3)

Whereas,

CF= Correction factor (10);

EE= Erythemogenic effect;

I= Intensity of solar light of wavelength;

A= Absorbance

Yield of Aqueous extract of Mycosporine-like amino acids (MAAs)

The dry weight of the aqueous extract of crude MAA = 4.6g

Yield of MAA extracts (%) = 100 % × 4.6/10

By applying into equation (1), the yield of crude MAA (%) extract from *A. spicifera* gives 46%.

Detection of MAAs

Spectrophotometric analysis of crude MAAs solution

The absorption spectra of crude MAAs solution are shown in Table 2. The absorption maximum peaks were detected, ranging from 292 to 362 nm. Graph 1 and Table 2 showed the maximum absorption spectra of the aqueous extract of crude MAAs at 292 nm. The graph 2(a, b, c, d) shows HPLC analysis which revealed the presence of four peaks at 3.06, 5.85, 3.581, 2.723 min with the absorption maximum (λ max) at 223nm, 237nm, 272nm, 328nm.

Estimation of amino acids in MAAs by ninhydrin method

The standard amino acids used is tryptophan. Fig 3 shows purple colour, which indicates the presence of amino acids. The amount of amino acid was estimated as 88.3 μg/ml present in 1 ml of the crude extract of MAAs. Control (DPPH only) – 1.15 nm. By formula (2), MAA showed 38% antioxidant activity. The antioxidant activity of MAA was evaluated using the DPPH radical scavenging assay. Ascorbic acid was used as a positive control. The MAA exhibited a significant DPPH scavenging activity, indicating moderate antioxidant potential.

Screening of antibacterial activity

Mycosporine-like amino acids (MAAs) showed (Table 5) antibacterial activity with a maximum zone of inhibition for *Staphylococcus aureus* – 20mm, followed by *Klebsiella pneumoniae* – 17mm than the control Azithromycin. MAA also inhibited *Escherichia coli* – 15 mm, little less when compared with the standard drug.

Physio-Chemical Test

Physical analysis:

Fig 8 shows the formulated cream.

- **Colour:** The colour of the cream was whitish yellow.
- **Odour:** It gives marzipan-like aroma.
- **Appearance:** Softy, creamy appearance.
- **Patch test for irritancy:** No irritation, oedema, or erythema was observed on the skin.
- **Homogeneity:** The formulation produced a uniform distribution of extracts in the cream. This was confirmed by visual appearance and by touch, which shows good homogeneity.

Stability test: The formulation was stable at different temperatures, 4^{o}C (in refrigerator), 30^{o}C (incubator).
Emulsion stability: No phase separation was observed after 24hours, days of 3, 5, 7, 14 21 days of storage.
pH determination: The pH value of the formulation is 6.87.
Washability: The cream appears to be washable easily.

Total plate count (TPC):

There were no colonies observed in the plate after 24 hrs of the cream prepared.
The total plate count test shows 0 CFU/mL. Fig. 10a (10-1 dilution) shows that there is no microbial contamination in the 24-hour formulated cream. This indicates the cream was prepared under sterile conditions.

Determination of invitro SPF

By applying the equation (3), the total of EE × I × ABS gives 1.765 multiply into correction factor which is constant and it gives,

SPF= 10 X 1.765
= 17.6

The Sun Protection Factor (SPF) value of the formulated cream was 17.6.

DISCUSSION

Acanthophora spicifera (Vahl) Borgesen (spiny seaweeds) is an erect edible marine plant belongs to the largest family of Rhodophyta, Rhodomelaceae. MAAs are synthesized and accumulated as photoprotective compounds by marine phototrophs (e.g., dinoflagellates, cyanobacteria and macroalgae). MAAs are nitrogeneous secondary metabolites of low molecular weight (<400KDa) with the maximum absorption ranging from 310 to 360nm (Nishida *et al.,* 2020). In the present study, mycosporine like amino acids were extracted using water as a solvent and gave the yield of 46% and compared with the study of Sun *et al*., 2021 reported that the yield of MAA extracts from the red algae, *Bangia fusco-purpurea*, and *Gracilaria confervoides* gave the higher yield of 12% and 9% when water was used as a solvent when compared with 25% ethanol and 25% methanol extract of MAAs. Aqueous extract of MAAs from *Acanthophora spicifera* gave higher yield than the MAAs extract of the red algae, *Bangia fusco-purpurea*, *Gracilaria confervoides* and *Palmaria palmata* reported by Sun *et al*., 2021 and Nishida *et al*., 2020.

Nishida *et al*., 2020 reported that water extraction of MAAs yield from the red algae, *Palmaria palmata* were two times higher than that by methanol extraction. The present study of aqueous extract of MAA from the red algae, *Acanthophora spicifera* is in consistent with the study of Sun *et al*., 2021 and Nishida *et al*., 2020. The spectrophotometric analysis revealed maximum absorption peaks of the crude MAAs solution in the range of 292 to 362 nm with absorbance (Table 2). Chrapusta *et al*., 2017 reported that absorption of mycosporine like amino acids is 268-362nm.The presence of these peaks indicates the successful extraction of MAAs, which are known for their strong UV absorption properties. The absorbance of *A. spicifera* in the peak of 362nm shows 1.8 which is consistent with Sun *et al*., 2021 reported the UV absorption of *Bangia fusco-purpurea* shows peak between 330-350nm with highest absorbance of 1.3. The HPLC analysis revealed four peaks with retention times at 3.06, 5.85, 3.581, and 2.723 minutes, corresponding to absorption maxima at wavelengths of 223 nm, 237 nm, 272 nm, and 328 nm. The distinct peaks and absorption maxima observed in this study suggest the presence of multiple MAAs in the crude extract, which is typical for marine algae, as they often contain a variety of different mycosporine-like compounds with diverse UV-absorbing properties. The aqueous solution of MAAs from *Ceramium sp* shows HPLC results as Shinorine (λ_{max} = 332.3nm), Porphyra (λ_{max} = 333.5nm, Palythinol (λ_{max} =332.5) with retention time 1.27, 2.13, 4.61mins (Pandey *et al*., 2017). The red algae *P. rosengurtii* of HPLC as Shinorine (λ_{max} = 332.8nm), Porphyra-334 (λ_{max}= 334nm), Palythinol (λ_{max} = 334nm) with retention time at 5.07, 5.09, 7.09min and *G. corneum* shows Asterine (λ_{max}=330nm), Palythine (λ_{max}=319nm) with retention time at 18.0, 14.0 mins (Coba *et al*., 2009). Nishida *et al*., 2020 reported the crude extract of MAAs of HPLC analysis revealed the presence of six prominent peak as 329-331, 319, 325-328, 331, 357, 358nm with retention time at 4.42, 4.79, 5.27, 7.73, 13.36 and 13.43min.

In comparison, the 38% DPPH scavenging activity observed for crude MAAs extract from *Acanthophora spicifera*. This compared with the findings from Rastogi *et al*., 2016, who reported antioxidant activity of UV induced MAA in *Nostoc sp*, which shows 20µg/ml of MAA shows 19% of inhibition activity. The lower activity in some extracts could be due to the specific extraction conditions used, which may not fully capture all the bioactive compounds responsible for the antioxidant effects. The antibacterial activity of extracted MAAs from *A. spicifera* showed antibacterial activity against the tested bacteria, *Escherichia coli, Klebsiella pneumoniae and Staphylococcus aureus* (Table 5). By comparing with Lavakumar *et al*., 2012 ethanolic extract of *A. spicifera* showed antibacterial activity against *S. aureus* with a zone of inhibition, 19mm, *E. coli* - 11mm, *K. pneumoniae* - 10mm, with positive control as ciprofloxacin. The antibacterial activity results of MAA against *S.aureus* agree with the study of Lavakumar *et al*., 2012. Oumaskour *et al*., 2013 tested antibacterial activity against Gram-positive bacteria in red algae, *Halopitys incurvus* in which *S. aureus* shows greater than 15mm. The observed antibacterial activity is attributed to the bioactive nature of MAAs, which may inhibit bacterial growth through their UV-absorbing properties or by disrupting bacterial cell membranes.

The physiochemical analysis of formulated sunscreen cream using MAAs of *A. spicifera* shows pH 6.87, Sun Protection Factor (SPF) shows 17.6, and Total Plate Count (TPC) shows 0 CFU/ml. By naturally *A. spicifera* have

antibacterial, antifungal, antiviral, antioxidant. The formulated cream containing the MAA extract displayed several desirable characteristics. The cream was stable at different temperatures, and no phase separation was observed during storage, indicating good formulation stability. These results are compared with Putri *et al*., 2021 used chitosan extract which shows 6.19, SPF 14.8, and TPC 0. The pH value of the formulation (6.87) suggests that the cream is suitable for topical use, as it is close to the natural pH of human skin, which ranges from 4.5 to 7.5. The cream also passed the patch test, with no irritation or erythema, which further supports its potential for cosmetic use. The microbial test confirmed the absence of microbial contamination in the cream, with no colonies observed after 7, 14, or 21 days of testing. This suggests that the formulation is microbiologically stable, making it suitable for long-term use in cosmetic applications and ensuring the safety of such products. The sunscreen product Helioguard™ 365 contains two MAAs, shinorine and porphyra-334, Helionori™ contains palythine, porphyra-334, shinorine and both were isolated from red seaweed *Porphyra umblicalis* have traditional UV filter but in this study it is formulated by the base cream and only MAA as UV protectant which gives good sun protection.

CONCLUSION

This study demonstrates that *Acanthophora spicifera* is a promising source of Mycosporine-like amino acids (MAA), which exhibit moderate antioxidant and significant antibacterial activities. The incorporation of MAAs into a cream formulation enhances its potential for natural UV protection due to the UV-absorbing properties of these compounds. Additionally, the cream formulation showed excellent stability across varying storage conditions, good homogeneity, and a safe pH, making it suitable for topical use. The physicochemical tests confirmed that the cream has desirable qualities, such as an appealing appearance, pleasant aroma, and ease of washability, alongside an excellent safety profile. These findings suggest that the cream is a stable, effective, and safe skincare product with the potential for broader use in sunscreens and anti-aging formulations. This study contributes to the growing interest in marine bioactives and their promising role in consumer products.

ABSTRACT

The widespread use of mobile phones has significantly transformed the lifestyle and learning habits of school students. Smartphones provide students with access to educational resources, online learning platforms, and instant communication. However, excessive and uncontrolled mobile phone usage may adversely affect students' academic performance, concentration, study habits, sleep quality, and overall well-being. This study aims to examine the impact of mobile phone usage on the academic performance of school students in Chennai. Overall, the research contributes to a better understanding of how mobile phone usage influences students' academic performance and emphasizes the importance of maintaining a healthy balance between digital technology and educational activities.

Keywords: Academic performance, study habits, sleep quality, emphasizes

INTRODUCTION

In the digital era, mobile phones have become one of the most essential technological devices used by people of all age groups. Over the past decade, the rapid advancement of smartphone technology and the widespread availability of affordable internet services have significantly increased mobile phone usage among school students. Smartphones are no longer used only for communication; they have become multifunctional devices that support online learning, information retrieval, educational applications, entertainment, gaming, social networking, and digital collaboration. As technology continues to transform the education sector, mobile phones have become an important learning tool

for students both inside and outside the classroom. The integration of digital technology into education has created numerous opportunities for enhancing students' learning experiences. Mobile phones provide instant access to educational websites, e-books, online tutorials, virtual classrooms, digital libraries, and interactive learning applications. During and after the COVID-19 pandemic, mobile phones played a vital role in ensuring continuity of education through online classes and digital learning platforms. Students increasingly rely on smartphones to complete assignments, attend virtual classes, communicate with teachers, participate in group discussions, and access academic resources. Consequently, mobile phones have become an indispensable component of modern education.

Despite these educational benefits, excessive and uncontrolled mobile phone usage has emerged as a major concern among educators, parents, and policymakers. Many students spend a substantial amount of time on social media platforms, online gaming, video streaming, instant messaging, and other entertainment applications. Excessive screen time may reduce the amount of time devoted to studying, completing homework, reading textbooks, and engaging in physical activities. It can also negatively affect students' concentration, attention span, memory, classroom participation, and overall academic performance. Academic performance is one of the most important indicators of a student's educational achievement. It reflects the extent to which students successfully acquire knowledge, develop skills, and achieve learning objectives. Academic performance is influenced by various factors, including study habits, learning environment, parental support, motivation, teacher effectiveness, health, and technology usage. Among these factors, mobile phone usage has become increasingly significant due to its widespread adoption among school students. While smartphones can facilitate learning when used appropriately, excessive dependence on mobile devices may distract students from academic activities and reduce their productivity. One of the major challenges associated with mobile phone usage is digital distraction. Frequent notifications from social media applications, online games, entertainment platforms, and messaging services interrupt students' learning process and reduce their ability to focus on academic tasks.

Continuous multitasking between studying and smartphone activities may lead to lower concentration levels, reduced comprehension, and poor examination performance. Furthermore, prolonged mobile phone usage during late-night hours often affects sleep quality, resulting in fatigue, reduced cognitive performance, and decreased classroom attention. At the same time, it is important to recognize that mobile phones also offer significant educational advantages. Educational applications, digital dictionaries, online quizzes, learning management systems, language-learning tools, and collaborative platforms enable students to learn more effectively. Smartphones allow students to access current information instantly, participate in online discussions, develop digital literacy skills, and engage in self-directed learning. Therefore, the impact of mobile phone usage on academic performance depends largely on how students use the technology and the amount of time they spend on academic versus non-academic activities. In Chennai, one of India's leading educational and technological hubs, school students have widespread access to smartphones and internet connectivity. The increasing affordability of mobile devices and digital services has made smartphone usage common among students from different educational and socio-economic backgrounds. As schools continue to integrate technology into teaching and learning, understanding students' mobile phone usage patterns has become increasingly important. Parents and teachers often express concerns regarding excessive smartphone use, reduced academic focus, behavioural changes, and declining academic achievement among students. These concerns highlight the need for systematic research on the relationship between mobile phone usage and academic performance.

REVIEW OF LITERATURE

Ruiz-Martínez, Castañeda, and Fernández Breis (2022) conducted a systematic review on mobile learning applications. The study reported that educational mobile applications improved students' learning performance, motivation, and engagement when integrated effectively into teaching and learning processes. The authors concluded that smartphones can positively contribute to education when used primarily for academic purposes.

Ancy Albert et al. (2020) conducted a systematic review on smartphone usage and academic performance. The review concluded that smartphone addiction was one of the major factors affecting students' academic achievement. The authors recommended creating awareness among students regarding healthy and responsible smartphone usage. Giunchiglia et al. (2020) investigated the relationship between mobile social media usage and academic performance using smartphone usage data. Their findings revealed that excessive use of social media applications was negatively associated with students' academic achievement and effective time management. The researchers recommended encouraging responsible smartphone usage among students. Amez and Baert (2020) conducted a systematic review on smartphone usage and academic performance. The study reviewed empirical research from different countries and found that excessive smartphone usage was generally associated with lower academic performance. However, the authors also noted that the strength of this relationship varied depending on how smartphone use and academic achievement were measured. Kates, Wu, and Coryn (2018) carried out a meta-analysis to examine the relationship between mobile phone use and educational outcomes. The analysis concluded that increased mobile phone usage had a small but statistically significant negative effect on students' academic performance. The study suggested that excessive mobile phone use can reduce students' attention, concentration, and learning effectiveness. Samaha and Hawi (2016) explored the relationship between smartphone addiction, stress, and academic performance.

The study revealed that excessive smartphone dependence increased academic stress and reduced students' educational performance. The authors recommended promoting digital well-being and time management skills among students. Lepp, Barkley, and Karpinski (2015) investigated the relationship between smartphone use and academic performance among students. The results indicated that higher smartphone usage was associated with lower grade point averages, reduced study time, and increased academic distractions. The researchers emphasized the importance of self-regulation in smartphone use Anitha (2014) examined factors affecting student engagement and learning performance. The study reported that students' engagement, effective study habits, and supportive learning environments significantly enhanced academic achievement. The findings indicate that distractions such as excessive mobile phone usage may reduce students' academic engagement. Junco (2012) examined the impact of multitasking and social media use among students. The study found that frequent use of mobile phones for texting and social networking during study hours negatively affected concentration and academic performance. The author recommended limiting non-academic smartphone use while studying. Hazelhurst, Johnson, and Sanders (2011) examined internet and mobile web usage patterns among students and found that students with heavier internet usage generally achieved lower academic scores than those who used digital technologies more moderately. The study emphasized the importance of balanced technology usage to maintain academic success.

Statement of the Problem

Mobile phones have become an essential part of the daily lives of school students. They are widely used for communication, online learning, accessing educational resources, entertainment, gaming, and social networking. The increasing availability of affordable smartphones and internet services has significantly increased mobile phone usage among students in Chennai. While mobile phones provide several educational benefits, excessive and uncontrolled usage has become a growing concern for parents, teachers, and educational institutions. Many school students spend a considerable amount of time on social media, online games, video streaming, and messaging applications. Excessive screen time may reduce the time available for studying, completing assignments, reading, and participating in extracurricular activities. It may also affect students' concentration, memory, classroom participation, sleep quality, and overall academic performance. Frequent mobile phone usage during study hours can distract students from their learning objectives and negatively influence their educational achievement. At the same time, mobile phones also serve as valuable educational tools by providing access to digital classrooms, e-books, educational videos, online assessments, and learning applications. Therefore, the impact of mobile phone usage depends on the purpose, duration, and pattern of usage. Understanding whether mobile phone usage supports or hinders students' academic performance has become an important issue in educational research. In Chennai, smartphone usage among school students has increased rapidly, making it necessary to examine its influence on academic performance. This study aims to investigate the relationship between mobile phone usage and students'

academic achievement, identify the factors associated with excessive smartphone use, and suggest measures for promoting responsible mobile phone usage among school students.

Objectives of the Study

Primary Objective

To study the impact of mobile phone usage on the academic performance of school students in Chennai

Secondary Objectives

- To identify the pattern and frequency of mobile phone usage among school students in Chennai.
- To examine the purposes for which school students use mobile phones.
- To analyze the relationship between mobile phone usage and students' academic performance.
- To assess the impact of mobile phone usage on students' study habits and concentration.

Scope of the Study

The present study focuses on examining the impact of mobile phone usage on the academic performance of school students in Chennai. It includes students studying in selected government, government-aided, and private schools. The study analyzes the frequency, duration, and purpose of mobile phone usage and evaluates its influence on academic performance, study habits, concentration, classroom participation, sleep quality, and time management.

The study also investigates whether demographic variables such as age, gender, and class level influence mobile phone usage patterns. The findings of the study will be useful for students, parents, teachers, school administrators, educational planners, and policymakers in understanding the educational implications of smartphone usage. The recommendations of the study may help educational institutions develop awareness programmes and policies that encourage responsible mobile phone usage while maximizing its educational benefits.

Limitations of the Study

- The study is limited to selected schools in Chennai and therefore the findings may not be generalized to all school students in India.
- The study considers only a sample of 100 respondents, which may not fully represent the entire student population.
- The research is based on primary data collected through a structured questionnaire, and the responses depend on the honesty and accuracy of the respondents.
- The study focuses only on the impact of mobile phone usage on academic performance and does not examine other digital devices such as tablets or laptops.

RESEARCH METHODOLOGY

Research Design

The study employs a Descriptive Research Design. This design is appropriate because it describes the characteristics, behaviour, and mobile phone usage patterns of school students and examines their impact on academic performance without manipulating any variables.

Area of the Study

The study is conducted among school students in selected government, government-aided, and private schools located in **Chennai City**.

Nature of Data

The study is based on both Primary Data and Secondary Data.

Primary Data

Primary data are collected directly from school students using a structured questionnaire. The questionnaire includes questions related to demographic characteristics, mobile phone usage patterns, study habits, sleep quality, classroom participation, and academic performance.

Secondary Data

Secondary data are collected from:

- Books
- National and international journals
- Research articles
- Government reports
- Educational websites
- Newspapers
- Magazines
- Online databases

These sources provide theoretical and empirical support for the study.

Sampling Technique

The study adopts the **Simple Random Sampling** technique to select respondents. This method provides each student with an equal opportunity to participate in the study and helps reduce selection bias.

Sample Size

A total of **100 school students** are selected as respondents for the study.

Data Anlysis and Interpertaion

Interpretation

The demographic analysis shows that out of the 100 respondents, 56% are male and 44% are female. Most respondents (40%) are aged 15–16 years. Regarding class of study, 28% are studying in Class X, followed by 26% in Class XII, 24% in Class XI, and 22% in Class IX. Nearly half of the respondents (48%) are from private schools, while 30% are from government schools and 22% from government-aided schools. A majority (66%) study in the English medium. With regard to parents' educational qualifications, 34% have an undergraduate degree and 26% have a postgraduate degree. Most parents (36%) are employed in the private sector. In terms of family income, 38% belong to families earning between ₹25,001 and ₹50,000 per month. Concerning mobile phone usage, 36% of the students use their phones for 3–4 hours daily, while 32% primarily use them for social media. This demographic profile provides an overview of the respondents and forms the basis for further statistical analysis. Factor analysis was carried out to identify the underlying dimensions influencing the impact of mobile phone usage on the academic performance of school students. Twenty statements relating to mobile phone usage were included in the analysis. The KMO value of **0.821** indicates that the sample is adequate for factor analysis, as it exceeds the recommended value of 0.60. Bartlett's Test of Sphericity is statistically significant ($\chi^2 = 985.427$, $p < 0.001$), indicating that the variables are sufficiently correlated for factor analysis. Hence, factor analysis is appropriate for the present study. Five factors with Eigenvalues greater than 1 were extracted. Together, these five factors explain **71.58%** of the total variance, indicating that they adequately represent the variables included in the study

Findings of the Study

- The majority (56%) of the respondents are male students, while 44% are female students.
- Most of the respondents (40%) belong to the age group of 15–16 years.
- A higher proportion (48%) of the respondents are studying in private schools.
- The majority (66%) of the respondents study in the English medium.
- Most respondents' parents (34%) possess an undergraduate qualification.
- The majority (36%) of the respondents' parents are employed in the private sector.
- Most respondents (38%) belong to families with a monthly income between ₹25,001 and ₹50,000.
- The majority (36%) of the students use mobile phones for 3–4 hours daily.
- Social media (32%) is the primary purpose of mobile phone usage among the respondents.
- The KMO value of 0.821 indicates that the sample is adequate for factor analysis.
- Bartlett's Test of Sphericity is statistically significant, confirming the suitability of the data for factor analysis.
- Five major factors were extracted, explaining 71.58% of the total variance.

- The extracted factors are Educational Usage, Social Media and Mobile Dependency, Academic Distraction, Health and Sleep Impact, and Responsible Mobile Phone Usage.
- Educational usage has a positive influence on students' learning when mobile phones are used for academic purposes.
- Excessive social media usage and mobile dependency negatively affect students' concentration and academic performance.

18. Usage as significant predictors of Students' Academic Performance.

Suggestions

Based on the findings of the study, the following suggestions are offered:

- Students should use mobile phones primarily for educational purposes rather than excessive entertainment and social media activities.
- Parents should monitor and regulate their children's daily screen time through appropriate guidance and supervision.
- Schools should organize awareness programmes on responsible smartphone usage and digital well-being.
- Teachers should encourage students to utilize educational applications and online learning resources effectively.
- Students should prepare daily study schedules and avoid using mobile phones during study hours.

CONCLUSION

Mobile phones have become an indispensable part of students' educational and personal lives. When used appropriately, smartphones provide valuable opportunities for learning, communication, and skill development. However, excessive and uncontrolled mobile phone usage can adversely affect students' academic performance, study habits, concentration, sleep quality, and overall well-being. The findings of the study reveal that prolonged mobile phone usage, particularly for social media and entertainment, has a negative impact on students' academic achievement. At the same time, educational usage of smartphones positively contributes to learning outcomes. The factor analysis identified five major dimensions influencing academic performance: Educational Usage, Social Media and Mobile Dependency, Academic Distraction, Health and Sleep Impact, and Responsible Mobile Phone Usage. The study concludes that mobile phones are beneficial educational tools when used responsibly and in moderation. Students, parents, teachers, and school administrators should work together to promote healthy digital habits, encourage academic use of technology, and minimize excessive smartphone usage. By maintaining a balanced approach to mobile phone use, students can improve their academic performance while benefiting from the opportunities offered by modern digital technology.

ABSTRACT

In this paper, we introduce and investigate the notion of fuzzy 2-absorbing ideals in the setting of non-commutative rings. This concept extends both the theory of fuzzy ideals and the classical notion of 2-absorbing ideals to a broader algebraic framework where commutativity is not assumed. Our results generalize known characterizations in commutative rings and contribute to a deeper understanding of fuzzy ideal theory in non-commutative algebraic systems.

Keywords: Fuzzy 2-Absorbing Ideal, Fuzzy Right Ideal, Fuzzy Left Ideal.

INTRODUCTION

The theory of fuzzy sets, introduced by Zadeh in 1965, has provided a powerful framework for handling uncertainty and partial membership in various branches of Mathematics. Fuzzy set theory has been successfully applied to algebraic structures, leading to the development of fuzzy algebra. In particular, the notion of fuzzy ideals in rings has attracted considerable attention due to its ability to generalize classical ideal theory and capture graded membership behaviour. Badawi[1] established that a non-zero proper ideal I of R is a2-absorbing ideal. Gronewald[2] classified2-absorbing ideals into two classes namely 2- absorbing and strong 2- absorbing. He established that the intersection of two prime ideals isa 2- absorbing ideals. He characterized that 2 absorbing ideals by the product of two left ideals.SerkanOnar, DenizSönmez, Bayram Ali Ersoy, GürselYeşilot&Kostaq Hila [3] studied about Fuzzy 2-absorbing Primaryideals. Also, SerkanOnar [4] discussed about On Fuzzy 2-absorbing ideals in rings.

The concept of prime and semiprime ideals plays a central role in ring theory. Motivated by these classical notions, Badawi introduced the concept of 2-absorbing ideals as a natural generalization of prime ideals. This notion has since been extensively studied and extended to various algebraic settings. Non-commutative ring theory presents additional challenges due to the lack of symmetry in multiplication, which necessitates careful distinctions between left, right, and two-sided ideals. In the fuzzy setting, these challenges become more pronounced, as the sup–min composition used to define the product of fuzzy subsets interacts nontrivially with non-commutative multiplication.

PRELIMINARIES

Definition: 2.1
A fuzzy subset of R is a functionμ:R→[0,1] where $\mu(x)$ measures the degree of membership of x.

Definition: 2.2
Considering the ring is non-commutative, we distinguish left, right, and two-sided fuzzy ideals.

Fuzzy left ideal:
A fuzzy set $\tilde{\mu}$ on R is a fuzzy left ideal if for all $\tilde{x},\tilde{y},\tilde{r} \in$ RIt shouldhave additive closure i.e.$\tilde{\mu}(\tilde{x}-\tilde{y}) \geq \min\{\tilde{\mu}(\tilde{x}),\tilde{\mu}(\tilde{y})\}$ and the left absorption $\tilde{\mu}(\tilde{r}\tilde{x}) \geq \tilde{\mu}(\tilde{x})$.

Fuzzy right ideal:
A fuzzy set $\tilde{\mu}$ on R is a fuzzy right ideal if for all $\tilde{x},\tilde{y},\tilde{r} \in$ R.It should have additive closure i.e.$\tilde{\mu}(\tilde{x}-\tilde{y}) \geq \min\{\tilde{\mu}(\tilde{x}),\tilde{\mu}(\tilde{y})\}$ and the rightabsorption $\tilde{\mu}(\tilde{x}\tilde{r}) \geq \tilde{\mu}(\tilde{x})$.

Definition:2.3
The fuzzy set $\tilde{\mu}$ is called a fuzzy 2-absorbing ideal of R if:$\tilde{\mu}$ is a fuzzy ideal of R, and for all a,b,c∈R, $\tilde{\mu}(abc) \geq \min\{\tilde{\mu}(ab),\tilde{\mu}(ac),\tilde{\mu}(bc)\}$.

Some Theorems on Fuzzy 2-Absorbing Ideals in Non-Commutative rings
Theorem: 3.1
Let$\tilde{A}$ be a fuzzy 2 absorbing ideal of Rand let $\tilde{I}$ be a fuzzy right ideal ofR. If b,c ∈ R,$\tilde{I}RbRc \subseteq \tilde{A}$ then$\tilde{I}b \subseteq \tilde{A}$ or $bc \in \tilde{A}$ or $\tilde{I}c \subseteq \tilde{A}$.

Proof:
Assume that$\tilde{I}RbRc \subseteq \tilde{A}$,
suppose, to the contrary that
$\tilde{I}b \not\subseteq \tilde{A}$, $bc \notin \tilde{A}$, $\tilde{I}c \not\subseteq \tilde{A}$.
Then there exists element $a, a_1 \in R$ such that
$\tilde{I}(a) > \tilde{A}(ab)$ and $\tilde{I}(a_1) > \tilde{A}(a_1c)$ ---- (i)
Since $\tilde{I}$ is a fuzzy right ideal, we have
$\tilde{I}(ab) \geq \tilde{I}(a)$, $\tilde{I}(a_1\tilde{c}) \geq \tilde{I}(a_1)$ ----- (ii)
By the hypothesis$\tilde{I}RbRc \subseteq \tilde{A}$, it follows that
$\tilde{A}(abc) \geq \tilde{I}(a)$, $\tilde{A}(a_1bc) \geq \tilde{I}(a_1)$----- (iii)
Now focus only on a. Since $\tilde{A}$ is a fuzzy 2 – absorbing ideal, we have
$\tilde{A}(abc) \geq \min\{\tilde{A}(ab),\tilde{A}(bc),\tilde{A}(ac)\}$ --- (iv)
From our assumption $\tilde{A}(bc) < \tilde{I}(a)$, $\tilde{A}(ab) < \tilde{I}(a)$
By the choice of a from $\tilde{I}b \not\subseteq \tilde{A}$, so
$\min\{\tilde{A}(ab),\tilde{A}(bc),\tilde{A}(ac) \leq \tilde{A}(ab) < \tilde{I}(a)$ --- (v)

but from (iii) and (iv),
Therefore, $\tilde{A}(abc) \geq \min\{\tilde{A}(ab), \tilde{A}(bc), \tilde{A}(ac)\}$
Combining this with (v) gives
$\tilde{A}(abc) < \tilde{I}(a)$
Which contradicts (iii), which says $\tilde{A}(abc) \geq \tilde{I}(a)$
This contradiction shows that our assumption is false. Therefore
$\tilde{I}b \subseteq \tilde{A}$ or $bc \in \tilde{A}$ or $\tilde{I}c \subseteq \tilde{A}$.

Theorem: 3.2
Let$\tilde{A}$ be a fuzzy 2 absorbing ideal of R and let $\tilde{J}$ be a fuzzy right ideal ofR.If $a,c \in R$, $aR\tilde{J}Rc \subseteq \tilde{A}$ thena$\tilde{J} \subseteq \tilde{A}$ or $\tilde{J}c \subseteq \tilde{A}$ or $ac \in \tilde{A}$.

Proof:
Assume that $aR\tilde{J}Rc \subseteq \tilde{A}$.
Suppose, for contradiction, that
$a\tilde{J} \not\subseteq \tilde{A}$, $\tilde{J}c \not\subseteq \tilde{A}$, $ac \notin \tilde{A}$.
Then there exists $j \epsilon \tilde{J}$ such that
$\tilde{A}(aj) < \tilde{J}(j)$and $\tilde{A}(jc) < \tilde{J}(j)$. --- (i)
By hypothesis$a\dot{R}\tilde{J}\dot{R}c \subseteq \tilde{A}$, in particular
$\tilde{A}(ajc) \geq \tilde{J}(j)$--- (ii)
Since $\tilde{A}$ is s fuzzy 2 – absorbing ideal, we have
$\tilde{A}(ajc) \geq \min\{\tilde{A}(aj), \tilde{A}(ac), \tilde{A}(jc)\}$ --- (iii)
By assumption (i), and the fact that $ac \notin \tilde{A}$, we have
$\tilde{A}(aj) < \tilde{J}(j), \tilde{A}(ac) < \tilde{J}(j), \tilde{A}(jc) < \tilde{J}(j)$,
So
$\min\{\tilde{A}(aj), \tilde{A}(ac), \tilde{A}(jc)\} < \tilde{J}(j)$ --- (iv)
From (iii) and (iv) it follows that
$\tilde{A}(ajc) < \tilde{J}(j)$
Which contradicts (ii), which say $\tilde{A}(ajc) \geq \tilde{J}(j)$
This Contradiction shows that our assumption is false.
Hence$a\tilde{J} \subseteq \tilde{A}$ or $\tilde{J}c \subseteq \tilde{A}$ or $ac \in \tilde{A}$.

Theorem:3.3
Let$\tilde{A}$ be a fuzzy 2 absorbing ideal of R and let $\tilde{K}$ be a fuzzy right ideal ofR. If$a,b \in R$,$aRbR\tilde{K} \subseteq \tilde{A}$then$ab \in \tilde{A}$ or $b\tilde{K} \subseteq \tilde{A}$ or $a\tilde{K} \subseteq \tilde{A}$.

Proof:
Assume that $aRbR\tilde{K} \subseteq \tilde{A}$.
Suppose, for contradiction, that
$ab \notin \tilde{A}$or$b\tilde{K} \not\subseteq \tilde{A}$ or $a\tilde{K} \not\subseteq \tilde{A}$.
Then there exists $k \epsilon \tilde{K}$ such that
$\tilde{A}(bk) < \tilde{K}(k)$and $\tilde{A}(ak) < \tilde{K}(k)$. --- (i)
By hypothesis $aRbR\tilde{K} \subseteq \tilde{A}$, in particular
$\tilde{A}(abk) \geq \tilde{K}(k)$ --- (ii)
Since $\tilde{A}$ is s fuzzy 2 – absorbing ideal, we have
$\tilde{A}(abk) \geq \min\{\tilde{A}(ab), \tilde{A}(bk), \tilde{A}(ak)\}$ --- (iii)

By assumption (i), and the fact that $ab \notin \tilde{A}$, we have
$\tilde{A}(ab) < \tilde{K}(k)$, $\tilde{A}(bk) < \tilde{K}(k)$,$\tilde{A}(ak) < \tilde{K}(k)$,
So
$\min\{\tilde{A}(ab), \tilde{A}(bk), \tilde{A}(ak)\} < \tilde{K}(k)$ --- (iv)
From (iii) and (iv) it follows that
$\tilde{A}(abk) < \tilde{K}(k)$
Which contradicts (ii), which say $\tilde{A}(abk) \geq \tilde{K}(k)$
This Contradiction shows that our assumption is false.
Henceab $\in \tilde{A}$ or $b\tilde{K} \subseteq \tilde{A}$ or $a\tilde{K} \subseteq \tilde{A}$.

Theorem: 3.4
Let $\tilde{A}$ be a fuzzy right ideal of R then the following statements are equivalent: Statement:1For any fuzzy right ideal $\tilde{I}$ofR and any $b, c \in R$, $\tilde{I}RbRc \subseteq \tilde{A}$ implies $\tilde{I}b \subseteq \tilde{A}$ or $bc \in \tilde{A}$ or $\tilde{I}c \subseteq \tilde{A}$.
Statement:2 For any fuzzy right ideals $\tilde{I}, \tilde{J}$ of R and $c \in R$,$\tilde{I}R\tilde{J}Rc \subseteq \tilde{A}$ implies $\tilde{I}\tilde{J} \subseteq \tilde{A}$ or $\tilde{J}c \subseteq \tilde{A}$ or $\tilde{I}c \subseteq \tilde{A}$

Proof:
Assume that the statement (statement :1) holds.
Let $\tilde{I}$ and $\tilde{J}$ be anyfuzzy right ideals of R, and let $c \in R$such that
$\tilde{I}R\tilde{J}Rc \subseteq \tilde{A}$ -- (i)
We must prove that
$\tilde{I}\tilde{J} \subseteq \tilde{A}$ or $\tilde{J}c \subseteq \tilde{A}$ or $\tilde{I}c \subseteq \tilde{A}$ --- (ii)
Let $b \in R$ be such that $\tilde{J}(b) > 0$
For any $x \in R$
$(\tilde{I}RbRc)(x) \leq (\tilde{I}R\tilde{J}Rc)(x)$
So by (i)
$\tilde{I}RbRc \subseteq \tilde{A}$ --- (iii)
From the statement: 1 and from (iii), it follows that for every $b \in R$ with $\tilde{J}(b) > 0$
$\tilde{I}b \subseteq \tilde{A}$ or $bc \in \tilde{A}$ or $\tilde{I}c \subseteq \tilde{A}$ – (iv)
Case (i) $\tilde{I}c \subseteq \tilde{A}$, then the statement (ii) holds immediately
Case (ii) $\tilde{I}c \not\subseteq \tilde{A}$, then from (iv), for every $b \in R$ with $\tilde{J}(b) > 0$
$\tilde{I}b \subseteq \tilde{A}$ or $bc \in \tilde{A}$ --- (v)
Subcase (i)$\tilde{I}b \subseteq \tilde{A}$ for all $b \in R$with $\tilde{J}(b) > 0$, then for every $x \in R$,
$(\tilde{I}\tilde{J})(x) = \sup_{x=yb} \min\{\tilde{I}(y), \tilde{J}(b)\} \leq \tilde{A}(x)$,
So$\tilde{I}\tilde{J} \subseteq \tilde{A}$
Subcase (ii) There exists $b_0 \in R$ with $\tilde{J}(b_0) > 0$ such that $b_0 c \in \tilde{A}$.
Since $\tilde{A}$ is a fuzzy right ideal,we conclude that
$\tilde{J}Rc \subseteq \tilde{A}$
In all cases, $\tilde{I}\tilde{J} \subseteq \tilde{A}$ or $\tilde{J}c \subseteq \tilde{A}$ or $\tilde{I}c \subseteq \tilde{A}$
Thus statement (2) follows from statement (1)
Hence the proof.

Theorem:3.5
Let $\tilde{A}$ be a fuzzy right ideal of Ṙ then the following statements are equivalent: Statement:1 For any fuzzy right ideal $\tilde{J}$ of Rand any $a, c \in R$, $aR\tilde{J}Rc \subseteq \tilde{A}$ implies $a\tilde{J} \subseteq \tilde{A}$ or $\tilde{J}c \subseteq \tilde{A}$ or $ac \in \tilde{A}$
Statement:2 For any fuzzy right ideals $\tilde{J}, \tilde{K}$ of Rand $a \in R$, $aR\tilde{J}R\tilde{K} \subseteq \tilde{A}$ implies $a\tilde{J} \subseteq \tilde{A}$or $\tilde{J}\tilde{K} \subseteq \tilde{A}$ or $a\tilde{K} \subseteq \tilde{A}$

Proof:

Assume that S1 Holds.

Let $\tilde{J},\tilde{K}$ be a fuzzy right ideal of Rand a ∈ R such that

$aR\tilde{J}R\tilde{K}\subseteq\tilde{A}$ --- (i)

We want to show

$\tilde{J}\subseteq\tilde{A}$or $\tilde{J}\tilde{K}\subseteq\tilde{A}$ or $a\tilde{K}\subseteq\tilde{A}$ --- (ii)

Choose an element c ∈ R such that $\tilde{K}(c) > 0$. This is standard in fuzzy ideal arguments

For any x ∈ R

$aR\tilde{J}Rc(x) \leq aR\tilde{J}R\tilde{K}(x)$

Because $\tilde{K}(c) > 0$

Using (1) we get $aR\tilde{J}Rc\subseteq\tilde{A}$ --- (3)

By S1, one of the following holds $a\tilde{J}\subseteq\tilde{A}$, $\tilde{J}c\subseteq\tilde{A}$, $ac\in\tilde{A}$

Case (i) $a\tilde{J}\subseteq\tilde{A}$, then (2) is true immediately

Case (ii) $a\tilde{J}\not\subseteq\tilde{A}$, then for each c ∈ R with $\tilde{K}(c) > 0$

$\tilde{J}c\subseteq\tilde{A}$ or $ac\in\tilde{A}$ --- (iv)

Subcase (i) $\tilde{J}c\subseteq\tilde{A}$ for all c with $\tilde{K}(c) > 0$

Then by the sup – min composition of fuzzy ideals

$(\tilde{J}\tilde{K})(x) = \sup_{x=yc} \min\{\tilde{J}(y), \tilde{K}(c)\} \leq \tilde{A}(x)$

So $\tilde{J}\tilde{K}\subseteq\tilde{A}$

Subcase (ii) There exists $c_0\in R$ with $\tilde{K}(c_0) > 0$ such that $ac_0\in\tilde{A}$

Since $\tilde{A}$ is a fuzzy right ideal, by the property of fuzzy right ideals

$a\tilde{K}\subseteq\tilde{A}$

Thus, in this subcase, the third option of (2) holds.

In all cases, one of the three alternatives in (2) holds

$a\tilde{J}\subseteq\tilde{A}$or $\tilde{J}\tilde{K}\subseteq\tilde{A}$ or $a\tilde{K}\subseteq\tilde{A}$

Hence the proof.

Theorem:3.6

Let $\tilde{A}$ be a fuzzy right ideal of R then the following statements are equivalent: Statement:1 For any fuzzy right ideal $\tilde{J}$ of R and any a, b ∈ R, $aRbR\tilde{K}\subseteq\tilde{A}$ implies $ab\in\tilde{A}$ or $b\tilde{K}\subseteq\tilde{A}$ or $a\tilde{K}\subseteq\tilde{A}$

Statement:2 For any fuzzy right ideals $\tilde{I}, \tilde{K}$ of R and b ∈ R, $\tilde{I}RbR\tilde{K} \subseteq \tilde{A}$ implies $\tilde{I}b \subseteq \tilde{A}$ or $b\tilde{K} \subseteq \tilde{A}$ or $\tilde{I}\tilde{K} \subseteq \tilde{A}$.

Proof:

Assume that S1 Holds.

Let $\tilde{I},\tilde{K}$ be a fuzzy right ideal and let b ∈ R such that

$aR(bR\tilde{K})\subseteq\tilde{A}$ --- (i)

We want to show

$\tilde{I}b \subseteq \tilde{A}$ or $b\tilde{K} \subseteq \tilde{A}$ or $\tilde{I}\tilde{K} \subseteq \tilde{A}$ --- (ii)

Choose an element a ∈ Rwith$\tilde{I}(a) > 0$. This is standard in fuzzy ideal arguments

For any x ∈ R

$aR(bR\tilde{K})(x) \leq \tilde{I}RbR\tilde{K}(x)$

Because $\tilde{I}(a) > 0$

Hence $aR(bR\tilde{K})\subseteq\tilde{A}$ --- (3)

By S1, one of the following holds $ab\in\tilde{A}$, $b\tilde{K}\subseteq\tilde{A}$, $a\tilde{K}\subseteq\tilde{A}$

Case (i) b$\tilde{K} \subseteq \tilde{A}$, then (2) is true immediately

Case (ii) b$\tilde{K} \not\subseteq \tilde{A}$, then for each a ∈ R with $\tilde{I}(a) > 0$

ab∈$\tilde{A}$ or a$\tilde{K} \subseteq \tilde{A}$ --- (iv)

Subcase (i) a$\tilde{K} \subseteq \tilde{A}$ for all a with $\tilde{I}(a) > 0$

Then by the sup – min composition of fuzzy ideals

$(\tilde{I}\tilde{K})(x) = \sup_{x=ak} \min\{\tilde{I}(a), \tilde{K}(k)\} \leq \tilde{A}(x)$

So $\tilde{I}\tilde{K} \subseteq \tilde{A}$

Subcase (ii) a$\tilde{K} \not\subseteq \tilde{A}$ for all a with $\tilde{I}(a) > 0$

Then ab∈$\tilde{A}$ for all such a.

By sup – min composition $(\tilde{I}b)(x) = \sup_{x=ab} \min\{\tilde{I}(a), 1\} \leq \tilde{A}(x)$

So $\tilde{I}\, b \subseteq \tilde{A}$

In all cases, one of the three alternatives holds

$\tilde{I}b \subseteq \tilde{A}$ or b$\tilde{K} \subseteq \tilde{A}$ or $\tilde{I}\tilde{K} \subseteq \tilde{A}$.

Hence the proof.

Theorem: 3.7

Let $\tilde{A}$ be a fuzzy right ideal of R then the following statements are equivalent: Statement:1 For any fuzzy right ideal $\tilde{I}, \tilde{J}$ of R and any c ∈ R, $\tilde{I}R\tilde{J}Rc \subseteq \tilde{A}$ implies $\tilde{I}\tilde{J} \subseteq \tilde{A}$or $\tilde{J}c \subseteq \tilde{A}$ or $\tilde{I}c \subseteq \tilde{A}$

Statement:2 For any fuzzy right ideals $\tilde{I}, \tilde{J}, \tilde{K}$ of R, $\tilde{I}\tilde{J}\tilde{K} \subseteq \tilde{A}$ implies $\tilde{I}\tilde{J} \subseteq \tilde{A}$ or$\tilde{J}\tilde{K} \subseteq \tilde{A}$ or $\tilde{I}\tilde{K} \subseteq \tilde{A}$

Proof:

Assume that S1 Holds.

Let $\tilde{I}, \tilde{J}, \tilde{K}$ be a fuzzy right ideal of R such that

$\tilde{I}\tilde{J}\tilde{K} \subseteq \tilde{A}$ --- (i)

We want to show

$\tilde{I}\tilde{J} \subseteq \tilde{A}$ or $\tilde{J}\tilde{K} \subseteq \tilde{A}$ or $\tilde{I}\tilde{K} \subseteq \tilde{A}$ --- (ii)

Choose an element c ∈ R with $\tilde{K}(c) > 0$. This is standard in fuzzy ideal arguments

Then, for any x ∈ R

$\tilde{I}\tilde{J}Rc(x) \leq \tilde{I}\tilde{J}\tilde{K}(x)$

Because $\tilde{K}(c) > 0$

Hence $\tilde{I}\tilde{J}Rc \subseteq \tilde{A}$ --- (3)

By S1, one of the following holds $\tilde{I}\tilde{J} \subseteq \tilde{A}$, $\tilde{J}c \subseteq \tilde{A}$, $\tilde{I}c \subseteq \tilde{A}$

Case (i) $\tilde{I}\tilde{J} \subseteq \tilde{A}$, then (2) is true immediately

Case (ii) $\tilde{I}\tilde{J} \not\subseteq \tilde{A}$, then for each c ∈ R with $\tilde{K}(c) > 0$,

one of the following conditions must hold

$\tilde{J}c \subseteq \tilde{A}$ or $\tilde{I}c \subseteq \tilde{A}$ --- (iv)

Subcase (i) $\tilde{J}c \subseteq \tilde{A}$ for all c with $\tilde{K}(c) > 0$

Then by the sup – min composition of fuzzy ideals

$(\tilde{J}\tilde{K})(x) = \sup_{x=yc} \min\{\tilde{J}(y), \tilde{K}(c)\} \leq \tilde{A}(x)$

So $\tilde{J}\tilde{K} \subseteq \tilde{A}$

Subcase (ii) $\tilde{J}c \not\subseteq \tilde{A}$ for some $c_0 \in R$ with $\tilde{K}(c_0) > 0$

Then$\tilde{I}c_0 \not\subseteq \tilde{A}$

By sup – min composition

$(\tilde{I}\tilde{K})(x) = \sup_{x=ak} \min\{\tilde{I}(a), \tilde{K}(k)\} \leq \tilde{A}(x)$

So $\tilde{I}\tilde{K} \subseteq \tilde{A}$

In all cases, one of the three alternatives in (2) holds

$\tilde{I}\tilde{J} \subseteq \tilde{A}$ or $\tilde{J}\tilde{K} \subseteq \tilde{A}$ or $\tilde{I}\tilde{K} \subseteq \tilde{A}$

Hence the proof.

Theorem: 3.8

Let $\tilde{A}$ be a fuzzy right ideal of Rthen the following statements are equivalent: Statement:1 For any fuzzy right ideal $\tilde{J}, \tilde{K}$ of R and any a ∈ R, $aR\tilde{J}R\tilde{K} \subseteq \tilde{A}$ implies $a\tilde{J} \subseteq \tilde{A}$or $\tilde{J}\tilde{K} \subseteq \tilde{A}$ or $a\tilde{K} \subseteq \tilde{A}$

Statement:2 For any fuzzy right ideals $\tilde{I}, \tilde{J}, \tilde{K}$ of R, $\tilde{I}\tilde{J}\tilde{K} \subseteq \tilde{A}$ implies $\tilde{I}\tilde{J} \subseteq \tilde{A}$ or $\tilde{J}\tilde{K} \subseteq \tilde{A}$ or $\tilde{I}\tilde{K} \subseteq \tilde{A}$

Proof:

Assume that S1 Holds.

Let $\tilde{I}, \tilde{J}, \tilde{K}$ be a fuzzy right ideal of R such that

$\tilde{I}\tilde{J}\tilde{K} \subseteq \tilde{A}$ --- (i)

We want to show

$\tilde{I}\tilde{J} \subseteq \tilde{A}$ or $\tilde{J}\tilde{K} \subseteq \tilde{A}$ or $\tilde{I}\tilde{K} \subseteq \tilde{A}$ --- (ii)

Since $\tilde{I} \neq 0$, Choose an element a ∈ R such that

$\tilde{I}(a) > 0$.

This is standard in fuzzy ideal arguments.

For any x ∈ R

$(aR\tilde{J}R\tilde{K})(x) \leq (\tilde{I}\tilde{J}\tilde{K})(x)$

Because $\tilde{I}(a) > 0$ contributes positively to the sup – min composition

Hence, from (1)

$aR\tilde{J}R\tilde{K} \subseteq \tilde{A}$ --- (3)

By S1 and from (3), one of the following holds

$a\tilde{J} \subseteq \tilde{A}$or $\tilde{J}\tilde{K} \subseteq \tilde{A}$ or $a\tilde{K} \subseteq \tilde{A}$ --- (iv)

Case (i) $\tilde{J}\tilde{K} \subseteq \tilde{A}$, then (2) is holds immediately

Case (ii) $\tilde{J}\tilde{K} \not\subseteq \tilde{A}$ Then, for every a∈ R with $\tilde{I}(a) > 0$, (iv) implies

$a\tilde{J} \subseteq \tilde{A}$or $a\tilde{K} \subseteq \tilde{A}$ -- (v)

Subcase (i) $a\tilde{J} \subseteq \tilde{A}$for all a with $\tilde{I}(a) > 0$

For any x∈ R

$(\tilde{I}\tilde{J})(x) = \sup_{x=ay} \min\{\tilde{I}(a), \tilde{J}(y)\} \leq \tilde{A}(x)$

Hence,$\tilde{I}\tilde{J} \subseteq \tilde{A}$,

Thus (2) holds

Subcase(ii) There exists $a_0 \in R$ such that

$\tilde{I}(a_0) > 0$ and $a_0\tilde{J} \not\subseteq \tilde{A}$

By (v), it follows that

$a_0\tilde{K} \subseteq \tilde{A}$

For any x ∈ R

$(\tilde{I}\tilde{K})(x) = \sup_{x=ak} \min\{\tilde{I}(a), \tilde{K}(k)\} \leq \tilde{A}(x)$

And therefore $\tilde{I}\tilde{K} \subseteq \tilde{A}$, Thus (2) holds

In all cases, one of the following holds

$\tilde{I}\tilde{J} \subseteq \tilde{A}$ or $\tilde{J}\tilde{K} \subseteq \tilde{A}$ or $\tilde{I}\tilde{K} \subseteq \tilde{A}$. Hence the proof.

Theorem: 3.9

Let $\tilde{A}$ be a fuzzy right ideal of R then the following statements are equivalent: Statement:1 For any fuzzy right ideals $\tilde{I}, \tilde{K}$ of R and b ∈ R, $\tilde{I}Rb R\tilde{K} \subseteq \tilde{A}$ implies $\tilde{I}b \subseteq \tilde{A}$ or $b\tilde{K} \subseteq \tilde{A}$ or $\tilde{I}\tilde{K} \subseteq \tilde{A}$.

Statement:2 For any fuzzy right ideals $\tilde{I},\tilde{J},\tilde{K}$ of R , $\tilde{I}\tilde{J}\tilde{K}\subseteq\tilde{A}$ implies $\tilde{I}\tilde{J}\subseteq\tilde{A}$ or $\tilde{J}\tilde{K}\subseteq\tilde{A}$ or $\tilde{I}\tilde{K}\subseteq\tilde{A}$.

Proof:

Assume that S1 Holds.

Let $\tilde{I},\tilde{J},\tilde{K}$ be a fuzzy right ideal of R such that

$\tilde{I}\tilde{J}\tilde{K}\subseteq\tilde{A}$ --- (i)

We want to show

$\tilde{I}\tilde{J}\subseteq\tilde{A}$ or $\tilde{J}\tilde{K}\subseteq\tilde{A}$ or $\tilde{I}\tilde{K}\subseteq\tilde{A}$ --- (ii)

Since $\tilde{J}\neq 0$, Choose an element $b\in R$ such that

$\tilde{J}(b)>0$.

This is standard in fuzzy ideal arguments.

For any $x\in R$

$(\tilde{I}R(bR)\tilde{K})(x)\leq(\tilde{I}\tilde{J}\tilde{K})(x)$

Because $\tilde{J}(b)>0$ contributes positively to the sup – min composition

Hence, from (1)

$\tilde{I}R(bR)\tilde{K}\subseteq\tilde{A}$ --- (3)

By S1 and from (3), one of the following holds

$\tilde{I}b\subseteq\tilde{A}$ or $b\tilde{K}\subseteq\tilde{A}$ or $\tilde{I}\tilde{K}\subseteq\tilde{A}$ --- (iv)

Case (i) $\tilde{I}\tilde{K}\subseteq\tilde{A}$, then (2) is holds immediately

Case (ii) $\tilde{I}\tilde{K}\not\subseteq\tilde{A}$ Then, for every $b\in R$ with $\tilde{J}(b)>0$, (iv) implies

$\tilde{I}b\subseteq\tilde{A}$or $b\tilde{K}\subseteq\tilde{A}$ -- (v)

Subcase (i) $\tilde{I}b\subseteq\tilde{A}$for all bwith $\tilde{J}(b)>0$

For any $x\in R$

$(\tilde{I}\tilde{J})(x)=\sup_{x=ab}\min\{\tilde{I}(a),\tilde{J}(b)\}\leq\tilde{A}(x)$

Hence, $\tilde{I}\tilde{J}\subseteq\tilde{A}$,

Thus (2) holds

Subcase(ii) There exists $b_0\in\dot{R}$ such that

$\tilde{J}(b_0)>0$ and $\tilde{I}b_0\not\subseteq\tilde{A}$

By (v), it follows that

$B_0\tilde{K}\subseteq\tilde{A}$

For any $x\in R$

$(\tilde{I}\tilde{K})(x)=\sup_{x=bk}\min\{\tilde{J}(b),\tilde{K}(k)\}\leq\tilde{A}(x)$

And therefore $\tilde{J}\tilde{K}\subseteq\tilde{A}$, Thus (2) holds

In all cases, one of the following holds

$\tilde{I}\tilde{J}\subseteq\tilde{A}$ or $\tilde{J}\tilde{K}\subseteq\tilde{A}$ or $\tilde{I}\tilde{K}\subseteq\tilde{A}$. Hence the proof.

Theorem: 3.10

Let $\tilde{A}$ be a fuzzy right ideal of R. If for any fuzzy right ideals $\tilde{I},\tilde{J},\tilde{K}$ of R , $\tilde{I}\tilde{J}\tilde{K}\subseteq\tilde{A}$ implies $\tilde{I}\tilde{J}\subseteq\tilde{A}$ or $\tilde{J}\tilde{K}\subseteq\tilde{A}$ or $\tilde{I}\tilde{K}\subseteq\tilde{A}$then $\tilde{A}$ be a fuzzy 2 absorbing ideal of $\dot{R}$

Proof:

To prove that $\tilde{A}$ is a fuzzy 2 – absorbing ideal, we must show that for all

$a,b,c\in R$

$\tilde{a}\tilde{b}\tilde{c}\subseteq\tilde{A}\Rightarrow\tilde{a}\tilde{b}\subseteq\tilde{A}$ or $\tilde{b}\tilde{c}\subseteq\tilde{A}$ or $\tilde{a}\tilde{c}\subseteq\tilde{A}$

Where $\tilde{a}, \tilde{b}, \tilde{c}$ denote the fuzzy points at a,b,c respectively

Let $a, b, c \in R$ be arbitrary and suppose

$\tilde{a}\tilde{b}\tilde{c} \subseteq \tilde{A}$ -- (i)

Let $\tilde{I} = \tilde{a}$, the fuzzy ideal generated by a

$\tilde{J} = \tilde{b}$, the fuzzy ideal generated by b

$\tilde{K} = \tilde{c}$, the fuzzy ideal generated by c

Then $\tilde{I},\tilde{J},\tilde{K}$ are fuzzy ideals of $\dot{R}$ and

$\tilde{a} \leq \tilde{I}, \tilde{b} \leq \tilde{J}, \tilde{c} \leq \tilde{K}$

By monotonicity of the fuzzy product

$\tilde{a}\tilde{b}\tilde{c} \subseteq \tilde{I}\tilde{J}\tilde{K}$

Combining this with (i), we obtain

$\tilde{I}\tilde{J}\tilde{K} \subseteq \tilde{A}$ -- (ii)

From (ii) and the hypothesis, one of the following holds.

$\tilde{I}\tilde{J} \subseteq \tilde{A}$ or $\tilde{J}\tilde{K} \subseteq \tilde{A}$ or $\tilde{I}\tilde{K} \subseteq \tilde{A}$ – (iii)

Since $\tilde{a}\tilde{b} \subseteq \tilde{I}\tilde{J}$ or $\tilde{b}\tilde{c} \subseteq \tilde{J}\tilde{K}$ or $\tilde{a}\tilde{c} \subseteq \tilde{I}\tilde{K}$

It follows from (iii) that

$\tilde{a}\tilde{b} \subseteq \tilde{A}$ or $\tilde{b}\tilde{c} \subseteq \tilde{A}$ or $\tilde{a}\tilde{c} \subseteq \tilde{A}$

Therefore, by the definition, $\tilde{A}$ is a fuzzy 2 – absorbing ideal of R

Hence the proof.

CONCLUSION

The purpose of this paper is to introduce and study fuzzy 2-absorbing ideals in non-commutative rings. We investigate their fundamental properties, characterize them in terms of fuzzy ideal products, and examine their relationships with fuzzy prime and fuzzy semiprime ideals. Several illustrative examples are provided to demonstrate the distinct behavior of fuzzy 2-absorbing ideals in the non-commutative setting. Moreover, we establish conditions under which a fuzzy ideal becomes fuzzy 2-absorbing and explore how these ideals behave under ring homomorphisms and factor rings. This study not only extends existing results on fuzzy 2-absorbing ideals to a broader algebraic framework but also contributes to a deeper understanding of fuzzy ideal theory in non-commutative rings, opening avenues for further research in fuzzy algebra and its applications.

ABSTRACT

Loai Distribution using Control charts and probability distributions of process and quality characteristic data are the foundation of the statistical process control approach. Many manufacturing processes have skewed distributions by definition. In this instance, the capabilities of the process serve as the foundation for traditional control charts. Such erroneous assumptions would increase production costs and cause competitors to lose clients. Many researchers create control charts based on different distributions depending on the kind of process they are working with in order to allay such worries. The length biased Loai distribution is used in this study to create control charts that analyze the effectiveness of the production process.

Keywords: Statistical Quality control, Control charts, length biased Loai distribution

INTRODUCTION

Product quality is affected by variations in the manufacturing process. Both controllable and uncontrollable factors can cause process variation. Control charts are crucial instruments for guaranteeing superior products. Control charts, which are now a crucial tool in quality development, were first used by Professor Shewhart Walter. Control charts are used to keep an eye on a manufacturing process. Control charts should be used to guide quick decisions about the process; in other words, if a control chart analysis shows that the process is under control, no action should be taken. However, appropriate action should be taken to bring the process back under control if the control chart shows that it has moved. Consequently, a control chart shows the appropriate observation or time for remedial action. The upper and lower control limits (UCL and LCL) are two control limits that are used to track the process

mean or variance. These limitations are particularly helpful in lowering the quantity of faulty goods and, on the other hand, raising industrial revenue. Control charts that guarantee quality improve a sector's standing in the marketplace. when the distribution of interest quality is normal. Shewhart control charts are frequently used in the field to keep an eye on procedures. The variable of interest may actually have a non-normal distribution rather than a normal distribution. Many academics have created a variety of control charts over the course of the year. The application of the central limit theorem to control chart generation is illustrated using control charts for a normal distribution. Once more, gathering data in groups isn't always feasible. Because of this, in practice, classical distributions often fall short of offering sufficient correction for real data. For instance, the normal distribution is not a good choice if the data are asymmetric. The pertinent literature is evaluated in Section 2. The length Biased Loai distribution and related measurements are explained in Section 3. The statistical characteristics of the characteristic function and the moment generating function are covered in Section 4. The limitations of control are covered in Section 5. Section explains how to identify out-of-control situations using real data. There is a summary in Section 6.

REVIEW OF LITERATURE

Fisher (1934) was the first to propose using recently created probability models known as weighted probability distributions to examine how the method of ascertainment affects the distribution of recorded observations. Rao (1965) suggested and formulated the conventional practise of using standard distributions in connection with statistical data modelling in a general method after it was demonstrated to be incorrect. The use of weighted distributions alters the likelihood of events as witnessed and transcribed. The concept of weighted distributions provides an integrative technique for dealing with model specification and data interpretation.Weighted distributions provide a way for fitting the model to the unknown weight function when samples can be obtained from both the original and produced distributions. Khatree (1989) was the first to compare weighted and length biased distributions; they presented stability results as well as various biased distribution features. When the weighted function just considers the length of units, the weighted distributions become length skewed. More broadly, a distribution is said to be size biassed when the sampling process selects units with a proportionate probability to size. Several authors have analysed and investigated the different weighted probability models, as well as presented instances of how they are applied in various fields.Roy et al. discussed the Length Biased Weighted Weibull distribution (2011). Mir et al. also addressed the length biased beta distribution of the first kind (2013). Jing and Broderic also obtained the length biased inverse weibull distribution (2012). PalakomSeenoi et al. found the length biased Exponentiated inverted Weibull distribution (2014). Nelson proposed the Shewhart Control chart tests for distinct causes (1984). The length biassed erlang truncated exponential distribution with applicability was Rather (2020) were able to acquire the length biased Shanker distribution as an alternative to the classical distribution.Ganaie and Rajagopalan (2020) discussed the length biased Weighted Quasi Gamma distribution with characterizations and applications, discovering that it was more trustworthy and effective than the original distribution. The length biased weighted distribution has a variety of applications, including biology, ecology, the branching process, and reliability. Shanker and Shukla have investigated a two-parameter length biased shukla distribution (2019). The length biased Shukla distribution is utilised in the study to monitor the control chart and estimate the manufacturing process control limits. Recently introduced. Sakthivel and Pandiyan (2024), A stochastic model for length biased loai distribtution with properties and its application. I take that model newly introduced in Statistical Quality control charts.

Description of the distribution

$$f(x) = \frac{\theta^2}{\alpha+1}\left[\frac{1}{2}\, a\, \theta\, x^2 + \frac{1}{\theta+1}(1+x)\right] e^{-\theta x} \qquad (1)$$

In this section, we define the probability density function (pdf) and Cumulative distribution function of the Length biased Loai Distribution. We have considered a random variable x with a probability density function f(x). let w(x) bea non-negative weight function denote a new probability density function

$f_w(x) = \frac{w(x)*f(x)}{E\,[w(x)]}; x > 0$

There w(x) be the non-negative weight function and
$E[w(x)] = \int w(x)\ f(x)\ dx < \infty$ (2)

And corresponding random variable by X_w which is called the weighted random variable corresponding to X. When $w(x) = x^2\ ;\ x > 0$.
We say that X_w size biased of order c. Such a selection procedure is called Size-biased sampling of order C. When c=1,2, . . ., X_w is simply called Size-biased (or length biased) and has a probability density function.

$$f_w(x) = \frac{x\,f(x)}{E\,(x)};\quad x > 0$$

The Weighted distribution is obtained by applying the weighted function as $w(x) = x^c$, in weights we use c=1, then $w(x) = x$ to the Loai distribution in order to obtain the length biased Loai distribution. The pdf of the Length biased Loai distribution is given by

$$f_w(x;\ \alpha,\theta) = \frac{x\,f(x,\theta)}{E(x)}\ ,\quad x > 0,\ \theta > 0, \alpha \quad (3)$$

Where,

$$E\,(x) = \int_0^\infty x\,f(x;\theta)\,dx$$

After simplification we get gamma function is given by

$$\Gamma(z) = \int_0^\infty t^{z-1}e^{-t}\ dt$$
$$E\,(x) = \left[\frac{3\,\alpha\,(\theta+1)+\theta+2}{(\alpha+1)(\theta+1)\,\theta}\right] \quad (4)$$

Substitute the value of equation 1 & 4 in equation 3 we get the pdf of Length Biased Loai distribution

$$f_1(x;\ \alpha,\theta) = \left[\frac{\theta^3\,(\theta+1)}{3\,\alpha\,(\theta+1)+\theta+2}\right] * x\left[\frac{1}{2}\,\alpha\,\theta\,x^2 + \frac{1}{\theta+1}(1+x)\right] *\ e^{-\theta\,x} \quad (5)$$

After simplification using lower incomplete gamma function is given by

$$\gamma\big((z+1),\theta,x\big) = \int_0^{\theta\,x} t^{(x+1)-1}e^{-t}\ dt$$

We will get cdf of Length Biased Loai distribution is given by

$$f_L(x;\ \alpha,\theta) = \int_0^x f_l(x;\ \alpha,\theta)\,dx$$
$$= \left[\frac{\theta^3\,(\theta+1)}{3\,\alpha\,(\theta+1)+\ \theta+2}\right] * x\left[\frac{1}{2}\,\alpha\,\theta\,x^2 + \frac{1}{\theta+1}(1+x)\right] *\ e^{-\theta\,x}\,dx$$
$$= \frac{\theta^3(\theta+1)}{3\,\alpha\,(\theta+1)+\theta+2}\left[\frac{\alpha}{2}\int_0^{\theta\bar{x}} t^3\,e^{-t}dt\ + \frac{1}{\theta+t}\left(\int_0^{\theta\bar{x}}\ \theta\,t\,e^{-t}\,dt\right) + \int_0^{\theta\,\bar{x}} t^2e^{-t}\,dt\ \right] \quad (6)$$

After simplification of equation 6 , we obtain the cumulative distribution function of Length Biased Loai distribution.

$$f_L(x;\ \alpha,\theta) = \frac{(\theta+1)}{3\,\alpha\,(\theta+1)+\ \theta+2}\left[\frac{\alpha}{2}\,\gamma(4,\theta x) + \frac{1}{\theta+1}\big(\theta\,r\,(2,\theta x) + \gamma\,(3,\theta x)\big)\right] \quad (7)$$

Statistical properties

In this section, we have obtained various statistical properties of length Laoi distribution including its Moment Generating Function, Characteristic function, Moments, Mean and Variance, Maximum Likelihood Estimation are discussed and obtained.

Moment generating function

Let x_l follows Length biased Loai distribution then the moment generating function (mgf) of X is obtained as

$$Mx(t)=E(e^{tx})=\int_{-\infty}^{\infty} x\, f_l(x;\alpha,\theta)\, dx \text{ using taylors series}$$

$$Mx(t)=\left[1+\ tx+\ \frac{(tx)^2}{2!}+\cdots\right] f_l(x;\alpha,\theta)dx$$

$$Mx(t)=\frac{(\theta+1)}{[3\alpha(\theta+1)+\theta+2\}}\sum_{j=0}^{\infty}\frac{t_j}{j!\theta!}\left[\frac{\alpha}{2}\Gamma(j+4)+\frac{\theta\Gamma(j+2)+(j+3)}{\theta+1}\right.$$

Characteristic function

Similarly, the characteristic function of length biased Loai distribution can be obtained as

$$\varphi_x(t)=M_X(it)$$

$$Mx(t)=\frac{(\theta+1)}{[3\alpha(\theta+1)+\theta+2\}}\sum_{j=0}^{\infty}\frac{(it)^j}{j!\theta^j}\left[\frac{\alpha}{2}\Gamma(j+4)+\frac{\theta\Gamma(j+2)+(j+3)}{\theta+1}\right.$$

Performance measures of the Length Biased Loai distribution

Let X be the random variable following length biased Loai distributionwith parameters θ and α, then the r^{th} order moment$E(x^r)$of Xabout origin can be obtained as

$$E(x^r)=\ \mu_r^{'}=\ \int_0^{\infty} x^r f_i(x;\ \alpha,\theta)$$

$$=\int_0^{\infty} x^r\frac{\theta^3\ (\theta+1)}{3\ \alpha\ (\theta+1)+\ \theta+2}\ x\ \left[\frac{1}{2}\ \alpha\ \theta\ x^2+\frac{1}{\theta+1}(1\ +x)\right]e^{-\theta\ x}\ dx$$

$$\mu_r^{'}=\frac{(\theta+1)}{\theta^r\ [3\ \alpha\ \ (\theta+1)+\theta+2]}\left[\frac{\alpha\ \Gamma(r+4)}{2}+\frac{\theta\ \ \Gamma(r+2)+\ \Gamma(r+3)}{\theta+1}\right] \quad (8)$$

Putting r = 1,2,3,4, in equation 8 the mean of Length Biased Loai distribution is obtained as

$$\mu_1^{'}=\frac{12\ \alpha\ (\theta+1)+2\ \theta+6}{\theta[3\ \alpha\ (\theta+1)+\ \theta+2]}$$

$$\mu_2^{'}=\frac{60\ \alpha\ (\theta+1)+6\ \theta+24}{\theta^2\ [3\ \alpha\ (\theta+1)+\ \theta+2]}$$

$$\mu_3^{'}=\frac{360\ \alpha\ (\theta+1)+24\ \theta+120}{\theta^3\ [3\ \alpha\ (\theta+1)+\ \theta+2]}$$

$$\mu_4^{'}=\frac{2520\ \alpha\ (\theta+1)+120\ \theta+720}{\theta^4\ [3\ \alpha\ (\theta+1)+\ \theta+2]}$$

$$variance=\ \mu_2^{'}-\ (\mu_1^{'})^2$$

$$\sigma^2=\left[\frac{60\ \alpha\ (\theta+1)+6\ \theta+24}{\theta^2[3\ \alpha\ (\theta+1)+\ \theta+2]}\right]-\left[\frac{12\ \alpha\ (\theta+1)+2\ \theta+6}{\theta[3\ \alpha\ (\theta+1)+\ \theta+2]}\right]^2$$

$$\sigma^2=\frac{60\ \alpha\ (\theta+1)+6\ \theta+24}{\theta^2[3\ \alpha\ (\theta+1)+\ \theta+2]}-\frac{12\ \alpha\ (\theta+1)+2\ \theta+6}{\theta[3\ \alpha\ (\theta+1)+\ \theta+2]}$$

After simplification, we get

$$var\ (x)=\ \sigma^2=\frac{36\ \alpha^2\theta^2+72\ \alpha^2\ \theta\ +36\ \alpha^2+15\ \alpha\ \theta^2-3\ \alpha\ \theta-18\ \alpha-20\theta-3\theta^2-\ 32}{\theta^2[3\ \alpha\ (\theta+1)+\ \theta+2]^2}$$

Maximum Likelihood Estimation and Fisher's Information Matrix

In this section, we will estimate the parameters of length biased Laoi distribution by using the method of maximum likelihood estimation and also derive its Fisher's information matrix. Let $X_1, X_2,,X_n$be a random sample of size n from the length biased Loai distribution, then the likelihood function is given by

$$L(x) = \prod_{i=1}^{n} f_l(x)$$

$$\Delta = \frac{L_1}{L_2} \prod_{i=1}^{n} \frac{f_l(x;\, \alpha, \theta)}{f(x_i, \theta)}$$

$$\Delta = \prod_{i=1}^{n} \frac{\frac{\theta^3}{3\alpha(\theta+1)+\theta+2} x_i \left[\frac{1}{2}\alpha\theta {x_i}^2 + \frac{1}{\theta+1}(1+x_i)\right] e^{-\theta x_i}}{\frac{\theta^2}{\alpha+1}\left[\frac{1}{2}\alpha\theta {x_i}^2 + \frac{1}{\theta+1}(1+x_i)\right] e^{-\theta x_i}}$$

Because of the complicated form of above likelihood equations, algebraically it is very difficult to solve the system of non-linear equations. Therefore, we use the numerical technique like Newton-Raphson method for estimating the required parameters of the proposed distribution.

In order to obtain the confidence interval, we use the asymptotic normality results. We have that if $\hat{\lambda} = (\hat{\theta},\ \hat{\alpha})$ denotes the MLE of $\lambda = (\theta,\ \alpha)$. We can state the result as follows:

$$\sqrt{n}(\hat{\lambda} - \lambda) \to N_2(0,\, I^{-1}(\lambda))$$

Where $I^{-1}(\lambda)$ is Fisher's Informationmatrix.i.e.

$$I(\lambda) = -\frac{1}{n}\begin{pmatrix} E\left(\frac{\partial^2 \log L}{\partial\theta^2}\right) & E\left(\frac{\partial^2 \log L}{\partial\theta\,\partial\alpha}\right) \\ E\left(\frac{\partial^2 \log L}{\partial\alpha\,\partial\theta}\right) & E\left(\frac{\partial^2 \log L}{\partial\alpha^2}\right) \end{pmatrix}$$

Since λ being unknown, we estimate $I^{-1}(\lambda)$ by $I^{-1}(\hat{\lambda})$ and this can be used to obtain asymptotic confidence intervals for θ and α.

Control limits using Length Biased Loai Distribution

Three sigma UCL and LCL are obtained as specified by Montgomery (2012) and one can get the control limits for Length biased two parameter Rani Distribution using (8) and (10) and are given by

$$\text{UCL} = \frac{12\alpha(\theta+1)+2\theta+6}{\theta[3\alpha(\theta+1)+\theta+2]} + 3\sqrt{\frac{36\alpha^2\theta^2+72\alpha^2\theta+36\alpha^2+15\alpha\theta^2-3\alpha\theta-18\alpha-20\theta-3\theta^2-32}{\theta^2[3\alpha(\theta+1+\theta+2)]^2}}$$

$$\text{CL} = \frac{12\alpha(\theta+1)+2\theta+6}{\theta[3\alpha(\theta+1)+\theta+2]}$$

$$\text{LCL} = \frac{12\alpha(\theta+1)+2\theta+6}{\theta[3\alpha(\theta+1)+\theta+2]} - 3\sqrt{\frac{36\alpha^2\theta^2+72\alpha^2\theta+36\alpha^2+15\alpha\theta^2-3\alpha\theta-18\alpha-20\theta-3\theta^2-32}{\theta^2[3\alpha(\theta+1+\theta+2)]^2}}$$

Numerical Illustration

An example regarding the construction of control limits is considered for illustrating the applications of the proposed method. The control limits of the Length biased Loai Distribution are obtained using simulated data set for parameters θ *and* α.All the generated samples are reported in Table 4.1.

Data Set:

A production manager for a phone flipcovers company has inspected the number of defective covers in five random samples with 300 flipcover in each sample. The table below shows the number of defective flipscover in each sample of 300 flipcovers.

5,	8,	4,	5,	7,	9,	5,	8,	5,	3,	8,	9,
5,	7,	3,	4,	5,	8,	6,	7,	3,	6,	2,	5,
6,	7,	4,	3,	5,	2,	4,	7,	4,	7,	5,	3,

When the process is non- normal distribution, a novel algorithm is given for sentencing the process while manufacturing. The Control limits are given for the Legth Biased Loai distribution with different values of parameters θ *and* α. Table 4.3 is constructed to help to the selection of the parameters based on the type of data the manufacturing engineer is faced with. The Control chart is drawn by considering the parameters α =7 and θ =1 where the observation is in control because it is the value of parameter α. Hence it is advisable to keep the α greater than the observed process data.

ABSTRACT

Employee welfare initiatives are important in enhancing the quality of work life for employees along with increased job satisfaction and organizational commitment. Employee welfare initiatives are more critical than ever in the software industry as organizations face fierce competition to hunt for, motivate, and retain skilled women employees. Creating a supportive work environment involves more welfare measures such as health and wellness programs, maternity benefits, flexible working arrangements, childcare support, transportation facilities, career development opportunities, workplace health and safety practices for support from top management to employee assistance programs. It is important for organizations in knowing what works and does not work in improving employee satisfaction, productivity an the success of these welfare measures. The aim of the current research is to investigate the impact of employee welfare measures on job satisfaction among women employees working in software companies. It tries to find out the significant welfare measures by various organizations, assesses job satisfaction of women employees and examines the relationship between employee welfare strategies and job satisfaction. It also examines the perceived impact of demographic variables such as age, education, experience, marital status and income on employees' perception towards welfare measures.

Keywords: Analyze, work experience, welfare measures, workplace safety

INTRODUCTION

In the era of stiff competition in every business sector, human resources are recognized as the most tangible asset for an organization. The dependability of a huge association lays on the devotion, motivation and fulfilment of its representatives. Employee welfare measures are one of the most important human resource management practices, because they enable workers get satisfactory minimum standards and provide health care to employees so that they work for well-being. Employee welfare entails the systems, means and perks given by the employer for the betterment of employees' physical, emotional, social and economic wellbeing. These measures do not only effect in enhancing the quality of work life but also improve the organizational climate resulting in higher employee morale and productivity. Women employees form large chunk of the workforce in various sectors like information technology, banking, education, healthcare, manufacturing and service industries. As more women are gaining traction in the workforce, organizations have put a greater emphasis on creating an environment that has been specifically tailored to meet the needs of females and focus on their unique challenges. Professional women manage their careers while also being burdened with family, custodial and personal matters. Thus, appropriate welfare measures are necessary to help the women employees in balancing work and home front responsibilities.

Using employee welfare measures refers to providing numerous facilities related to medical benefits, maternity leaves & paid leave, transportation facilities, flexible working hours, childcare support, workplace safety, various aspects of insurance coverage (healthcare plans), recreational facilities such a gym or garden and yoga rooms in office space; canteen service; training and development programmes that enhance the overall knowledge of an employee along with career advancement opportunities (providing a growth path) formally known as Employee Assistance Programme. Such welfare programs ensure that employees feel more valued, safe and motivated resulting in better job satisfaction and improved organizational commitment. Job satisfaction can be defined as a positive emotional state that is the result of an employee's evaluation of his or her job and work environment. It is a measure of how much do employees enjoy their job, find it motivating or feel that existing policy & practices in organization are fair. The job satisfaction of employees tends to generate higher productivity, better performance, strong organizational loyalty, low absenteeism and turnover intentions. On the contrary, inadequate welfare facilities can lead to dissatisfaction and stress causing poor morale, low efficiency and high employee attrition. Pragmatism on the job: Welfare measures have a profound impact on women employees when it comes to job satisfaction. Maternity leave, flexible work hours, health care benefits, safe transportation, child-care facilities at workplace, equal opportunity in career and grievance redressal systems will enable women to strike a good balance between their personal and professional life. Organizations that focus on employee well-being build a nurturing and enabling workplace culture for their women Employees, which motivates them to stay loyal and contribute towards the organization.

REVIEW OF LITRATURE

Kumari, A., & Rani (2018) were conducted a study on employee welfare practices in private and observed that good welfare facilities increase the motivation level of an employee, reduce absenteeism & turnover intentions from organization. The research pointed out that welfare programmes have significant positive impact on both employee wellbeing and organizational effectiveness. Hence, Gupta and Singh (2019) conducted a study in the banking sector on employee welfare measures resulted that welfare benefits can affect Employees satisfaction positively. Medical insurance, leave policies, retirement benefits and training programmes greatly improved employee engagement and productivity in the office. Prasad, Rao(2020) explored study of Welfare measure women employees in Healthcare institutions. The researchers found also that occupational safety, stress management programmes, transportation facilities and work-life balance initiatives with the highest impact on job satisfaction and employee commitment. Research among female employees working in information technology firms by Patel and Shah (2021) Flexible work arrangements such as telecommuting, wellness programmes, career development opportunities and employee

assistance programmes had a statistically important effect on satisfaction with their jobs and conducting better at work. Karthikeyan, N. and Mahalakshmi, S. (2022) Employee Welfare Practices in Educational Institutions: An Empirical Study of Management Schools in India. They concluded that welfare initiatives like medical infrastructure, leave benefits, professional growth programs and grievance redressal practices substantially enhanced faculty job satisfaction and organizational commitment. Ramesh and Priya (2023) investigated employee welfare measures of women employees' organisation in service organisations found that the higher were the organization provided with comprehensive welfare benefits, greater was employee satisfaction, organisation commitment strengthened and attrition reduced. The study suggests that there is a need to keep reassessing the welfare policies in order to address changing needs of women employees.

Statement of the Problem

They also have a human resource management component (employee welfare measures). Many organizations provide different types of welfare measures such as medical facilities, maternity leaves, flexible working hours, transportation facilities from pick up point to the workplace and back again along with self housekeeping devices at home, crèches for allowing wards to stay close by during work while being looked after well, safety amenities required in factories and recreational rooms / areas within firms etc. You will also benefit if employers allow wage incentives through higher earnings on completion of targets. These not only meet statutory requirements but also boost employee morale, organizational commitment, and overall productivity. Female employees have become an integral part of the workforce in different industries. However, they also face some challenges that are peculiar to them - juggling professional life and family, work pressure, health issues, safety concerns and lack of growth opportunities. Without proper welfare, these challenges may adversely impact the degree of job satisfaction among your employees. While several organizations have implemented employee welfare programs, not all seem to be addressing the unique needs of women employees. Today, in a competitive business environment Effort satisfaction has emerged as one of the important causes for employee performance, retention and organizational efficiency (Rawal et al. If women employees are happy about the welfare facilities that their organizations provide them, they will remain committed and motivated towards work along with being productive. On the other hand, poor or ineffective welfare activities will result in dissatisfaction, absenteeism, low productivity, bad work-life balance and attrition.

Objectives of the Study

Primary Objective

- To examine the role of employee welfare measures in enhancing job satisfaction among women employees.

Secondary Objectives

- To identify the various employee welfare measures provided to women employees in the organization.
- To assess the level of awareness and satisfaction of women employees regarding the welfare measures offered by their organization.
- To examine the relationship between employee welfare measures and the job satisfaction of women employees.
- To evaluate the impact of welfare measures on the work-life balance of women employees.
- To identify the welfare measures that most significantly influence the job satisfaction of women employees.

Scope of the Study

The objective of current study is to explore the impact of employee welfare measures towards job satisfaction among women employees. It is an attempt to assess different organisations in terms of the welfare amenities they provide and its impact on job satisfaction, motivation and overall health. The key welfare measures discussed in the study are health and medical benefits, maternity benefits, workplace safety, transportation facilities, flexible working hours, daycare and childcare support, insurance policy &benefits, leave benefits, training and development programme recreational facilitates work and life balance.

This study also evaluates the awareness and satisfaction of ladies faculty regarding welfare schemes provided to them by their organizations. Specifically, it explores the extent to which job satisfaction can be attributed to welfare measures and vice versa as well as identifying the elements with greatest contribution towards general employees' enthusiasm. Further, the research explores how demographic variables like age, education, marital status, work experience and monthly income affect employees' perception of welfare measures.

Limitations of the Study

- The study finding cannot be generalized since it is limited to women employees working in selected organizations.
- The study is mainly based on primary data collected through a structured questionnaire. The respondents themselves need to be honest and have a good understanding of the situation and they must also be willing to answer honestly for the findings from this are only as true as their answers.
- The research exclusively reviews a few aspects of employee welfare and job satisfaction. But work culture, leadership style, salary and promotion opportunity and personal situations may contribute to the job satisfaction which could not be part of this study.

RESEARCH METHODOLOGY

Research Design

The study is based on a descriptive research design, as it aims to describe the existing employee welfare measures and analyze their influence on the job satisfaction of women employees.

Nature of the Study

The study is analytical and descriptive in nature. It evaluates the relationship between employee welfare measures and job satisfaction among women employees.

Area of the Study

The study was conducted among women employees working in selected organizations. (The researcher may specify the organization, city, or district based on the actual study area.)

Sources of Data

Primary Data

Primary data were collected directly from women employees using a well-structured questionnaire. The questionnaire consisted of demographic questions and statements related to employee welfare measures and job satisfaction, measured using a five-point Likert scale.

Secondary Data

Secondary data were collected from books, research journals, magazines, company reports, government publications, conference proceedings, dissertations, and authentic online sources related to employee welfare and job satisfaction.

Sampling Technique

The study adopted convenience sampling, a non-probability sampling technique, to select respondents who were easily accessible and willing to participate in the survey.

Sample Size

The study was conducted among 100 women employees selected from the chosen organizations.

Data Analysis and Interpertation

Interpretation

The table shows that 42% of the respondents belong to the 25–35 years age group. 52% are postgraduates, 64% are married, 38% have 2–5 years of work experience, and 40% earn a monthly income between ₹20,001 and ₹40,000. The highest mean score (4.42) is recorded for Maternity Benefits, indicating that respondents perceive it as the most important welfare measure. Health & Medical Benefits ranks second (Mean = 4.35), while Recreational Facilities receive the lowest mean score (3.74). Since the calculated Chi-square value (13.482) is greater than the table value (12.592) and the p-value (0.036) is less than 0.05, the null hypothesis is rejected. Therefore, there is a significant association between age and job satisfaction among women employees.

Findings,

- 42% respondents were of the ages between 25–35 years
- Postgraduate students comprise over half (52%) of the participants.
- Most of respondents (64%) are married.
- About 38% of all respondents are also in the range 2–5 years work experience.
- 40% of the respondents earn between ₹20,001 and ₹40,000 per month
- Both surveys found that most respondents were happy with the employee welfare measures offered by their employer.
- Among all welfare measures, maternity benefits received the highest satisfaction ranking.
- Health and medical benefits constitute the second most important welfare measure.
- Women employees benefitted significantly due to flexi working hours which steadied work life balance.
- Changes in workplace security and safety measures had a favorable outcome on employee confidence and job contentment.
- Improvement and archive opportunity for better exposure for employees by timely training and development programmes.
- Feedback on childcare and recreational facilities saw lower satisfaction ratings, prompting the council to propose improvements.

Suggestions

Based on the findings, the following suggestions are offered to improve employee welfare measures and enhance job satisfaction among women employees:

- Organizations can improve healthcare and medical welfare programmes with employee health insurance, regular health check-ups and wellness programs.
- Increase flexibility in working arrangements such as hybrid or flexible work, informal leave models, and work from home where possible to support women in meeting both professional and personal responsibilities.
- Employers should develop or enhance crèche establishments and support programmes that assist working mothers.
- Better workplace safety needs to be provided by better security systems, anti-harassment policies and grievance redressal mechanisms as well as awareness programmes.

CONCLUSION

Employee wellbeing measures are an integral part of good human resource management and play a vital role in employee satisfaction, motivation & organisational success. The current study explored the association between welfare measures for women employees and job satisfaction and established that welfare schemes positively impact employees' work experience overall. The results of this study show that welfare measures like health and medical benefits, maternity benefits, flexible working hours, workplace safety & training and development programs play a major role in job satisfaction. High commitment by women employees in terms of motivation, productivity, and

loyalty towards the organization when they feel appropriate welfare help. The result of the statistical analysis establishes a significant positive correlation between employee welfare practices and job satisfaction. Companies which implement thorough welfare programs often find it easier to keep their best employees, as well as less of a problem with absenteeism and turnover, due to feeling supported and welcome into their place of work. To summarise, treating employee welfare as another regulatory requirement would be a huge mistake but if seen in the form of strategic investment, it would end up paying infinite dividends. Since women bring in a lot of corporate value, they need to be understood where their welfare policies centering around job satisfaction at the workplace will certainly make them satisficed leading to an upward spiral for balancing talent and organization genius which eventually leads to sustainable improvement.

ABSTRACT

The English language has undergone a major change in the recent times with the usage of social media. It has not only affected the word selection and construction of the sentence but also influence the very notion of language among the youngsters. The current research paper tries to understand the way social media platforms such as Twitter, Facebook, Instagram, LinkedIn and many other such platforms have enhanced the change in the language with the use of abbreviations, emojis, internet slang and informal use of language. The paper explores the current trend of limitations on the character and AI generated content and the multi fold introduction of the tools. Though the significance of the social media in young generation is acknowledged, the paper tries to understand the implications at academia and professional levels. The social media acts as double-edged sword that enhances the creativity and enrichment of the language but also endangers the writing skills of the future generations. It accelerates the usage of informal and machine language in the university level thereby threatening the whole experience of academia. The paper by using the survey method, looks at the contradictory nature of social media that acclaims the benefits it brings to the field of education but questions the possibility of risk generation to the development of English language.

Keywords: Social Media, Formal Communication, Grammar, Linguistic Change

INTRODUCTION

Social media and Contemporary Communication- An Introduction

The upsurge in the social media platforms in the recent times has completed changed the way that people interact in the modern digitalised world. The introduction of Twitter, Instagram, TikTok, Facebook and LinkedIn have led to the introduction of new form of communication that has brevity, visual representation and more of interactive

engagement in communication. There are four main purposes for using social media applications, namely: entertainment, socialization, informative and academic. (Yang,2020).

> "Social media is basically a media which is used through various electronic devices and rechargeable devices like mobile phone, computer, tablets, and so many other ways to facilitate the people while sharing their ideas with others in an easy and systematic way. It is used mostly for communication and awareness around the world" (Kaplan Andreas and Michael, 2010).

With the increase in the multiple platforms the users are reinventing the English language that suits their needs. The conformist method of written communication such as letters and formal emails have rapidly lost its old sheen. It is now digitalised, and social media conversations are making an impact on the professional, academic and research writing community.

.

Need of Examining Social Media Influence on English Writing

The advancement of digital communication has initiateda discussion on the implications o English language. The social media analysts are of the opinion that it acts as a catalytic agent for linguistic development, fosters the growth of new vocabulary, abbreviations and informal visual-written communication. On the contrary, the critics raise certainconcerns about the diminishing formal writing skills, accuracy of grammar and the penetration of informal expressions in the formal academic writing. A comprehensive understanding of these dynamics is imperative for educators, linguists, and communication specialists, as it informs strategies to address the evolving demands of language use in the digital age.

LITERATURE REVIEW

The recent changes we find in the emergence of new short cuts, abbreviations and the rampant use of these words among all age groups is of considerable academic interest. The research done by various scholars on this topic varies from the linguistics influence on alteration in pedagogical readings. In the book Language and the Internet, Crystal (2011) throw light on how the online communication pushes a more eased and interactive style that is tending with the use of either abbreviations or acronyms. Though he appreciates the informality that adds to rapid communication, he also has raised concerns about the possibility of the spill over into the academic writing. Another work by Thurlow and McKay, (2004) have pointed out that the usage of social media has added to rise of 'Netspeak or textspeak'. This results in the adoption of the creative spellings, deviations in the conventional grammar usage and symbolic representation through pictures. In addition, the trends of using GIFs, mems into semi formal communication have become a daily phenomenon in the educated world. This sort of multimodal approach (Kress & van Leeuwen, 2001) to express the emotions makes a significant shift in the way communication is made and interpreted that blurs the line between conventional formal writing and pictorial representation.

Research Objectives and Methodological Framework

The current research paper tries to navigate the penetration of social media in the lives of the life in relation to the usage of English language. It uncovers the impressions and influence on English spelling, grammar, syntactic structures, and lexical choices. The study is a result of the carefully drafted questionnaire and filled by sample group of people using social media on everyday basis. The quantitative research design was aimed to capture the respondents 'social media pattern, and to understand how the minds of the people is perceiving the new change in the language pattern due to social media. The finding of the survey will surely contribute to understanding whether social media acts as a constructive force in the progression of new age English or detrimental factor in the growth of the English language. The study by that means adds to the ongoing pedagogical discourse on the convergence of technology and language

Social Media Usage Trends and Their Linguistic Implications

The recent upsurge in the usage of social media has affected both the formal and informal communication. The study takes a survey or tour to recognize how digital communication platforms has exerted influence on the English writing. Thus, it tries to get a get a deeper dive in the changed practices in online and offline linguistic practices.

Preferred Social Media Platforms and Their Linguistic Influence

The new generation of social media users have a varied options when it comes to choosing a particular platform based on its features, limitations, and the user experience and expectations. The target group that was part of the survey reveals how and why they use a particular platform.

Twitter/X: The platform is popular among the young generation as it has 280-character limit and attracts brevity, condensed thoughts, and frequent use of abbreviations like 'IMO' for 'in my opinion'. It also permits the users to omit the grammatical constraints. This kind of new writing though helps the youngsters to have a immediate attention in the larger world, it adversely affects their capacity of constructing longer and grammatically meaningful sentences in formal academic writing,

Instagram & TikTok: The fascination for a visual representation of the thoughts in a concise way has promoted these platforms. The social media platforms promote informal, casual language that is accompanied by hashtags and emojis. It shifts the focus on visual and communicative communication than on grammatical excellence. The visual description encourages brevity of expression added with emotional expression.

Facebook: A platform which mile stoned itself with many users in the early 2000s , provides a hybrid space where both formal and informal writing go hand in hand. The users get the liberty to choose their limit, style and narrative based on the purpose and the audience that the user is looking for. This flexibility in formal and informal communication made it quite sought after platform among all age groups and professions.

Reddit: Unlike the earlier discussed platforms, Reddit is identified for its structured elaborate discussions. It is a forum that helps to have baffling, complex and serpentine discussions and makes it well known as one of those few platforms where conventional formal writing is still intact.

LinkedIn: Though it started initially as professional networking sight, in the recent times, we witness a rise in the number of casual storytelling and narration of personal anecdotes. This shift emphasises the broader base of the platform to involve more of informal interaction even in the professional setup.

The current research paper tries to identify through survey method theplatform preferences. The study identifies correlations between specific platforms and users' writing styles, offering insights into how digital environments shape linguistic habits. The insights received from the questionnaire suggest that most of the respondent groups range between 18 to 25 years of age, which is highly valuable as the said age group is highly active and engaged in digital communication and social networking platforms. Among the different platforms that are discussed in the above section, the most popular in the youth is Instagram followed by Twitter/X, Facebook and Reddit.

Time Spent on Social Media and Its Linguistic Impact

It is observed that the amount of time spent on social media has a direct co relation to the language patterns, abbreviations in language. The questionnaire has divided the respondents into four groups based on the time they spend on a regular basis on the social media. The respondent who spends less than an hour is considered as a light user and the one who spends more than four hours is taken as heavy users. In between the two groups follow under moderate users. The survey understands to find a pattern in these groups with reference to the language change patterns. Statistical analysis of these trends helps identify thresholds at which social media usage significantly impacts writing habits, providing valuable data for educators and linguists.The on and average digital interaction of around 1 to 4 hours -as analysed through the response-points at the speed with which we need to embrace the new changes in the communication patterns.

Frequency of Abbreviations, Slang, and Emojis in Digital Writing

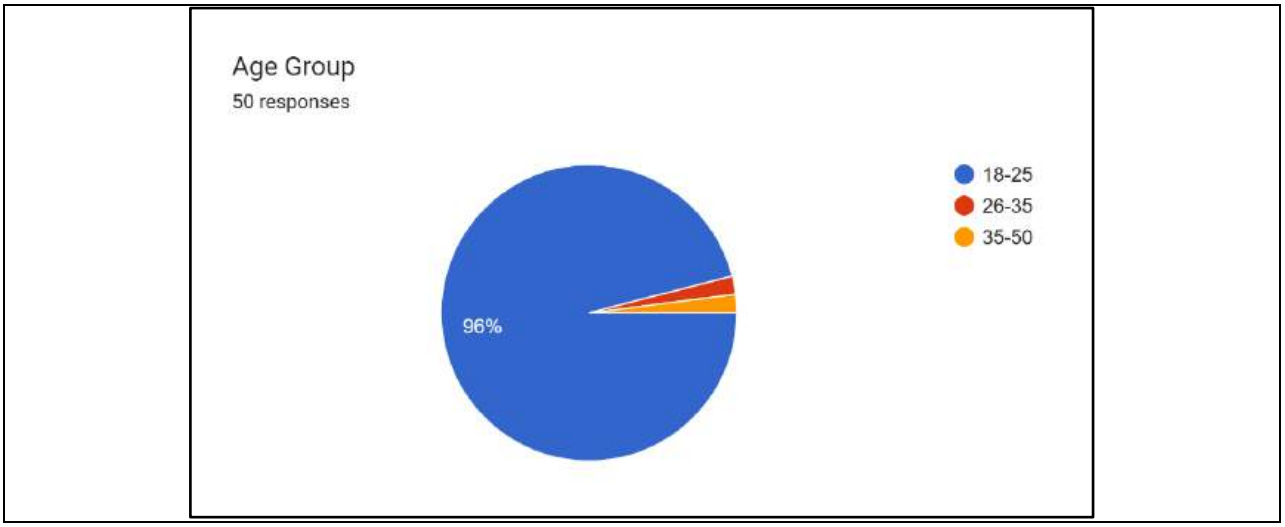
The need of the quick and brief effective communication has invented the abbreviations, internet slang, emojis and GIFs. The visual representation adds a curiosity and fun to the communication which in turn makes it effective. The rise in the social media has added to the invention of many a new abbreviation which were unheard in the conventional English language. The abbreviation has gained recognition in the semi formal writing. The research paper tried to examine the extent to which social media has influence language usage and writing style.

The frequent usage of these abbreviations and visual representationcertainly adds sheen to the informal digital communication but the frequent usage always puts a threat to the formal writing skills particularly among the young users. It is noted that many young generationsis quite familiar with and persistent on using and merging the emojis in the formal communication. The response received indicate it is a common practice among digital users to use the abbreviationsoften. Similarly, it is understood that visual and symbolic representations are in a larger way complementing the written textual communication. However, the use of memes as a part of formal communication is not widespread and used by the respondents on an occasional time and used with a selective purpose.

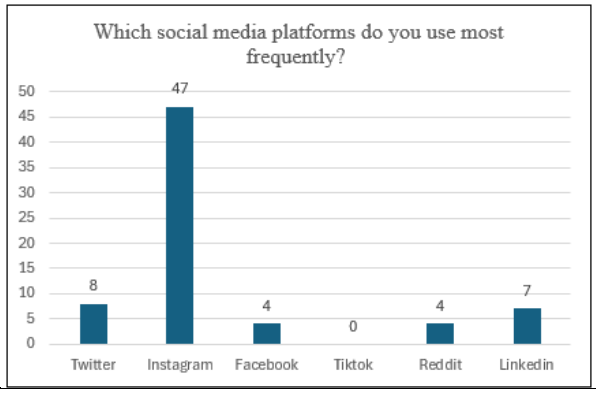
A critical element of exploration of the research study was to identify the adaptation of writing style s in between formal and informalcontexts. The responses collected however makes it clear that the respondents consciously make use of academic or professional communication in the official setups. This way of code switching where individuals adjust their linguistic choices based on the different communicative settings tells that the young generation takes care of choicest of the lexical sets. In addition, when asked the participants about the impact of social media on grammar and spelling, majority of the respondents a small influence. This indicates that while social media has introduced linguistic innovations, it may in the future raise concerns regarding grammatical accuracy and orthographic consistency.

This study looks at how social media language is changing the way we write, both online and offline. It explores how aware people are of different writing styles, the impact of things like hashtags and abbreviations, and how much social media language creeps into formal writing. The study found some people consciously switch between formal and informal writing, while others stick to traditional rules. It also shows how hashtags and shortened phrases have become a big part of online communication, often simplifying complex ideas or even changing how we structure sentences. A key finding is that social media language is influencing our formal writing, sometimes even showing up in emails or schoolwork. While some people are careful to keep the two separate, others mix them without realizing it, which could affect writing skills in the long run. The study also found examples of social media slang accidentally being used in formal settings. Basically, the study shows how social media is changing writing, and it gives educators and policymakers some food for thought about how to deal with these changes.

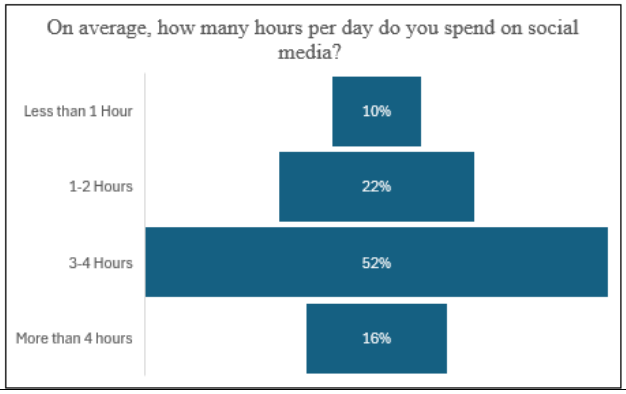
Analysis of Challenges and Perceptions



The present research paper findings from the research perspective offers some important understanding of the connection between the influence of social media on English writing. It is clearly state that though the social platforms have contributed to linguistic creativity, with new modes of expression, it has drastically changed the conventional language writing norms with a threat to grammatical precision. The study establishes the fact that though the respondents show the awareness of formal writing conventions despite being dominated by digital language. This sort of situational adaptation is commendable among the youngsters. The shift in the communication style is observed in the survey where visual communication elements like memes, emojis and GIFs are adding brevity and symbolic meaning to the messages. This is prioritized by the respondents over extensive textual descriptions.



To conclude, it is found that there exists a complex and evolving connection between social media and English writing. The positive part of the whole survey was that the students can compartmentalise the writing practices based on the context of writing. Nevertheless, there is a concern of language erosion but the ability to switch between



linguistic registers is crucial in contemporary digital communication. A further study in the field could explore how digital linguistic trends have a long-term effect on the writing proficiency of English language.

ABSTRACT

To compare the clinical and radiographic outcomes of platelet-rich fibrin (PRF) membrane versus resorbable collagen membrane, each combined with beta-tricalcium phosphate (β-TCP), in terms of implant stability and buccal bone width preservation around immediately placed implants in the anterior maxilla. Sixty patients requiring immediate implant placement in the anterior maxilla were randomly allocated to two groups (n = 30 each): Group A (PRF membrane + β-TCP) and Group B (collagen membrane + β-TCP). Implant stability quotient Revise to reflect that ISQ was assessed only at 3 months (per Methods/Results) e.g. Buccal bone width by CBCT at baseline and 3 months postoperatively; ISQ was assessed at 3 months postoperatively. Independent Student t-test and Student Paired t-test were used ($p < 0.05$). At 3 months post-operatively, Group A demonstrated a significantly greater mean buccal bone width (2.63 ± 0.56 mm) compared to Group B (2.08 ± 0.43 mm), with a statistically significant mean difference of 0.56 mm ($p = 0.004$). Mean ISQ values were also significantly higher in Group A (77.47 ± 3.25) than in Group B (74.63 ± 4.16), with a mean difference of 2.84 ($p = 0.04$). Both groups demonstrated significant intra-group increases in buccal bone width from baseline to 3 months ($p < 0.001$). Both PRF membrane and collagen membrane combined with β-TCP are effective for guided bone regeneration

around immediate implants. However, PRF membrane combined with β-TCP resulted in significantly superior buccal bone width preservation and implant stability at 3 months. PRF, as an autologous, growth-factor-rich, and cost-effective biomaterial, represents a promising alternative to collagen membrane for guided bone regeneration in the aesthetic zone.

Keywords: Platelet-Rich Fibrin; Beta-Tricalcium Phosphate; Dental Implants; Guided Bone Regeneration; Osseointegration.

INTRODUCTION

Immediate implant placement in fresh extraction sockets has become a widely practised surgical technique offering several clinical advantages: reduced treatment duration, preservation of alveolar bone architecture, maintenance of soft-tissue contours, and improved patient satisfaction [1,2]. In the anterior maxilla, where aesthetic demands are particularly high, the success of immediate implant placement depends critically on buccal bone plate preservation, adequate primary stability, and undisturbed soft-tissue healing. Despite its advantages, immediate implant placement is complicated by the peri-implant gap between the implant surface and socket walls, combined with inherent post-extraction resorption of the buccal cortical plate. These factors can lead to crestal bone loss, marginal tissue recession, and compromise of the aesthetic outcome [3,4]. The buccal bone plate at maxillary anterior sites may resorb by 30–50% in width within the first year following extraction, underscoring the need for effective bone preservation strategies at the time of implant placement [4]. Guided bone regeneration (GBR) has been established as a reliable technique for the management of peri-implant bone defects. GBR involves the use of a barrier membrane, with or without a bone grafting material, to exclude non-osteogenic soft tissue cells from the defect space and allow selective repopulation by osteogenic progenitor cells. Beta-tricalcium phosphate (β-TCP) is a widely used synthetic resorbable bone substitute that has demonstrated favourable osteoconductive properties, biocompatibility, and a controlled resorption profile that parallels new bone formation [5,6]. Its three-dimensional granular structure provides a scaffold for vascular ingrowth and osteoblast colonisation, making it a suitable graft material for the management of peri-implant extraction socket defects.

Collagen membranes have long represented the standard resorbable barrier membrane in GBR procedures, valued for their biocompatibility, haemostatic capacity, and low immunogenicity [7]. However, their relatively rapid enzymatic degradation, limited mechanical rigidity, and inability to actively promote bone regeneration through biological signalling remain recognised limitations [7]. Platelet-rich fibrin (PRF), introduced by Choukroun et al. in 2001, is a second-generation autologous platelet concentrate obtained by centrifugation of the patient's whole blood, requiring no exogenous thrombin or anticoagulants. The resultant PRF membrane is a three-dimensional fibrin matrix rich in platelets, leukocytes, and growth factors — including PDGF, TGF-β, IGF, FGF, VEGF, and EGF — released gradually over one to two weeks to provide a sustained biological stimulus for angiogenesis, cell migration, proliferation, and osteogenic differentiation [8,9]. The fibrin scaffold additionally stabilises the wound clot and guides tissue repair, properties not replicated by conventional collagen membranes [8,9].

A number of clinical and experimental studies have investigated the application of PRF as a barrier membrane or adjunct in various oral surgical and regenerative procedures, reporting favourable outcomes in terms of bone formation, soft-tissue healing, and implant stability [10–13]. However, direct comparative data evaluating PRF membrane versus resorbable collagen membrane, each used in conjunction with β-TCP, specifically around immediately placed implants in the anterior maxilla, remain limited. The present prospective randomised clinical trial was therefore designed to evaluate and compare the effects of these two membrane configurations on buccal bone width preservation and implant stability at a 3-month follow-up period, with the aim of providing clinically relevant evidence to guide biomaterial selection in immediate implant placement protocols.

MATERIALS AND METHODS

Study Design, Setting, and Ethical Approval

This prospective randomised parallel-group clinical trial was conducted at the Department of Oral and Maxillofacial Surgery, M.R. Ambedkar Dental College and Hospital, Bengaluru, from July 2022 to January 2024. The study was approved by the Institutional Ethics Committee (IEC/MRADC&H/EC040/2022) and conducted in accordance with the Declaration of Helsinki (1975, revised 2008). Written informed consent was obtained from each participant prior to enrolment.

Patient Selection

Consecutive patients presenting to the department requiring extraction of a single non-restorable tooth in the anterior maxillary region (2nd premolar to 2nd premolar) and fulfilling the eligibility criteria were enrolled. Inclusion criteria were: age ≥18 years; diagnosis of a non-restorable anterior maxillary tooth requiring extraction; presence of adequate bone volume at the extraction site to accommodate an implant of at least 3.5 mm diameter and 10 mm length with ≥3–4 mm of apical bone engagement beyond the socket apex; absence of active periapical pathology; and willingness to comply with the follow-up schedule. Exclusion criteria were: systemic conditions affecting bone metabolism, uncontrolled diabetes (HbA1c >8%), immunosuppressive or bisphosphonate therapy, active infection, heavy smoking (>10 cigarettes/day), pregnancy, head and neck irradiation, and inadequate bone volume. Eligible patients were randomly allocated using a computer-generated sequence to Group A (PRF membrane + β-TCP) or Group B (collagen membrane + β-TCP), with 30 patients per group.

Surgical Protocol

All procedures were performed under local anaesthesia (2% lidocaine with 1:100,000 adrenaline) by the same surgeon using a standardised protocol. A minimally traumatic, flapless or minimal-flap extraction technique was employed. Following atraumatic extraction using periotomes and forceps, the socket was thoroughly debrided of granulation tissue and remnant periodontal ligament fibres using curettes and copious saline irrigation. An implant osteotomy was then prepared in the apical and palatal regions of the socket, following the manufacturer's recommended drilling protocol. A JD implant system was selected and placed immediately into the fresh extraction socket with a minimum of 3–4 mm of apical bone engagement to ensure adequate primary stability. The peri-implant gap between the implant surface and the socket walls was measured, and the gap was subsequently filled with β-TCP granules in both groups, providing an osteoconductive scaffold for bone in-growth.

In Group A (PRF group), autologous PRF was prepared immediately prior to surgery from 10 mL of the patient's peripheral venous blood drawn into sterile glass-coated tubes without anticoagulant. Blood was centrifuged at 2700 revolutions per minute (rpm) for 12 minutes using an A-PRF centrifuge. Following centrifugation, the PRF clot was separated from the red blood cell fraction and compressed between two sterile gauze pieces to obtain a PRF membrane of uniform thickness (approximately 1–2 mm). This membrane was placed over the β-TCP graft material to cover the peri-implant defect and the coronal aspect of the socket. In Group B (collagen membrane group), a resorbable synthetic collagen membrane (ColoGide®)of appropriate size was adapted and placed over the β-TCP graft material (B-OstIN HT Granules, Size 0.125–0.500 mm, Basic Healthcare, India), covering the peri-implant defect in a manner analogous to that employed in Group A. Wound closure was achieved with interrupted 3-0 silk sutures in both groups. Patients received standardised post-operative instructions and were prescribed a 5-day course of amoxicillin 500 mg (three times daily), ibuprofen 400 mg (three times daily as needed for pain), and 0.2% chlorhexidine gluconate mouthwash (twice daily for two weeks). Sutures were removed at 7–10 days post-operatively. The final prosthetic restoration was not placed within the 3-month study period, and all implants were allowed to heal in a submerged fashion with healing abutments.

Outcome Measures

The primary outcome measures were: (1) buccal bone width (mm) assessed by CBCT at the pre-operative period and at 3 months post-operatively, measured at implant platform level 1 mm apical to the buccal bone crest (120 kVp, 5 mA, 0.2 mm voxel size), evaluated by a single calibrated radiologist blinded to group allocation; and (2) ISQ values assessed by resonance frequency analysis (Osstell® device, SmartPeg) at 3 months post-operatively. ISQ ranges from 1 to 100, with higher values indicating greater stability.

Statistical Analysis

Statistical analysis was performed using SPSS v22.0 (IBM Corp., USA). Continuous data are expressed as mean ± SD. Normality was assessed using the Shapiro–Wilk test. Inter-group comparisons used the Independent Student t-test; intra-group comparisons used the Student Paired t-test; categorical variables were compared using the Chi-square test. Significance was set at $p < 0.05$. The sample size of 30 per group was calculated based on the expected difference in buccal bone width with 80% power and an alpha of 0.05.

RESULTS

Patient Demographics and Baseline Characteristics

Sixty patients completed the study (30 per group). Groups were well matched at baseline for age (Group A: 34.6 ± 8.2 years; Group B: 35.1 ± 7.9 years), sex distribution, and pre-operative buccal bone width ($p = 0.79$, Table 1). Most patients presented with loss of maxillary central or lateral incisors due to trauma or failed endodontic treatment. Primary stability was achieved in all cases at the time of surgery.

Buccal Bone Width

The mean buccal bone width at the pre-operative period in Group A was 0.98 ± 0.34 mm and in Group B was 1.01 ± 0.31 mm, with a mean difference of −0.03 mm (95% CI: −0.26 to 0.20; $t = −0.274$; $p = 0.79$), indicating no statistically significant difference between the two groups at baseline (Table 1). At 3 months, the mean buccal bone width was significantly greater in Group A (2.63 ± 0.56 mm) than in Group B (2.08 ± 0.43 mm; mean difference 0.56 mm; 95% CI: 0.20–0.92; $t = 3.158$; $p = 0.004$) (Table 2, Figure 1). Both groups showed significant intra-group increases from baseline: Group A by 1.65 mm (95% CI: 1.32–1.98; $p < 0.001$, Table 4) and Group B by 1.06 mm (95% CI: 0.83–1.29; $p < 0.001$, Table 5), confirming that both configurations effectively promoted buccal bone gain, with PRF achieving significantly greater width.

Implant Stability Quotient

At 3 months post-operatively, the mean ISQ value in Group A was 77.47 ± 3.25, which was significantly higher than in Group B (74.63 ± 4.16), with a mean difference of 2.84 ISQ units (95% CI: 0.09 to 5.60; $t = 2.109$; $p = 0.04$) (Table 3, Figure 2). ISQ values in both groups were within the range considered indicative of adequate implant stability for prosthetic loading. These findings suggest that the use of PRF membrane with β-TCP is associated with a measurably greater degree of implant stability at 3 months compared to the collagen membrane with β-TCP configuration.

DISCUSSION

The results of the present randomised clinical trial demonstrate that immediate implant placement with PRF membrane combined with β-TCP in the anterior maxilla results in significantly greater buccal bone width preservation and implant stability at 3 months compared to the use of a resorbable collagen membrane combined with β-TCP. Both interventions led to statistically significant intra-group gains in buccal bone width from baseline, confirming that each biomaterial configuration is clinically effective for guided bone regeneration in this setting; however, the superior outcomes observed in the PRF group provide clinically relevant evidence to support the

preferential use of PRF as the barrier membrane of choice in immediate implant protocols. The significantly greater buccal bone width in Group A at 3 months is consistent with Mizar et al. [10], who reported superior bone fill and reduced dehiscence defects with PRF versus collagen membrane combined with β-TCP around immediately placed implants. Unlike collagen membranes, which act as a passive barrier, PRF provides an active biological environment through the sustained release of autologous growth factors — PDGF, TGF-β, IGF, FGF, and VEGF — over one to two weeks [8,9]. PDGF and TGF-β promote osteoblast recruitment, differentiation, and matrix synthesis; IGF and FGF support angiogenesis and cell proliferation, resulting in a more robust and accelerated osteogenic response compared to passive collagen membranes [8,9,11].

The three-dimensional fibrin matrix of PRF plays an equally important role in the regenerative process. This scaffold not only mechanically stabilises the blood clot and the underlying β-TCP graft material in the immediate post-operative period, but also facilitates the guided migration of osteogenic progenitor cells and endothelial cells into the defect space [8]. The fibrin network gradually reorganises as healing progresses, being replaced by newly formed granulation tissue and subsequently by woven and lamellar bone. In contrast, collagen membranes, while providing an effective physical barrier, are subject to faster enzymatic degradation by collagenase activity in the wound environment, potentially compromising space maintenance and barrier function before complete bone regeneration has occurred [7]. This difference in degradation kinetics may account, at least in part, for the superior bone width outcomes observed in the PRF group at 3 months.

The significantly higher ISQ values recorded in Group A at 3 months further support the clinical superiority of the PRF membrane configuration in this study. These findings are consistent with the observations of Öncü and Alaaddinoğlu [12] and the systematic review and meta-analysis by Tabassum et al. [13], both of which reported higher ISQ values and greater implant stability in PRF-treated implant sites compared to controls. The mechanism by which PRF enhances osseointegration is multifactorial: the growth factors released from PRF, particularly PDGF and TGF-β, are known to upregulate the expression of key osteogenic transcription factors and bone matrix proteins, promoting osteoblast recruitment and mineralisation of the peri-implant bone [8,9,11]. Additionally, PRF has been shown to modulate the local inflammatory response, reducing the duration and intensity of the early inflammatory phase and facilitating a more rapid transition to the proliferative and reparative phases of healing [19]. This earlier establishment of a favourable healing environment may contribute to accelerated bone-to-implant contact and higher ISQ values at earlier time points.

The reliable performance of β-TCP as an osteoconductive scaffold in both groups of the present study is in agreement with the established literature on this material [5,6]. The gradual, controlled resorption of β-TCP granules, matched to the rate of new bone formation, ensures that the defect space is progressively replaced by host bone tissue rather than fibrous connective tissue. Furthermore, β-TCP has been demonstrated to interact with resident mesenchymal stem cells to upregulate the expression of osteogenic genes, including Runt-related transcription factor 2 (RUNX2), secreted phosphoprotein 1 (SPP1), and bone gamma-carboxyglutamate protein (BGLAP), thereby actively contributing to the osteogenic differentiation process beyond its passive scaffolding role [15]. The combination of β-TCP with either PRF or collagen membrane appears to provide a synergistic regenerative environment, with the membrane maintaining the defect space and directing healing while the graft material supports new bone formation.
From a clinical perspective, PRF also offers practical advantages: as an autologous material, it carries no risk of disease transmission or immunological rejection — concerns relevant to animal-derived collagen membranes [7]. PRF preparation requires only a standard centrifuge and can be completed chair-side in approximately 15 minutes at minimal additional cost, in contrast to commercial collagen membranes, which represent a significant financial consideration in resource-limited settings [8,9].

Limitations include the short follow-up of 3 months (insufficient for long-term crestal bone and aesthetic assessment), absence of histomorphometric analysis, inherent CBCT measurement limitations, single-centre design, and the lack of aesthetic scoring parameters. The sample size of 30 per group was adequate for the primary outcomes assessed but

limits subgroup analysis. Future multicentre randomised trials with longer follow-up and histomorphometric assessment are warranted.

CONCLUSION

Both PRF membrane and collagen membrane combined with β-TCP effectively promote buccal bone regeneration and implant stability around immediate implants. The PRF group demonstrated significantly superior buccal bone width (2.63 ± 0.56 mm vs 2.08 ± 0.43 mm; p = 0.004) and ISQ values (77.47 ± 3.25 vs 74.63 ± 4.16; p = 0.04). As an autologous, biologically active, and cost-effective biomaterial, PRF membrane combined with β-TCP represents a superior alternative to collagen membrane for guided bone regeneration in immediate implant placement in the anterior maxilla.

ABSTRACT

Digital innovation within the banking sector has grown rapidly and mobile banking is now an essential service offered to customers. But this is not the case with all users as awareness and actual use of mobile banking services vary largely from person to person. It focuses on the awareness and usage of services provided through mobile banking, insight of factors that influence the adoption of banking services through mobile device and challenges faced by customers in using these services. The research employs a quantitative approach and uses primary data obtained from a structured questionnaire among customers of these banks. Data Secondary data were collected from journals, reports and official banks sources. The study following descriptive design, the data is interpreted through tools percentage analysis and graphical representation. Results indicates that adequate number of respondents are aware about mobile banking services but usage is dependent on multiple factors like ease of use, security issues, internet availability and technology literacy. Younger respondents and those with higher degrees are also more likely to adopt these technologies than the others. Problems such as fear of fraud, lack of technical knowledge and trust barriers limit the wide-ranging use, despite the greater convenience provided.

Keywords: Awareness, Digital Technology, Graphical Representation, Convenience

INTRODUCTION

Ever since the Information and Communication technology has grown on a fast lane, one of the industries which is now unrecognizably transformed through technology is banking. The evolution of banking is gradually moving from traditional banking methods to digital banking platforms, as with the rapid advancement of technology, customers can hardly visit banks anymore but can still access its service effortlessly. Mobile banking is one of the most popular digital banking channels, thanks to its ease of use, accessibility and efficiency. Mobile banking, which involves the use of mobile devices like smartphones and tablets to conduct banking transactions and access financial services via mobile applications or internet-based platforms. It enables customers to perform a variety of banking functions — from checking balances and transferring funds, to paying utility bills, mobile recharges for prepaid and post-paid services, opening deposits, applying for loans and tracking transactions anytime anywhere. SBI (State Bank of India) is the largest public sector bank in India and it has played a big role in promoting digital banking services. SBI has launched multiple mobile banking apps and digital moves to offer more convenience for customers and better productivity of banking services. Applications like YONO SBI have completely changed the way customers interact with banking services, offering a complete suite of financial and nonfinancial services on a single digital platform.

Although mobile banking is gaining a lot of popularity, customers' perceptions regarding its use are influenced by ease of use, security, assurance, accessibility, awareness and satisfaction. Banks should capture customer perception with tools that help them understand the in-depth areas of their digital services and identify their specific concerns that can stop effective adaptation and use of this mobile banking facility. SBI Siruseri Branch is a full-fledged branch that caters to the financial needs of employees, business professionals, students & residents in the local area. Due to the huge penetration of smartphones and internet, more clients in the branch are adopting mobile banking services. But customers can faces technical problems, security issues, network issues or lack of knowledge about advance mobile banking features. The objective of the study is to analyze how customer attitude towards mobile banking services in SBI Siruseri Branch. This study, concentrated on the customers of M-Banking services, assesses their awareness and usage patterns of mobile banking along with the satisfaction level, advantages they perceive and any challenges faced by them while availing M-Banking Services. According to the study, SBI should know customer expectations and formulate strategies to improve service quality, customer satisfaction and digital banking adoption. With an uptick in the number of choices available to consumers looking to leverage the benefits of mobile banking services, perception as a customer about your offering is key in determining whether you sink or swim. Hence this study gives an idea in mobile banking service perception of customer and its acceptance and continuance usage at SBI Siruseri Branch.

Statement of the Problem

More infographic facts and stats about the rapid digitalisation of banking sector — Amounting to a digital transformation over-the-time, mobile banking has gained incredible global adoption owing to fast growth for digital technology. Via smartphones and other mobile devices, Mobile Banking gives your customers the ability to conduct banking transactions around-the-clock. To offer more convenience to customers, improve the efficiency and practice of services offered, SBI offers multiple mobile banking facilities through Mobile Banking Application (SBIMB). Although mobile banking services have numerous benefits, consumers also encounter several problems such as security issues, technical faults, unawareness of the operations in mobile banking applications, challenges with network connectivity and trust issues. These factors could affect customers perception, satisfaction levels and their willingness to use Mobile Banking services frequently. Banks will need a good sense what customers feel so as to gauge how well their mobile banking services are doing and where they can use some enhancements. SBI, with its Siruseri Branch serves a customers who represent diverse backgrounds with different degree of tech knowledge and experience in banking. Thus, it is essential to understand consumer perceptions of mobile banking services, the service usages, perceived benefits and encountered problems. The aim of the current study is to investigate customer awareness level about mobile banking services of SBI Siruseri Branch and finding the factors affecting customer

acceptance, satisfaction and usage of mobile banking. The study results will assist the bank improve its digital banking services and boost customer satisfaction.

Need for the Study

The surge of digital banking led to the understanding of customers perception and use of mobile banking services. Even if mobile banking is accessible and efficient, customers may have difficulties using it due to lack of awareness, security concerns, technical problems, etc. Hence this is a study which is to be done for knowing awareness and Usage Mobile Banking Services between the Customers of SBI, Siruseri branch. It assists in identifying the factors affecting adoption, satisfaction of customers and also in understanding the problems faced by household through usage of mobile banking services. It can help the bank to make improved services and better customer experience.

Objectives of the Study

Primary Objective

- To study the customers' perception of mobile banking services offered by SBI Siruseri Branch.

Secondary Objectives

- To study the level of awareness of mobile banking services among SBI customers.
- To analyze the usage pattern of mobile banking services.
- To identify the factors influencing the adoption of mobile banking.
- To examine customer satisfaction with SBI mobile banking services.
- To identify the problems faced by customers while using mobile banking.

Scope of the Study

The present study aims to analyse the perception of customers towards mobile banking services provided by SBI Siruseri Branch. Mobile banking is a digital banking channel but it allows you to perform many financial transactions conveniently through your mobile device. This study seeks to a) Understand customer perspective on these services & b) How do customers use it in their quotidian banking. The study covers a range of aspects such as awareness, usage patterns, satisfaction levels and perceptions of customers about mobile banking facilities provided by SBI It also explores the determinants of mobile banking acceptance and continuity, including thoughts on convenience, accessibility, security, reliability and ease of use. Scope of the study: The scope of this study is only among the mobile banking customers using who are aware at SBI Siruseri Branch We have included several demographic factors like age, gender, educational qualification, occupation and income to know who impact of these factors over customers perception and usage behaviour.

Limitations of the Study

- This study is limited to only customers of SBI Siruseri Branch. Hence, the findings may not be generalized for other customers of SBI or any other banks.
- The analysis uses the responses of respondents. Therefore, the results depend upon participants being honest and mindful.
- As the study is performed in a specific timeframe, there could be changes in customers perception over time and may not be captured during this study.
- Limitations of the study only a small sample size has been chosen for this research and it may not represent all the customers in SBI Siruseri Branch.
- The study is restricted to the mobile banking services and does not include other channels of digital banking such as internet banking, ATM services or branch.
- What you do is dependent upon experiences, the technology and brand wealth at hand, and what you prefer, Person A to Person B may be completely different in it all.

RESEARCH METHODOLOGY

Research methodology refers to the systematic process used to collect, analyze, and interpret data for achieving the objectives of the study. It provides a framework for conducting research in a scientific and organized manner. The present study aims to analyze customers' perception of mobile banking services offered by SBI Siruseri Branch.

Research Design

The study adopts a descriptive research design to understand and analyze customers' perceptions, satisfaction levels, awareness, and usage patterns regarding mobile banking services provided by SBI Siruseri Branch.

Sources of Data

Primary Data

Primary data are collected directly from the respondents through a structured questionnaire. The questionnaire includes questions related to awareness, usage, satisfaction, benefits, and challenges associated with mobile banking services.

Secondary Data

Secondary data are collected from various sources such as:

- Books and journals related to banking and digital banking
- SBI annual reports and official publications
- Research articles and websites
- Magazines, newspapers, and online databases

Area of the Study

The study is conducted among the customers of SBI Siruseri Branch, Chennai.

Population of the Study

The population consists of all customers of SBI Siruseri Branch who are aware of or use mobile banking services.

Sample Size

A sample of 100 customers is selected for the study.

Sampling Technique

The study uses Convenience Sampling Technique, where respondents are selected based on their availability and willingness to participate in the survey

Data Analysis and Interpretation

Interpertation

The above table shows the age-wise distribution of respondents. Out of the 200 respondents, 150 respondents (75.0%) belong to the age group of 21–30 years, which constitutes the majority of the respondents. About 30 respondents (15.0%) are below 20 years of age, while 20 respondents (10.0%) belong to the age group of 31–40 years. Thus, it is evident that most of the respondents are in the 21–30 years age category. The above table shows the gender-wise distribution of respondents. Out of the 200 respondents, 120 respondents (60.0%) are female and 80 respondents (40.0%) are male. It is evident that female respondents constitute the majority of the sample. Therefore, the study indicates that a higher proportion of female customers participated in the survey compared to male customers.

Hypothesis 1: Association between Gender and Mobile Banking Usage

H_0: There is no significant association between gender and mobile banking usage.

H_1: There is a significant association between gender and mobile banking usage.

Interpretation

The calculated Chi-Square value is 0.641 with 1 degree of freedom, and the p-value is 0.423, which is greater than the significance level of 0.05. Therefore, we fail to reject the null hypothesis. There is no significant association between gender and mobile banking usage among SBI customers at the Siruseri Branch. This implies that mobile banking adoption is gender-neutral in the sample

Hypothesis 2: Association between Age Group and Awareness of Mobile Banking

H_0: There is no significant association between age group and awareness of mobile banking services.

H_1: There is a significant association between age group and awareness of mobile banking services.

Interpretation

The Chi-Square statistic is 0.784 with 2 degrees of freedom and a p-value of 0.676, which is greater than 0.05. Thus, we fail to reject the null hypothesis. There is no statistically significant association between age group and awareness of mobile banking services. High awareness levels across all age groups support this finding. Satisfaction Score Analysis The average satisfaction scores across all attributes range from 3.55 to 3.90 on a 5-point scale, indicating a generally positive perception of mobile banking services. Overall satisfaction (3.90) and willingness to recommend (3.85) are the highest-rated attributes, suggesting that satisfied users are likely to recommend mobile banking services to others. Accessibility received the lowest score (3.55), indicating opportunities for improvement in service availability and connectivity.

Findings of the Study

The study on awareness and usage of mobile banking services among SBI customers at the Siruseri branch yielded the following key findings:

- Most respondents (75%) are from the 21-30 age group, with females accounting for 60% and males for 40%.
- Three out of four respondents were well-informed (85%), with sources being mainly friends and family (50%) and staff from their bank branch (40%).
- YONO SBI is the best-known mobile banking platform with 65% respondents being aware of it.
- 65% of respondents are already using mobile banking services, and 35% know about them but have not yet used them.
- Network issues (45%) are the leading reported issue, followed by technical errors and security issues.
- Chi-Square tests of association for gender, age group and occupation all do not cause to reject the null hypothesis, in our sample it would seem that these 3 factors cause no significant differences between mobile banking awareness or usage.
- Satisfaction scores (4–13) are from 3.55 to 3.90 out of 5 on average, which indicates a positive user experience in general.
- The highest rated attributes are overall satisfaction (3.90) and willingness to recommend (3.85).

Suggestions

Based on the findings of the study, the following suggestions are recommended:

- SBI should strengthen the network stability and performance of mobile banking applications. At present YONO has certain network issues widespread to provide seamless connectivity for its offer set across India, this is one of major reasons that SBI is not able to utilize mobile platform completely.
- Focus awareness activities on customers above 30, as the adoption rates are relatively lower for this group. This can include offline workshops and in-branch demonstrations.
- To cope with security issues and raise confidence among doubtful consumers, the financial institution ought to use more potent and obvious safety features.
- Easy/simple on boarding &/or user tutorial in the YONO app to reduce any difficulties in login and technical errors (e.g. forged fingerprints etc) while using the application by HNWIs, FTUs should be addressed.
- WhatsApp Banking should be marketed as an available option for non-tech-savvy customers.

- Strengthening customer feedback mechanisms for continual monitoring and enhancement of the mobile banking experience.

CONCLUSIONS

The study is focused on the customers of SBI at Siruseri branch regarding their awareness and usage of mobile banking services. The results reinforce that although awareness is high actual use lags behind due to technical and psychological inertia. This study indicates that although Indian mobile banking has progressed to an emergent level, there are many opportunities for greater penetration of the technology. The demographic hypothesis testing results conclude that factors such as gender, age and occupation have no significance on the acceptance of mobile banking in this specific sample, which leads to the conclusion that obstacles are more behavioral or situational. SBI can substantially increase usage of mobile banking services by ensuring to provide targeted interventions and enhancing technical infrastructure- given the nature of its customer base.

ABSTRACT

Leaves of *Dodonaea viscosa* (L.) Jacq. have long been used in ethnomedicine to treat various human diseases. The focus of this study was to screen major phytochemical classes and determine their contents, and evaluate *in vitro* antioxidant activities. The total content of phenolic (TPC), flavonoid (TFC) and *in vitro* antioxidant activity (using hydroxyl, nitric oxide and DPPH assays) of ethanolic extracts were determined using spectro photometric method. Quantitative analysis of phytochemical constituents was performed using the Folin- Ciocalteu assay for TPC and the aluminium chloride colorimetric method for TFC estimation. The antioxidant capacity of the extract was subsequently evaluated through a series of *in vitro* radical scavenging assays, including DPPH, hydroxyl, and nitric oxide models, to comprehensively assess its free radical neutralizing potential. The results indicated substantial levels of phenolic content (80.53 mg GAE/g), and total flavonoids (26.59 mg QE/g) in the extract. The ethanolic leaf extract exhibited potent antioxidant activity in the DPPH assay, achieving up to 79% radical inhibition at the highest tested concentration, with an IC_{50} value of 47.43 µg/ml. In comparison, the extract showed moderate scavenging activity against hydroxyl and nitric oxide radicals, with IC_{50} values of 386.05 µg/ml and 560.66 µg/ml, respectively. Collectively, these findings highlight the strong antioxidant potential of the extract, which may be largely attributed to its rich phenolic and flavonoid composition. The findings also justify its relevance as a promising candidate in pharmaceutical development and pharmacological studies.

Keywords: ethnomedicine, phytochemical, Folin- Ciocalteu, phenolic and flavonoid composition.

INTRODUCTION

The family Sapindaceae comprises approximately 2000 species within 136 genera and still have been extensively recognized for its unique contribution as herbal medicine for the primary healthcare systems [1]. *Dodonaea viscosa*, a member from this family, is commonly known as Hop Bush, an evergreen shrub or small tree which is native to Australia and well-established in Western Ghats of India. Since ancient times, it has been used as a holistic medicine for the remedy of fever, rheumatism, gout, skin infections, diarrhoea, sore throat and haemorrhoids [2,3,4]. The leaf preparations are traditionally used for the treatment of sprain, bruises, etc and the bark employed for astringent bath and fomentations [5]. The long-term use of *Dodonaea* as traditional medicine by ethnic communities of different regions makes the plant to centralise its biological activity in modern medicines. A broad spectrum of vigorous plant derived compounds such as phenolics, flavonoids, alkaloids, terpenoids, anthraquinones, essential oils, saponins indicates its wide range of biological activities notably anti-diabetic, antimicrobial, insecticidal, antioxidant, antifertility, wound healing, anti-inflammatory, antidiarrheal,cytotoxic and detoxification effects[6]. Recent literature findings suggest that oxidative stress promotes the formation of free radicals, which are associated with various damaging effects, including cancer, neurogenerative, autoimmune, cardiovascular, inflammatory diseases and ageing[7,8]. Antioxidants are substances that prevent the oxidation of free radicals by acting as reducing agents, free radical scavengers, quenchers and metallic pre-oxidants[9].

Normally, the human body possesses an intrinsic antioxidant defence compounds like superoxide dismutase, glutathione peroxidase, glutathione reductase, thioredoxin, thiols, disulfide, vitamin E and vitamin C[10]. In addition, plants offer a diverse array of bioactive compounds with significant antioxidant activity. Phenolics and its subgroups such as phenolic acids, flavonoids, tannins, coumarins and lignin were the most occurring secondary metabolites and primarily act as phytoalexins, antioxidants, pollinator attractants, and protective agents against UV radiations [11]. Phenolic compounds and flavonoids are function as excellent antioxidant due to their redox properties [12]. Also, flavonoids are suggested to have a preventive role in the development of cancer, heart diseases, growth and defences [13]. Keeping these facts as references, phenolics and flavonoids present in *Dodonaea* are likely to contribute an inevitable role in mediating antioxidant activity. Several well-established biochemical and phytochemical methods have been commonly utilized to measure the phenolic richness and antioxidant capacities in medicinal plants, including total phenolic content (TPC) by Folin-Ciocalteu method, total flavonoid content (TFC) by aluminium chloride colorimetric method, hydroxyl radical ($OH^{\bullet}$), nitric oxide ($NO^{\bullet}$), DPPH (2,2-diphenyl-1-picrylhydrazyl) scavenging assays. Thus, the core purpose of this study is to evaluate the total phenolic content and total flavonoid content, along with the antioxidant potential of *D. viscosa* ethanolic leaf extract.

MATERIALS AND METHODS

Sample collection

The leaves of *D. viscosa* were collected from Nagercoil of Kanyakumari District, Tamil Nadu. Botanical authentication was done by Dr. G. Rajkumar, Principal scientist and Head PS & ES Division, JNTBGRI, Palode. The collected leaves were then washed thoroughly under tap water and subsequently shade dried for a period of three days.

Extract Preparation

The dried leaves sample was grounded into coarse powder by blender machine. About 30g of powdered sample was successively extracted with 300 ml of solvents of increasing polarity in petroleum ether, chloroform, ethyl acetate, ethanol, and methanol by Soxhlet extraction. After the completion of extraction, the solvents were allowed to evaporate under room temperature. The crude ethanol extract of *D. viscosa* was used for the determination of quantitative estimation of total phenolics, total flavonoids, and antioxidant activities.

Total phenolic content (TPC)

The total natural phenolic content in plant extract was quantified using the Folin-Ciocalteu method [14]. To 0.5 ml of the extract, 2.5 ml of Folin- Ciocalteu reagent was added. After 5 minutes, 2 ml of 75% sodium carbonate (Na_2CO_3) solution was added and kept the reaction mixture was undisturbed for an incubation period of 15 minutes at 45 ºC. The blue chromophore developed in the reaction mixture was measured at 765 nm against Gallic acid as the reference standard.

Total Flavonoid content

Aluminium chloride colorimetric method was used for summing up of total flavonoid content in the ethanol extract[15]. To 0.5 ml of test sample, 1.5 ml of methanol, 0.1 ml of 10% $Alcl_3$, 0.1 ml of 1 M potassium acetate and 2.8 ml of distilled water were added. The mixture was thoroughly mixed and hold back for incubation at room temperature for 30 minutes, and absorbance was measured at 415 nm. The result was expressed as milligrams of quercetin equivalent (mg QE)/g of dry sample weight.

Antioxidant Assays

Hydroxyl radical scavenging assay

The antioxidant activity of ethanolic extract by scavenging hydroxyl radical was executed using Fenton method with a slight modification [16]. To the different concentration of sample, 1ml of $FeSO_4$ (0.15Mm), 0.4ml of H_2O_2 (2Mm), 0.4ml of distilled water and 1ml of 6mM salicylic acid ethanol solution were mixed thoroughly and incubate for 1 hour at 37 ºC. After incubation, the absorbance was measured at 510 nm. Gallic acid and distilled water were used as standard drug and control, respectively. The hydroxyl radical scavenging activity was calculated as follows:

$$\text{Percent Scavenging activity} = \frac{[(Absorbance\ \ (control\ ) - Absorbance\ \ (Sample\ )]}{Absorbance\ \ (control\ )} \times 100$$

Nitric oxide scavenging assay

Nitric oxide radical inhibition by plant sample was estimated using Griess Illosvay reaction with slight modification in the reagent by using ethylene diamine dihydrochloride (0.1% W/V) instead of 1-napthylamine (5%)[17]. To a varying concentration of both ascorbic acid standard solutions and extracts, 3ml of Griess reagent, 2ml of 10Mm sodium nitroprusside, 0.5ml saline phosphate buffer were added and incubated for 150 minutes at 25º C. After incubation, 1ml sulfanilic acid reagent was mixed to 0.5ml of reaction mixture and allowed to stand for 5 minutes for the completion of reaction of diazotization. Further, 1ml of naphthyl ethylene diamine dihydrochloride was added, and incubate for 30 minutes at 25 ºC. The absorbance was read at 546 nm. Buffer was used as blank solution. The percent inhibition was calculated using the formula:

$$\text{Percent NO Scavenging activity} = \frac{[(Absorbance\ \ (control\ ) - Absorbance\ \ (Sample\ )]}{Absorbance\ \ (control\ )} \times 100$$

DPPH assay

The antioxidant activity of sample by scavenging a stable free radical DPPH was determined. Different concentrations of sample were taken in test tubes from the 1ml of extract prepared into 100 ml. Similarly, the ascorbic acid standard solution in different concentrations were also prepared from 1g of standard made up to 100ml with distilled water. All the test tubes were made up to 5ml. To initiate the activity, 1ml of DPPH was added to all the test tubes. The tubes were kept for incubation in dark for 1 hour. The absorbance was measured at 517 nm. The ethanol with DPPH solution was used as the control [18]. The graph of percent radical scavenging activity was plotted against the concentrations and the activity was calculated by the equation follows:

$$\text{DPPH Scavenges (\%)} = \frac{[(Absorbance\ \ (control\ ) - Absorbance\ \ (Sample\ )]}{Absorbance\ \ (control\ )} \times 100$$

RESULTS AND DISCUSSION

Polyphenols are hydroxyl-aromatic secondary metabolites involved in pigmentation, reproduction, and disease resistance. Flavonoids, represent the dominant class among polyphenolic compounds, due to their wide range of biological and chemical characterization [19]. Hence in the present study, preliminary quantitative estimation of total phenolic and flavonoids alongside *in vitro* antioxidant assays of ethanolic extract of *D. viscosa* were carried out. The quantitative phytochemical results of *D. viscosa* ethanolic leaf extract are presented in Table 1. Estimation of total phenol and total flavonoid in the plant extract exhibited 80.53 mg GAE/g and 26.59 mg QE/g, respectively. TPC assessed via Folin Ciocalteu method driven blue complex formation through electron transfer, and TFC was determined through Al^{3+}- flavonoid complexation produce a quantifiable yellow colour [20,21]. The body maintains a reliable oxidant- antioxidant status as a natural phenomenon. Although, free radicals like superoxide, hydroxyl, hydrogen peroxide, and nitric oxide are necessary for homeostasis, however, their accumulation elevated the risk of metabolic and cardiovascular diseases [22]. The antioxidant efficacy of phenolic compounds is largely due to their ability to sequester metal ions [23]. Flavonoids prevent the oxidative damage by inactivating the reactive oxygen species by acting as hydrogen donating molecules [24]. Free radical scavenging activity in ethanolic extract was appraised by *in vitro* antioxidant approaches such as hydroxyl radical scavenging assay, nitric oxide scavenging assay and DPPH assay.

Hydroxyl radicals are considered as major reactive species, and are highly related to inducing oxidative damage as it reacts with proteins, lipids, and nucleic acids [25]. Due to high reactivity, this radical claim either its scavenger is highly effective or may be present in higher concentration [26]. As depicted in Table 2, a gradual increase in radical inhibition was observed with increasing concentration, achieving 78.23 ± 0.1 µg/ml inhibition at 1000 µg/ml. Generally, the activity of the sample was slightly lower than that of gallic acid standard (81.24 ± 0.1 µg/ml) except at a concentration of 800 µg/ml. The Graph 1 indicates a concentration dependent increase in percentage inhibition, with the sample surpassing the standard at a concentration of 800 µg/ml. Nitric oxide (NO), are chemical mediators responsible for the regulation of various physiological processes[27]. However, the reaction of nitric oxide with either oxygen or superoxide makes it highly reactive and responsible for cellular components to alter their structural and functional behaviour [28]. The nitric oxide scavenging assay evaluates the competency of antioxidants with oxygen for nitric oxide, resulting in less nitrite formation. As shown in Table 3 and Graph 2, the extract and standard compete with nitric oxide at a concentration of 1000 µg/ml with a maximum scavenging activity of 75.47 ± 0.1 µg/ml and 80.4 ± 0.1 µg/ml, respectively. DPPH radical is an active stable free radical, widely used as substrate to determine the antioxidant activity of the plant extracts. The efficiency of plant extracts can be estimated by observing the bleaching of purple colour in DPPH absorption by donating either electron or hydrogen of antioxidants to DPPH[29]. Due to its exceptional stability, strong colour intensity and reduction to hydrazine through hydrogen donation from antioxidant compounds, marked it as an extensively used antioxidant assay[30]. From Table 4, the results clearly illustrate a noticeable quenching effect of ethanol extract on DPPH radical. At a maximum concentration of 100 µg/ml, the extract and standard exhibited an inhibition of 79.87 ± 0.10 µg/ml and 82.19 ± 0.10 µg/ml, respectively. The extract demonstrated a marked concentration dependent increase in scavenging activity, suggesting strong antioxidant potential. The Graph 3 indicates a positive correlation between concentration and DPPH radical scavenging activity for both standards and ethanolic extract. The IC_{50} value for each radical scavenging assays of both standards and ethanol extract are delineate as Table 5. The extract demonstrated differential antioxidant ability across different assays. A higher IC_{50} value of 386.05 µg/ml in hydroxyl radical and 560.66 µg/ml in nitric oxide radical scavenging assays compared to that of standards gallic acid (334.43 µg/ml) and ascorbic acid (408.5 µg/ml) respectively, reflecting moderate to weak activity. Conversely, relative lower IC_{50} value in the DPPH assay (47.43 µg/ml), which was slightly higher than the standard (32.11 µg/ml), indicates notable antioxidant potential.

CONCLUSION

Polyphenolic compounds are one of the largest and most extensively studied group of secondary metabolites in the plant kingdom and widely act as free radical terminators. Flavonoids, one of the major classes from this group shows significant antioxidant activity. The estimation of both secondary metabolites in the ethanol extract reveals this plant is rich in phenolic groups. Hence the quantification of total phenolic and flavonoid content are the key mediators to step on antioxidants studies. Also, the extract exhibits appreciable radical scavenging of hydroxyl, nitric oxide, and DPPH radicals. The quenching effect of the plant extract presumed that this exact is able to prevent many damages caused by free radicals. On the basis of the study regarding antioxidant capability *of Dodonaea*, it is scientifically proven that this plant is a good choice in pharmaceutical industries. It is worthwhile to further isolate the active antioxidant component in this plant favouring its antioxidant potentialities.

ACKNOWLEDGEMENT

The authors are gratefully acknowledging the Council of Scientific and Industrial Research (CSIR-UGC), Government of India, for providing the financial support for successfully carrying out this research work. We also acknowledge the institutional support and laboratory facilities.

ABSTRACT

The research carried out titled as "Factors Influencing Job Satisfaction among Bank Employees in Coimbatore District" examines the dimensions of job satisfaction. The research trend found includes factors like salary and compensation, promotion, work environment, job security, supervisory relationship with co-workers recognition of performance achieved in the workplace. Long term and short-term workload including a healthy ratio between work-family balance or work-personal life balance. These types of job satisfaction are also studied in relation to demographic variables. This research employs descriptive research design. A structured questionnaire was used to collect primary data from 100 bank employees of adequately selected public and private sector banks in Coimbatore District; The required data was collected from secondary sources like journals, books, websites and previous research. Statistical Package for Social Sciences (SPSS) was used to analyze the collected data. STATA 16 statistical tools (Percentage Analysis, Chi-Square Test, Independent Sample t-Test, One-Way ANOVA with Post-Hoc Tukey test one-way ANOVA built-in test functions in STATA version software) were used to interpret the data. The results of the study indicate that most bank employees enjoy moderate to high job satisfaction. The primary contributors to job satisfaction are salary, promotion opportunities, work environment and job security. Its analysis also revealed that workplace-related and management aspects such as supportive (50%), recognition for performance (39%) and work-life balance (38%) significantly enhance employee satisfaction. The result of the statistical analysis also show that some demographic variables are significantly related to job satisfaction. The study concludes that based on the conclusion, banks need to improve compensation packages and go about with fairness pertaining

to promotion policies, workplace conditions as well as some others by starting employee welfare programs. These measures will assist to raise employee satisfaction, minimize turnover intentions and promote organizational performance. The authors suggest that maintaining a high level of job satisfaction among bank employees is essential for sustainable growth and competitive advantage in the banking sector.

Keywords: Job Satisfaction, Bank Employees, Work Environment, Compensation, Promotion, Work-Life Balance, Employee Performance, Coimbatore District.

INTRODUCTION

The banking sector of India constitutes one of the main pillars of Indian economy and acts as a banker to the rest of the economy. The banking sector has witnessed a dramatic change in the last few years due to the rise of technology, growing competition, digital transformation and increased consumer expectations. Such developments also have raised the responsibilities and problems of bank employees, thereby making job satisfaction a key issue for both employees and management. Job satisfaction is how happy or content the employees feel with their jobs. It indicates the attitude of an employee with respect to salary, chances of promotions, job security and working conditions etc. Employee performance, productivity, commitment, absenteeism and employee turnover improves with job satisfaction factors. On the other hand, dissatisfaction leads to sub-optimal performance, stress, low morale and lesser effectiveness of your organization. In the banking sector, the employees are frontline performers as they are your first line of contact between you and customers. Hence, their job satisfaction directly influences quality of customer service and organizational success. Compensation, workload, opportunity for growth and development, work-life balance, supervisor support, organizational climate, and workplace environment are significant factors that impact employee satisfaction. Knowledge of these factors is critical for the formulation of effective human resource policies and maintaining an appropriate level of motivation in the workforce.

Coimbatore District is one of the prominent business and industrial hubs in Tamil Nadu and has an extensive network of banks including public sector, private sector, co-operative and regional rural banks. The district is also experiencing the thrive of financial activities thereby increasing the need for effective banking services and placing big burden on workers in banks. Therefore, evaluating the variables that affect job satisfaction is crucial to promoting organizational effectiveness and employee well-being. The current study is limited to recognising, and analysing the determinants of job satisfaction of bank employees in Coimbatore District. The paper focuses on the role of salary, promotion opportunities, work environment, job security, recognition, workload and work-life balance on employee satisfaction. It is anticipated that study findings would give meaningful guidelines to bank management for the development of intervention strategies and successful delivery of objectives at organizational level with respect to employees, given influence on overall performance. In the present competitive business world, companies that put employees at work first are mostly favoured in assuring ongoing growth and long-term success. Hence, it is imperative to have a basic understanding of the determinants of job satisfaction among bank employees in order to develop a customer driven workforce committed to be productive.

REVIEW OF LITRATURE

According to Locke (1976) a job satisfaction is one and the pleasurable or positive emotional state resulting from the appraisal of one's job or job experiences. This research highlighted the role of salary, promotion opportunities, supervision and working conditions as factors that impact employee satisfaction. Spector (1997) analyzed heterogenous aspects of job satisfaction and concluded that the sense of satifaction among employees is dependent on pay, promotion, supervision, fringe benefits, rewards, procedures for operation, co-workers,, nature of work and

communication. They came to a conclusion that Employees with high job satisfaction lead to organizational effectiveness. Oshagbemi (2000) explored the relationship among age, length of service, and job satisfaction. More experienced employees were found to have higher levels of job satisfaction because they feel more secure in regard to their jobs and that they are more committed to the company. Crossman and Abou-Zaki (2003) The impact of job satisfaction on employee performance 71 analyzed the employees in the banking sector and found that pay, promotion opportunity and management support make a large contribution. A positive work environment can play a key role in boosting employee morale, the study state. Malik, Nawab, Naeem, and Danish (2010)The main findings from this research look into the factors that affect job satisfaction among banking employees in Pakistan and discovered that compensation is a major factor of employee satisfaction but also career growth opportunities as well as organizational policies which affect bank morale. The researchers concluded that motivation and recognition of employees are integral to the improvement in satisfaction levels.

Puspakumari (2008) studied the effect of Job Satisfaction on Performance. Ohaleteh et al. The results showed a very high correlation between workers satisfaction and productivity. Job-oriented people usually achieve better performance and commitment to the organization. Based upon limited previous research, the focus of study was done on job satisfaction among employees in the service sector (Santhapparaj and Alam, 2005) In this regard work environment, management support, opportunities for professional development significantly influence employee satisfaction. The researchers proposed pro-worker policies that are likely to lead to better workplace wellness. Kumari and Pandey (2011) In this study the researchers have studied job satisfaction of public & private sector bank employees. Having better opportunities for career growth and incentive or performance based recognition Private Sector Bank employees are found to be more satisfied in their job. Kaur (2012) Studies Work Life Balance As A Determinant of Employee Satisfaction With Special Reference To Banking Sector. It was found that the employees who maintained a good balance of personal lives and jobs were less stressed and more satisfied at work. Singh and Jain (2013)The study attempts to know about the factors which affect job satisfaction of bank employees and concludes that salary, recognition, promotion, job security, inter-personal relations affects an individual employee satisfaction. Organizations are obliged to enhance satisfaction by offering injury coverage programs, the researchers stated.

Objectives of the Study

Primary Objectives

- To study the factors influencing job satisfaction among bank employees in Coimbatore District.

Secondary Objectives

- To examine the level of job satisfaction among bank employees in Coimbatore District.
- To identify the major factors influencing job satisfaction among bank employees.
- To analyze the relationship between demographic variables and job satisfaction.
- To assess the impact of salary and compensation on job satisfaction.
- To evaluate the influence of promotion and career growth opportunities on employee satisfaction.

Scope of the Study

This study is about the Determining factors of Job satisfaction of Bank Employee in Coimbatore District. The objective of study is to know the extent of job satisfaction among employees working in different public and private sector banks as well as the factors which affect their level of job satisfaction significantly. This includes salary and compensation, promotion opportunities, job security, work environment, supervisor support, recognition, workload and work home balance. The relationship between demographic variables such as age, gender, marital status, educational qualification (Q); designation (D) and work experience will be also examined in relation to job satisfaction. The results of the study will help the bank management in formulating better human resource policies and employee welfare programmes. Additionally, it would assist organizations in boosting employee motivation, productivity, decreasing attrition and increasing organizational performance. The study is limited to selected bank employees of Coimbatore District and the outcome of this research can help future researchers in understanding employee job satisfaction and human resource management.

Limitations of the Study

There are data limitations associated with the current investigation that must be acknowledged when interpreting results. First, the research is limited to public and private sector bank employees in few Public and Private Banks in Coimbatore District; thus, the results may not generalize on bank employees from another district or region. Second, the number of responses is restricted to 100 respondents which may not neccessarily all bank employees living in the district. Another limitation is the fact that this study mainly uses data from a structured questionnaire and the result based on respondents perceptions and opinion are biased. Thirdly, the research is limited only to key determinants of job satisfaction like salary, regular promotion opportunities, works environment, job security and supervisory support and work-life balance (e.g. Lastly, time constraints, cost and availability of respondents limited what data could be collected and analyzed. Nevertheless, while there are some limitations in this study, it has provided important information on factors to consider when studying the job satisfaction of workers in banks found in Coimbatore District.

RESEARCH METHODOLOGY

Research methodology refers to the systematic process adopted by the researcher to collect, analyze, and interpret data for achieving the objectives of the study. The present study entitled "Factors Influencing Job Satisfaction among Bank Employees in Coimbatore District" adopts a scientific approach to examine the various factors affecting job satisfaction among bank employees.

Research Design

- Descriptive Research Design

Area of the Study

- Coimbatore District

Sources of Data

- Primary Data
- Secondary Data

Sampling Technique

- Convenience Sampling Method

Sample Size

- 100 Bank Employees

Data Collection Instrument

- Structured Questionnaire

Statistical Tools Used

- Percentage Analysis
- Chi-Square Test
- Independent Sample t-Test
- One-Way ANOVA
- Correlation Analysis
- Multiple Regression Analysis

Software Used

- SPSS (Statistical Package for Social Sciences)

Data Analysis and Interpretation

Interpretation

From the above table, about 40 percent of respondents are from the age group of 31–40 years which indicates that this is mainly because these bank employees are in their working career. Most respondents (70%) are married. About education qualification, 52% have post-graduates and 20% have professional qualifications. Most (42%) are clerks,

while officers came next on 36%. Regarding work experience, 38% of have 6–10 years (up to October 2023). For monthly income, 36% earn ₹30,001 to ₹50,000 a month which is the second most frequently occurring income group among respondents. The demographic profile shows that most of the respondents are experienced, overqualified and themselves involved in banking operations

Association between Age and Job Satisfaction

Hypothesis

H0: There is no significant association between Age and Job Satisfaction among Bank Employees in Coimbatore District.

H1: There is a significant association between Age and Job Satisfaction among Bank Employees in Coimbatore District.

Interpretation

The above table shows that the calculated Chi-Square value is **13.547** with a **p-value of 0.035**. Since the p-value is less than the 5 percent level of significance (0.05), the null hypothesis is rejected. Hence, there is a significant association between age and job satisfaction among bank employees in Coimbatore District.

Findings of the Study

Demographic Findings

- Most of the respondents (40%) are from the age group between 31–40 years.
- The majority of respondents are married (70%)
- 52% of the respondents have a postgraduate degree.
- Clerk was the highest proportion (respondent 42% were having clerk jobs.
- The most respondents (38%) have 6–10 years of experience in the workplace.
- Thirty-six per cent of the respondents belong to the salary range between ₹30,001 and ₹50,000/month.

Findings Related to Job Satisfaction

- Most bank staff have a fair level of job satisfaction.
- Salary and compensation is one of the key issues that affects job satisfaction.
- Opportunities for career advancement and promotion have a significant impact on job satisfaction.
- Quality work atmosphere results in increased job fulfilment.
- Job security is one of the most important causes behind employee happiness in the banking industry.
- Supportive supervision and positive interpersonal relations promote job satisfaction.
- Work-life balance is one of the most important keys to creating employee satisfaction and reducing work demands.
- In fact, acknowledgement and appreciation from management enhances employee morale and commitment.

Suggestions

- To improve employee satisfaction, banks should offer competitive pay/promotion packages and attractive incentive schemes.
- For motivating employees, be transparent and have fair promotion policies.
- Management should develop a positive encoder work environment in which collaborate attitudes are supported.
- There need to be robust employee recognition and reward programs in place for amazing performance.
- Banks should plan for various training and development programs to help enhance skills of employees along with growth in their careers.
- Wherever feasible, flexible working arrangements and work-life balance initiatives should also be implemented.
- A mechanism for grievance handling should be there to provide immediate remedy.

CONCLUSION

Job satisfaction is an important factor affecting employee performance, productivity, commitment and success of the organization. Results The present study titled as "Factors Influencing Job Satisfaction Among Bank Employees In Coimbatore District" shows majority of bank employees have moderate level of satisfaction. The research outlines the various factors that have a major impact on job satisfaction; these are salary, promotion opportunities for career growth, work environment of an organization, job security for protecting their livelihood, supervisory support and work-life balance. It means that demographic variables like age, gender & marital status, designation, working experience & monthly income found to have significant impact on job satisfaction by statistical analysis. Factors which contribute towards employees being satisfied with their job are fairness in payment, employee growth opportunities, management support and a favourable working environment. Hence, bank management has to pay attention to enhancing the employee welfare and enhancing reward & recognition system, offering career development opportunity as well as fostering a core organizational culture. Improving job satisfaction of employees can increase performance and commitment among employees; as a reduces the weakness of OCB will directly affect customers, productivity and organisation survival in banking sectors.

ABSTRACT

The *in vivo* physiological stress of excessive ROS and RNS have been a great concern for their adverse effects on normal cellular metabolism. The excess free radicals can cause lethal cellular effects by oxidizing cellular proteins, DNA, enzymes and membrane lipids when it over whelms protective endogenous antioxidative enzymes such as superoxide dismutase (SOD), catalase (CAT), glutathione reductase (GR) and glutathione peroxidase (GPx). This is the major reason for oxidative stress and causes various health issues. Oxidative stress in the metabolic system of cells is associated with various health issues. Dietary antioxidants play significant roles to mitigate oxidative stress. The antioxidants are free radical scavengers to neutralize potential free radicals from exhibiting adverse effects to cells. Different improvised methods have been well established for testing various types of antioxidants for their activity. Some most commonly use methods based on their reaction mechanism such as HAT (hydrogen atom transfer), SET (single electron transfer) or both HAT-SET are discussed in this review. This review emphasizes on the nature and adverse effects of free radicals, their mitigation by antioxidants, and underlying mechanisms. The review concludes with an illustration on existing test methods for antioxidants which may suggest constructive improvements in future research on health issues relating to oxidative stress.

Keywords: Oxidative stress, free radicals, colorimetry, HAT, SET

INTRODUCTION

The importance of oxidation in living body has been well known and this oxidative metabolism is one of the most important biochemical activity for survival of cells. Besides the essentiality, there are side effects for this dependency due to over production of free redicals and other reactive oxygen species during normal *in vivo* cellular metabolism that cause oxidative changes [29]. Free radicals contain at least one unpaired electron in the outer shell which makes them highly reactive. Most common free radicals and reactive molecules in living organisms are derived from oxygen (ROS) and nitrogen (RNS) which are formed during electron transfer reactions, by losing/accepting electron(s)[16]. There are protective endogenous antioxidative enzymes such as Superoxide dismutase (SOD), catalase (CAT), glutathione reductase (GR) and glutathione peroxidase (GPx). The SOD converts $\mathbf{O_2^{\bullet-}}$(superoxide radical) to $\mathbf{H_2O_2}$ (hydrogen peroxide), GR provides electron (from NADPH) required for GPx activity while CAT and GPx break down $\mathbf{H_2O_2}$ into water and oxygen [33]. Oxidative damage occurs when excess free radicals overwhelm the protective endogenous Antioxidant enzymes. Besides these endogenous protective enzymes, dietary antioxidants play significant roles to mitigate oxidative stress [20]. The high content of antioxidants in various plant species can capture and neutralize free radicals that stimulate the interest of utilizing them in prophylactic and curative phyto tharapy. Fruits and vegetables have been the most important sources of antioxidants for the in vivo defence mechanism against oxidative stress in aerobic cells. Antioxidant tests are essential tools used to evaluate a compound's ability to neutralize free radicals and effectively reduce the oxidative stress. Broadly, antioxidant mechanisms are assessed based on their atom/electron transfer mechanisms [25] such as: Single Electron Transfer (SET), Hydrogen Atom Transfer (HAT), and mixed-mode (SET/HAT) methods.

Reactive oxygen species

Some specific derivatives of O_2 that contain free radical are so toxic to cells of aerobic organisms [14]. ROI (reactive oxygen intermediates), ROS (reactive oxygen species), and RNS (reactive nitrogen species) are emerging class of endogenous, highly reactive oxygen-/nitrogen-containing free radical compounds [2]. Table-1 highlights the free radical and non- radical species of ROS.

Antioxidants

Antioxidants are defined as any substance that significantly delay or inhibit oxidation of an oxidizable substrate even at comparatively low concentration while antioxidants themselves do not become unstable by the process of donating or accepting electrons [15]. According to their operating mechanisms, antioxidants have been divided into two classes- primary antioxidants (chain breaking antioxidants) and secondary antioxidants (preventative antioxidants) [19]. Exogenous primary antioxidants such as vitamin E, vitamin C, carotenoids, flavonoids, lycopene, polyphenols etc., directly neutralize free radicals by donating or accepting electrons to break oxidative chain reaction. Primary antioxidants, AH, may either delay or inhibit initiation step by reacting with lipid radical or inhibit propagation step by reacting with peroxyl or alkoxyl radicals as in the reaction [19]:

$L^{\bullet} + AH \rightarrow LH + A^{\bullet}$
$LOO^{\bullet} + AH \rightarrow LOOH + A^{\bullet}$
$LO^{\bullet}\ AH \rightarrow LOH + A^{\bullet}$
The antioxidant free radical may further interfere with chain propagation reaction to form peroxy antioxidant compounds:
$A^{\bullet} + LOO^{\bullet} \rightarrow LOOA$
$A^{\bullet} + LO^{\bullet} \rightarrow LOA$
Activation energy of the reaction increases with increase in A-H and L-H bond dissociation energy. So, efficiency of antioxidant increases with decrease in A-H bond strength [2]. Their antioxidant activity is either by quenching a free

radical directly or indirectly through radical scavenging activity [18]. These reduce the reactivity of free radicals and prevent further chain reactions.

Antioxidative enzymes and their assay

Endogenous enzymatic antioxidants such as superoxide dismutase (SOD), catalase (CAT), and glutathione peroxidase (GPx) are the primary enzymes while Glutathione reductase (GR), and glucoase phosphate dehydrogenase (G6PDH) are the secondary enzymes that play vital roles in controlling the oxidative stress [33]. They play important defence mechanism against ROS induced oxidative stress [23] as illustrated in Fig. 1. Superoxide ($O_2^{\bullet-}$) is converted to dihydrogen dioxide by the catalytic reaction of SOD. Catalase (CAT) dismutates dihydrogen dioxide into dioxygen and water. Glutathione peroxidase (GPx) catalyzes the reduction of the hydrogenperoxides by employing the electrons transferred from NADPH via glutathione reductase (GR) and glutathione(GSH) [3].

Antioxidant activity measurement

The features of oxidation include substrate, oxidant and initiator, intermediates, and final products. Measurement of effects on any of these features can be used to assess antioxidant activity [12]. Various highly sensitive and automated detection methods, coupled with chemical tests, have been used to detect antioxidant activities like scavenging activity against different types of free radicals or ROS, reducing power and metal chelation, among others [32]. There is differentiation of antiradical and antioxidant activity based on the target site of inhibition activity. The ability of compounds to react with free radical characterizes antiradical activity while the ability to inhibit the process of oxidation represents antioxidant activity. Tests based on the use of stable free radical like DPPH, ABTS, etc exhibit radical scavenging activity rather than unseemly using the term antioxidant activity [25]. Table-2 highlights the methods for testing antioxidant activity with brief principle and determination of result [25]. There are broadly two types of antioxidant test methods based on their chemical reaction involved in line with their mode of action, namely hydrogen atom transfer (HAT) and single electron transfer (SET) [25].

Tests based on HAT

The hydrogen atom transfer-based assays measure the potentiality of antioxidants to remove free radicals by donating a hydrogen atom (radical quenching). The mechanism of antioxidant action is represented in the following reaction where the hydrogen atom of ArOH is transferred to ROO$^\bullet$: ROO$^\bullet$+ AH/ArOH → ROOH + A$^\bullet$ /ArO$^\bullet$. Where the aryloxyl radical (ArO$^\bullet$) formed from the reaction of phenol (ArOH, an antioxidant) and peroxyl radical (ROO$^\bullet$) is stabilized by resonance and the AH are protected biomolecule which are otherwise the target molecule for oxidation. The Oxygen Radical Absorption Capacity(ORAC), Total Peroxyl Radical Trapping Antioxidant Parameter (TRAP) and Total Oxyradical Scavenging Capacity (TOSC) assays are typical example of HAT assay.

ORAC test

The ORAC (Oxygen Radical Absorption Capacity) test measures the splitting capacity of the radical (peroxyl radical) chain reaction by antioxidants (e.g., trolox) through inhibition of oxidation [10]. The peroxyl radicals are predominantly responsible for oxidation of lipids. Azo-compounds, such as lipophilic ∝,∝,-azobisizobutyronytril (AIBN), 2,2'-azobis(2-methylpropionamidine) dihydrochloride (ABAP), 2,2'-azobis(2,4-dimethylvaleronytril) (AMVN) and 2,2'-azobis(2-amidinopropane) dihydrochloride (AAPH, a hydrophilic compound) are commonly used ROO$^\bullet$ generators [7][10]. In ORAC test, a fluorescent probe (often fluorescein) reacts with ROO$^\bullet$emitted by a generator leading to loss/decay of fluorescence due to radical-induced oxidation. The decay of probe declines in the presence of antioxidant (trolox) by donating hydrogen atom to ROO$^\bullet$, which can be monitored under a fluorimeter. A slower decline in fluorescence indicates stronger antioxidant activity. The area-under-curve (AUC) technique is used to interpret the result, in presence and absence of antioxidant. The ORAC values of the screening antioxidants are described as trolox equivalent. The value obtained by subtracting the AUC of blank from the AUC of sample is the net AUC. One ORAC unit is the capability of an antioxidant to completely increase the area under the fluorescent probe decay curve. The trolox equivalent (relative ORAC value) can be determined by the equation [3]:

$$\text{Trolox equivalent} = \frac{(\text{AUC}_{\text{Sample}} - \text{AUC}_{\text{Blank}})}{(\text{AUC}_{\text{Trolox}} - \text{AUC}_{\text{Blank}})} \times \frac{(\text{Concentration of Trolox})}{(\text{Concentration of sample})}$$

Unlike other probes such as β-phycoerythrene, the fluorescent probe has advantages of greater photostability and specificity when interact with antioxidants [27]. A high-throughput assay method of using multichannel liquid handling system coupled with microplate fluorescence reader has been developed to improve this assay [17].

HORAC test

This assay relies on the oxidation of fluorescein by hydroxyl radicals via HAT mechanism [11]. The highly reactive hydroxyl radicals ($OH^{\bullet}$) are generated by Co(II)-mediated Fenton-like reaction in the presence of H_2O_2. The hydroxyl radicals quench the fluorescence offluorescein (probe decay) over time and lower the fluorescence.When an antioxidant is incubated with fluorescein and the Fenton mixture is subsequently added, the antioxidant inhibits hydroxyl radical-mediated oxidation of fluorescein. In the presence of the antioxidant, fluorescence increases due to the transfer of a hydrogen atom to$OH^{\bullet}$[11][27].The Co(II) is a transition metal catalyst in the reaction and has metal-chelating capacity that triggers antioxidants to inhibit the oxidation of fluorescein by hydroxyl radicals [31]. The area under the curve (AUC) of fluorescence decay is used to interpret the total hydroxyl radical antioxidant activity in the sample and is compared with a standard curve obtained using various concentrations of gallic acid. The antioxidant activity is expressed as gallic acid equivalents. Unlike other methods, the fluorescent HORAC assay is useful for measuring a wide range of phenolic antioxidants against hydrophilic chain-breaking hydroxyl radicals, in which the test sample blocks the oxidation of fluorescein by radicals [26].

TOSC test

The Total Oxyradical Scavenging Capacity test rely on inhibition capacity for formation of ethylene during oxidative stress [22]. Ethylene is the cleavage product formed when α-keto-γ-methiolbutyric acid (KMBA) undergoes oxidative degradation in the presence of ROS such as $\mathbf{ROO^{\bullet}}$, $\mathbf{OH^{\bullet}}$and $\mathbf{ONOO^{-}}$. The peroxyl radical ($\mathbf{ROO^{\bullet}}$) can also be generated by thermal homolysis of 2,2'-azobis(2-methylpropionamidine) dihydrochloride (ABAP).KMBA is produced through the deamination of methionine via a transamination reaction. Antioxidants scavenge the ROS and interrupt the chain reaction of oxidative stress to inhibit ethylene production [30]. Ethylene production is monitored by gas chromatography. The antioxidant activity is interpreted by comparing the area under the curve (AUC) for ethylene concentration in the presence and absence of antioxidants (control) over a reaction time of up to 300 minutes. A higher TOSC value indicates greater antioxidative capacity [6].

TRAP test

Total peroxyl radical trapping antioxidant parameter [34] measures the potential of antioxidants to inhibit peroxidation chain reactions. The initial method for this assay involves measuring oxygen consumption during a controlled lipid peroxidation reaction of plasma. The lipid peroxidation reaction is a chain process that consumes oxygen and is induced by the thermal decomposition of 2,2′-azobis(2-methylpropionamidine) dihydrochloride (ABAP), which generates ROO• when mixed with antioxidants (plasma). The thermal decomposition of ABAP typically occurs at 45°C, resulting in homolytic cleavage of the azo bond to produce radicals [21]. These radicals then react with oxygen to generate ROO•.The rate of oxygen consumption is inhibited/retarded by the activity of antioxidants which can be quantitatively measured by thermostated oxygen electrode to determine the TRAP value. The result is expressed as the amount of $\mathbf{ROO^{\bullet}}$trapped by the volume (liter) of the related solution(plasma) as shown in the equation:

$$\text{TRAP} = R_{ROO^{\bullet}} \times \tau_{\text{Plasma}}$$

Where $R_{ROO^{\bullet}}$ is the rate of $\mathbf{ROO^{\bullet}}$ formation and τ_{Plasma} is the delay time for oxygen consumption by the activity of antioxidant (plasma). There is limitation in this method as the oxygen electrode at the end point does not sustain its stability over the required period of time [3][26].

Tests based on Single Electron Transfer (SET)

SET, otherwise called ET (electron transfer), tests detect the ability of antioxidants to transfer electron in order to reduce metallic ions, carbonyl groups and free radicals [35]. The chemical mechanism of SET test methods can be summarized as in the reactions:

$ROO^{\bullet} + AH / ArOH \rightarrow R00^{-} + AH^{\bullet+} / ArOH^{\bullet+}$
$AH^{\bullet+} / ArOH^{\bullet+} + H_2O \leftrightarrow A^{\bullet} / ArO^{\bullet} + H_3O^{+}$
$ROO^{-} + H_3O^{+} \leftrightarrow ROOH + H_2O$

SET reactions are pH dependent due to primarily based on deprotonation (removal of H^{+})and ionisation (removal/addition of electron) potential of the reactive functional group [5]. Ionisation of AH / ArOH in the presence of $ROO^{\bullet}$results to produce $R00^{-}$. Deprotonation of H_3O^{+} (hydronium ion) in the presence of $R00^{-}$ gives H_2O resulting in protonation or acid-base neutralization of $R00^{-}$ (peroxyl anion) to ROOH (hydroperoxide). ArOH (hydroquinone) oxidised to corresponding quinone, Ar=O (benzoquinone), via oxidation of $ArO^{\bullet}$(aryloxyl radical) (Munteanu & Apetrei, 2021). The test of the cupric ion reducing antioxidant capacity (CUPRAC), the ferric reduction of antioxidant power (FRAP) and the Follin-Ciocalteu test (FC) are well developed spectroscopic SET based test methods to measure antioxidant activity of a sample for reducing an oxidant, which changes colour when reduced. The degree of colour change is proportional to the potentility of total antioxidant capacity.

The CUPRAC test

The CUPRAC assay for determining total antioxidant capacity was devised in early 2000 [4] applicable to various matrices containing both lipophilic and hydrophilic antioxidants. This antioxidant activity assay is based on the reduction of cupric ion (Cu^{2+}) to cuprous ion (Cu^{+}). $CuCl_2$ is the Cu^{2+} source in the reaction mixture for this assay. A sample blank without $CuCl_2$ is also used for comparison. Neocuproine (Nc; 2,9-dimethyl-1,10-phenanthroline) is the ligand commonly employed, like other assays, to form copper-ligand complex that facilitates absorbance measurement. Cu^{2+}-Neocuproine are the chromogenic oxidising agent that undergoes a colour change (Cu^{2+} blue colour to yellow-orange Cu^{+}-Nc) during the reduction reaction. The role of sample to test (antioxidant) is to reduce Cu^{2+} and gets itself oxidized. This is a redox reaction where the antioxidant is a reducing agent, donating electron to Cu^{2+} [26]. The reduced Cu^{+} binds to the neocuproine ligand, forming a highly yellow-orange coloured Cu^{+}-neocuproine chelate. This coloured complex can be measured spectrophotometrically at 450 nm, where it shows maximum light absorption. The higher absorbance indicates greater antioxidant capacity of the sample which can be expressed either as % of inhibition or equivalent of a standard compound. The Cu^{2+}-Ncreacts with the n-electron reductant antioxidant substances (AOX), as shown in the equation:

$nCu(Nc)_2^{2+}$ + n- electron reductant (AOX) $nCu(Nc)_2^{+}$ + n- electron oxidized product + nH^{+}

$$\mathbf{Cu(Nc)_2^{2+} + ArOH \rightleftarrows Cu(Nc)_2^{+} + ArO^{\bullet} + H^{+}}$$

The reactive Ar-OH groups of polyphenols and other antioxidants are oxidised to the corresponding quinones (Ar=O) simultaneously with the reduction of Cu^{2+}–neocuproine to the Cu^{+}–neocuproine complex, which is intensely coloured in yellow–orange. The rate of chromophore production at the end of the reaction is proportional to initial concentration of Cu^{2+}-Nc, influencing the attachment of Cu^{2+}-Nc in the initial stage. Antioxidants in the sample donate electrons to Cu^{2+}-Nc, reducing it to a cuprous ion and releasing protons[1]. The released protons are buffered in a solution containing ammonium acetate, with pH of 7.0. This pH is optimum for CUPRPAC assay because it is very close to the physiological pH (7.4).

The FRAP test

It is a typical SET based test method for screening the antioxidant activity in acidic environments of pH- 3.6 to maintain iron solubility. The complex ferric ions (Fe^{3+})-ligand which is colourless reduced to intensely blue colour ferrous (Fe^{2+})- ligand complex. Ferric chloride ($FeCl_3$) is the most commonly used Fe^{3+} source.The antioxidants donate

electron to Fe^{3+} forreduction to Fe^{2+} in presence of TPTZ ligand resulting in conversion of colourless to blue colour. TPTZ (tripyridyltriazine) and ferrozine are ligands used to assess the reducing power of antioxidants. The low pH decreases ionization potential that makes easier for antioxidant to donate electrons to Fe^{3+} which is the key step for dominant reaction mechanism in this method. The antioxidant activity is monitored spectrophotometrically at 593 nm for its absorbance. The high absorbance indicates high antioxidant activity which is expressed as micromolar equivalents of Fe^{2+} or in relation to a standardantioxidant[2]. The mechanism of chemical reaction is as given:

$[Fe^{III}(TPTZ)_2]^{3+} + ArOH \quad [Fe^{II}(TPTZ)]^{2+} + ArO^{\bullet} + H^{+}$

More recently, potassium ferricyanide has also been used very effectively as Fe^{3+} source that gives prussian blue colour after reduction reaction [8]. This method is abbreviated as PFRAP and have vast applicability. The sample absorbance is read at 700 nm. The reduction of Fe (III) to Fe (II) can be expressedas %inhibition or equivalent of a standard compound (e.g., Trolox)[36]. The summarized reduction reaction can be represented by the reaction below.

$4FeCl_3 + 3K_4[Fe(CN)_6]^{3-} \quad Fe_4[Fe(CN)_6]_3^{4-} + 12\ KCl$

The PFRAP test is a simple, cheap, widely used reliable test method with least possibility of interference from the reaction mixture as the absorbance is read at a high wave length.

The Follin-Ciocalteu test

The F-C assay is a SET based colorimetry method to determine the total phenolic content (TPC) of vast varieties of phenolic antioxidant samples. The main constituentfor antioxidant property of fruits, vegetables, grains, or plant samples are phenolic compounds. This test method is based on the reduction of Folin- Ciocalteu reagent with phenolic compounds in an alkaline state. The F-C reagent is a yellow-coloured complex mixture of phosphomolybdic and phosphotungstic acid. It is basically acidic reagent which upon addition of sodium carbonate (Na_2CO_3) neutralizes to optimal alkaline pH (approximately pH-10) for reduction reaction [31]. The phenolic compounds act as electron doners, reducing the F-C reagent to form a blue coloured complex which is read in spectrophotometer at 765 nm. A standard curve is created using gallic acid, a known phenolic compound, to relate the absorbance to the total phenol concentration.Results are typically expressed in Gallic Acid Equivalents (GAE).

Phenol + F-C Reagent Molybdenum- Tungsten Blue (Complex)

HAT and SET mixed mode methods

The mixed mode method of testing antioxidant activity is more comprehensive since many natural antioxidants follow both the mechanisms. This method is based on the elimination of stable chromophore like 2,2'-azinobis-3-ethylbenzthyazolin-6-sulfonic acid (ABTS) and 2,2-diphenyl-1-picrylhydrazil (DPPH),involving specific mechanisms such as HAT, ET and sometimes PCET (proton coupled ET) depending on factors like the pH of the solution, the solvent used, and the nature of the antioxidant.For example, a more basic pH might favor ET, while a more acidic pH could favor HAT.More often than not, the mechanism of antioxidant activity is either to transfer an electron to free radicals by antioxidants (SET) or transfer hydrogen atom to free radicals by antioxidants (HAT). Generally mixed mode methods of testing antioxidant capacity is highly reliable, including ABTS and DPPH as most commonly used methods. The N,N-dimethyl-p-phenylenediamine dihydrochloride (DMPD) radical neutralisation test is less commonly used mixed mode method.

ABTS

This assay is very widely used method to screen both lipophilic and hydrophilic antioxidant samples for their free radical scavenging activity. The ABTS (2,2'-Azino-bis (3-ethylbenzothiazoline-6-sulfonic acid)) or otherwise called TEAC (trolox equivalent antioxidant capacity test) originated in 1993 with multiple steps for $ABTS^{\bullet+}$ generation via $HO^{\bullet}$[24] and further improved by using other effective oxidants for single step $ABTS^{\bullet+}$ generation. At first, the TEAC

test started with reaction of Met-Myb (metmyoglobin, an oxidised form of myoglobin) and H_2O_2 to produce $HO^{\bullet}$which further react with ABTS to oxidize to radical cation $ABTS^{\bullet+}$ [24]. In the presence of antioxidant,the neutral and non-radical form of ABTS molecule is resulted. ABTS serves as a precursor in antioxidant capacity assays of TEAC. The mechanism of $ABTS^{\bullet+}$ generation via $HO^{\bullet}$is as in the reaction.

Met-Myb + H_2O_2 $HO^{\bullet}$

ABTS + $HO^{\bullet} \longrightarrow ABTS^{\bullet+}$ + ArOH $\longrightarrow$ ABTS + $ArO^{\bullet}$

The reaction is multiple step process and there are chances of being interfered $HO^{\bullet}$with ArOH rather than $ABTS^{\bullet+}$ generation.

DPPH

The $DPPH^{\bullet}$radical was discovered by Goldschmidt and Renn in 1922 and developed antioxidant assay in 1958 by screening $DPPH^{\bullet}$reduction to DPPH in the presence of antioxidants[9][13]. $DPPH^{\bullet}$can be generated by oxidizing hydrazines of DPPH using oxidants like lead dioxide, lead tetraacetate, potassium permanganate, or silver oxide carried out in non-polar solvents (benzene or dichloromethane). $DPPH^{\bullet}$is remarkably stable due to delocalization of the radical in aromatic rings. The 2,2-Diphenyl-1-picrylhydrazyl Radical Scavenging Capacity (DPPH) Assay is one of the most common free radical scavenging antioxidant assays. It works based on the ability of antioxidants to neutralize $DPPH^{\bullet}$, a stable free radical, by donating electrons or hydrogen atoms. The radical $DPPH^{\bullet}$ has deep purple colour. It has absorption peak at 517 nm. In the presence of antioxidant (reducing agent) the $DPPH^{\bullet}$ is reduced to DPPH or DPPH-H and colour changed to pale yellow. The extent of discoloration indicates the antioxidant capacity of the test sample. The result can be represented either as an equivalent of a standard reference (Trolox, gallic acid, ascorbic acid, BHA, BHT) or IC_{50} (Half Maximal Inhibitory Concentration).

$DPPH^{\bullet}$+ ArOH $\longrightarrow$ DPPH-H + $ArO^{\bullet}$(HAT mechanism)

$DPPH^{\bullet}$+ ArOH $\longrightarrow$ DPPH + $[ArOH]^{\bullet+}$ (SET mechanism)

The N,N-dimethyl-p-phenylenediamine dihydrochloride (DMPD) radical neutralisation test is less commonly used mixed mode method. The mechanism of DMPD is simillar to ABTS and DPPH as well. DMPD reacts with an oxidant (like potassium persulfate or ferric chloride) to form a pink-colored radical cation($DMPD^{\bullet+}$).If an antioxidant is present, it can donate a hydrogen atom to the $DMPD^{\bullet+}$, reducing it back to the uncolored DMPD. The decolouration of the $DMPD^{\bullet+}$ solution is proportional to the amount of antioxidant present, allowing for the measurement of antioxidant activity at 505nm.

CONCLUSION

The metabolic anomaly associated with free radicals (ROS, RNS) are the potential health hazards. An understanding of the nature, origin, and reaction mechanisms of free radicals is crucial in the present context for finding out ways to neutralize their adverse effects. Free radicals have unpaired electrons having the capacity of oxidizing vital bio molecules through various processes like lipid peroxidation, protein oxidation, and DNA damage. Radicals like hydroxy radicals ($OH^{\bullet}$) and superoxide radicals ($O_2^{\bullet-}$) are mainly responsible for these oxidative changes which potentially cause certain diseases. The antioxidants are free radical scavengers to neutralize potential free radicals from exhibiting adverse effects to cells. A single test method of antioxidant activity may not be reliable to draw conclusion for a test sample because a single method may not capture all aspects of the sample. At the least, three test methods are advisable to draw comprehensive conclusion. This review emphasizes the nature and adverse effects of free radicals, their mitigation by antioxidants, and underlying chemical mechanisms. The review concludes with an illustration of existing test methods for antioxidants, which may suggest constructive improvements for future research on health issues relating to oxidative stress.

Table 1: Few active ROS- Free radical species and non-radical species

Free radical species	Formula	Non-radical species	Formula
Superoxide radical anion	$O_2^{\bullet-}$	Hydrogen peroxide	H_2O_2
Hydroxyl radicals	$OH^{\bullet}$	Ozone	O_3
Peroxyl	$ROO^{\bullet}$	Singlet oxygen	$^1O_2$
Alkoxyl	$RO^{\bullet}$	Hypochlorous acid	HOCl
Semiquinone	$SQ^{\bullet-}$	Hypobromous	HOBr
Lipid radical	$L^{\bullet}$	Lipid hydroperoxide	LOOH
Lipid alkoxyl radical	$LO^{\bullet}$	Hypoiodous acids	HOI
Lipid peroxyl radical	$LOO^{\bullet}$	Hydroperoxides	ROOH
Carbonate	$CO_3^{\bullet-}$	Nitrite	NO_2^-
Nitric oxide	$NO^{\bullet}$	Dinitrogen trioxide	N_2O_3
Nitrogen dioxide radical	$NO_2^{\bullet}$	Peroxynitrite	$ONOO^-$

Table 2: Different techniques used to measure antioxidant activity

Test method (Techniques)	Principle of the Method	End-Product Determination
ORAC (Spectrometry)	Antioxidant reaction with peroxylradicals, induced by 2,20 -azobis-2-amidino-propane (AAPH)	Loss of fluorescence of fluorescein
HORAC (Spectrometry)	Antioxidant capacity to quench OH radicals generated by a Co(II) based Fenton-like system	Loss of fluorescence of fluorescein
TRAP (Spectrometry)	Antioxidant capacity to scavenge luminol-derived radicals, generated from AAPH decomposition	Chemiluminescence quenching
CUPRAC (Spectrometry)	Cu (II) reduction to Cu (I) by antioxidants	Colorimetry
FRAP (Spectrometry)	Antioxidant reaction with a Fe(III) complex	Colorimetry
PFRAP (Spectrometry)	Potassium ferricyanide reduction by antioxidants and subsequent reaction of potassium ferrocyanide with Fe3+	Colorimetry
ABTS (Spectrometry)	Antioxidant reaction with an organic cation radical	Colorimetry
DPPH (Spectrometry)	Antioxidant reaction withan organic radical	Colorimetry
Fluorimetric analysis e.g., ORAC, HORAC, TRAP (Fluorometry)	Emission of light/fluorescence by a reactive oxygen compound, which has absorbed/treated with dye/probe which are electromagnetic radiation of a different wavelength.	Recording of fluorescence excitation/emission spectra of the probe quenched by ROS
Voltammetry (Eletrochemical techniques)	The reduction or oxidation of a compound at the surface of a working electrode, at the appropriate applied potential, resulting in the mass transport of new material to the electrode surface and in the generation of a current.	Measurement of the current of the cathodic/anodic peak
Amperometry (Eletrochemical)	The potential of the working electrode is set at a fixed value with respect to a reference electrode	Measurement of the current generated by the oxidation/reduction an electro active analyte
Biamperometry (Electrochemical)	The reaction of the analyte (antioxidant) with the oxidised form of a reversible indicating redox couple.	Measurement of the current flowing between two identical working electrodes, at a small potential difference and immersed in a solution containing the analysed sample and a reversible redox couple.
Gas chromatography	Separation of the compounds in a mixture is based on the repartition between a liquid stationary phase and a gas mobile phase	Flame ionisation or thermal conductivity detection.
HPLC (Chromatography)	Separation of the compounds in a mixture is based on the repartition between a solid	UV-Vis (e.g., diode array) detection, fluorimetric detection, mass spectrometry

	stationary phase and a liquid mobile phase with different polarities, at high flow rate and pressure of the mobile phase.	or electrochemical detection.
TLC	Seperation of compound based on repartition between solid stationary phase and liquid mobile phase (mixture of acetate, formic acid and water).	Photographed under visible light.

ABSTRACT

The acanthaceae family comprises 60 accepted species that widely utilized in traditional medicine by local communities of Dausa district (Rajasthan, India), Kantarawichai district (Sarkham Province, Thailand), Northern, central and Northeastern Thailand, and Mount Cameroon Region. In these regions, various species are employed for the treatment of ailments such as pneumonia, diabetes, tuberculosis, asthma, bronchitis, malarial fever, gonorrhea, sore throat, diarrhea, and anemia. This review comprehensively evaluates the ethnomedicinal relevance, phytochemistry, pharmacological activities, and toxicological aspects of plant species within the acanthaceae family. Acanthaceae family plants are rich in bioactive compounds, including aliphatic glycosides, alkaloids, flavonoids and terpenoids, which contribute to their pharmacological activities. The crude extracts and their isolated constituents have been reported to exert a wide spectrum of pharmacological effects under both in vivo and in vitro conditions, encompassing antibacterial, antifungal, antidiarrheal, anti-inflammatory, antinociceptive, and cytotoxicity activity. Furthermore, available toxicological evidence suggests that plant species of acanthaceae family are generally safe and non-toxic at therapeutic doses. Despite substantial progress in phytochemical and pharmacological research, further efforts are required to achieve pharmaceutical standardization, clarify the molecular mechanisms of action of bioactive constituents, and conduct rigorous toxicological assessment. These studies are key to harnessing the full therapeutic potential of derived products from plant species from acanthaceae family.

Keywords: Acanthaceae family, Bioactive phytocompounds, Ethnomedicinal plants, Pharmacological activities, Toxicological activity

INTRODUCTION

There are around 229 genera and 3,450 species in the vast pantropical family Acanthaceae worldwide (Somprasong*et al,* 2014;Clarke,1885).There are few spiky varieties, but the majority are plants or shrubs, including twining forms and mainly reported from Africa, Brazil, Central America, and Indo-Malaya, with a few in the temperate zone (Cramer,1998; Somprasong *et al,* 2014).Their growing habitat are swamps, open and deep woods, thickets, wet plains and valleys, the seashore and marine regions, and swamp forests (Benoist, 1936; Imlay, 1938; Somprasong*et al,* 2014). In general, diversity of this family is recorded from Paleo (old world) and Neo (New world), but highest species diversity presents at temperate latitude (Manzitto-Tripp *et al,* 2022; Frank and Daniel, 2015).Most species rich and diverse habitats are the tropical thorn, dry forests, and savannas in Brazil and Mexico; the tropical Andean foothills wet forests in Bolivia, Peru, Ecuador, Colombia, and Venezuela; the tropical and northeastern and central African semi-deserts, savannas, dry forests, and submontane wet forests; the tropical and dry forests of Madagascar; the Namib Desert and surrounding grasslands and bushlands in Namibia and Angola; and diverse tropical Asian ecosystems, especially in India(Manzitto-Tripp *et al,* 2022).

Secondary metabolites like alkaloids, phenols, terpenoids, tannins, quinones, cardiac glycosides, saponins, carbohydrates, flavonoids, and proteins are reported from various plant species from family acanthaceae and are useful for the treatment of lethal diseases.Some of the plant species like *Adhatoda beddomie, Adhatoda zylanica Medik. Neelagirianthasis sp., Justecea gendurusa Burm.f., Barleria priorities L. and Hemigraphiscorolata(Blume) H.G.Hallier* have ability to kill and reduce the growth of many micro-organisms like pseudomonas (Prasad, 2014; Shinwari, 2017). Through the GC/MS analysis, 2-Propanone, Methyl hydrazone, Acetaldehyde, cyclopentane and many more compounds are reported from *Asteracantha longifolia* (L.) Nees. Which are utilized in pharmaceutical and cosmetic industry (Doss and Rani, 2017). Numbers of phytocompounds like flavonoids, glycosides, glycoglycerolipids, cerebrosides, and monoacyl-monogalatosylglycerolreported from *Clinacanthus nutans(Burm.f.) Lindau*. These compounds are anti-inflammatory, antiviral, anti-oxidant and anti-diabetic activity (Alam *et al.*,2016).

Traditional Medicinal Use of Acanthaceae Family Plant

Medicinal plants from family acanthaceae family have been used for therapeutic purpose. Various genus is used by the traditional medicators to treat various maladies in Rajasthan, Thailand, Mount Cameroon region, Jammu and Kashmir and Malaysia. These speciesand their local and traditional applications are the main topics of this review.
Mahendra CP, 2020 reported 9 genus and 11 species of family Acanthaceae, which were used by tribals from Dausa district, Rajasthan.Some of the pla nts are used for the treatment of some major diseases. For the treatment of tuberculosis leaves of *Adhatoda vasica Nees.* is used. Anemia is cured by the *Barleria cristata* L. Ash of *Hygrophila auriculata* (Schum.) is useful to remove kidney and urinary stones. Priyaporn*et al.*, 2024 did an ethnomedicinal survey in Kantarawichai district, Sarkham province, Thailand. During the study they have recorded 9 species with 2 variations belonging to same genera. These plant species are used as food, medicine and as religious purpose by local tribal community from Kantarawichai district, Sarkham province, Thailand. Young leaves of *Anrographis paniculata*(Burm.f.) Nees either eaten or boiled with Indian Acalypha to cure cough, fever, sore throat and act as detoxicant. Young leaves consumed alongside pandan leaves, either boiled or raw, to treat analeptic condition. Leaves are mixed with alcohol to treat fever and sore throat. Decoction of leaves is useful to cure stomachache.

Tea made from leaves or from the whole plant to treat diabetesmellites. Decoction of root is act as detoxicant. Leaves of *Barleria prointes* L. is boiled with water for the treatment of cancer. *Justicia gendarussa Burm.f.* whole plant powder is effective in treating various diseases (Panchrest). Young leaves of *Rhinacanthus nasutus* (L.)Kurz are boiled with water to facilitate the remove kidney stone, Additionally, leaves are also boiled with water and consumed to relieving a number of ailments, including hematinic. Ethnobotany of acanthaceae in Mount Caeroon region was carried out by Fongod A.G.N 2013. During the study period they recorded 18 species used medicinally, 16 species with ornamental potentials and qualities out of the over 70 species of acanthaceae identified. The survey revealed that 32% of plant species used as medicine while 72% of plant species being used for food, rituals, forage and hunting. Winai

Somprasong *et al.*,2014 conducted taxonomic study of the family Acanthacese used as traditional medicinal plants for ethnic groups in Northern, central and Northeastern Thailand. Study revealed 39 species with 1 variety with their medicinal use by various ethnic groups like Karen, Yao, Hmong, Akha, Lahu, Paluang,Shan, Lisu, Haw, Lawa, Khmu, Phutai, Kha (So), Nyan, Kaloeng, Yoy, Buru, Kula, Thai song dam and Native people.

Phytochemical Profile

Preliminary Phytochemicals from various Ethnomedicinal plants of family Acanthaceae:

Alkaloids

A limited number of alkaloids, including derivatives of hydroxamic acids, have also been identified in certain species of Blepharis(Rattan 2023, Dirar *et al.*,2021).23 quinazoline alkaloids are identified from leaves in ethanolic extract of *Adhatoda beddonei*C.B Clarke and *Adhatoda vasica*Nees. (Singh *et al.*, 2015). Six quinazoline alkaloids were identified in leaves of Justicia adhatoda -vasicoline, vasicolinone, vasicinone, vasicine, adhatodine and anisotine (Jha *et al.*,2012). The chloroform fraction contains the most bioactive phytochemicals with anti-inflammatory and antibacterial property, including vasicine, vasicinone, vasicine acetate, 2-acetyl benzyl amine, and vasicinolone (Singh and Sharma, 2013).Blepharin, a bitter glucoside, was initially extracted from *Blepheris edulis* Forssk. (Lal, 1936) was followed by confirmation of its structure N-deoxy-2,4-dihydroxy-1,4 benzoxazin-3-one glucoside (Chatterjee *et al.*,1990).Allentoin, Betain, Blepharin and Blepharigenin (N-Deoxy DIBOA) were identified in *Blepheris scindica T. Anderson* Stocks ex T. Anderson (Ahmad *et al.*, 1984). Blepharin was reported from the *Acanthus montanus(Nees) T.Anderson* (Amin *et al.*, 2012).

Flavonoids

Four chemicals were obtained from *Avicennia officinalis*L. by using the ethyl acetate extract to preparative thin layer chromatography and normal and reverse phase RP-18 silica gel column chromatography. These include Chrysoeriol 6″ -(3‴,5‴-dimethoxycoumaroyl)-7-O-β-D-glucopyranoside, Luteolin 7-O-β-D-glucopyranoside, 3′Methylluteolin 4′-O-β-D-glucopyranoside. A novel chemical among them is Chrysoeriol 6″ -(3‴,5‴-dimethoxycoumaroyl)-7-O-β-D-glucopyranoside (Nguyen *et al.*,2019).In addition to seven known compounds, including methyl veratrate, methyl venillate, protocatechuic acid, naringenin-7-o-(3″-acetyl 6″-E-p-coumaroyl-b-D- glucopyranoside), Apegenin-7-O-(6″-E-p- coumaroyl-b-D- glucopyranoside), acetoside, genistein 7-O-(6″-E-p- caffeoyl-b-D-glucopyranoside) was isolated through a phytochemical analysis of the aerial parts of *Blepharis ciliaris* (L.)B.L.Brutt. (El-Shanawany*et al.*, 2013). 5,7,3′-Trihydroxy -6,4′ dimethoxy flavone-7-O-Glucoside, homoplantagenin, and linaroside were reported from the *Acanthus montanus (Nees) T.Anderson* (Amin *et al.*, 2012). From *Barleria cristata* L. ethanolic extract of bark, flavonoid compounds were isolated like 6-O-α-L-rhamnopyranoside 3,7,3′-O-trimethylated-8-hydroxy quercetin, 3-methoxy quercetin, Gossypetin 8-methyl ether, 6-O-quercetagenic, Tamarixetin, Gossypetin, and Quercetin (Salib *et al.*,2013).

Glycoside

Acetoside, β sitosterol 3-O-b-D glucoside are reported from the *Acanthus montanus* (Nees.) T.Anderson(Amin *et al.*, 2012).

Phenol

Based on the 1H and 13C NMR data, two compounds- avicinol-C and Stenocarpoquinone-B from the tropical mangrove *Avicennia officinalis* L.(Assaw*et al.*, 2020). From the extract of *Blepharis linariifolia* Pers., four phenolic components were separated and identified like verbascoside, vanillic acid, apigenin, and 6″-O-p-coumaroylpurine (Dirar *et al.*, 2019). The root of *Blepheris edulis* Forssk. have yielded 2-benzoxazolinone (Chatterjee *et al.*,1990).

Terpenoids

Fraction of fresh leaves undergone in the analysis by GLC, revealed the presence of neutral triterpenoids like taraxerol, β-amyrin, α-amyrin and lupeol (Misra *et al.*,1985). Three pentacyclic triterpenoids-betulin aldehyde, betulinic acid and botulin were isolated from the ariel roots of *Avicennia officinalis*L..Cytotoxicity was also exhibited by the compound betulinic acid (Ramanjaneyulu *et al.*, 2015).

Iridoid

The leaves of *Avicennia officinalis*L.have yielded the new iridoids avicennioside, 7-cinnamoyl-8 epilogannic acid, in addition to well-known substances geniposidic acid and 2′ cinnamoyl mussaenosidic acid by using NMR spectroscopy, chemicals from *A. officinalis* (König and Hunkler 1987). The compounds include velutin, α-tocopherol, areaviridoid, (*1S, 5R, 8S, 9R)*-2′-(E-coumaroyl) mussaenosidic and combination of 6-methoxynephtho [2,3-b] furan-4,9-quinone and 7-methoxynephtho [2,3-b] furan-4,9-quinone. As far as we are aware, areaviridoid is a novel chemical (Thu *et al.*,2019).

Stigmasterol

Stigmasterol and Stigmasterol-3-O-β-D glucopyranose was reported from the *B.ciliaris* L.Burtt.for very first time (Ahmad *et al.*,1983). Benzaxazoline-2-one, stigmasterol, octacosyl alcohol and stigmasteryl- β-D-glucopyranosoid were isolated from the root of *Acanthus ilicifolius* L. (Kokpol*et al.*,1986). B-sitosterol-3-O-b-D- glucopyranoside, stigmasterol octadecenoate, β-sitosterol octadecenoate ans stigmasterol-3-O-b-D-glucopyranoside are found in the root of *Acanthus illicifolius*L.(Huang *et al.*,2014).

Pharmacological Activity of Ethnomedicinal Plants from Acanthaceae

Previous studies have demonstrated the wide-ranging therapeutic uses of different species of the acanthaceae family, as well as its extract and chemical components, in a variety of in vivo and in vitro test settings. It has been shown that some members of the acanthaceae family possess cytotoxic, antioxidant, antibacterial, antifungal, anticancer, and antiproliferative property at varying concentration.

Antibacterial activity

Hexane and chloroform leaves extract obtained from the leaves of *Adhatoda zeylanica Medik.* have been found to inhibit the growth of several pathogenic bacterial strains, including *Escherechia faecalis, staphylococcus epidermidis, actinomyces spp., Vibrio parahaemolyticus, Serratia marcescens, Staphylococcus haemolyticus, Bacillus spp., and Vibrio cholerae.* The hexane extract showed zone of inhibition ranging from 17-27mm, while chloroform extract produces zones of 15-20 mm at a concentration of 400μ/ml. In contrast, the methanol extract exhibited smaller zones of inhibition (Ilango *et al*,2009). Ethanolic extract od *Barleria cristata* L. bark against four bacterial strain like Staphylococcus aureus, Bacillus subtilis, Escherichia coli, and streptococcus mutans, with the zone of inhibition in the range of 28-15 mm. From this ethanolic extract of bark, flavonoid compounds were isolated like 6-O-α-L-rhamnopyranoside 3,7,3′-O-trimethylated-8-hydroxy quercetin, 3-methoxy quercetin, Gossypetin 8-methyl ether, 6-O-quercetagenic, Tamarixetin, Gossypetin, and Quercetin. These compounds were tested for the minimum inhibition concentration. MIC values were ranging from 0.025-0.095 mg/ml, whereas Quercetagetin and Tamarixatin show moderate MIC value which is ranging from 0.075-0.08 mg/ml (Salib *et al.*,2013). Vasicine was isolated from chloroform extract of *Adhatoda vasica*Nees. rootsand had excellent antibacterial activity against *E. coli* at doses of 20g/ml (Singh and sharma, 2013)

Anti diarrheal activity

Loperamide HCl (3mg/kg) and ethyl acetate extract of *Gendarussa vulgaris* Nees. leaves at doses of 200 mg/kg and 400 mg/kg considerably decrease the overall number of diarrheal stools in the mice with castor oil induced diarrhea. Total amount of diarrheal feces in the mice with magnesium sulphate induced diarrhea was decreased by administering 200mg/kg and 400 mg/kg of Loperamide HCl (3mg/kg) and ethyl acetate extract. By using 400 mg/kg ethyl acetate extract, the percentage if diarrhea inhibition (50.00%) was discovered (Rahman *et al.*,2018)

Antifungal activity

The antifungal activity of the ethanolic extract of *Barleria cristata* L.was evaluated by Chellathai*et al.*,2015. The extract was tested against five fungal species: *Candida albicans, Aspergillus flavus, Aspergillus niger, Panicillium spp.,* and *Trichophyton* spp. Overall, these fungal species exhibited resistance against ethanolic extract. Among them *Aspergillus*

niger showed maximum zone of inhibition, measuring 6mm at concentration of 1000 µg/ml. The remaining fungal species displayed minimum zone of inhibition zones, ranging from 3-5 mm in diameter (Chellathai*et al.,* 2015). At doses more than 55g/ml of vasicine, which was extracted from *Adhatoda vasica*Nees. roots, exhibits the strongest antifungal activity against *Candida albicans* (Singh and Sharma, 2013)

Analgesic activity

Whole methanolic extract of *Elytraria marginata* Vahl. effectively reduced acetic acid induced writhing in rats, with inhibition rates of 59.94%, 74.55%, and 79.00% at dosages of 50, 100, and 200 mg/kg, respectively (Ogbiko*et al.*2016).

Anti-inflammatory activity

Six hours after carrageenan administration, vasicine which was isolated from *Adhatoda vasica*Nees. chloroform extract of roots exhibited the strongest anti-inflammatory effects (59.51%) at a dose of 20.0 mg/Kg, while four days following CFA injection, Vasicinone exhibited highest inhibition rate (63.94%) at a dose of 10.0 mg/kg. (Singh and Sharma, 2013). The methanolic whole plant extract of *Elytraria marginata* Vahl. (50,100 and 200 mg/kg) and the reference drug substantially inhibit carrageenan-induced paw oedema from the first hour, with the anti-inflammatory activity reaching its peak at 4-hours. The extract exhibited dose dependent inhibition at three hours after histamine injection (40.30%, 57.09% and 76.94%), which was similar to that of the reference medication (84.59%). The inhibitory action of indomethacin peaked between 2 and 3 hours (Ogbiko*et al.*2016).

Antinociceptive activity

The ethyl acetate extract of Gendarussa vulgarisNees.leaves significantly reduce the duration of paw licking in both the early and late stages of the formalin test. At the dose of 200 mg/kg and 400 mg/kg, early phase paw licking time were 62.50±7.39 and 48.50±3.70 seconds, respectively, resulting in 50.74% and 61.78%inhibition. The extract significantly reduces writhing in a dose depended manner, with 400 mg/kg showing greater inhibition (13.60±1.57) than 200 mg/kg (17.60±1.33).200 mg/kg and 400 mg/kg doses provide 33.83% and 48.87% protection (Rahman *et al.*,2018)

Cytotoxicity activity

Cytotoxicity results from the MTT assay showed that *Rhinacanthus nasutus* L. Kurz. exhibited significantly higher toxicity, with 91.73% cell death at 250 µg/ml and a lower IC_{50} value of 62.06 µg/ml, compared to *Acanthus ebracteatus* Vahl, which showed 52.50% cytotoxicity at the same concentration and and IC_{50} value of 115.36 µg/ml (Saenghae*t al*., 2023).In both human gingival and dermal fibroblast cell lines, the ethanolic extracts of *Barleria prionitis* L. and *Barleria grandiflora* Dalz.exceeding 1000µg/ml. Conversely, chlorhexidine exhibited a greater degree of cytotoxicity, with CTC_{50} values of 12.5-25 µg/ml for gingival and 25 µg/ml for dermal fibroblasts (Sawarkar *et al.*,2016)

Toxicity

Administration of the extract of *Gendarussa vulgaris* Nees. up to a dose of 4000mg/kg did not result in any mortality, behavioral abnormalities, or observable signs of toxicity (Rahman *et al.*,2018). Over the course of 72-hour observation period, rats given graded oral doses of methanolic extract of whole plant of *Elytraria marginata* Vahl. (1000-4000 mg/kg) did not exhibit any applicable behavioral and physiological alternations (Ogbiko*et al.*2016).

CONCLUSION

The review highlightsthe ethnomedicinal significance of various acanthaceae species, widely used in traditional system of medicine across different regions. Phytochemical investigationsof these plants have led to isolation of diverse bioactive compounds, including alkaloids, flavonoids, glycosides, and terpenoids which exhibits a wide range of pharmacological effects. For instance, *Andrographis paniculata* (Burm.f.) Nees.has demonstrated strong anti-inflammatory, antipyretic, and hepatoprotective effects; *Adhatoda vasica*Nees. has shown bronchodilator and antimicrobial activity; *Barleria cristata* L. is reported for notable antioxidant and wound healing property; and

Elytraria marginata Vahl. exhibits analgesic and anti-inflammatory properties in periclinal models. These findings not only validate traditional medicinal knowledge but also emphasize the therapeutic potential of acanthaceae members. However, further pharmacokinetic, toxicological and clinical evaluations are essentials to translate these discoveries in to standardized herbal formulations or lead drug candidates.

ABSTRACT

The police profession in India has traditionally been considered a demanding and male-dominated occupation. In recent years, however, the participation of women in the police force has increased significantly due to changing societal attitudes, improved educational opportunities, and greater emphasis on gender equality. Women police personnel play an essential role in maintaining law and order, ensuring public safety, and addressing issues related to women, children, and vulnerable sections of society. Despite their growing presence in the police department, women police personnel often face considerable challenges in maintaining a healthy balance between their professional and personal lives. The nature of police work involves long and irregular working hours, shift duties, emergency assignments, frequent transfers, and high levels of occupational stress. These job-related demands can make it difficult for women officers to fulfil their family responsibilities and personal commitments effectively.

Keywords: Ensuring public safety, Gender equality, job satisfaction, examine, policymakers

INTRODUCTION

Work-life balance has emerged as an important aspect of employee well-being in modern organizations. It refers to an individual's ability to effectively manage the demands of both professional and personal life without experiencing excessive stress or conflict. A healthy work-life balance contributes to improved job performance, higher job

satisfaction, better physical and mental health, and overall quality of life. In today's dynamic work environment, achieving a balance between work responsibilities and family commitments has become a significant challenge, particularly for women employees. The policing profession is one of the most demanding occupations, requiring personnel to work under stressful conditions, extended working hours, shift duties, emergency situations, and unpredictable schedules. Women police personnel, in addition to fulfilling their professional responsibilities, are often expected to manage household duties, childcare, and family obligations. The dual responsibilities of work and family can create considerable pressure, making it difficult for them to maintain an effective work-life balance. With the increasing participation of women in the police force, the issue of work-life balance has gained greater attention. Factors such as workload, organizational support, working hours, leave policies, family support, and workplace environment significantly influence the ability of women police personnel to balance their professional and personal lives. An imbalance between these roles may lead to stress, burnout, reduced job performance, and lower levels of overall well-being. Chengalpattu District has witnessed a growing presence of women in various police roles, contributing significantly to public safety and law enforcement. However, the unique nature of police work often poses challenges to maintaining harmony between work and personal life. Therefore, understanding the work-life balance of women police personnel is essential for developing policies and support mechanisms that enhance their well-being and effectiveness. The present study aims to analyze the work-life balance among women police personnel in Chengalpattu District. It seeks to identify the factors influencing their work-life balance, assess the challenges they face in managing professional and personal responsibilities, and suggest measures to improve their overall quality of work and life. The findings of the study are expected to assist police administrators and policymakers in formulating strategies that promote a supportive work environment and better work-life integration for women police personnel.

REVIEW OF LITERATURE

Greenhaus and Beutell (1985) identified work-life balance as the absence of conflict between work and family roles. Their study highlighted that excessive work demands, long working hours, and role ambiguity create conflicts that negatively affect employees' personal lives and overall well-being. Clark (2000) proposed the Work-Family Border Theory, which explains how individuals manage and negotiate the boundaries between work and family domains. The study emphasized that organizational support and flexible work arrangements are essential for maintaining a healthy work-life balance. Noor (2004) examined the relationship between work-life balance and job satisfaction among working women. The study found that women who were able to balance their professional and family responsibilities reported higher levels of job satisfaction and lower levels of stress. Devi and Rani (2012)The researchers investigated work-life balance among women employees in public service organizations. The study revealed that long working hours and family responsibilities significantly affected employees' ability to maintain balance between work and personal life. Kumari and Devi (2014)This study focused on women employees in government sectors and found that organizational support, leave facilities, and family support played a crucial role in improving work-life balance. The study also highlighted that work-life balance positively influences employee performance and morale.

Reddy and Reddy (2016)The researchers analyzed work-life balance among women professionals and concluded that workplace stress, workload, and irregular work schedules were the major factors affecting their personal and family lives. The study recommended flexible working conditions and employee welfare measures. Sharma and Mishra (2018) Their study on women police personnel revealed that irregular duty hours, emergency assignments, and lack of family time were major challenges affecting work-life balance. The researchers suggested counseling programs and family-friendly policies to reduce work-related stress. Kaur and Kaur (2020)The study examined work-life balance among women working in law enforcement agencies. The findings indicated that supportive supervisors, flexible leave policies, and organizational welfare measures significantly improved employees' ability to balance work and family responsibilities. Singh and Verma (2022)The researchers found that women police officers often

experience role conflict due to demanding job responsibilities and family commitments. The study emphasized the need for stress management programs and better organizational support systems to enhance work-life balance.

Objectives of the Study

Main Objective:

- To study the work-life balance among women police officers in Chengalpattu District.

Specific Objectives:

- To examine the level of work-life balance among women police officers in Chengalpattu District.
- To identify the factors influencing work-life balance among women police officers.
- To analyze the impact of working hours, shift duties, and workload on the work-life balance of women police officers.
- To assess the challenges faced by women police officers in balancing their professional and personal responsibilities.
- To study the relationship between demographic factors (age, marital status, education, and years of service) and work-life balance among women police officers.

Scope of the Study

The present study focuses on examining the work-life balance among women police officers in Chengalpattu District. It aims to understand how women police personnel manage their professional responsibilities and personal commitments while performing their duties in the police department. The study covers various factors that influence work-life balance, such as working hours, shift duties, workload, organizational support, family support, stress levels, and welfare facilities. The research is limited to women police officers serving in different ranks and departments within Chengalpattu District. It seeks to identify the challenges they face in balancing work and family life and to assess the impact of these challenges on their overall well-being and job performance. The study also explores the relationship between demographic variables such as age, marital status, educational qualification, and years of service with work-life balance. The findings of the study are expected to provide valuable insights to police administrators, policymakers, and human resource professionals for developing effective strategies, policies, and support systems that promote a healthy work-life balance among women police personnel. The recommendations of the study may contribute to improving employee well-being, job satisfaction, productivity, and organizational effectiveness within the police department.

Limitations of the Study

1. The study is confined to women police officers working in Chengalpattu District; therefore, the findings may not be generalized to women police personnel in other districts or states.
2. The study focuses only on women police officers and does not include male police personnel for comparison.
3. The research is based on primary data collected through questionnaires, and the accuracy of the findings depends on the honesty and understanding of the respondents.
4. Time and resource constraints limited the size of the sample selected for the study.

Data Analysis and Interpretation

Interpretation

The demographic profile shows that the majority of women police officers are in the age group of 31–40 years (40.0%) and are married (65.4%). Most respondents hold an undergraduate degree (52.3%) and work as Police Constables (47.7%). A considerable number have 6–10 years of service experience (35.4%) and belong to nuclear families (60.0%). The findings indicate that women police officers manage both professional and family responsibilities, making work-life balance a significant concern. The KMO value of 0.821 indicates that the sample is adequate for factor analysis. Bartlett's Test is significant ($p < 0.001$), confirming that factor analysis is appropriate.

Factor-wise Interpretation

Factor 1: Work Environment

This factor explains 32.04% of the variance and includes flexible working hours, workload management, and shift scheduling.

Factor 2: Family Support

This factor explains 17.62% of the variance and includes family cooperation, child care support, and spouse support.

Factor 3: Organizational Support

This factor explains 13.60% of the variance and consists of supervisor support, welfare measures, and leave facilities.

Factor 4: Stress Management

This factor explains 9.37% of the variance and includes stress handling ability, time management, and physical and mental well-being.

CONCLUSION

Despite their growing presence in the police department, women police personnel often face considerable challenges in maintaining a healthy balance between their professional and personal lives. The nature of police work involves long and irregular working hours, shift duties, emergency assignments, frequent transfers, and high levels of occupational stress. These job-related demands can make it difficult for women officers to fulfil their family responsibilities and personal commitments effectively.

ABSTRACT

In a highly competitive market with workforce shortages and the undeniable need for providing superior patient care, employee retention has become one of the most pressing challenges facing healthcare organizations today. Multispecialty hospitals heavily invest in talented doctors, nurses, bio medical engineers and administrative staff to deliver organized health care services. Utilizing the work force turnover not only increases recruitment and training costs but also subsequently affects quality of services, patient satisfaction and organizational performance. This paper attempts to study the employee retention practices followed by multispecialty hospitals in Chennai and their effectiveness towards managing employee retention. The research covers the major variables of retention including compensation of key personnel, opportunities for career growth and development, work-life balance, leadership support; recognition for performance; employee welfare policies; organizational culture and job satisfaction. For the purpose of data collection, a structured questionnaire will be used and 100 employees will fill this questionnaire. Statistical tools: Percentage analysis, Mean& Standard deviation; Chi-Square Test, Independent sample t-Test & One-Way ANOVA. The conclusions drawn from this study will hence, enable hospital management a better understanding of employees' expectations and strengthen the retention strategies for a sustained organizational performance leading to the continuity of quality healthcare services.

Keywords: Employee Retention, Healthcare, Multispecialty Hospitals, Human Resource Management

INTRODUCTION

One of the most important sectors contributing to a nation perpveconomy and social development is the healthcare sector. Multispecialty hospitals offer extensive healthcare services accomplished through the collaboration of skilled healthcare practitioners and operational support staff. Human resources within every hospital is the most basic ingredient for the continuity and quality of patient care, their commitment to a high standard of competence. Given the current state of the healthcare landscape, it is become harder to keep great employees. Lack of career opportunities, pay and benefits, poor work-life balance, lack of supportive leadership, lack of growth or development opportunities and lack of recognition for contributions are all common reasons employees leave an organisation. If an experienced workforce continues to leave, it increases the cost of hiring new employees as well as other disruptions in the provision of healthcare services and the morale of health care personnel. Employee retention means to keep employees within the organization and putting into place systematised human resource management practice and positive environment. Hospitals are strategizing measures like salary packs, performance incentives, talent development programs, engaging employees with morale boosters, encouraging participation in career advancement opportunities and ongoing training avenues supporting flexible work schedules employee welfare initiatives and leadership support. The situation in Chennai is even worse with many multispecialty hospitals being set up and competing for the right doctors. This is the reason that hospitals should always reiterate their measures of retention to keep a stable and motivated workforce. Objective the purpose of this study is to evaluate the effectiveness of employee retention strategies and the factors affecting employee intention to stay in multispeciality hospitals in Chennai Few studies were done regarding the effect of employee retention & their interfaces with thier intention to stay.

Statement of the Problem

With employee turnover becoming higher and higher, workforce shortages looming large, a lot of hospitals pitted against one another, Employee retention has become one of the biggest challenges for Healthcare organizations. On these multi specialty hospitals, you needs the services of the skilled and very expert health professionals to provide the excellence in medical science. On the other hand, employees often leave their companies for low pay, lack of career progression opportunities, high workloads, work-related stress and poor work-life balance, a lack of recognition and feedback on their performance and sometimes poor working conditions. Crossing medical and operational boundaries, high personnel turnover specifically impedes hospital operations via higher recruitment and training costs; lower employee productivity; decreased patient satisfaction and continuity of care. Indeed, hospitals deploy a number of retention strategies in practice; however, those practices will vary based on employee needs and how an organization operates. Therefore, it is necessary to analyze the employee retention strategies used by multispecialty hospitals in Chennai to measure their effectiveness on increasing employee satisfaction level, organizational commitment and long term employee retention. This study will help hospital management plan more meaningfully to buy their human resource policies and retention strategies.

Objectives of the Study

Primary Objective

- To analyze the employee retention strategies adopted by multispecialty hospitals in Chennai.

Secondary Objectives

- To identify the factors influencing employee retention in multispecialty hospitals.
- To examine the level of employee satisfaction with the existing retention strategies.
- To evaluate the relationship between demographic variables and employee retention.
- To analyze the impact of compensation, career development, work-life balance, and leadership on employee retention.

Scope of the Study

The under laying theme of this research is to study about the retention strategies of employees in multispecialty hospitals at Chennai. This study seeks to understand what gives employees the impression that they need to remain with their organizations. It covers things like compensation & benefits, developmental opportunities, work-life balance, leadership support as well as employee recognition and training and development organizational culture job satisfaction. The study is restricted to employees working at selected multispecialty hospitals in the Chennai. For this study primary data collection 100 respondents through structured questionnaire. The results of this study will assist hospital management in determining the efficacy of existing retention strategies and recommendations on improving job satisfaction, organizational commitment and employee retention.

Limitations of the Study

The study has been limited to few multispeciality hospitals at Chennai, hence findings may not be applicable across all hospitals or other healthcare organizations. The sample size is fairly small with a full deduction of 100 respondents in total, which cannot encapsulate the voices of all hospital employees. The study predominantly relies on respondents' self-reported perceptions through a semi-structured questionnaire that opens up the possibility of biased responses. The study is only conducted for a short period of time due to limitations in time and resources.

RESEARCH METHODOLOGY

Research methodology is a systematic way of solving a research problem. Provides a scientific framework to investigate the research problem and ensure reliable and valid findings. This research is conducted in the quantitative aspect, where it analyzes the employee retention factors for multispecialty hospitals at Chennai.

Research Design

The study adopts a descriptive research design, as it aims to describe and analyze the employee retention strategies and the factors influencing employee retention in multispecialty hospitals.

Nature of the Study

The study is **descriptive and analytical** in nature.

Source of Data

The study is based on both **primary and secondary data**.

- **Primary Data:** Primary data will be collected from employees of selected multispecialty hospitals in Chennai through a structured questionnaire.
- **Secondary Data:** Secondary data will be collected from books, journals, research articles, magazines, company reports, hospital websites, and other published sources related to employee retention and human resource management.

Area of the Study: The study is conducted in selected multispecialty hospitals in Chennai.

Population of the Study: The population of the study comprises employees working in selected multispecialty hospitals in Chennai.

Sample Size: The sample size for the study consists of 100 employees.

Sampling Technique: The study uses the Convenience Sampling Technique, a non-probability sampling method, to select respondents based on their availability and willingness to participate.

Data Analysis and Interperation

Objective To examine whether there is a significant association between Gender and Employee Retention Level.

Hypothesis

Null Hypothesis (H_0): There is no significant association between gender and employee retention.

Alternative Hypothesis (H_1): There is a significant association between gender and employee retention.

Interpretation

The calculated Chi-Square value (11.462) is greater than the table value (9.488), and the p-value (0.022) is less than 0.05. Therefore, the null hypothesis is rejected. It is concluded that there is a significant association between gender and employee retention among employees of multispecialty hospitals in Chennai.

ONE-WAY ANOVA

Objective To determine whether employee retention differs significantly based on Years of Experience.

Hypothesis

Null Hypothesis (H_0): There is no significant difference in employee retention among different experience groups.

Alternative Hypothesis (H_1): There is a significant difference in employee retention among different experience groups.

Interpretation

The calculated F-value is **4.286**, and the significance value is **0.007**, which is less than 0.05. Hence, the null hypothesis is rejected. It is concluded that employee retention significantly differs among employees with different levels of work experience.

MULTIPLE REGRESSION ANALYSIS

Objective To examine the influence of compensation, career development, work-life balance, leadership support, and training & development on employee retention.

Dependent Variable

- Employee Retention

Independent Variables

- Compensation
- Career Development
- Work-Life Balance
- Leadership Support
- Training and Development

Interpretation

The R Square value of **0.610** indicates that **61.0%** of the variation in employee retention is explained by the selected independent variables. The remaining **39.0%** is explained by other factors not included in the model. The significance value is **0.000**, which is less than **0.05**. Therefore, the regression model is statistically significant and suitable for predicting employee retention.

Findings

Based on the analysis and interpretation of the data collected from 100 employees working in selected multispecialty hospitals in Chennai, the following findings were identified:

- Most of the respondents are in the age range of 31–40 years.
- The majority of respondents are female employees, which is consistent with the workforce composition in the healthcare sector.
- Most respondents hold either undergraduate or post-graduate qualifications.
- Employees have around 3 to 10 years of work experience;
- Most employees were satisfied with patient centric employee retention practices employed by their hospitals.
- Throughout the world, competitive compensation and benefits related to the employment experience were examples of the most management actions directly influencing employees' decision making in regard to staying with an organization.
- It was concluded that career development and promotion opportunities had a significance effect on staying in the organisation.
- The ability to balance their work commitments with those life outside of work meant that employees had more reason to stay and be satisfied in the workplace

- Organizational commitment was more influenced by leadership support & communication.
- Training and development programs made the employees work more effectively in the organization and also enhanced their intention to stay in an organisation.
- Results achieved by Chi-Square test revealed an association between selected demographic variables and employee retention.
- The One-Way ANOVA test was carried out and it showed that the employee retained levels vary significantly between employees having different years of work experience.
- The results of Multiple Regression Analysis revealed that five factors predict employee retention: compensation, career development, work-life balance, leadership support and training & development.

Suggestions

Based on the findings of the study, the following suggestions are offered:

- To attract & retain skilled professionals, offering competitive salary packages and attractive employee benefits is a must.
- Implementation of clear career development and promotion policies will result to employee behavioral motivation.
- There should be regular training and professional development programs, so that the employees become competent.
- The management of hospitals should take measures to encourage a good work-life balance by implementing flexible work schedules, wherever possible.
- Strengthen employee recognition and reward programs to appreciate outstanding performance.
- It should be ongoing communication between supervisors and managers that gives constant support to the employees.
- There is an urgent need to improve employee welfare by expansion in health benefits, counseling and wellness measures.
- Measure satisfaction of employees Employee surveys regarding satisfaction must be performed regularly to identify concerns and gaps to enhance the HR policies in place.
- Positive organizational culture at hospitals that allows teamwork, trust and employee engagement should be created.
- Retention strategies should be evaluated from time to time so that the turnover of employees can be minimized and there is a better performance in the organization overall.

CONCLUSION

One of the most critical factors in long-term success for healthcare organizations is employee retention. Together, the results of this study show that firm-level retention strategies like compensation, career development opportunities, work-life balance experiences, supportive leadership and training programs have an impact on employees' desire to stay with their organizations. Hospitals that spend on the well-being and professional growth of employees are more likely to hang onto the high-quality healthcare professionals who unfold excellence in care delivery. Through good human resource practices, multispecialty hospitals in Chennai can curtail employee turnover intent, facilitate job satisfaction, positively affect organizational commitment and impart high quality health care services. Thus, organizations require a regular evaluation and enhancement of employee retention strategies, which helps them to be excellent in their field and ensures sustainable growth.

ABSTRACT

Functional movement screening (FMS) is widely used to evaluate movement patterns to identify asymmetries and ability to perform fundamental movements. This cross-sectional study evaluated and compared FMS performance among recreational gym trainees (static training emphasis) and amateur football players (dynamic training emphasis), aged 19-20 years. The objective was to determine how activity-specific training influences FMS performance across seven tests assessing mobility, stability, and motor control. Fifty male participants (RGT= 25 & AFP = 25) completed the Seven-item FMS test protocol. Between group differences were assessed by independent samples t-test (α =0.05), prior to that statistical assumptions like homogeneity of variance and normality were verified. RGTs exhibited superior performance in deep squat (2.92 ± 0.27 vs 2.48 ± 0.50, p<.001), in-line lunge (2.96 ± 0.20 vs 2.68 ± 0.47, p<.001), and trunk-stability push-ups (2.96 ± 0.20 vs 2.64 ± 0.48, p<.001). AFPs excelled in shoulder mobility (2.80 ±0.40 vs 2.00 ± 0.76, p<.001), and active straight leg raise (2.92 ± 0.27 vs 2.60 ± 0.57, p=.001). Overall FMS scores were similar (RGTs=18.56 vs AFPs=18.88), both exceeding the established injury risk threshold ≤14.These findings suggest that the observed functional competency is consistent with low injury risk profile and the movement differences among RGTs and AFPs reflect activity-specific training adaptations rather than functional deficits.

Key Words: Functional Movement Screening (FMS™), Movement Pattern, Football Players, Gym Trainees, Training Adaptations, Injury Risk.

INTRODUCTION

Many people are focused on getting fit and healthy these days. They're working on things like flexibility, strength, and how long they can keep going. The authors of this piece think that some people are doing advanced exercises even though they don't move very well. It's like they're trying to get in shape without fixing the way they move. They often avoid the things they're not good at when they work out (Cook et al., 2014). Functional movement screening is a prevalent method employed to evaluate Movement patterns, rather than as a standalone injury prediction method (Eckart et al., 2025; Moore et al., 2019; Warren et al., 2018 & Shultz et al., 2013). The review on FMS by Kraus et al., (2014) showed evidence that FMS can be used to assess general functional asymmetries and postural stability in different populations. Until now, most of the studies have focused on the Functional Movement Screening (FMS) of a single game or activity by using the FMS test. However, the important component of this equation is to focus on comparison among different activities and highlighting the importance of FMS in such activities that are dynamic and static in nature. As we know that, the FMS test is unique in assessing and measuring the asymmetry of the body through the study of basic movement patterns of the body (Łyp, M. et al., 2022). RGTs predominantly demand bilateral, controlled, sagittal-plane movements, while AFPs require dynamic, reactive, multi-planar movement execution (Lyp et al., 2022; Cook et al., 2014) making it an informative construct for evaluation of training specific fundamental movement adaptations.

Purpose

Movements in Football being predominantly dynamic in nature reports more injuries (Łyp, M. et al., 2022) as compared to Gym strength activities which are predominantly static in nature and demand for controlled and symmetrical movements (Cook, et al., 2014). If movement pattern differences among populations demonstrate training adaptations rather than functional deficit, then targeted supplementary training can be designed to address group-specific limitations. This study was designed to assess and compare the FMS performance between Recreational Gym Trainees and Amateur Football Players. The aim is to determine how activity-specific training shapes movement pattern profiles across the seven FMS components.

Hypothesis

The RGTs would demonstrate superior FMS scores in static stability patterns (Deep Squat, Trunk Stability Push-Up), while AFPs would excel in dynamic movement patterns (Active Straight Leg Raise, Shoulder Mobility), reflecting the specific movement demands of each training modality.

METHODOLOGY

Participants

Fifty (50) male participants aged 19-20 years (25 Recreational Gym Trainees and 25 Amateur Football Players) were selected through random sampling for this cross-sectional study. All participants were active in their respective activities at the time of data collection.

Inclusion Criteria

Only those participants were included who had a minimum of two years of consistent participation in RGT and AFP and had a current training frequency of 4 days a week.

Ethical Approval and Informed Consent

This study was approved (NO:- CUK/Phy.Edu./DISS/2023/01/01) by the Departmental Research Committee of the Department of Physical Education, Central University of Kashmir. All procedures followed the declaration of Helsinki.

Sample Size Justification

Although a formal a priori power analysis was not conducted prior to data collection the adequacy of the sample size can be evaluated post hoc through the results. Statistically significant between-group differences were detected in five of the seven FMS components at $p < .001$, and one component at $p = .001$. The detection of large and moderate effect sizes at this threshold with 25 participants per group suggests that the sample provided sufficient statistical power to identify meaningful between-group differences. Future studies should conduct formal a priori power analyses based on expected effect sizes derived from the current findings to determine appropriate sample sizes for replication.

FMS Test Procedure

The FMS protocol was selected because it is specifically designed to assess fundamental movement quality rather than sport-specific performance capacity. Functional Movement Screening (FMS™) test was used to assess the functional movement across seven test items that measure squatting ability, stepping over obstacles, lunging in a straight line, raising a straight- leg, maintaining trunk-stability during push-ups, shoulder mobility, and assessing rotary-stability among Recreational Gym Trainees and Amateur Football Players. The nature of both events emphasizes that training and execution of skills require mobility, stability, and balance in a certain way. In the gym, most functional movements are performed in a static position, while football requires one to perform functional movements in a dynamic position.

Scoring

Each test was scored on a 0–3 ordinal scale, with a maximum composite score of 21. The assessment involves testing five movement patterns using bilateral testing, which gives two scores for each pattern. The lower of the two scores is the final score, but both are important for understanding the results and data collection process. Three tests—Shoulder-Mobility, Trunk -Stability Push-Up, and Rotary-Stability—have additional "clearing tests" that are graded as either pass or fail. If someone fails any of these clearing tests, their overall score for that assessment is zero. Each part of the assessment uses a scoring system where 3 is excellent, 2 is average, and 1 is below average. All seven tests were administered in standardized sequence according to the FMS™ testing manual.

Inter-Rater Reliability

Before the administration of FMS assessments, the examiner had a number of practical sessions under the expert guidance of an Assistant Professor at the Department of Physical Education, Central University of Kashmir. To ensure examiner competency, the data on FMS items of 10 students was correlated with the data taken by another Assistant Professor from the same department under similar conditions. The average coefficient was 0.81. Thus, examiner's competency was established. This is acknowledged as a methodological limitation. Future studies should report ICC values for both intra-rater and inter-rater reliability to strengthen the credibility of FMS scoring.

Statistical Analysis

Descriptive (mean ± SD) were calculated for all test items. Between group differences were assessed by independent samples t-test (α =0.05), prior to that statistical assumptions like homogeneity of variance and normality were verified and confirmed for all variables. Composite FMS scores were treated as approximately continuous for the purpose of parametric analysis, which is consistent with established practice in FMS research literature (Kiesel et al., 2007; Chorba et al., 2010). Analysis was done with the help of IBM SPSS Statistics (Version 20.0, Windows IBM).

RESULTS

Table 2 presents the mean and SD and p-values for all seven FMS components and overall composite score. Statistically significant between-group differences were found in Five of the seven components. The calculated p-value was ($p<.001$) for deep squats ($p<.001$), In-line-Lunge ($p<.001$), Shoulder-Mobility ($p<.001$), Active-Straight-Leg

Raises (p =.001), and Trunk -Stability Push-Ups (p<.001) at a 0.05 level of significance. In case of Hurdle-Step (p=.64) and Rotary-Stability (p=.14) no significant difference was found between the groups at 0.05 level of significance.
RGTs demonstrated superior performance in components consistent with controlled, bilateral, sagittal-plane movement: deep squat (2.92 ± 0.27 vs. 2.48 ± 0.50), in-line lunge (2.96 ± 0.20 vs. 2.68 ± 0.47), and trunk stability push-up (2.96 ± 0.20 vs. 2.64 ± 0.48). Lower standard deviations in the RGT group across these components indicate greater consistency within the group. AFPs demonstrated superior performance in components aligned with dynamic flexibility and multi-planar mobility: shoulder mobility (2.80 ± 0.40 vs. 2.00 ± 0.76) and active straight leg raise (2.92 ± 0.27 vs. 2.60 ± 0.57). The study hypothesis was therefore accepted. Overall composite FMS scores were functionally equivalent: RGT = 18.56 and AFP = 18.88, a difference of 0.32 points representing approximately 1.5% of the 21-point scale. Both scores exceeded the established injury risk threshold of ≤14, indicating low injury risk in both groups (Kiesel et al., 2007).

DISCUSSION

The contradiction between statistically significant differences and identical overall scores is not a methodological inconsistency rather reflects the selective nature of training adaptations. This interpretation is consistent with the principle of training specificity, which implies that neuromuscular adaptations are specific to training demands (Cook et al., 2014). The notable methodological implication suggests that the FMS component level profiling offers more diagnostically relevant information than the overall composite score in comparative research context. Hence, relying only on overall scores in this comparison would lead to incorrect conclusion that the two groups are functionally similar. The statistical differences in RGTs (Deep-Squat, In-Line Lunge, Trunk -Stability) reflects bilateral, controlled, and Sagittal-plane mobility. Gym training involves squats, lunges etc. that directly train these capacities in controlled conditions. Besides that, lower SD in RGTs across all components further highlights homogeneous movement qualities reflecting the replicable nature of gym training. Notably, resistance training, core stability training, and functional training demonstrated the most significant positive impacts on FMS results. While FIFA training also showed some effect, it was less pronounced. They recommended the use of targeted exercise programs, especially those emphasizing resistance and core stability, to enhance FMS scores and, consequently, optimize movement patterns. Besides that, Clark, et al. (2022) concluded that functional training, muscle strengthening, core stability training, and resistance significantly improve the movement pattern. While statistical differences in AFPs (Shoulder-Mobility, Active-Straight Leg Raise) reflect dynamic, multi-planar sport demands. Shoulder mobility reflects bilateral and reciprocal range of motion in the shoulder girdle, including internal rotation with adduction and external rotation with abduction. Football-specific activities such as throwing, tackling, and goalkeeper movements repeatedly expose players to large shoulder range-of-motion demands.

Active straight leg raise reflects hamstring and gastrosoleus flexibility combined with contra lateral limb control and pelvic stability—qualities directly reinforced by the repeated dynamic lower limb actions of football training, including sprinting, kicking, and change-of-direction movements. These findings are consistent with Łyp et al. (2022), who documented that football training produces multi-planar dynamic flexibility adaptations. Both groups scored above the established injury risk threshold of ≤14 (Kiesel et al., 2007;Chorba et al., 2010), with composite scores of 18.56 for RGTs and 18.88 for AFPs. This indicates that neither training modality produces dysfunctional movement patterns in this age group. These results are consistent with the findings of Maleki et al. (2025), whose systematic review and meta-analysis demonstrated that resistance training, core stability training, and functional training produce the most significant improvements in FMS scores, and that both gym-based and sport-specific training can produce adequate movement quality outcomes. Clark et al. (2022) similarly, reported that functional training and muscle strengthening programs significantly improve movement patterns, supporting the adequacy of both training modalities assessed in this study. FMS is used to screen athletes and try to find out the predictive values of FMS about injuries (Chorba. et al., 2010). In contrast, our results showed FMS scores above 14 (precisely 18.56 and 18.88), suggesting a lower risk of injury (Kiesel et al., 2007). Our findings are supported by the systematic review and meta-analysis carried by Maleki, et al. (2025), assessed how various exercise interventions can positively influence FMS

scores, indicating potential improvements in movement quality. Finding in the present study showed very promising and notable improvements in overall FMS scores of both groups, indicating the effectiveness of such intervention programmes in functional movement patterns (Dinc, et al., 2017). The authors acknowledge, however, that the injury risk threshold of ≤14 was derived from a sample of professional American football players (Kiesel et al., 2007) and has not been validated specifically for the 19–20 year age group examined in the current study. The threshold is applied here as the most widely accepted benchmark available in the FMS literature, and the scores of both groups are sufficiently above it to suggest that the directional conclusion that both groups demonstrate low injury risk is defensible. Being cross-sectional the focus and limitation of this study does not allow causal attribution of observed FMS component differences to training stimuli.

Practical Implications

Coaches, Trainees, Trainers and Practitioners can benefit from the following observation of this study:

- Both groups scored above the established injury risk threshold and indicated that neither training modality produces dysfunctional movement patterns in this age group. Hence, supports the use of both types of training as foundational physical preparation methods.
- FMS movement pattern profiles suggest each group has identifiable movement pattern gaps as RGTs demonstrate lower scores in dynamic, multi-planar sport movements and AFPs demonstrated lower scores in bilateral, controlled, sagittal-plane mobility movements. Cross-modal supplementary training could address this gap by incorporating bilateral stability exercises in football training and by incorporating dynamic and rotational movements in gym training.

Limitations

- The cross-sectional design prevents causal inference regarding the relationship between training modality and movement pattern outcomes. The observed differences are consistent with training adaptation, but this interpretation cannot be confirmed without a longitudinal design.
- A formal a priori power analysis was not conducted prior to data collection. Although the detection of significant effects at $p < .001$ with 25 participants per group suggests that adequate power was achieved for the observed effect sizes, future studies should calculate required sample sizes before recruitment to ensure sufficient power for smaller or moderate effects.
- While training frequency and experience were documented descriptively (Table 1), these variables were not formally controlled or used as covariates in the analysis. Residual variability in training background within each group may have contributed to within-group score variability, particularly in the AFP group.
- The injury risk threshold of ≤14 applied in this study was established in a sample of professional American football players (Kiesel et al., 2007) and has not been validated for the specific age group (19–20 years) examined here. Findings related to injury risk should be interpreted with this limitation in mind.
- The sample was restricted to male participants aged 19–20 years. These findings should not be generalized to female populations, younger or older age groups, or higher levels of competitive participation without further investigation.

CONCLUSION

The study aimed to assess and compare functional movements of individuals involved in competitive football and those engaged in gym training. Functional movements refer to the specific movements and exercise that mimic real-life activities and are important for overall physical performance. This research has investigated functional movement patterns of Amateur Football Players and Recreational Gym Trainees. Screening was done by using the functional movement tests designed for flexibility, strength and stability such as; the deep squat, shoulder mobility, the Active-straight leg raises, the trunk-stability push-up, hurdle-step, in-line-lunge, and rotary-stability. These tests are designed to examine the movements required by the participants in their respective sport or activity. It was concluded that, RGTs exhibited superior performance in deep squat, In-line lunge, and trunk stability push-ups.

AFPs excelled in shoulder mobility, and active straight leg raise. Overall FMS scores were similar for RGTs and AFPs and both exceeding the injury risk threshold. RGTs excel in controlled, bilateral movements while AFPs excel in dynamic, multi-planar movements. Both groups demonstrated low injury risk. Both RGTs and AFPs showed functional competency and suggest FMS differences reflect training adaptation rather than deficits.

ACKNOWLEDGEMENT

We would like to acknowledge the active participation of all the participants of this study. Besides that, we acknowledge the technical support by the Department of Physical Education, Central University of Kashmir.

ABSTRACT

Home gardens are a part of the agricultural and food production systems in many developing countries and are widely used as a global food crisis. The ultimate aim of the study is to document the home garden plants and its utilization in Colachel municipality of Kanniyakumari district, Tamil Nadu, India. The indigenous uses of the plants were gathered from the local people by interview method. Totally, 105 species distributed in 90 genera under 45 families were recorded. According to habit wise distribution 41 species (39%) were herbs, it is followed by shrubs, trees and climbers of 33 species (32%), 18 species (17%) and 13 species (12%) respectively. The study also found that Euphorbiaceae is the dominant family includes 7 species and Solanaceae is the sub dominant family which includes 6 species. Most common of the plants were ornamental (49 spp.), followed by edible (42 spp.), medicinal (40 spp.) and other uses (27spp.). The findings of the study, home gardens are a type of production system that is kept for the purpose of collecting a variety of products and are key avenues for species conservation and food.

Keywords: Home garden, utilization, Colachel, Kanniyakumari

INTRODUCTION

Home gardens are traditional agro forestry systems characterized by the complexity of their structure and multiple functions [1]. Home garden is a bounded piece of land with a mixture of tended and cultivated plants on which a

house is built. The most distinguishing and important characteristic of all home gardens is their species diversity: their intimate admixture of plants of all types – herbs, shrubs, vines, trees, other perennials and so on, on the same parcel of land [2]. It is an integrated system which comprises different things in its small area (the family house, a kitchen garden, a mixed garden etc.). It produces a variety of foods, medicine and agricultural products. These products could be used both for home consumption and for incoming purpose. There are numerous types of home gardens were the serving of several functions. Vegetable gardens were the cultivation of different kinds of vegetables and fruits. Herbal gardens can be grown in a small a spot as a window box. Growing of culinary herbs and spices gives the freshest ingredients. Different herbs are usually separated through the planting design and cultivated in a pot. Home gardens are cultivation system for both food and non-food production. Nevertheless, home gardens are mostly known for their food production function considered to be their basic functions [3]. The socioeconomic and sociocultural issues and traditional knowledge of the local communities aided in the sustainability of agro – ecosystem [4].

Home gardens play an important role in the conservation of genetic resources and household livelihood and economy. It also provides food and supplementary income for the households [5]. Currently, the floristic composition of home gardens tends toward the ornamental plants [6]. In the wide meaning, home gardens serve as habitat for a large range of flora and fauna and thus help in biodiversity conservation provisioning services are those resources supplied by home gardens to human communities, which include food products, natural medicines, aromatic, relaxing and education [7]. Home garden is also important as a space to ensure food availability. Most of the home gardens have been influenced by local knowledge of people on how to manage the space surrounding main building [8]. It has attracted considerable attention of researchers during the past three decades mainly due to two reasons: Firstly, they contain characteristics which make them interesting models for research and design of sustainable agrosystems. Some of these characteristics include efficient nutrient cycling high biodiversity, low use of external inputs and soil conservation potential [9]; secondly they provide a diverse and stable supply of socio-economic produces and benefits to the families that maintain them [10]. Similar type of works were carried out by various authors in India and other countries [11, 12, 13 & 14]. The present study attempts to document the composition and utilization of home gardens in Colechel Municipality of Kanniyakumari District in Tamil Nadu, India.

MATERIALS AND METHODS

Study area

The study area Colachel is situated in Kalkulam Taluk of Kanniyakumari distrct, Tamil Nadu, India. It is a coastal town in the far south of India, located within the administrative jurisdiction of Kanniyakumari District. It is a natural harbour on the Malabar Coast, located 20 km North-West of Kanniyakumari (Cape comorin), the southernmost tip of India. Colchel is also an ancient port town, that Vasco da Gama called 'Colachi'. The occupation of the people of Colachel is fishing with catamaran (raft made of several tree trunks lashed together), deep sea fishing with mechanized boat, exporting fish, coconut fibre production, fibre works, coir making, palm fibre works, selling general merchandise, agriculture etc. and Colachel beach is a local tourist attraction and it is home to numerous historical sites and unspoilt beaches; it remains unexplored throughout the year.

Documentation

A field survey was conducted during the study period to record the plants which are growing on different parts of Colachel Municipality. Totally thirty visits were made to all the practically possible places in search of homegarden plants. The periodical trips were under taken to the different part of the study area to get information about home garden plants. The indigenous uses of the home garden plants were gathered from the owners of the home garden by interview method. The identification of plants was done by using local floras like Flora of Presidency of Madras [15] and an Excursion flora of Central Carnatic Tamil Nadu [16] and also with help of experts for plant identification.

RESULTS AND DISCUSSION

In the current study, a variety of plant species were grown and maintained in the home gardens survey from Colechel Municipality of Kanniyakumari District. Totally 105 species distributed in 90 genera under 45 families were recorded and these are growing naturally or cultivated in the home gardens, of these 105 species, 92 plants are dicotyledons, 10 plants are monocotyledons and 3 plants are Gymnosperms (Table 1). They include herbs, shrubs, trees and climbers. Among 105 taxa, 41 species (39%) were herbs, 33 species (32%) were shrubs, 18 species (17%) trees and 13 species (12%) were climbers and belonging to 41 different families were recorded. Family wise distribution of the home garden plants shows that Euphorbiaceae is a dominant family includes 7 species and Solanaceae is the sub dominant family which includes 6 species. It is followed by Amaranthaceae and Apocynaceae which are having 5 species each. Acanthaceae, Asteraceae, Cucurbitaceae, Lamiaceae, Leguminosae, Liliacaea and Verbenaceae are represented by 4 species each. The families such as Araceae, Malvaceae, Oleaceae, Piperaceae and Rutaceae are having 3 species each, 10 families are having 2 species each and 19 families are represented by single species each.
The most dominant genus is Solanum, it includes 4 species. It is followed by Phyllanthus consists of 3 species. 8 genera consist of 2 species each and the remaining 64 genera are represented by single species each.

Indigenous Uses of the home garden plants

Home gardens, according to local perceptions, have the following major use categories: ornamental (49 species) followed by, edible (42), medicinal (40), dye (9), oil (9), fuel wood (5), timber (3) and 1 Fibre yielding plant (Fig. 1). The collected plant specimens were tabulated with its binomial, family, uses, medicinal uses and Useful part (Table 2). Among the 49 ornamental plants, nearly 45 plants are cultivated for their colourful flowers and *Caladium bicolour*, *Dracaena reflexa* and *Codiaeum variegatum* are having colourful leaves. Cupressus and Araucaria are the ornamental trees. Ornamental plants are the most important use category with the recorded 49 species. According to [17] the presence of more ornamental and commercial plants in home gardens has been identified as a sign of high urbanisation and modernization among home gardening families. The flowers of most plants have the most attractive potential, although some species also have beautiful fruits and leaves. In the edible plants, fruits of 29 plants are used by the home garden owners in which raw fruits of 13 plants are used as vegetables. *Mangifera indica,Musa acuminata* and *Carica papaya* are used as both vegetable and fruit. Leaves and Stem is used as vegetable in *Centella asiatica*. Leaves of 9 plants, Bulb and Leaves of *Allium cepa*, Tuber of *Manihotesculenta* and Pseudostem and flower of *Musa paradisiaca* are used for cooking purpose. *Mangifera indica*and *Cocos nucifera*are present in most of the homes. Our finding coincides with the result of [5].

In this study 40 plants are used as traditional medicine by the home garden owners of the study area. Different parts of the plant body are used to treat various common illness. The most dominant useful part is Leaves which consists of 16 species. It is followed by Fruit which consist of 11 species. Whole plant of 8, Flowers of 6, Rhizome of 2 plants are used to treat various diseases. The other useful part such as Bulb and Latex of 1 species each also used by the people. These 40 plants are used to treat different diseases and these diseases are included under 11 categories. They are, 11 species are used to treat Respiratory diseases, Gastro Intestinal diseases and General Health are treated by 9 species each and 7 for skin diseases. Fever, diabetes and inflammatory diseases are treated by 4 species each, 3 species for Urino Genital diseases by 3 species, Hair problem and Eye problem by 2 species each and Antidote and Liver problem by 1 species each. Some of the home garden plants have efficiency to fight against more than one disease. Some plants used to treat more than one disease, for example *Aloe vera* is used to cure pimples and also act as a body coolant. Likewise, Annona muricata used to treat constipation and urinary problems. Oil obtained from 9 plants, fragrant oil from 5 plants are used in cooking purpose and oil from 4 plants are used for perfume industry. Timber obtained from *Artocarpus heterophyllus, Artocarpus hirsutus*, and *Tectona grandis* are used for making furniture, some of the plants are used as fuel wood and fibre obtained from *Cocos nucifera* is used to make rope and chord. The collected plants were tabulated with its binomial, family, habit, uses, useful part and the medicinal uses (Table 2). Home gardens are a remedy to alleviate hunger and malnutrition [18]. It act as a bridge between biological and social components conserving species and genetic diversity [19]. The garden reflects the wisdom of traditional culture and

ecological knowledge that have evolved over the years. Such valuable traditional culture and ecological knowledge systems are based on strong socio-cultural and traditional beliefs confounded by the economic status of the people [20].

CONCLUSION

Home gardens provide good economic and social conditions for outstanding production. They are an important production system of food, medicine and other essential products. It also provides environments in which part of the genetic diversity for many crop plants can be maintained. In the wake of a global food crisis and the soaring food prices, there has been increased emphasis on enhancing and building local food systems. In this context, there is renewed attentions to food production and livelihood enhancement through home gardens. However, more empirical evidence on the value and importance of home gardens in conflict and post-conflict situations needs to be researched and documented. There is also a need for research on the cost-benefit analysis of home gardening to determine the economic value and to derive viable models that hold the most promise in diverse circumstances. The areas of nutrition, access to new technologies, extension and advisory services, economic and non-economic benefits, women empowerment and long-term sustainability of home gardens specifically in post conflict situations need further research.
